Arizona

A classic symbol of America's Old West, Arizona is rich in legends of the Indian leaders Geronimo and Cochise and of such towns as Tombstone, where the feud between the Earp and Clanton brothers erupted into the West's most famous shoot-out, the gunfight at the O.K. Corral. The Arizona of the 1970s, with its modern cities, sprawling suburban developments, and nationwide transportation arteries, shows quite a different face, though in its broad expanses of sparsely settled country, its extraordinarily coloured rock walls and mountains rising above dramatic desert plains, and its mud adobe structures and baroque Spanish missions is preserved much of the natural and human landscape that characterized its frontier days.

During many decades of territorial status, Arizona developed strong regional ties with neighbouring California on the west and lesser but important exchanges with Mormon Utah on the north and Mexican Sonora on the south. The long-time bonds with Sonora give Mexicans distinctive status in Arizona. Arizona was the last of the contiguous 48 states to enter the Union, in 1912, and, though for long it was little more than a stretch of country that had to be crossed to get to somewhere else, it has become a stopping place as well. For many years it has been one of the tourist meccas of the nation and one of the fastest growing of the states.

Internal contradictions

Arizona is a deceptive state, even beyond its more obvious contrasts between sophisticated urban life and open ranges with cattle roaming across roadways. It has long been touted as one of the healthiest and most pollution-free areas of the world; yet for its poor, including its more than 90,000 Indians, the rate of infant mortality and of such diseases as tuberculosis and diphtheria is well above the national average. Industries and automobiles and other phenomena of modern living have begun to cloud the once clear skies of the state, especially around Tucson and Phoenix, the capital and largest city in the tier of Mountain States. Irrigated vegetable and cotton farms spread greenery from one horizon to another, but moisture for the arid land remains a critical need. This problem has led to disputes with California over the waters of the Colorado River and to continual draining of underground reserves that were built up over thousands of years. Arizona is attempting, like Israel, to build a modern industrial society in a dry land and, like Alaska, to conserve as much as possible pristine qualities that could so easily be sacrificed in the process. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; ROCKY MOUNTAINS; NORTH AMERICAN DESERT; GRAND CANYON; BASIN AND RANGE PROVINCE; and NORTH AMERICA.)

THE HISTORY OF ARIZONA

The history of the Southwest, both before and after the arrival of the European, paid little heed to boundaries, which, whether state or national, were often vague.

Aboriginal civilizations

Early inhabitants. Human settlement existed throughout the area from about 25,000 BC, whereas the nomadic Apache and Navaho Indians arrived within only a few centuries of the Spanish. These invaders arrived in large numbers after the collapse of the Anazazi and Hohokam civilizations. Cliff dwellings of the Anazazi and remnants of the elaborate Hohokam irrigation systems dot the northern and central sections of present-day Arizona. The dryness has helped preserve artifacts, even occasional bodies.

Spanish territory. Early Spanish exploration was concerned with finding the fabled seven golden cities, and settlement was mainly for mission work well into the 18th century. The entire area was called Nuevo Méjico, and most activity was in present-day New Mexico. Tucson was settled under Spain in 1776 and was the only post in Arizona that remained under the flag of Mexico after Apache warfare virtually emptied the land by the 1840s.

American territory and state. After the Mexican War, Arizona was ceded as part of New Mexico to the United States in 1848, and the Gadsden Purchase, an area south of the Gila River, was added in 1853. California gold brought adventurers and miners into the area in the 1850s, but the Civil War and troop withdrawal delayed settlement and allowed the Apache continued sway. In the 1870s and 1880s ranches and towns finally spread into former Indian lands, though a few lawless whites and Indians kept the bloody frontier tradition alive throughout the latter decade.

Following attainment of statehood in 1912, Arizona became the site of labour disputes involving copper-mine owners and the Industrial Workers of the World (IWW), culminating in 1917 in a deportation of suspected agitators that had repercussions for decades. Throughout the 20th century the state was in constant dispute with California over use of the waters of the Colorado River—the boundary of the two states. The 1963 Supreme Court decision in the main upheld Arizona's claims and has ushered in a new era of greater cooperation among all states of the lower Colorado River Basin.

THE NATURAL AND HUMAN LANDSCAPE

Next to climate, the beauty and variety of Arizona's landscape constitute its greatest natural attraction. The terrain combines generous amounts of sloping plains to provide a foreground for seemingly ever-present mountains, cliffs, and hills. The charm of its relief is enhanced by the widespread exposure of colourful rocks. The brilliant sunlight illuminates vegetative cover that ranges from green-carpeted pine and fir forests to bizarre shrub and cactus deserts, all augmented by brief bursts of colour from spectacular seasonal displays of wild flowers.

Physiographic characteristics. To Arizona's two major physiographic divisions, the Colorado Plateau and the Basin and Range Province, local authorities add the Transition. The northeastern two-fifths of Arizona is part of the scenic Colorado Plateau. Far less rugged than adjacent portions in Utah, these tablelands in Arizona consist mainly of plains interrupted by step-like escarpments. Though labelled mesas and plateaus, their ruggedness and inaccessibility has been exaggerated. The incomparable Grand Canyon of the Colorado River provides the major exception to what has proven to be an area easily traversed. Forest-clad volcanic mountains atop the plateaus provide the state's highest points, Humphrey's Peak, 12,633 feet (3,851 metres), in the San Francisco Mountains, and Baldy Peak, 11,590 feet (3,533 metres), in the White Mountains.

Land forms

Over 200 miles of the southern border of the Plateau is marked by a series of giant escarpments known collectively as the Mogollon Rim. West and south of the rim, a number of streams follow narrow canyons or broad valleys south through the Transition region and into the Basin and Range Province. The Transition region border-

ing the plateaus comprises separated plateau blocks, rugged peaks, and isolated rolling uplands.

The Basin and Range region of the southern and western third of the state, containing the bulk of the population but none of the large canyons and mesas for which Arizona is famous, consists largely of broad, open-ended basins or valleys of gentle slope. Isolated mountains rise like islands in the desert plain.

Contrary to desert stereotypes, sand dunes cover less than 1 percent of the state, and stony desert surfaces are seldom visible. The younger, transported soils of past and present river floodplains provide the more desirable soils for agriculture. Only the Colorado River and several dozen small headwater streams in the well-watered White Mountain–Mogollon Rim–Transition areas have year-round flow. Old records indicate that such major rivers as the Gila, Verde, San Pedro, and Santa Cruz once had stretches of permanent water complete with fish, beaver, and otter.

Climate. About half of Arizona is semi-arid, one-third is arid, and the remainder is humid. The Basin and Range region has the arid and semi-arid subtropical climate that attracts most winter visitors and new residents. Receiving over 80 percent of the possible sunshine, January days have a mean maximum temperature of 65° F (18° C) in Phoenix. Mild frosts can be expected at most locations during a four-month period, and light rains punctuate the winter months, interrupting exceedingly dry falls and springs. Summer daily maximum readings average 104° F (40° C) in Phoenix, and night temperatures drop to an average of 78° F (26° C).

Moisture-laden air from the Gulf of Mexico moves into Arizona during July, bringing more than two months of irregular but sometimes heavy thundershowers that are locally referred to as the "summer monsoon." Phoenix receives more than one inch (25 millimetres) of rain in both June and July, and Tucson receives twice that amount.

The Colorado Plateau has cool to cold winters and a semi-arid climate. Near mile-high elevations and direct exposure to polar air masses can produce January mean highs and lows as divergent as the 46° F (8° C) and 19° F (−7° C) in Winslow. Summer temperatures on the plateau are generally 10° cooler than those of Phoenix. Most of the region receives from 10 to 15 inches (255 to 380 millimetres) of rain, with a winter maximum along the western borders.

Because of the great amount of relief, climatic conditions within the Transition vary widely over small areas. Despite its desert image, 17 percent of Arizona falls into the humid class, much of it lying in the Transition and adjacent high southern edge of the Plateau.

Vegetation and animal life. Considering the great variety in relief and climate, it is not surprising to find similar diversity in the vegetation. About 10 percent of Arizona is forested, 25 percent woodland, 25 percent grass, and 40 percent desert shrub. Elevations above 6,000 to 7,000 feet host magnificent forests of ponderosa pine, topped in the highest areas by Douglas and other firs, spruces, and aspen. Below the forests, piñon pine dominates the plateau woodlands, and evergreen oak or chaparral the Basin and Range. Plains grasses cover about one-third of the plateau, and Sonoran or desert grass carpets the higher elevations of the basins. Mesquite trees are invading many of the former grasslands in the south. Foothills in the Tucson–Phoenix area carry exotic giant saguaro cacti of the Sonoran Desert, matched in areas of the northwest Basin and Range by dramatic stands of Joshua trees. Shrubs dominate the lowest portions of all areas: big sagebrush and saltbush in the plateau, creosote bush in the Basin and Range.

Variety of natural life

The animal life is even more varied, containing representatives of the Rocky Mountain, Great Plains, and Mexican ecological communities. Among the larger animals are black bear, deer, desert bighorn sheep, wapiti, or elk, and antelope. The tropical coati, a racoon-like mammal, has spread northward into Arizona, and the javelina ("wild pig") is a favourite game animal in the south. Among the several cats, the bobcat thrives, and the mountain lion is the most prized. Coyotes, skunks, and porcupine abound, as do cottontail and jackrabbits, and there are several varieties of foxes. Tropical birds include the thick-billed parrot and the brilliantly plumed, coppery tailed trogon, which visit the mountains along the southeastern border. Game birds include turkey and several varieties of quail and dove. Among native fish are the Arizona trout and the six-foot minnow known as the Colorado squawfish. Poisonous animals include the rattlesnake, the scorpion, and the Gila monster.

Patterns of human settlement. Despite Arizona's romantic image as a land of picturesque ghost towns and mining camps, isolated ranches, primitive Indian reservations, and bucolic cotton and citrus farms, more than three-fourths of its people are congregated in modern urban settlements of over 2,500 population. Phoenix and Tucson together account for about half of the state's population. The unincorporated status of mining centres with populations of up to 6,000 and of new towns comprising retirement and resort communities of from 2,000 to 15,000 people further obscures the degree of urbanization of the Arizona population.

Approximately 30,000 people live on the more than 6,000 recognized farm and ranch units. The typical ranch house and headquarters stands at the mouth of a canyon or some other source of dependable water. The irrigated lands of the central and southern regions contrast with the surrounding desert, presenting a flat, green, tree-studded landscape that often resembles cultivated plains of the Middle West and South. Rectangular fields planted in rows of cotton, sometimes paralleled by concrete-lined irrigation ditches with earthen banks, give regularity and linearity to the landscape.

Rural and ranching life

Most towns and cities have low-density populations, the result of large lots and considerable vacant land within built-up areas. Residential building during the 20th century adhered almost exclusively to styles popular in the West, producing relatively uniform neighbourhoods of bungalow, Spanish revival, and ranch-style houses. Smaller towns contain mostly wood-frame dwellings and brick commercial buildings, and structures of mud adobe can be seen in older areas throughout the southern part of the state. Prescott, the first capital of Arizona, reflects its founding by Northerners in its red-brick buildings, central courthouse square, and dwellings more typical of eastern America.

The dominance of the Phoenix trading area, which extends over most of the state, began with its selection as the permanent location for the state capital, its central location, and the extensive agricultural economy that developed after the completion of Roosevelt Dam and Reservoir on the Salt River in 1911. Tucson, the early centre of Mexican and Anglo settlement, continues to be the wholesale, retail, and entertainment focus of southern Arizona. It maintains well-developed commercial and medical ties with Sonora and northern Sinaloa.

THE ARIZONANS

Arizonans traditionally identify themselves as Anglo, Mexican, Indian, black, and Chinese Americans. The numerically dominant Anglos in the cities have a variety of European backgrounds, but few are foreign born, and ethnic identification is less important than association with a prior home state. Traces of the heavy Texas contribution to the rural population can be detected in speech, attitudes, and customs.

Minority ethnic groups. The more than 450,000 Arizonans with Spanish surnames proudly claim to be Mexicans, the term generally used in Arizona for the Mexican-Americans. These Mexicans are affected in varying degrees by the practice of social and residential segregation. Some are found in barrios where Spanish is the common tongue, whereas others disperse throughout the cities and participate fully in the overall business, political, and social life of their communities. Where language and lack of skills are not a barrier, equal employment opportunities generally prevail in southern Arizona's larger cities and companies. Some of the most prominent families of Tucson are of Mexican descent, and intermarriage in

The Mexican and Indian peoples

such border communities as Nogales is not uncommon. Mexican music, food, building styles, furnishings, clothing, and social customs have been widely adopted by all Arizonans.

Arizona has long been associated with the Indian American, for here occurred many of the final, dramatic conflicts between frontiersman and native. Few native Arizona Indian tribes experienced the tragic annihilation or displacement that occurred elsewhere, and today more Indian Americans live in Arizona and comprise a higher percentage of the total population than in any other state. More than 90,000 people group themselves into 14 tribes on 19 reservations, which range in size from the 1,400-acre Yavapai Reservation to the nearly 9,000,000-acre reserve of the Navaho people. The latter tribe, numbering over 50,000 in Arizona, presses vigorously to direct the development of its land and people, and the tribal government assumes partial or complete responsibility in many areas of social and economic life.

Among the remaining tribes, which number more than 30,000, the best known are the once-militant Apache and the highly talented Hopi people, each of whom also pursues aggressive development programs similar to those of the Navaho. Less well-known are the equally numerous Papago and Pima tribes, historic allies of the frontiersman. The peaceful Papago, whose median family income on the reservation is 6 percent of the national Anglo income, may well be America's poorest people. About half of them live off the reservation.

For Arizona's black population, comprising 3 percent of the total, living quarters remain largely segregated, but Arizona schools desegregated voluntarily in the early 1940s.

Demography. The 1970 population of 1,770,900 represented a 36 percent increase over 1960, but the rate of growth was only half that recorded during the previous decade. Conservative estimates project a 1980 population of 2,400,000. Immigration of persons seeking the state's climatic amenities and economic opportunities accounts for half the population gain, the remainder resulting from a birth rate well above the national average. The death rate remained below the national average, in part because the percentage of residents above 65 years of age is below the national average.

THE STATE'S ECONOMY

As Arizona's population grew, its economy shifted from a frontier stage emphasizing primary, natural-resource-oriented industries to secondary and tertiary industries associated with more advanced economies.

Manufacturing and tourism. Manufacturing has become the most important basic industry, notably in electrical, communications, aeronautical, and aluminum-product production. The great increase in manufacturing employment since World War II has given Arizona one of the most dynamic economies in the nation.

Tourist expenditures account in part for the high per capita employment and volume of retail sales. Manufacturing and tourism both depend upon natural resources in an essentially nonconsuming fashion. Manufacturers find a large, multitalented labour pool attracted to the state's climate and scenery. Tourism reflects even more directly the warm winter climate and the physical features of the landscape. Natural and human features of historic, scientific, and recreational value have been protected and developed by the government, probably to a greater extent in Arizona than in any other state. There are 34 federal parks, monuments, memorials, forests, recreation areas, historic sites, and game and wildlife refuges, as well as ten state and tribal parks.

Presence of the federal government

Government and land resource. The magnitude of the federal government's role in the Arizona economy is evident also in its numerous military facilities. The total personal income of federal military and civilian employees exceeds that from agriculture and mining combined, and only manufacturing generates a higher gross income. These expenditures reflect in part the federal government's ownership of 45 percent of Arizona's land and the holding in trust of another 27 percent in the form of Indian reservations. Only about 18 percent of Arizona is private land, but there is no shortage of acreage for urban settlement. Though the economic effects of large public holdings remain controversial, the positive contribution of public lands to the aesthetic quality of the landscape is unquestioned.

Agriculture and water supply. The most stable industry is agriculture. Acreage and employment have been dropping slightly, while income increases modestly. Although Arizona produces 47 percent of America's long-staple cotton, the demand is limited, and this premium variety accounts for only 10 percent of the total cotton acreage. Vegetable acreage, especially in lettuce, has increased so dramatically that winter produce is now the leading source of crop income. Citrus acreage continues to increase in the Yuma area, more than replacing acreage lost to urban expansion in the Salt River Valley. All but a few thousand acres on Indian reservations of the Colorado Plateau are under irrigation, producing yields double the national average for most crops. Farms are larger, more heavily capitalized, and more frequently organized on a corporate basis than in any other state.

The grazing of livestock occupies 30 times more land than crop raising, and its cash value is more than triple that of either cotton or vegetables but less than half that of tourist income. Feeder lots near agricultural areas, much less romantic than the open range, hold half of the more than 1,000,000 cattle within the state.

Arizona agriculture anticipates a water shortage stemming from the expansion of urban areas into surface-water irrigation districts and increased cost of pumping from declining water tables. Farms and ranches account for over 90 percent of the water used annually for all purposes. The annual overdraft of groundwater withdrawals over natural recharge has been between 3,500,000 and 4,000,000 acre-feet annually for some years.

Mining and forestry. Copper remains Arizona's most distinctive contribution to the national economy, accounting for over 50 percent of the nation's total annual production. The conversion of most mines to highly efficient open-pit operations employs a relatively small but growing labour force. Interest in small-scale mining, especially of gold and silver, greatly exceeds the actual production, most of which comes as a by-product of copper mining. Petroleum from the Four Corners area of the Navaho Reservation moves by pipeline to California, and coal from the Black Mesa area of the Hopi reservation will be sent by pipeline to Nevada generating stations.

The lumber and pulp-paper industry deserves notice because it clearly contradicts two widely held illusions about Arizona: that the state is all desert and that a shortage of water has deterred industrialization. Most of the ponderosa-pine lumber comes from the Mogollon Rim–White Mountain area.

Transportation. Arizona's transcontinental routes carry more people and goods through it than to it. The east–west route traversing the relatively level Colorado Plateau provides the nation's major highway and railway link between the Middle West and Southern California. A historically older but currently less used route through the valleys and basins of the south is followed by the Southern Pacific Railroad and a modern interstate highway. Divided, limited-access highways also serve most of the north–south route connecting Flagstaff, Phoenix, Tucson, and Nogales. The large amount of gentle relief and the small amount of rainfall make unpaved roads serviceable for remote areas, except immediately following a rain. Four-wheel-drive vehicles and motorcycles explore the backcountry on weekends—to the increasing concern of cattlemen and environmentalists. Both Phoenix and Tucson have direct air flights to major cities in the United States and to Mexico.

Historic and contemporary routes

ADMINISTRATION AND SOCIAL CONDITIONS

Governmental structure. The constitution of Arizona reflects the strength of the Progressive movement at the time of the constitutional convention in 1910. It provides for maximum citizen participation through initiative and referendum on legislation and recall of all elected of-

ficials, including judges. It also features a broad dispersal of executive power: the governor's office shares administrative authority with numerous other elective offices. The chief functions of the governor are to recommend and veto legislation, perform ceremonial acts, and mold public opinion, but there is a trend toward a stronger executive branch. The attorney general, who succeeds to the governorship in case of a vacancy, holds the second most contested elective office.

The legislature comprises a 60-member House of Representatives and a 30-member Senate. The massive growth of Phoenix and Tucson, combined with re-appointment, has given urbanized Maricopa and Pima counties three-fourths of the seats in both houses.

A constitutional amendment in 1960 restructured the judicial branch into a Supreme Court, Appellate Court, Superior Court, and local justice and appeals courts; there are no special courts. Despite repeated attempts to make judicial offices appointive, judges campaign for election on a nonpartisan basis after running in the primary with party identification. The state constitutes one entire federal judicial district.

The 14 counties, acting as agents of the state, constitute the basic medium of local government. Elected county supervisors are relatively free of legislative direction other than recently imposed restraints upon taxation and budgeting. There are no township governments. State law prescribes the type of town government available for settlements under 3,000 and the city form to be used by larger communities, but metropolitan centres have considerably more freedom in organization and operation.

Politics. Arizona has changed from a traditional one-party state dominated by the Democrats to a two-party distribution, in which Republicans repeatedly have won the highest offices since 1950 and gained control of the legislature for the first time in 1966. Liberal Democratic factions continue to receive support in mining communities, among traditionally Democratic Mexican-Americans, and from segments of the metropolitan populations, though conservative "Pinto Democrats" in rural areas often support Republican candidates.

Standards of living. Wages and income vary greatly between the extremes of manufacturing and the part-time seasonal work in agriculture and services, and average figures are meaningless. The large number of employees in high-paying electronic and military-related industries push the average wage in manufacturing to the national figure. The large underemployed Indian-, Mexican-, and Negro-American population, however, coupled with the potential inflow of unskilled labour, keeps wages for unskilled workers low.

Arizona as a health mecca

Health and welfare. Public opinion consistently ranks Arizona among the healthiest areas in the nation, if not the world, though actual data are not adequate to support the belief. Among Indians, infant mortality and a host of maladies occur at high rates, tuberculosis remains a problem among the general population, and San Joaquin Valley fever (coccidioidomycosis) has been almost endemic. Evidence indicates that the low humidity and mild winters have a therapeutic or arresting effect on certain forms of pulmonary and arthritic health problems, but it has not been demonstrated scientifically that the general native-born population or young immigrants can expect to be healthier than residents elsewhere in the United States.

The state Department of Health controls a variety of administrative, aid, and inspection services, including institutions for mental and tubercular patients in Phoenix. Several of the more populous counties maintain public hospitals. Private medical care in the metropolitan areas is excellent, but for the state as a whole, the number of physicians and dentists falls below the national level. Despite its attractiveness to the ill and the aged, Arizona has no more than its per capita share of the nation's hospitals and nursing homes. The recently established College of Medicine at the University of Arizona and two university-affiliated nursing colleges work toward expanding the supply of medical personnel.

A generally modern approach to public welfare by the legislature has been coupled with financial restraints that limit the effectiveness of the programs. The Department of Public Welfare works mainly through county agencies with a variety of programs for children and for the aged, blind, and permanently and totally disabled.

Education. Public education has struggled to meet the rapid increase in students accompanying the population boom. Five years of college work is required for secondary-school teachers, and children must attend school between the ages of 8 and 16. Elementary, secondary, and consolidated districts operate with the assistance of county and state superintendents and an appointed state Board of Education. State support for local districts has been increasing, accompanied by tighter controls over maximum annual budget increases. Public school districts have begun to supplement and replace some reservation schools operated by churches and the federal Bureau of Indian Affairs.

Like most states in the Rocky Mountains, Arizona's higher education is dominated by large public universities. The Arizona Board of Regents assumes responsibility for the University of Arizona (founded, 1885) in Tucson, Arizona State University (1885) in Tempe, and Northern Arizona University (1899) in Flagstaff. To meet the need for higher education throughout the state, seven junior colleges had been established by 1970 under the joint control and support of county boards and the state. There are two private four-year institutions, Grand Canyon College in Phoenix and Prescott College in Prescott, as well as the private Thunderbird Graduate School of International Management in Phoenix.

CULTURAL LIFE AND INSTITUTIONS

The arts. Traditionally a centre for Indian folk arts and crafts, Arizona had no early circles of painters and writers comparable to those of neighbouring New Mexico. Interest in painting, crafts, drama, music, and publishing, however, has increased with population growth. Architecture and the graphic arts are particularly aware of Southwestern regional themes. Writers of fiction and nonfiction alike have focussed their attention upon Arizona's 19th-century frontier era. Among the best-known earlier writers of popular fiction were Zane Grey and Harold Bell Wright, both of whom employed local settings and lived and worked in the state during periods of their careers. Later contributions of note were made by Oliver LaFarge, Will Comfort, and Ross Santee.

Indian arts and crafts

Contemporary arts and crafts of the Indian American, executed within the dynamic traditions of the tribes, but with considerable individual creativity, receive enthusiastic support from tribal organizations and the local general public. The Hopi and Navaho people have among them outstanding painters, silver and jewelry craftsmen, weavers, basketmakers, and potters; and Papago women produce a variety of handsome baskets.

No city dominates as an art centre, though Scottsdale, Tucson, Sedona, and Tubac have colonies of working artists. Outstanding collections, mainly paintings, can be viewed in the Phoenix Art Museum and the Museum of Art at the University of Arizona in Tucson. The Arizona State Museum in Tucson, the Heard Museum of Anthropology and Primitive Art in Phoenix, and the Museum of Northern Arizona in Flagstaff feature archaeological and traditional collections of Indian arts and crafts. The Arizona–Sonoran Desert Museum in Tucson has received worldwide attention as a living museum dedicated to the natural world of the Sonoran Desert and the implications of its occupancy by man.

Both Tucson and Phoenix support symphonies. Mexican and ranchero music are heard in the central and southern part of the state. Theatre has been popular since the early mining camps.

More than any other art form, architecture embodies the conflict between the regional traditions of the Southwest and modern international trends. The best known modern structure is Frank Lloyd Wright's auditorium at Arizona State University. Among the many structures in the Spanish idiom, the Heard Museum is outstanding, and the Nogales Public Library synthesizes the Spanish

Southwestern and contemporary styles. The most photographed and beloved building in Arizona remains the Mission San Xavier del Bac, the "White Dove of the Desert," in Tucson, completed by the Franciscans in 1797.

Libraries, publishing, and communications. The University of Arizona library is the largest in the state. In addition to other college and university libraries, there are several specialized collections. County and state regional systems supply library services throughout the state.

The state's leading book publisher, the University of Arizona Press, releases a variety of scholarly and popular titles, most with a Southwestern focus. The state's most widely known publishing venture, *Arizona Highways*, brings varied features of Arizona to a worldwide audience.

Of the 73 newspapers published, 13 are dailies, of which the Phoenix *Arizona Republic* has the largest circulation. Tucson's *Arizona Daily Star* is frequently the only major newspaper that supports Democratic candidates. Both have nearly statewide circulation.

Recreation. A variety of individual and organized sports and recreational activities compete with the arts and communication media to provide diversified entertainment and leisure activity. Varied desert and forest terrains and several dozen manmade lakes atttract thousands of hunters, fishermen, campers, hikers, and amateur prospectors and historians to the open country throughout the year. Rodeos revive the Old West in all the cities and on the larger Indian reservations.

Prospects. The political and economic institutions of Arizona are gradually adjusting to the recent growth in urban population, but problems of providing job opportunities and government services will remain for some time. With growth, local concern increases over the possible loss of the amenities of clean air and undisturbed desert and forest that initially attracted so many residents to the state. The eventual use or disposition of Indian and federal lands is a fundamental consideration in Arizona's future.

BIBLIOGRAPHY. UNIVERSITY OF ARIZONA FACULTY, *Arizona: Its People and Resources* (1971), the most comprehensive and reliable source available; ROGER DUNBIER, *The Sonoran Desert* (1968), a highly readable and competent treatment of southern Arizona and northwest Mexico, dealing with man and his use of the physical setting through time; BYRD H. GRANGER (ed.), *Arizona Place Names*, rev. ed. (1960), an excellent travelling companion as well as an armchair introduction to much of Arizona's geography and history; DONALD W. MEINIG, *Southwest: Three Peoples in Geographic Change, 1600–1970* (1971), a study of the manner in which the Indian, Hispano, and Anglo have given character to a region which includes west Texas, New Mexico, and Arizona; JOSEPH MILLER and HENRY G. ALSBERG (eds.), *Arizona, the Grand Canyon State: A State Guide*, 4th ed. (1966), though still not completely revised, this later edition of one of the best of the W.P.A. Writer's Guides is the most complete guide available; ODIE B. FAULK, *Arizona: A Short History* (1970), a well-written, factual account; *Arizona Highways* (monthly), excellent colour photographs of natural and human landscape features accompanied by sometimes lyrical, sometimes solid texts; ELDRED D. WILSON, "A Résumé of the Geology of Arizona," *Bull. Bur. Mines Univ. Ariz. 171* (1962), written for the curious, intelligent layman; WILLIAM SELLERS and CHRISTINE GREEN (eds.), *Arizona Climate*, rev. ed. (1964), all the reliable data available plus a discussion of the climate of the state of all stations with reasonably complete records; TOM BAHTI, *Southwestern Indian Tribes* (1968), one or two pages of accurate historical and contemporary information about the people, their reservations, and their crafts, plus sound suggestions for more detailed reading (well illustrated); BRUCE B. MASON and HEINZ R. HINK, *Constitutional Government in Arizona*, 2nd ed. (1965), an evaluation as well as a description of state government; JOSEPH WOOD KRUTCH, *The Voice of the Desert* (1955), along with *The Desert Year* (1952), Krutch's work represents the finest literary interpretation of the desert to appear in recent years.

(M.E.H.)

Arkansas

Ever since Arkansas was admitted as the 25th member of the United States in 1836, its people have maintained a remarkable homogeneity, and today most of them, whether white or black, are native to the state. Striking cultural contrasts exist within the state, however, with the long-isolated mountain peoples who eked out subsistence livings in the north and west counterposed to the peoples to the east and south who created a Southern environment in which cotton growing and sharecropping long were dominant modes of economic life. Between the two regions lies Little Rock, the capital and the urban and economic centre of the state. Its location and increasingly cosmopolitan character are symbolic of Arkansas's growing unification and urbanization, reflecting the broader patterns of American life in the 1970s.

Few of the more than 1,900,000 Arkansans counted in the 1970 census any longer feel complacent about the state's relative poverty and backwardness. Although Arkansas remains among the lowest ranking states in per capita income and other economic indicators, the 1960s saw this income rise by nearly 50 percent; value added by manufacture rose some threefold; the overall economy gained faster than that of the national average; and the population increased, reversing a long decline. The decade saw also the beginning of programs to increase these upward trends and to continue the process of equalizing the educational, economic, and social opportunities of black and white citizens.

Arkansas's 53,104 square miles (137,539 square kilometres) make it 27th in area among the states, but, except for Hawaii, it is the smallest state west of the Mississippi River. Its neighbours are Missouri to the north, Tennessee and Mississippi to the east, Louisiana to the south, Texas to the southwest, and Oklahoma to the west. A map of Arkansas shows not only the high Ozark and Ouachita Mountains in the north and west but also a heavy tracery of rivers cutting through rich agricultural lands. Nearly all of them flow from northwest to southeast and empty directly into the Mississippi, which forms the entire eastern boundary. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; CIVIL WAR, U.S.; NORTH AMERICA; and MISSISSIPPI RIVER.)

THE HISTORY OF ARKANSAS

Exploration and settlement. Arkansas's earliest inhabitants were bluff dwellers whose farming and hunting culture flourished *c.* AD 500. Later mound-building cultures left sepulchral mounds and other remains along the Mississippi.

Following Spanish and French explorations of the trans-Mississippi regions in the 16th and 17th centuries, the Frenchman Henri de Tonty founded the Arkansas Post on the Lower Arkansas River in 1686. The first permanent white settlement in the future state, it served as a fur-trading centre and a way station for travellers between the Gulf of Mexico and the Great Lakes.

Following the Louisiana Purchase by the United States in 1803, Arkansas lay within the territories of Louisiana until 1812 and of Missouri until 1819, when it became a separate territory. Its northern boundary, latitude 36° 30′ N, was the famous line of the Missouri Compromise in 1820 that was to separate the slave and free states in the newly opening West.

Statehood and Civil War. By the time of statehood in 1836, all land titles of the Quapaw, Osage, Caddo, Cherokee, and Choctaw Indians had been withdrawn by Congress, and the tribes were forced westward into the Indian Territory, the future Oklahoma. Violence broke out along the state's western border until near the end of the 19th century, when the frontier atmosphere disappeared with the white settlement of the Indian Territory.

War and reconstruction: conflicting sentiments

Although a slave state, Arkansas did not secede from the Union until May 1861—five months after South Carolina did so. Arkansas took this action only after the Confederate capture of Ft. Sumter and President Lincoln's call for volunteers. Union sentiment was strong in northern Arkansas; about 6,000 Arkansans joined the Federal forces. About 58,000, however, fought for the Confederacy. Little Rock fell to Federal troops in 1863,

and the state was a legislative battleground between secessionist supporters and the imposed Republican government for a decade. Arkansas was readmitted to the Union in 1868, but internal strife approached open warfare. In 1874 the state returned to the Democratic Party, and remained with it until Winthrop Rockefeller, a Republican, was elected governor in 1966.

The chief long-range effects of the war on Arkansas, in common with most of the former Confederate States, were a crop-lien sharecropping system, a race problem of formidable and new dimensions, a one-party political system, and widespread poverty. Economic development in Arkansas was severely handicapped by the collapse of state credit following repudiation in 1885 of bonded indebtedness including interest of nearly $14,000,000.

Recent decades. Until World War II, Arkansas experienced slow economic development, remained predominantly rural, and was tied to a single cash crop—cotton. The Depression of the 1930s was worsened by years of drought that turned many farm families into itinerant labourers across the nation. In 1957, federal troops entered Little Rock to maintain order there for a year, after the state militia had been ordered to prevent the desegregation of Central High School; the confrontation focussed international attention on the state. In the 1960s the state's attempts to improve its economic status seemed at last to be bearing fruit.

THE NATURAL AND HUMAN LANDSCAPE

The physical environment. *Geographical regions.* A line drawn from the southwest corner to the northeast corner of the state approximates the division between the highlands lying west and north and the lowlands lying south and east. The highlands are divided by the Arkansas River Valley into the Ouachita Province on the south and the Ozark Plateau on the north. The lowlands include the Mississippi Alluvial Plain in the east and the West Gulf Coastal Plain in the south and extreme southwest. The highlands are covered by the dense pine and hardwood forests of the Ouachita and Ozark national forests.

Mountains and plains of Arkansas

The Ozark Plateau is broken by broad, flat-topped ridges and steep valleys with fast moving streams. The more rugged southern edge, known as the Boston Mountains, contains the highest elevations. Excellent farmland, producing a wide variety of crops, lies in the northern part. The Arkansas River Valley contains the highest point in the state, Mt. Magazine, at 2,823 feet (860 metres). The western section has extensive coal and natural-gas deposits. Several peaks in the Ouachita Province reach 2,500 feet. The mountains are eroded, exposing faulted rock, and the ridges extend west and east. The famous Hot Springs National Park is in this area.

The West Gulf Coastal Plain has gentle hills suitable for livestock grazing as well as general farming. Much of this area consists of pine and white-oak forests, which sustain extensive lumbering industries. Petroleum and natural-gas deposits have been developed in the region around Smackover and El Dorado. The Mississippi Alluvial Plain, much of which was once a vast swamp, is now well-drained and protected against flooding. It contains the state's richest and most fertile farmland. Rice and soybeans have replaced cotton as the major crops. A long, narrow chain of hills, Crowley's Ridge, runs north and south through the centre of the plain.

Climate. The climate generally is mild in winter and hot in summer. Normal high–low temperatures in Little Rock in January are 51°–31° F (11°– −1° C); in July, 93°–71° F (34°–22° C). The normal annual precipitation of 48 inches (1,220 millimetres) is distributed about equally during the year, though summers tend to be drier.

Vegetation and animal life. A great variation in soil types and elevations in Arkansas provides environments for a large number of plant species. There are more than 200 species of trees, of which the pine, oak, hickory, maple, gum, ash, cypress, and elm are most important. The woods in fall and spring are colourful with dogwood, flowering fruit trees, redbud, innumerable wild flowers, and azaleas.

Arkansas is situated on the Mississippi flyway; migratory water birds and some 300 native species attract hunters to the rice fields and reservoirs of eastern Arkansas. Deer, quail, opossums, turkeys, squirrels, and rabbits are among the more abundant game animals. Bobcats and wolves are not uncommon in the hill country. The lakes and streams of the state offer an abundance of fish—including crappie, bass, drum, catfish, buffalo, gar, and trout.

The landscape under human settlement. *Regional diversities.* The inhabitants of the Ozarks and Ouachitas lived until recently in rural isolation, which bred an independence of spirit and a suspicion of strangers. They long lived off the land: hunting and fishing were essential to supplement the limited produce of their farms. Since a plantation economy was impracticable in the uplands, few slaves were brought into the region. In eastern Arkansas the plantation economy produced a vast gulf between the sharecroppers and tenants on one end of the social scale and the managers and landlords on the other. Small farmers and merchants constituted another class. The croppers lived a bare and meagre existence. Handicapped by lack of economic resources and education, they accomplished remarkable results through the Southern Farm Tenants Union, which they organized in eastern Arkansas in the 1930s; this organization has influenced the national farm policy of presidents from Franklin D. Roosevelt onward.

Contrast of cultures

Although changes in the economy of both regions were evident earlier, the rate of change since World War II has been dramatic. The Ozarks are no longer isolated. A network of paved highways brings tourists to enjoy the region's scenic beauty and varied recreational activities. Numerous "retirement villages" attract visitors and buyers from across the country. The tourist industry will probably remain the economic mainstay, though small industrial plants have taken advantage of the climate and the ample labour supply.

Mechanization of farming in eastern Arkansas and the shift from cotton farming to rice and soybeans has virtually eliminated the sharecropper—though not the rural poor. As the pace of mechanization increased, so did the exodus of the former tenant farmers to cities in the North and East. Farming is increasingly a corporate venture rather than a family affair. Eastern Arkansas is still, however, more Southern in character than the mountainous region. Many of the rural shacks have gone and the towns have grown, but mile after mile of cultivated fields are broken only by small woodlands and pastures. Here and in central Arkansas reside the majority of the blacks, many of whom still work the land as did their ancestors. The people still take pride in maintaining traditional "Southern hospitality."

Urban Arkansas. Much of the residential area of Little Rock lies in the low hills and valleys of the easternmost foothills of the Ouachita Mountains. Its downtown is being redesigned as part of an urban renewal project. The city is the major port on the Arkansas River, a marketing centre, and a fast-growing manufacturing centre. Fort Smith, the second largest urban centre on the Arkansas at the western boundary, is the most industrialized city in Arkansas and a regional centre for northwestern Arkansas and northeastern Oklahoma. The economy of Pine Bluff, some 50 miles downriver from Little Rock, depends primarily upon the surrounding agricultural area. Texarkana, contiguous with the Texas city of the same name, is important as a railway regional trade centre.

THE PEOPLE OF ARKANSAS

Composition and distribution. Prior to the Civil War, Arkansas's population was largely from Kentucky and Tennessee, a part of the westward movement of Scottish, Scots-Irish, and English stock from Virginia and the Carolinas since early Colonial times. The black population in 1860 was about 110,000, or 25 percent of the total; in 1970, it was nearly 360,000 but only about 18 percent. Three counties in eastern Arkansas were more than 50 percent black. The heaviest concentration of

population is in the fertile eastern alluvial plain, in the river valleys, and on the plateaus in the northwest.

Religion and social life. The largest religious denominations are the Baptist, Methodist, Presbyterian, Church of Christ, and Roman Catholic. The general religious atmosphere is that of conservative fundamentalism, and Arkansas is considered to be a part of the Middle American "Bible Belt." This fundamentalism underlies many characteristic attitudes of Arkansans. The state's law forbidding the teaching of the theory of human evolution never has been repealed, though federal Supreme Court decisions have rendered it unconstitutional. The sale of alcoholic beverages is subject to local option; many counties and cities prohibit their sale or permit it only in private clubs and certain other establishments in major cities. The right-to-work amendment to the state constitution in 1944, prohibiting compulsory union membership, was sponsored by the Christian Association, among others. Harding College in Searcy is the site of an annual Freedom Forum, which advocates a blend of religious fundamentalism, extreme patriotism, and free-enterprise capitalism.

Demography. Following a peak in 1940, Arkansas's population experienced two decades of sharp decline. Although it was close to the national average in natural increase (*i.e.*, in the greater number of births than deaths), Arkansas in each decade lost through emigration about one-third more blacks and about one-sixth more whites than it gained through immigration. The loss was checked after 1965 to produce a 7.7 percent gain during the decade, though the black population continued to decline, both relatively and absolutely.

Patterns of migration

The 50 percent urbanization of Arkansans recorded in 1970 reflects both a real growth in the cities and a real decline in the countryside, as well as a major change in the state's economy. Between 1950 and 1965, the number of persons engaged in agriculture declined by nearly 75 percent, to about 60,000. The loss of these former farmers to other states appears to have been checked by greater economic opportunity within the state.

THE STATE'S ECONOMY

Cotton is no longer king in Arkansas, and the state is no longer primarily agricultural. Industrialization and urbanization are major factors behind Arkansas' record of economic progress during the 1960s. Labour unions are strong in transportation, utilities, construction, and heavy industry, but most of the state's labour force is unorganized. In both political and economic policy-making, labour has been less influential than business.

Natural resources. Oil production began in 1921 in southern Arkansas, but conservation controls have restricted production. Natural gas is drawn from the oil fields and the Arkansas River Valley. Coal of near smokeless quality also is found in the valley. The bauxite (an aluminum-bearing ore) that is obtained by strip-mining to the south and southwest of Little Rock represents more than 90 percent of America's supply. Magnet Cove near Hot Springs contains more than 40 different minerals in one small valley; barite and titanium are the most important. Arkansas whetstones made from novaculite are regarded as among the finest in the world. Near Murfreesboro in southwest Arkansas is the only diamond mine in the nation, now operated only as a tourist attraction. Almost one-half of Arkansas is covered by forests, notably extensive stands of pine and white oak.

Mineral wealth

Hydroelectric power is produced at most of the dams erected by the U.S. Army Corps of Engineers and at one privately built dam, but steam-generated power plants produce most of the energy. Two nuclear-powered generating stations are under construction near Dardanelle.

Agriculture and manufacturing. As recently as 1960 cotton was still the major source of agricultural income, but by the end of the decade the major crops were, in order, soybeans, poultry, cotton, and rice. Commercial fish farming has begun to take advantage of the extensive rice paddies of eastern Arkansas. Farms have followed the national trend of increasing in size while decreasing in number.

Manufacturing is chiefly of the consumer-goods type. Industries that increased substantially in numbers of employees in the 1960s were food processing and manufacturing of wearing apparel, furniture, and electrical and nonelectrical machinery.

Tourism. Arkansas devotes considerable effort to its attractions for out-of-state vacationers, who annually contribute millions of dollars to its economy. State and national agencies stock lakes and streams with fish, and the state's preserves and conservation practices assure ample game in hunting seasons. The largest single attraction is Hot Springs National Park, which offers both out-of-doors and luxury-hotel recreation throughout the year. Blanchard Springs Caverns, which appears to rival New Mexico's Carlsbad Caverns in size, is being developed by the National Park Service; it is expected to be another major tourist attraction.

State finances. Although state revenue has been increasing, mounting needs for additional revenue led to tax increases in 1971, the first since 1957. The state hopes to generate future revenue by raising per capita incomes—increasing the number of employment opportunities and developing the human resources to their utmost.

Transportation. Five major railroads provide freight service on some 3,000 miles of track within Arkansas, as well as to major cities in the central United States. Airline service is provided by three national and two regional carriers to any point in the nation from a growing number of airports. Some 60 common truck carriers operate over more than 600 miles of interstate expressways, and 50 percent of the nation's population is within a two-day driving radius of Arkansas. The Arkansas River Project in navigation and flood control is the largest civil works project ever undertaken by the U.S. Army Corps of Engineers. The project has cost over $1,300,000,000 and provides access to more than one-half of the nation's navigable inland waterways.

The Arkansas River Project

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. Adopted in 1874, Arkansas's constitution has been amended more than 50 times. In 1970 the voters rejected a new constitution. The governor is elected to a two-year term; he has the authority to pardon convicts, to summon the legislature into special session, and to veto acts, though he may be overridden by a two-thirds vote in each legislative house. In 1971 the governor gained greater control over 13 previously independent executive agencies through the creation of "cabinet-rank" departments. The Senate has 35 members with four-year terms; the House of Representatives, 100 members with two-year terms. The judicial branch contains a Supreme Court of seven popularly elected members who serve eight-year terms, 18 circuit court districts, and 13 chancery districts. Where established, municipal courts have jurisdiction throughout the county.

Arkansas's penal system attracted nationwide attention during the 1960s, with allegations of brutality and murder at the prison work farms. Shocked, the state set about to remedy the worst abuses. The elected officials of the 75 counties include judge (the chief executive), clerk, treasurer, sheriff, and collector or surveyor or both. Elected justices of the peace compose a Quorum Court, which serves as an advisory body to the judge and exercises some legislative functions. There are numerous local improvement districts, and, of course, school districts. Although a number of incorporated cities have a city-manager form of government, the traditional mayor–council form is most common.

The Democratic Party has dominated political activity since Reconstruction, with the notable exception of the Republican Winthrop Rockefeller's terms as governor from 1967 to 1971. In recent years the Republicans have begun holding nominating primaries. Unless a candidate receives a majority of votes cast in a preferential primary, a runoff is required. Permanent voter registration replaced the poll tax in 1965.

Political life

The social milieu. Wage levels of Arkansas's workers are among the lowest in the nation, and living costs ap-

proximate those of the south central region. Blacks continue to live at distinctly lower economic and social levels despite an improved climate in the 1960s, and they emigrate in substantial numbers.

Civil rights movements. Public-school desegregation has been the primary target of civil rights movements in recent years. Attempts to alter discrimination in housing and employment have been less dramatic. The demonstration against school integration in Little Rock in 1957 was a momentary setback; school integration has subsequently gone ahead with little difficulty in most areas. Opposition has been strongest in eastern and southern Arkansas, where blacks make up a large percentage of some communities. Many private schools have been established to circumvent integration.

Status of race relations

Legalized discrimination through the Jim Crow laws no longer exists. Under Governor Rockefeller many blacks received appointive office or were sought out for employment by state agencies. Blacks seek election to the state and local legislatures in increasing numbers. A major problem of the black Arkansans, like that of blacks nationwide, is an economic one: to obtain and hold the better-paying jobs that require both education and skill.

Education. The public school system functions under a State Department of Education and district school boards. Specialized institutions include schools for the deaf and the blind. Two children's colonies for the retarded have attracted nationwide acclaim in the field.

In addition to its main campus in Fayetteville, the University of Arkansas operates in Little Rock a separate university as well as medical, technological, legal, and social-work centres. Several other state colleges and a university developed from institutions for the agricultural and mechanical sciences and for teacher training. The national trend toward establishing a statewide system of two-year colleges has not been strong in Arkansas.

Health and welfare. Problems of malaria, pellagra, and pinworm that once plagued the region have been virtually wiped out by widespread efforts of state and local health authorities. The state health department and welfare commission administer many programs funded in part by the federal government. Emigration of young people over the past two or three decades has aggravated health and welfare programs, especially in declining rural areas. Welfare payments are among the lowest in the nation. The mild climate and attractive scenery has fostered the establishment of retirement villages in the Ozarks.

CULTURAL LIFE AND INSTITUTIONS

Eastern Arkansas is typically Southern in speech pattern and customs, and a leisurely pace prevails. Central Arkansas reflects still its Southern heritage, but in speech and manners it is also Middle Western. The rural areas of the Ouachitas and Ozarks have retained to the fullest degree an unchanged culture.

The arts. The several symphony orchestras and community theatres and the civic ballet in Little Rock are not of a professional level. Most colleges and universities offer training and performance in these arts. A four-state opera workshop is held each summer in the Ozarks. Arkansas's richest contributions are in the folk arts of the Ozarks. A major folk-art centre in Mountain View has been designed to provide a showcase for local and visiting performers in dance and music, to preserve traditional skills in ceramics, jewelry, wood carving, hooked rugs, and basketry, and to offer instruction in the native folk arts. Other aspects of folk culture include the gospel singing of rural areas. Black spirituals and "soul music" flourished in Arkansas long before they became popular nationally.

Folk arts and culture

Preservations. The University of Arkansas has a fine collection of archaeological and mineral artifacts. A collection of Early American glassware is featured in the Museum of Science and Natural History, housed in the old federal arsenal in Little Rock. Historic sites include Arkansas Post, the first European settlement in French Louisiana; Washington, the Confederate state capital during the Civil War; and the Territorial Restoration and First State Capitol in Little Rock.

Communications. Little Rock has the oldest newspaper west of the Mississippi, The *Arkansas Gazette*, founded in 1819; like the *Arkansas Democrat*, it serves the entire state. Central Arkansas is served by radio and television affiliates of the major networks. The entire state is blanketed by commercial radio stations, and all major urban centres are able to receive one or more television stations. Cable serves the more isolated communities. Educational television is received only in central Arkansas.

Prospects. Arkansas has important natural and human resources that have yet to be utilized effectively. Progressive and enlightened leadership often has been lacking. The late 1960s and early 1970s saw some improvements in prisons, governmental planning, tax structures, race relations, and educational and welfare services. Such projects as the Arkansas River navigation program may well attract new industries, expand existing ones, and offer all Arkansans brighter economic prospects.

Armed Forces

In 1970 approximately 23,000,000 men were under arms throughout the world, and it was estimated that almost 60,000,000 civilians were engaged in economic activity related to military purposes (in Europe, the figure was about 10 percent of the economically active population).

The total cost of military preparations exceeded $200,000,000,000 in 1970. The significance of the armed forces may be measured in a different way: armies and navies are the largest organizations in the contemporary world, as well as the most technically developed. In many countries they form the strongest political force, establishing governments and controlling their policies.

Over the centuries the armed forces have developed a large intellectual body of military science and history. To this have been added more recently the studies of the military by psychologists, who have examined the internal problems of military organizations and the relations between the organization and its members. Sociologists have studied the military as a social organization, and political scientists have examined the relations between military and civil authorities. This article, which covers all of these areas, is divided into the following sections:

I. General characteristics of the armed forces

Although armed forces are as a rule national institutions, the forces of different nations are very similar in struc-

ture and function. They all tend to have the same values and norms of behaviour; they also resemble each other in rank system and organization pattern, technology and training programs, and rituals and life-styles.

Common characteristics of armed forces

One reason for this lies in the similarity of their function. In principle, all armed forces are in competition with each other, either in preparation for actual combat or in that modern form of military struggle known as an arms race. The competition extends to more than weapons; personnel and morale are also involved. Continual competition tends to make the armed forces of different countries increasingly alike.

Another reason for their similarity lies in their historical development. During the period following the Middle Ages, a type of military and naval organization came into being and has since become the standard model. While numerous variants have been developed and many innovations have risen from the technicalities of weapons (the most important of them being air forces), the basic structure of the military has remained essentially unchanged. The model was exported throughout the world by Europeans through their colonial armies and later was adopted by the armed forces of new nations.

Thus the armed forces are not only national instruments but an international type of social institution and may be studied on a comparative basis more readily than other social institutions.

THE MILITARY SYSTEM

The management of violence. The principal purpose of armed forces is, of course, the management and carrying out of violence; their effectiveness depends almost entirely upon their success in doing this. But modern armed forces have become complex and include not only combat groups but various support and service units with tasks that range from planning to transportation and from the improvement of morale to the cultivation of relations with the public. Perhaps an extreme has been reached in the U.S. Army, in which no more than 15 percent of the uniformed personnel have ground combat functions and the other 85 percent consist of mechanics and repairmen, craftsmen, administrative and clerical workers, electronic specialists, and various service personnel. The percentage of combat troops is even smaller in the U.S. Air Force. This is the culmination of a trend that began early in the century.

During the Civil War in the 1860s, about 90 percent of the lower army positions in the U.S. could be called strictly military, but the proportion diminished to 35 or 40 percent during World War I. A similar trend occurred in the U.S. Navy: whereas in 1800 about 90 percent of a frigate's deckhands, or almost its complete crew, were used for fighting and operating the ship, after 1880, when the steamship came into use, this percentage fell to 55.

Military forces are distinguished from other armed groups such as brigands or bands of rioters by the fact that their functions are usually carried out in the name of a legal authority. There are obvious exceptions to this. Armed revolts and guerrilla warfare represent illegal forms of military activity. If the rebels are successful, however, they are increasingly recognized as legitimate, while their opponents will come to be called counterrevolutionaries and terrorists.

Armed forces differ from police in that their operations are directed against the armed forces of other political communities, usually countries, but here, again, the lines cannot always be sharply drawn. In many states the police have paramilitary units that function together with the army in suppressing rebels and pacifying restive areas. These operations sometimes take on a semimilitary character. On the other hand, in a number of countries with military regimes, the army is not primarily an apparatus to be used against other countries but an internal factor of power employed by politicians and military leaders in the domestic political struggle.

Three criteria of armed forces

In general, however, armed forces are characterized by all three of the foregoing criteria: the collective exercise of violence, in the name of a legal authority, directed against other political societies.

Exceptional role of the military. Practically all countries have armed forces. In one case only (Tanzania after its proclamation of independence in the early 1960s) has a modern state hesitated for a moment in providing for military units. A modern state must have an army just as it has a post and telegraph service.

In modern times, nevertheless, armies are much less active than they have been in other historical periods when conflicts were more frequent and the military virtues more highly regarded. The military are now used only as a last resort, after other means have failed. War is felt to be a catastrophe for civilization.

The gap between social and military morale has seldom been wider than at present, and this has two far-reaching consequences for the armed forces and their social role. In the first place, they have an exceptional status in comparison with other social organizations, existing in a state of readiness but seldom being used. Their primary task is to keep themselves up-to-date with developments in military technology, strategy, and tactics. From the standpoint of psychology and morale, this means that in time of peace the armed forces are not much more than an enormous training and maintenance system oriented toward events that may not occur for generations. The prestige of military leaders, the morale of their troops, and the financial resources of the military apparatus may be difficult to maintain under these circumstances.

An allied problem arises in the transition from a peacetime army to a wartime army, which may be accompanied by enormous losses. Defense preparations carried out over many years and at great cost may fail completely, as in the classic case of France's Maginot Line in 1940.

A second consequence of the exceptional nature of military action is that the military institution becomes isolated within society. During war the isolation is lessened as civil society adopts and supports the values and aims of the armed forces. When peace returns the military system again becomes a painful symbol of collective violence. Since World War II, however, the role of the military has been less exceptional than it was in previous generations. Because of their use in international politics, the armed forces have become in some respects an essential part of the political order.

The armed forces as a formal organization. For all of the romance, tradition, and ceremony associated with military life, military institutions are rational and artificial constructions, quite consciously designed and developed for their purposes. In this respect they differ from other social organizations such as families or business enterprises. Their artificial character makes possible an extreme formalization and standardization of structure and function. Even early forms of military organization such as ancient and primitive armies have placed an emphasis on habit and routine. In large armed forces this formalizing has led to something that seems at first sight contradictory to the heroic and danger-loving tradition of the military craft: bureaucracy. Large armies were the earliest large social organizations to adopt bureaucratic ways, with their striving for calculability and predictability as norms of human behaviour. This formalizing of behaviour, subsequently adopted in many other large organizations such as government and industrial enterprises, goes further in the armed forces than elsewhere. All behaviour is exactly prescribed and standardized in manuals, from the writing of a letter to the greeting of comrades, from methods of bayonet fighting to the conduct of funeral ceremonies. In time of peace the ritualism and ceremonialism are often given an exaggerated and superfluous emphasis. The justification of such extreme regulation of behaviour lies in the necessity of working under stress and of being able to maintain a functioning organization even if the personnel are suddenly replaced. At the same time, there is a danger that those in command may lose the capacity to be flexible and to innovate. To prevent this, a military elite has to be placed above the managerial-bureaucratic level to control policy.

The military is more than a specialized organization: it contains within it almost all of the functions of civil so-

The military as a total organization

ciety, with the difference that in the military the separate, relatively autonomous institutions of civil life are combined into one large institution, a "total institution." A large military camp or base is for thousands of persons at the same time a restaurant, hotel, school, place of work, hospital, transportation system, repair station, and post office. The military establishment as a whole also comprises research institutions, administrative staffs, training grounds, warehouses, and even factories. The military world forms a kind of subsociety, making itself as independent as possible within the total society. In addition to being self-sufficient, it must also be mobile; it has to be able to cross oceans and to populate deserts. This comprehensive character of the armed forces is symbolically accentuated by the soldier's uniform, by the geographic isolation of military installations, and by the norm that members are technically in service 24 hours a day.

In recent decades, in some countries, the institutional claims of the military apparatus have been weakened. Relationships have become closer with the surrounding society, enlisted men more often take their furloughs at home, and terms of service have been shortened. The professional soldier of the military academy is less inclined to regard his career as a lifelong commitment, the more so as the military profession itself has come to resemble certain civil professions. But these and other changes have not gone so far as to alter the fundamental characteristics described above.

THE MILITARY BUREAUCRACY

Plural authority. The structure of power and authority in military organizations resembles that in other large organizations but with marked differences of degree. As in any bureaucracy, the hierarchic principle prevails: the office guarantees the authority of the man who, once appointed, enjoys all the authority connected with his position without regard to his personal characteristics. These offices are mutually related through quite detailed organization charts and managed with the aid of equally minute and elaborate organization manuals. The structuring of authority according to function is accompanied by very pronounced differentiations in rank. "An order is an order" means that any superior can give orders to any subordinate, even if it runs counter to or outside of the functional division of labour. The two sources of authority—function and rank—sometimes conflict with each other, in that men may be forced to choose between obeying regulations and following orders. Although this conflict exists in all large organizations, it is extremely severe in the armed forces. Business organizations usually give precedence to rank. Nonmilitary government organizations generally stick to the regulations. In military bureaucracies, however, rank and regulations are held to be equally important.

Authority in the military environment has, however, a third basis: the attained result. In time of war, particularly, the aims have to be attained at all costs. Consequently it is seldom useful to observe all the rules, and neither is it always best to follow only the formal lines of command. Informal hierarchies arise, determined by their success in action. Success may be rewarded later with citations, promotions, and important assignments.

Success, however, is not always easy to judge. Lower field officers have to take into account the expectations of their subordinates, who tend to measure successful leadership by the extent to which it reduces the casualty rate. Higher commanders have other criteria, such as occupying strategic points or wiping out enemy positions.

Modern peacetime armies tend to be bureaucratic, with an emphasis on regulations. Rank is emphasized by combat units in peacetime but by noncombat sectors only in wartime. The third basis of authority, results attained, becomes the ultimate one under conditions of wartime combat.

The armed forces of different countries vary in the types of authority to which they give most emphasis. Complex modern military forces tend to stress regulations. Less complex ones emphasize rank. For elite formations and for critical operations, a combination of rank and performance will prevail. But the social environment also plays a part. Armed forces that are very strong on rank will try to reduce the influence of the social environment by staffing themselves with volunteers or professionals rather than conscripts, unless they are functioning within a social order that accepts extreme emphasis on rank (as in Prussia). Armies with a citizen tradition (Switzerland, Canada, and Australia) will emphasize the ultimate result of the operations as a first standard for good military leadership.

Ascription and achievement. The distinction often made between social positions that are acquired and those that are taken without effort (for instance, through right of birth) can be applied to the sources of military authority.

The decline of class differences

In European countries membership in the officer corps was traditionally reserved to sons of the nobility. When commoners became officers, they were made peers. The tradition survives in the expressions "an officer is a gentleman," and *das Portepee adelt* ("the Portepee ennobles"—the *Portepee* is an ornamental tassel on the sabre). The rank and file, on the other hand, were recruited from the lowest and poorest categories of the population. Soldiers and sailors, particularly in the time before national armies and navies, had a very low occupational status.

By the latter part of the 20th century, the ascriptive base of military authority had been greatly diminished. The contemporary national army draws its officers as well as its enlisted men from all strata of society. The profession of officer has tended to become a middle class occupation, while the social and educational level of the troops has gone up. Class differences still persist: in the United States around half the officers come from white-collar families and a third from blue-collar families, while less than a fifth of the enlisted men come from white-collar backgrounds and over half from blue-collar families. But this is of secondary importance in the authority structure. Other important ascriptive sources of rank authority remain; for example, in racially divided societies in which black people are less frequently admitted to the higher ranks.

The caste system in the armed forces has not disappeared with the decline of class differences. The traditionally great distance between officers and men has become more self-sustaining; it is fixed in social intercourse, ritual, and language. Even in countries in which the social prestige of the officer is relatively low, as in many west European countries, his authority within the rank system has been little affected. Even the noncommissioned officer does not participate in this authority. The caste barrier makes it extremely difficult for noncommissioned officers to achieve promotion to commissioned officer rank. Even promotions on the battlefield are exceptional. It is quite common for very young, inexperienced officers to receive command over much older and experienced noncommissioned officers.

Generalists and specialists. A more important distinction in contemporary armed forces is that between generalists and specialists.

Specialization had its start at the periphery of the military system. Engineering and artillery were the first to develop special bodies of knowledge requiring formal training. The older sections of the military establishment resisted the idea of academies for officers until well into the 19th century, partly because officers came from the educated classes and partly because of the belief that leaders are born and not made.

The notion that military men should be generalists rather than specialists is still strong, although most officers attend a variety of schools and training courses during their professional careers. The practice of rotating officers among jobs is more prevalent in military than in civilian life. Table 1 compares the lengths of stay of officers at a U.S. air base and of the managers of a very large U.S. business corporation. Almost half of the officers had been stationed for one year or less on their base, while only 2 percent of the business managers had

Table 1: Length of Stay of Officers and Business Executives Within a Single Organization

length of time in the organization	military installation (percentage)	business firm (percentage)
1 year or less	45.5	2.1
2 years	18.8	2.0
3 years	15.7	3.9
4 years	14.4	4.6
5 years or more	5.6	87.5
Total	100.0	100.1
Number of cases	554*	1,219†

*Two cases were not ascertained. †21 cases were not ascertained.

been with their company for such a short period. Nine out of ten business managers had been at least five years with their company, while only one out of 20 officers had been on their base for that length of time. The same pattern prevails in other armed forces. While there are important differences between an air base and a business firm, the foregoing comparison shows the emphasis placed on mobility of personnel.

The general staff

The military solution to the problem of specialization was the development of the concept of the military staff. A staff consists of advisers and planners who assist the commander in issuing orders but do not have line or command authority; the commander alone is responsible and cannot delegate his responsibility. A distinction is often made between the general staff that is concerned with such areas as personnel, intelligence, operations and training, or logistics, and other staff groups specialized according to weapons and services. The latter include many more specialists than does the general staff, which is often populated with generalists who happen to be expert in particular problems. Naval staffs are of more recent origin than army staffs and have not acquired the size and importance of the former.

As weapons technology has grown more complex, the staff system has extended downward to lower levels of command. More and more specialists have been attached to line organizations, with the result that the old pyramidal structure of the armed forces has changed to a diamond-shaped structure, particularly in technical and maintenance units. Before World War II, 50 percent of the enlisted men in the U.S. Army and Air Force were in the lowest of the seven grades; after 1945, the percentage was less than 15.

Another result of technological change is a growth in the number of officers and noncommissioned officers who owe their rank to their technical skills rather than to the number of subordinates they command. The growth in size and complexity of the armed forces has produced a continuously expanding military bureaucracy. More and more officers work in offices at great distances from the troops. The moment when a professional soldier gives up active command of troops and takes a desk position in the higher echelons comes earlier and earlier in his career. In the ground forces particularly, the majority of the career officers work in high command and staff positions during wartime, while in many cases the combat forces are led predominantly by reserve officers and noncoms or even by men who have been conscripted.

Commanders and leaders

A distinction may be made between command and leadership—or between executive leadership and operational leadership. The act of commanding has an upward orientation; it is the carrying out of a general plan. The act of leading, on the other hand, points downward toward the people by whom the plan is to be carried out. The commander is essentially a coordinator who has to think in abstract terms while working with the aid of numbers and charts, while the leader must deal directly with people and induce them to act successfully in combat situations. The commander, though shielded from the hazards of battle, is exposed to types of uncertainty quite beyond the personal experiences of the leader. The tensions to which the leader is exposed are those of men in danger, facing immediate physical loss.

At some levels in the organization both roles are equally important. But in most cases the accent falls on one or the other, and, generally speaking, the senior officer acts as commander while the junior fulfills the role of leader. The military leader participates in the life and dangers of his unit as the person responsible for the welfare of his people as well as for the execution of assignments from the top.

The task of the leader is especially aggravated by two circumstances. Modern war has become, much more than the combat of earlier times, a matter of improvisation requiring initiative at the lowest level; there is no longer the blind obedience to orders of earlier times or troop movements directed en masse from the top; the junior officer has to make decisions himself. In the second place, authority in small combat units is no longer simply a matter of the leader dominating his subordinates but requires an ability to deal with and motivate men, to inspire confidence and loyalty.

Leadership is a difficult undertaking for young officers and noncommissioned officers, the more so when their advantages in age, education, and social class are often quite small. Modern military schools accordingly emphasize courses in leadership training.

THE PROFESSIONAL SOLDIER

The military mind. Much has been written about "the military mind," especially by critics of the military's performance. Although some of this is merely captious, one can discern among military men certain characteristic habits of thought. The soldier's occupation tends to lead to a less idealistic and more pessimistic view of man; he comes to be skeptical of words and promises and to place certainty only in power and the means of power. Power is for him the ultimate guarantee of the social and political order. In this respect the military man may not, as a rule, share the optimistic social philosophy of liberalism; his views may differ from those of liberalism in their emphasis on discipline and leadership. He may have less confidence in the development of the individual, seeing man as weak and irrational and in need of organization. His concern with order, however, may not make the soldier a natural supporter of extreme right-wing philosophies. He tends to distrust ideology and romanticism and notions of racial or national superiority.

The soldier's realism and pessimism

The realistic and conservative character of the military mind can be explained in several ways. One reason for it may be the hazardous character of the military enterprise, in which naked power is the main guarantee of success. In a world of international strife, the soldier is forced to see every neighbour as a potential enemy. His enormous responsibilities make him a distrustful and realistic thinker. Because it is difficult to estimate the character and weight of future risks, the soldier will always overestimate them. His desire for ever stronger forces and more potent weapons is perhaps given stimulus by the effect these have on his own prestige and chances of promotion.

A second cause of military conservatism is the soldier's traditional position among the social elite. Although these bonds have weakened in recent decades, the professional soldier tends to identify with the social order whose sword he wields. In many new countries in which rapid social and economic changes offer opportunities for careers, soldiers may side with progressives who aim to accelerate their countries' development. But they will usually reject extreme leftist tendencies, as has been shown, for example, by the military regimes of the Arab countries despite strong support from the Soviet Union.

A third explanation of the soldier's viewpoint is that he tends to have an authoritarian personality. It has been shown that this type of personality is more common in armed forces and police organizations than in other professions, probably because it is selected in the recruiting

process. The pattern may change in the future, however, given the gradual change in the style of military leadership and in the general requirements for a military career. It is also notable that there are important differences in attitude and outlook among the various services (the infantry, for example, being more traditional in outlook than the technologically oriented air force).

Comparison of the military profession with others

Military professionalism. The phrase professional soldier has traditionally been applied to soldiers who pursue a lifetime career with the armed forces. In the 19th century, particularly among officers, the professional soldier developed into a technician in the management of violence. Professionals came to form the backbone of all the armed services. But the phrase professional soldier is also used to mean that the career soldier has characteristics in common with those of the doctor, the teacher, the architect, and the engineer. The characteristics of such professionalism include (1) the monopoly of a well-integrated body of knowledge and skill imparted through formal training, (2) the capacity to apply this knowledge and skill according to ethical standards as a socially valued service, and (3) the legal establishment of the profession, including the right to control the admission, selection, and training of new members. While military officers share these characteristics in some degree, the officer as a professional figure almost always finds himself being used as an instrument of power by his government; he is also lodged in a hierarchy of command that prevents him from making independent decisions.

The degree to which the military services have been professionalized varies among countries. In Communist countries the officer is not only a military specialist but also part of the political elite. In some of the new countries, nonprofessional considerations such as ethnic origin, tribal relationship, class background, and political adherence are often the main factors in a military career. There is a parallel here with several European countries of the 19th century, where aristocratic origin and family ties were important; not until the end of that century did the profession of officer in Germany and Great Britain become accessible on the basis of competitive examinations open to the majority of the population.

Crisis of the military profession

Since World War II, military professionalism has been confronted with challenges from several directions. Technological change has created a number of new fields of specialization that differ radically from the traditional military skills. These technicians, logisticians, comptrollers, management specialists, and personnel administrators are not trained in the way that combat infantry officers and aircraft pilots are, and they tend to have more in common with their civilian counterparts than with their military colleagues. This means that the professional structure is becoming a congeries of diverse functions without much unity. The development of new weapons, particularly long-range ones, has undermined the old professional norms of military behaviour. The aerial bombardment of civilian populations and some of the methods of counterintelligence units are difficult to square with the traditional code of military conduct.

Another influence at work upon the profession is the politicization of the military through its involvement in the Cold War. The creation of multinational forces such as those of NATO in western Europe and the Warsaw Pact in eastern Europe requires political orientation among their officers; patriotism as the basis of morale tends to be replaced by a common ideology.

Along with this there has been an increase in civilian influence in military affairs, partly because of the new technical personnel referred to above and partly because of the so-called think tanks and strategic research institutes that have sprung up all over the world, manned by civilian experts. Important developments in military- and political-strategic thinking no longer originate with the professional soldier.

The increase in the proportion of noncombat troops in contemporary armed forces has had a subtle effect on the outlook of the officer corps: many officers are inclined to put intellectual standards above fighting spirit or to prefer managerial qualities to traditional military qualities. Some experts have even suggested that the military profession model itself upon civilian service institutions. This is not usually taken to be a viable solution, however, because it is felt that, while it might help to offset the unpopularity of the modern military apparatus by minimizing its destructive and violent aspects, it would at the same time be likely to increase the frustration of many career soldiers. Although some marginal functions of the military can very well be taken over by civilian authorities, the main task of the armed forces remains unique.

Middle class status

Social position of the professional soldier. The military profession is a middle class one. Its status has declined since the 19th century, when in some countries officers belonged to the social elite; today, in the developed countries, career officers are regarded as standing socially below the academic professions and quite often below public school teachers. In many developing countries, on the other hand, officers are highly esteemed because of their superior education and their competence in modern forms of activity; the profession in these countries attracts some of the most capable men. In Communist countries the position of the officer corresponds to what it was in western Europe in the 19th century: aloof from civil society, respected, seldom criticized, and sharing in the prestige of the regime.

The decline in status of the military in Western countries is reflected in the social class from which the majority of officers are drawn. Since World War II, in western Europe, officers have been mainly of middle class or even lower class origin. In the United States in 1910–20, one-quarter of the general officers were from the upper class, and two-thirds were from the upper middle class; in 1950, only 3 percent came from the upper class, while half came from the lower middle and lower classes.

The change has been greatest in the Communist countries, where the old aristocratic officers corps were eliminated and replaced by officers of very predominantly proletarian origin. In the U.S.S.R. after the 1917 Revolution, many former tsarist officers continued for some time to hold important positions. In the German Democratic Republic, Poland, Czechoslovakia, and other east European countries, however, where the Communists took power after World War II, the transition was so abrupt that nontrained proletarian officers were chosen above others who were thought to be less reliable. According to official data, in 1965 more than 80 percent of the officers in the German Democratic Republic, 60 percent in Czechoslovakia, and about 50 percent in Poland came from the working class. In the developing nations the majority of the officers are usually of the middle and lower middle class.

Many officers come from military families, although it is not clear that this tendency to follow the father's occupation is more pronounced among military men than in civilian professions. The proportion of officers coming from officers' families has ranged in recent decades from 10 to 50 percent, the highest percentages occurring in France, Spain, and Brazil. Prestigious military schools such as West Point, Sandhurst, and Saint-Cyr attract many officers' sons. Twenty-five percent of the 1960 class at West Point was composed of officers' sons.

PATTERNS OF ORGANIZATION

Armies vary greatly in the way they are organized and structured. Many are so loosely organized as to resemble social movements, as did the crusaders, the Teutonic Knights, and many revolutionary armies. Some armies combine mass enthusiasm for an ideal with a high degree of formal organization. Others show considerable egalitarianism—for example, the European mercenary armies of the 16th and 17th centuries, the guilds of the early artillerists, and the soldiers' councils of the 20th-century Russian and Hungarian revolutions.

The military emphasis on organization

As a rule, however, armed forces are the most strictly organized groups in existence, drawing much of their strength from the thoroughness with which they regulate the behaviour of their members. In this respect the military organization has served as a model for other fields.

Many of the early industrial principles or organization, such as standardization, line and staff, and training of personnel, were derived from the military.

Functions of organization. The main functions of organization are to reduce complexity and to cope with changing reality. The need for organization in the military field is particularly evident, since the degree of uncertainty confronting the soldier is so great.

Military organization has passed through two stages in its development. The first was one of simple organization, in which the emphasis was put on reducing everything to fundamentals. By standardizing actions (drill, routine, ritual), homogenizing elements (weapons, formations), and directing movements from a central point (through a hierarchy), a social machine was constructed that was well integrated internally and capable of absorbing external shocks. This was the system applied in the Roman legions, the European armies of the 16th century, the early naval formations, and many other armed forces before the 19th century. The drawback of the system was its rigidity.

The second stage emphasized flexibility. Military formations were decentralized, and authority was delegated to a larger number of officers who were expected to demonstrate more initiative. The new model had less internal cohesion but was more flexible in response to external challenges. This development has continued up to the present. The decentralization that began at the top and was carried down through the senior commanders to junior officers has now reached the smallest combat units (guerrilla warfare).

In peacetime the armed forces tend to fall back upon the simple system of organization. With the coming of war this structure collapses, and the organization must with great effort be transformed into one capable of responding to the exigencies of wartime. In early times this was done by concentrating the forces in a relatively small area, such as a battlefield or fleet formation, where they could easily be commanded; the early battlefield formations were compact and could readily be integrated as fighting forces. In modern times the task is more complex. Greatly extended formations are now the rule, and they require a network of long-distance communications to handle the continuous flow of information among their subdivisions. This also applies to the interaction between the armed forces as an organization and the social environment: the allocation of resources to the military has become largely a problem of communication; the carrying out of such functions as supply and transportation have become less physical and more mental than in former days.

But more than formal organization and coordination are required to keep modern armed forces in readiness. It is no longer sufficient to allot weapons and functions to military personnel and place them under a leader; the men must also be made to realize the meaning of their task as part of the larger whole.

Levels of responsibility

Organization and operation. In principle, every armed force has three levels of responsibility and control: political, professional, and technical. The political level is generally the uppermost, concerned with overall political and strategic matters. The technical level is at the bottom, where actual operations are carried on. In between is the professional level, in which the majority of officers do their work of management.

The centre of gravity in this organizational pyramid will vary, depending on circumstances. In matters involving nuclear weapons and strategic air operations, political as well as military men participate, and sometimes the head of state himself assumes responsibility. In guerrilla warfare the centre of gravity is very low, with important responsibility borne even below the level of the junior officers. This responsibility encompasses not only combat but also supply and intelligence tasks; the junior commander may even have to exercise political authority in areas in which his unit moves. In conventional warfare the centre of gravity lies in the middle of the organization, with the professional soldier; most of the preparation, planning, and organization, as well as control over the results, is in the hands of those at the managerial level.

Differences in outlook naturally arise among those engaged at different levels of the military operation. Those concerned with problems of nuclear weapons have scientific habits of mind, placing education and rational calculation above arguments from historical experience. Those in charge of special operations and counterinsurgent warfare think in terms of physical courage, group loyalty, and personal leadership. Many officers find themselves caught between these two types, disliking the new technocrats who differ so much from the traditional military type and at the same time feeling threatened by those on the lower level who regard the career soldier as obsolete. Tensions of this kind were visible in the revolt of the French officers in Algeria in 1958 and 1961.

Informal organization

Considerable research has been done on the primary (face-to-face) group and its functions in military life. It would appear that men tend to identify with their platoon, crew, or squad rather than with the larger organization; it is the world in which they are at home and within which almost all their interests are rooted; they find security in the small group, a sense of solidarity vis-à-vis the military hierarchy, a chance for prestige among their fellows, and norms of behaviour that are difficult to ignore. Under conditions of combat, these informal relations are greatly enhanced. Studies of German and U.S. units have shown that soldiers are motivated not by ideology or political purpose but by a sense of personal commitment to their comrades: "You can't let the guys down." The character of these bonds depends partly upon circumstances. Ground combat units draw their cohesion from the peril to the group in battle, while submarine or bomber crews relate to each other much more as specialists who must execute a mission together.

The existence of these primary groups often poses difficult problems for the commanders—particularly the noncommissioned officers, who are most exposed to pressure from a group and have the least prestige at their disposal. In practice they often follow the wishes of the group: their so-called leadership is in part a product of the group they lead. But this group behaviour has its advantages from the viewpoint of the top command. The small group at the base serves as a self-regulating system that can adapt to unforeseen circumstances. For this reason it appears to pay to keep the informal system intact, even to the extent of carrying out personnel replacements in a way that will not destroy particular groups.

Informal organization is not a phenomenon of the base level alone but runs through the whole military organization. Social and political groups and cliques play a decisive role at the highest levels. Their existence, partly concealed in many countries, is obvious in new countries, where a top military position is clearly a political acquisition. Military coups in such countries show the political leanings among the top leaders of the military apparatus, which vary from the right (Greece in 1967) to the left (The Sudan in 1971) and may sometimes divide the military leaders themselves (Indonesia in 1965).

THE MILITARY COMMUNITY

Styles of military life

The armed forces are much more than an organization; they form a community that encompasses the work and life of its members much more completely than do most other social organizations. The life of the professional soldier, however, is quite different from that of the enlisted man. The first, particularly if he is a member of the officers corps, experiences military service as his career; his manner and style of life are often set for him by tradition. The enlisted man, on the other hand, knows the military environment as a male community full of deprivations and rough behaviour.

The elitist style of life. The officers' milieu is characterized to some extent by a ceremonialism that has become passé among other social classes, a heritage of officers corps of the 18th and 19th centuries. This formal "old-fashioned" style is more than the pretension of belonging to an aristocracy: it has certain functional uses in that it helps to facilitate the integration of the members

into military life. The professional soldier is, after all, highly mobile both geographically and socially, continually forced to adjust to new milieus. His adjustment and assimilation are made easier if these milieus all observe the same formal patterns of behaviour. It is the more mobile and isolated parts of the armed forces that have most strongly developed their own styles of life, notably the navy and the old colonial armies.

The officer's wife plays a more important part in his professional life than is the case in most other professions. To some extent this belongs to the traditional style, which makes high demands upon etiquette and social contact. It is also a consequence of the isolation of military life in small communities in which work and residence coincide.

The enlisted man's style. The community life of enlisted men is very different from that of the officers. As an exclusively male community, separated from their families and often unmarried, their social traits resemble those of colonists, woodcutters, sailors, and dock-workers. While officers have an elitist subculture, that of the enlisted men reflects their position at the bottom of society. While the officer attaches an almost exaggerated importance to form, the private most likely will reject all form. The cool distance that characterizes the relationships of officers contrasts with the close ties that prevail among enlisted men.

The life of the enlisted man is reflected in his language —earthy, masculine, and aggressive, frequently with a heavy emphasis on sexuality. Much of his slang expresses the repugnance he feels toward the military hierarchy, for to him it seems that the officers make the mistakes and reap the rewards, while it is he who does the dirty work and wins the battles.

Enlisted men stationed in foreign countries are notoriously promiscuous in their sexual behaviour. In 1955 it was found that 59 percent of the U.S. enlisted men stationed in Japan had regular intercourse with prostitutes; in Korea in 1965 the percentage was 88.

II. Organizational problems

MANPOWER AND EXPENDITURES

The weight of the military effort

The power potential. The size and power of any military force are ultimately limited by a country's ability to sustain them. In the last analysis this depends on the number of men who can be mustered in time of war and on the country's economic strength. In France after 1871 there was much concern over the country's falling birth rate: while population size had not been important in the era of small professional armies, it became so low that France was competing with a more populous Germany in a day of total mobilization. At the outbreak of World War I in 1914, France had no more than 8,000,000 men of military age, while Germany had 15,000,000.

Military power in the contemporary world has to be defined as including potential power; it is the total ability of a nation or a coalition of nations to coerce other nations through the employment of military means or to resist such coercion by other nations. This means not only the ability to mobilize forces for immediate action but the ability to produce additional forces. Potential military power is, of course, relative. An international arms race will drastically influence the relative power of each of the participants, just as disarmament will be more advantageous for some than for others.

In pre-industrial societies, potential military power was very small. Countries with agricultural economies could not support large armies, and prolonged military efforts were carried on at the expense of a functioning economy: the troops sustained themselves by plundering and destroying, which brought impoverishment, depopulation, and famine. Not until after 1800 did the European countries have an agricultural surplus sufficient to maintain large armies. Manpower was also limited by the need for manual workers; the armies of 18th-century Europe were manned largely by nonproductive classes such as nobility, paupers, and foreigners.

A country's potential military power depends on its supply of manpower, its organizational capacity, and its economic resources. Manpower is first of all a function of the size of the population. During World War II only large countries such as the United States and the Soviet Union were able to recruit more than 10,000,000 men. Mass mobilization also requires a large number of trained military reserves. One of the secrets of 19th-century Prussia's success in war was that its system of universal military service produced extensive reserves of men who, with frequent retraining exercises, maintained their military capabilities until the age of 50. During the 20th century, military reserves have grown to be several times the size of the standing armies. In the mid-1930s, when 8,000,000 men were under arms around the world, an additional 2,000,000 were on immediate reserve, and another 30,000,000 had received training and were available for call. Another factor affecting manpower is the psychological readiness known as morale—the willingness to sacrifice safety, income, and personal freedom in the service of the military effort. While this factor cannot be expressed quantitatively, it is of no less importance than numbers in estimating potential power.

A high level of organizational capability is also required for the mobilization and maintenance of armies consisting of millions of men, so much so that only developed and industrial countries are successful at it. The power to mobilize quickly is very important, as the German Army demonstrated impressively in 1914, when it brought 2,000,000 men under arms within 48 hours and sent 1,000,000 soldiers across the Belgian border within a week. By contrast, one of the most important causes of the failure of the Arab countries in their fight against the young state of Israel was their lack of organizational capacity.

Growth rates. The mercenary armies of the 16th century seldom achieved a size greater than 20,000 to 25,000 men. When national armies began to develop in the 17th century, they reached 50,000 or 60,000 men and a century later even 80,000 or 90,000. In the Napoleonic era, armies became much larger, and some battles involved hundreds of thousands of men; at the peak of the French military effort, 1,000,000 men were under arms. Armies and navies continued to increase in size during the 19th century. Around 1850, the total number of men in the European armies was estimated at about 2,500,000; around 1900, at about 3,500,000. In the 1930s, before World War II, the total number of men in the standing armies of the world had risen to almost 9,000,000. The figures for the great powers in 1937 were China, 1,600,000; the U.S.S.R., 1,300,000; Japan, 950,000; France, 825,000; Germany, 760,000; Italy, 760,000; and the British Empire, 645,000.

As armed forces increase in size, they take on different characteristics. Large armies are more "democratic" in the sense that they represent a larger cross section of the population, but they are run more firmly at the top. A paradoxical consequence is that small professional armies are sometimes more dangerous to the established order than are large national armies that are more thoroughly controlled.

Armies in the modern world

Larger armies lead to still larger military reserves. In modern industrial countries, the organized reserves are from six to ten times the size of the active forces, and, when all of the forces are mobilized, the professional personnel become only a fraction of the total. Thus, great wars are fought mainly by reserve officers and conscripts. Germany, in World War I, sent a total of 46,000 professional officers to battle, of whom 11,350 were killed, as against 226,000 reserve officers, of whom 35,500 were killed. Of the Prussian contingent of 22,112 professional officers at the beginning of August 1914, 5,633 had already been slain by November 15.

A large army constitutes a heavy burden upon a country's economy. During the Napoleonic era, as much as 5 percent of the total French population was mobilized, compared with preceding centuries, when the proportion did not rise much above 0.3 percent, or the later 19th century, when approximately 0.5 percent of the population of the leading countries was under arms. The percentage of soldiers to the total labour force was much

higher. The United States had 18.6 percent of its labour force on active service in 1945. In the postwar period the proportion fell to 3 or 4 percent.

Recent developments. In 1964 the total active military manpower of the world was estimated at 20,900,000; in 1968 it was 23,800,000—a growth in the four years of 13.6 percent. The forces of the developing countries grew by 18.4 percent over that period. The fastest growing forces were the relatively small and often new armies of Africa and Oceania (almost 50 percent), followed by Southeast Asia (35.1 percent), the United States (30.1 percent), and the Middle East (26.6 percent). Much of this growth had to do with the existing war situation in various parts of the world, particularly in Southeast Asia and the Middle East. The European countries of the North Atlantic Treaty Organization reduced the size of their armed forces by 1.2 percent in the same period. The military manpower of the Warsaw Pact nations increased by 3.6 percent, the figure for the U.S.S.R. being 6.1 percent. The West and East German armies increased by 6.1 and 11.4 percent, respectively.

Military expenditures between 1964 and 1970 showed contradictory trends. When measured in constant dollars to eliminate the effect of inflation, the expenditures of the NATO countries levelled off between 1967 and 1969 and declined in 1970. In the developing countries the trend was quite different: the level of military expenditures (in constant dollars) rose in the developing countries after 1966 at a faster rate than their gross national products. Table 2 shows that in 1968 the developing countries maintained 12,800,000 men under arms, compared with the 10,900,000 men of the richer countries. On the other hand, the military expenditures of the two groups of countries amounted to $22,000,000,000 and $169,000,000,000, respectively, showing the stress placed by the latter upon technology. In proportion to total population, the developed countries were more substantially mobilized (11 per 1,000 of the population) than the developing countries (five per 1,000).

The burden of military expenditure at the end of the 1960s was heaviest in the countries of the Middle East and Southeast Asia: it was estimated to exceed 10 percent of the gross national product in Israel, Egypt, Jordan, Iraq, Saudi Arabia, North Vietnam, South Vietnam, Laos, North Korea, and the Republic of China (Taiwan). Expenditure was between 5 and 10 percent of the gross national product in the U.S., the U.S.S.R., the People's Republic of China, Great Britain, Poland, Cuba, and Portugal.

RECRUITMENT AND SOCIAL CONTROL

The ways in which a country recruits its military personnel are likely to have important consequences both for the armed forces and for the society from which they are drawn. Soldiers may feel a commitment to patriotic or idealistic aims; they may be coerced; or they may be motivated by pecuniary gain.

Voluntary armies

Moral commitment. The committed soldier is intensely involved in his organization and its success. The organization can draw upon his loyalty and can motivate him with nonmaterial rewards—glory and honour, prestige and status, shame and humiliation. Armed forces recruited in this way take on the characteristics of social and political movements. They have relatively little of the standard military structure with its regulations and its hierarchy; those at the top are accepted as leaders in a common effort toward a common goal, which can be attained only by following and supporting them. A strong ideology helps to maintain the cohesion of the fighting forces. Such voluntary armies have included those of the First Crusade, the religious Hussite armies of the late Middle Ages, the warriors of early Islām, and national revolutionary armies such as those of France after 1789 and Russia after 1917.

The successes of these armies stemmed from their collective élan and not from their training and their technical or tactical superiority. Their lack of structure and professional leadership became a source of weakness at times of internal stress (that is, in a later period when armed struggle continued and more stability and integration was needed). Methods had to be found to give form to the collective mass.

Revolutionary armies often begin with egalitarian institutions, such as the soldiers' councils and militia units of the French, Russian, Hungarian, and Indonesian revolutions. When confronted with the orderly armies of an enemy, they tend to fall back upon traditional hierarchic forms. The initial enthusiasm of the mass diminishes, while at the same time military service becomes obligatory rather than voluntary. The revolutionary armies thus adopt a system of conscription.

Another way of maintaining cohesion is by indoctrination and political training. The young Soviet Army was reorganized along classical lines with the introduction of general conscription, but at the same time a political shadow organization was built up in it through the Communist Party. This approach has been followed in many guerrilla armies, in which the military and political elements are strongly interrelated. In this way they obtain the advantages of the military system of coercion along with those of ideological motivation.

A third method lies in stressing patriotic symbolism such as the monarchy, the fatherland, honour, and glory, supported by a good deal of ritual. The soldier is taught to forget material interests and devote himself to higher ends.

Certain mixed forms exist, two of which are the professional officers corps and the militia army. The modern officers corps is built upon the concept of a military craft, embodying values and norms formerly cultivated by the nobility. These include ideas of honour and status, along with a disdain for the materialistic concerns that dominate the rest of society. Contemporary officers' attitudes, however, are moving away from this toward the attitude of a functionary who seeks remunerative, attractive work and a permanent job.

The other mixed form, the militia, is a citizen army in which the obligation of the soldier is to defend his city or country. Sometimes a militia is raised in defense of group interests, such as those of labourers, farmers, miners, students, or a political party. The militia is a mixed form because in many cases it is combined with conscription. The phrase compulsory militia is not entirely contradictory.

The moral basis of the militia lay traditionally in the defense of home and hearth, an idea embodied in Anglo-American history by such organizations as the Home Guard and the National Guard. The militia is seldom an aggressive, conquering army since citizens in arms cannot undertake long campaigns and military expeditions.

Militias have existed throughout history since the time of the Greek city-states. Examples in modern times are the armies of Switzerland and Israel, in which the professional core is very small and civilians hold all the military positions, including high command. In both countries military service is required of all men and in Israel of women.

The militia form has certain political and economic advantages: it avoids the danger of creating a state within the state and also the high costs of maintaining a standing army. The abilities and occupational skills of the population can be placed directly at the disposal of the military, although this means withdrawing them from the civilian society. The chief objection to the militia form is its inadequacy for the building of a technically advanced and specialized army with modern air forces and artillery. Another objection is that mobilization takes too long. For these reasons, large democratic countries with a citizen-soldier tradition have developed within their military forces extensive cadres of regular soldiers.

Criminals and conscripts

Compulsory enrollment. The opposite of voluntary enlistment is conscription, carried out by the national state. The resulting military force lacks the moral characteristics of a volunteer army; it is essentially a machine requiring severe discipline, its cohesion being maintained by the threat of punishment. Its great problems, desertion and slackness among the troops, can be kept within bounds only by strong organization and leadership. Con-

scription in its purest form was used to man some of the armies and fleets of Europe in the 17th and 18th centuries, when condemned criminals were permitted to choose service in lieu of imprisonment. More often, however, conscription is part of a program of universal military service accepted by the public and carried out in cooperation with it.

The system is based on rudimentary training given to all men of a certain age who are deemed physically and mentally fit. After their initial term of service, they are placed in the reserves and recalled periodically for retraining. If complex equipment is involved, the training period must be longer, and for that reason naval and air forces tend to have a high proportion of professional personnel and to rely less upon conscripts. The use of conscription assumes a government that is strong enough to coerce its citizens and a national consciousness that will accept this coercion. It may also find a basis in the democratic idea that all citizens ought to participate in the defense of their country. Conscription has, like the militia system, the advantage of obviating a standing professional army with its dangers of political intervention.

In recent years the system of conscription has been undergoing a crisis in many countries. On the one hand, there is a growing awareness that a complex war machine needs professional soldiers. At the same time, resistance to general military service has been increasing, partly from antimilitarism and partly from a decline in national consciousness in some countries. Many military men would prefer a professionalized army that would free them of the influx of less dedicated and reliable personnel. Against this there is the argument that only a system of conscription can supply the large forces required for a prolonged war. Another argument in favour of conscription springs from the idea that in a democratic country military service ought to be universal.

Soldiers for pay

Mercenaries. The mercenary soldier serves for pay. There is no question either of loyalty or of alienation. Armed forces composed of hired soldiers are therefore quite different social organizations from those discussed above. While the main problem of a revolutionary army is to preserve the enthusiasm for the cause and that of a conscript army is to maintain strict discipline, the main problem for the mercenary army is to provide the soldiers with their pay. When the army cannot be paid, as often happened in the 16th and 17th centuries, it can no longer be commanded.

The mercenary system, like the other systems, is of ancient origin. In Egypt and Mesopotamia, the state itself was based primarily on mercenary forces. The great military successes of Carthage were won by mercenaries, as were those of the Roman Empire in Europe. Mercenary armies reappeared after medieval times. They were employed in European colonial wars, the best known being the French Foreign Legion. Three sets of circumstances are conducive to the adoption of the mercenary system. Large empires cannot be built and maintained with militia armies, and this creates a demand for mercenary armies. Mercenaries, furthermore, are typical of the absolute state in much the way that militias are characteristic of political democracy. Finally, they often appear in commercial nations that are wealthy enough to maintain hired troops, as in the old state of Venice, in the Dutch republic, and in Great Britain.

The hirelings are usually recruited from densely populated countries and from countries with a military tradition. The Swiss and later the Germans served in armies all over Europe. The Roman emperors had their German guard and the French monarchs their Swiss regiments (of which system the Vatican's Swiss Guard is a relic). Small numbers of mercenaries are still involved in the conflicts of the developing countries. The present-day system of voluntary enlistment in such countries as Great Britain, Canada, and Australia is a variation of the mercenary system, since these countries can, in peacetime, define their problems of recruitment primarily in terms of the labour market and the national budget.

The mercenary system seems likely to become more common in the future, as political considerations lead to the abandonment of peacetime conscription and short-term enlistment takes its place. To a considerable degree, the modern military force reflects the business orientation of the surrounding society: many military jobs require the same techniques and skills as civilian jobs, and it has become necessary to allow military personnel to work under the conditions prevailing in the rest of society. Even trade unions and labour contracts are becoming important to the military employer, particularly in times when labour markets are tight.

FUNCTION AND ORGANIZATION

The formal purpose of armed forces is to act against foreign enemies. In reality, however, they have various other functions.

Domestic functions. In many countries, particularly developing countries, the army has great social and political significance. It stands as a symbol of unity and power. Young nations uncertain of their international role, and often internally divided, attach much value to an army as a national institution. This may first require disposing of the military forces inherited from the previous colonial regime, since many colonial armies were recruited from minorities the ruler found reliable—such as the Berber tribes in French Morocco, the Punjabi and Sikhs in British India, and the partially Christian population of Celebes and Amboina in the Dutch East Indies. The new national armies may resemble their colonial predecessors insofar as they continue the task of maintaining order in the country. If they do not succeed in this, the result may be civil war, as in Indonesia, Nigeria, and Pakistan.

The army as a modernizer

But the army in the newer countries is also an agency of modernization, somewhat in contrast to armies in the Western world, where the military has been for centuries a symbol of tradition and conservatism. It is one of the few well-organized and technically equipped modern institutions. The military career often leads to a successful civilian career, as in Israel. The army also brings together members of different ethnic and religious groups, thus becoming, as in the U.S., an institution of socialization for a heterogeneous immigrant population. No military force can escape this socially integrative function within a heterogeneous society. The task of integrating blacks and whites in the U.S. Army has had parallels in the integration of the French-speaking and English-speaking groups in the Canadian Army and of the Flemings and Walloons in the Belgian Army. In the new countries the army may also undertake a variety of social, cultural, and economic tasks. In the 1920s the Turkish Army of Kemal Atatürk set an example as a military modernization movement that still serves as a model for many countries with military regimes. The soldiers may be put to work building roads and bridges, working on irrigation and land development, or even teaching the population to read. Such uses of the military occur under governments of various political hues; even the Marxist revolutionary regimes of China and Cuba, in the early 1970s, were using soldiers for nonmilitary functions in the political as well as the socio-economic sphere.

Conflict management. The modern military force has lost almost all of the old conception of warfare as a heroic struggle, as it was seen in ancient Greece, some periods of the Middle Ages, and in the 18th century. Such attitudes linger on only in elite formations such as special forces and paratroops, in which individual performance is still important.

The prevailing conception of the military is an instrumental one. The military are seen as instruments of national policy, to be used to strike and destroy an enemy with all available means. As wars have become increasingly destructive, expanding to include the whole population, the military have been reduced to one element in a total national effort that involves political, strategic, social, and economic factors. This conception of total war has been tempered since the advent of nuclear weapons by the doctrine of limited warfare—a strategic pluralism in which various military forces are developed simul-

taneously for the purpose of providing appropriate responses in different types of situations. These include the whole array of traditional, or "conventional," forces together with counter-guerrilla forces. The military effort of a great power is now extremely differentiated, each of the subdivisions being equipped with its own philosophy, armament, and organization.

United Nations forces

The new doctrines of flexible response and limited warfare may be seen as a step toward the international management of conflicts. The effort to manage conflict has been made by forces of the United Nations, acting in an international police capacity, in the Middle East, the Congo, Cyprus, and elsewhere. The outlook of such peace forces differs from that of traditional military force in several ways: the goal is not victory but control of the conflict; there is no enemy, only parties whose conflict endangers the international situation; the peace force must act with as little violence as possible; and, unlike traditional military forces, it must work very cautiously and patiently. The task of the United Nations soldier is thus more akin to policing than to military action.

III. Historical trends

At the most primitive level of society, there is no military organization and no warfare in the conventional sense. Skirmishes among tribes take the form of random strikes and personal duels fought at a distance with weapons such as javelins, blowpipes, or bows and arrows.

Organized warfare first makes its appearance among agriculturalists and cattle breeders. Peasant societies are not inclined to war because of their dependence upon harvests and because their manpower is needed to till the land. But a separate warrior caste may develop within a peasant society, perhaps consisting of invading conquerors who constitute a noble or feudal class. The conquerors are likely to be nomadic people, accustomed to moving over large geographic areas with their cattle and inclined to attack and subdue sedentary people who may be more prosperous than they. In European history such conquerors have included the Huns, Magyars, Mongols, and Arabs. Others, on a smaller scale, are the North American Indians, the East African Masai, and the North African Tuaregs. They begin to develop tactical refinements such as ambush and manoeuvre and the use of spies and scouts, along with more destructive weapons.

HISTORICAL PARALLELS

Rise and decline of the aristocratic warrior

The development of military institutions among the great civilizations of history can be studied on a comparative basis. One can find common characteristics among the civilizations of ancient Egypt, Babylonia, Assyria, Persia, Greece, and Rome, as well as those of old India, old China, and pre-Columbian Mexico and Peru. In their earliest period they were governed by aristocracies that monopolized the military craft. The aristocratic class, rising above the peasant masses, was the only group that could afford military paraphernalia such as horses, chariots, and weapons. Sometimes there was also a militia, but it was at best an auxiliary force and militarily inferior.

This was the situation among the Greeks of the Homeric era, in Etruscan Rome, at the time of the Chou dynasty in China, and in India under the Aryan conquerors.

The rise of cities increased the manpower available for military service. In Greece and Rome a middle class that developed broke the dominance of the nobility. Heavy cavalry and chariot formations gradually gave way to foot soldiers and citizen armies, fighting to defend their cities.

The militia armies of this historical phase were gradually replaced by mercenary troops that were capable of more extended campaigns. Rising empires (such as Rome, Macedonia, the Chin and Han dynasties in China, the Mauryas in India, and some periods of the Aztec and Inca empires) relied upon professional soldiers supported by militia who were increasingly recruited from subject nations. Eventually the population and the army came to stand completely apart from each other, the army often becoming a state within the state. At their peak these empires became defensive in their outlook, and great fortifications were built, such as the Roman limes in central Europe, the wall of Hadrian in northern England, and the Chinese wall in northern China.

Military reformers throughout history have borrowed techniques from the parallel phases of other civilizations. The period of the Renaissance was not only an artistic and philosophical rediscovery of antiquity; the military also made certain acquisitions from Roman military science. Machiavelli, attempting to revive the ancient citizen armies in the Florentine militia, drew some of his ideas directly from the old city-states. Prince Maurice of Orange studied classical military writings and introduced Roman formations, drills, and training methods. Since Maurice, like the Romans, employed mercenary soldiers, the experiment succeeded beyond all expectation.

MEDIEVAL SOLDIERS

The Germanic states that arose in Europe after the fall of the Roman Empire represented a return to an earlier form of social organization with small armies and no military class. The kings of the early Middle Ages attempted to keep their empires intact, following the example of the Roman emperors, but they could raise only a few thousand horsemen at most and had no foot soldiers. Consequently they were easy prey for invaders such as the Magyars and the Norsemen. The European states were dismembered into a great number of smaller communities, and the feudal system came into existence. The kings and other rulers rewarded their retainers with land; the weak, on the other hand, became dependent upon their feudal lords, to whom they had to swear allegiance in exchange for protection.

Knights and nobles

This political system was primarily a military system. Landownership became the basis of military power. Only those who had at their disposal large material means (land, tenants, toll money) could afford the costly armour of the knight and the expenses of his vassals. The power of the kings declined, and local populations preferred to entrust themselves to the nearest lord rather than to the distant and powerless king. The knight became the centre of the military structure. All the lords were autonomous, and collective action became very hard to organize. There were no group military exercises. In battle each leader wanted a position in the forefront, since a position in the reserves or in the rear guard was considered dishonourable. The style of battle often assumed the character of a tournament. In the rare instances when large numbers were mobilized, as in the Crusades, there was little cohesion and cooperation; they were in fact conglomerations of small units under autonomous commanders. Naturally such armies produced little in the way of military tactics and techniques. The principal medieval innovations were in the art of siege. The castles and fortified towns were built to withstand assault, and therefore the battles over them were ingeniously fought.

The predominance of the mounted knight in battle ensured him a place in the aristocracy, since superiority in arms guaranteed political superiority. This led in turn to the glorification of warfare. The knight's obligation to avenge insults created a society in which violent battle was an everyday reality, because, when personal fidelity and loyalty were unavailing, a man could maintain himself only by his own resources.

The feudal mechanism gave way in the late Middle Ages to central monarchies. The new rulers allied themselves with the rising middle class of the cities and gradually brought hired knights into their service, thus squeezing out the feudal nobility. Royal standing armies came into being, including both cavalry and infantry (pikemen and musketeers), constituting a force that the haphazard combat groups of the nobility could not defeat. The military revolution was completed when the pistol won out over the lance, since troops with pistols required less training than knights. The development of artillery, a product of the commercial towns, hurried the downfall of the old nobility.

Another factor in the decline of the mounted knights

was the development of the infantry. As early as the 14th century, knights would often descend from their horses and mingle with the foot soldiers, but they were encumbered by their armour. Companies of archers began to win victories in the 14th and 15th centuries, the most famous being the Battle of Crécy in 1346, when English archers and dismounted men-at-arms defeated French knights. The most important postfeudal mercenary forces were the German Landsknechte (men of the plains) recruited by the emperor Maximilian I about the end of the 15th century; these were foot soldiers armed with pikes. The 16th-century infantry lacked discipline and solidarity; they were troublesome both to their commanders and to the populations they pillaged. They represented a transitional phase between the heroic feudal era and the new era of the centrally controlled monarchical army.

THE ARMIES OF THE KINGS

Basis of the modern army

The military revolution. In the period between 1550 and 1650, the basic structure of modern arms was developed. Important steps had already been taken under the Protestant commanders Maurice of Orange in the Netherlands, Gustavus II Adolphus in Sweden, and Cromwell in England, but now the system became common throughout Europe.

The most general element was a striving for rationality and flexibility. The military force was seen as an instrument to be used as efficiently and effectively as possible. Uniforms, regulations, and standardized equipment made their appearance. Training was systematized with exercises in the use of arms and the introduction of a command language. The specialization of forces was further developed, and the first administrative and clerical services appeared, along with staff organs.

Improved discipline of the troops was essential to all this; the excesses of the mercenary armies of the previous period had to be overcome. Although low-calibre mercenaries were still hired, the leaders maintained a firm grip on them through drill and training, severe punishment, and a clear-cut system of ranks. The traditional liberties of the Landsknechte, who had had the privilege of choosing their own immediate officers, were curtailed. The post of platoon commander was established; this officer, appointed from above, was responsible for the discipline of his men.

The new hierarchically guided and disciplined war machine reached its peak in the Prussian Army of the 18th century, created by Frederick II the Great. Its troops were intensively trained in battlefield manoeuvres. Much emphasis was placed on morale; esprit de corps was encouraged by regimental colours and other distinguishing symbols. The core of the system, however, was discipline: Frederick said of his soldiers, "They must be made to fear their officers more than danger" and "The slightest relaxation of discipline would lead to barbarization."

The absolute monarchs of the 17th and 18th centuries were able to support standing armies and navies. Private and municipal armies gave way to royal armies led by professional officers. These were not national armies like those of the 19th and 20th centuries, since most of the populace remained outside them; they were officered by the aristocracy and manned by foreigners, paupers, prisoners, and deserters. The productive categories of the population were not required to do military service. War was a contest among monarchs, carried on over the heads of the population.

The officers corps

The role of the aristocracy. The new armies of the kings opened military careers to the nobility, who had lost much of their political and economic power with the decline of feudalism. The transition from knight to officer was not a simple one, since the new armies also gave opportunity to adventurous commoners. Anybody who could ride a horse and handle a pistol was able to join the cavalry, which underwent a great expansion. But eventually commoners were excluded from officer rank except in engineering and the artillery, which were not attractive to the nobility. The aristocracy was able to maintain its social status and its life-style, while also being favoured in other ways because of its relation to the monarchy. Thus officers were exempted from taxes since they were considered to be paying an *impôt de sang* ("blood tax") on the battlefield.

A similar development took place in the navy, where in the 16th century the officer received his position as "gentleman commander" alongside the traditional post of master mariner, or "seaman commander." Such positions were given to the king's favourites, who did not have to work through the ranks and were not required to have any experience on ships. Access to an officership might also be gained through wealth. The outright sale of military rank became common, particularly in England and France; sometimes only the highest positions were secure from this moneyed incompetence. Sometimes the "boughten" rank was not even filled because the beneficiary was still a child.

The system inevitably led to great overstaffing. The French Army in 1787 had a total of 36,000 officers, of whom only 13,000 were in active service. Where the Prussian Army had 80 generals, the French Army, of equal size, had 1,171. This military elite was not much more than a collection of profiteers and favourites, with only a few capable officers; but it had the traits of an officers' caste, with a strong tendency toward isolation and a cultivation of feudal values and chivalrous ideas of honour.

The aristocracy was a European elite that cultivated relationships across national borders. This was one reason why the wars of the 18th century often resembled games conducted according to strict rules. The spirit of the time would not tolerate great hazards, and in any event there was little to be hazarded because the unwilling troops were not the material of which fighting armies are made. Military science was practically static, and the new military academies were little more than finishing schools for aristocratic young men.

National differences

Within these general tendencies there were important national differences. France pioneered in the development of a standing army. Under Louis XIV, in the second half of the 17th century, the army became the most powerful in Europe; at one time it numbered 400,000 men in a population of 23,000,000. The French war fleet was also a creation of the monarchy, developed in competition with the English Navy; France lacked the large merchant marine of England and the Netherlands that provided trained personnel for their navies.

England, living in bitter memory of Cromwell's militarism, kept its army small. The army and navy elite were less isolated from the populace than that of France; many officers served in Parliament and regarded themselves as members of the political establishment rather than as exclusively military. The Parliament, moreover, retained close control over the armed forces.

The purchase of military commissions was practiced in England on a large scale and regarded as one of the guarantees against military usurpation. The practice continued throughout much of the 19th century, even surviving the catastrophe of the Crimean War; not until 1871, after the Prussian victory over France, was the purchase system abolished in England.

Prussia's military organization, which reached its height in the 18th century, reflected the social, economic, and political backwardness of the country. It was feudalism controlled by an absolute monarch. The nobility, as vassals of the king, held the highest positions. In 1791 the 895 highest officers were from 518 noble families. In 1806 there were only about 700 commoners among the 7,000 to 8,000 Prussian officers, although there were more than 1,000 non-Prussians, particularly French aristocrats.

The ranks of the Prussian Army included not only paupers, criminals, and foreign mercenaries but also conscripts—the latter being tenants who followed their lords to war. Feudal Prussia was the first state to move toward a national army.

THE NATIONAL ARMY AND THE PROFESSIONAL SOLDIER

The 19th century saw the gradual development of national armies led by professional officers. The fullest ex-

pression of the "nation in arms" was in the Franco-German War of 1870–71. The age of mercenary armies came definitely to an end.

The breakdown of the old system. Many writers and military reformers had long held that the ideal army should be a national militia. The practical superiority of the militia had been shown in the American War of Independence (1775–83) and in the successes of the French revolutionary armies of the 1790s. In both cases, without appreciable changes in military tactics, regular forces were defeated by irregular armies of mobilized citizens. The American victories made a great impression throughout Europe. The colonial sharpshooters and the grim ferocity of Washington's forces were a departure from the gentlemanly tradition. From a military point of view, however, the French innovation had much greater consequences. The national *levée en masse* in 1793 raised large, untrained armies that, notwithstanding serious losses, were able to defeat the mercenaries.

Although 70 percent of the French officers were from the nobility, there was a strong new element of revolutionary egalitarianism and nationalism. In the early stages of the Revolution, the officers were often chosen from the ranks by the men themselves. Foreign contingents were abolished, and the French citizen took on the role of defender of his fatherland. The Constitution of 1793 declared: "Tous les Français sont soldats" ("Every Frenchman is a soldier"). This national army did not long maintain its pure form. Napoleon made use of the new enthusiasm, but he conducted his wars predominantly with professional soldiers supplemented by conscripts. The citizen army thenceforward became partially a conscript army and partially a professional army.

Prussian military reforms carried out after the German defeats in the Napoleonic Wars broke only partially with the past. In 1808 officership was opened to all, but the aristocracy retained its dominance. The establishment of a national army was resisted. Prussia's main innovation in 1807–13 was the development of the professional officers corps.

The new officer

The Prussian model. The Prussian reformers emphasized the systematic training of officers along scientific lines. Their efforts were crowned by the establishment of the Kriegs Akademie in Berlin in 1810. German military thinkers, among whom Carl von Clausewitz was the most famous and influential, led the world in developing the science of war. By 1860, it was estimated, half of Europe's military literature had been published in Germany.

A second important Prussian reform was the creation of the general staff, which after 1860 was the core of the professional elite. Preparation for military operations became systematic and minute business, making possible very rapid and efficient action at the start of a war.

Prussia also led in technical innovations such as breech loading for cannon and rifles and the development of the repeating rifle and machine gun. Another insight of the Prussians lay in their stress on transportation and communication. They used railways and postal and telegraph facilities in ways that greatly increased troop mobility, as well as strengthening the central direction of operations.

The Franco-German War of 1870–71 demonstrated Prussian military superiority, and the other German states proceeded to imitate the Prussian model. Other countries also began to copy it, notably defeated France, which built up a mass army with the help of conscription, extended the term of military service, and invested more heavily in military preparations. After 1870, when all of the European imperial powers and Japan introduced general conscription, the concept of the "nation in arms" finally took concrete shape.

An armaments race developed between 1870 and 1914, principally between the German and French armies and the German and British navies. Although it greatly increased the destructive power of the forces through the improvement of the artillery and the expansion of technical personnel such as the engineers and signal troops, it was not a military revolution. Armies grew in size, but no qualitative change occurred. Air power and armoured weapons had not yet become important.

IV. Armed forces and society

Relations between the military and the rest of society have never been easy. With their monopoly of the means of violence, the military inevitably acquire some degree of political power, even when a country's constitution and laws stipulate that the civilian authorities are to be dominant. Military intervention in politics is not as surprising as the fact that in many countries such intervention does not occur.

The following discussion deals first with civil–military relations in countries where military intervention in politics is exceptional; second, with the infiltration of political conceptions into the military; and, finally, with the militarizing of the political and social order in some countries.

CIVIL–MILITARY RELATIONS

The term civil–military relations is of course much too simple to describe the complex network of interests that usually exists between the various branches of the military and the various sectors of civil society. For example, the relation between the professional officers corps and society is of a character completely different from that between enlisted men and society.

The old and the new establishments

Only since the 19th century has it been possible to speak of civil–military relations in a clear-cut sense, for not until then did the military become a specialized institution with a professionalized leadership apart from the rest of society. In the 17th and 18th centuries, the lines of political authority converged upon the person of the monarch, and the military elite was an indissoluble part of the aristocracy or the social elite. The rank and file of the armed forces, on the other hand, were drawn from classes that were not yet part of political society. Consequently a difference between military and social interests was scarcely discernible except as between the aristocracy and the rising bourgeoisie.

In the 19th century the military elite began to dissociate itself from the political–social elite, while the development of conscription brought more civilians into the military apparatus. The technical development of the military led to internal differentiation, so that special military interests and groups arose parallel to similar groups in civil society.

The complex of civil–military relations thus created is often written about as if there were a contrast between military bellicosity and civil peaceableness. As a generalization this is false. Bellicosity may, in fact, be more characteristic of certain political and social movements, of certain intellectual traditions and nationalistic political parties, than of the professional soldier. It is nonetheless true that the military has obvious interests to pursue and that it often attempts to influence important elements in society or at least to maintain close relations with them. Particularly important to the military are the government, industry, and public opinion.

The government is the most important because it makes decisions about international relations and the size of the military budget. In developed countries the relationship of the military with the government is less a matter of exercising power than of bringing to bear the pressure of special military interests. The military is in this respect on a level with representatives of other special interest groups such as industry, education, and public health care. It differs from them in its relation to parliament since it cannot participate in elections as directly as other interests can; soldiers are often disliked by members of parliament and seek to defend themselves by closing their ranks and keeping parliamentary inquisitors as ignorant as possible of the internal problems of the military.

Inter-service rivalry

Another problem arises from rivalry and competition between the services, each of which may seek to enlarge its budget at the expense of the others, as occurs in the United States, where the army, navy, and air force have sometimes aired their rivalries in public. The rapid technical development of arms leads to new sources of friction such as the need to choose between the strategic air force and naval aircraft carriers or the question of giving the army and navy aircraft and missiles. Such interser-

vice rivalry can in theory be solved by a complete integration of the armed forces, which would also permit economies in auxiliary services such as training, research, developments, and medical services. Canada has carried out a far-reaching unification program, but such thoroughgoing centralization is not possible for large countries.

Special relationships between the military and industries that depend on military contracts, known in President Eisenhower's phrase as the "military–industrial complex," have aroused much controversy, but it is difficult to tell how significant the relationships are. To begin with, there is obviously a connection between military spending and general economic prosperity: if some countries were to disarm rapidly and extensively, they would face serious problems of unemployment. It is also true that some business firms in the electronics and aircraft industries receive very large military contracts. Many officers retire from service to take jobs with companies having military contracts; in the U.S. in 1968, according to a study by the Joint Economic Committee's Subcommittee on Economy in Government, the 95 largest prime military contractors together had 2,072 former high military officers on their payrolls.

The cultivation of public opinion has become of great importance, especially in countries where the mass media are highly developed and the protective isolation formerly surrounding the military has been lost. Much of the "image building" is carried on by specialized organs of the various services, as well as by information offices in the defense ministries. Civilian organizations devoted to the armed forces are important channels in the public relations effort. Of even more importance is the relation between military men and political leaders, particularly in matters of the budget.

A successful war usually results in greatly increased influence and status for the military. This was notably the case in the United States after World War II. Unpopular wars, by the same token, can be disadvantageous to the military, as shown in the cases of the French in Indochina and Algeria, The Netherlands in Indonesia, and the U.S. in Vietnam.

Politicization of the military. The traditional doctrine of civil–military relations presupposes a certain balance between political and military interests. It assigns to the military the role of a specialized apparatus for violence, while exempting it from political responsibility for its actions. This is the expression of a pluralistic society, in which every institution has a great deal of autonomy in respect to politics. Totalitarian regimes take a different view: soldiers are regarded not as professional specialists at the disposal of the state but as part of the political order. In an effort to meld the military with the political superstructure, totalitarian regimes manipulate a whole sequence of control mechanisms.

Totalitarian controls

One technique is indoctrination. High officers are always members of the political party, and military training includes courses in politics. Politicization is also advanced through the selection of military personnel. By drawing upon the politically active members of youth organizations and by continuously postulating loyalty to the political regime as a criterion of selection and advancement, an officers corps is created that thinks in terms of unity with the party. This is strengthened by having a party organization within the military force at all levels, as in Communist countries where political functionaries hold positions of authority in the military hierarchy. Another way of controlling the military is to establish special units under the direct authority of the party and detached from the military command. Examples of these were the troops of the Soviet security police (NKVD) under Stalin and the German Schutzstaffel (SS) under Hitler.

Democratic indoctrination

But democratic countries also attempt to politicize and indoctrinate their troops, particularly when they are in conflict with other political systems. The United States became especially concerned with political morale during the Korean War of the early 1950s, when American prisoners appeared to be unable to withstand the ideological pressure of the Chinese Communists. The indoctrination effort was diverted from its traditional concern with military victory to that of a struggle in the name of Western democracy against a detestable political system. The wave of indoctrination also reached the European allies of the United States. In West Germany an effort was made to combat the National Socialist past by stressing the meaning of political democracy. Since it is difficult to convey the positive aspect of democratic values without conjuring up an enemy, the political indoctrination of the Bundeswehr led to a form of anti-Communist schooling that had not been originally intended. The question remains whether the modern soldier can be expected to fight effectively without being imbued with political purpose.

The militarization of politics. Sometimes the soldier intrudes himself into the political sphere, and the result is the militarization of the political order. Militaristic tendencies take several forms. They may be confined to the social elite, as in some empires and monarchies, or they may extend to the population, so that the soldier will have unusual social prestige and the military virtues be regarded as superior, as in Prussia during the 19th century and in National Socialist Germany during the 1930s.

Militarism of a different character exists when the armed forces look after their own interests at the expense of the general welfare, by aggrandizing themselves economically or socially. The military then becomes a parasite on the political body of the state. This has happened in Latin America and in various new nations with military regimes, where the internal politics of the country come to be controlled by military men.

But militarism should be distinguished from militancy. Most democratic countries are averse to militarism and are extremely sensitive to any expansion of the soldier's political and social influence. Many young democratic countries, however, are very militant—as were the United States and revolutionary France. Switzerland is a classic example of the militant spirit and Israel another. Political thinkers since Edmund Burke and Alexis de Tocqueville have pointed out that democratizing the military apparatus may increase the aggressiveness of a country and thus be a cause of wars.

MILITARY INTERVENTION IN POLITICS

Frequency of military coups

The military coup d'etat is a normal occurrence in some countries. Attempts by the military to take over the state may occur as often as ten times in one year. This is not a new phenomenon. It happened in Latin American countries throughout the 19th century, particularly in Mexico, Peru, and Chile; Spain between 1832 and 1876 was plagued by military coups, and so were the Balkans for many decades. If military intervention in politics receives more notice in the present day, it is partly because such intervention occurs frequently in the numerous new countries around the world. In many cases it produces relatively stable regimes, so that the political role of military men cannot be considered an exceptional or transitory phenomenon.

Conditions of military intervention. Most of the successful military regimes are in countries that belonged to former colonial empires. The Latin American countries are the successors of the Spanish–Portuguese empire that broke up around 1820, while those in the Middle East are the successors of the Ottoman Empire. The new nations in Africa and Southeast Asia emerged from the empires of Great Britain, France, Belgium, and The Netherlands.

Countries seem most likely to resist military intervention if they have either a strong democratic tradition or a Communist political system. In the latter case the military is kept subordinate to the political power by a strong Communist political party; the effectiveness of the party can be seen by comparing North and South Korea and North and South Vietnam.

One factor leading to military intervention in politics is evidently an inability of the civilian elements to assert their legitimacy. When the tradition reserving the exercise of governmental power to political rather than mili-

tary institutions is lacking, the political arena is opened to the military on an equal footing. Another factor is the general ineffectiveness of government in the new nations. The high hopes of the struggle for independence are often followed by disappointment and internal unrest. The military represents a relatively efficient and uncorrupted instrument of power where other social and political institutions, such as political parties and labour unions, are weak and cannot act effectively.

In countries where the struggle for independence has been settled by arms, the military is strong and often has a popular following, as in Algeria and Indonesia. If the young nation has been humiliated by foreign pressure or by military defeat, the army may step forward to defend the honour of the nation, as in Turkey and Egypt. If the country's unity is threatened by internal tensions, the army as a national institution can undertake to save it, as in Nigeria, Indonesia, and Pakistan.

Origins of military regimes

Military regimes. The rise of military regimes comes about as a reaction to a worsening political situation, as can be seen in the new African countries. Initially, after the proclamation of independence, the armies are politically neutral. They enter politics at a later period, usually in protest against the presence of European officers and the government's policy in military matters. At this stage the army's opposition begins to take on a more purposeful character, and it enters the struggle for political power. Once it has achieved power it is slow to relinquish it. Practically every military regime that succeeds to a civilian government promises in the beginning to depart as soon as order is established and general elections have been held. But elections are time after time postponed or manipulated, as in Indonesia, or declared to be invalid, as in Pakistan, Argentina, and Brazil. A situation is created in which the government can be changed only by a new military coup, and finally this method of governmental change becomes the customary one; military rule is then permanent.

The term military regime applies to governments that may be superficially quite different from one another—some are headed by monarchs; in others a single political party has power; while still others preside over a multiparty system—but the ultimate power is in the hands of the military, which may or may not have official posts in the government. The degree of military intervention in social and economic life may range from almost none to the occupation of all the key economic, social, and cultural positions, including positions in the universities and public utilities.

Military regimes are little inclined to ideology. They prefer to approach their problems technically and pragmatically; they regard the internal development of their countries as a process of economic and social modernization, not as the achievement of a political utopia. In their external relations they are moved more by nationalist sentiments than by feelings of solidarity with international political movements or coalitions.

THE FUTURE OF THE ARMED FORCES

Decreasing use of warfare among great powers

Modern warfare has become increasingly restricted to great powers and to coalitions of highly developed nations. War is now impossible among many of the countries that were once traditional enemies, such as Germany and France. Large blocs of states such as NATO and the Warsaw Pact countries have suppressed their old national differences to the extent that a violent settlement of mutual disputes among them has now become extremely unlikely. And the development of nuclear weapons has reached the point at which they can no longer be used militarily but only politically. The public attitude to war has also changed, particularly in the Western democracies, where the use of violence in service of national interests is regarded as less and less tolerable. By the 1970s, many believed the aversion to war had become so great among the younger generation as to destroy the psychological climate in which war tensions develop.

If these trends were all that counted, one could project the future of the armed forces as a technologically elaborate, extremely costly means through which great combinations of states will make their mutual spheres of interest unassailable. The military will become more and more a body of professional specialists and managers carrying out their task in close cooperation with the political leaders.

But these great coalitions of rich countries represent only half of the world. The other half, that of the new nations and developing countries, is quite different in political, social, and therefore in military terms. The tens of new nations that have originated from the process of decolonization seem to most observers fated to travel the same long road of nationalism that Europe has now left behind. Bloody civil wars such as those in Indonesia, Zaire, Nigeria, and Pakistan can easily lead to international conflicts. Revolutionary wars as in Vietnam can lead to intervention by the great powers. Ethnic and cultural differences such as those in the Indian subcontient, in The Sudan, in the Middle East, and in Indonesia may also produce violent confrontations.

One consequence is that the traditional type of military force (light infantry supported by limited motorized units) is still in many parts of the world a decisive weapon of power, though it weighs heavily on the resources of poor countries. Another consequence is that the big powers who may become involved in these conflicts will seek to maintain conventional forces that can intervene, as did Great Britain in Malaysia and East Africa, the United States in Korea, Vietnam, and Latin America, the Soviet Union in the Arab world, and France in Chad. The United Nations may not furnish a substitute for this intervention by the great powers, and the peripheral areas between the blocs may remain the scene of various disputes in which weapons will be used. As the world becomes more unified, these peripheral areas may seem to multiply.

Armenian Language

The Armenian language, which forms a separate branch of the western group of Indo-European languages, is the mother tongue of the Turkish Armenians and of the Armenians in the Armenian Soviet Socialist Republic, where it is spoken by 2,000,000 people. In other parts of the Soviet Union, especially in the neighbouring republics of Georgia and Azerbaijan, it is used by some 1,700,000. Armenian emigrants and refugees have taken their language with them all over Asia Minor and the Middle East and from there to many European countries, especially Romania, Poland, and France, and to America, particularly the United States. In all, Armenian is probably spoken by about 5,500,000 people.

History of the language. Armenian was introduced into the mountainous Transcaucasian region (called Greater Armenia by the Greek historians) by invaders coming from the northern Balkans, probably in the latter part of the 2nd millennium BC. These invaders occupied the region on the shores of Lake Van that had previously been the site of the ancient Urartean kingdom. By the 7th century BC the Armenian language seems to have replaced the tongues of the native population. It is tempting to connect the invasion with the downfall of the Hittite empire in Anatolia.

Development of the alphabet

After the introduction of Christianity in the beginning of the 4th century AD, the language was reduced to writing; the alphabet, of 38 letters, was invented, according to tradition, by the bishop Mashtots (Mesrob) in about AD 400. Admirably suited to the phonology of Armenian, it is still used in various forms by Armenians all over the world. The oldest writings in the language date from the 5th century; they are preserved in manuscript form from the 9th century. Grabar, the written language of the 5th century, the golden age of Armenian culture, is traditionally said to be based on the dialect of Tarawn on Lake Van. To what extent the spoken language was split into dialects at that time is not known. The language of the literature from the 5th to the 8th century is remarkably homogeneous, but by the 9th century the influence of the spoken dialects was noticeable, especially in legal and historical texts. Among the Middle Armenian varieties of Grabar, the best known is the 12th- and 13th-century chancellery (court) language of the Armenian kingdom in Cilicia. More or less corrupted versions of Grabar continued as the literary language until the middle of the 19th century.

*The *spiritus asper*, ', indicates aspiration.

Modern East Armenian and West Armenian. In the 1800s, the writers Khachatur Abovean (1805–48) and Mikael Nalbandean (1829–66) and other Armenian nationalists made efforts to reach the populace with nationalist propaganda. As a result, a national revival occurred from which a new literary language emerged that was much closer to the spoken language. This is known in two varieties. East Armenian, now the official language of the Armenian Soviet Socialist Republic, is based on the dialect of the Ararat valley and the city of Yerevan; West Armenian has its foundation in the dialect of Istanbul. East Armenian is also spoken in other parts of the Soviet Union, whereas the western variety dominates in the Armenian colonies in the Middle East, Asia Minor, Europe, and America. The differences between these two written forms of Modern Armenian are slight, constituting no barrier to mutual intelligibility.

Dialects

In addition to the two literary languages, there are a great number of dialects, some of which are so different that the speakers cannot understand each other. It is estimated that before World War I some 50 distinct dialects were spoken. Today, the spoken dialects are losing ground in the Soviet Union, under the pressure of the standard written language. Accurate statistics on the extent to which Armenian dialects are used in Turkey and in other parts of the Middle East are not available.

When the scientific study of Armenian started in the 19th century, the language was considered an Iranian dialect, a mistake easily explained by the vast number of

Iranian loanwords in the vocabulary. Subsequent studies, however, have convincingly shown Armenian to be an independent member of the Indo-European language family. According to the Greek historian Herodotus, Armenian was a variety of Phrygian, a tongue presumed to be Indo-European. What little is known of the latter is insufficient to support or confirm such a claim.

Phonological characteristics. Phonetic developments in Armenian have radically changed the sound system of the old Indo-European parent language. In particular, the pattern of the plosive consonants—the stops—has been completely reshuffled. In the more conservative central Armenian dialects three series of stops are distinguished (voiced *b, d, g*, which in some dialects are aspirated; unvoiced *p, t, k;* and unvoiced aspirated *ph, th, kh*). In the dialects of the periphery, the three series have been reduced to two (aspirated *ph, th, kh* and unaspirated *p, t, k*, or, as in Istanbul, *b, d, g*). These differences are concealed in the traditional orthography. Sibilants (fricatives) of various types and affricates have emerged through palatalization of the old palatal and labiovelar stops. Thus, Old Armenian *dz* (*z*) and *ts* may go back to the Indo-European palatal stops *ǵh* and *ǵ*, and *dž* (*ž*) to the Indo-European labiovelar $g^{w}h$ before *e* and *i;* Old Armenian ts^{ϵ}, $t\check{s}^{\epsilon}$, and *tš* may derive from the Indo-European consonant clusters *sk, ky*, and *gy*. All Armenian dialects distinguish two types of *r*, one strongly trilled, one weakly trilled. Old Armenian also differentiated between two types of *l*, a neutral one and a velarized variety, which is made by moving the back of the tongue nearer to the soft palate at the back of the mouth. The latter type has developed into a voiced velar fricative in the modern dialects.

Sounds of Armenian

Grammatical characteristics. All of the spoken dialects and the two literary languages have maintained a fairly complicated system of noun declension, distinguishing six or seven cases. The plural stem, derived from the singular stem by the addition of the suffix *-(n)er*, is declined as a singular, according to the Turkish pattern. Characteristic of the changes in the Old Armenian verbal system is the general replacement of simple present tense forms by periphrastic expressions. These are groups of words, including auxiliaries, that take the place of a single word that is capable of being inflected to show tense or some other feature. The various types of periphrastic forms serve as the basis for the classification of the dialects. In Old and Modern Armenian, the main tense distinction is that between present, aorist (denoting occurrence without reference to completeness, duration, etc.), and periphrastic perfect tenses. The old subjunctive, still extant in classical Armenian, has been lost in the modern language. To express future time, Old Armenian used the subjunctive forms; Modern Armenian employs periphrastic expressions, as is done in the English future forms *I shall go* and *he will work*. Also characteristic of Modern Armenian is the importance of the passive forms of the verb, which are strictly parallel to the active forms, and the emergence of a special negative conjugation with differing forms for verbs in instances like "I read" and "I don't read." Whereas Old Armenian was rather close to ancient Greek in many respects, Modern Armenian is typologically much closer to Turkish. Among the features that illustrate this similarity are the agglutinative system of declension (*i.e.*, the compounding of several linguistic elements of independent meaning into a single word), the use of suffixes to indicate possession, the employing of passive and causative forms for all verbs, and the use of postpositions (grammatical elements placed after the word) instead of prepositions (as used in Old Armenian). The vocabulary of the written languages is purely Armenian, being based almost exclusively on that of Grabar, with very few loanwords from the neighbouring languages. (The Iranian loanwords mentioned above were incorporated into Armenian before the creation of the written language.)

(H.K.V.)

Armenian Soviet Socialist Republic

Occupying a landlocked area just south of the great mountain range of the Caucasus, and fronting on the northwestern extremity of Asia, the Armenian Soviet Socialist Republic, or Armenia, is the smallest of the 15 republics that make up the Soviet Union. Its area—11,500 square miles (29,800 square kilometres)—is no more than 0.13 percent of the national territory. To the north and east, Armenia is bounded by the Georgian and Azerbaijan Soviet Socialist republics, while its neighbours to the west and southeast are, respectively, Turkey and Iran. Armenia lies in the southern portion of the Transcaucasian region. By the mid-1970s it was the home of some 2,790,000 people.

Modern Armenia is part of (but not identical with) ancient Armenia, one of the world's oldest centres of civilization, whose peoples have long inhabited the highlands of the area. With the loss of autonomy in the 14th century AD, Armenia was subjected to constant foreign incursions, which, together with the centuries-old rule of Ottoman and Persian conquerors, imperilled the very existence of the Armenian people. The portion of Armenia lying within the former Russian Empire achieved its current political status on November 29, 1920. Its capital is Yerevan. (See further URARTU AND ARMENIA, HISTORY OF; ARMENIAN LANGUAGE; CAUCASUS MOUNTAINS.)

THE LAND

Relief features. Armenia is a mountainous country, characterized by a variety of scenery. Its average altitude is 5,900 feet (1,800 metres) above sea level. There are no lowlands: half the territory lies at altitudes of 3,300 to 6,600 feet (2,000 metres); a mere 10 percent lies below the 3,300-foot mark.

Mountainous terrain

The northwestern part of the Armenian highland—containing Mt. Aragats, the highest peak (13,418 feet, or 4,090 metres) in the republic—is a combination of lofty mountain ranges, deep river valleys, and lava plateaus dotted with extinct volcanoes. To the north and east, the Somkhet, Bazum, Pambak, Areguni, Sevan, Vardenis, and Zangezur ranges of the Little Caucasus lie across the northern sector of Armenia. Elevated volcanic plateaus (Lory, Shirak, and others), cut by deep river valleys, lie amid these ranges.

In the eastern part of the republic, the Sevan Depression, containing Lake Sevan (525 square miles, or 1,360 square kilometres) and hemmed in by ranges soaring to a height of 11,800 feet, lies at an altitude of about 6,200 feet (1,900 metres). In the southwest, a large depression—the Ararat Plain—lies at the foot of Mt. Aragats and the Gegam Range; the Araks River cuts this important plain into halves, the northern half lying in the Armenian S.S.R. and the southern in Turkey and Iran.

Climate. Armenia's climate, because of its position in the deep interior of the northern part of the subtropical zone, enclosed by lofty ranges, is dry and continental. Regional climatic variation is nevertheless considerable. Intense sunshine occurs on many days of the year. Summer, except in high-altitude areas, is long and hot, the average June and August temperature in the plain being 77° F (25° C); sometimes it rises to 108° F (42° C). Winter is generally not cold; the average January temperature in the plain and foothills is about 23° F (−5° C), whereas in the mountains it drops to 10° F (−12° C). Invasions of Arctic air sometimes cause the temperature to drop to −22° F (−30° C): the record low is −51° F (−46° C). Winter is particularly inclement on the elevated, windswept plateaus. Autumn, long, mild, and sunny, is the pleasantest season.

The ranges of the Little Caucasus prevent humid air masses from reaching the inner regions of the republic. On the mountain slopes, yearly rainfall approaches 315 inches (8,000 millimetres), while the sheltered inland hollows and plains receive only 80 to 160 inches (2,000 to 4,000 millimetres) of rainfall a year.

The climate changes with elevation, ranging from the dry subtropical and dry continental types found in the plain and in the foothills up to a height of 3,000 to 4,300 feet, to the cold type above the 6,600-foot mark. The plains and foothills are sufficiently well warmed to permit cultivation of such cold-sensitive fruits as figs, pomegranates, peaches, and grapes. Higher up, tobacco, cereals, and some fruits are raised; and grain crops, potatoes, and fodder grasses are found up to 6,600 to 8,200 feet.

Hydrology. Of the total precipitation, some two-thirds is evaporated, and one-third filters into the rocks, notably the volcanic rocks, which are porous and fissured. The many rivers in Armenia are short and turbulent with numerous rapids and waterfalls. The water level is highest when the snow melts in the spring and during the autumn rains. As a result of considerable difference in altitude along their length, some rivers have great hydropower potential; the total for the republic is nearly 22,000,000,000 kilowatt-hours a year.

Araks River

Most of the rivers fall into the drainage area of the Araks (itself a tributary of the Kura River of the Caspian Basin), which, for 300 miles, forms a natural boundary between the Soviet Union and Turkey and Iran.

The Araks' main left-bank tributaries, the Akhuryan (130 miles), the Razdan (Hrazdan; 90 miles), the Arpa (80 miles), and the Bargushat (110 miles), serve to irrigate most of Armenia. The tributaries of the Kura—the Debet (57 miles), the Agstev (80 miles), and others—pass through Armenia's northeastern regions. Lake Sevan, holding over nine cubic miles (39 cubic kilometres) of water, is fed by dozens of rivers, but only the Razdan leaves its confines.

Armenia is rich in springs and wells, some of which possess medicinal properties.

Biogeography. The broken relief of Armenia, together with the fact that its highland lies at the junction of various biogeographical regions, has produced a great variety of landscapes; though a small country, it boasts more soil types (over 15) and plant species (over 3,000) than the vast East European Plain. There are five altitudinal vegetation zones: semidesert, steppe, forest, alpine meadows, and high-altitude tundra.

The semidesert landscape, ascending to a height of 4,300–4,600 feet, consists of a slightly rolling plain covered with scanty vegetation, mostly sagebrush. The vegetation includes drought-resisting plants such as juniper, sloe, dog rose, and honeysuckle. The boar, wildcat, jackal, adder, gurza (a venomous snake), scorpion, and, more rarely, the leopard inhabit this region.

Steppes

Steppes predominate in the republic. They start at altitudes of 4,300–4,600 feet, and in the northeast ascend to altitudes of 6,200–6,600 feet. In the central region they reach 6,600–7,200 feet and in the south are found as high as 7,900–8,200 feet. In the lower altitudes the steppes are covered with drought-resistant grasses, while the mountain slopes are overgrown with thorny bushes and juniper.

The forest zone lies in the southeast of Armenia, at altitudes of 6,200–6,600 feet, where the humidity is considerable, and also in the northeast, at altitudes of 7,200–7,900 feet. Occupying nearly 10 percent of the republic's entire territory, the northeastern forests are predominantly beech. Oak forests predominate in the southeastern regions, where the climate is drier, and in the lower part of the forest zone hackberry, pistachio, honeysuckle, and dogwood grow. The animal kingdom is represented by the Syrian bear, wildcat, lynx, and squirrel. Birds—woodcock, robin, warbler, titmouse, and woodpecker—are particularly numerous.

The alpine zone lies above 6,600 feet, with stunted grass providing good summer pastures. The fauna is rich; the abundant birds include the mountain turkey, horned lark, and bearded vulture, while the mountains also harbour the bezoar goat and the mountain ram, or mouflon.

Finally, the alpine tundra, with its scant cushion plants, covers only limited mountain areas and solitary peaks.

Regions. One of the more important of the distinctive regions of Armenia is that including the Ararat Plain and the surrounding foothills and mountains. This is a prosperous and densely populated area, the centre of Armenia's economy and culture, and traditionally the seat of its governmental institutions.

The Ararat Plain

The other regions are the Shirak Steppe, the elevated northwestern plateaus, the republic's granary; Gugark, high plateaus, ranges, and deep valleys of the northeast, covered with forests, farmlands, and alpine pastures; the Sevan Basin, the hollow containing Lake Sevan, on whose banks are farmlands, villages, and towns; and Syunik, the two parts of which—the northern (Vayk) and the southern (Zangezur)—lie in the southeast. This last region is a maze of gorges and river valleys cutting through high ranges. It is an area rich in ores, with fields and orchards scattered here and there in the valleys and on the mountain sides.

THE PEOPLE

Origins. Armenians constitute nearly 90 percent of the republic's population. They were consolidated as a nation in the second half of the 1st millennium BC.

The Russian campaigns against the Persians and the Turks in the 18th and 19th centuries resulted in large emigrations of Armenians under Muslim rule to the Transcaucasian provinces of the Russian Empire and to Russia itself (Erivan, Tiflis, Karabakh, Shamakhi, Astrakhan, Bessarabia). At the time of the massacres in Turkish Armenia in 1915, some Armenians found asylum in Russia.

The Armenians were converted to Christianity *c.* AD 300 and have an ancient and rich liturgical and Christian literary tradition. Believing Armenians today belong mainly to the Armenian Apostolic (Orthodox) Church or the Armenian Catholic Church, in communion with Rome.

Demographic trends. In the first quarter of the 19th century slightly more than 160,000 persons lived within the republic's present borders. In 1920 Soviet Armenia had a population of 780,000. By 1939 this had reached 1,282,000; by 1959, 1,763,000; and by 1970, 2,493,000. This trebling of the population in 50 years was attributable to a high natural increase, which appreciably exceeded the national average, and to an influx of more than 220,000 repatriates from foreign countries. The population of Armenia by the 1970s included Azerbaijanis (nearly 6 percent of the total), Russians (about 3 percent), and a small number of Kurds, Ukrainians, and other groups.

Settlement patterns. The average population density is rapidly rising, from 111.4 persons per square mile (43 per square kilometre) in 1939 to 153.3 by 1959 and to 216.8 by 1970. By contrast, there had been only 13 per square mile in the early 19th century. Average figures, however, are relatively meaningless, as population densities vary widely across the republic.

The density is highest in the Ararat Plain, reaching more than 1,040 per square mile (402 per square kilometre). The river valleys in the southeast and northeast are the next most densely populated area. Half the population is in fact concentrated in the zone marked by an upper altitudinal limit of 3,300 feet, which makes up only about 10 percent of the entire territory.

Many people also live in the foothills, at altitudes of 3,300–4,900 feet, and in the mountains (4,900–6,600 feet). These regions account for a further third of the entire population, with an average density exceeding 155 persons per square mile (60 per square kilometre).

The high ranges and mountains are scantily peopled: less than 5 percent of Armenia's people live above the 6,600-foot mark, and no one resides above 7,700 feet.

Fundamental changes in the distribution of Armenia's population are being caused by the urbanization resulting from economic growth, particularly the republic's industrialization. Before the Revolution, the republic's four cities—Erivan (now Yerevan), Aleksandropol (Len-

inakan), Nor-Bayazet (Kamo), and Geryusy (Goris)—accounted for 10 percent of the total population. By 1974 the urban population numbered 1,699,000, or 62 percent of the total population.

There are 23 towns and 33 other urban-type settlements in the Armenian S.S.R. Urban communities are particularly numerous in the Ararat Plain and in the valley of the Razdan River.

Yerevan

Formerly a dusty town with small mud houses, Yerevan, founded 2,500 years ago, has grown since the 1920s into an industrial city serving as the republic's administrative and cultural centre, with a population that approached 900,000 in 1975. Many of its modern buildings show original architectural design. It is followed in importance by Leninakan, an industrial centre with a population of 180,000; Kirovakan, with 123,000 people; and the small centres of Kafan, Echmiadzin (of great significance in Armenian ecclesiastical and cultural history), Alaverdi, Razdan, and Oktemberyan.

The rural population of the Armenian S.S.R. has grown much less rapidly than the urban population; comprising some 916,000 people in 1939, it fell to 881,000 in 1959, and barely exceeded the 1,000,000 mark in 1974. This pattern is a result of the movement of many villagers to towns. There are nearly 1,200 rural settlements in the Armenian S.S.R., and about two-thirds of the rural population live in communities of 1,000 to 2,000 persons. The high country to the north of Shirak, and in Syunik, has small hamlets that lie in secluded glens, on riverbanks, and near springs; in the plain, such settlements cluster around mountain streams and irrigation canals, amid orchards and vineyards.

THE ECONOMY

Economic development. Armenia has become an industrial country with an important agricultural element. The share of industry in the country's economy—14 percent in 1913 in value terms—reached 73 percent by 1970, while, over the same half century, agricultural output grew 4.5 times, and industrial output increased 180-fold.

This rapid economic advancement—unparalleled among the Soviet republics—is attributable to national financial investments that made possible the creation of a diversified industry, the reconstruction of agriculture, and the development of transport. Formerly a supplier of copper, certain farm products, and cognac, Armenia is now a major supplier of chemicals, nonferrous metals, machines, equipment, precision instruments, textiles and clothing, wines, cognacs, and canned goods. The republic also has mineral resources, especially metal ores.

Electricity

At the initial stage of industrialization, the creation of a power base utilizing the hydraulic potential of mountain streams was of decisive importance. Production of electricity was combined with the building of irrigation works and water-supply systems for industries and cities. The Sevan–Razdan series of hydraulic power stations (six in all, with an aggregate capacity of 557,000 kilowatts) became a first-priority project that used not only the waters of the Razdan but also those of Lake Sevan. This project made possible the electrification of agriculture and helped to build numerous industries. In the 1960s emphasis shifted to thermal electric power stations, which a decade later accounted for 80 percent of the power produced in the republic. An atomic electric power station was also being built at the new town of Metsamor.

Industry. Mechanical engineering, machine tools and electrical power machinery, electronics, and the chemical and mining industries hold a prominent place in the republic's heavy industry, but light and food industries are also fairly well advanced. Yerevan, Leninakan, and Kirovakan are machine-building cities. The centres of the chemical industries are Yerevan, Kirovakan, and Alaverdi.

Nonferrous metallurgy—in Gugark and Zangezur—includes the mining and dressing of copper, molybdenum, and other ores; the smelting of copper; and the extraction of precious and rare metals.

The food industry processes various farm products, meets domestic demand, and supplies other parts of the Soviet Union. The most advanced branches are involved in the primary processing of grapes and production of high-quality cognacs, wines, canned fruits, and vegetables for export.

Light industry—a modern innovation—specializes in the production of woollen, silk, and cotton fabrics; knitted goods and clothes; carpets; and footwear.

Yerevan is the foremost industrial centre, accounting for nearly three-fifths of the total industrial output in the republic; but other industrial centres and regions are developing, notably in the north, where Leninakan and Kirovakan are now major industrial centres.

Agriculture. Agriculture still plays a major role in the Armenian economy, even though industry has taken precedence.

Agriculture engages nearly half the population; many items are shipped to other republics, and farm products provide raw materials for a number of industries. By the mid-1970s there were some 376 state farms (*sovkhozy*) and 338 collective farms (*kolkhozy*) in the republic, with fleets of tractors, combine harvesters, and other farm equipment.

Agriculture in Armenia has to contend with many difficulties. Arable land is scarce; in the densely populated areas there are only 3.7 acres (1.5 hectares) of plowland per capita. Cultivated lands (plowland, orchards, and vineyards) occupy only 20 percent of the republic's total area. Pastures and meadows mowed for hay cover a larger area, approaching 28 percent of the territory. Farmlands in mountain regions form a mosaic of cornfields, orchards, vineyards, and pastures. Considerable tracts of arable land also are found in the Ararat Plain, the Shirak plateau, and the southern part of the Sevan basin.

The extensive irrigated lands in the low, sunny Ararat Plain and cultivated stretches in the northeastern and southern river valleys yield high-quality grapes and fruits. Storage lakes, dams, and pumping stations have been built and irrigation canals dug. More than half the total arable land area is irrigated. Farming, above an elevation of 3,300 feet, also combines with cattle raising; grain crops are cultivated and cattle raised in the mountains, while tobacco and potatoes are raised in the lower, warmer part of the mountain belt.

The leading branch of agriculture is viticulture. Among the many orchard crops, peaches and apricots are commonest. Apples, cherries, mazzards (sweet cherries), and pears are cultivated in the colder climate, and walnuts, hazelnuts, almonds, pomegranates, and figs are also produced in this area. Vegetables are grown in the main agricultural regions, potatoes in the cooler mountains. Quality tobaccos are widely cultivated.

Cotton and sugar beets, formerly grown in the Ararat Plain, are being succeeded by more valuable crops, such as grapes. The area under grain crops has been sharply reduced.

Extensive alpine pastures raise the productivity of animal husbandry, whose main branches are the raising of beef and milk cattle and sheep. Pig and poultry raising, as well as sericulture and apiculture, play subsidiary roles.

Transportation. Mountains are a serious impediment to the construction of land transport routes of any kind, although distances between towns and regions are not great. A railway line, leading to Tbilisi in the north and Baku in the east, runs through the northern, western, and southern regions of the Armenian S.S.R. Yerevan is linked with the Sevan basin by a line running along the Razdan River. Clustered along the rail routes are major industrial centres.

Road network

The network of motor roads is much denser, with Yerevan as the main hub. Road transport—whose role in freight and passenger traffic is growing—carries many times as much cargo as the railways, and buses remain the chief mode of travel between towns and villages.

Local air transport is being used increasingly. Air routes link Yerevan with many towns in the republic, and planes carry fresh fruits and grapes to Moscow, Lenin-

grad, and other Soviet cities. Gas pipelines link Armenia with the Azerbaijan and Georgian S.S.R.'s.

These transportation facilities enable the other union republics to supply Armenia with coal, petroleum products, metals, timber, grain, industrial raw materials and equipment, while Armenia, in turn, exports lighter but more valuable products.

ADMINISTRATION AND SOCIAL CONDITIONS

Constitutional framework. The state structure of the Armenian S.S.R., defined by the constitution adopted in 1937, is similar to those of the other union republics.

The highest organ of state power is the Supreme Soviet of the Armenian S.S.R., elected for a four-year term from a single list of candidates. The Supreme Soviet designates its Presidium to administer the state in the periods between its own brief sessions, and it appoints the Council of Ministers and enacts laws.

The organs of state power in the districts, cities, and rural areas are the soviets of working people's deputies, elected by the population for two years.

The Supreme Court of the republic, whose members are elected by the Supreme Soviet for five years, is the highest judicial body. The procurator of the Armenian S.S.R. is appointed, for five years, by the procurator general of the Soviet Union. The Armenian S.S.R. has a coat of arms, a state flag, and a national anthem.

Communist Party

Political life is under the direction of the Communist Party, part and parcel of the Communist Party of the Soviet Union. It was founded in 1920 through the unification of Armenia's Bolshevik organizations. In 1922 it had a membership of 2,000 with a further 3,000 candidate members. By 1974 the Communist Party of Armenia had 137,000 members and candidates. The Young Communist League (Komsomol) of Armenia has a membership of more than 339,000. It was formed in 1921 in close contact with the party.

The trade unions of Armenia in 1974 had a membership of 1,200,000. By 1970, they operated 60-odd clubs and palaces of culture, nearly 100 public libraries, nearly 300 sports facilities, sanatoriums, and rest homes.

Education. By the 1970s, countrywide eight-year schooling was being introduced. In the 1973–74 school year about 1,600 general schools existed, with a combined enrollment of about 700,000 younger pupils. Forty buildings cater to the children's organization known as the Young Pioneers, and there are a number of sports establishments for children. There are also clubs for young technicians, nature lovers, and the like. Education of all types is free of tuition charges, being supported by taxes.

The republic in the mid-1970s had 50 trade schools (30,000 pupils), 64 secondary specialized educational establishments (more than 51,000 students), and 12 other institutes and colleges (52,800 students). Establishments of higher learning include Yerevan State University; polytechnical, medical, agricultural, pedagogical, and theatrical institutes; and a conservatory.

There are about 1,300 public libraries. They include the A.F. Myasnikyan State Public Library of the Armenian S.S.R. and the Matenadaran archives in Yerevan containing 10,000 Armenian manuscripts, the largest collection in the world. There are also about 1,200 clubs and 35 museums, including a comprehensive State Historical Museum of the Armenian S.S.R.

Social services. In the mid-1970s there were more than 230 hospitals with about 24,000 beds, and about 500 outpatient clinics. There was one doctor for each 315 people. The republic also has some two dozen sanatoriums. Medical treatment in hospitals and clinics is free of charge for all citizens, being supported, like education, by taxation.

More than 1,500,000 persons were rehoused between 1961 and 1970, some in the 21,000 to 26,000 apartments built annually, others in new houses built by the state, and others in new houses built by individuals on their own account.

Cultural life. Armenian written literature began in the 5th century AD, and monasteries became the principal centres of intellectual life. The earliest works were historical, Moses of Khoren's *History of Armenia* being representative. The masterpiece of classical Armenian is Eznik Koghbatzi's *Refutation of the Sects*. The first great Armenian poet (10th century) was St. Gregory Narekatzi, renowned for his mystical poems and hymns. During the 16th–18th centuries, popular bards, or troubadours, called *ashugh*, arose, outstanding among them being Nahapet Kuchak and, especially, Aruthin Sayadian, called Sayat-Nova (died 1795), whose love songs are still popular. In the 19th and early 20th centuries, Hakob Paronian and Ervand Otian were outstanding satirical novelists, and Grigor Zohrab wrote Realist short stories. Paronian was also a comic playwright, whose plays still entertain Armenian audiences. The most celebrated novelist was Hakob Meliq-Hakobian, called Raffi, and perhaps the best dramatist of recent times was Gabriel Sundukian (died 1912).

Among Armenian composers, Aram Khachaturian has achieved world-wide renown.

By the mid-1970s, publishing houses were producing more than 1,000 books (including more than 700 in Armenian), with a total of 9,800,000 copies per year. The broadcasting system has been operating since 1926 and the Yerevan television centre since 1956. Broadcasts and telecasts are conducted in Armenian, Russian, Azerbaijani, and Kurdish.

The republic boasts a State Academic Theatre of Opera and Ballet, several drama theatres, theatres for children, orchestras, a national dance company, and the Yerevan film studios, which produce feature, documentary, and popular science films. The traditional folk arts, especially singing, dancing, and artistic crafts, are thriving.

Armenian science, like its culture, has its roots in antiquity, but research institutions are a 20th-century development. The Armenian Academy of Sciences is composed of 39 institutes engaged in research problems in natural and social sciences.

Academy of Sciences

PROBLEMS AND PROSPECTS

The chief problem to be dealt with in the course of the future economic development of Armenia is believed to be the structural improvement of the production complex as a whole. There is also a growing need for a more efficient utilization of the republic's relatively limited natural resources—the mineral wealth, lands, and waters—and, consequently, for a comprehensive development of those process industries that require skilled labour for a more effective utilization of raw materials.

(A.A.M./Ed.)

Armour

Armour refers to any body covering designed for protection in combat. From very early times, armour for the fighting man and his horse was improved steadily to counteract improvements in weapons and, to some extent, tactics. For the greater part of its history only excavated fragments survive; the main evidence is found in art, where its interpretation is often difficult and subject to argument. Development was at first slow, but in Europe, between the 13th and 17th century, improvement of blade-making techniques and the introduction of more efficient missile weapons helped accelerate the development of plate armour. In the 16th and 17th centuries, improved firearms forced armourers to increase the thickness and, therefore, the weight of their product, until finally plate armour was largely abandoned in favour of increased mobility. However, armour never entirely disappeared among European cavalry, surviving in the form of a hat lining or helmet, a cuirass for the body, and high boots, until modern times. Elsewhere it survived until rendered obsolete by the introduction of firearms.

The large number of head wounds caused by overhead shell bursts during World War I led to the adoption of steel helmets by all combatant nations. Renewed interest in experiments with various types of body armour began at the time of the American Civil War, and such armour was used on a limited scale by both sides in both world wars. Continuing experiments now aim at development

of body armour that is bulletproof yet sufficiently light and flexible for the infantryman to wear in action.

TYPES OF ARMOUR

Armour falls into three main groups, depending on its construction: leather or fabric, sometimes of several thicknesses, sometimes reinforced by quilting with some material such as cotton; mail, consisting of interlocking iron or steel rings; and rigid armour of metal, whalebone, ivory, horn, bark, wood, plastic, or *cuir-bouilli* (leather hardened by boiling in wax). The last group can be further divided according to the methods of connecting the pieces: (1) small overlapping plates attached outside a leather or fabric garment (scale) or attached inside the garment (brigandine); (2) lamellar, which consists of small overlapping plates held together by laces; (3) small plates held together by mail or let into mail garments; (4) large plates, usually of metal, linked by loosely closed rivets and by internal leathers to allow the wearer maximum freedom of movement.

Cuir-bouilli

Leather armour. Armour of hide is probably the oldest of all types, and in its simplest form is indistinguishable from ordinary clothing. Coats made of five to seven layers of rhinoceros skin were worn in China in the 11th century BC, and an apparently similar armour of ox hide was used by the Mongols in the 13th century AD. North American Indians, such as the Shoshoni, wore jackets of several layers of hide glued or sewn together and also had leather horse armour. The jaguar skin jackets of Aztec chiefs seem to have been part of their regalia and not defensive. Coats made of stout buff leather were first worn under European plate armour in the 16th century. The leather sleeves and skirts, retained after plate arms were abandoned, were sufficiently sturdy to deflect a sword cut, and buff leather was used for the cuffs of cavalry gauntlets until the 19th century. Leather has also been used widely as a base for other defenses, such as the boars' tusk helmets of Mycenae and a much later jacket covered with modern coins found in Alaska.

Fabric armour. Early evidence of fabric armour is rare since fabric rarely survives on archaeological sites. A fragment consisting of 14 layers of linen was found in a Mycenaean grave of the 16th century BC, and there are occasional literary references throughout antiquity. The Assyrians of Xerxes are said to have had linen armour, and the Greek heavy infantry of the 5th–4th centuries BC wore a linen cuirass in preference to bronze, probably to increase their mobility. Throughout the Middle Ages quilted coats (aketons) were worn either alone or under mail or plate to prevent chafing. Silk quilted armour was experimentally introduced in England in the 17th century. In northern India quilted coats, sometimes with helmets and trousers to match, were worn until the 19th century and were usually velvet covered and studded with small gilt nails, with some steel plates let into their surface (see Figure 1, left). Quilted coats and helmets were also worn in China and Korea. The short jackets, with or without sleeves, illustrated in Central American art, may be the quilted armour reported by the conquistadores. Horse armour of quilting has been used in many areas, from England in the 13th century to Nigeria in the 20th. Particularly elaborate rope armours made from coir, a coarse fibre obtained from coconut husks, were worn until the 19th century in the Gilbert and Ellice Islands. Fabric armour is used today in, for example, the U.S. Navy's four-pound, synthetic-felt combined life jacket and armoured vest.

Mail. The place and date of the origin of mail is at present unknown, but pieces have been found on a site near Kiev dating from the 5th century BC. Surviving examples are of iron or steel wire, occasionally with brass rings around the edges or, in Oriental mail, forming an all-over pattern. Mail is flexible and relatively impervious to slashing strokes when worn over quilting, although a thrusting weapon can force the rings apart in spite of their rivetted closure. In the form of a simple shirt, mail was worn throughout the Roman Empire and beyond most of its frontiers (see Figure 1, centre). It formed the

The mail shirt

main armour of western Europe until the 14th century, with leg harnesses of mail appearing in the 11th century, mail hoods added during the 11th–13th century, and long sleeves ending in mail gloves added during the later period of its use. The mail shirt and aketon were worn in India and Persia until the 19th century, and in the Sudan and Nigeria until modern times. After the development of complete plate armour in Europe, mail gussets were laced to the arming clothes to close the gaps in the plates. A curtain of mail was often attached to the lower edge of the conical helmet, acting as a throat and neck protection, on the 14-century European basnet and also on many Oriental helmets, particularly Indo-Persian. Sleeves of mail were used by light troops in the 16th century, and mail shoulder straps were adopted by light cavalry in the 19th century. The Japanese used mail to a limited extent from the 14th century AD, but the Japanese rings were arranged in a variety of ways, producing a more open construction than found in Europe.

Scale armour. Although usually of metal, scale armour has been made of horn, bone, and leather and from the scales of such naturally armoured animals as the pangolin. The small plates usually have a curved or pointed lower edge overlapping a joint in the next row. The area of distribution of scale armour differs slightly from that of lamellar. Scales have been found on an Egyptian site of the 17th century BC. It is found throughout the Middle East; in the classical Greek area including southern Russia; in the Roman Empire; and in all of Europe, particularly in the 10th–12th centuries AD, but occasionally as parts of an armour until the 15th century; and in eastern Europe in the 17th century. It was worn in India and China until the early 19th century and was readopted at that time by European heavy cavalry for use as shoulder defenses.

Brigandine. The origin of brigandine is at present unknown. Although studs are shown on a garment represented in art, there is no proof of the presence of plates within the garment. Brigandine apparently was in use in the 8th century AD in China and later in Korea; in both places it was worn until the 19th century. From the 18th century some Chinese brigandines are purely ceremonial, made with rivets but without plates. A number of cuirasses made up of many plates originally rivetted to a cloth cover have been excavated on European sites of the 14th century, and apparently similar garments occur in European paintings from about 1240. These remained the most common form of body armour until about 1400, after about 1360 usually with a one-piece breastplate also under the cover. Short brigandine coats remained popular for European light troops until about 1600, particularly in a less costly version—the jack—with its plates simply tied in. Brigandine construction was also used for other parts of the armour, including gauntlets and thigh defenses. Fifteenth-century Persian and later Mughal miniatures show what are probably brigandine coats.

Bulletproof jackets

The construction of most modern bulletproof jackets is based on the principle of the brigandine or jack. Small overlapping plates of alloy steel line a waistcoat and a groin protection. The plates are not rivetted but are contained in pockets within a vest of synthetic fibre or snapped into a plastic framework. Metal is now being replaced by such synthetics as fibre glass or boron carbide, making the garment less cumbersome and more bullet resistant.

Lamellar armour. Lamellar armour consists of strips made up of numerous narrow plates with their long axes vertical, each overlapping its neighbour. The strips usually overlap upward. This armour is more flexible than scale and cheaper to manufacture than mail. Although illustrated in Egyptian paintings of the 15th century BC, lamellar probably originated in Persia and was carried to western Europe by the Avars and to the Far East by other nomads. It was usually made up into a shirt, sometimes with capelike sleeves or, in the East, with a separate bolero to which the sleeves were attached. Lamellar was worn in Persia until the 16th century, during its later use with plate forearm and shin defenses. The construction reached China and Korea by the 1st century AD, passing to Japan in the 5th century and achieving its greatest elaboration in the colourfully laced and lacquered armours of the Japanese Heian period (794–1185). Lamellar remained in use in Japan (see Figure 1, right) until armour was abolished in 1867 and was still employed in Tibet, for man and horse, early in the present century. Although it is illustrated in Mughal miniatures, no actual example of lamellar has been found south of the Himalayas. The simple cuirasses of wooden slats and rods laced together worn by North American Indians before the introduction of firearms probably derive from the bone and ivory lamellar armours of Siberia and Alaska.

Plate and mail armour. Small plates linked by mail or let into mail garments first appeared in Persia and Turkey in the 15th century AD in the form of hoops around the body with smaller overlapping plates in the arms and skirts. Sixteenth-century Russian and Turkish armours of that construction had a large circular breastplate let into the mail and narrow vertical rows of small plates at the back. Full armours of this type, including helmets and trousers, were used in northern India in the 17th–19th centuries. Horse armours, and even elephant armours, were made in the same way. Similar armour worn by the Moros of the Philippines, made with brass mail and plates of either brass or horn, probably derived from contacts with the Arabs, although their helmets were based on European models.

HELMETS

The head, the most vulnerable area, has been protected by plate since early times. The basic form of most helmets is a conical or hemispherical bowl, sometimes extended downward to protect the base of the skull, as shown in Sumerian monuments of about 3000 BC. This type, with or without a neck guard, cheek or ear pieces, with or without a mail or scale curtain to protect the throat and neck, is found in almost all periods and areas. The bowl was sometimes made up of several plates rivetted or laced together, a form carried to extremes in Japan, where a bowl sometimes consisted of as many as 62 segments. Occasionally, as in Persia, Turkey, and Russia in the 16th century, the helmet reached an acute apex. In Turkey, in the 15th century, a peak was added over the eyes with a movable nasal or nosepiece. The prestige of the Turkish armies made this form widely popular in Europe until about 1650. The movable nasal was also adopted in Persia and India. The European helm of the 13th–14th centuries developed from the uniting of the neck guard with a nasal that had gradually spread to cover all of the face but the eyes. The helm never completely ousted the basic bowl forms, which from about 1300 were often fitted with a movable visor. Close helmets, made by hinging or pivoting plates to the bowl, completely enclosing the head and turning with it, appeared in western Europe about 1410, remaining in use until about 1650. Light troops continued to wear open-faced helmets, usually peaked or brimmed, until the late 17th century. From the second half of the 15th century the bowl of European helmets was strengthened by a fore and aft comb, increasing in height until about 1600.

The visored helm

ANCIENT AND MEDIEVAL ARMOURING

A complete bronze armour, consisting of a cuirass, a deep skirt of overlapping hoops, broad shoulder defenses, and short greaves to protect the lower leg, was found in a Mycenaean grave of about 1450 BC. As the disappearance of the war chariot necessitated lighter equipment, Greek armourers of the 7th–5th centuries BC produced a combination worn by the Greek foot soldier: cuirass, long greaves sprung onto the shins, and a deep helmet—all of bronze. The large, round shield of bull's hide, sometimes faced with bronze, had both a handgrip and a forearm brace. Later bronze cuirasses, modelled closely on the muscles of the torso, extended down over the stomach, a type also worn by Roman commanders, and possibly at Byzantium, and revived for parade use in the Renaissance.

Roman steel armour

The corselet of the Roman legionary, worn between the end of the 1st century AD and the beginning of the 3rd century, consisted of a cylindrical cuirass made up of some seven horizontal hoops of steel, with openings at the front and back, where they were laced together. The cuirass was buckled or hooked to a throat piece flanked by several half-hoops protecting the shoulder. The individual plates were linked internally by articulating leathers, as on all later plate armour, allowing free movement.

Apart from helmets, armour of large plates was probably unknown in western Europe during the Dark Ages, but in the late 12th century references occur to the *cuirie*, a leather body armour reinforced with plates. During the 13th and 14th centuries the entire body and limbs were gradually enclosed in plate, although the body armour itself, until 1400, was usually of brigandine, sometimes having a steel breastplate fixed over it. The complete steel body armour, with no cover and consisting of breast, back, and a hooped skirt opening down the side, appeared about 1400. The design of the armour was perfected during the 15th and 16th centuries, with added reinforcement, and adapted for a variety of combats. By the 16th century a good-quality armour would normally have had a number of pieces of exchange to adapt it for use in the field or tournament, mounted or on foot (see Figure 2).

Wealthy nobles and princes had great series of armours, decorated to match, for use in a variety of combinations. The major European manufacturing centres were in iron-producing areas—Milan, Brescia, Innsbruck, Augsburg, Nürnberg, and Landshut. Besides finely etched and gilded armours for the aristocracy, large numbers of uniform armours were turned out to equip the specialized regiments that developed during the 16th century. Most courts employed a small group of armourers to supply armour for their own immediate needs and to be presented as diplomatic gifts. Although full armour still appears in portraits of commanders in the 18th century, all but the cuirass and helmet had actually been discarded by about 1650.

Plate armour, consisting of forearm defenses and four large plates around the thorax, was worn in Persia and India until the 19th century, usually over a mail shirt. There was an increasing use of plate in Japan, sometimes disguised as lamellar, from the 15th century.

BIBLIOGRAPHY. A.M. SNODGRASS, *Arms and Armour of the Greeks* (1967); H.R. ROBINSON, *Oriental Armour* (1967); and C. BLAIR, *European Armour, circa 1066 to circa 1700* (1958), are three completely reliable works basic for the study of this subject. Extensive bibliographies are included in G.C. STONE, *A Glossary of the Construction, Decoration and Use of Arms and Armor in All Countries and in All Times* (1934); SIR GUY LAKING, *A Record of European Armour and Arms Through Seven Centuries*, 5 vol. (1920); and SIR JAMES MANN, *Wallace Collection Catalogue of European Arms and Armour*, part 3 (1944) and vol. 2 (1962). P. COUISSIN, *Les Armes romaines* (1926), although now somewhat dated, has not been replaced as the major study of Roman armour. Other interesting works are B. DEAN, *Helmets and Body Armor in Modern Warfare* (1920), on the modern period up to and including World War I; and W. HOUGH, "Primitive American Armor," *Annual Report of the Board of Regents of the Smithsonian Institution*, part 2, pp. 631–680 (1893–95), the only writer to deal with the armour of the American Indians. A bibliography of new works is published as they appear in the *Journal of the Arms and Armour Society* (1953–).

Arms Design and Decoration

The design of arms for hunting or fighting usually has been determined by the specific purpose for which the arms are to be used. Combat weapons must be designed to cut, pierce, or crush, while armour must absorb shock or offer a glancing surface to deflect the enemy's weapon. At the same time, the embellishment of arms and armour expresses man's artistic nature. In combat armour, the decorations must be subordinated to the functional design; for example, the deflecting surface must be left intact. In parade or dress armour, however, decoration may be used for its artistic effect alone.

Decorations also have had functional purposes; for example, they acted as a means of identification. Highly ornamented battle armour and weapons often served to identify a leader. The emblazoning of shields, one of the oldest and most widespread types of arms decoration, was another means of identifying combatants.

In many cultures the right to bear arms was a privilege, and arms and armour therefore became symbols of socio-economic status. As a mark of distinction, they often were decorated so extravagantly that they could be regarded as jewelry, made in fanciful shapes from precious materials and free of all functional considerations. Hunting weapons were usually more elaborately decorated than military arms because of their association with sport and pleasure. The decoration of offensive weapons varied widely according to their function and the status of the bearer. The mass-produced pole arm of the common foot soldier could be "plain as a pike staff," while the decoration on the dagger scabbard of his captain might be highly elaborate and worked or designed by famous artists.

Psychological and symbolic aspects

Psychological effect has long been an important factor in the design and decoration of arms and armour. In the *Iliad*, the ancient Greek epic by Homer (flourished 9th century BC), "the dreadful crest nodding from the helmet's peak" served to overemphasize the height of the fighter to overawe and intimidate the enemy. Grimacing war masks, *menpo*, were worn as a part of the combat armour of the Japanese samurai war lords.

Symbolic considerations also affect arms design. A Christian knight's sword, for instance, was interpreted as a cross, and his triangular shield was symbolic of the Trinity. A Malayan kris blade if wavy symbolizes a running snake, and if straight, a sleeping snake. The hilt of a kris, though often of a highly stylized design, represents the eagle-demon Garuda as a helper in battle. A circular opening in the top of a samurai helmet was designed to allow the spirit of the Shintō war god Hachiman to enter the fighter's body, but its practical purpose was ventilation.

The decoration of arms and armour in most cases was subject to the overall design of the object. Usually accentuating the functional design, the ornamentation was located at the brow, or crest, of a helmet; on the upper part of a breastplate; on the face of a shield; on the hilt of a sword; on the fuller, or groove, of a blade. Swords intended for combat seldom have a decorated grip because the ornamentation would be hidden by the clenched fist. Sword decoration was concentrated on the hilt and on the parts of the blade left untouched by grinding. The obvious places for gun decoration were the lock and stock, which was often ornamented with relief carving, inlay, and mountings of precious metals. The barrel might be decorated over its entire length or only at the rear. Care was required in cutting the reliefs, which

could weaken the metal. Master craftsmen sometimes engraved delicate ornamentation on the inner parts of gun locks, which were seen only when the lock was taken apart for cleaning.

Stylistic aspects

The design of arms and armour generally reflects the prevailing artistic style of the period or region. In European design, for example, there is a striking difference in style between 15th-century armour of the late Gothic period and 16th-century armour of the Renaissance. In Gothic armour, the vertical line is accentuated, and the general outline is dominated by a spiky elegance comparable to tracery in Gothic architecture. In Renaissance armour, the horizontal is emphasized, giving a generally rounded and massive appearance, like Renaissance architectural forms. In Gothic armour, which was more often used in combat, decoration was subordinated to utilitarian considerations; in Renaissance armour, which was more frequently used for display, the decoration was more elaborate.

ORNAMENTAL MOTIFS AND DEVICES

The range of motifs used for the embellishment of arms and armour is endless, though, ironically, scenes of fighting and killing are rare. Animals are among the figurative motifs most widely used in all cultures and ages. They are commonly used on hunting arms but also are found on battle arms and armour. Floral motifs, either as individual decorative elements or as a background embellishment for narrative scenes, are often used, particularly in the Islāmic world, where the faith prohibits figural representation. Heraldic devices, such as coats of arms and other identifying insignia and emblems, are widely used. Calligraphic or written ornamentation was extensively employed on Islāmic arms and armour. Examples of calligraphic decoration also are found on ancient Egyptian and Mesopotamian weapons. The writing that appears on medieval and Renaissance European arms usually consists of inscriptions or protective magic formulas. The maker or place of manufacture was sometimes decoratively inscribed on European arms, as in the swords produced in Toledo, Spain.

Effects of materials and techniques

Decorative effects often were related to the materials and techniques of manufacture. Metals, for instance, in addition to their practical values, have long been appreciated for their decorative appearance—the golden shimmer of bronze, the cold glint of steel, the colourful contrast of gilding on iron. Decoration achieved through materials alone is exemplified on African shields, from ancient Egypt to the Zulu, on which the natural spotting of cowhide or leopard skin creates the decorative effect. The beauty of modern weaponry usually depends upon precision craftsmanship, and the decorative qualities of the material, such as the fine grain of a wooden gunstock.

The technique of fabricating pattern-welded (Damascus) steel produces a decorative effect of its own. When a blade, or gun barrel, is shaped from numerous steel strands of different carbon content, the surface of the steel acquires a mottled appearance, which can be arranged into regular patterns by twisting or braiding the strands. Vikings tended to see the coils of dragons or the scaly hides of snakes in these patterns called *wurmbunt*, while in Islāmic countries such patterns as "Muhammad's ladder" and the "chain of vertebrae" were highly prized. Nineteenth-century gunsmith virtuosos might

spell out their names in elaborate calligraphies on Damascus steel gun barrels. The edge of the Japanese sword was hardened by coating the pattern-welded blade with clay, scraping the edge clean, and then alternately heating it and quenching it, by thrusting it in water. The hardened parts became lighter with polishing, and a skillful swordsmith, by dexterous scraping, could produce designs such as waves or scenic views.

Migration of motifs

Decorative motifs were usually disseminated through the trade or conquest of decorated objects or by the migration of the artists. Etruscan armour based on Greek prototypes suggests the first method, and Scythian gold scabbards of Greek workmanship indicate the second. Both methods might have been responsible for the spread of the spiral motif on Bronze Age weapons or of gold and garnet incrustations on the sword mountings of Central Asian steppe nomads and Germanic tribes during the migration period of the 5th to the 7th centuries AD.

After the invention of printing in the West in the 15th century, book decorations were exploited for ornamental motifs. By the early 16th century, model books of ornamental motifs were published for decorative artists. Prints by famous artists or graphic reproductions of well-known paintings were sometimes adopted either in their entirety or in part. From the 17th to the 19th centuries in Japan woodcuts served as sources for decorative devices on sword furniture. Major artists in both the East and the West have made drawings specifically for the embellishment of arms, such as those by Hans Holbein the Younger (1497?–1543) for dagger scabbards.

TECHNIQUES

Arms techniques are as diverse as the materials used. Ornamentation is either three-dimensional (*e.g.*, carving, embossing) or two-dimensional (*e.g.*, colouring, etching, inlay). In many objects both types of ornamental techniques are used. The construction of plate armour was, in fact, the forming of a sculpture in steel.

Incised decoration of arms is probably as old as carving, both techniques dating from about 30,000 years ago. At Ice Age archaeological sites in the Pyrenees mountains of Spain and France (Le Mas d'Azil, Bédeilhac, Bruniquel), spear-throwers decorated with animal carvings have been found, while engraved ornamentation was preferred by the Magdalenian inhabitants of such Pyrenean sites as Lorthet or Teyjat in the French *département* of Dordogne. Etching of metallic surfaces was developed by medieval armourers in Europe. In the 15th century it was noticed that accidental scratches in the blacking—a metallic preservative—became imprinted by corrosion into the metal surface of the armour itself. An acid-resistant mixture of wax and resin was developed for coating polished steel surfaces. Designs were either scratched with a needle into the coating (Italian method) or painted with a brush onto the metal (German method). In both methods, acid was poured over the treated area, eating away the uncovered portions. Because the relief of the etching was so shallow, the glancing surface of the armour plate was not impaired, and etching became the most popular form of decoration for combat armour. The colour could be heightened by gilding or blackening.

Etching

Carving lends itself obviously to the embellishment of stone, wood, and bone weapons, the earliest known arms. Small parts of metal weapons, such as the gunlock or the pommel (the counterweight at the end of a sword hilt), were frequently decorated with designs and images cut in relief or in the round.

Embossing, or raised surface ornamentation, has been used since ancient times. The rough shape of the decoration was hammered out from the reverse side, using the yielding surface of a block of wood, lead, or pitch as an anvil. Fine details were hammered, filed, chiselled, or punched from the right side.

Leather was tooled and used for armour or arms accessories such as scabbards and sword belts. The dyeing of leather was widespread, particularly in the Islāmic world. Highly sophisticated stencilled designs in various colours appeared on the leather parts of Japanese armour from the 12th to the 16th centuries. *Cuir-bouilli*, or leather that had been softened by soaking and then molded, embossed, or stamped before drying, was hard enough to be used for lightweight armour.

Since ancient times arms and armour have been decorated by inlay or the application of ornament. Openwork figures and animals set in cutouts, mosaics of various materials ranging from stone to feathers, and inlaid wood and ivory have been used in various periods and regions. Even in the 20th century, inlaying of precious and semiprecious materials is used for decorative effect, as in a mother-of-pearl inlaid revolver handle. Mountings of colourful metals, such as plaques of embossed and engraved gold, brass, copper, and silver or settings of precious stones have been widely used. The surmounting of helmets with such decorative devices as crests and masks has been widespread. Feathers, shells, and beads are common decorative materials in less technically developed cultures, as are decoratively woven or plaited fibrous materials, such as the coconut fibre armour of the Gilbert Islanders in the Pacific.

Colouring techniques

Metallic arms and weapons could be decoratively coloured through the use of heat, a process usually called blueing. Skillful use of heat could produce not only blue but also shades of russet and purple. Occasionally, European medieval and Renaissance armour was blackened by burning linseed oil into the hammer-rough surface. Besides furthering the psychological effect of a "Black Knight" or a "Black Guard," this technique was a rust-proofing device. Colouring was also achieved by gilding and occasionally by coating with silver foil. Both for pro-

tection from rust and for colour effect, the Japanese lacquered the scales of their lamellar armours, usually in gold or black. Painting on metal was commonly used by European armorers of the 13th to the early 16th centuries to enliven the metallic surfaces with colour and decorative imagery.

Another surface treatment with colour effect was damascening. In this technique wires of soft metals such as gold, silver, or sometimes copper are either inlaid into grooves with a dovetail cross section cut into the steel or are more simply hammered onto a roughened cross-hatched surface. The first method is more durable, but much more time consuming. Damascening was widely used in ancient Mycenae and in other parts of Europe during the early Middle Ages, especially among the Vikings of Scandinavia and the Moors of Spain, and in Islāmic countries, where it remains one of the most important methods of arms decoration.

PERIODS AND CENTRES OF ACTIVITY

Among the earliest artifacts made by man are examples of decorated weaponry. During the stone ages elaborately carved and incised spear-throwers made of staghorn and bone were produced, especially in southwestern France and northern Spain. Finely worked flint blades with their chippings arranged in regular patterns were made throughout the prehistoric world.

Arms of the ancient Western world

Ancient Egyptian and Mesopotamian civilizations produced richly decorated arms of stone, ivory, and metal as did the Phoenecians and Mycenaeans. Other important centres of arms decoration in the pre-Graeco-Roman ancient world were in Anatolia among the Hittites and in Iran during the Luristan culture. In northern Europe the bronze weapons of the Hallstatt and La Tène cultures have spiral decorative motifs that were probably derived from Mycenaean arms.

The decoration of arms and armour in ancient Greece was relatively restrained compared with the opulence of contemporary Persian work. Each Greek region, such as Attica, Corinth, or Sparta, had its own decorative style. Etruscan and Roman arms and armour were deeply indebted to Greek tradition.

Graeco-Roman arms decidedly influenced the contemporary weaponry of northern European Teutonic and Celtic tribes, while the design and workmanship of Persian arms influenced the Thracians of the Lower Danube region in the Balkans. Also at this time there flourished in the steppes of eastern Europe and Central Asia a decorative style using bizarre, contorted animals. This so-called animal style is best known through the works of the Scythians. In northwestern Europe the Celts developed a flamboyant geometric style, which was particularly prominent in the British Isles.

With the 4th-century invasion of Europe by the Huns and other steppe nomads, a new and highly distinctive style of almandine and gold incrustation spread through the Germanic tribes. The major arms-producing centre of northern Europe during this early medieval period became the German Rhineland around Cologne, where the Celtic, Germanic, and Roman cultures met. Also in the early Middle Ages, the Byzantines and Sāsānian Persians produced individually styled weapons of elaborate design, although few examples have survived.

In contrast to the Christian crusaders, whose arms and armour were simple in design and relatively austere in decoration, the warriors of Islām, particularly the Mamlūks, delighted in richly decorated arms. The important centres of manufacture were Alexandria and Damascus. Islāmic Persia, Turkey under the Ottomans, and India under the Moghuls excelled in cut steel and damascened work in scimitar and dagger hilts of Indian carved jade, which were exported to be mounted locally.

15th- and 16th-century armour

The design, construction, and decoration of armour was especially outstanding from the 15th to the 17th centuries. The most renowned centre of production, Milan, Italy, produced many of the greatest armourers, notably such family dynasties as the Negrolis and the Missaglias and individual geniuses such as Lucio Piccinino (*c.* 1535–after 1595).

Initially influenced by the Milanese workmanship, independent styles of design and decoration emerged in northern Europe in the 16th century, centred in Nürnberg, Augsburg, Innsbruck, Landshut, and Cologne. The great workshops were those of the Seusenhofers in Innsbruck, Helmschmieds in Augsburg, Kunz Lochner and Valentin Siebenbürger in Nürnberg. They were assisted by famous etchers, such as Jörg Sorg and Daniel Hopfer.

In the Metropolitan Museum of Art, New York.

Sixteenth-century court workshops, such as those of the emperor Maximilian I at Innsbruck, of Henry VIII at Greenwich near London, and of Henry II of France at Paris (Louvre school), produced especially rich armour for state and presentation purposes. The Royal French workshop under Étienne Delaune (*c.* 1519–83) and that of Elisaeus Libaerts in Antwerp specialized in lavishly embossed armour. While German and English armour kept high decorative standards throughout the 16th century, Italian armour of the late 16th century tended to display rather slipshod ornamentation.

The decoration of swords to be worn ceremonially at court and firearms for duelling or sport became more important in the 17th and 18th centuries than the ornamentation of armour, which was no longer worn. The centres of production were European capitals—Paris, London, Vienna, Prague, Dresden, Munich, Venice, and Naples. Cut steelwork was especially popular. In the 16th and 17th centuries, regional styles of decoration developed. Silver hilted swords were made in London and Paris, and carved ivory pistol stocks were made by Dutch craftsmen in Maastricht. Arms from the Russian town Tula and the Caucasus Region were decorated with niello (*i.e.*, the filling of incised designs with a black alloy of sulfur and silver, copper, or lead).

During the 18th century, the French were the arbiters of fashion including that of arms design and decoration. After the French Revolution, France continued to be

the leader of fine arms production. A special workshop was installed at Versailles near Paris, under Nicolas Noël Boutet (1761–1833), that provided Napoleon with presentation pieces of superb quality. This workshop was the last great one before the decline. In the 19th century, style in arms design deteriorated, and the handcrafting of arms decoration decreased as a result of the machine manufacturing and mass production that were introduced by the Industrial Revolution.

China, Japan, and India

During the Shang, or Yin, period (*c.* 1766–*c.* 1122 BC), the Chinese produced bronze blades of exquisite form and workship, sometimes richly inlaid with gold and silver wire. Most of China's later weapon types and decorative motifs were adapted from the arms and ornamentation of the nomadic peoples of the Central Asian steppes, such as the Scythians and Mongols. The traditional conservatism of the Chinese arms maker preserved many of these ancient forms and ornamental motifs until the 19th century, when more modern weaponry was introduced through Western trade.

Japanese armour was lamellar, or made of interconnected scales, of such materials as metal or lacquered leather. Leaving little surface for ornamentation, the Japanese warrior relied for aesthetic effect largely on armour accessories such as helmet crests, war masks and colourful lacings.

Among the Japanese, the fashioning of swords and sword furnishings, such as hilt mountings and sword guards (tsuba), was one of the main occupations of artisans working in metal. Comparable to the importance of the jewelers craft in medieval Europe were schools of sword furniture makers in Japan from the Kamakura period (1192–1333) to the 19th century. There were about 30 schools or traditional styles of design and craftsmanship. The classical style was established in the 15th century by the famed Gotō school, whose swords were considered to be the only correct ones for court use. Perhaps the most renowned individual master of tsuba was Aoki Kaneiye (flourished mid-16th century), who founded the important Kaneiye school of sword furniture manufacture.

India, apart from its Islāmic influences, has a very exuberant and colourful tradition of arms decoration. Indians have long ornamented their weapons with brilliant gems and colourful inlay or used relief carvings of floral scrolls interspersed with human figures, animals, and mythical creatures. The influence of Indian craftsmanship is reflected in many of the distinctive local styles of Indonesia.

Africa, Oceania, and pre-Columbian Americas

The decoration of arms in Africa varies widely according to the region and culture. The Muslim peoples of North Africa design and decorate their arms according to the general traditions followed throughout the Islāmic world. There are local variants, however, notably the renowned silver mounted Berber and Kabyle guns of Morocco. Sword hilts with gold leaf overlay are found in West Africa, but in most of the Negro cultures weapon decoration consists largely of wood and ivory carving. Chieftains' axes from the Congo area are particularly elaborate in their carved decoration.

On the islands of the South Pacific, the choice of materials for making arms and armour was severely limited. Metals, and sometimes even suitable stone, were unavailable. Nearly all of the objects for combat and hunting made by these Oceanic peoples, therefore, had to be produced from such perishable materials as wood, bone, and fibres. For this reason only recent historic examples have been preserved. Because of the geographic isolation of the islands, each group or tribe had its own tradition of design and decoration. In general, however, most of the ornamentation carved on spearheads, war clubs, and shields consists of highly stylized human and animal forms. The most distinctive styles of arms decoration are those of the Marquesas and Tonga Islands, the Solomon and Trobriand Islands, the Asmat and the Sepik region of New Guinea, and Maori work from New Zealand.

From pre-Columbian North America, few examples of decorated weapons have been preserved. Among them are the stones finely modelled in bird shapes that were probably intended as weights for spear throwers. Carved warclubs (tomahawks) and buffalo shields, which the

North American Plains Indians painted with magic protective motifs, have survived only from recent history. A few examples of ancient Meso-American decorated arms have been preserved: carved spearthrowers called *atlatl* and shields with feather mosaics. The splendour of the arms and armour of pre-Columbian Mexico and Central America is primarily known through representations in sculpture, painted murals, and the illustrated codices that have survived from Aztec and early colonial days. The arms excavated in Peru of the ancient Mochica and Inca civilizations are basically similar in form, varying only in decorative motifs.

COLLECTING AND STUDY

The first great armour collection was brought together by the Austrian archduke Ferdinand at Schloss Ambras, Tirol, in the 16th century. It was conceived as a "Gallery of Heroes," representing all great generals of the time by a suit of their armour. The Waffensammlung in Vienna —the largest and most important collection of arms and armour in the world—is largely based upon Archduke Ferdinand's collection.

Some other large collections that have been based on extant princely armories include the Real Armería in Madrid, the Historische Museum (Rüstkammer) in Dresden, the Armouries in the Tower of London, and the Livrustkammaren in Stockholm. Important collections of arms and armour assembled from artistic points of view are in the Musée de l'Armée in Paris, the Armeria Reale in Turin, the Museo Stibbert in Florence, the Wallace Collection in London, and the Metropolitan Museum of Art in New York.

During the 19th century many collections of arms and armour were assembled, and many scholarly handbooks were published, though most of them treated the subject as history rather than art. Artistic interest in the collection of armour, which dates largely from the 20th century, was influenced by the growing appreciation of Japanese arms.

BIBLIOGRAPHY. Books about arms and armour in general, but with special interest in arms decoration include: SIR GUY FRANCIS LAKING, *A Record of European Armour and Arms through Seven Centuries*, 5 vol. (1920–22); CLAUDE BLAIR, *European Armour circa 1066 to circa 1700* (1958), *European and American Arms c. 1100–1850* (1962); YIGAEL YADIN, *The Art of Warfare in Biblical Lands*, 2 vol. (Eng. trans. 1963); V.A.B. NORMAN, *Arms and Armour* (1964); R.E. OAKESHOTT, *The Sword in the Age of Chivalry* (1964); A.M. SNODGRASS, *Early Greek Armour and Weapons* (1964); H.L. BLACKMORE, *Arms and Armour* (1965); MERRILL LINDSAY, *One Hundred Great Guns* (1967); H.R. ROBINSON, *Japanese Arms and Armour* (1969), *Oriental Armour* (1967); WENDELIN BOEHEIM, *Handbuch der Waffenkunde* (1890), *Meister der Waffenschmiedekunst* (1897); ERICH HAENEL, *Kostbare Waffen aus der Dresdner Rüstkammer* (1923); WALDEMAR GINTERS, *Das Schwert der Skythen und Sarmaten in Südrussland* (1928); BRUNO THOMAS, ORTWIN GAMBER, and HANS SCHEDELMANN, *Die schönsten Waffen und Rüstungen aus europäischen und amerikanischen Sammlungen* (1963); ALEXANDER VON REITZENSTEIN, *Der Waffenschmied* (1964); GIANNI VIANELLO, *Armi in Oriente* (1966); MARTIN DE RIQUER, *L'Arnés del Cavaller* (1968); and L.G. BOCCIA and E.T. COELHO, *L'arte dell'armatura in Italia* (1969).

Books specifically treating arms decoration are: G.C. STONE, *A Glossary of the Construction, Decoration, and Use of Arms and Armor* (1934); J.F. HAYWARD, *The Art of the Gunmaker*, 2 vol. (1962–64); S.V. GRANCSAY and MERRILL LINDSAY, *Master French Gunsmith Designs of the XVII–XIX Centuries* (1970); B.W. ROBINSON, *The Arts of the Japanese Sword* (1961); H. STOECKLEIN, *Meister des Eisenschnittes* (1922); RUDOLF CEDERSTROM and K.E. STENEBERG, *Skoklosterskölden* (1945); KONRAD ULLMANN, *Schmuck alter Büchsen und Gewehre* (1964); and LUMIR JISL, *Japanische Schwertzierate* (1967).

Among the vast literature about arms and armour a considerable part is dedicated to their decoration. Many articles have been published in periodicals such as: *Archaeologia* (1770–), the *Jahrbuch der Kunsthistorischen Sammlungen (Wien)* (1883–), *Zeitschrift für Historische Waffenkunde* (1897–), *Metropolitan Museum of Art Bulletin* (1905–), *Armi Antiche* (1954–), and the *Journal of the Arms and Armour Society* (1955–).

Armstrong, Edwin H.

Edwin Howard Armstrong laid much of the foundation of modern radio and electronics in a series of brilliant and basic circuit designs. While still in college, he invented the regenerative circuit, which was at one and the same time the first amplifying receiver and the first reliable, continuous-wave transmitter. His most widely known circuit, invented in 1918, was the so-called superheterodyne circuit, a highly selective means of receiving, converting, and greatly amplifying very weak, high-frequency electromagnetic waves, which today underlies 98 percent of all radio, radar, and television reception. His crowning achievement was the invention in 1933 of wide-band frequency modulation, which later became known as FM radio, a radical new system of nearly static-free broadcasting that transmits the full, natural frequency range of audible sound.

Fabian Bachrach

Armstrong, 1933.

Armstrong's career revolved around New York City. He was born on December 18, 1890, into a genteel, devoutly Presbyterian family in the old Chelsea district of Manhattan. His father, born in the same district, was a publisher, his mother a former schoolteacher, from a neighbouring family. Armstrong was a shy boy interested from childhood in engines, railway trains, and all mechanical contraptions.

At the age of 14, fired by reading of the exploits of Guglielmo Marconi in sending the first wireless message across the Atlantic, Armstrong decided to become an inventor. He built a maze of wireless apparatus in his family's attic, by then removed to the suburbs, and began the solitary, secretive work that absorbed his life. Except for a passion for tennis, acquired from his father, and later, for fast motor cars, he developed no other interest. Wireless was then in the stage of crude spark-gap transmitters and iron-filing receivers, producing faint Morse-code signals, barely audible through tight earphones. Armstrong joined in the hunt for improved instruments. On graduating from high school, he commuted to Columbia University's School of Engineering on a red motorcycle, a graduation gift from his father, to pursue his search.

Early life and schooling

In his junior year at Columbia, Armstrong made his first, most seminal invention. Among the devices investigated for better wireless reception was the then little understood, largely unused Audion, or three-element vacuum tube, invented in 1906 by Lee De Forest, a pioneer in the development of wireless telegraphy and television. Armstrong made exhaustive measurements to find out how the tube worked and devised a circuit, called the regenerative or feedback circuit, that suddenly, in the autumn of 1912, brought in signals with a thousandfold

amplification, loud enough to be heard across a room. At its highest amplification, he also discovered, the tube's circuit shifted from being a receiver to being an oscillator, or primary generator, of wireless waves. As radio-wave generator this circuit is still at the heart of all radio–television broadcasting.

Armstrong's priority was later challenged by De Forest in a monumental series of corporate patent suits, extending over 14 years, argued twice before the Supreme Court, and finally ending—in a judicial misunderstanding of the nature of the invention—in favour of de Forest. But the scientific community never accepted this verdict. The Institute of Radio Engineers refused to revoke an earlier gold-medal award to Armstrong for the discovery of the feedback circuit. Later he received the Franklin Medal, highest of U.S. scientific honours, reaffirming his invention of the regenerative circuit.

This youthful invention that opened the age of electronics had profound effects on Armstrong's life. It led him, after a stint as an instructor at Columbia, into the U.S. Army Signal Corps laboratories in World War I in Paris, where he invented the superheterodyne, a circuit going far beyond the regenerative in amplification. It brought him into early association with the man destined to lead the postwar Radio Corporation of America (RCA), David Sarnoff, whose young secretary Armstrong later married. Armstrong himself returned after the war to Columbia to become assistant to Michael Pupin, the notable physicist and inventor and his revered teacher. In this period he sold patent rights on his circuits to the major corporations, including RCA, for large sums in cash and stock. Suddenly, in the radio boom of the 1920s, he found himself a millionaire. But he continued to teach at Columbia, financing his own research, working along with Pupin, whose professorship he inherited, on the long-unsolved problem of eliminating static from radio.

Invention of FM broadcasting

In 1933 Armstrong secured four patents on advanced circuits that were to solve this last basic problem. They revealed an entirely new radio system, from transmitter to receiver. Instead of varying the amplitude or power of radio waves to carry voice or music, as in all radio before then, the new system varied or modulated the waves' frequency (number of waves per second) over a wide band of frequencies. This created a carrier wave that natural static—an amplitude phenomenon created by electrical storms—could not break into. As a result, FM's wide frequency range made possible the first clear, practical method of high-fidelity broadcasting.

Since the new system required a basic change in transmitters and receivers, it was not embraced with any alacrity by the established radio industry. Armstrong had to build the first full-scale FM station himself in 1939 at a cost of over $300,000 to prove its worth. He then had to develop and promote the system, sustain it through World War II (while he again turned to military research), and fight off postwar regulatory attempts to hobble FM's growth. When FM slowly established itself, Armstrong again found himself entrapped in another interminable patent suit to retain his invention. Ill and aging in 1954, with most of his wealth gone in the battle for FM, he took his own life (January 31 or February 1).

The years have brought increasing recognition of Armstrong's place in science and invention. FM is now the preferred system in radio, the required sound channel in all television, and the dominant medium in mobile radio, microwave relay, and space-satellite communications. Posthumously, Armstrong was elected to the pantheon of electrical greats by the Union Internationale des Télécommunications, to join such figures as the French physicist and mathematician André-Marie Ampère; Alexander Graham Bell, the inventor of the telephone; the English electrical pioneer Michael Faraday; and Guglielmo Marconi, the Italian developer of wireless telegraphy.

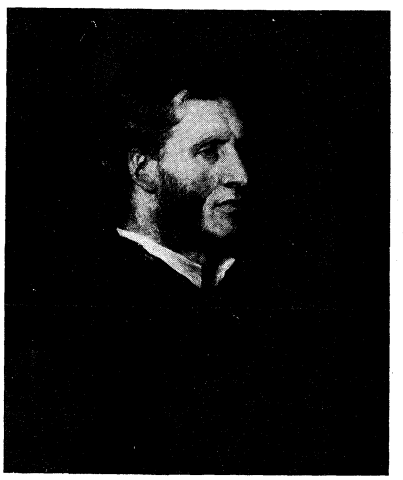
Arnold, Matthew

An English poet who ranks among the best of his time, Matthew Arnold was also a critic whose theories have worn better than those of his Victorian contemporaries. He is above all notable for his grasp of the defects of much of the romantic poetry of his time and for opening what was then a still largely insular culture to the influence of Europe. His social, religious, and educational writings were also of great importance in their time and are of enduring interest today.

By courtesy of the National Portrait Gallery, London



Arnold, oil painting by G.F. Watts (1822–88). In the National Portrait Gallery, London.

Early life and education. Arnold was born at Laleham, Middlesex, on Dec. 24, 1822, the eldest son of the famous Dr. Thomas Arnold, who was appointed headmaster of Rugby in 1828. From his mother, Mary (*née* Penrose), he inherited Cornish blood and with it something of what he would have distinguished as the "Celtic" strain in his sensibility. After a year at Winchester, Matthew Arnold entered Rugby School (1837). His first publication was a Rugby prize poem, *Alaric at Rome* (1840). He entered Oxford as a scholar of Balliol College in 1841, won the Newdigate Prize with his poem *Cromwell* (1843), and graduated with second-class honours in 1844. At Oxford, probably in half-reaction from the earnestness of his father's Rugby, he affected a certain dandyism and ironic detachment and struck some of his contemporaries as a trifler. But he was elected to a fellowship at Oriel (1845). Arnold's levity was only a mask; though, actually, "radiant, adorn'd outside," he had even then "a hidden ground of thought and of austerity within." Far from breaking with his father, he reverenced him and spent much of his later life in advocating and furthering his educational and religious aims.

For Oxford, too, Arnold retained an impassioned affection. His Oxford was the Oxford of John Henry Newman—of Newman just about to be received into the Roman Catholic Church; and although Arnold's own religious thought, like his father's, was strongly liberal, Oxford and Newman always remained for him joint symbols of spiritual beauty and culture. Oxford, like Newmanism, might be a part of the dead or dying world; it might be "the home of lost causes and impossible loyalties," and yet: "steeped in sentiment as she lies, spreading her gardens to the moonlight, and whispering from her towers the last enchantments of the Middle Age, who will deny that Oxford, by her ineffable charm, keeps ever calling us nearer to the true goal of all of us, to the ideal, to perfection?"

Educational inspector. In 1847 Arnold became private secretary to Lord Lansdowne, who occupied a high cabinet post during Lord John Russell's Liberal ministries. And in 1851, in order to secure the income needed for his marriage (June 1851) with Frances Lucy Wightman, he accepted from Lansdowne an appointment as inspec-

tor of schools. This was to be his routine occupation until within two years of his death, and it has often been thought an incongruous task for so rare and sensitive a spirit. The incessant travelling in all kinds of weather and the constant exposure not only to provincial hotels but to provincial rawness and philistinism certainly cost him much in strength and energy. Yet education was in his blood, and he loyally (if stoically) accepted the role of propagandist and missionary for culture and for state schools. Indeed, his fame as poet and critic should not lead us, as it has often done, to forget the extent and significance of his educational work. At a time when state action of any kind was regarded with suspicion as "interference," he saw the vital necessity in a modern democracy of organizing public education, primary and secondary, for the middle classes and for the populace.

Educational work

Always critical of Victorian insularity and laissez-faire and always eager to correct British national complacency from a European standpoint, he made it his business to point out to his countrymen what had already been done in this direction on the continent. He was several times sent by the government to inquire into the state of education in France, Germany, Holland, and Switzerland, and his reports show how conscientiously he devoted some of his best energies to the work. Two of his reports on schools abroad were reprinted as books, and his annual reports on schools at home attracted wide attention, written, as they were, in Arnold's own urbane and civilized prose. Though all this routine work could have been done by lesser men, it is salutary to remember that Arnold did it, especially as a corrective to the notion of him as the "elegant Jeremiah" or the aloof and superior exponent of "culture."

Poetic achievement. The work that gives Arnold his high place in the history of literature and the history of ideas was all accomplished in the time he could spare from his official duties. Yet there is a unity in his whole output; his verse and his literary, social, and religious criticism, no less than his educational reports, proceed from a consciousness exposed to the spirit of his age and a sensibility quick to feel, and an intelligence alert to diagnose, the deeper maladies of the age. His first volume of verse was *The Strayed Reveller, and Other Poems. By A.* (1849); this was followed (in 1852) by another under the same initial: *Empedocles on Etna, and Other Poems.* In 1853 appeared the first volume of poems published under his own name; it consisted partly of poems selected from the earlier volumes and also contained the well-known preface explaining (among other things) why *Empedocles* was excluded from the selection: it was a dramatic poem "in which the suffering finds no vent in action," in which there is "everything to be endured, nothing to be done." This preface foreshadows his later criticism in its insistence upon the classic virtues of unity, impersonality, universality, and architectonic power and upon the value of the classical masterpieces as models for "an age of spiritual discomfort"—an age "wanting in moral grandeur." Other editions followed, and *Merope,* Arnold's classical tragedy, appeared in 1858, and *New Poems* in 1867. After that date, though there were further editions, Arnold wrote little more verse.

First published poems

In a letter to his mother, written in 1869, he sums up his own poetic achievement thus:

> My poems represent, on the whole, the main movement of mind of the last quarter of a century, and thus they will probably have their day as people become conscious to themselves of what that movement of mind is, and interested in the literary productions which reflect it. It might be fairly urged that I have less poetical sentiment than Tennyson, and less intellectual vigour and abundance than Browning; yet, because I have perhaps more of a fusion of the two than either of them, and have more regularly applied that fusion to the main line of modern development, I am likely enough to have my turn, as they have had theirs.

He not only "had his turn" but has continued to hold his place as, if not the most admired, yet for many readers the most congenial, of the Victorian poets and as the poet who addresses them with the voice of a human contemporary speaking directly to their condition. Not much of Arnold's verse will stand the test of his own criteria; far from being classically poised, impersonal, serene, and grand, it is often intimate, personal, full of romantic regret, sentimental pessimism, and nostalgia. As a public and social character and as a prose writer, Arnold was sunny, debonair, and sanguine; but beneath ran the current of his buried life, and of this much of his poetry is the echo:

> From the soul's subterranean depth upborne
> As from an infinitely distant land,
> Come airs, and floating echoes, and convey
> A melancholy into all our day.

"I am past thirty," he wrote a friend in 1853, "and three parts iced over." The impulse to write poetry came typically when

> A bolt is shot back somewhere in the breast,
> And a lost pulse of feeling stirs again.

Though he was "never quite benumb'd by the world's sway," these hours of insight became more and more rare, and the stirrings of buried feeling were associated with moods of regret for lost youth, regret for the freshness of the early world, moods of self-pity, moods of longing for

> The hills where his life rose
> And the sea where it goes.

At Fox How, his father's holiday home in Westmorland, Matthew's earlier life had been steeped in Wordsworthian sentiment; he knew and revered the aged poet, who lived a stone's throw away at Rydal Mount. And Arnold may be thought of as a Victorian Wordsworth—a Wordsworth exiled from the hills, dwelling on lower reaches of the river of time, further from the sources of life and inspiration, and moved to yearning rather than to rapture by Nature's grandeur, calm, and self-dependence. Yet, though much of Arnold's most characteristic verse is in this vein of soliloquy or intimate confession, he can sometimes rise, as in "Sohrab and Rustum," to epic severity and impersonality; to lofty meditation, as in "Dover Beach"; and to sustained magnificence and richness, as in "The Scholar Gipsy" and "Thyrsis"—where he wields an intricate stanza form without a stumble.

In 1857, assisted by the vote of his godfather (and predecessor) John Keble, Arnold was elected to the Oxford chair of poetry, which he held for ten years. It was characteristic of him that he revolutionized this professorship, lecturing in English instead of Latin and concerning himself not with "the trade in classic niceties" but (as the American critic Lionel Trilling put it) "with the demand which humanity makes for a poetry *adequate* to the time in which it is written." The keynote was struck in the title and contents of his inaugural lecture: "On the Modern Element in Literature," "modern" being taken to mean not merely "contemporary" (for Greece was "modern"), but the spirit that, contemplating the vast and complex spectacle of life, craves for moral and intellectual "deliverance." Several of the lectures were afterward published as critical essays, but the most substantial fruits of his professorship were the three lectures *On Translating Homer* (1861)—in which he recommends Homer's plainness and nobility as medicine for the modern world, with its "sick hurry and divided aims" and condemns Francis Newman's recent translation as ignoble and eccentric—and the lectures *On the Study of Celtic Literature* (1867), in which, without much knowledge of his subject or of anthropology, he uses the Celtic strain as a symbol of that which rejects the despotism of the commonplace and the utilitarian.

Arnold as critic. It is said that when the poet in Arnold died, the critic was born; and it is true that from this time onward he turned almost entirely to prose. But in fact the critic had been alive in him from the start, and his poetry had itself been the outcome of his effort to apply intelligence, as well as feeling, to the problem of "the world's multitudinousness." It is a mark of Arnold's distinction and many-sidedness that, instead of writing more and worse poetry, he went on to produce those essays

A new kind of criticism

that place him first among Victorian critics and high among those few European critics who have permanently influenced the course of opinion about the nature and function of poetry. In Arnold appears what is virtually a new phenomenon: the "literary" intelligence playing freely upon the great concerns of human life. He saw and proclaimed the importance, for the modern world, of those qualities of mind and spirit that literary culture can give; and literary criticism has gained immensely from his expansion of its scope.

Some of the leading ideas and phrases put into currency in *Essays in Criticism* (First Series, 1865; Second Series, 1888) and *Culture and Anarchy* (1869) will be considered briefly. The first essay in the 1865 volume, "The Function of Criticism at the Present Time," is an overture announcing briefly most of the themes he developed more fully in later work. It is at once evident that he ascribes to "criticism" a scope and importance hitherto undreamed of. The function of criticism, in his sense, is "a disinterested endeavour to learn and propagate the best that is known and thought in the world, and thus to establish a current of fresh and true ideas." It is in fact a spirit that he is trying to foster, the spirit of an awakened and informed intelligence playing upon not "literature" merely but theology, history, art, science, sociology, and politics, and in every sphere seeking "to see the object as in itself it really is."

In this critical effort, thought Arnold, England lagged woefully behind France and Germany, and the English accordingly remained in a backwater of provinciality and complacency. Even the great Romantic poets, with all their creative energy, suffered from the want of it. "Life and the world being in modern times very complex things, the creation of a modern poet, to be worth much, implies a great critical effort behind it." The English literary critic must know literatures other than his own and be in touch with European standards. This last line of thought Arnold develops in the second essay. "The Literary Influence of Academies," in which he dwells upon "the note of provinciality" in English literature, caused by remoteness from a "centre" of correct knowledge and correct taste. To realize how much Arnold widened the horizons of criticism requires only a glance at the titles (but better to read the content) of some of the other essays in *Essays in Criticism* (1865): "Maurice de Guérin," "Eugénie de Guérin," "Heinrich Heine," "Joubert," "Spinoza," "Marcus Aurelius"; in all these, as increasingly in his later books, he is "applying modern ideas to life" as well as to letters and "bringing all things under the point of view of the 19th century."

Attack on the provinciality of English literature

The first essay in the 1888 volume, "The Study of Poetry," was originally published as the general introduction to T.H. Ward's anthology, *The English Poets* (1880). It contains many of the ideas for which Arnold is best remembered. In an age of crumbling creeds, poetry will have to replace religion. More and more, we will "turn to poetry to interpret life for us, to console us, to sustain us." Therefore we must know how to distinguish the best poetry from the inferior, the genuine from the counterfeit; and to do this we must steep ourselves in the work of the acknowledged masters, using as "touchstones" passages exemplifying their "high seriousness," and their superiority of diction and movement.

The remaining essays, with the exception of the last two (on Tolstoy and Amiel), all deal with English poets: Milton, Gray, Keats, Wordsworth, Byron, and Shelley. All contain memorable things, and all attempt a serious and responsible assessment of each poet's "criticism of life" and his value as food for the modern spirit. Arnold has been taken to task for some of his judgments and omissions: for his judgment that Dryden and Pope were not "genuine" poets because they composed in their wits instead of "in the soul"; for calling Gray a "minor classic" in an age of prose and spiritual bleakness; for paying too much attention to the man behind the poetry (Gray, Keats, Shelley); for making no mention of Donne; and above all for saying that poetry is "at bottom a criticism of life." On this last point it should be remembered that he added "under the conditions fixed . . . by the laws of poetic truth and poetic beauty," and that if by "criticism" is understood (as Arnold meant) "evaluation," Arnold's dictum is seen to have wider significance than has been sometimes supposed.

Culture and Anarchy (1869) is in some ways Arnold's most central work. It is an expansion of his earlier attacks, in "The Function of Criticism" and "Heinrich Heine," upon the smugness, philistinism, and mammon worship of Victorian England. Culture, as "the study of perfection," is opposed to the prevalent "anarchy" of a new democracy without standards and without sense of direction. By "turning a stream of fresh thought upon our stock notions and habits," culture seeks to make "reason and the will of God prevail."

Arnold's concept of English society

Arnold's classification of English society into Barbarians (the aristocracy: with their high spirit, serenity, and distinguished manners and their inaccessibility to ideas), Philistines (the great middle class, the stronghold of religious nonconformity, with plenty of energy and morality but insufficient "sweetness and light"), and Populace (the masses, still raw and blind) is well known. Arnold saw in the Philistines the key to the whole position; they were now the most influential section of society; their strength was the nation's strength, their crudeness its crudeness: Educate and humanize the Philistines, therefore. Arnold saw in the idea of "the State," and not in any one class of society, the true organ and repository of the nation's collective "best self." No summary can do justice to this extraordinary book; it can still be read with pure enjoyment, for it is written with an inward poise, a serene detachment, and an infusion of mental laughter, which make it a masterpiece of ridicule as well as a searching analysis of Victorian society. The same is true of its unduly neglected sequel, *Friendship's Garland* (1871).

Religious writings. Lastly Arnold turned to religion, the constant preoccupation and true centre of his whole life, and wrote *St. Paul and Protestantism* (1870), *Literature and Dogma* (1873), *God and the Bible* (1875), and *Last Essays on Church and Religion* (1877). In these undeservedly neglected books, Arnold really founded Anglican "modernism." Like all religious liberals, he came under fire from two sides: from the orthodox, who accused him of infidelity, of turning God into a "stream of tendency" and of substituting vague emotion for definite belief; and from the infidels, for clinging to the church and retaining certain Christian beliefs of which he had undermined the foundations. To Arnold himself, it seemed that his religious writings were constructive and conservative. Those who accused him of destructiveness did not realize how far historical and scientific criticism had already riddled the old foundations; and those who accused him of timidity failed to see that he regarded religion as the highest form of culture, the one indispensable without which all secular education is in vain. His attitude is best summed up in his own words (from the preface to *God and the Bible*): "At the present moment two things about the Christian religion must surely be clear to anybody with eyes in his head. One is, that men cannot do without it; the other, that they cannot do with it as it is." Convinced that much in popular religion was "touched with the finger of death" and convinced no less of the hopelessness of man without religion, he sought to find for religion a basis of "scientific fact" that even the positive modern spirit must accept. A reading of Arnold's *Note Books* will convince any reader of the depth of Arnold's spirituality and of the degree to which, in his "buried life," he disciplined himself in constant devotion and self-forgetfulness.

Arnold died suddenly, of heart failure, on April 15, 1888, at Liverpool and was buried at Laleham, with the three sons whose early loss had shadowed his life.

MAJOR WORKS

POETICAL WORKS: *Alaric at Rome* (1840; Rugby School prize poem); *Cromwell* (1843; Newdigate Prize poem); *The Strayed Reveller, and Other Poems. By A.* (1849); *Empedocles on Etna, and Other Poems. By A.* (1852); *Poems* (1853; in-

cluding "Sohrab and Rustum," "The Forsaken Merman," and "The Scholar Gipsy"); *Poems, Second Series* (1855); *Merope* (1858; classical tragedy); *New Poems* (1867; including "Thyrsis" and "Dover Beach").

PROSE WORKS: *The Popular Education of France with Notices of that of Holland and Switzerland* (1861; revised text of the 1860 report prepared by Arnold for the Education Commission); *On Translating Homer* (1861); *On Translating Homer: Last Words* (1862); *A French Eton; or, Middle Class Education and the State* (1864); *Essays in Criticism* (1865; including "The Function of Criticism at the Present Time," "The Literary Influence of Academies," "Maurice de Guérin," "Eugénie de Guérin," "Heinrich Heine," "Joubert," "Spinoza," and "Marcus Aurelius"); *On the Study of Celtic Literature* (1867); *Schools and Universities on the Continent* (1868; reprinted from Arnold's report *On Secondary Education in Foreign Countries* of 1866); *Culture and Anarchy* (1869); *St. Paul and Protestantism* (1870); *Friendship's Garland* (1871); *Literature and Dogma* (1873); *God and the Bible* (1875); *Last Essays on Church and Religion* (1877); *Mixed Essays* (1879); *Irish Essays* (1882); *Discourses in America* (1885); *Essays in Criticism. Second Series* (1888; including "The Study of Poetry" and essays on Milton, Thomas Gray, Keats, Wordsworth, Byron, Shelley, Tolstoy, and Amiel); *Reports on Elementary Schools 1852–1882,* edited by Sir Francis Sandford (1889; new edition with added material and introduction by F.S. Marvin, 1908).

BIBLIOGRAPHY. The first collected edition of Arnold's poems was published in 1869, other editions appeared in 1877 and 1881, and a library edition in 1885. A new and complete edition was published in "Oxford Standard Authors Series" (1950), ed. by C.B. TINKER and H.F. LOWRY, who also edited *The Poetry of Matthew Arnold: A Commentary* (1940, reprinted 1970). *Arnold's Letters (1848–1888)*, collected and arranged by G.W.E. RUSSELL (1895; 2nd ed., 1901); ARNOLD WHITRIDGE (ed.), *Unpublished Letters* (1923); *Letters to Arthur Hugh Clough,* with an introductory study by H.F. LOWRY (ed.) (1932, reprinted 1968). There is a complete edition (literary contents) of *The Note-Books of Matthew Arnold,* ed. by H.F. LOWRY, K. YOUNG, and W.H. DUNN (1952). An edition de luxe of Arnold's complete *Works,* 15 vol. (1903–04), includes a bibliography by T.B. SMART, who published a separate bibliography in 1892 (reprinted 1968). For a more recent bibliography, see T.G. EHRSAM and R.H. DEILY (comps.), *Bibliographies of Twelve Victorian Authors* (1936; suppl. by J.G. FUCILLA in *Modern Philology*, 37:89–96, 1939). This gives a full bibliography of Arnold's essays, contributions to periodical literature, and editions of and introductions to literary works.

It was Arnold's expressed desire that his biography should not be written; there are, however, a number of monographs and biographico-critical works, among them LIONEL TRILLING, *Matthew Arnold* (1939), the best full-length study; J. DOVER WILSON, *Leslie Stephen and Matthew Arnold As Critics of Wordsworth* (1939); SIR E.K. CHAMBERS, *Matthew Arnold: A Study* (1947); J.D. JUMP, *Matthew Arnold,* "Men and Books Series" (1955); G. ROBERT STANGE, *Matthew Arnold: The Poet As Humanist* (1967).

Essays on Arnold: HENRY SIDGWICK, *Miscellaneous Essays and Addresses* (1904, reprinted 1968); T.S. ELIOT in *The Use of Poetry and the Use of Criticism* (1932) and "Arnold and Pater" in *Selected Essays,* new ed. (1950); BASIL WILLEY in *Nineteenth Century Studies* (1949); MERLE M. BEVINGTON in *M. Arnold's "England and the Italian Question"* (1953); JOHN HOLLOWAY in *The Victorian Sage* (1953 and 1965).

(B.W.)

Arrhenius, Svante August

A Swedish chemist, Svante Arrhenius was a founder of the modern science of physical chemistry, his best known contribution being his theory of electrolysis. Arrhenius was the first to suggest that electrolytes, certain substances that dissolve in water to yield a solution that conducts electricity, are separated, or dissociated, into electrically charged particles, or ions, even when there is no current flowing through the solution. He estimated the degree of dissociation of various electrolytes at various dilutions.

Early training

He was born at Vik, Sweden, on February 19, 1859. His father was a surveyor and estate manager. Svante, the second son, is said to have taught himself to read at the age of three and to have become interested in mathematics from watching his father add columns of figures. He attended the Cathedral School at Uppsala and went on to the university, where he studied physics, mathematics, and chemistry. In pursuit of his doctorate he migrated to Stockholm to work on electrolysis under Erik Edlund. In 1883 he published his first paper and in May 1884, at Uppsala, defended his doctoral thesis containing in embryo the dissociation theory.

Arrhenius, 1918.

The thesis was greeted with incredulity and awarded the fourth class, a bare pass; the university in effect condemned an important and original thesis. The faculty at Uppsala were skeptical of hypotheses and devoted to accurate experimental work, while Arrhenius boasted (not quite truly) that he had never performed an exact experiment in his life; moreover, his subject fell awkwardly between chemistry and physics. Even to the sympathetic English physicist Sir Oliver Lodge, who in 1886 described the theory to the British Association for the Advancement of Science, Arrhenius seemed sometimes "to indulge in . . . manipulation of imaginary data," producing "a confusion" from which emerged so-called theoretical deductions. In reality, Arrhenius had a statistical sense and an ability to frame formulas to fit his facts, both of which were rare among chemists of his day. He had prudently sent copies of his thesis to the most prominent physical chemists of the day, who were able to understand it; and in August 1884 the German physical chemist Wilhelm Ostwald went from Riga to Uppsala to offer Arrhenius a post. He was at once given a lectureship in physical chemistry at Uppsala; and in 1886 Edlund got him a travelling fellowship from the Swedish Academy of Sciences.

Gradual acceptance of his theory

Arrhenius spent from 1886 to 1890 working with other eminent scientists—Ostwald at Riga, F.W. Kohlrausch at Würzburg, Ludwig Boltzmann at Graz, and Jacobus van't Hoff at Amsterdam. During these years he refined his theory, which gradually began to win adherents. In 1891 he was offered a chair at Giessen, Germany, where Justus von Liebig, half a century earlier, had revolutionized the teaching of chemistry; but he wished to remain in Sweden and obtained a post at the Royal Institute of Technology in Stockholm. In 1895 he became professor of physics and, in 1896, rector of the school. Abroad, his reputation stood very high; but he was not elected to the Swedish Academy of Sciences until 1901, and even then with strong opposition. In 1902 he received the Davy Medal of the Royal Society of London, which in 1911 elected him a foreign member; and in 1903 his own countrymen made amends when he became the first Swede to be awarded a Nobel Prize.

In 1905 he was offered a chair at Berlin, then the most eminent position open to an academic chemist. On patriotic grounds, he refused; and the directorship of the Nobel Institute for Physical Chemistry at Stockholm was created for him. This gave him ample opportunity for research and writing, and his later years were contented.

In 1911 he visited the United States to receive the first

Willard Gibbs Medal and to deliver the Silliman Lectures at Yale University, published as *Theories of Solutions* (1912). He died in Stockholm on October 2, 1927.

Arrhenius was a genial, energetic man who made many friends on his visits abroad. His memory was excellent, he loved nature, but he was indifferent to the fine arts and literature. His range of scientific interests was very wide: over the years, he moved away from the study of solutions into immunology, where he made pioneering studies on toxins, and then into geology and cosmology. In *Worlds in the Making* (1908), he suggested that cool stars might collide and form nebulae from which new stars and planets would arise; and so the process would go on indefinitely, life being spread about the universe by bacteria propelled by light pressure. These speculations have not found their way into modern cosmology.

BIBLIOGRAPHY. The only full-length biography of Arrhenius is E.H. RIESENFELD, *Svante Arrhenius* (1931), in German. Brief English-language biographies may be found in the *Dictionary of Scientific Biography*, vol. 1, pp. 296–302 (1970), with a full bibliography; E. FARBER (ed.), *Great Chemists* (1961); and J.R. PARTINGTON, *A History of Chemistry*, vol. 4 (1964).

(D.M.K.)

Art, Philosophy of

There are many disciplines called "philosophy of . . .": philosophy of science, philosophy of religion, philosophy of history, philosophy of education, philosophy of art. In each of these cases, what does the phrase "philosophy of" signify? Those who are concerned with "the philosophy of" a certain discipline (1) attempt to give careful analyses of the principal concepts employed in that discipline, and, by means of such analyses, (2) attempt to determine the truth or falsity of very general statements used in that discipline or about it. Thus, in the philosophy of religion, clarity is sought about the use of such terms as supernatural, God, miracle, cause, create, and in the light of these to discover whether statements such as "God exists" and "God created the world" are true or false. Similarly, in the philosophy of art, attempts are made to clarify concepts that are constantly used in discourse about the arts—for example, "form," "expression," "meaning," "symbol," "representation," "abstraction," "beautiful"—and in the light of these clarifications to examine such statements as "Art is expression" and "Every work of art is a symbol." Conclusions arrived at by philosophers of art are very general in that, while they can be applied to particular works of art, they are not primarily about particular works of art: whether a certain painting is beautiful is a matter left for critics of painting to decide; the philosopher of art is content if he has answered to his satisfaction the question, "What is it for a work of art to be beautiful?"

This article is divided into the following sections:

I. Conceptual foundations of the philosophy of art

DISTINGUISHING CHARACTERISTICS

The philosophy of art is distinguished from art criticism, which is concerned with the analysis and evaluation of particular works of art. Critical activity may be primarily historical, as when a lecture is given on the conventions of the Elizabethan theatre in order to explain some of the devices used in Shakespeare's plays. It may be primarily analytical, as when a certain passage of poetry is separated into its elements and its meaning or import explained in relation to other passages and other poems in the tradition. Or it may be primarily evaluative, as when reasons are given for saying that the work of art in question is good or bad, or better or worse than another one. Sometimes it is not a single work of art but an entire class of works in a certain style or genre (such as pastoral poems or Baroque music) that is being elucidated; and sometimes it is the art of an entire period (such as Romantic). But in every case, the aim of art criticism is to achieve an increased understanding or enjoyment of the work (or classes of works) of art, and its statements are designed to achieve this end.

Difference between the philosophy of art and art criticism

The test of the success of art criticism with a given person is: has this essay or book of art criticism increased his understanding or enhanced his appreciation of the work of art in question? Art criticism is particularly helpful and often necessary for works of art that are more than usually difficult, so that the average person would be unable adequately to understand or enjoy them if left to himself.

The task of the philosopher of art is more fundamental than that of the art critic in that the critic's pronouncements presuppose answers to the questions set by the philosopher of art. The critic says that a given work of music is expressive; but the philosopher of art asks what is meant by saying that a work of art is expressive and how one determines whether it is. In speaking and writing about art, the critic presupposes that he is dealing with clear concepts, the attainment of which is the task of the philosopher of art.

The task of the philosopher of art is not to heighten understanding and appreciation of works of art but to provide conceptual foundations for the critic by (1) examining the basic concepts underlying the critic's activities to enable him to speak and write more intelligibly about the arts, and by (2) arriving at true conclusions about art, aesthetic value, expression, and the other concepts that the critic employs.

The meaning of "art"

Upon what does the philosopher of art direct his attention? "Art," is the ready answer; but what is art and what distinguishes it from all other things? The theorists who have attempted to answer this question are many, and their answers differ greatly. But there is one feature that virtually all of them have in common: a work of art is a man-made thing, an artifact, as distinguished from an object in nature. A sunset may be beautiful, but it is not a work of art. A piece of driftwood may have aesthetic qualities, but it is not a work of art since it was not made by man. On the other hand, a piece of wood that has been carved to look like driftwood is not an object of nature but of art, even though the appearance of the two may be exactly the same. This distinction is being challenged in the 20th century by artists who declare that *objets trouvés* ("found objects") are works of art, since the artist's perception of them as such makes them so, even if the objects were not man-made and were not modified in any way (except by exhibition) from their natural state.

Nevertheless, according to the simplest and widest definition, art is anything that is man-made. Within the scope of this definition, not only paintings and sculptures but also buildings, furniture, automobiles, cities, and garbage dumps are all works of art: every change that human activity has wrought upon the face of nature is art, be it good or bad, beautiful or ugly, beneficial or destructive.

The ordinary usage of the term is clearly less wide. In daily life when works of art are spoken of, the intention is to denote a much narrower range of objects, namely, those responded to aesthetically. Among the things in this narrower range, a distinction, although not a precise one, is made between fine and useful art. Fine art consists of those works designed to produce an aesthetic response or that (regardless of design) function as objects

of aesthetic appreciation (such as paintings, sculptures, poems, musical compositions)—those man-made things that are enjoyed for their own sake rather than as means to something else. Useful art has both an aesthetic and a utilitarian dimension: automobiles, glass tumblers, woven baskets, desk lamps, and a host of other handmade or manufactured objects have a primarily useful function and are made for that purpose, but they also have an aesthetic dimension: they can be enjoyed as objects of beauty, so much so that a person often buys one brand of car rather than another for aesthetic reasons even more than for mechanical reasons (of which he may know nothing). A borderline case is architecture: many buildings are useful objects the aesthetic function of which is marginal, and other buildings are primarily objects of beauty the utility of which is incidental or no longer existent (Greek temples were once places of worship, but today their value is entirely aesthetic). The test in practice is not how they were intended by their creators, but how they function in present-day experience. Many great works of painting and sculpture, for example, were created to glorify a deity and not, insofar as can be ascertained, for an aesthetic purpose (to be enjoyed simply in the contemplation of them for their own sake). It should be added, however, that many artists were undoubtedly concerned to satisfy their aesthetic capabilities in the creation of their work, since they were highly perfectionistic as artists; but in their time there was no such discipline as aesthetics in which they could articulate their goals; in any case, they chose to create "for the greater glory of God" by producing works that were also worthwhile to contemplate for their own sake.

Other senses of the term "art"

This aesthetic sense of the word "art," whether applied to fine art or useful art, is the one most employed by the majority of critics and philosophers of art today. There are two other senses of "art," however, that are still narrower, and, to avoid confusion, their use should be noted: (1) Sometimes the term "art" is restricted to the visual arts alone or to some of the visual arts. Thus, the art department in 20th-century colleges and universities is usually the department of painting and sculpture (and sometimes architecture). But as philosophers of art use the term (and as it is used here), art is not limited to visual art; music and drama and poetry are as much arts as painting, sculpture, and architecture. (2) Sometimes the term "art" is used in a persuasive sense, to include only those works considered good art. "That's not art!" exclaims the viewer at an art gallery as he examines a painting he dislikes. But if the term "art" is to be used without confusion, it must be possible for there to be bad art as well as good art; the viewer, then, is not really denying that the work in question is art (it is a man-made object presented to be contemplated for its own sake) but only that it is worthwhile.

The word "art" is also ambiguous in another way: it is sometimes used to designate the activity of creating a work of art, as in the slogan "Art is expression"; but it is more often used to designate the product of that process, the completed artwork or artifact itself, as in the remark "Art is a source of great enjoyment to me." There will be occasion later to remark on this ambiguity.

Countless proffered definitions of "art" are not definitions at all but theories about the nature of art that presuppose that the ability to identify certain things in the world as works of art already exists. Most of them are highly unsatisfactory even as theories. "Art is an exploration of reality through a sensuous presentation"—but in what way is it an exploration? Is it always concerned with reality (how is music concerned with reality, for example)? "Art is a re-creation of reality"—but is all art re-creation, even music? (It would seem likely that music is the creation of something, namely, a new set of tonal relationships, but not that it is the re-creation of anything at all.) "Art is an expression of feeling though a medium"—but is it always an expression (see below *Art as expression*) and is it always feeling that is expressed? And so on. It appears more certain that Shakespeare's *King Lear* is a work of art than that these theories are true. All that seems to be required for identifying something as a work of art in the wide sense is that it is not a natural object but something made or transformed by man; and all that is required for identifying it as art (not as good art but as art) in the narrower sense is that it functions aesthetically in man's experience, either wholly (fine art) or in part (useful art); it is not even necessary, as has been shown, that it be intended by its creator to function in this way.

THE INTERPRETATION OF ART

Works of art present problems of both interpretation and evaluation. Evaluation is not the concern of this article (see AESTHETICS); but one problem about interpretation deserves to be mentioned. Works of art are often difficult, and how to interpret them properly is far from obvious. The question then arises as to what factors should guide efforts at interpretation.

Isolationism and contextualism

At one extreme lies the view known as isolationism, according to which a knowledge of the artist's biography, historical background, and other factors is irrelevant to an appreciation of the work of art and usually is harmful in that it gets in the way, tending to substitute a recital of these facts for the more difficult attempt to come to grips with the work of art itself. If the work of art is not understood on first acquaintance, it should be read (or heard, or viewed) again and yet again. Constant re-exposure to it, so that the recipient is totally absorbed in and permeated by it, is the way to maximum appreciation.

At the other extreme, contextualism holds that the work of art should always be apprehended in its context or setting and that not merely knowledge about it but total appreciation of it is much richer if it is approached with this knowledge. According to the contextualists, not only literature (ordinarily appreciated contextually) but also the other arts, even nonrepresentational painting and music, should be apprehended in this way.

No critic or art lover need hold to either position in its undiluted form: a person could well be an isolationist about some kinds of art, such as music, and a contextualist about others, such as historical dramas and religious paintings. It is essential to be more specific, however, about the factors—other than careful and repeated perusal of the work of art itself—that the contextualist holds are either necessary or extremely helpful in the appreciation of works of art:

1. Other works of art by the same artist. If the artist has created other works, particularly in the same genre, acquaintance with them may enhance appreciation of the work at hand. Quantity of works has no particular merit in itself; but, when, say, one of the piano concertos of the 18th-century Austrian composer Wolfgang Amadeus Mozart is heard, the auditor may (often largely unconsciously) compare its mode, thematic material, and method of development and resolution with some of Mozart's 25 other piano concertos. Knowledge of the entire corpus of his work in a certain genre may heighten enjoyment of a particular work.

2. Other works of art in the same genre by other artists, particularly in the same style or tradition. Appreciation of the pastoral poem "Lycidas," by the English poet John Milton, is doubtless enhanced by a study of the pastoral tradition in poetry, with which Milton supposed his readers to be acquainted. To study "Lycidas" in isolation would needlessly deprive the reader of much of the richness of texture of the poem and would even make some of the references in it unintelligible.

3. A study of relevant facts about the artistic medium, such as the instrumental limitations or advantages of pipe organs in the time of the German composer Johann Sebastian Bach (1685–1750) or the modes of presentation of ancient Greek tragedies in the Athenian theatre. An acquaintance with the artistic conventions and idioms in which the artist operated often leads to better understanding of certain aspects of his work and helps to avert misunderstandings of it.

4. A study of the age in which the artist lived—the spirit of the time and its current ideas, the complex influ-

External influences on the artist

ences that molded the artist, even the social, economic, and political conditions of the time and place in which he worked. Sometimes such knowledge is of dubious relevance: it can be argued that no aid to the study of the 82 string quartets and 104 symphonies of the 18th-century Austrian composer Joseph Haydn is provided by reading about the political and economic conditions of his day. It is interesting to study the evolution of the string quartet or symphony from its origin through Haydn to the present; but this would appear to be an evolution traceable entirely within the art form and not dependent on factors outside it. This, however, is not always so: particularly in literature, where a study of such exterior factors seems to be of much more relevance. It would seem important to know, for example, that Milton was aware of the new Copernican astronomy but deliberately chose in *Paradise Lost* to make his cosmos Ptolemaic, the antiquated astronomical system that was already steeped in literature, mythology, and tradition.

5. A study of the artist's life. Anthologists of literature constantly assume that this is an important consideration, since they supply detailed biographies prior to their selections by each author. It is true, of course, that knowledge of the artist's life can distract attention from his work, as with those who cannot hear Beethoven's late quartets without constantly thinking, "What a pity it was that he was deaf at the time!" Yet such knowledge may also heighten experience of a work; some would say, at any rate, that it helps to know that Milton was blind when he wrote the sonnet "On His Blindness." It is the relevance of this kind of knowledge to an appreciation of the poem, as a poem, that is in dispute. In every case, however, it should be kept in mind that acquaintance with the artist's biography is a means toward an end, the enhanced appreciation and understanding of the work of art, and that otherwise it is aesthetically irrelevant. The facts about the artist's life are the means and the enhanced appreciation the end, not the other way around, as is often found, for example, in psychoanalytic essays attempting to infer facts about the artist's subconscious conflicts from his work; in these cases the work is being taken as the means and the study of his life as the end.

6. A study of the artist's intentions. It is this factor that has prompted the principal controversy in the mid-20th century. When difficulties arise as to what to make of a work of art or when several conflicting interpretations come to mind, how is the difficulty to be resolved? One obvious suggestion is to consult the artist or his records or memoirs or the testimony of people who knew him, to discover what his intentions were with regard to the work or the passage. It is tempting to believe that whichever way he intended it this is the way the work should be interpreted; for in regard to his own work, surely the author's own word should be law.

"Intentional fallacy"

This temptation is hotly decried by other critics as "the intentional fallacy"—the fallacy (if it is a fallacy) of believing that whichever way the artist intended it is by definition the way it really is. A work of art should stand on its own, without help from the artist; if he has not sufficiently realized his intentions within the work, forcing the recipient to go outside for help, this is held to be an artistic defect. Once the artist has completed his work, moreover, and presented it to the world, it belongs to the world and no longer exclusively to him: in the interpretation of it he now becomes just one critic among many, whose word should be respected but not taken as the final authority. Perhaps other critics can think of better interpretations than he did, which give a greater aesthetic reward in subsequent encounters with the work; perhaps there are even acceptable interpretations (such as the Freudian interpretations of Shakespeare's *Hamlet*) that he could not possibly have thought of himself at the time.

In the late 18th and early 19th centuries, Johann Wolfgang von Goethe set forth three criteria for critics to consider in interpreting and evaluating a work of art: (1) What was the artist trying to do? (2) Did he do it? (3) Was it worth doing? The first of the three is intentionalistic; and, says the intentionalist, surely this is plausible: an artist can hardly be blamed for failing to do what he had no intention of doing. It must first be known, then, what he was trying to do.

But the anti-intentionalist points out that the intention makes no difference, only the product does. If the ballerina excuses her fall in the middle of the dance by saying that she intended it, the dance is just as marred aesthetically as if she had fallen accidentally. And if a poet admits that he wrote rubbish and says that this is just what he intended to write, one does not rate the poem any higher because the poet's intention was fulfilled.

The persistent questioner might ask, however, if there are not at least some works of art in which the intentions of the artist have to be known? Suppose that a contemporary critic reads a dull, stodgy, moralistic Victorian novel and says at the end, "What an excellent parody of a Victorian novel!" But it was not a parody; its intentions were deadly serious—and should not this be known in order to interpret and evaluate it properly? Not at all, replies the anti-intentionalist; all the critic has to say is, "As a Victorian novel, this is deadly dull; as a parody of a Victorian novel, it is brilliant; if the author intended it in the former way, so much the worse for him—his work can still be praised for being brilliant parody, even if it wasn't intended as one. He just achieved something better than he knew at the time."

The author's statement of intention

Still, the intentionalist has a point: sometimes the clue to unlock an otherwise intransigent work may come from the author's statement of intention, and a plausible interpretation might be unobtainable without it. Such a suggestion might have come from a reader other than the author; but there is no point in disdaining helpful hints, regardless of their source. If the suggestion does come from the artist himself, that is nothing against it. Perhaps a work is less aesthetically perfect because it requires outside clues to its interpretation, but few works of art even approach perfection, and they may yet amply repay attention, all the more if some plausible suggestion comes from the outside. The 20th-century Russian composer Sergey Prokofiev intended his *Classical Symphony* to be a parody of the classical symphonies of Mozart and Haydn—and regardless of whether the suggestion that it be construed this way came from Prokofiev (as it did) or from someone else, if it is rewarding to listen to it in this way, then no one gains by refusing to accept the suggestion. A statement of intention is not the only key to unlocking the secrets of works of art, but it is one key among many, and there appears to be no good reason why it should not be used.

THE MEDIUMS OF ART

In the context of every work of art there are three items to consider:

1. The genesis of the work of art.
2. The artifact, or work of art, which is a publicly available object or thing made by the artist and viewed by the audience.
3. The effects of the work of art upon the audience.

The first item comprises all the artist's mental states, both conscious and unconscious, in the creation of the work, including his intention with regard to the work, as well as all the factors that led to these states of mind: for example, the spirit of the age, the socio-economic conditions of the times, his exchange of ideas with other artists, and so forth. Whatever factors helped to form the work of art in the artist's mind fall under this heading. The experiences undergone by the artist in the creation of the work constitute the artistic experience.

The third item includes all the effects of the work of art upon those who experience it, including both aesthetic and nonaesthetic reactions, the influence of the work of art upon the culture, on the state of knowledge, on current morality, and the like. The experience that involves the observer's attention to the work of art for its own sake and not for the sake of some ulterior end is called aesthetic, but of course art has many effects that are not aesthetic. The aesthetic experience belongs to the consumer of art, as opposed to the artistic experience, which belongs to the creator of art.

The second item is what is usually called the work of art

itself. According to some writers, such as the Italian philosopher Benedetto Croce (1866–1952), the work of art exists only in the mind of the artist, and the physical artifact then counts as an effect of the work of art. But in ordinary usage, as well as the usage of most philosophers of art, the work of art is identified with the physical artifact, as it exists in the physical medium. What goes on in the creator's mind is already contained in the first item.

Every work of art occurs in a medium; that is, there is some physical object or series of events by which the work is communicated to the recipient (listener, observer, reader) by means of his senses. In painting, the medium is paint; in sculpture, such materials as stone or wood or plastic. It might at first be thought that the medium of music consists of the musical score on which the composer writes the notes; but the written notes are not music, they are a set of visual cues for the production of the tones to be emitted by the various instruments. If every player had a perfect memory, he would have no need for the written score; indeed, music existed long before there were any written scores and was played or sung from memory from one year or generation to the next. It could be said more plausibly that the medium of music consists of the physical sound waves by means of which the sound sensations enter the consciousness of the listener. The medium of literature can truly be said to be words, yet not words as abstract entities conceived in the mind but words as spoken (in oral presentation) or written. The physical medium of literature, then, is either auditory or visual, although what is conveyed through the medium is not.

The medium of music

Classifying arts by their mediums. There are many ways of classifying the arts—by their purpose, by their intentions, by their effects. But the most usual and the most fundamental method of classifying the arts is by their mediums:

Visual art. This includes two-dimensional visual arts such as drawing and painting and also three-dimensional visual arts such as sculpture and architecture. Some of these should doubtless be called visuo-tactual art: buildings are ordinarily touched as well as seen, sculptures could be more fully appreciated if touched as well as seen, and even paintings may sometimes have enough three-dimensionality to repay touch experience. At any rate, all these arts appeal first and foremost, though not exclusively, to the sense of sight; and the artifact is an object in the visual medium.

Auditory art. This includes music in all its forms but not song, opera, and those arts that combine music with literature (see below). Just as the medium of visual art is sight, so the medium of auditory art is sound.

In auditory art there is—unlike visual art—no physical object (other than the score, which as has been seen is not the music). There is only the temporally successive series of sounds: sound waves emanating from the various instruments. While no such tones are being emitted, no sounds exist; only the musical score exists (and the memories of listeners, some of whom might enable the score to be reproduced if it were lost), from which music can be reproduced. Unlike the existence of paintings and sculptures, the existence of musical sounds is intermittent. In what sense, then, does the music exist between performances? It exists only in the sense that it is reproducible from the written score.

Verbal art. The art of literature is clearly different from both visual and auditory art. There are sound values in poetry, particularly when read aloud; but as sound alone, literature would be the most poverty-stricken of arts: what makes the sounds of poetry effective is (at least 99 percent) knowledge of the meanings of the words heard. Listening to the sounds of a poem or play uttered in an unfamiliar language gives some idea of the importance in literature of knowing the meanings of the words. Note that "murmuring," one of the most pleasant sounding words in English, has almost the same sounds as "murdering." It is almost exclusively a knowledge of word meanings that makes it possible to appreciate the art of literature.

The meanings of words

Nor is literature a visual art, although it is customary to read works of literature from a printed page. A critic who said, "I think this poem is a bad one, because it is written in unpleasant small type in double-column pages on yellowed paper," might be giving advice to typesetters and book designers (these two groups are engaged in the practice of visual arts), but he would be saying nothing about the merits of the poem. The printed or written word or for that matter the spoken word is only a vehicle for the meanings. Literature, then, must be placed in a separate class from either auditory or visual arts.

Mixed arts. Other arts variously combine the above three types of arts; this group includes all the arts of performance. Drama combines the art of literature (verbal art) with the visual arts of costuming, stage designing, and so on. Opera combines the art of music (its predominant component) with the art of literature (the libretto) and the visual arts of stage design. Dance combines the visual spectacle of moving bodies (the principal component) with musical accompaniment, sometimes with accompanying words and often with stage design. Song combines words with music. The motion picture combines the visual component (a series of pictures presented in such rapid succession that they appear to be moving) with the verbal component (the script) and usually an intermittent musical background as well.

Spatial arts and temporal arts

All the visual arts are also spatial arts, or arts of space; music and literature are both temporal arts, or arts of time. This leads to very great differences in the things each can do. In temporal arts, the parts do not appear together before the audience but appear successively in time, the second moment not beginning until the first one has finished. In spatial arts, the entire work of art is present simultaneously; attention to the parts of it is successive—it is impossible to concentrate on the whole at once, at least on first viewing—but the entire object is nevertheless there, and it is up to the viewer which part he shall examine first. In three-dimensional art, such as sculpture and architecture, the entire object is present, but it is impossible even to see (much less to look at) all of it at once: the back of a statue cannot be seen at the same moment as the front and the exterior of a cathedral cannot be viewed by someone inside it.

Temporal arts must be attended to in a certain order: it is impossible to hear the symphony played backward, or the drama, or the movie; even when technically it can be done (as in running a motion picture in reverse), the results usually are an aesthetic catastrophe. The recipient is supposed to attend to the temporal work's various parts in an order predetermined by the artist. For this reason, painting is not capable of telling a story in the way that a novel is; for a story is a series of temporally successive happenings, and a painting can at best take a series of represented persons and objects and show them as they exist at one moment only, one knife-edge of time; whereas a novel can depict the temporally successive happenings in the order of their occurrence (or in a different order, such as flashback).

The German aesthetician and dramatist Gotthold Lessing made this distinction the basis of his study *Laokoon*, contending that the function of visual art is to create beautiful objects and that the artist should select that stance or moment at which the person or object appears most beautiful, to enable the viewer to continue looking at it with pleasure; whereas literature, being temporal, is equipped to tell a story that includes many moments other than pleasing ones (moreover, the scenes in literature are not seen with the eyes but only imagined). Lessing's thesis that each art should restrict itself to what it can do best or is peculiarly equipped by its medium to do is a highly controversial one: it would virtually eliminate program music, for example, and descriptions of nature in novels. The tendency of art today is to attempt to curtail distinctions between time and space rather than to preserve them.

Differences in the arts related to mediums. Very significant differences among the arts occur because of the differences in their mediums:

Literary and nonliterary. The greatest difference among the arts is between the literary and the nonliter-

ary. Literature consists of a system of symbols with assigned meanings. A word is not simply a noise (or a mark on a printed page); a word is a noise or a printed mark with an assigned meaning. In different languages, different noises have been assigned meanings, and the language must be learned in order to understand what is being said. To appreciate the work of the 11th-century novelist Lady Murasaki Shikibu, one must learn Japanese; to fully appreciate Molière, the 17th-century playwright, one must learn French. No other art has this problem: the Englishman can appreciate German music as well as a German—or if he does not, it is not for lack of learning a language.

Assigned meanings of words

Shapes, colours, and tones do not have assigned meanings. That is not to say that these elements when present in art cannot be said to have some sense of the term "meaning." There are many meanings of the word "meaning," and a colour, for example, can have meaning in that it may symbolize something, as red symbolizes courage; or it may have strong emotional or other effects upon the viewer, evoking all manner of strong associations. But a colour or a tone has no assigned meaning: if the question were asked, "What does middle C mean?", the answer would be, "It has no assigned meaning at all; in that sense, it means nothing—it just has certain effects." But if the meaning of a certain word in a poem is not known, the reader is to that extent prevented from appreciating the poem; for the medium of poetry is not noises, not printed marks, but words, and the difference between a noise and a word lies in the fact that a word is a noise with a meaning.

This fact makes for an enormous difference between literature and the other arts. A colour in a painting may be the colour of an object represented; a colour may even "mean" something; for example, the white of a white flag that a person depicted in a battle painting is holding up as a sign of surrender. But a colour, as a colour, has no meaning at all; and the same is true of musical tones. A pattern of musical tones may occasionally acquire a meaning (the first four tones of Beethoven's *Fifth Symphony* were used to symbolize victory in World War II), but when this happens it really has very little to do with the music, and in any case most music is appreciated without any such symbolism being present. But a noise, however pleasing to the ear, is only a noise and not a word unless it has an assigned meaning; and one must know what that meaning is in order to appreciate a poem or any other work of literature.

The translation problem. Because literature consists of conventional symbols, there exists in literature the problem of translation, which does not exist in the other arts. When one seeks to make a work of literature available to a wider audience than that composed of only the native speakers of the language in which the work was written, the process of translation must be resorted to, and, in this process, a great deal of the work's original character is lost.

Difficulties in translating poetry

In a poem there are (1) the sounds, (2) the dictionary meanings of the words, and (3) the connotations of the words—the manifold associations that they evoke (sensory, intellectual, and emotional) in the minds of readers. The sounds are the least important of the three, and many a great poem as sheer sound is hardly even pleasing. The finding of like dictionary meanings is usually a simple matter, and when there is a word that has no rough equivalent in the other language, it may be simply retained in the original language (for example, the German word *Weltanschauung*, meaning something like "world outlook," is often retained in English translations of German works). As for the associations that hover about a word, they may vary from language to language, so that if a work is translated rather literally, the associative values of the words are lost. Thus, "My God!" is a much stronger expletive in English than "mon dieu" is in French, so that if the French expression is translated into the English one, it is, though literally correct, quite unfaithful to the weaker emotive force of the French expression. Words can often be found in the second language that have a roughly equivalent associative value to the original one, but these will usually not provide a literal translation; thus, the translator is faced with the dilemma of being able to provide a literal-meaning translation or a translation that renders the spirit or "feel" of the original but not both.

The question of correspondence to actuality. The arts also differ from one another, according to their mediums, in whether the items in the medium correspond to items in the world. Objects with colours and shapes are represented on canvas, and objects with colours and shapes also exist in the outside world. Even when a painting is nonrepresentational, it consists of colours and shapes, which are items in the outside world (even though certain individual colours and shapes in the painting may not exist in the outside world). But the case with music is different: though the visual arts may (to varying degrees) convey the sights of nature, music does not convey the sounds of nature. Even when a work of music attempts to represent the sound of an iron foundry or the clattering of horses' hooves, it really does not sound like these things: musical instruments emit tones, and in nature are found largely noises, and between the two there is an enormous auditory difference. Some rhythms of nature can be duplicated by musical instruments but hardly the sounds themselves.

The medium of literature, words, is indeed man created; but of course this feature is far from unique to literature. Words were devised and employed in countless situations of daily life before they were ever embodied in literature; so in literature, as in visual art, a medium is being employed that existed before the art itself.

II. Theories of the nature, functions, and effects of art

ART AS IMITATION (REPRESENTATION)

The view that "art is imitation" is at least as old as the Greek philosopher Plato (428–347 BC), and, although not widely held today, its long and distinguished history is evidence of its continuing hold on human beings as an account of the distinctive function of art. A terminological point, however, is in order here: in the interests of clarity, an artist should be spoken of as representing in his work the persons and things and scenes of the world but as imitating the work of other artists. Thus, "In this painting he represents a barn and some wheat fields, and in his style he is imitative of Vincent van Gogh." This distinction will be employed here, with the result that these traditional theories of art will be spoken of as theories of representation rather than of imitation.

At some period in the history of art, aestheticians and critics wrote as if nature should be recorded by the artist with photographic fidelity. The invention of photography (which can do this better than any painter) could plausibly be said to have relieved the artist of any such responsibility. Still, art can represent reality: the representation of a house in a painting may not look exactly like a house—it cannot, since the real house is three-dimensional and the painting is two-dimensional—but it looks enough like one to enable everyone unhesitatingly to identify it as a house.

Distinction between depiction and portrayal

A distinction should be made between depiction and portrayal. A painting may be said to depict a house if it looks more like a house than like anything else. Thus, most persons unhesitatingly classify this as a man, that as a tree, and so on; only when the painter has distorted or abstracted so much that a thing looks somewhat like a wolf and also somewhat like a bobcat, do they hesitate in saying what the object represented is. A picture may depict a rather short man in a French general's uniform of the early 19th century; but it may, in addition, portray Napoleon. It portrays Napoleon if (1) the artist intended it to represent Napoleon (for example, if the title of the painting is "Napoleon") and (2) the painting does look like Napoleon to some degree at least—at any rate it contains no important characteristics known to be incompatible with those of Napoleon. Clearly, if it is a painting that depicts a tree in someone's yard, it cannot be considered a portrait of Napoleon, no matter how much the artist said he intended it to be one. Depiction subjects

can ordinarily be recognized at once with a little knowledge of the world and the names of the things in it. Portrayal subjects require knowledge of whomever the artist intended to portray; even when that seems obvious, as in the case of Napoleon (who would be instantly recognized, unlike the portrait of a private in his army), the viewer would have to be told, by the title or otherwise, that not only does the painting depict a man in a French general's uniform but that it was intended by the artist to be a portrait of this particular man. Otherwise, how would the viewer know that it did not actually portray his double, or his stand-in? The word represent, as used in connection with art, can mean either "depict" or "portray."

Analysis of representation. Representation always involves a certain degree of abstraction; that is, the taking away of one characteristic or more of the original. Even a fairly realistic painting of a person, for example, lacks some features that characterize actual persons: the painting is two-dimensional, whereas every actual person is three-dimensional; the surface of a painting is paint, but not so the person; the actual person has very numerous pores and other marks on his face that are lacking (in whole or in part) in the painting, and so on. The depiction of a person in a painting is usually sufficient to enable human viewers to recognize the figure as a person—though it is apparently not sufficient for an animal, who sees only a coloured canvas where people see on the coloured canvas a representation. When the degree of abstraction is so great that it is no longer possible to recognize this shape as a human shape or as the shape of any identifiable object, the painting is then spoken of as nonrepresentational. (In popular parlance such paintings are called abstract; but this is misleading, for abstraction is a matter of degree, and, as has just been shown, all depictions are necessarily abstract—that is, abstracted from reality to some degree.) The actual object with all its millions of qualities is at one end of the spectrum, and the painting so abstracted that a depiction subject is unrecognizable is at the other end; between the two extremes lie all the possible degrees of abstraction.

Representation in literature

Literature can be representational but not in the same way as visual art. It is quite natural to say that in a novel or drama a number of characters and actions are represented. The representation is, of course, not a visual one; it is representation through language. The painter portrays Napoleon by making a portrait of him; the writer does so by describing him in words. The writer, unlike the painter, can also depict action. Not all literature, of course, is representational in this way: a sonnet may contain no characters at all and no action, consisting solely of an expression of feeling by some unspecified speaker.

Any of the mixed arts that include words as part of their medium, such as drama or film, can be, like literature, representational. Indeed, they have a further advantage: they can depict action not only through words but also by showing the characters and exhibiting the action before the spectator. These arts are visual as well as verbal, and since they are not limited to one moment in time, as painting and sculpture are, they are temporal arts as well as spatial. These mixed arts, then, can be doubly representational.

Is it possible for music, too, to be representational? Music cannot visually show characters or objects, nor can it describe them in words; can it "depict them in tones"? Program notes at concerts usually assume without question that it can. The audience is told about the tone poem *Don Quixote*, by the Austrian composer Richard Strauss, "The composer has given us a musical representation of the Don's adventures. The 17th-century Spanish writer Miguel de Cervantes has described them in words, and Strauss has done so in tones." But the claim to representation in music is, to say the least, quite dubious. Without the title, with the music alone, would there be any clue that the music was supposed to be "about" the adventures of Don Quixote? True, there is a passage that resembles the bleating of sheep sufficiently for that much to be guessed; but even to conjecture that this passage is a representation of sheep bleating is a far cry from being able to reconstruct the entire story. Suppose that Strauss had left every note in the score just as it was but changed the title; would the piece then have been a representation of something else? The very fact that this question can be asked shows how different music is from visual art: if a painter has drawn a house but indicated in the title that it was supposed to be a tree, the viewer could still say, on the basis of what he saw in the picture, that it was not a tree but a house. But in music the listener is never in this situation: if he says that this series of tones represents the adventures of Don Quixote, he says this because of the title Strauss used. If the composer had given it no programmatic title, one listener might think of one represented subject, another a different one, and a third none at all, and there would be no way of showing who was right or even whose opinion was to be preferred. The conclusion seems to be that music by itself—without title, without words, without depicted action (as in a combination of music and drama such as opera)—is incapable of representing anything. There is simply a series of musical tones that may suggest differing associations, programmatic or otherwise; but the musical tones by themselves cannot be said to represent anything at all.

This might be objected to as an overstatement. If a picture can represent a house by looking more like a house than anything else, cannot a work of music represent the sea by sounding more like the sea than any alternative? And is this not the case in, for example, the French composer Claude Debussy's tone poem *La Mer?* Even this, however, is highly questionable; almost no one guesses the title to Debussy's tone poem without first knowing what it is; it may seem obvious enough after the composer has channelled the listener's response by means of his title but not beforehand. And surely this is because the sounds in the tone poem do not sound more like the sea than like anything else: the tone poem consists, after all, of a series of complex musical tones, emitted by violins, cellos, clarinets, flutes, trumpets, and so on; and it would be difficult indeed for these sounds, which are musical tones, to sound very much like the sea, whose sounds consist after all of a series of complex noises. There is no great similarity between any one series of musical tones and any one series of nature's noises. Hence, the first cannot be said to constitute a representation of the second.

Musical attempts to represent the soundless

The matter is even more obvious in the case of those numerous programmatic titles in which the supposedly represented subject contains no sounds at all. Debussy's *Reflets dans l'eau* (*Reflections in the Water*) is taken by some as a musical representation of reflections in the water. But reflections in the water emit no sounds at all, not even noises. No one, then, could say that the sounds in Debussy's piano composition resemble the sounds of reflections in water. The resemblance, if there is any, is much more remote: it may be that the feeling obtained when Debussy's composition is heard is somewhat like the feeling that arises when reflections in water are seen. This is highly improbable without knowledge of the title, but at most it would provide a mood resemblance, which is far removed from a representation by music of things in the world. The conclusion seems inescapable that music is not to be classified as a representational art, at least not in the same straightforward meaning of "representation" that applies to the other arts.

So much, then, for the capacities of the various arts as far as representation is concerned. But the question remains: in those arts that are properly called representational, what should be the nature of the representation?

That art should be an outright duplication (incorrectly called "imitation") of reality is a view that was put forward by the French novelist Émile Zola in his book *Le Roman expérimental* (*The Experimental Novel*) and has been occasionally held (though not practiced) by painters reacting against Romanticism, such as the 19th-century French artist Gustave Courbet. Zola advocated a novel that resembled a scientific investigation into reality. Plot was to be of no importance, rather an aspect of reality was to be examined searchingly, and from this the story would unfold without imaginative effort. Persons or

groups of persons would be depicted, and from them the action would evolve.

Objections to Zola's theory of duplicating reality

It would be impossible, of course, to carry out such an ideal of art as "report" and undesirable even if it were possible. First, the author or painter must select a subject; and, within the subject, he must select which details to treat, for he cannot in a hundred lifetimes describe them all: since every object and event has an indefinitely large array of qualities, there is no point at which a description of it would be completed. Besides, the very language used (no matter how neutral a description is attempted) will colour the account. Even if the words were colourless, the mode of putting them together would yield a style, which would colour the account once again. Indeed, should such an ideal be achieved (as in the verbatim transcription of an actual trial) it would be the deadliest possible bore.

Art, even representational art, is not a reproduction of reality; it is a transformation of reality. How, specifically, is reality transformed in being represented in art? There is probably no general satisfactory answer to this question. Each art, each style of art, and each work of art transforms reality in its own way—the 19th-century French painters Paul Cézanne in one way, Pierre-Auguste Renoir in another; the 19th-century Russian writers Fyodor Dostoyevsky in one way, Leo Tolstoy in another. No set of rules can lead to predictions as to what transformation of reality will be conceived in the mind of the next creative artist. Reality is the common base, but each artist deals with it in his own unique way.

Subject matter. Do all works of art have a subject matter? The answer to this depends on what is meant by the term subject matter, which signifies basically what the work is about. There are several senses of being "about" that may be referred to:

1. "What is the subject matter of the *Odyssey* by the ancient Greek poet Homer?" The most natural answer would be: "The wanderings of Odysseus." This is the "representational content" of the work. A person who read it simply for the story could easily give this answer. There is contained in the work itself an account of the wanderings of a character named Odysseus, who has no counterpart in the outside world (that is, he is a fictional character) but who does resemble people in the outside world in that he is a man, he is away from home, he is beset by many vicissitudes, and so on. If the subject matter were stated in greater detail, the result would be an account of the plot.

Does painting have subject matter in this sense? If "subject matter" is taken to mean representational content, the answer is often yes; representations of people and trees and the like are easily identifiable in the painting. Sometimes the subject could not be ascertained except for the title, which is not strictly a part of the painting (the title is not a piece of visual art, consisting as it does of words). But quite clearly it cannot be said that the subject matter of the painting is whatever the title says it is: if the title says "Clouds" and the painting is obviously a still life with pears and grapes, it can hardly be said that the painting has clouds as its subject matter simply because the title says so. It was long said that the painting called "Sacred and Profane Love" by the 16th-century Italian artist Titian had sacred and profane love as its subject matter; but Titian himself gave it no such title—the title was added more than a century later by someone else. It cannot be said that the subject matter is what whatever title it came to be given says it is (it could be given numerous incompatible titles); the subject matter, in this sense, must be evident from—or at least not incompatible with—what is seen in the painting itself. The same remarks apply to music: music cannot be "about" anything that the composer happens to seize on as a title; if it were, and he changed the title without changing a note of the music, would the subject matter of the music have changed? Strong reasons already have been given to doubt that music can have a subject matter at all.

2. In addition to a subject matter in the sense of representational content, a work of art may have subject matter in the sense of theme, or underlying idea. The subject matter in the sense of representational content of *Jude the Obscure*, by English novelist and poet Thomas Hardy, is the intellectual ambitions of the main character, Jude, and the vicissitudes befalling him along the way; but the subject matter in the sense of theme or underlying idea is man's struggle to realize his ambitions; and the thesis (implicit message) of the novel is (or may be) that man's highest ambitions are doomed to frustration. Not all novels and dramas and poems have a theme or thesis; they may simply tell a story and nothing more. Works of literature do sometimes operate in both dimensions: a story and a theme or thesis underlying the story. Works of representational visual art may also do so: one might allege that the theme of "Guernica," by the 20th-century Spanish artist Pablo Picasso, is the horror of war. Again, it is doubtful whether works of music can be said to have a theme at all (indeed, the term theme applied to music has a very different meaning: it refers to a set of tones around which variations or developments are composed). If someone were to say that the theme of a work of music was the human condition or man's fear of death, how would such a view be supported? Since music is not representational, what musical passages would he take as evidence for his theory, and why? A composer might indeed title his work "The Human Condition," but this would no more show that the music was about the human condition (had the human condition as its subject matter) than giving the programmatic title "Clouds" to a musical composition shows that the composition actually is about clouds.

Thematic subjects

Symbols in art. Works of art may not only have subject matter, they may also contain symbols. Certain elements in a work of art may represent, say, a whale; but the whale thus represented may be (as it is in *Moby Dick* by the 19th-century U.S. writer Herman Melville) a symbol of evil. In Tolstoy's *Anna Karenina* is represented a gallery of characters dominated by Anna herself, and a tremendous number of actions in which these characters engage; but there is a constantly recurring item in the representational content, namely, the train. Time and again the train causes or accompanies frustration, disaster, betrayal, and other evils—so much so that before the novel is ended it becomes apparent that the train here is a symbol of the iron forces of material progress toward which Tolstoy had such great antipathy.

What is it that makes an item in a work of art a symbol? It is something represented in the work of art—an object, an action, or a pattern of objects and actions, or even (less frequently) simply a nonrepresentational item such as a colour or a line—that does the symbolizing; what is symbolized is a characteristic, such as evil or progress or courage. But by virtue of what does the first (A) become a symbol of the second (B)?

Conventional and natural symbols

The answer is not the same for all symbols, since some are conventional and some are natural. The cross is a symbol of Christianity, and it is a conventional symbol of suffering; in order for it to become a symbol, people had to adopt or accept the cross as standing for suffering. Other symbols are natural—the sun as the symbol of life and strength, a river as the symbol of eternal change and flowing, and so forth; in these cases there was no agreement (convention) as to what would stand for what, for the relation is too obvious—the symbolism is much the same in the tradition of all nations and civilizations.

Various symbols have, to varying degrees, elements of both the conventional and the natural: the eagle on the standard of the United States of America symbolizes strength—this is natural, because the eagle is strong, and conventional, because the eagle was officially adopted as the symbol of the United States. In the case of many symbols, the natural relation between symbol and thing symbolized is not strong enough by itself to achieve the symbolism, and the conventional relation was entered into in order to effect a symbolism that already had a certain natural basis. When A is a symbol of B, there must be some relation, either natural or conventional, between the symbol and what is symbolized. When the natural relation is strong, the conventional is minimal or nonexistent, and vice versa.

But there is another element in symbolism if it is to function with full-bodied effectiveness in a work of art, and that is what has been called a "vital basis" provided by history and tradition. In the U.S. flag there is very little natural basis for symbolism; it is almost wholly conventional. But the fact that it has been saluted for so long, that it has been present on battlefields, that the bodies of military dead have been wrapped in it, and so on—that is, the fact that it has acquired a life, a history—have given it an "affect" (human emotion or mood) it did not have before. Melville and Tolstoy not only represented the whale and the train: they invested these representations with such strong emotional affect that the reader is much more inclined than he would be otherwise to say that these objects are the symbols of the qualities he ascribes to them.

When some item in a work of art is construed as a symbol, it is always infused with these vital qualities. Clearly, not every case of one thing standing for something else is a symbol in this sense: a carrot in a painting does not, just by itself, symbolize growth. But barbed-wire fences do symbolize tyranny, not only because many prisoners have been enclosed in barbed-wire fences (this is the natural basis for the symbolism) but also because of concentration camps and the countless tragic events of recent history that have provided the "vital basis" for the symbolism.

Meaning. Do works of art have meaning? The answer depends once again on how the question is construed: the word "meaning" is an equivocal term that can itself mean many different things.

Clouds mean rain, a falling barometer means that a storm is coming, a twister in the sky means an approaching tornado—that is, the one is a sign of the other; these relations exist in nature and were discovered, not invented, by man. On the other hand, a bell ringing means the end of class, this note on the score means that D sharp is to be played on a certain instrument, and the word cat to someone who knows English means a certain species of domesticated quadruped; these relations are conventional, established by man. But both the natural and the conventional items are examples of meaning in its most general sense—one thing (A) standing for another (B).

Meaning in literature

Since the medium of literature is words, and words are conventional vehicles of meaning, literature has meaning in a way that the other arts do not, since every word, to be a word at all, must have a meaning. In the sense in which the word cat means something, middle C and an ellipse do not have meanings at all.

When the question is asked about meaning in art, however, it is not usually the individual ingredients in it that are being referred to: if it were, the answer could simply be, "Yes, this word has a meaning and that word has; so does the sentence as a whole; and items in paintings sometimes have meaning; for example, the halo over the Madonna's head symbolizes holiness." What is being asked is whether the work of art as a whole has a meaning. But what does the question itself mean? Several different things can be meant: (1) The inquirer may be asking, "What is it about?" in which case the question is about subject matter, already discussed. (2) He may be asking, "What is its theme?"—for example, is the motion picture *He Who Must Die* really a parable about the life of Christ? (3) He may be asking, "What is its thesis?" For example, what is the message of the Anglo-Irish author Jonathan Swift to the reader in "A Modest Proposal"? (4) The inquiry may be about the effects of a work of art on the recipient—either what these effects are or what they could or should be. In this sense, all works of art have meaning, since they all have effects (whether there is one type of effect that a given work of art should have is another question). This is, however, an extremely misleading use of the word "meaning." Indeed, the entire discussion of "meaning in art" is a most confusing one—and the fault does not lie in art, but in the human users of words. Endless unnecessary mysteries can be created by using such nebulous words as "meaning" as if they were simple, straightforward, and susceptible to one interpretation. It would contribute greatly to the clarification of discussions of philosophy of art if the word meaning were not used in them at all but some conception clearer and more specific.

ART AS EXPRESSION

The view that "art is imitation (representation)" has not only been challenged, it has been moribund in at least some of the arts for more than a century. It has largely been replaced by the theory that art is expression. Instead of reflection states of the external world, art is held to reflect the inner state of the artist. This, at least, seems to be implicit in the core meaning of "expression": the outer manifestation of an inner state. Art as a representation of outer existence (admittedly "seen through a temperament") has been replaced by art as an expression of man's inner life.

The terms "express" and "expression"

But the terms "express" and "expression" are ambiguous and do not always denote the same thing. Like so many other terms, "express" is subject to the process–product ambiguity: the same word is used for a process and for the product that results from that process. "The music expresses feeling" may mean that the composer expressed his feeling in writing the music or that the music when heard is expressive (in some way yet to be defined) of human feeling. Based on the first sense are theories about the creation of art; founded on the second are theories about the content of art and the completion of its creation.

Expression in the creation of art. The creation of a work of art is the bringing about of a new combination of elements in the medium (tones in music, words in literature, paints on canvas, and so on). The elements existed beforehand but not in the same combination; creation is the re-formation of these pre-existing materials. Pre-existence of materials holds true of creation quite apart from art: in the creation of a scientific theory or the creation of a disturbance. It applies even to creation in most theologies, except some versions of Christian theology, in which creation is *ex nihilo;* that is, without pre-existing matter.

That creation occurs in various art mediums is an obvious truth. But once this is granted, nothing has yet been said about expression; and the expressionist would say that the foregoing statement about creation is too mild to cover what he wants to say about the process of artistic creation. The creative process, he wants to say, is (or is also) an expressive process; and for expression something more is necessary than that the artist be creating something. Great care must be taken at this stage: some say that the creation of art is (or involves) self-expression; others say that it is the expression of feeling, though not necessarily of one's own feeling (or perhaps that and something more, such as the feeling of one's race, or of one's nation, or of all men); others say that it is not necessarily limited to feelings, but that ideas or thoughts can be expressed, as they clearly are in essays. But the distinctively expressionist view of artistic creation is the product of the Romantic movement, according to which the expression of feelings constitutes the creation of art, just as philosophy and other disciplines are the expression of ideas. It is, at any rate, the theory of art as the expression of feelings (which here shall be taken to include emotions and attitudes) that has been historically significant and developed: art as specially connected with the life of feeling.

When a person is said to be expressing a feeling, what specifically is he doing? In a perfectly ordinary sense, expressing is "letting go" or "letting off steam": man expresses his anger by throwing things or by cursing or by striking the person who has angered him. But, as many writers have pointed out, this kind of "expressing" has little to do with art; as the U.S. philosopher John Dewey said, it is more of a "spilling over" or a "spewing forth" than expression. In art at least, expression requires a medium, a medium that is recalcitrant and that the artist must bend to his will. In throwing things to express anger, there is no medium—or, if the man's body is called the medium, then it is something he does not have

to study to use for that purpose. It is still necessary to distinguish a "natural release" from an expression. If poetry were literally "the spontaneous overflow of powerful feelings," as William Wordsworth said, it would consist largely of things like tears and incoherent babblings. If artistic creation can plausibly be said to be a process of expression, something different from and more specific than natural release or discharge must be meant.

Emotional expression in art

One view of emotional expression in art is that it is preceded by a perturbation or excitement from a vague cause about which the artist is uncertain and therefore anxious. He then proceeds to express his feelings and ideas in words or paint or stone or the like, clarifying them and achieving a release of tension. The point of this theory seems to be that the artist, having been perturbed at the inarticulateness of his "ideas," now feels relieved because he has "expressed what he wanted to express." This phenomenon, indeed a familiar one (for everyone has felt relieved when a job is done), must still be examined for its relevance. Is it the emotion being expressed that counts or the relief at having expressed it? If the concern here is with art as therapy or doing art to provide revelations for a psychiatrist, then the latter is what counts; but the critic or consumer of the art is surely not concerned with such details of the artist's biography. This is an objection to all accounts of expression as process: how is any light at all cast upon the work of art by saying that the artist went through any expressive process or through any process whatever in the genesis of it? If the artist was relieved at the end of it, so much the better for him; but this fact is as aesthetically irrelevant as it would be if he had committed suicide at the end of it or taken to drink or composed another work immediately thereafter.

Another problem should be noted: assuming that the artist does relieve his oppressed state of mind through creating, what connection has this with the exact words or score or brushstrokes that he puts on paper or canvas? Feelings are one thing, words and visual shapes and tones are quite another; it is these latter that constitute the art medium, and in it that works of art are created. There is doubtless a causal connection between the feelings of the artist and the words he writes in his poem; but the expression theory of creation talks only about the artist's feelings, while creation occurs within the art mediums themselves; and to speak only of the former is not to tell anything about the work of art—anything, that is, that would be of interest other than to the artist's psychiatrist or biographer. Through what paroxysms of emotion the artist passed does not matter anymore, insofar as one's insight into his work is concerned, than knowing that a given engineer had had a quarrel with his wife the night before he began building his bridge. To speak of anything revelatory of works of art, it is necessary to stop talking about the artist's emotions and talk about the genesis of words, tones, and so on—items in the specific art mediums.

Distinction between art and craft

The expressionists have indeed brought out and emphasized one important distinction: between the processes involved in art and in craft. The activity of building a bridge from the architect's blueprint or constructing a brick wall or putting together a table just like a thousand others the artisan has already made is a craft and not an art. The craftsman knows at the beginning of the processes exactly what sort of end product is wanted: for example, a chair of specific dimensions made of particular materials. He knows at the beginning how much material it will take to do the job, which tools, and so forth, and, if he does not know these things, he is not a good (efficient) craftsman. But the creative artist cannot work in this manner: "The artist doesn't know what he is going to express until he has expressed it" is a watchword of the expressionist. He cannot state in advance what the completed work of art will be like: the poet cannot say what words will constitute the completed poem or how many times the word "the" will occur in it or what the order of the words will be—when he knows that, he has completed the creation of the poem, and until then he cannot say. Nor could he set about working with such a plan: "I shall compose a poem that contains the word 'the' 563 times, the word 'rose' 47 times," and so on. What distinguishes art from craft is that the artist, unlike the craftsman, "does not know the end in the beginning"; he cannot state until his work is finished what the completed product will be like—if he could, he would not have to undergo the "divine agonies" of creation in order to produce it.

The distinction seems valid enough, but whether it supports the expressionist's view is more dubious; for it can be held regardless of the attitude assumed toward the theory of expression. The open-ended process described as art rather than craft characterizes all kinds of creation: of mathematical hypotheses and of scientific theory, as well as art. What distinguishes creation from all other things is that it results in a new combination of elements, and it is not known in advance what this combination will be. Thus, one may speak of creating a work of sculpture or creating a new theory, but rarely of creating a bridge (unless the builder was also the architect who designed it, and then it is to the genesis of the idea for the bridge, not to its execution, that the word creation applies). This, then, is a feature of creation; it is not clear that it is a feature of expression (whatever is being done in expressing that is not already being done in creating). Is it necessary to talk about expression, as opposed to creation, to bring out the distinction between art and craft?

There does not seem to be any true generalization about the creative processes of all artists nor even of great artists. Some follow their "intuitions," letting their artistic work grow "as the spirit moves" and being comparatively passive in the process (that is, the conscious mind is passive, and the unconscious takes over). Others are consciously active, knowing very much what they want in advance and figuring out exactly how to do it (for example, the 19th-century U.S. writer Edgar Allan Poe in his essay "The Philosophy of Composition"). Some artists go through extended agonies of creation (the 19th-century German composer Johannes Brahms, weeping and groaning to give birth to one of his symphonies), whereas for others it seems to be comparatively easy (Mozart, who could write an entire overture in one evening for the next day's performance). Some artists create only while having physical contact with the medium (for example, composers who must compose at the piano, painters who must "play about" in the medium in order to get painterly ideas), and others prefer to create in their minds only (Mozart, it is said, visualized every note in his mind before he wrote the score). There appears to be no true generalization that can be made about the process of artistic creation—certainly not that it is always a process of expression. For the appreciation of the work of art, no such uniformity, of course, is necessary, greatly though it may be desired by theorists of artistic creation.

Problems in drawing conclusions about the creation of art

The main difficulties in the way of accepting conclusions about the creative process in art are (1) that artists differ so much from one another in their creative processes that no generalizations can be arrived at that are both true and interesting or of any significance; and (2) that in the present stage of psychology and neurology very little is known about the creative process—it is surely the most staggeringly complex of all the mental processes in man, and even his simpler mental processes are shrouded in mystery. In every arena hypotheses are rife, none of them substantiated sufficiently to compel assent over other and conflicting hypotheses. Some say—for example, Graham Wallas in his book *The Art of Thought*—that in the creation of every work of art there are four successive stages: preparation, incubation, inspiration, and elaboration; others say that these stages are not successive at all but are going on throughout the entire creative process, while still others would produce a different list of stages. Some say that the artist begins with a state of mental confusion, with a few fragments of words or melody gradually becoming clear in his mind and the rest starting from there, working gradually toward clarity and articulation; whereas others hold that the artist sets him-

self a problem, which he gradually works out during the process of creation, but his vision of the whole guides his creative process from its inception. The first view would be a surprise to the dramatist who sets himself from the beginning to write a drama in five acts about the life and assassination of Julius Caesar; and the second would be a surprise to artists like the 20th-century English artist Henry Moore, who has said he sometimes begins a drawing with no conscious aim but only the wish to use pencil on paper and make tones, lines, and shapes. Again, as to psychological theories about the unconscious motivations of artists during creation, an early Freudian view is that the artist is working out in his creation his unconscious wish fulfillments; a later Freudian view is that he is engaged in working out defenses against superego charges, "proving something to himself." Views based on the ideas of the 20th-century Swiss psychologist Carl Jung reject both these alternatives, substituting an account of the unconscious symbol-making process. Until a great deal more is known about the empirical sciences that bear on the issue, there is little point in attempting to defend one view of artistic creation against another.

The expressive product. Although talk about expression as a process is hedged with difficulties and in any case seems irrelevant to the philosophy of art (as opposed to the psychology of art), there is another way in which talk about expression may be both true and important to the philosophy of art. Mention is made about expressive properties as belonging to works of art: for example, it is said that a certain melody expresses sadness, that there is a feeling of great calm expressed in a particular painting, or that tension is expressed in the thrusts of a tower or the development of the plot of a novel or drama.

Metaphorical expression of emotion

The question arises at once of what it means to say such things. Melodies and sentences are not joyous or tense or melancholy; only persons have these qualities. The artist can have them, but how can the work of art? Clearly, to speak of a work of art as having emotions, if it is not to be utter nonsense, must be metaphorical. But what is the meaning of this metaphor? What does it mean to say that the music expresses sadness, if not in the sense of process; *i.e.*, that in writing it the composer expressed his sadness?

The music is heard, the painting is seen; each presents itself to the senses. But there is much more involved in music than simply hearing (or even listening to) the sounds and in visual art than simply seeing (or even looking at) the colours and shapes. Even very simple combinations of sounds and shapes and colours seem to express certain qualities of life: a curved line, it is said, is graceful or sprightly; the drooping willow tree is sad, as are certain passages in music. It is virtually impossible for most persons to view art as a series of sensory stimuli only. Even when a picture contains no story, no plot, no program, the viewer "reads into the script": he attributes to works of art qualities of human moods, feelings, emotions—in short, "affects." It would be safe to say that in all art, every percept is suffused with affect. The problem is: What is it that makes certain percepts expressive of certain affects?

The simplest answer, that "The melody is sad" means no more or less than "Hearing the melody makes me (or other listeners, or most listeners) feel sad," is surely inadequate. (This would be a theory of evocation, not of expression.) "The music expresses whatever feelings it arouses in me when I hear it." But often the listener does not feel emotions at all (he may imagine them), or, if he does, he feels very different emotions from the ones he believes to be expressed in the music. He may consider the rondo delirious with joy, but if he is grief stricken on a given day he hears it without feeling joy; and if he has heard the same rondo 30 times that day he feels only boredom or fatigue, while still believing that the piece is expressive of joy. Nor is it an adequate analysis to say that "The melody expresses joy" means "I am disposed to (or inclined to) feel joy when I hear it," for many people seem to recognize joy as a quality of the music without feeling it at all: or they may imagine it or just recognize the emotion without feeling it or believe that what they hear sounds the way joy feels—or any of a number of other accounts.

The true analysis of expressiveness in art must be more complex than this: it is not that the melody evokes emotion X, but that emotion X is somehow embodied in the music. But this leads back again to the question, how can an emotional quality be in a work of art? There is no single answer to this question that would be accepted by all philosophers of art, but most accounts begin by noting certain similarities, or analogies, between features of music and features of human feeling; so that when X (a passage of music, for example) is said to express Y (a state of feeling), there are certain similarities (for example, of structure) between X and Y. The physical accompaniments to a mood, say, of restlessness, such as rapid breathing and drumming fingers, have their musical equivalents: trills, quavers, increases in tempo, and the like.

Emotional qualities embodied in art

When a listener says that a certain melody is sad, he is saying that the music literally has certain qualities A, B, C, D that can be perceived in the music. Slowness is surely one such quality (the same melody played fast would not be called sad); another is the absence of large intervals between tones; another is that the sounds tend to be hushed rather than, for example, strident; another is that the tendency of the musical movement is downward rather than rising. When a listener says that the music is sad, he is saying that it has these qualities.

But why these qualities rather than others? Why is it said that the music is sad when it has A, B, C, D rather than when it was M, N, O, and P? Because A, B, C, D are the qualities that also characterize people when they are sad, such as slowness and soft and low speaking voices. If this theory or anything like it is true, it explains how emotional characteristics can be attributed to works of art—why it can be said that the melody is sad, that the horizontal lines in a painting make it calm (horizontal being the position of rest and peace, sleep and maximum relaxation, and from which one does not fall), why the lines in a painting are droopy (they are lines similar in shape to that of, say, an old woman with hunched shoulders), and so on. These qualities, it should be noted, are qualities of the work of art, not of the artist (whether he was sad when he wrote sad music is a separate question, to which the answer may sometimes be no) and not of the listener or observer (the melody is sad even if I am not sad when I hear it). They are, so to speak, embodied in the music, quite independently of the state of the artist or of the observer, or listener, though of course it requires the presence of a listener to recognize them and be moved by them.

Talk about artistic expressiveness, then, can be justified. But there is no need to resort to the language of expression in order to state it: instead of saying, "The music expresses sadness," it can simply be said, "The music is sad." But regardless of the terminology employed, it is important to have justified this conclusion.

ART AS FORM

The formalist position. Against all the foregoing accounts of the function of art stands another, which belongs distinctively to the 20th century—the theory of art as form, or formalism. The import of formalism can best be seen by noting what it was reacting against: art as representation, art as expression, art as a vehicle of truth or knowledge or moral betterment or social improvement. Formalists do not deny that art is capable of doing these things, but they believe that the true purpose of art is subverted by its being made to do these things. "Art for art's sake, not art for life's sake" is the watchword of formalism. Art is there to be enjoyed, to be savoured, for the perception of the intricate arrangements of lines and colours, of musical tones, of words, and combinations of these. By means of these mediums it is true that objects in the world can be represented, scenes from life depicted, and emotions from life expressed; but these are irrelevant to the principal purpose of art—indeed, art is much less adapted to the telling of

"Art for art's sake"

a story or the representation of the world than it is to the presentation of colours, sounds, and other items in the art medium simply for their own sake.

Most people who claim to enjoy paintings, for example, enjoy them not as presentations but as representations of things and situations in life; and thus their response is not of a kind that is unique to art, but one that takes them back to the emotions of life, from which they came. They could use art to take them into a realm of pure form unknown to anyone who is unacquainted with art; but instead they use it to direct them back to the feelings and situations of life. Thus, according to the formalists, these viewers miss the opportunity of being taken into a fresh world of purely aesthetic experience and get from a work only what they bring to it: familiar experiences and emotions they employ the work to recall.

What, then, should be brought from life to art? Knowledge of life's struggles and emotions? Knowledge at least of what people are like, and what visual objects look like? Not even these things, for even they get in the way. Representation is not bad in itself, it is merely irrelevant. Only if the representation is satisfactory as form and contributes to the general abstract design can it be said to matter aesthetically.

Most formalists have directed their attention primarily to visual art. The prerequisite for appreciating this, they believe, is a sense of form and colour and a knowledge of three-dimensional space (the last required because otherwise a cube, for example, would appear in a painting as a flat pattern and would be unable to play the architectural role intended for it). Armed with this bit of knowledge from life, they have all they need (as far as knowledge of the world outside art is concerned) for appreciating visual art. Armed with more than this, they would find their attention drawn away from the sublimities of art to the more approachable concerns of humanity (such as representation). Shorn of this extraneous knowledge and coming to painting with eyes innocent of extraneous concepts, the viewer could then be in a position to look at what painting presents directly to his vision—complex arrangements of forms and colours—which, for reasons thus far unexplained, have the capacity to move the recipient deeply with emotions utterly alien to the emotions of life.

The formalist's account of music runs along similar lines: not only representation (program music) is excluded but so is the entire realm of human feeling—not the feeling that the contemplation of pure form can give but only the feelings of life, such as love or terror. As to literature and all those arts in which words play a part (song, opera, drama, cinema), the formalist position would seem to be impossible; and indeed formalists have seldom attempted to extend their theory to literature. The medium of literature is words and sentences; and words and sentences are not merely noises but noises with meanings; and these meanings inevitably have to do with the objects, actions, qualities, and situations of life. As sound, literature is a poor thing—as a complex of meanings, it can be profound and beautiful. Take these away, and literature could cease to be. Literature does have formal properties—a drama can be as tightly knit as a fugue or a symphony—but the appreciation of it can never consist of these formal properties alone; and the reason lies in the very nature of the medium. It is the role of words to indicate images and meanings and emotions, and these are the stuff of life—therefore verbal art is inescapably humanistic. Whatever sensory beauty words have in their sounds is slight and secondary; not so with painting, where colour, line, and space have a beauty all their own and need stand for nothing outside themselves to satisfy the eye.

Inapplicability of the formalist position

Formal principles in art. What, then, are the specific qualities in works of art that the formalist is seeking? Most formalists have held that a partial account can be given of these but that, in the end, the presence of the qualities must be felt intuitively and cannot be described. Accounts of formal qualities in works of art go back as far as Aristotle's *Poetics*, written in the 4th century BC, and usually include (though sometimes in different terminology) the following as principal ingredients:

Organic unity. A work of art must have what Aristotle called "a beginning, a middle, and an end"; it must be unified, it must "hang together" as one entity. Everything, of course, has some degree of unity or other; even a collection of things, such as a woodpile, has some unity inasmuch as it can correctly be called one thing: it is a collection, but it is a single collection. But the unity desired in works of art is much greater than this: it is more like the unity of the higher organisms in which every part functions not independently of the others but interdependently with them; and it is this interdependency of the parts that constitutes an organic unity. Take away one part, and the remainder of the parts fail to function as before. This is only approximately true of organisms: without a heart or a brain a person could not continue to exist, and the activity of the other organs would cease; but without an ear or a toe they surely would. Philosophers of art have often noted that the purest examples of organic unity in the universe are not organisms but works of art: here the interdependency of parts often achieves a state of such perfection that it could often be said, of a melody or a sonnet, that if this note (or word) were not there, in just the place that it is, the effect on the entire remainder of the melody or poem would be disastrous.

Complexity, or diversity. This principle is the natural accompaniment of the first one. A blank wall has unity but no variety and is not long worth contemplating. Nor is there any triumph in achieving unity at so small a price. The work of art must hold in suspension (as it were) a great diversity of elements and unify them—the greater the complexity that is integrated into a unity, the greater the achievement. This fact is so universally recognized that the two criteria are often stated as one, unity-in-diversity, or variety-in-unity.

Unity-in-variety in works of art

Very many great works of art are much less than perfect organic unities (which is another way of saying that unity-in-variety is not the only criterion for excellence in works of art). Particularly in long poems or novels or operas, some parts are clearly more important than the others, though contributing to the whole, and some parts may be simply "padding." One could hardly allege that the entire ancient Greek epic the *Iliad* is an organic unity and that if (for example) the catalog of ships were removed the entire epic would be ruined (some even say it would be improved). In Dostoyevsky's novels there are whole chapters that are unnecessary from the point of view of relevance to the rest of the story, and, aesthetically (though perhaps not in other ways), these are a pure excrescence. In most works of art there are high spots and low spots, and there is a great deal of elasticity as to what could follow what. But in spite of this, unity-in-variety is quite universally recognized as a criterion for artistic excellence. If a drama consisted of two plots that never connected with one another, even at the end, such a play would be condemned at once for lack of unity; and a work of art is never praised for being disjointed or disunified, though it might be praised in spite of being disunified.

Theme and thematic variation. In many works of art there is a dominant theme, or motif, which stands out and upon which the other portions are centred. This theme is then varied in different ways in other portions of the work. This is a special case of unity-in-variety: if every line in a work of music or literature were entirely novel and different from the other ones, there would be enormous diversity but no unifying connecting links; whereas if there were simply a repetition of the initial theme or of entire sections of the work (as sometimes happens when a composer does not know how to develop the thematic material with which he has begun) there is unity but no variety. Both unity and variety are preserved by having central themes, with other material that is related to them (unity) but not identical with them (variety).

Development, or evolution. In works of temporal art, each part develops or evolves into the next, each part being necessary to the succeeding part, so that if an ear-

lier part were altered or deleted, all the subsequent parts would have to be altered in consequence. If a portion of Act IV could be interchanged with a portion of Act II without loss of effect, the principle of development has not been observed, for then the material occurring in between would not have made any difference.

Balance. The arrangement of the various parts should be balanced, usually in contrasting ways (the adagio movement coming between two faster movements, for example). In painting, there should be a balance between the right and left halves of the canvas. The many ways, other than simple mechanical symmetry ("for every item on the left there should be an item on the right," which soon becomes monotonous), in which a painting may have variety and yet retain balance are too complex to be discussed other than in a book of art criticism. But in its simplest essentials, the principle is acknowledged by everyone: the housewife who places all the furniture on one half of the living room while leaving the other half empty finds the arrangement aesthetically displeasing because the room lacks balance.

Generalizations based on formal principles

There are many descriptions of principles of form in art, which differ from one another in their terminology more than in their final outcome. In general, however, few if any of these principles would be denied (only the detail of their formulations might be) by most philosophers of art. Why certain principles of form are found satisfactory and others are not is a fascinating psychological question, leading back to a discussion (necessarily vague in the present state of knowledge) of the nature of the human organism and the discriminatory powers of the human mind. But however obscure the explanation, the facts of the case seem clear enough: certain formal principles in art must be observed, and, to the degree that they are ignored or violated, aesthetic catastrophe occurs: the work of art cannot evoke our interest or sustain it long once it is initiated.

Though a discussion of these formal principles is helpful particularly to those who have little native sense of form and who want "to know what to look for" in art, they are sufficiently vague so that many critics can agree on a formal principle, such as unity, and yet disagree on the degree to which a specific work possesses it.

In addition, these principles are far from complete: a work of art can possess unity and the other requirements in high degree and yet be unsuccessful even as form. The requirements listed seem only to have skimmed the surface. Yet what more is required to distinguish a formally correct but dull work of art from a brilliant one seems to defy precise analysis. Moreover, the majority of critics who have assented to these principles are not formalists: they have acknowledged and even insisted on the great importance of form in works of art, but they have not alleged, as formalists do, that these principles constitute the sole criteria of excellence in works of art. They have held that the fulfillment of formal criteria counts as a necessary condition for artistic excellence but not a sufficient condition.

PRAGMATIC THEORIES OF ART

There are theories of art that differ from one another in what they allege to be the real purpose or function of art but are at one with each other in the belief that art is a means to some end, whether that end be the titillation of the senses or the communization of the nations of the world or the conversion of mankind to belief in God or the improved moral beliefs or moral tone of the reader or viewer. In every case, the work of art is considered as a means to some end beyond itself, and hence what counts in the final analysis is not the nature of the work of art itself but its effects upon the audience—whether those effects be primarily sensory, cognitive, moral, religious, or social.

Hedonistic theories of art. According to one kind of theory, the function of art is to produce just one kind of effect upon its audience: pleasure. It may also inform or instruct, represent or express, but first and foremost it must please. The more pleasure it gives, the better the art.

If the theory is left in this simple form, it yields the result that glossy and superficial works and those containing nothing difficult or obscure are the best works of art: thus, on the hedonistic account, *King Lear* might come out far behind Henry Wadsworth Longfellow's *The Song of Hiawatha*, or Joyce Kilmer's "Trees," in view of the difficulty of comprehending Shakespeare by many people and the pleasant, easy lilting quality of Longfellow's poem; and similarly a simple ditty might come out ahead of Bach's *Mass in B Minor*. True, Shakespeare and Bach might produce more pleasure in the long run since their works have endured through more centuries. But on the other hand, the simple works can be apprehended and enjoyed by vastly more people.

The meaning of "aesthetic pleasure"

In any case, the theory has often been amended to read "aesthetic pleasure" rather than simply "pleasure"—thus placing great importance on exactly how the term "aesthetic" is to be defined. The definition of this troublesome term is beyond the scope of this article (see AESTHETICS); it will simply be said here that no quick and easy way of distinguishing aesthetic pleasures from other pleasures will suffice for the task at hand. If it is said, for example, that aesthetic pleasure consists in satisfaction taken in the contemplation of sensuous particulars (tones, colours, shapes, smells, tastes) for their own sake—that is, for no further end and without ulterior motive—then one confronts the fact that as much pleasure may be taken in single smells and tastes for their own sakes, without any reference beyond them, as may be taken in the most complex works of art. For that matter, pleasure in playing a game (one not played for money) is pleasure in doing something for its own sake, as is the pleasure of robbing a house if it is done not for money but for "kicks." If something is found pleasurable, ordinarily the pleasure is what one wants from it, not something else beyond it.

Moreover, if it is said that a work of art should be a means toward pleasure, that is treading suspiciously near to the opposed view that art should not be a means to an end but an end in itself. If someone says, "Why do you go jogging every morning for three miles? Because you feel the exercise is good for you?" and another person answers, "No, not that at all, I just enjoy doing it," this would ordinarily and quite sensibly be taken as saying that he did not do exercise as a means toward an end but as an end in itself. If something is done just because it is enjoyed, in common parlance this would be taken to be "doing it as an end in itself"; and if one objected, "No, I'm not doing it as an end in itself, I'm doing it as a means toward the enjoyment I'll get out of it," his reply would be considered sophistical, for doing it for enjoyment's sake is precisely what is ordinarily meant (or one thing that is ordinarily meant) by the statement that a thing is being done for its own sake.

In any case, the effect of great works of art upon a reader or viewer or listener can hardly be described as merely hedonistic. No one would presumably wish to deny that art can and should give us pleasure; but few would wish to assert that pleasure is all that it should give us. If one were to ask, "How did viewing Picasso's 'Guernica' affect you?" and the reply was, "I found it pleasant," we would conclude that his reaction to the painting was, to say the least, inadequate. Great art may please; it may also move, shock, challenge, or change the lives of those who experience it deeply. Pleasure is only one of many kinds of effects it produces.

Art as a means to truth or knowledge. One of the things that has been alleged to be the purpose of art is its cognitive function: art as a means to the acquisition of truth. Art has even been called the avenue to the highest knowledge available to man and to a kind of knowledge impossible of attainment by any other means.

Knowledge in the most usual sense of that word takes the form of a proposition, knowing that so-and-so is the case. Thus, it can be learned from sense observation that the sun is setting, and this is knowledge. Is knowledge acquired in this same sense from acquaintance with works of art? There is no doubt that there are some propositions (statements) that can be made after acquaintance with works of art that could not be made before: for ex-

ample, that this performance of Beethoven's *Eroica Symphony* was 47 minutes long, that this painting predominates in green, that this piece of sculpture originated around 350 BC. The question is whether there is anything that can be called truth or knowledge (presumably knowledge is of truths, or true propositions) that can be found in works of art.

The cognitive function of literature

Literature is surely the most obvious candidate; for literature consists of words, and words are combined into sentences, and sentences (at least declarative sentences) are used to convey propositions; that is, to make assertions that are either true or false. And works of literature do certainly contain many true statements: a novel about the French Revolution conveys facts about the series of events; in a verse of the English scholar and poet A.E. Housman (1859–1936), it is said that "The tears of all that be/ Help not the primal fault." Since literature contains statements, it would be surprising indeed if at least some of them were not true.

But the relevance of this fact to literature as an art is extremely dubious. If an 18th-century novel gives a true picture of English country life of that time, this makes it useful to read as history; does it also make it a better novel? Many, at any rate, would say that it does not: that a tenth-rate novel might give more facts about 18th-century life than a first-rate novel of the same century. For that matter, many of the propositions in a novel are, taken at face value, false; it is false, for example, that there was a foundling named Tom Jones who had an uncle named Squire Western. The thousands of pages of description in novels of fictional characters, ascribing to them thoughts and actions, are all false, since these characters never actually existed. Yet this fact in no way impugns their value as literature. Shakespeare, in *The Winter's Tale*, sets part of the action on the seacoast of Bohemia; but the fact that Bohemia has no seacoast does not damage *The Winter's Tale* as literature, though it would as geography. The fact that Milton used the outdated Ptolemaic astronomy does not make *Paradise Lost* less valuable, nor does the nonexistence of the lands described in *Gulliver's Travels* in any way diminish Swift's work. There is no doubt, then, that works of literature can contain true statements and false ones; but it is tempting to ask, what does their truth or falsity matter? Literature is not astronomy or geography or history or any branch of knowledge, particular or general.

Many would hold that the above statements are indeed irrelevant, as are any that encroach upon the domain of science; but, they would add, there are other assertions that matter a great deal: for example, the statements in which a world view is presented in a poem or drama or novel. The main burden of the ancient Latin poet Lucretius' *De rerum natura* ("On the Nature of Things") is a presentation of the materialism of the Greek philosopher Democritus; and an embodiment of the world view of medieval Catholicism is the very warp and woof of Dante's *Divine Comedy*—and such considerations (it would be contended) are relevant to these works as literature.

In reply, however, it might be said that while it is true that these world views must be understood and taken into consideration in the reading of these poems and that they cannot be understood or appreciated without knowing them, the truth or falsity of these views still does matter aesthetically. If Lucretius' view is true, then Dante's must be false, and vice versa, since they are incompatible; but in order to appreciate the poem it is not necessary to know which (if either) is true. Appreciating art, unlike taking a stand for or against a cause in life, does not require a yes or no to statements. It requires only that the viewer look and appreciate, that he experience as richly and fully as possible the feelings and attitudes involved in the world view that is presented. Philosophers and scientists are concerned with whether the Democritean materialism of Lucretius is true; appreciators of art are concerned only to capture the feeling appropriate to the world view in question.

Many statements in works of literature are not explicitly made at all but are implicit: Hardy never tells in his novels what his world view is, but it emerges rather clearly before the reader is halfway through any of them. Probably the most important points made in works of literature that contain a central thesis are implicit rather than explicit. How, in that case, can it be determined what thesis it is that is implied? In a court of law, if someone says, "He didn't say it exactly, he just implied it," the judge would be likely to rule that this was insufficient evidence of slander, since the person did not actually say it. Still, many statements in daily life are not stated but implied—in the sense that they are intended; the trouble lies in proving that the speaker intended them, since no one else is in a comparable position to say what his intentions were; and, in the case of deceased authors, there is no evidence of their intentions other than what they said. One is doubtless on safer ground, therefore, saying that many statements are implied in the sense that they are suggested (whether the speaker intended to do so or not) by the tone of voice and the juxtaposition of the words used. Thus, "They had children and got married" suggests, though it does not state, that they had the children before they were married; any normal user of the English language would tend to construe it thus. And it is surely no overstatement to say that Swift's *Gulliver's Travels* suggests that the author was misanthropic or that the novels of the French author Marcel Proust (1871–1922) suggest a pessimistic view of love and other human relationships close to that of the German philosopher Arthur Schopenhauer (1788–1860). A serious reader of literature will become increasingly sensitive to what is suggested in the works he is reading.

Explicit and implicit statements in literature

But, once again, the importance of the suggested statements, even when they are true, in no way shows that they must be accepted as true by the reader if he is to value them as works of art. Is the sincere Roman Catholic who finds Dante's world view congenial and Lucretius' repellent committed to saying that Dante's is the better poem? If so, he may be accused of confusing his moral and theological judgments with his aesthetic ones. Still, it should be noted that there are some critics who believe that if two works of literature are both equal in excellence on all counts, yet one presents a true view of reality and the other fails to, the one presenting a true view is better—better even as a work of art—than is the other one.

There is, however, another way of talking about truth in literature that is not or is not as obviously connected to propositions. A characterization in a novel or drama is spoken of as being true to human nature, true to the way people actually speak or behave or feel. No matter that Becky Sharp—in the English novelist William Thackeray's *Vanity Fair*—is a fictional character, it would be said, as long as she is depicted as a person of a certain type would behave, she is being depicted truly; truth in fiction does not mean truth of the statements (for the statements in Thackeray's novel describing her are false), but truth to human nature.

The notion of "truth to human nature" in literature

But what exactly does "truth to human nature" mean? The criterion is as old as Aristotle, who wrote that poetry is more true than history because it presents universal truths whereas history gives only particular truths and that poetry (dramatic fiction) shows how a person of this or that kind probably or necessarily would behave (or think, or feel). This criterion, however, is too vague as it stands: what is probable or plausible behaviour in one person is not in another, and what is probable in one set of circumstances is not so in another. The test of truth to human nature would be roughly as follows: Would a person such as has been described thus far (in the novel or drama) behave (or think or feel or be motivated) in the way that the author depicts this character as behaving in the circumstances described? It is often very difficult to decide this question, because knowledge of human beings is insufficient or because the dramatist himself has not provided enough clues. Still, once readers or critics are convinced that the character described would not have behaved as the novelist depicts him as behaving, they may criticize the characterization (at least with regard to this bit of behaviour or motivation) as implausi-

ble. If a character who has been described as spending years working toward a certain goal is represented by the novelist as abandoning it once he is within sight of it, the reader will have considerable reservations about this delineation unless the author has depicted the character as being unstable or masochistic or in some way as being the kind of person who might in these circumstances do this kind of thing. It is true that there are people in the world who abandon their goals within sight of them after years of labour, but the conviction must be implanted that the character already presented by the novelist belongs to this classification or the behaviour will seem reasonless and unmotivated.

Is truth to human nature aesthetically relevant? That is, when present does it make the work of literature better and when absent or flawed does it make the work worse as literature? Here again there would be some difference of opinion, but a very large number of critics and aestheticians, in the tradition of Aristotle, would say that it matters aesthetically a great deal. The novelist does not have to be true to geography or history or astronomy, but he must be, as the 19th-century U.S. author Nathaniel Hawthorne said of all literary artists, true to the human heart. A literary artist may tamper with all the other truths with impunity, but not this one: his characters must be convincing, and they will not be convincing if they are not depicted as having anger, love, jealousy, and other human emotions that real people have and in pretty much the contexts in which real people have them. If a novelist's characters were not motivated in much the way that human beings are motivated, the reader would not even be able to understand them—they would be alien and unintelligible to him. Even when a writer (such as the Englishman Kenneth Grahame in *The Wind in the Willows*) depicts animals as central characters in novels, however much they may differ from human beings in external appearance, they must psychologically be presented as human beings—how else and in what other terms could their behaviour and their motivation be understood? Such, then, are the reasons for saying that whatever else a literary artist does, his depictions must be truthful to human nature.

Truth to human nature in arts other than literature

Can works of art other than literature possess truth to human nature? It would seem that in a limited degree they can. Motion pictures and operas and other mixed arts clearly can, but they employ words, and literature is a principal ingredient in them. But what of arts that employ no words at all? Painting and sculpture, not being temporal arts, cannot depict action, and action is all-important in the representation of human character. These arts contain depictions of persons (real or imaginary) only in a knife-edge of time. Still, sometimes something may be inferred even from a knife-edge. The late self-portraits of the 17th-century Dutch artist Rembrandt do seem to reveal an agonized yet sometimes serene inner spirit, suggesting that there are flashes of human insight to be found in depictions of human beings in visual art. As for musical art (music without the accompaniment of words), it contains nothing that could be called depiction, not even depiction at a knife-edge of time; and, if this is so, there can be no such thing here as true depiction or false depiction. Music may be expressive of human feelings, in the sense already described, but this is a far cry from saying that it contains depictions that are true to human nature.

Even if truth to human nature in the depiction of character is aesthetically relevant (which many would question), to say this is still far from saying that it is the only criterion for excellence in works of art, or even that this is the principal thing that art gives or its main excuse for being. To go so far would be to discount colour and form and expressiveness as criteria for excellence in art; and this virtually no one is willing to do. It would seem, then, that in no case is truth (even truth to human nature) necessary in works of art, seeing that entire genres of art, such as music, exist without it; and that even when it is present and when its presence increases the merit of a work of art (which again many would deny), it is only one virtue among many. Thus, the view that the purpose or function of art is to provide truth is quite surely mistaken; perhaps the person who wants truth and is indifferent to the presence of anything else had better turn to science or philosophy rather than to the arts.

Art as a means to moral improvement. To say that a work of art is aesthetically good or has aesthetic value is one thing; to say that it is morally good or has a capacity to influence people so as to make them morally better is another. Yet, though the two kinds of judgments differ from one another, they are not entirely unrelated. Three views on the relation of art to morality can be distinguished:

Moralism. According to this view, the primary or exclusive function of art is as a handmaiden to morality —which means, usually, whatever system of morality is adhered to by the theorist in question. Art that does not promote moral influence of the desired kind is viewed by the moralist with suspicion and sometimes with grudging tolerance of its existence. For art implants in people unorthodox ideas; it breaks the molds of provincialism in which people have been brought up; it disturbs and disquiets, since it tends to emphasize individuality rather than conformity; and works of art are often created out of rebellion or disenchantment with the established order. Thus, art may undermine beliefs and attitudes on which, it is thought, the welfare of society rests and so may be viewed with suspicion by the guardians of custom. When art does not affect people morally one way or the other (for example, much nonrepresentational painting), it is considered a harmless pleasure that can be tolerated if it does not take up too much of the viewer's time; but, when it promotes questioning and defies established attitudes, it is viewed by the moralist as insidious and subversive. It is viewed with approval only if it promotes or reinforces the moral beliefs and attitudes adhered to by the moralist.

Plato's moralistic view of art

Plato is the first champion in the Western world of the moralistic view of art—at least in *The Republic* and *Laws*. Plato admired the poets and was himself something of a poet; but, when he was founding (on paper) his ideal state, he was convinced that much art, even some passages in Homer, tended to have an evil influence upon the young and impressionable, and accordingly he decided that they must be banned. Passages that spoke ill or questioningly of the gods, passages containing excessive sexual passion (and all works that would today be described as pornographic), and even passages of music that were disturbing to the soul or the senses were all condemned to the same fate. Plato's concern here was with the purity of soul of the men who would become members of the council of rulers of the state; he was not concerned with censorship for the masses, but, since one could not predict which young people would pass the series of examinations required for membership in the council of rulers and since it was (and is) practically impossible to restrict access to works of art to a certain group, the censorship, he decided, would have to be universal. The objection might be raised, to be sure, that rulers to be should not be hothouse plants separated from the influences of the outside world and that they would be better off facing all of reality, including its evils. But Plato's view was that these influences should be kept from them during their formative years—that during this critical time, when the whole tenor of their lives was being shaped, art could be an influence for evil and had to be sacrificed in the interests of morality. In other dialogues of Plato, such as the *Ion* and the *Phaedrus*, when he was not concerned with building a state, he extolled the virtues of art and even held the artist to be divine (although madly divine); but when it came to a conflict between art and morality, it was art that would have to go.

Tolstoy's moralistic view of art

The most famous champion of the moralistic view of art in modern times is Tolstoy. Long after he had finished writing his novels, he fell under the influence of primitive (prechurch) Christianity, the principal tenet of which was the brotherhood of all mankind. This one idea became such an obsession with him that everything else, includ-

ing the pursuit of art to which he had devoted his life, became subordinate to it. Almost all the literature of his own time, including all his own novels, he condemned as inimical to the brotherhood of man by emphasizing class distinction and pitting one group of mankind against another. Even art that appealed primarily (in his opinion) to "upper class" tastes, such as the symphonies of Beethoven and the operas of Richard Wagner, both 19th-century German composers, were condemned as "false art." The art that remained after these colossal excisions included such items as folk songs that peasants might sing in the fields as they worked and pictures and stories either illustrating the tenets of primitive Christianity or fostering the spirit of Christianity by promoting the brotherhood of all mankind.

The moralistic view of art is still, on the whole, the unarticulated view of art held by the masses, particularly when they are under the sway of a dominant religious or political doctrine. Historically, Christianity has been suspicious of all art except those works that depicted some aspects of biblical history or could be used to further the spread of Christian belief and practice (although this is no longer strictly true). It would probably be fair to say that the view of art held by the Soviet government is a moralistic one: works of fiction and poems must praise Communism or further its doctrines, and works of music must be melodic and singable (Soviet composers such as Dmitry Shostakovich have often been condemned by the official hierarchy as "too German" or "too materialistic"). Whenever a culture or nation is under the sway of a dominant view, whether moral or religious or political, the tendency of the rulers of that nation is to promote it at all costs—and one of the casualties in the process is art, at any rate that great body of art that is either indifferent or hostile to the reigning dogma.

Aestheticism. Diametrically opposed to the moralistic view is aestheticism, the view that instead of art (and everything else) being the handmaiden of morality, morality (and everything else) should be the handmaiden of art. The proponents of this view hold that the experience of art is the most intense and pervasive experience available in human life and that nothing should be allowed to interfere with it. If it conflicts with morality, so much the worse for morality; and if the masses fail to appreciate it or receive the experience it has to offer, so much the worse for the masses. The vital intensity of the aesthetic experience is the paramount goal in human life. If there are morally undesirable effects of art, they do not really matter in comparison to this all-important experience which art can give. When the son-in-law of the 20th-century Italian dictator Benito Mussolini waxed lyrical in his description of the beauty of a bomb exploding in the midst of a crowd of unarmed Ethiopians, he was carrying to its fullest extent the aestheticist's view of art.

Aesthetic values versus moral values

Few persons would wish to go so far. Even the most ardent lovers of art would stop short of saying that the value of art holds a monopoly over all other values. It may well be that the experience of works of art is the greatest experience available to human beings (though this, too, could be questioned), but at any rate it is not the only one available, and, this being the case, the others should be considered as well. There is a plurality of values; and aesthetic values, although far greater, admittedly, than most persons realize, are still just a few among many. It is therefore necessary to consider the relation of the values derived from art to the values derived from other things, such as the conduct of life apart from art: no one can devote every waking hour to the pursuit of art, even if for no other reason than the need for survival, and thus the values of such mundane things as food and shelter have also to be considered.

Mixed positions. The moralistic and aesthetic positions are extremes, and the truth is likely to be found somewhere between them. Indeed, art and morality are intimately related, and neither functions wholly without the other. But to trace the precise relations between art and morality is far from easy; for want of a better term, "interactionism" could be used to label the view that aesthetic and moral values each have distinctive roles to play in the world but that neither operates independently of the other.

It would be admitted, first of all, that works of literature (which will be examined first, since of all the arts the relation of literature to morality is most obvious) can teach valuable moral lessons through explicit presentation: the genre that has this as its aim is didactic literature, as exemplified by *Pilgrim's Progress* by the English Puritan John Bunyan and *Back to Methuselah* by the Irish dramatist George Bernard Shaw. But most works of literature do not exist to teach a moral lesson: possibly, Shakespeare did not write *Othello* merely to attack racial prejudice or *Macbeth* to prove that crime does not pay. Literature does teach but in a far more important way than by explicit preachment: it teaches, as John Dewey said, by being, not by express intent.

Expression of morality in literature

How does literature achieve this moral effect? It presents characters and situations (usually situations of difficult moral decision) through which the reader can deepen his own moral perspectives by reflecting on other people's problems and conflicts, which usually have a complexity that his own daily situations do not possess. He can learn from them without himself having to undergo in his personal life the same moral conflicts or make the same moral decisions. The reader can view such situations with a detachment that he can seldom achieve in daily life when he is immersed in the stream of action. By viewing these situations objectively and reflecting on them, he is enabled to make his own moral decisions more wisely when life calls on him in turn to make them. Literature can be a stimulus to moral reflection unequalled perhaps by any other, for it presents the moral choice in its total context with nothing of relevance omitted.

Perhaps the chief moral potency of literature lies in its unique power to stimulate and develop the faculty of the imagination. Through literature the reader is carried beyond the confines of the narrow world that most persons inhabit into a world of thought and feeling more profound and more varied than his own, a world in which he can share the experiences of human beings (real or fictitious) who are far removed from him in space and time and in attitude and way of life. Literature enables him to enter directly into the affective processes of other human beings, and, having done this, no perceptive reader can any longer condemn or dismiss en masse a large segment of humanity as "foreigners" or "wastrels," for a successful work of literature brings them to life as individuals, animated by the same passions as he is, facing the same conflicts, and tried in the same crucible of bitter experience. Through such an exercise of the sympathetic imagination, literature tends to draw all men together instead of setting them apart from one another in groups or types with convenient labels for each. Far more than preaching or moralizing, more even than the descriptive and scientific discourses of psychology or sociology, literature tends to unite mankind and reveal the common human nature that exists in everyone behind the facade of divisive doctrines, political ideologies, and religious beliefs.

This is not to say, of course, that those who read great works of literature are necessarily tolerant or sympathetic human beings. Reading literature alone is not a cure for human ills, and people who are neurotically grasping or selfish in their private lives will hardly cease to be so as a result of reading works of literature. Still, wide and serious reading of literature has an observable effect: people who do this kind of reading, no matter what their other characteristics may be, do tend to be more understanding of other people's conflicts, to have more sympathy with their problems, and to be able to empathize more with them as human beings than do people who have never broadened their horizons by reading literature at all. No one who has read great literature widely and for a considerable period, so as to make it an integral part of his life, can any longer share the same provincialism and be dominated by the same

narrow prejudices that seem to characterize most people most of the time. Literature, perhaps more than anything else, exercises a leavening influence on the temper of a man's moral life. It looses him from the bonds of his own position in space and time; it releases him from exclusive involvement with his own struggles from day to day; it enables him to see his own local problems and trials from the perspective of eternity—he can now view them as if from an enormous height.

The leavening influence of literature

To have moral effects, it is not necessary that a work of literature present a system of morality. Its moral potency is perhaps greatest when it presents not systems but human beings in action, so that through the exercise of the imagination the reader can see his own customs and philosophies as he sees theirs: as some among many of the countless adjustments and solutions to human problems that different circumstances and man's endlessly varied and resourceful nature have produced.

Works of literature, then, develop more than anything else the human faculty of the imagination; and the 19th-century English poet Percy Bysshe Shelley said that the imagination is the greatest single instrument of moral good. Perhaps this sounds like an absurd overstatement, but consider what morality is like without the imagination. Consider the average morality of a small community, relatively isolated from centres of culture and unacquainted with any artistic tradition. Its morality is rigid and circumscribed; the details of each member's personal life are hedged about with constant annoyances, and everyone's life is open to the prying eyes of others who are unfailingly quick to judge, with or without evidence. Outsiders are looked upon askance; people of a different religion, race, or culture are viewed with suspicion and distrust; and anyone who does not subscribe to whatever moral code is dominant in the community is condemned or ostracized. No doubt these people are sincere—they are dreadfully sincere, deadly sincere. But sincerity without enlightenment can be as harmful to the achievement of good as intelligence without wisdom when that intelligence is possessed by political leaders playing with hydrogen bombs. Generally speaking, the people of a small community have not known the leavening influence of literature. Their morality is rigid, cramped, and arid. If these same people had been exposed from early youth to great masterpieces of literature and had learned through them to appreciate the tremendous diversity of human mores and beliefs held by other groups, with the same degree of sincerity that they themselves possess, they would be less likely to be as harsh, intolerant, and rigid as they are.

People are usually inclined to separate art and morality into two hermetically sealed compartments. They talk as if morality were already complete and self-sufficient without art, and that art, if it is to be tolerated at all, can grudgingly be permitted, provided that it conforms to the moral customs of the time and place of those judging it. But this view is surely to conceive the relation between art and morality in far too one-sided a manner. If art must take cognizance of morality, equally morality must take cognizance of art. Almost everything that is alive and imaginative about morality comes from the leavening influence of art.

Influence of ancient dramatists

To consider examples from ancient Greece alone, what would morality be today without the influence of the dramatists Aeschylus and Sophocles, without Socrates as described in Plato's dialogues, even without the historians Herodotus and Thucydides with their quiet humour, gentle prodding skepticism, and tolerance for other customs and views? It is through great works of art that the most vivid conceptions of various ways of life are obtained. What is it about other times and places that people most remember? Is it their political squabbles, their wars, their economic upheavals? These events are known in general to intelligent laymen and in detail to historians, but even then such events do not usually make much of a dent in peoples' personal lives in the way that art does. What is alive today about ancient Greece is its sculpture, its poetry, its epic and drama; what is alive today about the Elizabethan period, even more than the defeat of the Spanish Armada and the reign of Queen Elizabeth I, is its poetic drama, with its vivid characterizations and boundless energy. Other civilizations and cultures may be sources of facts and theories that enlighten modern understanding, but what enables contemporary man to share directly their feelings and attitudes toward life is not their politics nor even their religion but their art. Art alone is never out of date. Science is cumulative; even the science textbooks of ten years ago are now discarded as obsolete; the science of the ancient Greeks and the Elizabethans is studied today primarily for its historical value. But great art is never obsolete; it can still present to modern man its full impact, undiminished by time. Shakespeare will not be out of date as long as human beings continue to feel love, jealousy, and conflict in a troubled world. A biblical statement might be paraphrased and applied to past cultures: "By their arts shall ye know them." The artists whose works are now revered may have died unsung; most of them, even those who were appreciated during their lifetimes, were considered far less important than the latest naval victories or the accession of the current king; yet today these things have all passed into history, but art survives with undiminished vigour. The art of the past molds in countless ways the attitudes, responses, and dispositions of modern man's daily life. Most of what is perceptive and imaginative in morality owes its origin to art, and, when morality loses contact with the tradition of art, it becomes dead and sterile. Yet, in spite of this, some people tell us that art is merely the salve of morality, to soothe its stringency.

Already, in the preceding paragraph, mention has begun of arts other than literature. How, it could be asked, can they have any moral effects on those who view them or listen to them? Yet there are effects of these arts on the observer that, in a broad sense, are moral (as opposed to nonmoral) and that account for the attempts of many people to censor them.

Aristotle's theory of catharsis

Historically, the most famous supposition about the moral effect of art on its audience is Aristotle's theory of catharsis; Aristotle applied the theory to tragedy only, but many since his day have applied it to art in general. According to this view, art acts as an emotional cathartic and achieves a "purgation of the emotions." Certain emotions man would be better off without (Aristotle limited them to pity and fear, but they could easily be extended) are generated during the course of daily life. Art is the principal agency that should help to dispel these emotions. By observing works of art (witnessing a drama, listening to a powerful symphony, looking at certain works of sculpture or painting) the recipient can work off these emotions rather than let them fester inside him or take them out in unpleasant ways on his fellow men. Art siphons off these disturbing inner states rather than letting them grow rancid within man.

As it stands, this view is undoubtedly somewhat crude, especially in the light of modern psychology; and fault could be found in many respects with the Aristotelian doctrine of catharsis. Yet the experience of reading, viewing, or listening to a work of art does give a peculiar release, a feeling of freedom from inner turbulence. The mere act of plunging, for a few hours, into an entirely different world when attending a play or a concert is often enough to transform, however temporarily, the tone of people's daily lives. It is not merely that for a few hours they can forget their troubles—any form of entertainment, however worthless, might do this. It is not merely that art provides a break or interruption in the course of people's lives at the end of which they are exactly what they were before. It is that through the aesthetic process itself, in the very act of concentrating energies on an art object of great unity and complexity and depth, a kind of inner clarification is achieved that was not present before.

It is not true, therefore, that reading novels of crime and detection leads people to indulge in a life of crime; on the whole, those who read such novels are law-abiding people, and, if anything, the reading of such novels is a

substitute for aggressive activity (it is aggression vicariously experienced) rather than an incitement to it. Nor do works of art of a licentious nature usually incite people to rape or adultery; far from acting as incitements to action, they are safety valves against action by providing a kind of substitute gratification. It has been said, for example, that Shakespeare's *Antony and Cleopatra* is an immoral work because it celebrates the passionate surrender to an illicit love and the victory of this love over practical, political, and moral concerns. But is there any evidence that people who read this play will behave like the lovers in question because they read the play? On the contrary: it could be argued that reading the play has an instrumental value in that it presents another example of a complex moral situation, the perusal of which provides many avenues for moral reflection, and that the play also possesses the intrinsic value of acute characterization, dramatic power, and poetry whose imagery and intensity are among the most splendid in the English language. Again, it is said that American youth has been demoralized by such 20th-century U.S. writers as Ernest Hemingway and William Faulkner in that these writers set an example of bad behaviour. But to say that they are capable of demoralizing an entire generation is certainly to attribute to them too much moral power, especially over people who have never even heard of them. Even among those who do read serious literature, the effects are probably more beneficial than harmful: through books the horizons of such readers have been expanded to include other ways of life than they would have previously known.

The essential morality of the aesthetic experience

Quite apart from the ultimate effect of a work of art on a man's emotions, it would appear that the very act of experiencing the work may itself have a moral effect. If he is really concentrating on the details of a work of art and not just passively letting it play upon his senses, this effect—the heightening of his sensibilities and the refining of his capacities for perceptual discrimination—will make him more receptive to the world around him, thus raising the tone of his daily life and making his experience of the world richer than before.

Most of what passes for aesthetic appreciation does not begin to have this effect; but its failure is only because it is not aesthetic appreciation at all—it is a kind of tired reverie rather than an intense absorption in the aesthetic object. Most people, when they hear music, simply allow themselves to be inundated by the sheer flow of sound. Such people do not actively listen to the music and are not even aware of the most elementary kind of ebb and flow occurring within it; they only receive it passively, perhaps using it as a springboard for a private reverie or an emotional debauch of their own. Music has for them not an aesthetic effect but an anesthetic effect. It is not just hearing music that will have the required effect. The aesthetic experience, which involves nothing less than a total concentration on the perceptual details of the aesthetic object, is an experience that heightens consciousness, exercises man's capacity for perceptual awareness and discrimination, and helps him come alive to the sight and texture of the world around him. After a viewer has seen an exhibition of landscapes by Cézanne, the entire world may seem to him to have changed its structure and complexion: it may, indeed, take on the look of Cézanne's landscapes. And is not anything that increases awareness and subtlety of discernment and discrimination a potentially moral agent? Art provides the most intense, concentrated, and sharply focussed of the experiences available to man. Because of this, art can have an enormous influence on the tenor of a person's life, more influential no doubt than any particular system of morality. In its ability to do this, it has an effect on man's life that, in an extended sense at least, can surely be called moral. Morality transcends particular systems of morality; and art, by being for many persons the dominant influence in their lives, thus transcends them also.

Art Conservation and Restoration

Conservation, including maintenance, preservation (protection from damage or deterioration), and restoration, has become an increasingly important aspect of the work not only of museums but also of civic authorities and all those concerned with works of art, whether artists, collectors, or gallery goers. Technical advances of the 20th century have made possible new methods of safer cleaning and repairing of objects. Art restoration has become an important tool of research, and it enables the viewer to appreciate the original intention of the artist.

ARCHITECTURE

Development of architectural restoration. Conservation and restoration of architecture is a relatively modern phenomenon. The oldest buildings that have survived tend to be those that received religious veneration. When they were no longer venerated, they disappeared like other buildings. Even the famed ancient Egyptian Sphinx at Giza lay for centuries under the sand, and it was not until the early 19th century that the Forum of ancient Rome was uncovered and explored.

Medieval builders treated the work of their forebears with a healthy lack of awe. Every new Gothic chapel or chantry and, sometimes, every stage in the development of a single Gothic building followed the style of its own day. With the Renaissance in Europe grew a new respect for classical antiquity and a new interest in its architectural forms. By the end of the 18th century a knowledge of archaeology had become an accepted accomplishment of the educated man. Architectural design itself became a matter of "correctness." Old buildings everywhere began to be "restored" to the style of periods especially favoured. The French architect and writer E.-E. Viollet-le-Duc brilliantly restored the Sainte-Chapelle (1840–67) and the cathedral of Notre-Dame de Paris (1845–64). The ancient walls of Carcassonne in France and of Windsor Castle in England were not only repaired but also largely rebuilt in the 19th century.

With the spread of the Industrial Revolution, the labour of hands became more costly, and the value of craftsmanship gained a new significance. Old buildings began to command a new respect, and the English art critic John Ruskin (1819–1900) was even able to assert that "the greatest glory of a building is its age." In 1877 the pioneers of the conservation movement, led by the English artist and writer William Morris (1834–96), founded the Society for the Protection of Ancient Buildings (SPAB). Nicknamed Anti-Scrape, the society vehemently opposed the indiscriminate refacing of old stonework and the "conjectural restorations" still so fashionable, such as the new west front of St. Albans Cathedral in England (1880–83). The movement gathered force, and in the 20th century groups throughout the world now devote their efforts to architectural conservation.

An added local impetus has been given by national pride; postwar reconstruction became, for countries like Poland, the symbol of national resurgence. Almost every civilized country is increasingly conscious of its heritage of ancient buildings, while cultural bodies such as the United Nations Educational, Scientific, and Cultural Organization have lent to the conservation movement a powerful international impetus.

Effects of economic and social change. Architecture is a sensitive index of social change. The economic climate and social preoccupations of each age have combined to generate its own architecture and its own towns. Almost every decade of new building displays its own peculiar characteristics and modifies by constant adaptation the buildings and towns of yesterday. But the urban environment is society's investment in its future, and the cycle of renewal is continuous, if often slow. Thus, the problems of building maintenance and renewal are complicated by long-term economic and social change.

Perhaps the most marked trends are still those that brought about the conservation movement itself. First is the accelerated pace of physical growth. Old buildings have become not only relatively rarer but often virtually irreplaceable in terms of labour and craftsmanship, as well as in their use of building materials that are rare in more recent structures. In many cases, old buildings give to a locality much of its special character and identity, as, for example, in any English country village where thatched roofs still predominate. Another and rarer asset is a sheer and intrinsic merit of architectural form. And alongside all these is the tangible evidence that any old building provides for its community of a kind of social and environmental continuity—a reassuring reference point in a constantly changing world.

The factor of land value

Under the increasing pressure of population, the value of land has climbed steeply, with some curious effects on old buildings. Increased demand brings increased values and, at first, better prospects of repair and maintenance. But as values rise higher, the older building must also justify itself in terms of economic efficiency. All over the world, the town houses of the 19th century and earlier serve with varied grace in the 20th century as centres of modern industry and commerce. Their fabric is subjected to new strains, and their room shapes and capacity may become incompatible with new and changed demands. There comes a point at which the old building on a valuable town site can compete no longer with redevelopment. Then it is quickly overtaken, and financial subsidy is powerless. The old building in a deteriorating neighbourhood is at the same time likely to be in no better a situation. Its maintenance may become no longer worthwhile, condemning it to early death by neglect. The destructive effects of both over- and undervalue are clearly displayed side by side in a fine Georgian city like Dublin or in once-distinguished neighbourhoods like Bloomsbury in London or the Marais in Paris.

The most successful neighbourhood conservation occurs where values have been held in pace with the architectural capacity of a community, as at Bath in England, or in the Georgetown section of Washington, D.C.

The factor of increased mobility

Another social change is the rapid increase in mobility. The automobile brought better roads and an incentive to use them. Old city centres, after centuries of essentially domestic life, begin to be abandoned in favour of ring upon ring of suburbs. This peripheral accretion of cities is allied with their central decay as communities. As a universal result, the twice-daily thrombosis of the highways urges on a constant process of road widening, in which many an intervening historic area has been completely eroded away.

New possibilities of travel are increasingly open to

many. Cultural tourism can bring an antidote to the destructive forces, so that in countries such as Italy and Spain architectural conservation attracts quite a new order of investment and national energy.

Role of the law. In all conservation, the first effective step is to decide and define what is worthy of protection. For most countries this has involved a systematic process of inventory and survey. In Britain, for example, the Royal Commission on Historic Monuments (RCHM) was set up in 1908, and the Civic Amenities Act of 1967 was promoted by an independent body, the Civic Trust. The act required local planning authorities to define special areas for "conservation and enhancement." In France, the Commission des Secteurs Sauvegardés was set up in 1962 under André Malraux, minister for cultural affairs, to pursue an active program for public protection of historic areas. In the United States, the Historic American Buildings Survey was designed to assemble a national archive of historic American architecture.

Criteria for conservation

Criteria for conservation are rarely well defined. Architectural merit clearly must rank highly—especially in the case of any building which authentically exemplifies its period. Historical associations, such as the birthplace of a famous person, are less easily rated. One pernicious effect of all selection is the way in which it is the most outstanding example of any period, rather than the truly typical, that in the end remains to represent it. Another is that defects as well as merits may be kept warm under the same blanket. This is particularly so in the larger groups of buildings that are coming to be recognized as worthy of conservation.

Once defined, a building's next defense is in specific legal powers for its protection. These may be of varied degree and effectiveness. The most obvious form of legislation is the restriction against demolition. A higher degree of legal sophistication occurs in powers for the annexation of property and its maintenance by the state. Covenanted rights and restrictions are a variant of this principle. Next in the scale of effectiveness comes positive encouragement to owners by means of grants, bringing a public share and interest in the actual work of repair. In this way, actual legal rights over private property may be confined to a minimum while finance is encouraged from private pockets. Probably the most effective ultimate defense has been a selective protection, exercised as a regular part of everyday town- and country-planning control.

Negative legislation itself varies in degree. In Italy it is possible to insist upon the return even of certain pictures or chattels illegally dispersed from a building where these are adjudged to be of sufficient national importance. But negative powers are inherently weak. They convey no control over the philistine or intransigent owner and, at best, can only slow down neglect and demolition, deliberate or otherwise. The value of a historic site for redevelopment is a strong counter-magnet to the architectural heritage for many a private conscience.

The national acquisition of buildings for conservation in Britain has been carried out chiefly under the Ancient Monuments Consolidation and Amendment Act of 1913, by which suitable unoccupied properties can be "taken into guardianship." A much more rigorous application of the principle is sometimes possible in the United States, whereby the owners of whole groups of buildings held to be of sufficient distinction can in fact be legally dispossessed. These erstwhile owners may then be allowed to remain in residence on condition of the repair and rehabilitation of their buildings to a specified standard. In this way, whole areas of buildings, such as Society Hill in Philadelphia, have been taken over, concentrated redevelopment by high-rise apartments being permitted in selected inner locations but the buildings with frontage being restored in period styles.

Williamsburg, Virginia

The most exhaustive of all restoration projects is in the United States, at Williamsburg, Virginia. This small town, the colonial capital of Virginia from 1699 to 1780, has attracted the most expensive restoration program ever. Commenced in 1926, the project is dedicated to the purpose "that the future may learn from the past." By 1970 over $70,000,000 had been spent on the careful and scholarly restoration of buildings. Environmental management is of a high order. Tourist automobile traffic is excluded from the restored area in season, when a free bus service is provided. The emphasis is frankly educational. The enterprise not only owns its buildings but also staffs them, its employees wearing correct period costume.

Perhaps the most dramatic rescue operation has been in Egypt. There the ancient temples (*c.* 1250 BC) of Abu Simbel were threatened with destruction by the rising waters of the new Aswan High Dam. They were sawed into giant blocks and successfully reassembled 200 feet (60 metres) above the original site. This act of preservation was the result of intense and international negotiation and expertise.

Another variant on public ownership may be found in acquisition by a private body, such as the National Trust in Britain. Founded in 1895, this property-owning body opens to the public over 200 of its properties. The trust receives no direct government subsidy and relies upon careful economic management, although certain legal preferences operate in its favour. In the United States the American National Trust operates in the same manner.

Among bodies devoted to grant aid, the Historic Buildings Council (HBC) for England was set up in 1953 and disburses grants within a small annual budget, largely to help building owners penalized by heavy estate duties. These grants are administered to encourage owners to take a pride in their own buildings.

A pioneer architectural-conservation program has been established by the Faculty of Architecture of Rome University. Of six months' duration, the course is aimed at providing specialist training in conservation for architects of all nationalities. At national level in various countries, several comparable courses are becoming available, meeting a demonstrable need for suitably qualified and experienced architects.

Techniques of building conservation. The first requisite in any conservation project is an adequate historical survey. The conservator first researches the life history of the building and its development through the ages. Every building has its own biography. The Parthenon in Athens was originally built from 447 to 432 BC as a temple and subsequently served as a Christian church, a mosque, and a powder magazine before it became one of the world's greatest attractions for the tourist and art lover. A knowledge of the whole life of a building brings an essential understanding of its features and its problems.

Next, the conservator will need a thorough, measured survey. Generally, this is prepared by hand, with tape and rod and level. Modern measuring techniques, including photogrammetry and, sometimes, stereophotogrammetry, are also used, for they are quick and remarkably accurate. A full photographic record is invaluable.

Assessing the structure's soundness

Third, the architect or surveyor will analyze the structural stability of his subject and its living pattern of movement. No structure is permanently still. Subsoil expands and shrinks, thrust moves against thrust, and materials move with heat and wind. Complicated exercises, like bell ringing, have an even greater effect on a building's stability. Clay soil is the worst: the building protects the ground underneath but not around; and, with every downpour, a wall of accumulated clay may vary the lean of the building. Many ancient buildings had piled foundations—Winchester Cathedral's east end was built on oak piles that rotted after centuries, once the subsoil drainage was improved; and the only answer was to send down a diver to underpin. Framed structures can move a great deal. The skeleton of a timber-framed medieval house can be incredibly crooked without losing strength, if it is well triangulated and its joints are made sound. A wall is theoretically safe until it leans far enough to develop tension on one side, yet even then it may be stiffened by structural cross-walls. Generally, the old, evenly spread load will be stable, and any new point load or thrust will be suspect. Where it is necessary, the surveyor checks his observations over a period; *e.g.*, by measure-

ment with plumb lines or by marking devices placed across a crack.

The survey will not only analyze but also clearly convey its observations, defining remedies and their relative urgency and relating all to the function of the building and the available budget.

The next job in architectural conservation is to stabilize and consolidate the structure. Ideally, this is best done by restraining, or tying, the point of active thrust and, perhaps, by replacing, splinting, or in some way giving fresh heart to a failing or defective member. Adding heavy weights such as buttresses often does more harm than good. A load can frequently be spread more widely or more evenly. A structure can, in effect, be corseted by inserting (for example, around a tower) a continuous beam or ring of concrete. This can be done even in delicate masonry and, as in underpinning, by removing alternate sections of a wall, threading in reinforcement, and casting one and then another set of concrete stitches, until the whole becomes one strengthening beam. Or all that is necessary may be a single tie bar, a metal rod inserted along a direct line of thrust or weakness to join the structural elements in need of support.

Damp in buildings

After structural movement, the next serious adversary in building conservation is damp. Not only of itself but also allied with almost every other trouble, damp accelerates decay. Weather may be penetrating through whole surfaces, such as porous brickwork, or finding its way through cracks or defects in the roofing. Especially vulnerable are gutters or any part of the rainwater-collecting system. Wet weakens walling, rots timbers, and spoils finishes. The eradication of damp may mean patching or renewing a roof. Frequently it can be cured by inserting a continuous moisture barrier, perhaps even in a modern material like stout polyethylene. In this case, special care is needed to avoid future damage by concentrating more trouble at any possible defect. Modern techniques of waterproofing wet walls include the insertion of high-capillary tubes, designed to draw the moisture to themselves and to expel it, and also the injection of latex and similar water-repellent solutions, deposited in the heart of the walling. A new technique is that of electro-osmosis, designed to reverse the moisture path from ground to walling. The traditional ditch, or dry area, drained if necessary, disposes of the water before it reaches the wall. Double or cavity walls, with air between them, are another defense against damp.

Again, dampness compounds decay, and the first attention should be to such structural devices as sloping wall coverings, such as copings, which are designed to keep walling dry. Both in stonework and in brickwork, much harm can be caused by damp, especially when allied with an overly hard mortar jointing. This traps moisture along the lines of the joints, bringing any harmful salts to the surface, where they crystallize and damage the facing. Mortar jointing should always be softer than the brick or stone of a wall.

Unsound walling

Much decay is the result of poor construction. Defects are almost always accelerated by the simple contravention of good building practice. In walling, a typical cause of structural instability is a double-skin construction with rough rubble between in which, by uneven loading, one skin has been caused to bulge and to release loose material in the core of the wall. Once on the move, this rapidly gains momentum as a live wedge, forcing apart its two faces. The conservator generally inserts temporary support, then distributes the load more evenly and rebuilds the affected area. In some cases, through washing out loose material and then, either by gravity or at high pressure, grouting up the unseen cavities, it may be possible to restore a wall without disturbing the facing stonework.

The roof is a building's first defense. It must be impervious and collect water clear of a building. Roof finishes are commonly either of unit materials such as tiles, slates, or stone, or of boarding covered in sheet metal, preferably lead. The failure of unit materials is usually caused by decay of the materials that hold them in place. Iron nails are especially destructive and are usually replaced by nonferrous materials, such as copper. The battens that carry the tiles or slates have a longer lifespan but also need periodic renewal. Leadwork failure is usually the result of sheer age. This material has a very long life, but, if it has been used in sheets of excessive size, there is a tendency to buckle and creep as a result of expansion—especially in sunshine. Leadwork can readily be recast. It needs firm support and elements to fix it in place. Temporary repairs are executed by lead burning, in which a patch may be actually welded with the original lead, rather than by soldering, which tends to crack away.

The chief enemies of timber are the natural predators of the forest—fungi and wood-boring insects. In ancient buildings, the former are especially damaging.

The most voracious fungus that attacks building timbers is dry rot (*Merulius lacrymans*). This can spread along infected wood to sound timber, carrying its own moisture supply. It extracts cellulose, which forms the chief part of plant cells, and leaves behind a tindery and useless shell. Stagnant air and warmth accelerate its spread. Eradication must be thorough, or the trouble will rapidly re-establish itself. Modern fungicides are highly effective.

Wood-boring insects include the furniture and deathwatch beetles. From eggs laid in cracks, the larvae tunnel into timber and damage it before emerging as beetles to lay more eggs.

The deathwatch beetle inhabits mostly the outer sapwood of oak, preferably when wet or softened by rot. The furniture beetle lives mostly in deal, especially when sappy or damp. Both can be eradicated with modern pesticides.

The conservator lastly tests all services, especially electrical wiring, with its risk of fire; gas lines, with their danger of seepage and explosion; and plumbing, with its danger of leaks. These services are frequently redesigned and are often simplified as well as improved. Lightning conductors and fire-fighting equipment are an important part of the protection of any ancient building and need regular servicing. (D.W.I.)

PAINTINGS

The conservator of paintings aims above all at "true conservation," the preservation of the objects in conditions that, as far as possible, will arrest material decay and delay as long as possible the moment when restoration is needed. The correct choice of conditions of display and storage is, therefore, of the first importance. Ideally, each type of painting requires its own special conditions for maximum safety, depending on the original technique and materials used to compose it. Broadly speaking, most paintings can be divided into (1) easel paintings, on either canvas or a solid support, usually wood; (2) wall, or mural, paintings, executed in a variety of techniques; and (3) painting on paper and ivory.

Easel paintings. More or less portable paintings on canvas or panel are called easel paintings. Basically, they consist of the support (the canvas or panel); the ground, ordinarily a white or tinted pigment or inert substance mixed with either glue or oil; the paint layer itself, which may be complex in structure; and, finally, the surface coating, usually a varnish, to protect the paint and modify its appearance aesthetically. These four layers have many variants but must be constantly borne in mind when considering the problems of conservation.

Paintings on wood. Wood-panel supports were used almost universally in European art before about 1450, when canvas began to gain ground. Wood has the disadvantage of swelling and shrinking across the grain with variations in the relative humidity of the atmosphere. In northern temperate climates, variations in humidity can be considerable. In England, for example, the seasonal variation in a museum that is centrally heated in the winter can be from 25 percent in midwinter to 90 percent in summer. Although paint has a certain elasticity, it cannot usually take up much movement and generally cracks in a network referred to as craquelure. In continental land masses, such as the United States, the average relative humidity in dry zones may be consistently low, so that European paintings with wooden supports

Effects of humidity

air-seasoned to a higher humidity may suffer considerably. In both Europe and America, the effect of an unsuitable background of low or changing relative humidity and the restraining effect of the paint layer often produces a permanent bowing of the panel, which is convex at the front surface. To counteract both the shrinkage and the bowing (especially the latter), restorers in the past placed wooden strips called battens or more complex structures across the back of the panel as constraints. This often led to severe distortion of the front surface and cracking of the whole panel in lines along the wood grain. Extensive damage to the paint sometimes occurs, and drastic restoration is needed. In terms of preservation, the ideal solution is a form of air conditioning in which the relative humidity is maintained as nearly constant as possible at what is generally agreed to be the most reasonable level; *i.e.*, about 55 percent. The apparatus for achieving this is expensive and can be considered only by wealthy museums. In smaller museums and private houses, humidifiers either incorporated into central heating installations, if possible, or in the form of small portable machines are often used during the winter months.

Use of secondary supports

When warping and cracking have already occurred or when the latter seems likely as a result of the mistaken application of secondary supports, such as cross-battens, expert restoration treatment is required. In principle, this consists of removing the cross-battens and applying a reinforcement to the back that imposes a uniform but gentler constraint over the whole surface. It is normal in the 20th century to accept as inevitable some permanent convex curvature. The adhesives used and the composition of the new secondary support take many forms. One consists in backing the panel with strips of a very light, open-textured wood (balsa), using as a cement a mixture of beeswax, a natural resin, such as dammar or colophony, and an inert filler. This thermoplastic cement, applied as a hot, creamy liquid, solidifies without contraction. The epoxy group of resins, which harden without contraction, have also been used and have the advantage of not requiring heat. The material and cement used are chosen according to the nature of the original panel. Some restorers reduce the strength of the original panel, before applying the secondary support, by reducing its thickness. This practice is not universally approved. Occasionally, when the panel is badly worm eaten or severely cracked, it has to be removed from the paint and ground altogether in the process known as transfer. This is accomplished by pasting a substantial support of paper and, possibly, canvas to the front surface of the paint and then gently gouging away the wood on the back. An entirely new, inert support of balsa wood or compressed board is then cemented to the back surface and the front facing removed.

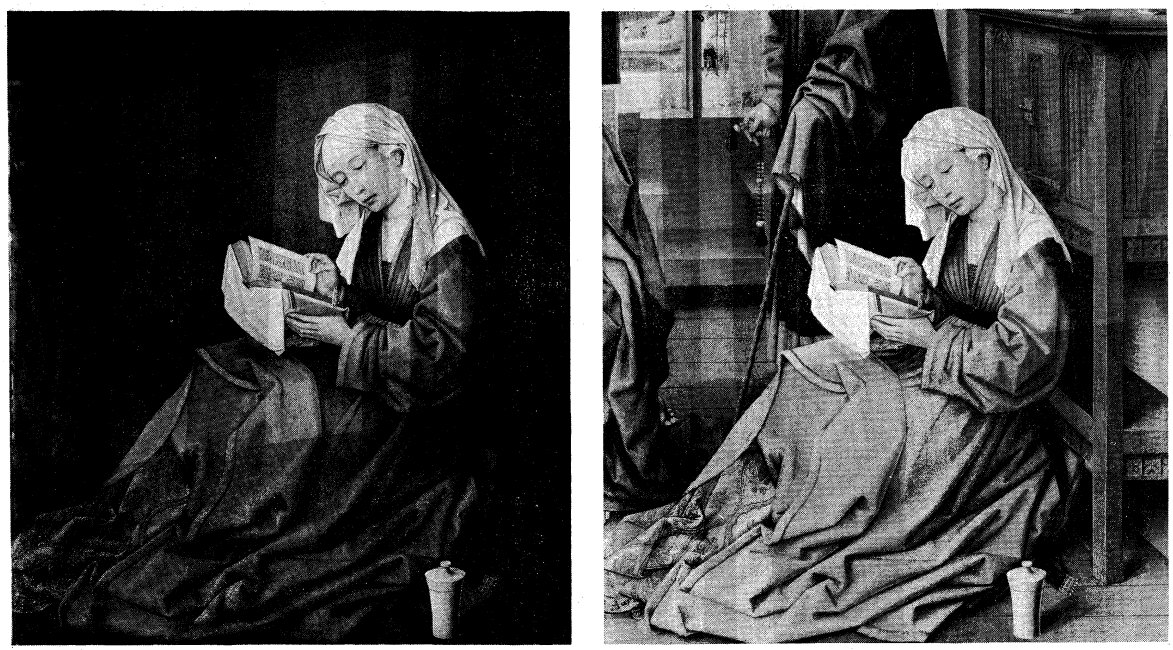
Paintings on canvas. A canvas support expands and contracts with variations in relative humidity, but the effect is not as drastic as with wood. Canvas, however, will deteriorate with age and acid conditions. In many cases, parts of the paint and ground will lift from the surface, a condition described as flaking, blistering, or scaling. In the case of paintings on canvas, the process of transfer is almost never performed. Instead, the canvas is reinforced at the back by attaching a new canvas to the old. This lining process (almost always referred to as relining) can be done in two ways. The traditional method consists of ironing the new canvas to the old, using as adhesive a warm, fluid mixture of animal glue and a farinaceous paste, sometimes emulsified with a resinous plasticizer, such as Venice turpentine. The second, formerly known as the Dutch method, uses as adhesive the wax–resin mixture mentioned above, at a temperature of about 70°–80° C. It is ironed as it cools and provides a thermoplastic bond. The advantage of this method is that it penetrates the front surface and fixes loose paint to the canvas, whereas, with the glue–paste method, fixing the paint would require a second operation. Also, the permanence and moisture impermeability of the wax mixture helps to protect the painting and the canvas from humidity changes and atmospheric impurities. A notable advance in the wax–resin method since 1950 is becoming universally adopted. This consists of employing the pressure of the atmosphere instead of a heavy iron during solidification. This is achieved by carrying out the process on an electrically heated platen (the "hot table"). The painting and its new canvas, treated with layers of the adhesive, are placed on the smooth metal surface of the table and covered with a latex sheet, after which the space between is evacuated with a pump through holes in the table. The cooling process is accelerated with fans. A notable advantage of this method is that the impasto (*i.e.*, the raised brushstroking of the paint) is not flattened, as used often to occur when heavy irons were used.

Advantage of the Dutch method

The ground (*i.e.*, the inert paint layer covering the support below the painting itself) can ordinarily be regarded for conservation purposes as part of the painting layers. Occasionally, when the ground is composed of glue and an inert substance such as whiting or gypsum, the glue may deteriorate and the ground lose its adhesion to either the support or the paint layers. In extreme cases, with wood-panel supports, a complete transfer is required, in which not only the support but also the ground must be removed. The restorer has a brief opportunity of seeing the painting or at least its lowest layers in reverse before applying a new ground and support.

The paint layers themselves are subject to a number of maladies as a result of natural decay, faulty original technique, unsuitable conditions, ill treatment, and improper earlier restorations. It must be remembered that, whereas housepaint usually has to be renewed every few years, the paint of easel paintings is required to survive indefinitely and may be already 600 years old. The most prevalent defect, as mentioned above, is flaking, or scaling, where, in local areas of paint, small particles become partly or wholly detached from the support. If the loss is not total, the paint can be secured, according to circumstances, with either a dilute gelatin adhesive or the wax–resin adhesive. The paint is usually pressed firmly into place with an electrically heated spatula. For easel paintings the binder for the coloured pigments is usually either egg yolk, oil, or, occasionally, glue. The first type of method, called egg-tempera painting, was universal before the mid-15th century, when oil painting began to be used increasingly. The condition of egg-tempera paintings where damage has not been caused by deterioration of support or ground is usually good. The condition of oil paintings is often less satisfactory. Sometimes the original technique of the artist is at fault, and this becomes increasingly so from the 18th century onward. Too much oil may have been used, leading to ineradicable wrinkling, or superimposed layers may have dried at different rates, producing a wide craquelure as a result of unequal shrinkage. An enhanced version of the latter occurred increasingly, as the 19th century progressed, by the use of a brown pigment called bitumen. Bitumenous paints never dried completely, producing a surface effect similar to crocodile skin. These defects cannot be cured and can be visually ameliorated only by judicious retouching. The most notable defect arising from poor conservation is the fading or changing of the pigments by excessive light. Although this is more evident with thin-layer paintings, such as watercolours, it is also visible in oil paintings. The palette of the earlier painters was, in general, stable to light; however, some pigments, notably the lakes, which consisted of vegetable dyestuffs mordanted onto translucent inert materials, often faded easily. A transparent green, copper resinate, much used from the 15th to the 18th century, became a deep chocolate brown after prolonged exposure to light. After the discovery of synthetic dyestuffs in 1856, a further series of pigments was created, some of which were later discovered to fade rapidly. Unfortunately, it is impossible to restore the original colour, and in this case conservation, in its true sense of arresting decay, is important; *i.e.*, to limit the light to the lowest level consistent with adequate viewing—in practice about 15 lumens per square foot (15 footcandles; 150 lux).

Problems in the original paint



"The Magdalen Reading," oil painting by Rogier van der Weyden (1399/1400–64). In the National Gallery, London. Cleaning and restoration in 1956 (right) revealed that the painting was a fragment from an altarpiece, not a complete painting as it had appeared (left).

By courtesy of the trustees of the National Gallery, London

Almost every painting of any degree of antiquity will have losses and damages, and a painting of earlier than the 19th century in perfect condition will usually be an object of special interest. Before a more conscientious approach to restoration became general in the mid-20th century, areas that had a number of small losses were often—indeed, generally—entirely repainted. It was considered normal in any case to repaint not only losses or gravely damaged areas but also a wide area of surrounding original paint, often with materials that have visibly darkened or faded with time. Large areas with significant detail missing were repainted inventively in what was supposed to be the style of the original artist. It is customary nowadays to repaint only the actual missing areas, matching carefully the artist's technique and paint texture. In some cases, as with skies in which areas have been worn away by injudicious cleaning, very little repainting is done at all. Some restorers adopt various methods of inpainting in which the surrounding original paint is not imitated. The inpainting is done in a colour or with a texture that is intended to eliminate the shock of seeing a completely lost area without actually deceiving the observer. The aim in inpainting is always to use pigments and mediums that do not change with time. Egg tempera has been a preferred medium, though it is difficult to use, and various stable, modern resins are employed in place of or in addition to tempera. Exact imitation of the original entails close study of the painter's technique, especially with the earlier multilayer methods, since the successive layers, being partly translucent, contribute to the final visual effect. Minute details of texture, brushstrokes, and craquelure must also be simulated.

Inpainting

This work of inpainting ordinarily has to be done after the top layer, or the varnish, has been removed. Because all varnishes before about 1930 and many since have undergone changes in colour and transparency, they partially obscure the appearance of the original paint and, therefore, must be taken off.

While the use of varnish was partly to protect the paint from accidental damage and abrasion, its main purpose was to improve the appearance. Oil paint, over the course of time, changes chemically by oxidation and polymerization and becomes harder and more brittle. A remarkable range of injurious cleaning agents, including sand and caustic alkali, is known to have been used for cleaning the surface of the paint in the past. As a consequence, some of the hardened oil medium is lost, and the painting becomes matte, or without lustre, and lifeless. A varnish, visually at least, revives it, and if a varnish itself becomes matte a further coat of varnish revives the former varnish coat, and so on. Unfortunately, the varnishes used consisted of hard resins, such as copal, or, more often, soft resins, such as mastic and dammar. These become yellow, brittle, and slightly opaque and also less soluble in harmless solvents, such as turpentine. Occasionally, as in London's National Gallery in the mid-19th century, lead driers were added to the varnish to quench the bloom, a blue haze that covered the varnish as a consequence of the prevalent coal smoke combined with a high and variable humidity. This varnish, known as the "Gallery Varnish," yellowed even more rapidly than the resins alone. The removal of these disfiguring natural-resin varnishes from paintings is an operation that must be carried out with great skill to avoid damaging the original paint. The work of restorers in removing varnish (usually described as cleaning) has been the subject of occasional vehement public criticism from 1850 onward. The criticisms centre on two points: first, that the solvents used are likely to damage the paint, which is said to contain proportions of soluble material, even when soluble resinous additives are not present (as they sometimes were in the 18th and 19th centuries); secondly, that some earlier artists themselves used a toned varnish to unify their colours and that, if this still remains, varnish removal is likely to produce an overcleaned effect that was not intended.

Varnishing

The removal of the varnish is usually done in the 20th century by solution in a solvent mixture of which the active ingredient is often one of the lower alcohols (ethanol or isopropyl alcohol) or acetone. Careful, minute tests are always made on representative areas, and the solvent is sparingly applied on a cotton-wool swab. For revarnishing, the natural resins have been almost universally abandoned in the mid-20th century in favour of a limited group of synthetics whose common characteristics are stability to light, oxygen, and moisture and, in general, a chemical stability that will permit eventual removal by safe solvents. These synthetic varnishes are also optically effective, adhere satisfactorily, and are adequately protective. The first synthetic resin varnish with these characteristics was polyvinyl acetate, which was introduced in the United States in 1930 and has been used continuously since. To this may be added a group of resins of the polycyclohexanone type (almost but not completely

stable to light) and an acrylic resin that is finding increasing use.

Wall paintings. From the point of view of conservation, the different types of wall painting have a number of features in common, though the techniques of restoration inevitably differ in detail.

Among the wall painting techniques is buon fresco, or true fresco, in which pigments mixed with water are painted onto a freshly prepared layer of damp lime plaster. Fresco secco is a method, often used in conjunction with buon fresco, in which a mixture of pigment and egg tempera is painted onto the dry plaster or is used as a retouching or enhancement of a dried buon fresco painting. Wall paintings are also executed with pigments mixed in oil applied either to a prepared dry plaster wall or on canvas, which is then fixed to the wall.

As far as pure conservation is concerned, there are two outstanding factors. The first, which applies to all methods of wall painting and especially to aqueous, or water-based mediums, is the exclusion of damp. This can attack the painting from several sources. One source is damp rising through the walls of a building; this first affects the bottom of the wall painting and then spreads upward. This is prevented by inserting a metallic or resinous damp course. New damp courses in old buildings are often prohibitively expensive, in which case a possible amelioration is to dig out exterior soil to a depth of at least six inches below the interior floor. The second source of damp is from the outside wall. It is important at least to avoid treating the painting with a water-impermeable material, such as wax or silicates, so that the damp can penetrate freely without meeting a barrier at the inner surface. The third source is condensation on the inner surface, which is particularly prevalent in churches that are heated only on weekends. More continuous and uniform heat is the solution, provided that the air is not dried out so rapidly that efflorescence, the formation of a powdery surface, occurs. The fourth and most easily remedied source, though often neglected, is from leaking roofs and clogged drainpipes.

Deterioration of lime

The second important hazard is more insidious. It affects solely those murals painted on lime mortar, which inevitably, by the action of air, becomes calcium carbonate. Since 1900, with the increasing use of motor vehicles and of fuel-burning industries, the percentage of sulfur dioxide in the atmosphere has greatly increased. In the presence of moisture the calcium carbonate is changed to calcium sulfate, whose volume is almost twice that of the original carbonate of the mural. As a result, disintegration in some areas of a mural can be rapid. In Italy this sort of disintegration has greatly increased and has made necessary the development of drastic though highly expert methods of transfer of frescoes from the original walls. These range from the method of *strappo* to that of *stacco*. While in practice they are not always clearly distinguishable, *strappo*, the more usual method, consists in gluing canvas firmly to the surface of the fresco, followed by pulling and easing away with long spatulas a thin layer of the plaster that contains the pigment particles of the fresco. The bond between the facing and the fresco must be stronger than the internal cohesion of the plaster. Excess plaster is removed, revealing the fresco in reverse. This is then fixed to a rigid support with synthetic resins, using inert substances mixed with resins as an intermediate layer to stimulate optically the original underlying plaster. In the *stacco* method, a thicker layer of plaster is removed with the fresco and is smoothed flat on its back surface before sticking the rigid composite layer to a board. Where possible, consolidation without detachment is performed. The removal of previous repaintings and overlying whitewash is often the most tedious part of the work.

In humid, temperate climates, such as England's, limewater is usually used as a consolidant. Earlier consolidations, often of wax or natural resins, are not only difficult to remove but also have frequently accelerated deterioration. In dry parts of the world, synthetic resins such as polyvinyl acetate have been used with success as consolidants.

Paintings on paper and ivory. Environmental conservation for these objects, which are ordinarily painted in an aqueous medium, consists in maintaining a stable relative humidity in the region of 50–60 percent. At lower humidities, both paper and ivory (the latter often used as a thin layer for portrait miniatures) tend to shrink, and the former becomes more brittle. The thin ivory of miniatures, which often tends to crack, may crack along the grain if constrained under conditions of varying humidity. At higher humidities, there is a possibility, especially when ventilation is poor, of mold growth, which can occur above about 68 percent relative humidity. Watercolour paintings are particularly vulnerable to light, which ideally should not exceed 5–10 lumens per square foot (5–10 footcandles, 50–100 lux). Some pigments fade rapidly, whereas others do not alter, and there is inevitably not only a loss of colour but also a distortion of the artist's intention. It should be noted that a warm light, as from an ordinary incandescent lamp, is less damaging in general than an equal amount of daylight or light from a fluorescent lamp. Daylight should be particularly avoided.

Restoration of paintings on paper has many detailed variations. After removal of the material on which the paintings are mounted, local brown stains, usually known as foxing, are sometimes reduced. The painting is freshened by washing gently in water with or without a little neutral detergent (which should not be of the household variety). Often a watercolour painting will resist washing without loss of colour, but it is generally advisable merely to damp the back before proceeding to reduce the stains locally with an oxidizing bleach. A mild form of bleaching agent known as chloramine-T is sometimes used. Other, stronger oxidizing bleaches can be used subsequently, but there are various disadvantages. Stains other than the characteristic foxing must be identified and the specific solvents used. Japanese prints may be treated similarly, though with even more care, since some colours (notably, a range of mauves) must never be damped.

Portrait miniatures on ivory require expert treatment, and it is even possible to damage them irrevocably in removing them from their lockets.

The restoration and conservation of prints are dealt with in the article PRINTMAKING. (N.S.B.)

SCULPTURE

Efforts have been made for some time to develop a means of preserving valuable marble and limestone sculpture. It was only in the mid-20th century, however, that the seriousness of the problem became universally recognized. Much sculpture exhibited out-of-doors suffers from the effect of air pollution. With Italian sculpture from the 14th century onward, the problem is acute. Such work often suffers from its age or what could well be called stone fatigue. The two main elements detrimental to stone sculpture are agreed to be the high concentration of sulfur dioxide usual in modern industrial environments and frost, which obviously has been a constant historic factor. When both detrimental effects are concurrent, a relatively rapid destructive cycle is activated. The degeneration of the stone surface by the repeated expansion of freezing water and the fast thawing in the morning sun opens pores of the stone to the industrial gases, which quickly change the chemical nature of calcium carbonate stones to calcium sulfate. This brings about an increase of the stone's volume, resulting in a shedding of the degenerate layer.

Cleaning sculpture

Attempts to clean sculpture in the past have often proved ineffective or positively harmful. Before cleaning can be undertaken, the nature of the dirt must be determined. A marble statue may be affected by incorrect cleaning, deliberate toning (oiling or waxing; the latter includes the result of handling), and sulfation, the reaction of sulfur oxides in the air with the calcium in the stone. Later, dirt must be dealt with before removal of the film caused by the sulfation is possible. Most superficial dirt can be removed by applying a solvent such as methylene chloride or toluene on a patch at a time and

removing the dissolved methylene dirt with a series of clean swabs. This treatment leaves the marble clean except for the film of sulfation, which can vary in colour from cream to black. Attempts to remove this deposit with soap and water are unlikely to be successful, as tapwater does not dissolve the calcium sulfate, and the soap reacts with the calcium carbonate to form still another waterproof film. The problem is easily solved by using deionized water (ultrapure water), which dissolves the sulfation film. The deionized water is suspended in position in a mudlike pack for some 12 hours, the suspender being magnesium silicate. At the end of this period, the now dry mud is brushed off, and the marble is rinsed once more with deionized water. The remaining problem is to prevent a repetition of the decay.

One method is to use a solution of two parts of cosmoloid wax and one part of Ketone N resin made up in white spirit to form a thin cream. This is massaged into the surface of the marble, leaving no excess. This coating inhibits the action of sulfur dioxide and sulfation. The whole work is then brushed over with talc, which eliminates the dust-attracting property of the wax–resin coating. Subsequent cleaning need only take the form of wiping with damp cotton when necessary. This treatment, however, is not suitable for painted or gilded sculpture. Mist spraying with tap water is more practical for outdoor sculpture.

Repair of breaks

Modern adhesives are so effective in repairing broken sculpture that care must be taken in using them, as the chances of altering the repair after they have set is remote. Both the epoxy and polyester resins employed as adhesives are used only on clean, dry stone. The adhesive must be applied so that it does not appear on the surface, as it tends to yellow with age and become visible.

Dowelling is a commonsense operation. If a life-size arm is broken in two, for example, a stainless-steel dowel of about three-eighths of an inch diameter will suffice, and, if the stone is sound, it need only be six inches in length. A spot of coloured paint is applied to the centre of one half, and the two pieces are fitted together. Upon removal of one half, the paint will have reported on the other half. A hole is then bored with a mason's drill, a little over three inches in depth, in each piece, and slightly broader than three-eighths of an inch in diameter, great care being taken to ensure that both holes are aligned. The dowel is then inserted and the halves fitted together dry. If the union is undisturbed by the introduction of the dowel, the polyester adhesive should be applied to both holes and a little to cover the break. The pieces are then firmly fitted together and held in position until set.

Chips and missing areas in a piece exhibited indoors are generally replaced by using solid polyvinyl acetate, which can be coloured to match the surrounding material and is easily molded. An item such as a hand can be produced satisfactorily by using a water-clear epoxy as a casting medium.

The traditional, although usually unsatisfactory, method for doing this work out-of-doors is to use a cement with crushed marble as an aggregate. An epoxy resin with an aggregate of ground, white glass is usually found to be much more aesthetically pleasing and durable. Grafting a new piece of marble onto a statue not only means that the break must be trimmed back but also calls for a degree of sculpting comparable to the original.

While there is a reluctance on the part of painters to repaint pictures, painted sculpture has not experienced this repression. Wooden sculpture from the 14th century may have five to seven layers of repainting. The age and insolubility of these old repaintings inevitably means that to uncover the original layer the subsequent layers have to be removed manually, a long and delicate job. The techniques are similar to those for restoring panel paintings. Final varnishing, however, is of a lower gloss than that usual with panels.

DECORATIVE ARTS

Furniture. The need for restoration of furniture stems from several causes—physical damage, destruction by woodworm, decomposition of glue caused by dampness. A major problem is damage by central heating. Old furniture was constructed with timber seasoned to be compatible with a more natural humidity level. Today much of the world's fine furniture has found its way into centrally heated museums, galleries, and private homes. The drier conditions affect the wood and glue, causing shrinking, which results in splitting of wood, peeling veneer, and loosening of inlay. The correct use of humidifiers usually averts this problem if introduced in time.

Woodworm is best treated with methyl bromide gas. Liquid pesticides are often impractical because they may destroy or mar painted or gilded surfaces.

The restoration of a damaged piece of furniture requires many techniques and skills. It is, first, very difficult to obtain properly seasoned rare woods with which to execute repairs. The staining and polishing of the repair element present problems of subsequent fading and must not interfere with the original patina of the surrounding area. Polyvinyl acetate and epoxy resins have largely superseded traditional animal glue. The restoration of veneers and inlays of diverse materials such as tortoiseshell, ivory, pewter, and mother-of-pearl all require individual processes of restoration, as do the restoring of leather coverings, fabric upholstery, or caning.

Stained glass. Generally damaged by war, vandalism, or degeneration of the lead support and, less commonly, by devitrification of very old glass, stained-glass windows can be restored. Missing pieces are usually recut from new glass especially made for the purpose. If there was painting on the original glass, it must be skillfully redrawn on the new glass. Care is taken to match the delicate original shading. After painting or staining, the glass is fired and then annealled. To restore flashed glass (clear glass coated with coloured glass), the coloured coating is masked with wax so that the unmasked area can be removed or refined with hydrofluoric acid. Occasionally, the coating is ground off to produce a design.

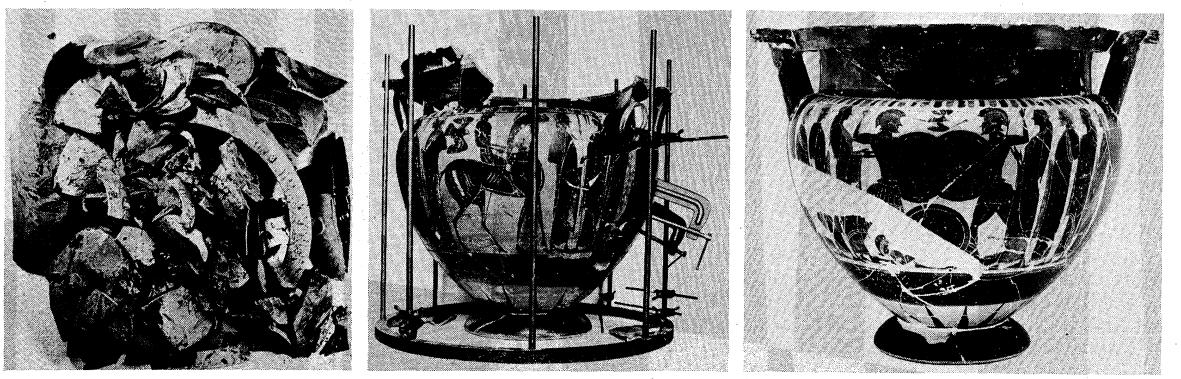
Broken fragments are often found leaded together, but this tends to confuse the design. Often no attempt has been made to produce a new missing piece, but an odd fragment, perhaps from another window, has been cut to fit. Stained-glass windows have to be completely releaded if the original leading has decomposed. Very old glass sometimes becomes completely opaque, and sometimes the external surface becomes chalky. With great care and patience, this film can be ground or etched off with acid, restoring the glass to something of its original beauty.

Textiles. In terms of preservation, textiles are one of the most fragile mediums of the decorative arts. Made of plant fibres and animal hair, textiles are very perishable and generally do not survive the test of time except in dry desert climates such as parts of Central Asia, Egypt, and Peru. Sunlight fades the dyes used to colour textiles. Sometimes only certain colours will be so affected. Usually the colours that are darker in hue are more faded or decayed because they absorb the most light. When exhibited, therefore, the rooms or cases where these materials are installed are air-conditioned and lighted with ultraviolet filtered light.

Hanging textiles, such as tapestries, often tear from their own weight or cause the weaving of the fabric to separate. Such tears can be averted by sewing the hanging to a backing of another textile. If there are torn or moth-eaten areas, new warp threads can be inserted and the damaged design rewoven into the work.

The storage and display of delicate fabrics is even more crucial than for tapestries. Damaged silks that are beyond needle restoration are sometimes reinforced by being welded onto a supporting material with polyvinyl acetate emulsion. Consolidation of decaying fabric is also effected by soluble nylon or polyvinyl acetate. A whole range of techniques is called for in the cleaning of the many types of textile materials. The success of cleaning still depends on the skill of the conservator more than on the use of modern chemicals.

Ceramics. The principles that govern the restoration of pottery are exactness, durability, and noninterference



Greek black-figure vase from Orvieto destroyed during the flood of 1966 in Florence, Italy, shown (left to right) before, during, and after restoration.
By courtesy of the Soprintendenza alle Antichita d'Etruria, Florence

with visual appreciation. Breaks are sometimes disguised by complete overspraying, which often alters the character of the glaze. Much skill is required in the reconstruction of a fragmented object, even with the use of modern adhesives such as epoxy resins and polyvinyl acetate emulsions. It is crucial to induce the maximum intimacy between the breaks. This means little adhesive, no dirt or loose particles, and precise positioning. Missing parts are usually made with a modern cellulose filler or a composition formed by mixing kaolin with epoxy resin. This exercise must be perfect, for, however well the join is painted, it will never be satisfactory if the filling is imperfect. When the restorer is satisfied with the form and surface of his repair, he views it in an oblique light to show up imperfections.

The missing heads, arms, or hands of figurines are often modelled in low-temperature firing clay and fired onto the original. This is rarely done by museum restorers, for the process may alter the appearance of the original or endanger the glaze. A cold curing resin can safely be used as a medium for retouching. (K.F.B.H.)

Artevelde, Jacob van

Jacob van Artevelde was a 14th-century Flemish leader who played a leading role in the preliminary phase of the Hundred Years' War. A citizen of Ghent, van Artevelde kept the Flemish cities neutral at first; then he sided with England, in spite of the nominal allegiance of Flanders to France.

Life. Van Artevelde was born in Ghent *c.* 1295; his profession is unknown, but he belonged to the wealthy bourgeoisie and owned land both in Ghent and in the surrounding area. His children's marriages indicate a connection with the nobility. His second wife, Kateline de Coster, took an active and capable part in public life. She travelled several times to England, in van Artevelde's name, to obtain payment of sums promised by the English king to the Flemish towns. One of their sons, Philip (born 1340), led a revolt against Count Louis II of Flanders in 1382. Van Artevelde had already reached middle age when he began to take part in public affairs. The only mention of him before 1338 is as a supporter of Louis I, count of Flanders, during a revolt against Louis in Ghent in 1325. But as relations between England and France worsened in the 1330s, tension arose between the Count and the Flemish towns. Louis, a vassal of the French king Philip VI, sided with France. The towns, although Philip offered them inducements, needed English wool for their textile industry and could not afford to alienate Edward III of England.

Artevelde's rise to power

At that point, van Artevelde emerged as a leader. Early in 1338, the people of Ghent, under his leadership, declared their neutrality. Bruges and Ypres, the other major towns, followed suit. France was forced to acquiesce, and the vital trade with England was safeguarded.

Van Artevelde governed Ghent with a group of four other "captains." At least three of his colleagues were wealthy merchants. A dean of the weavers was also elected, and the extent of the power conferred on a member of the less prestigious artisan class was characteristic for the social aspect of van Artevelde's reforms.

Flanders remained neutral for only two years. At the beginning of 1340, it joined the English, thereby obtaining further commercial advantages and a promise by Edward III to help reconquer some Flemish areas under French control. To give the new situation some show of legality, the English king, probably on van Artevelde's initiative, let himself be proclaimed king of France in Ghent (Jan. 26, 1340). Edward overcame the French fleet near the Flemish port of Sluis and then, with van Artevelde, besieged the French city of Tournai.

Unlike his subjects, the Count of Flanders fought on the French side, and the Flemings, under van Artevelde, repudiated his authority. When a truce was declared after the siege of Tournai, the Count returned to Flanders, but he was subjected to the control of a council dominated by van Artevelde's supporters. When Louis extricated himself by flight, his relative Simon van Mirabello, a wealthy Lombard who had become a citizen of Ghent, was made regent by van Artevelde to replace him. Van Artevelde never made formal changes in institutions. His name never appears on an official document, but Edward III's correspondence shows that he exercised power. He owed his influence to the support of the great towns, whose interests he promoted. When necessary, he sacrificed the interests of the small towns and the rural population to his end.

Van Artevelde maintained his position unchallenged until the beginning of 1343, when an unsuccessful attempt to overthrow him was made by a onetime alder-

man, Jan van Steenbeke. A second attempt, in May 1345, was more successful. A conflict arose between the weavers and fullers, putting an end to the policy of balance among all classes, on which van Artevelde's authority rested. He lost his position as chief captain but retained the confidence of Edward III. That was fatal to him. In July 1345 Edward came to Sluis to negotiate the continuation of the alliance with Ghent's representatives. Van Artevelde quarrelled with his colleagues, who thought him too compliant. On his return to Ghent, he was murdered during a riot (*c.* July 22). Jacob van Artevelde long remained a controversial figure; more or less forgotten in the 17th and 18th centuries, his memory was resurrected by Belgian-nationalist historians in the 19th century.

His death

Personality. It is difficult to assess van Artevelde's personality. Most of the surviving information about him comes from his enemies. His only known writings are three letters, written in French during the winter of 1342–43 and addressed to the king of England, the queen, and the prince of Wales. They are businesslike in tone, without exaggerated compliments. It is possible to deduce from his actions some of the characteristics that made him stand out: a strong conviction about the needs of his people and how to secure them, a willingness to break with accepted values, and the ability to act without hesitation. His violent disposition, which led him to kill an opponent in a quarrel, was a quality he shared with many of his contemporaries.

(H. van W.)

Arthropoda

The phylum Arthropoda is the largest and probably the most diverse phylum in the animal kingdom. Its members, which form about 75 percent of the known animal species, differ widely in anatomy, physiology, behaviour, and habitat. One characteristic that distinguishes arthropods from other animal phyla is a resistant outer covering called a cuticle, which is composed in part of a protein (chitin) and is shed at periodic intervals (molt, or ecdysis). The cuticle serves as a protective device and functions as an exoskeleton, providing surfaces for muscle attachment. Other distinguishing characteristics of arthropods include a segmented body, a six-segmented head in Mandibulata, chitinous jointed appendages (hence the name Arthropoda, meaning jointed legs), many specialized sense organs, a circulatory system containing vascular spaces collectively called a hemocoel, and bilateral symmetry.

More than 925,000 arthropod species have been described, of which about 90 percent are insects. The total number of arthropod species has been estimated at 6,000,000 or more. The phylum Arthropoda may be divided into three subphyla: Trilobitomorpha (containing only the extinct trilobites), Mandibulata, and Chelicerata. The Mandibulata include the water-inhabiting crustaceans (class Crustacea) and the terrestrial insects (class Insecta), springtails (class Collembola), and myriapods, a collective name commonly used to refer to members of four closely related classes (Pauropoda; Diplopoda, or millipedes; Chilopoda, or centipedes; and Symphyla) with similar leg-bearing body regions unlike those of insects. The Chelicerata include the marine class Merostomata (xiphosurids and eurypterids), the class Arachnida (scorpions, spiders, mites, opilionids), and the marine class Pycnogonida (sea spiders).

Of uncertain relationships are the arthropod-like tardigrades, pentastomids, and onychophores; they are described fully in the article ONCOPOD.

Arthropods are common on land and in marine waters and fresh waters. In the sea, minute crustaceans are a major component of the zooplankton, which serves as food for other invertebrates, fishes, and whales. The land is dominated by the insects, which are of economic importance both as pests and as pollinators of crop plants. Spiders, mites, scorpions, and other arachnids also live on land. Centipedes, millipedes, symphylids, and pauropods, which live in damp habitats, are of little economic importance. The trilobites, which become extinct by the Permian (about 280,000,000 years ago), were dominant arthropods in the Early Paleozoic seas (about 550,000,000 years ago); their earliest fossil remains, found near the bottom of the Lower Cambrian rocks, are about 570,000,000 years old.

GENERAL FEATURES

Size range and diversity of structure. The hard external skeletons of arthropods influence their ultimate size. Only aquatic forms are able to attain substantial sizes because their bodies are supported in part by the surrounding water. The extinct Eurypterida, for example, reached a length of 1.8 metres, and some present-day crustaceans grow to more than twice that size; giant spider crabs may weigh up to 6.4 kilograms and span 3.8 metres. The strongly calcified body coverings of crustaceans provide weight that is advantageous to bottom-dwelling aquatic forms.

Influence of external skeleton

The weight of the exoskeleton, however, is not the only factor that limits arthropod size; molting also plays a role. The cuticles of terrestrial arthropods, strengthened by sclerotization (a hardening process analogous to the tanning of leather), are not only tough and rigid but also light in weight. Animals encased in rigid exoskeletons, be they light or heavy, can increase in size only by molting; and, after attaining certain sizes, their linear dimensions increase only slightly during intervals between molts (called instars). The necessity for molting, or ecdysis, therefore, sets an upper limit to the size of arthropods.

Terrestrial arthropods do not attain large sizes. The largest insects and spiders do not weigh more than 100 grams. The beetle *Goliathus regius* measures 15 centimetres in length and ten centimetres in width, while the butterfly *Ornithoptera victoriae* of the Solomon Islands has a wing span exceeding 30 centimetres. The phasmid *Pharnacia serratipes* is one of the longest insects at 33 centimetres. It is probable that the size of terrestrial arthropods may be limited not only by the weight of the exoskeleton but also by their vulnerability; significant, perhaps, is the fact that scorpions and Solifugae are nocturnal, a habit that may be related to preventing attacks by vertebrate enemies.

The smallest arthropods include some parasitic wasps, beetles of the family Ptiliidae, and mites that are less than 0.25 millimetre in length, despite their complex structures, and may weigh less than the nucleus of a large cell. Ants 1.5 centimetres long weigh less than one gram.

Distribution and abundance. The only region of the earth in which insects are not dominant invertebrates is the sea; the probable reason is that every suitable habitat had been exploited by other arthropods, the crustaceans, before the insects evolved. The crab *Ethusina abyssicola* is known from a depth of more than 4,000 metres, while Collembola and jumping spiders (Salticidae) are found on Mt. Everest at heights exceeding 6,700 metres. Collembola and orabatid mites are among the permanent inhabitants of Antarctica. Many arthropods are parasites in or on other animals.

Importance. Arthropods are of great economic and medical importance. Despite increases in knowledge and the development of powerful insecticides, insects and ticks and other mites (Acarina) remain serious disease threats to man and other animals throughout the world; arthropod-carried human diseases include malaria, yellow fever, rickettsial diseases, plague, filariasis, and other worm infections. Arthropods also cause harm by their poisonous stings and bites and by their destruction of crops, timber, and stored products.

Soil arthropods, which include some crustaceans, myriapods, insects, and collembolans, play an important role in the formation of humus from decomposed leaf litter.

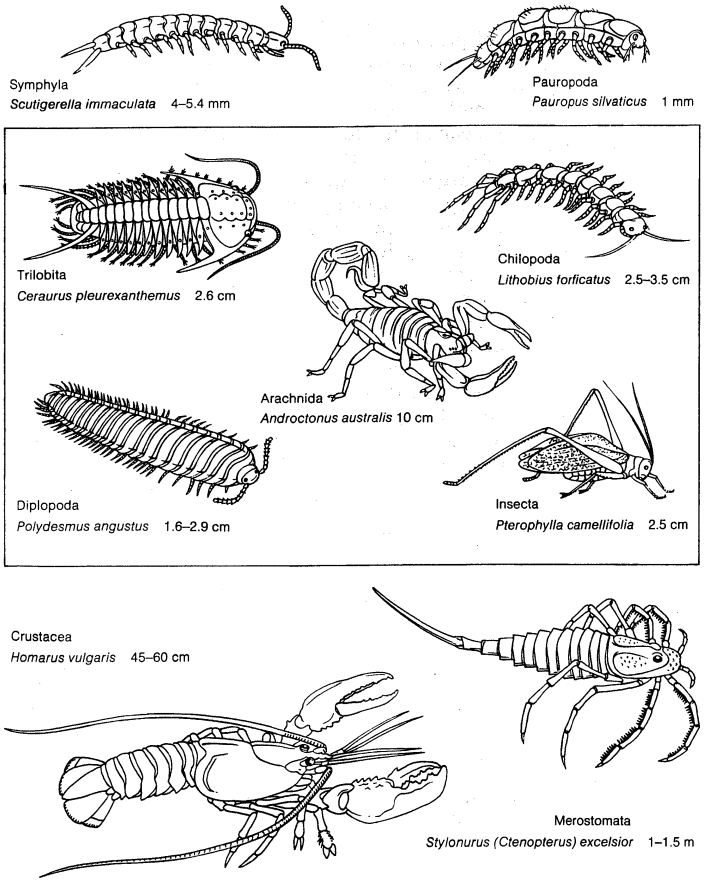

Figure 1: Diversity of arthropod body plans.

Crustaceans are important food supplies of man and other animals.

NATURAL HISTORY

Reproduction and life cycle. With few exceptions, the sexes are separate in arthropods; *i.e.*, there are both males and females. The paired sex organs, or gonads, of each sex are connected directly to ducts, called gonoducts, which in turn are connected to regions that lead outside the animal (gonopores); glands frequently are associated with the ducts. The gonoducts open through gonopores to the exterior at different regions of the body of the various arthropod groups (*e.g.*, gonopores are near the rear of the body in centipedes and insects; at the hind end of the thorax in Crustacea; close to the head in millipedes, pauropods, and Symphyla; and near the middle of the body in Arachnida). The abdomen of the pycnogonids contains little more than the terminal part of the alimentary canal, so that the gonads are displaced into the leg segments, and eggs pass through openings in the second segment.

Spermatophores

Throughout the Arthropoda, spermatozoa often are transferred to the female in sealed packets known as spermatophores. During this primitive method of transfer, the spermatozoa are not diluted by the surrounding medium, in the case of aquatic forms; nor, on land, do they suffer from desiccation. Spermatophores, characteristic of centipedes (Chilopoda) and Arachnida in which mating is delayed by elaborate courtship behaviour, also occur typically among certain insect groups—*e.g.*, Orthoptera (grasshoppers, crickets), Dictyoptera (cockroaches, mantids), Lepidoptera (butterflies, moths), many Coleoptera (beetles, weevils), and Trichoptera (caddisflies). The transfer of free spermatozoa occurs in the Diptera (true flies), some Heteroptera (true bugs), Diplopoda (millipedes), Opiliones, and some mites.

In its simplest form in arachnids such as Solifugae, Ricinulei, and some Acarina, the spermatophore, a mucilaginous mass of spermatozoa, is transferred to the female by the male with the aid of his appendages (*e.g.*, chelicerae, pedipalps, or legs). In other arachnids (*e.g.*, Scorpionida, false scorpions, Amblypygi, Thelyphonida, Schizomida, and some Acarina) in which the complex, rodlike spermatophore is deposited on the ground, mating involves a nuptial dance, during which the male manoeuvres the female into a position such that she can gather the spermatozoa into her genital opening. In spiders (Araneida), spermatozoa are transferred to the female by processes, called palpal organs, attached to the male prosoma. The tarsal and metatarsal segments of the third pair of legs of Ricinulei are modified for a similar purpose.

Unusual methods of reproduction found among arthropods include the development of unfertilized eggs (parthenogenesis), the birth of living young (viviparity), and the appearance of several embryos from a single fertilized egg (polyembryony). Arthropod eggs are usually rich in yolk; in all groups, especially among Crustacea, however, are species whose eggs have little yolk.

Most crustacean and many myriapod embryos have fewer body segments than the adult forms. A free-swimming microscopic larval stage (nauplius) of some crustaceans, for example, has only three segments in addition to an anterior nonsegmented portion (acron); additional segments appear at regular intervals when shedding of the exoskeleton (molting) occurs. In contrast, in many chelicerates and insects, most segments form during embryological development within the egg.

Locomotion. *Walking and running.* The locomotion of living arthropods is similar to that of the more primitive wormlike onychophorans, the bodies of which are extensible. The number of locomotory appendages, which varies among the arthropod classes, is greatest in burrowing forms—*e.g.*, millipedes that push their way through crevices and certain centipedes that move through soil. The ability to move rapidly, associated with a reduction in the number of limbs and a shortening of the body, is best developed in arachnids, which are equipped with four pairs of legs, and in insects, with three pairs. It is noteworthy that Solifugae, the fastest of the Arachnida, run with the last three pairs of legs only, holding the first pair above the ground.

In order to maintain stability, an insect must keep at least three of its legs on the ground. No foreleg or middle leg can be lifted until the limb behind it has taken up a supporting position, and each leg alternates with the corresponding leg of the same segment. The legs usually move in a set sequence—foreleg, opposite middle leg, and hindleg—but many variations occur. Claws on the fifth leg segment (tarsus) are used to walk over rough surfaces; padlike adhesive organs on the tarsus (*e.g.*, the arolium) are employed on smooth surfaces. Most insects that leap (*e.g.*, grasshoppers, fleas) do so by suddenly extending the fourth segments of the hindlegs (tibiae). In contrast, all of the legs of jumping spiders (Salticidae) are extended together by an increase in blood pressure.

Flight. Insects are unique among animals in that they have acquired wings directly and not through the modification of limbs, as is the case with birds, bats, pterodactyls, flying frogs, and flying fishes.

The origin of flight is still a matter of dispute. Some authorities believe that wings first evolved in large insects that were forced to escape predation by ancestral mygalomorph spiders. According to this hypothesis, the spiders evolved the ability to construct aerial webs after their prey developed ways to fly. An alternative hypothesis postulates that wings first arose in small ancestral insects that comprised part of the aerial fauna.

In many flying insects except Odonata (dragonflies), the power by which the wings are moved is provided by indirect wing muscles; in Dictyoptera, however, the muscles that drive the wings also are concerned with moving the legs. Analysis of the possible sequence of muscular movements in walking and in flight suggests that, in the primitive condition, a common central nervous pattern of control could have served the needs of both running and flying.

Modifications of insect wings

In many insects, the two pairs of wings are able to act as a single pair. In some groups, bristles and lobes couple the fore- and hindwings on each side. In others, one pair of wings may be used for functions other than flight; *e.g.*, in the Diptera (flies), the hindwings are reduced to structures called halteres, which contain many sense organs that act to control flight.

Ecology. With the exception of wood lice and land crabs, the Crustacea inhabit salt water or fresh water. Not only do they form an important element of zooplankton but they also are the primary scavengers of shore regions. The other mandibulate arthropods (*i.e.*, the myriapods and the insects) are primarily terrestrial in habit; some centipedes and insects, however, inhabit the shoreline between tide marks (littoral), and some insects (*e.g.*, among the Coleoptera, Diptera, Hymenoptera, Lepidoptera, Heteroptera) have developed an aquatic habit secondarily, mostly in fresh water. Least modified for an aquatic habit are insects with an open respiratory system in which air enters tubules called tracheae through holes known as spiracles. Other insects have developed a closed (apneustic) tracheal system, into which oxygen passes from the surrounding medium; elaborations of this system include tracheal gills and spiracular gills, the latter being adapted for respiration both above and below water in streams whose water level may fluctuate rapidly.

Extant chelicerates are terrestrial, except for horseshoe crabs (Xiphosura), the Pycnogonida (sea spiders), and a few spiders and mites that, like some of the insects, have returned to the water. Terrestrial arthropods differ very little from their marine relatives, with the exception of respiratory modifications and the evolution of wings (in insects). Arthropods function efficiently either in water or on land. Most of the differences between aquatic and terrestrial forms are concerned with functional variations.

Many primitive arthropod and arthropod-like animals, which live in soil, humus, and leaf litter, represent an intermediate stage between aquatic and terrestrial habits; tardigrades (water bears), for example, frequently inhabit mosses. Some crustaceans, including copepods and ostracods, are soil dwellers, as are, among others, myriapods, collembolans, termites, ants, flies, and mites.

The soil fauna lives in comparative security and has sufficient oxygen and little risk of desiccation. The large numbers of primitive arthropods that live beneath objects (known as cryptozoic arthropods) include Pauropoda, Symphyla, and a few Arachnida (Palpigradi, Ricinulei). Usually small and lacking pigmentation and efficient respiratory mechanisms for controlling water loss by evaporation, cryptozoic arthropods have poorly developed visual sense organs but well-developed tactile and taste sensillae. Cryptozoa may molt throughout life even though growth no longer occurs; these soil arthropods, which have a long fossil history, play a vital part in soil formation (see also SOIL ORGANISM).

Parasitic arthropods

Arthropods also exhibit many highly specialized parasitic forms. Pentastomida are entirely parasitic, and parasitic adaptations are common among certain crustaceans, cirripedes, copepods, and isopods; *Sacculina*, for example, is a cirripede that parasitizes crabs. Among insects, Phthiraptera (fleas), Mallophaga (biting lice), and Anoplura (sucking lice) are entirely parasitic in habit; many Heteroptera (bugs), Diptera (flies), and Hymenoptera (wasps) also are parasitic during some stage of their life cycle. Dipterous and hymenopterous parasites play an important ecological role in regulating the numbers of their insect hosts. Although most arachnids are carnivorous, many mites are parasitic—*e.g.*, harvest mites (Trombiculidae), the itch mite (*Sarcoptes scabei*), follicle mites (*Demodex*), and ticks (Ixodidae).

FORM AND FUNCTION

Immature forms. The newly hatched young of arthropods often are very different from adults in appearance and habits. One biological advantage of larval stages in development is that the young do not compete with the adults; a disadvantage is that larval young may be vulnerable to predators. The developmental stage during which an animal hatches depends upon the amount of yolk present in the egg; among arthropods in which embryonic development is direct and the young hatch as miniatures of adults, fewer eggs are produced per female.

Trilobites had larval forms. Crustaceans typically hatch as minute, nonsegmented nauplius larvae with three pairs of appendages and a single median eye. This stage may be passed in the egg, however, and the animal then hatches as a metanauplius larva (or even as a zoea) that has developed beyond the nauplius stage but is not yet an adult. Special larval stages occur in several crustacean groups—*e.g.*, cypris larvae in Cirripedia, cyclops larvae in copepods, zoeae in Malacostraca.

The pauropod egg hatches into an immobile stage with two pairs of legs; after molting, a six-segmented larva appears with three pairs of legs. Most millipedes hatch with seven trunk segments: the second, third, and fourth each with one pair of legs; the fifth and sixth each with two pairs of limb buds. The young of certain centipedes (Scolopendromorpha and Geophilomorpha), because they hatch with the adult number of segments, are said to undergo epimorphic development; other centipedes (Lithobiomorpha and Scutigeromorpha), however, like Pauropoda, Diplopoda, Symphyla, and insects of the order Protura, hatch with fewer than the adult number of segments and legs (anamorphic development).

Some insects hatch as nymphs that superficially resemble the adults (exopterygote insects); others (endopterygotes) characteristically pass through several immature stages (*e.g.*, larva, pupa) before becoming adults. Endopterygote insect larvae (*e.g.*, caterpillars, maggots, grubs) differ markedly from adults, inhabit different environments, and eat different foods. A pupal or chrysalis stage bridges the gap in form and habit between larva and adult. The differences between adult and immature stages of exopterygotes, however, are so slight that the necessary changes can be accomplished without metamorphosis.

The young of most arachnid classes develop directly. In the case of scorpions, Amblypygi, and wolf spiders, the young climb onto their mother's back immediately after birth. The eggs of some scorpions, rich in yolk, develop in the mother; in the family Scorpionidae, however, the fertilized egg lacks yolk and is nourished by nutrient fluids from the wall of the mother's intestine. The wall of the egg-producing organ (ovary) in pseudoscorpions be-

comes glandular after the eggs are formed and secretes a nutrient fluid on which the embryos feed. The young of false scorpions usually emerge as nymphs called protonymphs that molt to form tritonymphs and then adults. The young of Opiliones, Solifugae, and spiders resemble their parents; in mites (Acarina), however, four postembryonic development stages occur, separated by molts. The six-legged larvae may pass through several stages (protonymph, deutonymph, tritonymph), which usually resemble the adults.

Body regions and appendages

Adult structure. The success of the arthropods derives from the presence of an exoskeleton and division of the adult body into regions that may, or may not, be marked off sharply. The specialized body regions of arthropods are sometimes called tagmata. In Onychophora and mandibulate arthropods, for example, the head is followed by a trunk region, which, in crustaceans and insects, is divided into thoracic and abdominal tagmata. The foremost region (tagma) of arachnids, called the prosoma or cephalothorax, bears the legs and the appendages used in feeding; the divisions of the hinder part of the body, called the opisthosoma or abdomen, may be divided into a mesosoma and metasoma, or tail. A nonsegmented terminal part of an arthropod often is called a telson. Any arthropod tagmata may be nonsegmented externally as a result of the fusion of segments during embryonic development. Head and thorax (or cephalothorax) are often covered by a protective cover (carapace).

The number of segments incorporated into the head varies among the different arthropod classes—*e.g.*, two in trilobites, and probably six in crustaceans, myriapods, and insects. The arachnid cephalothorax, or prosoma, consists of seven segments. The second and third segments bear the feeding appendages (chelicerae and pedipalps); the remaining four carry the legs.

The paired appendages of arthropods consist of several parts arranged as a linear set (uniramous) or as a bifurcated set (biramous). Two basic limb types are distinguishable in Crustacea, a flattened unsegmented one (phyllopodium) and a rounded one (stenopodium). The primitive limb type may have consisted of nine segments bearing a biting process, or gnathobase, on the first segment and an outer branch, or exopodite, on a more distal segment.

Changes in shape and relative size of parts of arthropod limbs have resulted in organs variable in appearance and function. Limbs may be modified for swimming, walking, respiration, reproduction, or as sense organs or mouthparts; the spinnerets of spiders, for example, are modified abdominal limbs. The mouthparts of primitive insects (*e.g.*, cockroaches) resemble crustacean limbs; parts of the maxilla (lower jaw), for example, are similar in origin to those of a crab. Primitive mouthparts adapted for chewing, as found in cockroaches, earwigs, locusts, and beetles, have evolved various modifications for piercing and sucking; these occur in the mouthparts of numerous insects—*e.g.*, bugs, bees, fleas, flies, butterflies.

Exoskeleton

The exoskeleton surrounding each body segment consists basically of four plates—a dorsal tergum, a ventral sternum, and two lateral pleurites. The plates around each segment and those of adjacent segments are attached by internal segmental muscles.

Functional features. Arthropods have exploited every conceivable source of food; in many cases, digestion is assisted by bacteria or protozoans that live in symbiotic associations in the arthropod alimentary canal. The alimentary canal consists of a chitin-lined foregut and hindgut and a midgut, or mesenteron. Salivary glands open at the mouth or the anterior part of the foregut; digestive glands open into the mesenteron. The hindgut terminates at the anus, which is usually situated on the under side of the telson. The excretory system of aquatic groups consists of glands, called coxal glands or green glands, which are found at the bases of certain of the segmental appendages. Terrestrial arthropods and Amphipoda (Crustacea), but not Collembola, possess Malpighian tubules for excretion of nitrogen-containing wastes; the principal excretory product is uric acid (guanine in arachnids), and the urine is semisolid.

The blood, or hemolymph, that bathes the internal organs, is circulated by a tubular, segmented heart. In arthropods with localized respiratory organs, such as gills and lung books (paired respiratory structures internally arranged as pages in a book), the blood contains a respiratory pigment, hemocyanin. No respiratory carrier is found in arthropods with tracheate respiratory systems because oxygen is conveyed directly by small tubes (tracheoles) to a pigment (cytochrome) in the tissues.

The nervous system consists of segmented ganglia that may unite during embryonic development into larger units, such as cerebral and subesophageal ganglia; these may have both nervous and neurosecretory functions. The gonads of most arthropods have no segmentation; in a number of groups, the left and right gonads are fused. The cavities in which the gonads lie represent the remnants of an ancestral body cavity (coelom).

Cuticle

The exoskeletal integument, or cuticle, of arthropods consists of a thin, impermeable, nonchitinous outer layer (epicuticle) and a thick, elastic, permeable, lamellar inner layer (endocuticle), composed largely of the protein chitin. The outer layers of the endocuticle usually are hardened by sclerotization or in Xiphosura, Crustacea, and Diplopoda by deposition of a salt (calcium carbonate). Molting is controlled by hormones; before the hard outer layers of the cuticle are shed, the inner layers are digested by an enzyme (organic catalyst). The arthropod swallows water or air to create a pressure that is distributed by the vascular spaces (hemocoel) to all parts of the body, which remain swollen until the new cuticle has hardened.

From H. Weber, *Grundriss der Insektenkunde*, 4. A. (1966); G. Fischer, Stuttgart

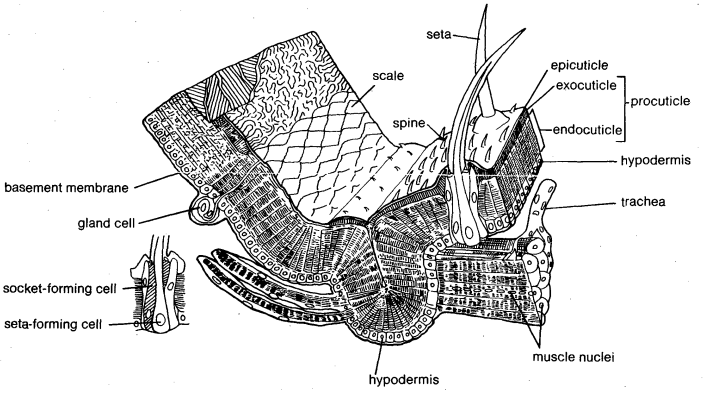

Figure 2: Body wall of an insect.

The integuments of terrestrial arthropods function not only in support and protection but also in preventing water loss, of vital importance in view of their small size and proportionately enormous surface area. Many cryptozoic forms (*e.g.*, wood lice, myriapods, Collembola) live in damp or humid environments, such as those found beneath stones, leaves, bark, and in soil and crevices. Most insects and arachnids, however, avoid desiccation by an epicuticle, which is waterproofed with a wax layer that is protected from the environment by a cement layer secreted by epidermal gland cells. The cuticle thus is impervious not only to water vapour but also to oxygen and carbon dioxide. A specialized respiratory mechanism sensitive to carbon dioxide permits gaseous exchange to take place while minimizing water loss; *e.g.*, the spiracles of insects and the lung books of arachnids open to facilitate respiration only when carbon dioxide begins to accumulate in the body. Before molting takes place, a new wax layer is secreted beneath the old cuticle, so that molting occurs with minimal water loss.

Excretion and nutrition also are closely concerned with water conservation. Insoluble excretory compounds, such as uric acid and guanine, were probably first acquired in association with the evolution of an enclosed egg. Uric acid and guanine are equally important to the periods between molts (instars) of larval and adult forms of terrestrial arthropods, however, since both compounds can be concentrated in the Malpighian tubules and excreted

with feces from which water has been withdrawn. It is probable that the fate of water ingested with food may be controlled by factors produced by a cerebral neurosecretory system.

Arthropod hormones control colour change, retinal pigment migration, growth, molting, changes in body form (metamorphosis), and sexual development.

Arthropods may develop poison glands that are associated with a variety of functions. In centipedes, scorpions, false scorpions, and spiders, poison glands are used to aid in the capture and digestion of prey. In certain hymenopteran insects (*e.g.*, wasps), poison glands are associated with the egg placement structure of the female (ovipositor) or a sting; the larvae of several lepidopterans (butterflies) have poison glands that may be associated with projections such as setae or spines. When broken, these projections allow the discharge of a fluid that causes an itching sensation in man. Certain glands that produce substances with repugnant odours function in defense and are found in wood lice, millipedes, harvest spiders, Schizomida, and Thelyphonida.

Sense organs

Apart from the eyes, which may be simple or compound, the sense organs, or sensilla, of arthropods are either tactile hairs (trichoid sensilla) or modifications sensitive to smell (olfactory), taste (gustatory), sound (auditory), or internal (proprioceptive) stimuli. Chemotactile pegs and cones often are located on the antennae, as are humidity and temperature receptors; chordotonal sensilla are attached to tympanal organs of sound reception. Receptors called proprioceptive campaniform sensilla, which measure tensions in the cuticle, are found near insect wings. Lyriform organs on the legs of spiders respond to vibrations of the web, so that the struggles of potential prey can be distinguished from the web plucking of a courting male. Arthropod senses usually are acute.

EVOLUTION AND PALEONTOLOGY

The arthropods have much in common with annelid worms of the class Polychaeta, and it is generally accepted that both are derived from the same ancestral stock. The peculiarities of arthropods, like their successors, may be related to the development of the cuticle into a jointed exoskeleton, which allows the segmented appendages to become adapted to a variety of functions—*e.g.*, feeding, locomotion, respiration, sensory reception, and reproduction. Associated with the development of muscular limbs is the replacement of the body cavity (coelom) by vascular spaces (hemocoel), in which the organs of the body are bathed in blood. The nervous system is like that of the Annelida.

The earliest known arthropods, the trilobites, were marine, as were the scorpion-like Eurypterida. Of the extant arthropods, only the crustaceans are predominantly aquatic; the Arthropoda, however, contains the largest proportion of terrestrial members of any invertebrate phylum.

Although fossil arthropods have been reported from Precambrian rocks (more than 570,000,000 years old), the validity of such records has not yet been established. Since fossils of certain trilobites, branchiopod Crustacea, and merostomes date from Early Cambrian times (about 550,000,000 years ago), the Arthropoda had a long Precambrian existence, during which they became modified from their annelid ancestors and branched along various evolutionary lines. The earliest known arachnid fossils appear in Upper Silurian strata (about 400,000,000 years ago); Collembola, insects, millipedes, and sea spiders (Pycnogonida) appear in the upper parts of the Devonian system (about 350,000,000 years ago). Fossils of tardigrades and pentastomids have not been found.

CLASSIFICATION

Distinguishing taxonomic features. The phylum Arthropoda is divided into classes on the basis of comparative anatomy, embryology, and function. Differentiation of habits in similar environments appears to have been of great importance in the evolutionary differentiation of terrestrial groups. Modification, specialization, number, and appearance of body segments and appendages (especially anterior ones such as antennae and mouthparts) are important criteria in distinguishing arthropod classes. Other structural features of taxonomic significance include location of the gonopore, structure of the head, and adaptations of the respiratory and excretory systems. In the classification below, the group marked with a dagger (†) is wholly extinct and known only from fossils.

Annotated classification.

PHYLUM ARTHROPODA

Bilaterally symmetrical invertebrates with joined exoskeleton covering body and legs; appendages specialized for specific functions; body wall containing cuticle secreted by epidermal cells; outer endocuticle thickened to form skeletal plates (sclerites); waxy compounds of cuticle reduce water loss in terrestrial forms; cuticle shed periodically (molt, or ecdysis); body musculature complex, sometimes specialized (*e.g.*, for flight, sound production); coelom reduced, replaced by hemocoel; nervous system consists of dorsal brain and a double ventral nerve cord; cilia absent; development highly modified with eggs typically rich in yolk.

†**Subphylum Trilobitomorpha** (trilobites)

Extinct arthropods; head (or cephalon) composed of 5 segments bearing a pair of segmented antennae, compound eyes; body with 3 regions, cephalon, thorax, and pygidium.

Class Trilobita

Numerous in Cambrian (about 500,000,000–570,000,000 years ago) and Silurian (395,000,000–430,000,000 years ago) but extinct by the Mesozoic Era; marine organisms with oval, flattened body molded longitudinally into 3 lobes; trunk and pygidium (tergites usually fused) with biramous appendages; eggs hatched into protaspis larvae; length 3.5–75 cm; over 4,000 fossil species known.

Subphylum Mandibulata

Head with antennae, mandibles, and food-handling appendages (maxillae); thorax with appendages (uniramous or biramous) sometimes associated with mouthparts; abdomen undivided from thorax, with appendages, or distinct from thorax, with or without appendages.

Class Crustacea

Mostly aquatic in habit; respiration by gills; strong exoskeleton, 2nd and 3rd segments with antennae, 4th with a pair of mandibles; eyes, when present, stalked or unstalked; evolutionary tendencies include specialization of limbs, shortening of body, reduction in number of segments, and development of carapace; many parasitic adaptations; size range 0.5 mm–2 m; over 25,000 living species known (see CRUSTACEA).

Class Pauropoda

Very small myriapods with 2 pairs of appendages transformed into mouthparts and 8–11 (usually 9) pairs of walking legs; antennae with 4 (rarely 6) segments with short branches and long, multiarticulate flagella; length up to 1.9 mm; about 180 living species known (see MYRIAPOD).

Class Diplopoda (millipedes)

Elongated myriapods; abdomen an indefinite number of double segments, each with 2 pairs of legs and spiracles; head with mandibles, maxillae fused (form a gnathochilarium), sometimes simple eyes (ocelli), and short, club-shaped antennae; thorax of 4 single segments with gonopores in the 3rd (progoneate); length 3 mm–28 cm; about 8,000 living species known (see MYRIAPOD).

Class Chilopoda (centipedes)

Elongated myriapods with many distinct abdominal segments; each with 1 pair of legs; head with ocelli, flagellate antennae, mandibles, 1st and 2nd maxillae; limbs of 1st abdominal segment modified as poison claws; gonopore on last segment (opisthogoneate); length about 5 mm–26.5 cm; about 2,800 living species known (see MYRIAPOD).

Class Symphyla

Small myriapods with 3 pairs of mouthparts, 12 pairs of walking legs, and a posterior pair of spinnerets; gonopore usually on 4th trunk segment; length up to 8 mm; about 120 living species known (see MYRIAPOD).

Class Collembola (springtails)

Small, widely distributed, insect-like opisthogoneate arthropods; mouthparts ectognathous, antennae usually 4-segmented; eyes simple; 3 thoracic segments with legs; 6-segmented abdomen with forked springing organ; tracheae usually absent; no Malpighian tubules; length up to 5 mm; about 1,500 living species known (see APTERYGOTE).

Class Insecta (*Hexapoda*)

Mandibulate arthropods with 3 pairs of appendages modified to form mouthparts; head of 6 segments with 1 pair of flagel-

late antennae, usually both median and lateral eyes; thorax of 3 segments, each with a pair of legs and wings (usually on 2nd and 3rd), abdomen of 11 segments, without appendages in adult; gonopores posterior; length 0.25 mm–33 cm; about 750,000 living species known (see INSECTA).

Subphylum Chelicerata

Prosoma without antennae but with pincerlike chelicerae, and sometimes pedipalps; uniramous walking legs on thoracic segments; if present, appendages on abdomen highly modified.

Class Merostomata

Large marine chelicerates with gill books; prosoma completely covered by carapace; opisthosoma bears a long spine; of 2 orders, only Xiphosura has living representatives (4 species); Eurypterida (= Gigantostraca) includes 200 fossil species, the largest 1.8 metres long.

Class Arachnida

Chelicerate arthropods with body divided into prosoma and opisthosoma, sometimes connected by a narrow pedicel; prosoma bears chelicerae, pedipalps, and 4 pairs of legs; opisthosoma usually lacks appendages; respiration by means of lung books, tracheae, or both, opening on the opisthosoma; gonopore always on lower surface of 2nd opisthosomal segment; length 0.25 mm–18 cm; almost 60,000 living species (see ARACHNIDA).

Class Pycnogonida (Pantopoda) (sea spiders)

Marine chelicerates with body divided into a cephalon trunk and abdomen; cephalon with a tubular proboscis and typically 3 pairs of appendages; trunk extremely narrow, consisting of 4 segments, each with a pair of jointed legs; abdomen reduced to a small oval stump; no respiratory organs; no segmental excretory organs; length 2 mm–6 cm; about 600 living species.

Class Pentastomida (Linguatulida)

Elongated vermiform parasites with secondary annulation, 2 pairs of claws at sides of mouth; without respiratory or circulatory systems; adults live in lung, gut, and coelom of reptiles, birds, and mammals; larvae free-living or encysted in an intermediate host, often a fish; length, up to 9 cm; about 70 living species known (see ONCOPOD).

Class Tardigrada (water bears)

Small and widely distributed; 4 pairs of stumpy legs end in claws, oral stylets, and a suctorial pharynx; no definite circulatory or respiratory systems; length, usually less than 1 mm; about 350 living species known (see ONCOPOD).

Critical appraisal. Although there is a close evolutionary relationship between the Annelida and the arthropods, it is not known whether the phylum Arthropoda is monophyletic–derived from a single source–or has evolved from different annelid types that have subsequently undergone parallel evolution. If the latter is the case, the phylum must be polyphyletic. Opinion is not unanimous in favour of either view. Because of such uncertainties, the classification of the arthropods and their close relatives is a matter of debate. In particular, the affinities of the Onychophora, Tardigrada, and Pentastomida are by no means clear. For this reason they are sometimes included together; for a discussion of these groups as oncopods, see ONCOPOD. Alternatively, the Onychophora are often elevated to the rank of phylum, while the Tardigrada and Pentastomida are regarded either as proarthropods or as orders of Arachnida. Some authorities treat all three groups as distinct phyla.

The classification adopted above is based on that suggested by Lord Rothschild in 1965, except that the Collembola are treated here as a separate class rather than as an order of apterygote insects; for a discussion of Collembola as apterygotes, see APTERYGOTE. The Xiphosura and Eurypterida are combined in the above classification into a single class (Merostomata) and not regarded as orders of Arachnida. Some authorities increase the number of arthropod classes by using Merostomoidea, Marellomorpha, and Pseudocrustacea and including a number of fossil forms, more usually regarded as Trilobita or Crustacea.

The ancestry of the myriapods and insects can only be guessed since there are no fossils to indicate their origins. These groups resemble Crustacea in that they are mandibulate and have antennae. On the other hand, the Merostomata, Arachnida, and Pycnogonida feed by means of chelicerae that terminate in pincers and are reduced in spiders. The division of classes into the subphyla Mandibulata and Chelicerata is a fundamental one. The chelicerates not only lack antennae, whose tactile function is taken over by the pedipalps, but they have no distinct head; rather, the region is fused with the thorax to form a prosoma, or cephalothorax. In the Onychophora, myriapods, and insects a whole limb has become a mandible, and the tip is used for biting. The Crustacea chew with the aid of a structure called a gnathobase, assisted by other segmental appendages.

Although the Symphyla share a number of characters in common with apterygote insects (*e.g.*, styles, coxal sacs, spinnerets, total cleavage, embryonic dorsal organ), they differ in location of the gonopore and in number of abdominal segments.

Artiodactyla

The mammalian order Artiodactyla, or even-toed ungulates, includes the pigs, peccaries, hippopotamuses, camels, chevrotains, deer, giraffes, pronghorn, antelopes, sheep, goats, and cattle. It is one of the larger mammal orders, containing about 150 species, a total that may be somewhat reduced with continuing revision of their classification. Many artiodactyls are well-known to man, and the order as a whole is of more economic and cultural importance than any other group of mammals. The much larger order of rodents (Rodentia) affects man primarily in a negative way, by competing with him or impeding his economic and cultural progress.

GENERAL FEATURES

Abundance and distribution. Artiodactyls were once the dominant herbivores (plant-eating mammals) of almost every continent. They are an important link in the chain by which the sun's energy, having been used by green plants, is made available to other forms of life. They tend to be medium- or large-sized animals. If they were any smaller they would compete with rabbits and the larger rodents, and if they were larger they would compete with elephants and rhinoceroses, the largest of terrestrial herbivores. The success of artiodactyls has depended on skeletal adaptations for running and on the development of digestive mechanisms capable of dealing with plant foods; none is adapted to flying, burrowing, or swimming. The individual species tend to be fairly narrowly adapted, in comparison with other mammals, but many of them nonetheless have broad distributions.

Native artiodactyls are absent only from the polar regions and from Australasia, but many have been introduced into Australia and New Zealand. In Australia, the position of medium and large herbivores is occupied by kangaroos. Through most of its evolutionary history, the order was absent from South America; only within the last few million years have some groups entered that continent. The occurrence of the majority of living artiodactyls in the Old World is a recent phenomenon; a considerable variety once inhabited North America.

Families of living artiodactyls

The order Artiodactyla contains nine families of living mammals, of which the Bovidae (antelopes, cattle, sheep, and goats) is by far the largest, containing nearly 100 species. There are five Eurasian and four African species of pigs (family Suidae) and two Central and South American species of piglike peccaries (Tayassuidae). The two hippopotamus species (Hippopotamidae) are African.

The more familiar large species were until recently widespread throughout Africa south of the Sahara and in the Nile Valley; the pygmy hippopotamus has a restricted distribution in West Africa. The camel group (Camelidae) was formerly abundant in North America, the now extinct North American stocks having produced the camelids of South America (wild guanaco and vicuña, domestic llama and alpaca) and the Old World dromedary and Bactrian camel.

The remaining artiodactyls (*i.e.*, the suborder Ruminantia) are all ruminants (cud chewers), the most primitive of which are the chevrotains (Tragulidae), with three species in Asia and one, the water chevrotain, in West Africa; the chevrotains are clearly remnants of a group that was once more numerous and widespread. Deer (Cervidae) are basically Eurasian and have not spread into sub-Saharan Africa, although they have reached the Americas. There are about 30 species, the greatest number being concentrated in South America and tropical Asia. The giraffe and the okapi (Giraffidae), two distinctive African species, are closely related to deer. The pronghorn (Antilocapridae), although sometimes called pronghorn antelope, is not a true antelope; it is the only survivor of a stock of ruminants that was very successful in the later part of the Tertiary Period in North America (about 2,500,000 to 65,000,000 years ago). The family Bovidae is primarily African and Eurasian, with a few members in North America. Bovids are advanced artiodactyls, many of which live in open grassland and semi-arid areas.

Importance to man. Artiodactyls have long been exploited by man for economic purposes. At Olduvai Gorge in East Africa there is clear evidence of the use of antelopes for food almost 2,000,000 years ago. In Europe during Paleolithic times (about 30,000 years ago) Cro-Magnon man depended heavily on the reindeer. By this time the use of animals other than as food had become established; skins were used as clothing and footwear, and bones were used as tools, weapons, and accessories.

The domestication of animals was a major advance in human history (see DOMESTICATION, PLANT AND ANIMAL). Domestication of herd animals probably arose gradually, perhaps before agriculture. Domesticated goats and sheep are first known from the Near East at some date close to 7000 BC. Cattle and pigs were domesticated at some subsequent date but certainly before 3000 BC. In South America the llama, now used for transport, and the alpaca, which provides a source of wool, were developed from guanacos by the Incas or their predecessors. The dromedary (*Camelus dromedarius*), domesticated in Arabia, was introduced into the Southwestern United States, southwestern Africa, and inland Australia in the 19th century. A large feral population now exists in Australia.

In addition to providing meat, milk, hides, and wool, artiodactyls have served man in a number of other ways. In Kashmir, the underfleece, or pashm, of the Siberian ibex (*Capra ibex*) and of local domesticated goats has been used as the basis for the manufacture of cashmere shawls. In southwestern France, pigs have been used to locate underground truffles (the fruiting bodies of certain edible fungi).

No group of mammals is more extensively hunted than the artiodactyls. Sport hunting of various deer supports a multimillion-dollar industry in North America and Europe. In many cultures hunting has been reserved for monarchs or the aristocracy. In the centuries after the Norman Conquest of England, the forest law provided severe punishment for the slaughter of deer and boars. Père David's deer (*Elaphurus davidianus*) of China now survives only because it was preserved first in the hunting park of the emperors of China and later by the Duke of Bedford after the slaughter of the Chinese herds at the end of the 19th century.

Wild ungulates were the primary source of meat for human populations long before the appearance of modern man. Prehistoric man hunted the large mammals of his environment with an ever increasing effectiveness that was certainly instrumental in his survival. The extent to which man was involved in the extinction of some of the larger Pleistocene animals (*i.e.*, those that were abundant 10,000 to 2,500,000 years ago) is still being investigated. There is now known to have been a wave of late Pleistocene extinction of large mammals, including artiodactyls; in North America this wave reached its zenith about 9000 BC. Many animals also became extinct in Africa, where long-horned buffalo and large relatives of hartebeests survived until very recently. More of the large mammals have survived in Africa than elsewhere, but the reason for their survival is not known. A second, probably final, wave of extermination of the larger mammals has taken place with the spread of European culture and firearms in the past 300 years. It has been marked by wanton slaughter and has ultimately produced an interest in conservation. It now seems, however, that the unprec-

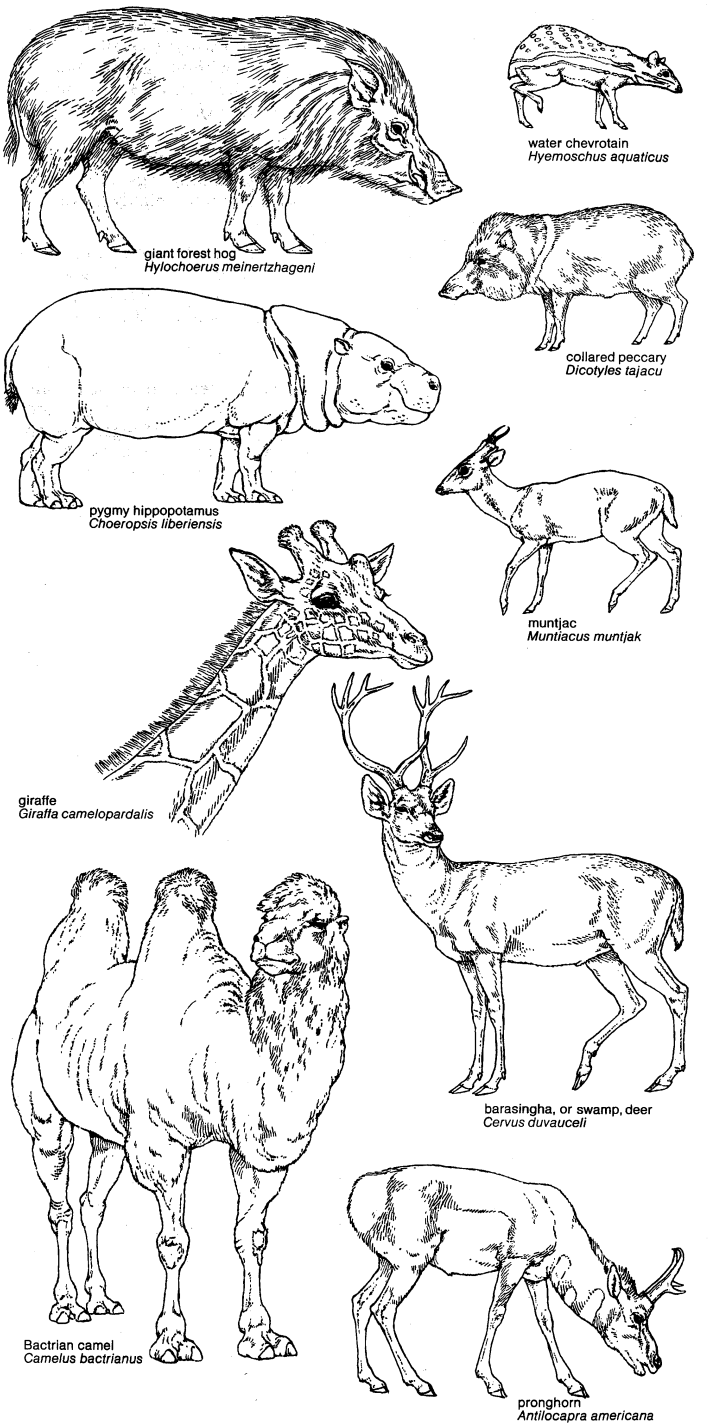

Figure 1: Representative non-bovid artiodactyls.
Drawing by R. Keane

edented demands on the environment being made by rapidly expanding human populations will result in a nearly complete extinction of large wild mammals.

Artiodactyls, like so many other animals closely associated with man, are a part of his religion and folklore, exemplified, for instance, by Aesop's *Fables* and the Persian worship of Mithras (see ANIMALS AND PLANTS IN MYTH AND LEGEND).

NATURAL HISTORY

Behaviour. *Migration.* Many artiodactyls undertake seasonal migrations between their breeding grounds and feeding areas or between different feeding areas. They can then take advantage of the seasonal changes in different areas. This means that larger populations, and hence a larger biomass (*i.e.*, the total weight of all individuals in an area), can be supported than if all passed their lives in one area. The North American mule deer (*Odocoileus hemionus*) comes from its summer pastures at high altitudes as the first snow falls and returns at the end of winter, several weeks after the snow has melted.

Seasonal changes

Social behaviour. Although the popular image of artiodactyls is one of great herds numbering thousands of individuals, some species are solitary, and many others form only small family groups. The maternal family unit, in fact, is the most cohesive one, providing the basis for herd formation. Most artiodactyls are more or less social, and grazing forms may be found in especially large aggregations. It appears that the practice of aggregating gives protection, favouring those members of the species that are the most active contributors to the gene pool (thus the most available to natural selection), since the individuals most frequently taken by predators are old, solitary males, males maintaining territories, and animals of either sex separated from the herd.

The advantage of herd behaviour

Social facilitation (the instigation of collective behaviour) takes place in herds. After one animal flees, all of the others flee, and the predator may thus not catch any. Social facilitation may also promote a restricted season for births; this helps survival of the young by denying these easy-prey individuals to predators through much of the year, and keeps the predator population lower than if young were available throughout the year. Another advantage of herding is that the older generation in a herd can guide migrations to water, feeding areas, or mating grounds.

Females and young are usually in herds separate from those of the younger males, but territorial (the older, proven) males may accompany the females. There are some variations of this behaviour. In the Eurasian roe deer (*Capreolus capreolus*), for example, the basic unit includes the doe, her litter of two, and often the young of the previous year. During the rutting (mating) season males associate with females in heat but do not gather harems. The female herds of red deer (*Cervus elephas*) are separate from the males except in the breeding season, when the stag will defend his female herd against other males. Among cattle and related species, the males associate with the females and young, but the bulls are ranked below a so-called master bull, each defending its place within the rank order. Female hippopotamuses and their young form a group in water and have a favourite resting and basking sandbank. The males have their resting places around this area. Each male's rank in the social hierarchy determines how close to the females he may be.

There can be some flexibility of social organization within a species. During the rutting season the male Rocky Mountain goat (*Oreamnos americanus*) makes little effort to herd females within a fixed area if there is little snow, but he does drive off other males. When there is much snow, he neither fights other males nor defends individual females.

Forest-dwelling artiodactyls often live singly, as does the okapi (*Okapia johnstoni*) of central Africa; individuals meet only for mating. Female moose (*Alces alces*) with calves are intolerant of their own young of the previous year and of adults, so even small herds do not form.

The territory of an animal is an area from which the possessor attempts to exclude other individuals of the same species (and occasionally other species). An animal in an area lacking its own scent is more timid and ready to flee. Among solitary artiodactyls the territory holder defends an area sufficient to meet his needs for food and shelter. Among social artiodactyls the territorial system is interwoven with breeding activities, and territories are normally defended only by certain males. Other males are driven off, and a percentage of males are prevented from mating.

Territoriality

The most simple territorial organization among artiodactyls is that of the common wild pig (*Sus scrofa*), which lives within a home range including resting, feeding, drinking, and wallowing places. There is little sign of territorial defense, and the herd (called the sounder) may move to a new area. At the other extreme, male Uganda

kob antelopes (*Kobus kob*) hold territories, for breeding only, that are as small as 15 to 30 metres (50 to 100 feet) in diameter. There are 30 to 40 territories on the breeding ground of a herd, and groups of females and young move about the territories despite the efforts of individual males to detain them. The semi-arid Serengeti plains of northern Tanzania contain nomadic aggregations of blue wildebeest (*Connochaetes taurinus*), males of which defend temporary territories only while an aggregation remains stationary.

In territorial defense an aggressive encounter between males is generally preceded by visual signalling of intentions. Chital deer (*Cervus axis*), for example, have several sorts of threatening displays. When sharp, potentially lethal horns appeared in early ruminants, intimidating displays rather than combats would doubtless have been favoured. Horns or antlers eventually functioned to maintain head contact during struggles rather than to bruise, slash, or gore. This stylized fighting, in which the competing males interlock horns or antlers and try to "outwrestle" each other, minimizes the danger of killing an opponent of the same species (conspecific). It evolved in two ways: further development of the wrestling, found in stags and some of the antelopes, and ramming, as in sheep. In sheep the horns are the sole organs of display. They increase in size throughout life and parallel the dominance order of the males, so that unnecessary fighting is minimized. Ramming may have intermediate forms; goats, for example, butt with a sideways hooking motion. In the fighting of hornless artiodactyls, such as pigs, the combatants may be badly mauled or even killed. The fighting behaviour of camels retains primitive elements of biting, kicking, and neck wrestling.

Reproduction. Many advanced artiodactyls have elaborate courtship behaviour, a regular component of which is for the male to sniff or lick the female's urine, and afterward to raise his head slightly with upcurled lips. This behaviour, which has been called *flehmen*, apparently enables the male to recognize females in heat. In the mating ceremonies of tragelaphine antelopes (kudus, bushbucks, and others) the male follows the female, nuzzling her neck several times. When he mounts, he lays his neck along hers so that their heads touch. In Thomson's gazelle (*Gazella thomsoni*), following the *flehmen* behaviour, the male runs close behind the female and finally taps her hindleg with his foreleg. Similar leg contact also occurs in some other antelopes. Its function could be to test the female's readiness to mate, to habituate her to contact, or to heighten her readiness to mate. It appears to be equivalent to the neck contact of tragelaphines. During mounting, the male Thomson's gazelle holds his head high and does not touch the female's flanks with his forelegs; the pair may continue walking. This is probably a more advanced pattern of events than that in tragelaphines. The kob antelope has elaborate displays after mating. These and the specialized sexual displays seem to be a consequence of this species' tightly clustered territories on the mating grounds. Another pattern occurs in the normally solitary Indian hog deer (*Cervus porcinus*); as many as 20 or 30 aggregate loosely in a certain area, then females and males leave in pairs and usually remain together until they have mated. Mating in artiodactyls often intensifies toward dawn and dusk.

Gestation periods

Gestation periods vary and are related in part to the size of the animal. They range from four months in the small chevrotain to 14 months in the Bactrian camel (*Camelus bactrianus*) and over 14 months in the giraffe. Females of normally gregarious species become solitary a few days before giving birth. The female chital, or axis deer, for example, remains near a patch of dense bush and high grass to which she can retreat if endangered. The female collared peccary (*Dicotyles tajacu*) withdraws to a burrow. The European wild pig gives birth in a rough nest.

In temperate regions, birth takes place in spring or early summer, and in tropical areas there are often more births during or just after the rainy season. The absence of a well-defined breeding season in a species may indicate less rigorous environmental conditions, which sometimes vary in different parts of a species' range. Warthogs have one restricted breeding season in most of eastern and southern Africa, while elsewhere two seasons or year-round breeding have been recorded. The breeding season of the waterbuck (*Kobus ellipsiprymnus*) is continuous in Uganda, but in Zambia there is a sharp peak at the height of the rains.

Most modern artiodactyls have one young at each birth, but there are some well-known exceptions among ruminants. The Chinese water deer (*Hydropotes inermis*) bears twins or triplets, but during gestation carries even more fetuses; early records (now known to be incorrect) of large litters were based on observations of dead pregnant females containing the large number of fetuses. The mule deer, white-tailed deer (*Odocoileus virginianus*), roe deer, pronghorn (*Antilocapra americana*), nilgai (*Boselaphus tragocamelus*), four-horned antelope (*Tetracerus quadricornis*), and saiga (*Saiga tatarica*) commonly bear twins. In the white-tailed and mule deer and in the saiga, a higher percentage of twins are borne by the older females; this is probably true in other species. The number of young is usually three in the warthog, five in the European wild pig, and two in peccaries.

The female wild pig almost ignores her young, which free themselves from their birth membranes and seek a teat. Female camels show comparatively little maternal attention and do not eat the afterbirth (the fetal membranes and placenta). Ruminants generally eat the afterbirth, as well as the dung and urine of the young, thus helping to prevent discovery of the young by predators. Licking of the young tends to facilitate its recognition

by the mother. An artiodactyl is normally precocious (well developed) at birth and may weigh one-tenth as much as its mother. An extreme example of precocity is the wildebeest calf, which rises within five minutes of birth, follows its mother within another five minutes, and can move as fast as an adult in 24 hours. Young deer fawns "freeze" during danger but rejoin the herd when the danger is long past or when retrieved by the mother.

Pigs and hippopotamuses are weaned after a few months, but among higher artiodactyls, lactation lasts longer. Wildebeest, for example, suckle for almost a year, although they start to eat grass when only a few days old. This may either maintain a bond between parent and offspring and form the base for larger social groupings or help to "develop" the four-chambered stomach. Higher artiodactyls eat soil when they begin to eat solid food, probably to establish a normal flora and fauna in the rumen (the first of the four stomach chambers).

Locomotion. Artiodactyls are preyed upon by carnivores and therefore need speed and agility to escape death. They have an added disadvantage in the sheer weight of their very large stomachs, which they need in order to digest plant food. Running ability reaches an extreme in advanced artiodactyls living in open country. The hippopotamus, with an adult weight of 2,500 to 3,000 kilograms (2¾ to 3⅓ tons), is the only living artiodactyl big enough to need heavy, pillar-like limbs for support.

In the normal walking of artiodactyls the legs move in the following order: (a) left front, (b) right rear, (c) right front, (d) left rear. This basic pattern is masked in faster walking or trotting by each foot being lifted off the ground before the one ahead of it in the sequence reaches the ground, resulting in telescoping the first (a and b) and second (c and d) pairs of movements. In galloping or fast running the two front legs leave the ground one immediately after the other, then the two back legs. The chief propulsive force in locomotion comes from the back legs, except in the giraffe (*Giraffa camelopardalis*), in which the front legs provide the main propulsive power.

Camels often amble, both legs of each side moving together, and the giraffe and the okapi always use this walking gait. Here the middle two (b and c) and the first and last (a and d) actions of the normal walking pattern occur together. The giraffe, having a short body and great height, could not adopt the normal ruminant gait without tripping. The long neck moves back and forth in time with the strides and helps smooth the movement. Galloping by the giraffe is of the normal ungulate type.

Artiodactyls living among bush or rocky cover may develop a bounding sort of gait in which the legs are pulled up very sharply during each stride. Deer and some antelopes are examples. When walking, species in such habitats are supported by the diagonally opposite legs for a greater length of time in each stride than are fast-running, open-country ruminants. This is a more primitive stable position and allows an easier leap from hidden danger. Some bovids, notably goats in Eurasia and the klipspringer (*Oreotragus oreotragus*) of Africa, are especially agile on rocky slopes and precipitous ground.

Maximum speeds of locomotion

The maximum speeds of some artiodactyls are: warthog, 48 kilometres (30 miles) per hour; camel, 14–16 kmph (9–10 mph); giraffe, a little over 48 kmph (30 mph); Cape buffalo (*Syncerus caffer*), 56 kmph (35 mph); Thomson's gazelle, 80 kmph (50 mph).

Ecology. *Food habits.* Most artiodactyls are closely tied to the resources of their environment. They are dependent, for example, on feeding areas not being covered by too much snow or shrivelled under a drought, and on the regulating effects of fire or other herbivores on the seasonal succession of vegetation. Various grazing species feed on grass at different heights. Browsers, those that feed on the foliage of shrubs and trees, show more extreme variation in feeding height, the maximum being that of the giraffe.

Herbivorous animals need less initiative and intelligence to collect food than do the meat-eating, hunting carnivores, but digestion is more difficult. Advanced artiodactyls have evolved the ability to bolt food and to ruminate it (chew it more thoroughly) at a later time or while resting in an area where they may be less obvious to predators and can conserve energy. Tropical artiodactyls frequently have adaptations for water conservation, having developed to a high degree internal physiological regulation (homeostasis).

Primitive artiodactyls were probably omnivorous but favoured plant foods, a characteristic still found in pigs. The latter dig with the snout and, to a lesser extent, with the front legs and upper tusks (canine teeth). The warthog of Africa (*Phacochoerus aethiopicus*) has a modified method of gathering food. When food is scarce it forages for young grass shoots under very low bushes; its tusks and localized thickening on its skin protect the eyes and muscles from thorn damage, and small incisors enable it to pluck food.

Hippopotamuses (*Hippopotamus amphibius*), although they spend a great deal of time submerged in lakes or rivers, do not feed in the water. They graze at night, wandering over well-used trails, sometimes far from water, often damaging crops.

Most members of the camel family are found in arid habitats. The vicuña (*Lama vicugna*) of the South American Andes lives at high altitudes where it grazes on soft grasses and herbs. It has much the same food requirements as domestic sheep.

Chevrotains live in dense undergrowth close to water or in marshes, where they browse on soft vegetation, roots, and tubers, following a way of life probably not unlike that of their ancestors.

The other ruminants browse or graze. They may take many plant species in the course of the year, but at any one season a large part of the diet consists of only five or six plants. Some ruminants are strongly specialized. The reindeer of the Arctic (*Rangifer tarandus*), for example, eats a variety of sedges, grasses, and herbaceous plants in summer but, as the long winter approaches, gradually shifts to a diet of lichens. It uses its front feet to scrape snow away from lichens to a depth of about 60 centimetres (two feet). The females are unique among deer in possessing antlers, which are thought to help them get scarce food in late winter by driving off the males that have by then shed their antlers. Reindeer may eat lemmings. The red deer, on the other hand, has catholic feeding habits. In woods it browses on lichens, berries, fungi, and the leaves of most deciduous trees; in open country it eats grass, heather, berries, and lichens. Shrubs and trees are used more in winter. When the red deer lives in the same areas as other ruminants it can be a serious competitor for food.

The importance of grasses in the ruminant diet

Grasses form a substantial part of the diet of many ruminants. Young grass consists of about 5 percent protein, 1 percent fat, 3 percent minerals, and 20 percent carbohydrates; the remaining percentage is water. The most noticeable changes as grass ages are an increase in carbohydrate content to 75 percent and a large decrease in the amount of water. Such food, especially when coated with silica, as are many grasses, or when covered with dust, would be impossible for nearly all nonruminant herbivores to eat or digest. The major evolutionary trend in ruminants has been to make use of grasses, and grasslands and the higher ruminants have evolved largely in adaptive balance with one another. This adaptive balance was shown during a study of the change from plains to thickets of scrub growth in an area in the eastern Congo over a period of about ten years. There was an accompanying decrease in numbers of antelopes and warthogs, no change in buffalo, and an increase in elephants and hippopotamuses.

There is not usually a one-to-one dependence of any artiodactyl species on one plant. The plant species that constitute the major part of the diet may vary with the season, and similar parts of different plants may be eaten in preference to other parts of the same plant. Food resources in an area are thus parcelled out among the various artiodactyls present. Sometimes behavioral differences minimize competition between closely related

species in the same area. A study has shown that in central Africa the roan antelope (*Hippotragus equinus*), a grazer, favours open areas with taller, ranker perennial grasses and is more or less sedentary within a small area; the sable antelope (*H. niger*), also a grazer, prefers savanna woodland or the edges of open areas, and herds follow a more or less cyclic annual route over an area of about 200 square miles. When pasturage is restricted, sheep will cut grass very short, and goats will damage trees and bushes. An American zoologist, George B. Schaller, has observed that, in Kanha Park in central India in the hot season, blackbuck (*Antilope cervicapra*) continue to graze on grass shoots in open areas; chital deer seek out tender grass blades, especially along forest edges, and also feed on leaves and fruits; barasingha (*Cervus duvauceli*) eat dry and moderately coarse grass along ravines; sambar deer (*Cervus unicolor*) browse on leaves and crop coarse grasses in the forest; and gaur (*Bos gaurus*) graze on tall, coarse grass and break down saplings to get at the leaves. The choice of habitat also varies: chital avoid steep terrain and forests with an unbroken canopy; blackbuck require less water than the others and thus remain in drier regions; sambar and gaur are less specialized in habitat requirements, and both are active primarily at night; barasingha prefer reed beds but also enter forests and climb hills.

It has also become evident that grazing successions are one of the mechanisms that enable the maximum use to be made of environmental resources. On the Serengeti plains, for example, the wildebeest grazes on ground already covered by the zebra and leaves the grazed grass in a condition suitable for the Thomson's gazelle. Interactions take place between artiodactyls and some plant species. It has been noted in the Tarangire area of northern Tanzania that *Acacia* seedlings germinate only where the impala (*Aepyceros melampus*) has left its dung. In parts of southern Peru plants growing on or close to the dung of the vicuña are different from those of the surrounding pasture.

Artiodactyls often favour the boundary zone between habitats. In Rhodesia, Lichtenstein's hartebeest (*Alcelaphus lichtensteini*) is usually found at the edge of clearings adjacent to woodland.

Areas of distribution. Some artiodactyls have surprisingly small ranges; Hunter's hartebeest (*Beatragus hunteri*) and the dibatag (*Ammodorcas clarkei*), for example, are found in two very restricted areas in eastern Africa. Others have extremely large ranges, such as the roe deer, which lives from the western shores of Europe to the eastern shores of Asia, or the red deer, which is found in a similar band across Eurasia and is regarded by many as conspecific with the North American wapiti or elk (otherwise called *Cervus canadensis*). Sometimes a considerable area may be occupied by a chain of related species, an example being the oryxes; the beisa and gemsbok (races of *Oryx gazella*) occur in South and East Africa, the scimitar-horned oryx (*O. dammah*) in West Africa, and the Arabian oryx (*O. leucoryx*) in Arabia.

The influence of climate on the distribution of artiodactyls

It is well known that climate is one of the factors limiting the ranges of artiodactyls. A number of South African antelopes differ, at the species level, from their ecological counterparts farther north in Africa. The bontebok and blesbok, races of *Damaliscus dorcas*, are found in the south and the sassaby (*D. lunatus*) farther north; the black wildebeest (*Connochaetes gnou*) occurs in the south and the blue wildebeest (*C. taurinus*) farther north. This probably is a result of climatic or climatically influenced factors; each species evidently functions best in a certain temperature and aridity range. Wide distributions can occur more easily along lines of latitude than they can by spanning the tropics to temperate or polar regions. Species that cross lines of latitude are often associated with mountain chains, examples being the Rocky Mountain goat, with its wide latitudinal range in western North America, and the goral (*Nemorhaedus goral*), found from Indochina to the Amur River. Climatic effects on distributions sometimes occur with regard to altitude. In Central Asia, the goa (*Gazella picticaudata*) is found in valleys from 10,000 to 12,000 feet above sea level, the chiru (*Pantholops hodgsoni*) and the yak (*Bos mutus*) are on the very high steppe between 18,000 and 20,000 feet.

South America has a more impoverished artiodactyl fauna than Africa, being limited to deer and camelids. This arises in part from the late arrival of the artiodactyls (deer in middle to late Pliocene, about 4,000,000 years ago, camelids perhaps a little later) and in part because a number of large rodents compensate for the shortage of large herbivores. The cervids in South America have not shown the same capacity for radiation in open country as have bovids in the Old World.

The areas of distribution and numbers of individuals are determined by complicated interweaving of effects not yet completely understood. Bloodsucking flies are thought to be the main reason that red deer in Scotland ascend to higher feeding grounds in June, and reindeer are afflicted by horse flies (*Tabanus*) and other dipteran pests. It is questionable whether the level of artiodactyl populations is controlled by predation, by availability of food, by reproductive rate, by disease, by climate, or by competition, insofar as these can be regarded as separate factors. It is known that undernourishment increases the susceptibility of an animal to the effects of parasites. If such an infected animal, say a pig, is caught by a leopard, it would be an oversimplification to assign a single reason for its death; it could have died from starvation, parasites, or predation. There is no evidence that artiodactyls are affected more than marginally by predators during most of their mature lives. Mortality is greatest among juvenile and aged animals. In a study of central African warthogs, it was estimated that a 60 percent loss occurred during the first six months of life in an expanding population and 95 percent in a declining one. Although predation was thought to be the main cause, another was the fact that the piglets had only limited control over their body temperatures and were thus more at the mercy of environmental temperature change. Food supply may sometimes be decisive, either directly or through the indirect action of intermediate agencies such as drought. The year 1961 lacked long rains, causing a severe shortage of forage in the Nairobi Game Park in Kenya. Many antelopes died of starvation, populations fell, and those of the blue wildebeest had not recovered nine years later, perhaps for reasons unconnected with the initial drought. Disease has generally been considered to have only a secondary importance in regulating numbers.

Thickness of the snow cover in winter is a very important factor for Asian artiodactyls. The saiga, for example, cannot move in snow deeper than about 40 centimetres (16 inches), and the wild sheep *Ovis ammon* in snow deeper than 60 centimetres (24 inches), at the most. The snow may have other effects; a layer of ice on top of snow may damage an animal's legs and weaken the animal to the extent that it is caught by a predator. Saiga may be unable to dig through even a shallow layer of compacted snow. Hoarfrost on vegetation is especially dangerous when prolonged or when it occurs in consecutive winters, though elk may escape the worst effects by feeding in winter on bark and high shoots. Massive periodic mortalities among Palearctic (Eurasian) ungulates in winter have been known since ancient times. The saiga has adapted to these crises by migrating great distances in a short time away from snowstorms or from areas where fodder is short. It also has a very rapid maturation to a reproductive state, ensuring that populations will build up after heavy mortalities.

Population density over the range of a species is affected by social behaviour, such as the effects of territoriality, dispersal of the young, and whether the species lives in herds. Fecundity may be reduced in overcrowded conditions by effects on reproductive control mechanisms, reduced viability of the young, or retarded maturation.

FORM AND FUNCTION

General structure. Artiodactyls have larger stomachs and longer intestines than carnivorous animals because

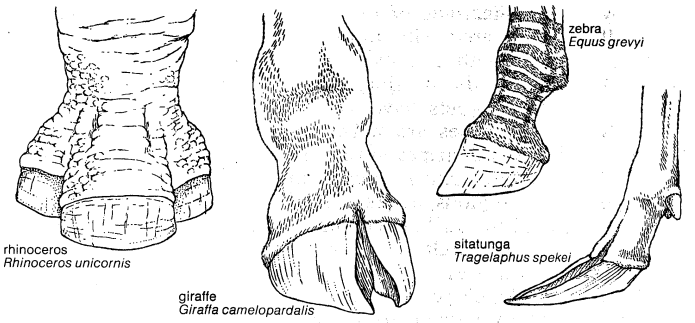

Figure 4: Comparison of even-toed (artiodactyl: giraffe and sitatunga) and odd-toed (perissodactyl: rhinoceros and zebra) ungulate feet.
Drawing by R. Keane

plant food is less easily digested than meat. The necessity of escaping predators and the handicap of a heavy digestive system have resulted in limb bone adaptations.

Comparison of odd- and even-toed ungulates

In all artiodactyls the main weight-bearing axis of the leg passes through the third and fourth toes together. This has been called paraxonic support and is contrasted with the mesaxonic limb support of the other great order of herbivorous mammals, the perissodactyls (rhinoceros, horse, tapir), in which the weight-bearing axis passes through the third or central toe alone. As artiodactyls evolved there was increasing development of the third and fourth toes and a parallel decline of the second and fifth toes flanking them. Progressive simplification of limb extremities has characterized their evolution, and even in the earliest known artiodactyls, the pollex and hallux (corresponding to the big toe and thumb of man) were already rare.

The other main morphological characteristic of artiodactyls is that the astragalus, one of the bones in the ankle, has upper and lower rounded articulations (areas of contact of bones) and no constricted neck, instead of simply one rounded articulation above a neck, as in other mammals. This character is so basic to artiodactyls that it has not developed very much within the known history of the order, having already been present in long extinct members. The artiodactyl astragalus also has an articulation on its rear surface for the calcaneum (heel bone). The three articulations are in nearly parallel planes, allowing the astragalus to rotate vertically.

Other features of the limbs, skull, and dentition distinguish artiodactyls. The ulna (posterior forearm bone) and fibula (posterior bone of the lower leg) have become reduced. The humerus, the upper bone of the foreleg, is large and has a large protrusion, the greater trochanter, to which muscles are attached. The femur, the upper bone of the hindleg, has a large greater trochanter and a second, lesser trochanter, but lacks the third trochanter characteristic of perissodactyls. There are typically 19 thoracic and lumbar (upper and lower back) vertebrae. The separate lumbar region of the spine is retained with its forwardly directed transverse processes (lateral projections on the vertebrae). There is no clavicle, or collarbone, in the shoulder girdle. The hip girdle shows fore-and-aft elongation and a well-developed ischium (upper anterior bone of the pelvis). There is never a penis bone.

The large tongue is very mobile and can be thrust forward. The brain is moderately developed, with folding of the surface of the cerebral hemispheres variably developed, often less in small artiodactyls than in large ones. The olfactory region of the brain is well developed and hearing is acute. The brains of earlier artiodactyls, such as the extinct entelodonts, were smaller than those of later forms. There are often scent glands on the head and body.

Specializations of the head. The skulls of pigs and peccaries lack a complete bony bar behind the eye (postorbital bar) as in most suiform artiodactyls and the early camels. The hippopotamuses, most camels, all ruminants, and two fossil suiform groups (entelodonts and oreodonts) have a complete postorbital bar. Any surface exposure of the periotic bone (bone around the ear) on the skull is called the mastoid, and skulls without such a surface exposure are described as being amastoid. Amastoid skulls are found in most suiform groups (including entelodonts, anthracotheres, and all living suiform groups); mastoid skulls occur in some early suiform groups, oreodonts, and all remaining artiodactyls that have lived since the end of the Eocene Epoch (about 38,000,000 years ago). Hippopotamuses have many modifications for aquatic life—large lungs, eyes and nostrils on top of the head, nostrils that can be closed by muscular control, and small ears. They are able to remain submerged for at least five minutes.

The distinction between horns and antlers

Horns and antlers. Pigs, peccaries, hippopotamuses, camels, and chevrotains have no horns or antlers. In the early Miocene, Old World ruminants related to giraffes and deer first developed such appendages. The majority of deer have antlers, defined as solid, bony, branched outgrowths of the frontal bones, present only in the males (but also in female reindeer) and shed seasonally. They are not covered by a horny sheath but, during a growth period of about four months, have a fine-haired skin or "velvet." The antlers have two basic branches, the anterior or brow tine, and the posterior branch or beam. The brow tine is unbranched, except in Père David's deer, in which both it and the beam are branched, the brow tine forming the dominant part of the antler. Antlers are specialized sex characters used for fighting by males in the rutting season and to scrape or slash at trees and bushes for territorial marking.

A study of the chital deer showed that antlers increase in size up to the seventh year, remain at a constant size until the ninth year, then decline. The horn of bovids consists of a hollow, unbranched horny sheath (formed of modified skin like fingernails and toenails) that fits over a bony core; horns are often present on both sexes. If such a horn is accidentally lost it is not regenerated; this is unlike the situation in deer, in which normal shedding is followed by regrowth. In the giraffe, but not in the okapi, horn growth is mainly from the parietal bone. The pronghorn has horns in both sexes. The sheaths are shed each year after the breeding season, and new ones develop under the old ones. The sheath is two pronged, but the underlying bony core is unbranched.

Teeth. There is a complete set of teeth in early artiodactyls and in modern pigs of the genus *Sus*, consisting on each side of three upper and lower incisors, an upper and lower canine, four upper and lower premolars, and three upper and lower molars. There has been a tendency toward reduction of the front teeth and development of a gap (diastema) between them and the back teeth. There has been very little tendency for the premolars to molarize, and the first premolar often disappears. Early forms had five-cusped upper molars, but the fifth cusp (protoconule) disappeared early.

Members of the suborder Suiformes have the full complement of incisors and canines, except for peccaries, which lack the lateral pair of upper incisors. Hippopotamuses have continuously growing incisors and canines, the lower canines being very large.

The canines of pigs grow continuously. In this group the canines are weapons for offense and defense, the sharp

cutting edges of the lower canines being maintained by wear against the uppers. Young camels retain the full complement of front teeth, with three incisors and one canine in the upper and lower jaws; the upper incisors are extremely small. In the upper jaw of the adult only the rear incisor and canine are present. The vicuña has continuously growing lower incisors.

The molars of pigs are low crowned (except those of the warthog) and have many cusps; those of peccaries are more simple. Peccaries have one less premolar than pigs; camels also have reduced premolars. Chevrotains have rather flattened lower premolars but have incipiently selenodont molars; *i.e.*, in which the cusps are drawn out into longitudinal crescents. Premolars of ruminants are wider, and the molars definitely selenodont. In many bovids and the pronghorn, but not in giraffes or deer, the molars are markedly high crowned.

Limb adaptations for fast running. Adaptations for fast running reach an extreme in advanced artiodactyls living in open country. In addition to the increased rotation of the astragalus, which increases the propulsive thrust at the ankle and enables a quicker recovery at the end of a stride before starting the next one, there are other features that help to increase the speed of striding. The legs of most camels and ruminants have lengthened, especially in the lower parts; the number of toes, or digits, in the feet is reduced from the original mammalian five, and ruminants walk on the tips of their toes. The muscles are inserted high on the legs; only tendons pass lower, so that a large mass is not concentrated near the tip of the limb, where its inertia would restrict speed of movement. Muscle contraction is fast. The movement of each leg is almost limited to a fore-and-aft plane. Emphasis on the fore-and-aft articulations between the limb bones is especially pronounced in many bovids, the alternating bones in the wrist (carpus) and ankle (tarsus) taking the strain of impact on uneven ground.

Pigs have four toes on each foot, but only two of them touch the ground. Their limbs are short and not very advanced. Peccaries have lost the outer accessory hind hoof in the back leg. All four toes of each foot of hippopotamuses touch the ground, and the terminal phalanges have nail-like hoofs. The toe bones of camels are completely enclosed in hardened, horny hoofs, and lateral toes spread across the broad pad which aids in walking on desert sands. Chevrotains have four hoofed toes on each foot; deer often retain the first and second phalanges (sections) of their lateral toes; but all bovids have lost the bones of their lateral toes.

The fibula bone in the back leg and the ulna in the front leg have been reduced in different artiodactyl lineages. Both are still complete in pigs and hippopotamuses, although the fibula is slender. In most other artiodactyls, the lower end of the fibula has survived, and the upper end is occasionally found, but always less noticeably. In camels the ulna has fused with the radius. Pigs, hippopotamuses, and camels have separate navicular and cuboid bones in the ankle, and magnum and trapezoid bones in the wrist; other artiodactyls have a fused naviculo-cuboid and magnum-trapezoid. In chevrotains and some deer, the adjacent ectocuneiform is sometimes joined with the naviculo-cuboid.

Modifications of the foot

The artiodactyl method of limb support through the third and fourth toes, with the attendant lengthening of lower limb bones, has frequently led to a fusion of the two principal metacarpal and metatarsal (midfoot) bones in the forelegs and hindlegs, respectively, forming cannon bones. The nearest approach to a cannon bone in the living Suiformes is the proximal fusion (*i.e.*, at the upper ends) of the two central metatarsals in peccaries. Camels have front and rear cannon bones, but the fusion does not extend right to the bottom, the lower articular surfaces being less pulley-like than in ruminants. There is a hind cannon bone in all chevrotains and, in addition, a front one in Asiatic species (*Tragulus*). All other living artiodactyls have front and rear cannon bones. Lateral metatarsals and metacarpals survive in chevrotains; splints of lateral metacarpals often survive in bovids; and either upper or lower splints of metacarpals in deer.

Modifications of the skin. *Hair and coloration.* Pigs are covered with rather sparse, coarse hairs, and peccaries with a denser coat of coarse hairs. Except for those of the warthog and the babirusa (*Babyrousa babirussa*), piglets have longitudinal stripes or flecks. Hippopotamuses are naked. Tragulids have light-coloured flecks and stripes in their fur. The coats of camelids and deer are much thicker in species living toward the polar regions, at great heights, or in deserts, but are not noted for striking colours or patterns. Many young deer and the adults of a few species have pale flecks and stripes, and some South American deer have reddish fur. Antelopes have a wider range of coat colours, and some are strikingly marked; *e.g.*, the oryxes, bontebok, and blesbok of southern Africa.

Scent glands. External glands occur in various places on artiodactyls. Preorbital glands, immediately in front of the eyes, are present in the giant forest hog (*Hylochoerus meinertzhageni*), in all cervids except the roe deer, and, among the bovids, in duikers, many neotragines, gazelles and their allies, and the hartebeest group. These glands are apparently required in small forest forms and have disappeared in many, but not all, open-country forms. In some, the glands are definitely connected with territorial marking; a firm object is marked by rubbing, soft vegetation by swinging the head gently from side to side. Foot, or pedal, glands are present in the African bush pig (*Potamochoerus porcus*), camels, tragulids, the pronghorn, some bovids, and on the back legs only of most American deer.

Inguinal (belly) glands are found in bovids, there being two in sheep, saiga, chiru, gazelles, duikers, and blackbuck, and four in members of the tribes Reduncini and Tragelaphini. Carpal (wrist) glands are present in some pigs, some gazelles and allies, and the oribi (*Ourebia ourebi*). Glands in other positions are rather less frequent, but postcornual ones (behind the horns) occur in the Rocky Mountain goat, the pronghorn, and the chamois (*Rupicapra rupicapra*), supraorbital ones in muntjacs (several species of *Muntiacus*). There are jaw glands in the pronghorn; neck glands in camels; dorsal glands on the back of peccaries, pronghorn, and springbok; and preputial glands (in front of the genital region) in several pigs, grysbok (*Raphicerus melanotis*), and the musk deer. Tail glands are found in musk deer, pronghorn, and goats; tarsal glands in pronghorn and American deer; and metatarsal glands in camels, some deer, and the impala. Pronghorn, blackbuck, gazelles, and oribi are thus particularly well equipped with glands. The use of such glands, apart from the use of preorbital glands in some species for territorial marking, is a matter for conjecture. Chital deer, when alarmed, thump the ground several times with their hind feet, which possess glands; the scent remaining on the ground may function as a danger signal. In general, mammals often mark with their glands when they are threatening other individuals of their own species.

Digestive system. The higher artiodactyls feed only on plant matter, which consists largely of cellulose and other carbohydrates and water. This necessitates adaptations of the structure and functioning of the stomach and intestines. Even pigs have enlarged stomachs—they have a pouch near the cardiac orifice (the upper opening) of the stomach—and in peccaries the stomach is more complicated. In hippopotamuses the stomach is divided into four compartments, and micro-organisms ferment food as part of the digestive process. Unlike pigs, hippopotamuses have lost the cecum (a blind pouch) further on in the gut.

The multichambered stomach

In the most advanced ruminants, the much enlarged stomach consists of four parts. These include the large rumen (or paunch), the reticulum, the omasum (psalterium or manyplies)—which are all believed to be derived from the esophagus—and the abomasum (or reed), which corresponds to the stomach of other mammals. The omasum is almost absent in chevrotains. Camels have a three-chambered stomach, lacking the separation of omasum and abomasum; the rumen and reticulum are equipped with glandular pockets separated by muscular

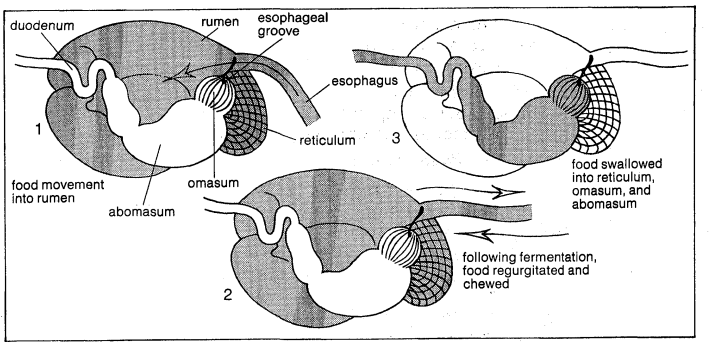

Figure 5: Stages of digestion in the four-part stomach of a representative ruminant.
Drawing by R. Keane

walls having sphincters (valves) and glands. The esophagus opens into the rumen, not into the area between rumen and reticulum; these and other differences suggest that camels evolved the ruminating habit independently of the true ruminants. The total stomach of the domestic ox (*Bos taurus*) occupies nearly three-quarters of the abdominal cavity, and, even in medium-sized cattle, the rumen alone can have a capacity of 25 to 75 gallons, having undergone a tremendous growth in early life, with the changeover from a milk diet.

Food taken into the rumen is later regurgitated into the mouth and completely masticated, then swallowed again and passed to the reticulum, omasum, and abomasum. The regurgitation and chewing in the mouth is called rumination.

In the rumen many different species of minute protozoans (animals) and bacteria live without free oxygen. The digestion of the cellulose of plant cell walls is the main function of the fauna and flora in the rumen, since mammalian digestive juices are incapable of digesting cellulose. The contents of the plant cells are thus released for digestion. Large volumes of saliva are secreted into the rumen to help digestion. Soluble products of microbial action, mainly fatty acids, are absorbed through the rumen wall. In the omasum, some fatty acids and 60–70 percent of the water are absorbed; in the abomasum gastric juice containing hydrochloric acid is secreted, as in an ordinary mammalian stomach.

In the rumen any ingested protein is degraded into fatty acids and ammonia; the ammonia and other simple nitrogen-containing substances are used by the micro-organisms for their own cell-protein synthesis. These organisms are ultimately digested in the abomasum and small intestine, thus providing the ruminant with protein.

Many artiodactyls are adapted to living in conditions of water shortage. The best known and one of the most spectacular examples of this is the camel. Its body temperature can fluctuate according to the outside temperature, thus minimizing water loss through sweating; it excretes rather dry dung and a concentrated urine (*i.e.*, high in urea and low in water) and is not seriously weakened by as much as a 25 percent dehydration in its body, since water is not withdrawn from the bloodstream and the continuing circulation avoids any buildup of excessive internal temperatures. The thick coat hinders the inward transference of heat from the environment (the temperature of which may often exceed the animal's body temperature); a thirsty camel can take in water very rapidly. Oryxes and gazelles are antelopes noted for needing little water, the dorcas gazelle (*Gazella dorcas*) in the Sudan depending on leaves of *Acacia* bushes for its water. The zebu (a form of domesticated cattle) needs less water than most temperate climate breeds.

Reproductive specializations. The testes of male artiodactyls descend outside the body cavity but may regress into the abdomen in the nonbreeding season. Female pigs have many teats, but ruminants have only two to four (although domestic cattle occasionally have as many as six). Among the bovids, the alcelaphines (hartebeests, wildebeests, and relatives), gazelles, and some caprines (sheep, goats, and relatives) have two, the rest have four.

The unborn mammal within its mother breathes, feeds, and excretes through an organ called the placenta, which is connected with the tissues of the mother's uterus (womb) wall. Hippopotamuses and pigs have an epitheliochorial placenta, a layer of fetal tissue merely pressed close against the uterus wall, but camels and ruminants possess a syndesmochorial placenta, in which the epithelium of the maternal tissues is eroded to facilitate intercommunication. This is an advance over the epitheliochorial placenta, but the artiodactyls are not particularly advanced, when compared with other mammals, in which there may be still closer association of maternal and fetal blood vessels (endothelial and hemochorial placentas). Even in many syndesmochorial placentas the uterus lining may be wholly or partly restored before the end of pregnancy. Although there is no erosion of maternal tissues in the epitheliochorial placenta, the capillaries beneath the fetal and maternal surface layers may pass just beneath the surface layers, making them thin. The actual fingerlike processes (villi), through which the placenta contacts the uterus, are evenly distributed ("diffuse" placentas) in hippopotamuses, pigs, camels, and tragulids; in higher artiodactyls they are in pockets or groups called cotyledons ("cotyledonary" placentas). It is interesting that there are few of these cotyledons in deer—for instance only five in Père David's deer—but many in giraffes and bovids (up to 160 or 180 in giraffes and goats). The musk deer (*Moschus moschiferus*) is exceptional among deer in retaining a diffuse placenta.

The epitheliochorial and syndesmochorial placentas

EVOLUTION AND PALEONTOLOGY

The artiodactyls can be traced back to a probable descent from a group of early generalized mammals called condylarths, and were certainly distinct by the Eocene Epoch, which ended about 38,000,000 years ago. Fossil artiodactyls can be more or less convincingly classified in three suborders; the more primitive Suiformes, centred around pigs, the Tylopoda, centred on camels, and the Ruminantia or ruminants. The most primitive artiodactyls are the suiform group Palaeodonta, which had four functional toes on each foot, primitive, low-cusped cheek teeth, and the typical artiodactyl astragalus. The artiodactyls became more prominent in the Oligocene (between about 38,000,000 and 26,000,000 years ago) with a decline of the then dominant perissodactyls, and the later history of artiodactyls appears as successive waves of groups, each better adapted than its predecessors to the changing environment. In the suiform line, the earlier palaeodonts are succeeded by other groups such as the entelodonts, giant "pigs" of the European and North American Oligocene, characterized by very large skulls (some nearly a metre long), very small brains, and a large, bony flange below the eyes. The functionally two-toed ruminants succeeded four-toed suiforms in the Miocene, and within the Old World ruminants of the bovid subfamily Caprinae, the zenith of the tribe Caprini, for example, followed that of the mainly Pliocene tribe Ovibovini.

The earliest artiodactyls

The artiodactyls had an interesting history in North America through the Tertiary Period. Some forms, such as the entelodonts, were shared with the Old World, but

others were characteristic of North America. One very prominent New World family was the merycoidodonts (or oreodonts), which lasted until the early Pliocene (about 6,000,000 years ago). They had somewhat piglike proportions, short faces, a large upper canine and a caniniform first lower premolar, and selenodont molars. A close relative, *Agriochoerus*, had clawed feet, the function of which remains uncertain.

Camelids evolved in North America and, at or toward the end of the Tertiary, spread into South America and into the Old World. By the end of the Pleistocene they all became extinct in their homeland, just as horses did. The hypertragulids were a mainly Oligocene group of chevrotain-like forms related to the Protoceratidae. The latter had horns above their noses, a position unique among artiodactyls, as well as in the usual position. The North American Miocene (26,000,000 to 7,000,000 years ago) produced some ruminants, such as *Blastomeryx*, that are hard to distinguish from the early palaeomerycine relatives of giraffes and deer in the Old World, which, with the North American groups, constitute the family Palaeomerycidae. Some developed horns, and the dromomerycine *Cranioceras* even had a third horn above the back of its skull. During the Miocene and Pliocene there finally appeared relatives of the surviving pronghorn, an example being *Merycodus*. Many of these North American groups have parallels with Old World groups, and the subject of North American artiodactyl evolution is of great interest. Only further finds will indicate whether *Blastomeryx*, the dromomerycines, *Merycodus*, and the pronghorns evolved from hypertragulids already in North America or sprang from some immigrant ruminant and, if the latter, whether the supposed hypertragulid *Leptomeryx* could be such an immigrant ruminant. It is uncertain whether the hypertragulids are nearer the tragulines or the camels, and how close the oreodonts are to the anthracotheres. Of the great New World radiation there survived after the Pleistocene only three or four camelid species and the pronghorn (deer and bovids in the Americas are immigrants), whereas in the Old World as little as 200 years ago, Eurasia and Africa had abundant deer and antelopes.

Until the Miocene there were some archaic artiodactyls in Europe, the xiphodonts, which have cautiously been taken as tylopods, and the cainotheres and anoplotheres, which are classified near anthracotheres.

A possible ruminant ancestor was *Archaeomeryx* from the upper Eocene of China, a small animal that already had a fused naviculo-cuboid bone in the ankle. Tragulids occurred in Africa and Eurasia back to the Miocene, and the more advanced gelocids are known from the upper Eocene and lower Oligocene. At the end of the Oligocene, the first ruminants began to appear with teeth more advanced than those of tragulids. From early in the Miocene they began to be recognizable as giraffes, deer, or antelopes, although the last were relatively uncommon before the late Miocene. Much remains to be learned about the detailed early history of these groups. Several different giraffids lived in later Miocene and early Pliocene times, but the group has since declined to only two species. Deer gradually acquired more complicated antlers, which became very large in some lineages. Different subfamilies of bovids originated in Eurasia and Africa, and it is of zoogeographic interest that representatives of African subfamilies have been found as fossils in northern India and Pakistan.

CLASSIFICATION

Annotated classification. The following classification is principally based on that of American paleontologist George Gaylord Simpson, with alterations in the bovid subfamilies, in the placing of early relatives of giraffes and deer in a giraffoid subfamily Palaeomerycinae, and in the placing of hypertragulids and protoceratids with camels. Groups indicated by the dagger (†) are known only as fossils.

ORDER ARTIODACTYLA

Cloven-hoofed ungulates, the major group of herbivorous mammals. Weight supported mainly through 3rd and 4th toes; astragalus with upper and lower articulations rounded. Stomach compound and, with intestines, enlarged for plant digestion. About 150 species.

Suborder Suiformes

Complete dentition, bunodont (low-cusped) molars, short legs, 4-toed feet are among their important characteristics.

†Infraorder Palaeodonta

Eocene to lower Miocene. Primitive, small-brained artiodactyls. Two superfamilies, Dichobunoidea and Entelodontoidea, with 5 and 3 families, respectively, and collectively about 30 genera.

Infraorder Suina

Lower Oligocene to present. Includes the living pigs, peccaries, and their likely ancestors and extinct relatives.

Family Suidae (pigs). Lower Oligocene to present; Old World. Small to moderate size; shoulder height to about 100 cm (39 in.). Coarse hair. Omnivorous, with sharp-edged tusks. Five Recent and about 22 fossil genera.

Family Tayassuidae (peccaries). Differ from pigs by having 1 fewer incisor and premolar, smaller canines, less advanced cheek teeth; hindleg with a cannon bone, more complicated stomach and more densely haired coat.

Infraorder Ancodonta

†Family Anoplotheriidae. Eocene and Oligocene; Europe; uncertain relationships.

†Family Anthracotheriidae. Eocene to Pleistocene. Mainly Old World, a few in North American Oligocene. Large, with cheek teeth showing beginnings of selenodonty.

Family Hippopotamidae (hippopotamuses). Middle Pliocene to present. Thought to be derived as late as the Pliocene from anthracotheres. Old World, now restricted to Africa. One large (shoulder height to 170 cm; weight to 3,000 kg) and one small species (height to 90 cm). Feed on land but frequently resort to water.

†Family Cainotheriidae. Mainly Oligocene; small European forms of uncertain relationships.

†Infraorder Oreodonta

†Family Merycoidodontidae (North American oreodonts). Eocene to early Pliocene. No suppression of upper incisors, an incisiform lower canine, selenodont cheek teeth, short faces and short limbs.

†Family Agriochoeriidae. Eocene to lower Miocene. Close to the above family but with clawed feet.

Suborder Tylopoda

Some reduction of upper incisors, reduced premolars, selenodont cheek teeth; cannon bones present. Feet became 2-toed early in the geological history of the group.

†Family Hypertragulidae. Upper Eocene to lower Miocene; North America. Like Old World Tragulina (see below) but with a canine-like first lower premolar. Fused naviculo-cuboid in the ankle.

†Family Protoceratidae. Oligocene to lower Pliocene; North America. Some with horns on the top and at the front of the skull. Later ones with hindleg cannon bone. Generally considered close to hypertragulids, but failed to fuse navicular and cuboid bones.

Family Camelidae (camels and lamoids). Upper Eocene to present; now a relict group, represented in southern South America, in Asia, and in North Africa. Red blood corpuscles oval. Gallbladder absent. The hump of the 2 Old World camels is composed of fibrous connective tissue and fat.

†Family Xiphodontidae. Eocene and lower Oligocene of Europe. Already 2-toed, despite their antiquity, and tentatively placed with the camels.

Suborder Ruminantia (ruminants)

Upper incisors lacking; lower canine incisor-like; cheek teeth selenodont. Fused magnum-trapezoid bone in the wrist. Two-toed feet evolved within suborder.

Infraorder Tragulina

†Superfamily Amphimerycoidea

†Family Amphimerycidae. European Eocene and Oligocene of Europe; poorly known. Asian *Archaeomeryx*, usually placed in the Hypertragulidae, but may fit here; it retained upper incisors and had a fused naviculo-cuboid in the hind leg.

†Family Gelocidae. Eocene-Oligocene of Europe and Asia.

Superfamily Traguloidea

Family Tragulidae (chevrotains). Miocene to present. Sabre-like upper canines in males; incipiently selenodont molars.

Bony carapace often develops above the pelvic girdle in males.

Infraorder Pecora

Mostly with horns or antlers and without upper canines. Hollowed auditory bullae. Four-chambered stomach.

Superfamily Giraffoidea

†*Family Palaeomerycidae*. Upper Oligocene to upper Pliocene; North America, Europe, Asia, Africa. Three subfamilies, the Palaeomerycinae (Old World basal stock for giraffes and deer), Blastomerycinae, and Dromomerycinae (the last two New World).

Family Giraffidae (giraffes and okapi). Miocene to present; Old World, now confined to Africa. Living giraffes long-necked and long-legged; the okapi more compact. Giraffes may be up to 5.5 m (18 ft) in total height. Extinct relatives including the large, short-legged, and grotesquely horned sivatheres. Living species have no gallbladder.

Superfamily Cervoidea

Family Cervidae (deer).

Subfamily Moschinae (musk deer). Pleistocene and present; Asia. One recent species, the musk deer (*Moschus moschiferus*) with sabre-like upper canines, gallbladder present (lacking in most other deer).

Subfamily Muntiacinae (muntjacs). Lower Miocene to present; southern Asia. Includes the living muntjacs (*Muntiacus*), with small, 2-pronged antlers above a long, skin-covered base; and tufted deer (*Elaphodus cephalophus*) with tiny antlers. Eurasian fossil genus *Dicrocerus* had larger, 2-pronged antlers. All have large, curved upper canines.

Subfamily Odocoileinae. Pliocene to present. Characterized by the persistence of the lower ends of the lateral metacarpals, thickly haired skin between the hoofs, and in all except the moose a large interdigital gland in at least the hindfoot. The vomer is fused far back posteriorly with the palate in the American deer and in the reindeer. Includes moose (Eurasian elk), reindeer, roe deer, perhaps the Chinese water deer (which has long canines but no antlers), and the deer of North and South America other than the wapiti (American elk), a cervine.

Subfamily Cervinae. Pliocene to present. Top ends of the lateral metacarpals persist. Smooth skin between the hoofs; interdigital glands lacking. Branching of beam of antler differs from that in New World deer; red deer and wapiti, fallow deer, chital, sika, Père David's deer.

Superfamily Bovoidea

Family Antilocapridae (pronghorn and merycodonts). Miocene to present; North America. Smooth, branched horns consisting of hollow sheaths over bony cores; only sheaths shed annually; in fossil Merycodontinae, 1 or more burrs at base of cores. Teeth high-crowned.

Family Bovidae (cattle, sheep and goats, antelopes). Wild cattle, sheep, and goats were ancestral to domestic livestock not differing in any fundamental characters from antelopes. Great variety in horn shape. Many with high-crowned teeth.

Subfamily Bovinae (cattle and some antelopes). Miocene to present. African tribe Tragelaphini, with keeled, spiral horns and not very advanced teeth, includes eland, kudu, nyala, and bushbuck. Tribes Boselaphini and Bovini, mainly Eurasian, former including the Indian nilgai, the 4-horned antelope, and some extinct forms, the latter including cattle, bison, and buffaloes. Bovini are descended from extinct Boselaphini; large size, up to 180 cm at the shoulder. Teeth specialized for grazing. Animals wallow frequently.

Subfamily Cephalophinae (antelopes). Mostly small, with tiny horns set toward the back of the head. Gallbladder lacking. Generally forest-living. African duikers.

Subfamily Hippotraginae (antelopes). Moderate-sized, stocky, mainly grazing antelopes; shoulder height 60–160 cm. High-crowned teeth. Tribe Hippotragini includes the roan, sable, oryx, and addax antelopes; and Reduncini the reedbuck, kobs, lechwes, and waterbucks. Oryx and addax inhabit arid areas; others near water with adjacent cover or high grass. All except nearly extinct Arabian oryx are now native only to Africa, but the subfamily formerly occurred in India.

Subfamily Alcelaphinae (antelopes). African wildebeests, hartebeests, topis, and several extinct lineages. Long-faced, plains-living, grazing antelopes. Sometimes included in the Hippotraginae.

Subfamily Antilopinae (antelopes). Tribe Neotragini includes some small African antelopes, and Antilopini include gazelles, springbok, and the Indian blackbuck. Graceful, long-legged antelopes of arid, open country. Subfamily may also include the saiga and the Tibetan chiru (tribe Saigini), hitherto classified with Caprinae.

Subfamily Caprinae (sheep, goats, and relatives). Mainly Eurasian. Moderate-sized, shoulder height often 90–100 cm. High-crowned teeth. Agile animals; many species in mountains or on steep, rocky slopes. Tribe Caprini comprises sheep and goats; Ovibovini the musk-ox (*Ovibos*), the Chinese takin, and some bizarre extinct forms; Rupicaprini the chamois, serow, goral, and Rocky Mountain goat.

Critical appraisal. The great 18th-century classifier Carolus Linnaeus recognized the camels and ruminants as associated but placed some nonartiodactyls with them. It was the French naturalist Henri de Blainville who, at the beginning of the 19th century, first recognized the complete order of artiodactyls as it is accepted today. Nine discrete groups exist among the living forms: pigs, peccaries, hippopotamuses, camels, chevrotains, deer, giraffes, pronghorn, and bovids; their classification presents no great problems, apart from a few genera. Fossils, however, bring confusion to various schemes.

The relationship of North American Tertiary artiodactyls to those of the Old World is a basic question in the study of their zoogeography, history, and classification. It can be agreed that the camels evolved in North America and are as old as the tragulines, which in the Old World were ancestral to ruminants. Most paleontologists today believe that the hypertragulids, protoceratids, and oreodonts were related to the camels, but others have linked the first two groups with the tragulines and the oreodonts with the anthracotheres. Other questions affecting the higher levels of artiodactyl classification are the placing of the North American native ruminants and whether the earliest Old World pecorans should be taken as giraffoids or cervoids.

The subdivisions of the Bovidae remain controversial. Modifying a classification proposed by German zoologist Max Schlosser, some authorities have grouped the Bovinae, Cephalophinae, and Hippotragineae as the Boödontia and the Alcelaphinae, Antilopinae, and Caprinae as the Aegodontia, to indicate phyletic lines believed to have arisen early in bovid history. Boödonts and aegodonts have evolved differently in Africa and Eurasia, and there is much to be said for developing a classification that reflects these geographical relationships. Until additional evidence of phylogenetic relationships is available, however, the modified version of Simpson's classification above will remain favoured by most taxonomists.

Arts, Classification of the

As long as the term "arts" is applied to a realm so vast and indefinite as to embrace literature, music and dance, theatre and film, the visual and decorative arts, and other equally diverse activities, their classification—the ways in which each is regarded as being either unique or like others—will remain a controversial but necessary undertaking. Classification is a useful approach to the organization of knowledge in any field: the classification of plants and animals in the 18th century led to the discovery of evolution in the 19th. In the arts, classification can be of immense help in understanding the interrelations between the arts and in drawing attention to characteristics of each that might otherwise go unnoticed. Whether it is consciously devised or largely unconscious, some sort of classification is implicit in any serious exploration of the arts. Related to it is an appraisal of the importance and value of each of the arts. Admirers of a particular art often feel that it is unique and deny that it is like any other. Logically, however, anything correctly described as a work of art, whether a poem, a picture, or a sonata, belongs to that class and hence resembles other members of the class to some extent. Some works or types of art are more nearly unique than others in resembling fewer others or in resembling others in fewer respects. On the other hand, no type or example is exactly like any other, but the differences may be negligible for all practical purposes.

Classifying the unique

There is no one correct way of making a classification. The aims and interests of the person making the classification, and his philosophical orientation, are usually significant factors. The emphasis may be placed on sensory qualities, for example, or on moral and religious ideals. Regardless what classification is used, however, as it is subdivided into smaller groups, detailed similarities and differences are brought out in the emotional, intellectual, and social features of the works or art involved.

The classification of the arts is closely related to subjects that receive more extensive treatment in the articles AESTHETICS; ART, PHILOSOPHY OF; and ARTS, CRITICISM OF THE. More extensive discussions of certain specific systems of classification may be found in articles such as ARTS, STYLE IN THE; PRIMITIVE, FOLK, AND POPULAR ARTS; and ARTS, SOCIAL AND ECONOMIC ASPECTS OF THE. The relationship between the arts within a given culture is discussed in such articles as SOUTH ASIAN PEOPLES, ARTS OF and comparable articles on the arts of other peoples.

The article that follows will attempt only to draw the reader's attention to the importance of the subject of classification in the study of the arts and to offer him means of applying thoughtful scrutiny to a process that has too often remained subconscious.

BASES OF CLASSIFICATION

To classify things is to arrange them in groups or sequences according to a plan, especially on the basis of some characteristic that they are thought to have in common. Thus, the names in a directory may be arranged according to the letter of the alphabet with which each last name begins. A biologist classifies the kinds of animal or plant within a certain area. A museum of art may place its sculptures in one gallery, its paintings in another. It may also classify them according to historical period, such as Italian Renaissance or 18th-century French.

A base or basis of classification is a concept of what the members of a certain class are thought to have in common, a factor that can be used either for grouping them or for separating them from other classes. "Subject represented" is one such base: it may be used to separate "paintings" into three or more groups, such as portraits, landscapes, and narrative scenes. This involves classification in a narrow sense of the term; that is, as grouping certain items or subgroups together under certain headings. It also involves division, which can be regarded as the opposite of classification, but the latter term is usually made to cover both processes. A large, complex art such as literature can be divided into smaller ones, such as poetry and prose. Each of these also can be subdivided, as into epic, dramatic, and lyric poetry. A relatively complex, detailed division and classification of the arts from a philosophic point of view is called a system of the arts.

The study and scientific practice of classifying phenomena in an extensive field is called taxonomy. In biology and other exact sciences, it is highly complex and consistent, with precise definitions. Thus a "genus" in biology comes between a "family" and a "species." In classifying arts, however, such terms are used more loosely. Thus, genus can mean, in aesthetics, any fairly large, inclusive group, capable of including subgroups and also of being subsumed under a still larger group. A species, in the broad sense, is one of the main divisions of a genus, and the traits or characteristics of a genus are generic traits. Differentiae are ways in which individuals or subgroups in a larger group are significantly unlike. Aristotle distinguishes between epics and tragedies in poetry in terms of differentiae.

Taxonomy in the arts

To define or locate a particular example or subgroup in a system of classification, it must be ascertained, first, what genus (inclusive group) or genera it belongs to and then how it differs from others in that group or groups. A species is one of the main divisions of a genus, but it may also act as a genus (in the broader sense of that word) by including smaller groups.

Problems of definition. What are the arts, and what is art in general? This is still a controversial question after centuries of debate. No particular definition commands universal assent. Several meanings are still frequently used, of which the oldest is the broad, technical sense. In this sense, the English term art and its equivalents in Greek and Latin covered not only what are now called "fine arts" or "aesthetic arts" but any kind of transmitted, useful skill, such as agriculture, medicine, and war. This sense of "art" survives in such terms as Bachelor of Arts, a degree that is often awarded for a course of study that involves no aesthetic arts at all.

In the 18th century, the so-called beaux arts, the beautiful or fine arts (also called "elegant" or "polite" arts), were distinguished from the merely useful arts on the ground that they were aimed at giving aesthetic pleasure to the beholder. In the 19th and 20th centuries, there has been a tendency to abandon the term art in speaking of the purely utilitarian skills and to call them instead "industries," "technics," "branches of engineering," or "applied sciences." Without the prefix fine, the word art alone is now commonly understood to mean the fine or aesthetic arts. To produce an experience of beauty or aesthetic satisfaction is said to be their distinguishing function or characteristic but not necessarily their only one. In this moderately broad, technical sense, some, but not all, architecture, furniture, and clothing can qualify as arts in spite of their useful purposes. They can be called useful arts, rather than merely useful skills, because they combine aesthetic and utilitarian forms and functions. On the other hand, such technics as coal mining and placing metal pipes underground do not qualify as arts at all, since they do not ordinarily involve aesthetic perception.

In psychology, anthropology, and other sciences, a particular product or performance does not have to be beautiful or aesthetically satisfying to qualify as art. The same can be said of much primitive art, children's art, and art produced by the insane. They may be classed as art if they belong to types of product or performance that have been socially recognized as having an aesthetic function. In this sense, any picture, clay figure, dance, or traditional song can be accepted as a work of art, whether beautiful or not. Being nonevaluative, this conception makes it possible for the scientist to study the arts as a field of cultural phenomena for investigation, without having to show in advance that they are pleasant, good, or beautiful.

In another sense of "art," called the expressionist theory, art has been defined as the expression and transmission of remembered emotion. This definition is not inconsistent with the technical meanings, but it puts an emphasis on the artist's procedure rather than on the effects and functions of the product.

In a third sense (an extremely narrow one), the concept of art is limited to painting and drawing alone, sometimes to the visual arts alone. This definition has the disadvantage of excluding music, poetry, dance, and many other arts that have long been recognized as "fine" or "aesthetic." It is confusing in that painting and the other visual, manual arts were themselves long excluded from the category of "liberal arts."

Decorative and industrial arts

The decorative arts are a species of visual art whose main function is to combine utility with beauty or aesthetic satisfaction. They tend to emphasize visual ornamentation and design along with fitness for some useful end or ends. Although Western painting and sculpture in the past traditionally tended to emphasize representation, the decorative arts used both abstract and representational design. Utility, design, and representation appear with varying degrees of emphasis in such arts as medieval book illumination, jewelry, Greek or Chinese vase painting, Persian rugs, and French rococo furniture. Some styles of decorative art are comparatively plain and simple in order to achieve an effect of visual design without superficial ornament.

Ironworking is usually classed as an industry not an art, because most of its activity is devoted to products that have no aesthetic intent. A small branch of the industry, however, may be devoted to making decorative designs in iron and steel, perhaps for use in architecture. This branch may be called a useful art or a decorative art; the two categories overlap. If old-fashioned hand methods are used there, the term handicraft is also applicable.

The term industry, or industrial art, is now applied chiefly to arts in which machinery and mass production are commonly employed, with many specialized workers cooperating, as in motion pictures. It may be applied to the process of making large numbers of colour-print reproductions from paintings. Such art used for advertising, however, as in newspaper layouts and street posters, is called "commercial art." The industrial arts include many types of large-scale manufacture in which an aesthetic appeal is sought, as in the manufacture of books, magazines, refrigerators, typewriters, furniture, television sets, automobiles, airplanes, or appliances. The aesthetic factor in such work is sometimes called "styling."

Bases in status. Until the 18th century, the most common basis for classifying the arts was in terms of their social and psychological status. This system, which was devised by the ancient Greek philosophers, involved a wide separation between the so-called liberal and servile arts. In ancient Greece and Rome, the liberal arts were conceived as: (1) those that befitted a freeman and were thus comparatively noble, aristocratic, or genteel; (2) those requiring the exercise of superior mental ability, rather than mere hand labour, however skillful; and (3) those tending to elevate the minds of the artist and of his patrons, rather than merely providing material comforts, pleasures, and conveniences. The servile arts were those befitting only a person of a lower class, at least as far as the work itself was concerned. It was beneath the dignity of a lady or gentleman to work in them but not to use and enjoy such products. For the wealthy aristocrat, even to practice painting as a hobby exposed him to ridicule. Aristotle notes that even if the gentleman practices music for his own pleasure, he should not do it too well.

Liberal and servile arts

From the medieval period through the Renaissance, the class distinction between liberal and servile was retained in modified form. The "seven liberal arts" of the Middle Ages were composed of the trivium, or literary group—comprising grammar, dialectic, and rhetoric—and the quadrivium, or mathematical group—comprising arithmetic, geometry, music, and astronomy. Music was theoretical in emphasis, with little attention to its sound and much to the numerical relations among the tones. In the 12th century, literature, including poetry, tales, and dramas, was classed as a mere supplement or aid to philosophy. Modern taste admires the visual arts of the Middle Ages, but many churchmen and philosophers of the time condemned them as sensuous, perhaps idolatrous. The artist in a material medium such as stone or metal was low in social status until well along in the Renaissance.

In and after the Renaissance, art was conceived as being more hedonistic, more devoted to providing aesthetic pleasure through the sensuous perception of beautiful forms. This conception partly replaced the emphasis on moral and intellectual qualities in the ancient Greek and Roman traditions. The manual arts of decoration and design gradually rose in prestige, along with the arts of music, poetry, ballet, and theatre. Visual artists in such media as architecture, landscape, design, and pageantry gained in respect and in financial rewards. High status in them depended more on success in pleasing a luxury-loving aristocracy than on moral and intellectual virtues. But some philosophers urged that art at its best combines both sets of values.

Elite and popular arts

A hint of social status persists today in the distinction between "elite" and "popular" art, which includes products of the "mass media" such as film, newspaper and magazine illustration, radio, and television. But this distinction refers more to the level of taste and education supposedly required to appreciate these arts, and to their different publics, than to social or financial status.

Certain arts have been grouped from time to time as "lively," suggesting animation and gaiety, in contrast with the supposed solemnity of classical, "highbrow" art. Such arts are, on the whole, suited to popular taste, though often appealing also to the scholarly. They often are easy to grasp and involve a simple narrative. The comic strip is static, but it suggests movement, often playfully exaggerated into mock violence. Some, but not all, lively arts involve directly presented motion, as in the film, which has rapidly ascended from a popular to a serious art. At its best, it can achieve all types of aesthetic value, including emotional expression, character, and plot, but it does not always try to avoid banality.

Major and minor arts

The antithesis between "major" and "minor" arts is partly dependent on the social status and cultural context of the arts concerned, though it is often mentioned as if certain arts were inherently and permanently greater than others. The ground of superiority of an art, according to some philosophers, is its greater ability to express thoughts and feelings of universal, lasting value. Poetry and other forms of literature have been regarded as superior in this respect to the decorative arts, which were associated with superficial, thoughtless luxuries. As the decorative and useful arts rose in critical esteem, however, a tendency to reject these evaluations has become evident. A Persian rug or a sonata, it is said, is not necessarily inferior in aesthetic, moral, or spiritual values to a poem, play, or novel. Its value depends on what it does in its own medium. What seems at first to be mere trivial ornament may have deep, symbolic meanings for the culture in which it originated. Certainly the relative size of the products provides no sure measure of value, as, for instance, between a badly designed cathedral and a well-designed miniature painting. The major–minor antithesis may be useful if applied to the relative status of an art in its own cultural context. The status of an art may change within a culture and differ widely from one culture to another. Tattooing has been a major art in some primitive cultures, notably among the Maori people of New Zealand. Mosaic was a major art in Byzantine culture. Poetry, for the present, has declined in importance in Western civilization. The creative energies of man flow at different times through different channels.

Mode of presentation as a base. One way to avoid questions of value in a descriptive classification of the arts is to use as a base the concept of the sense to which the work is primarily addressed, instead of fineness or beauty. Painting, sculpture, and architecture are said to be addressed primarily to the sense of vision; hence they are now increasingly known as "visual arts." Music is an "auditory" art. Opera and sound film with colour are "audiovisual." An armchair is addressed not only to vision but also to the sense of touch and to muscular sensations of comfort and fitness for the posture or range of postures desired. Thus, a throne, a theatre seat, and a dentist's chair will have somewhat different forms and functions. From the aesthetic standpoint, the visual characteristics of physical objects are usually emphasized.

Some philosophers have pursued this approach into the realm of "lower senses," providing for the "gustatory" art of cuisine and the "olfactory" art of smell, as in perfume and ritual incense.

Painting is one species of visual art, and it can be subdivided in various ways. One is according to style, such as baroque or romantic. Another is based on the amount of representation, whether the work is realistic, abstract, or nonobjective. The words abstract and nonobjective are sometimes used interchangeably, to mean nonrepresentational or intentionally devoid of resemblance to any outside object. At other times, an abstract painting is said to be one that started with a representational conception but omitted some or all its representational details, while a nonobjective picture is one conceived and executed from the beginning in terms of lines and colours without any definite outside reference.

Abstract and nonobjective art

Painting can also be divided according to the subject represented; that is, into portraiture, landscape, fantasy, and so on. Some paintings are colouristic in style; others are linear. Some emphasize perspective, with imaginary vistas into deep space. The other arts can be similarly divided: narrative literature can be in prose or verse; prose narrative can be divided into novels, short stories, and so on.

Poetry is sometimes presented aurally, as in speaking it aloud; at other times, visually, as in reading it silently; at still other times, tactually, as in reading Braille type for the blind. In opera, poetry is presented audiovisually. Originally, when few persons could read, it was presented to the sense of hearing. Now, it is more often read silently. A poem is fundamentally the same whether read silently or heard. In reading it silently, the word sounds are imagined rather than heard. For purposes of classification, the art of poetry may be described as primarily auditory, but now, often visual or audiovisual; in short, it is variable.

The "performing arts" are so designated because of the ways in which they are presented to the attention of observers. Most of the visual arts perform automatically, so to speak. The artist who created the painting or statue did his performing once and for all time, when he made it. There is a temporal sequence in perceiving any complex, three-dimensional work of art, especially a large one such as a cathedral, since the observer must walk around it and perhaps inside it in order to see it fully as a three-dimensional form. The form itself may change in appearance from moment to moment, through changes in sunshine, atmosphere, and shadows. Such changes are usually considered to be indeterminate and superficial, however, not enough to characterize the work of art itself as mobile. In mobile sculpture, such as that of the modern American Alexander Calder, the form as a whole changes in accord with air currents and other pressures from outside. Unless moved in a definite way, as by a motor, the succession of arrangements in mobile sculpture is somewhat indeterminate.

Mobile and static arts

Arts in which the objects do not ordinarily have to move or change radically in order to be properly observed have been called "static arts," "space arts," or "arts of rest," in contrast with "mobile," "dynamic," or "time" arts such as music and dance. Some arts, notably cinema and ballet, unfold actively in both space and time. In cinema, the product—the film projected on the screen—is made to perform automatically; the operator does not have to influence the showing unless something goes wrong. The main performance was done permanently in the photographing, editing, and other processes involved in producing it. Much the same can be said of a phonograph record or tape, since the performance was completed by the musician before the record was made or marketed. Slight adjustments in tone, balance, volume, and the like may be required at the start; after that, the record performs automatically.

What is meant in speaking of "performing arts," however, is, for example, what the actor does in speaking his lines and moving or gesturing as directed, what the musician does in playing a certain sonata on his piano or violin, and what the dancer does in moving his body as required by the choreography. In these examples, there is usually a set of directions, prepared by the designer, the creative artist or group of artists, and made available to the performer. As a rule such directions allow some scope for original interpretation or minor departures from the score, so that the performance is not purely automatic. Different performances of the same script or printed score may vary considerably as to nuances of expression and yet be recognizable as renditions of the same composition. Such variations help to distinguish an original interpretation (good or bad) from a merely mechanical reproduction. Of course, a creative performer may at times compose his own score or improvise without the aid of any directions.

Early theories contrasted "arts of motion" with "arts of rest" and put painting in the latter category. With the advent of the film, especially such works as Walt Disney's "animated cartoons" in colour, photography and painting began their rapid development as arts of time. They are now arts of both space and time, rest and motion. This development illustrates the need for flexibility in classification, to allow for the accelerating evolution and unpredictable variation of the arts.

Arts of notation. Arts in which works are shown or sounded in a definite temporal sequence tend to acquire an appropriate notation to guide that sequence. Chief among these are the performing arts of spoken literature (especially poetry and drama), music, dance, pantomime, and other temporal arts of the theatre. Stage design, costume, and lighting are sometimes classed as theatre arts but are not necessarily shown in temporal order.

The first notation of art

Poetry was the first art for which a definite notation, that of writing and literature in general, was developed. As sung or recited by the ancient bards, poetry left a great deal to be supplied by tradition and individual taste. Indications of rhythmic variation—by separating lines, sentences, and phrases with the aid of punctuation, capital letters, and italics—were slowly developed. Some of the earliest musical notation consisted of a few conventional marks above the words of a poem. Dance steps, which were simple and regulated by tradition with the aid of music in songs and rituals, remained long without notation.

The notations of music, from the Renaissance to the mid-20th century, became very precise in directing pitch, melody, chord structure and progression, rhythm, metre, phrasing, dynamics (loud and soft), and many nuances of expression. Because of its scope, precision, and adaptability to many styles of music, the printed score was widely used as a framework for forms that combined music with words, such as song, cantata, oratorio, or opera. It was found impossible, however, to record Oriental, primitive, and other exotic styles of music and dance in Western musical notation. Such music includes pitches that cannot be precisely indicated in Western scales; its rhythms tend to overflow European bar lines, and the timbres of its instruments and voices cannot be exactly described in conventional Western notation. Such limitations were even more keenly felt as Western avant-garde composers sought to use a great variety of sounds, instrumental and otherwise, that had not been previously used in serious music—sounds of nature, city life and countryside, birdsongs and traffic noises, flowing water, thunder and lightning, and many new sounds derived from electronic machinery. In music of the 20th century, timbre and tone quality tended to be emphasized rather than conventional melodic and chordal progressions. Timbre, rather than rhythm or pitch, became the principal component of experimental music. Physical scientists cooperated with composers in adapting the new knowledge of electronic sound to music.

For the dance also, conventional musical notation came in the 20th century to seem less than adequate for guiding movements. Traditionally, the mobile designs of dance had been based on a set of conventional postures and movements, mostly devised in the 18th century. Light and graceful whirls, leaps, and glides on tiptoe could be fairly well symbolized in a simple choreographic notation, which is still used to some extent in traditional

solo dance and ballet. As in music, however, style leaders felt the need of a more flexible notation, capable of recording new types of emotional expression.

Another motive for breaking with the past in this regard was the feeling that dance should not be a handmaid to music or limited to expressing musical forms and feelings in bodily movement. Experiments were tried in dancing without music or with rhythm alone, and new bases were sought for recording the moods and movements of the dance in visual symbols.

Imperfections of notation

It would be unreasonable to expect a perfect notation in so complex an art as modern ballet. Even in such a long established notation as the printing of poetry, many qualities—*e.g.*, tempo—cannot be specified. Verbal notation is always incomplete, partly because both poet and reader usually prefer to have much of the word-sound content, along with other meanings, left to the imagination. Printed words are enough to start the reader on an approximate path toward understanding. The sound film and the phonograph offer new, partial substitutes for printed notation as guides to performing the temporal arts.

Other types of base. Three main types of base for classification and division of the arts may be distinguished. They may also serve as aids in defining particular arts or be combined into one system of the arts.

The first is that of medium or material. It is used in the names of such arts as painting, metalwork, woodcarving, jewelry, and ceramics. These refer to the physical materials out of which the work of art is made. Sound waves in music and light waves in cinema are also physical media. Tools and instruments, such as pianos, voices, brushes and canvas, chisels and marble, the human body (as in dance), are all distinctive materials of the various arts. Perceptual qualities such as rhythm, pitch, and colour are parts of the medium of sound film. Poetry also uses rhythm.

The second type of base is that of the process or technic employed, for example, the hands or other parts of the body, or instruments or machines, such as the cameras and projectors used in motion pictures. Shaping, sounding, and verbalizing are three main types of artistic process. They often overlap and combine in various arts.

When photography is conceived merely in terms of operating a camera, it is a medium of art rather than an art itself. It can be used either for purposes of art, as a scientific instrument, as a means of recreation, or in other ways. It approaches art when used as a device for giving someone an aesthetic, visual experience by means of the resultant picture.

Some technics are overt, as in dance, employing the whole body; others are mental and inner, as in memorizing a dramatic role. Some artistic skills are professional or managerial, some mechanical or manual. An architect plans and oversees the construction of buildings and the making of plans and specifications. A landscape architect works with plants, roads, levels of ground, hills and valleys, roads, lawns, bridges, and sprinkler systems. An author may do little that is overt muscular work but much dictating or typewriting.

Some art production is solitary, some cooperative. Some emphasizes visual shaping; some sounding; some verbalizing, usually organizing words and meanings approximately in accord with the rules of grammar and syntax in the language employed.

The third type of base is that of the form, design, and functions of the product, including its function as an aesthetic object; that is, as a stimulus to aesthetic perception and imagination. Arts can be grouped or distinguished as to the amount of emphasis on the following:

Types of formal emphasis

(1) Presentative (*i.e.*, directly perceptible) and suggestive factors; (2) modes of suggestion (*e.g.*, mimesis symbolism, common association); (3) components in aesthetic form (*e.g.*, melody, harmony, rhythm, perspective, plot, characterization); (4) modes of composition: utilitarian (*e.g.*, as church or palace), representational (*e.g.*, narrative, dramatic, lyric), expository (*e.g.*, essay, symbolic picture), thematic design (*e.g.*, fugue, sonata, Persian rug, sonnet).

HISTORICAL DEVELOPMENT

In European philosophy, the classification of the arts, or "system" of the arts as it is usually called, has formed an integral part not only of the philosophy of art but of philosophic systems in general. This has been especially true since the work of the late 18th-century German philosopher Immanuel Kant (*q.v.*). European philosophers have not limited themselves to making superficial, verbal arrangements but have undertaken to show the role of each art in the mind of man, in world history, and in civilization. A system of the arts may also be used in an attempt to evaluate the arts and to list them in a hierarchy according to their metaphysical and moral roles. In the Western democracies, the classification of the arts has usually been given a more modest, secondary role in philosophy, limited to showing empirical relations.

Thinkers as different as Saint Augustine of Hippo (AD 354–430), one of the chief influences in Christian thought, and Francis Bacon (1561–1626), the English philosopher who was instrumental in the development of modern science, felt the need of a systematic survey of the aesthetic arts as part of a general survey of human knowledge and experience. Separated by more than 1,000 years, Augustine and Bacon disagreed on the value of worldly knowledge obtained through empirical science. Augustine disapproved of such knowledge, while Bacon approved of it. Looking back over his youth, Augustine found much to regret and repent in the pleasures afforded by the various arts to the five senses. Bacon, in his monumental survey the *Advancement of Learning*, admired the progress of the sciences and foresaw their future benefits to man; to poetry, painting, and music he gave a fairly high place, but in the "voluptuary arts," which appeal to the lower senses, he found little to praise.

Kant, writing toward the end of the 18th century, covered the field in a tolerant, empirical way, avoiding moral and metaphysical dogmatism. Beginning with "art" in general (in the broad, technical sense including all transmitted human skill), he distinguished it from nature, science, and paid handicrafts. He then distinguished between aesthetic art and mechanical art, the first of which he subdivided into fine, or beautiful, art and agreeable, or pleasant, art. His division of fine art into the arts of speech, the shaping arts, and the arts involving the beautiful play of sensations led him eventually to further subdivisions into poetry, music, landscape gardening, the art of colour, buildings, and furniture. Under agreeable art. he assigned a place for dinner music, table arrangement, and entertaining narrative.

Georg Wilhelm Friedrich Hegel (1770–1831), another German philosopher who was vitally concerned with the arts, offered a system combining the ancient Greek philosophical conception of a cosmic mind (which embraced all man recognizes as reality) with the theory of evolution. In the world process envisaged in his scheme, he assigned an important role to the arts: architecture is most capable of expressing the early, symbolic stage in world history; sculpture, the classic stage; painting, music, and poetry, the romantic stage.

The symbolic, classical, and romantic stages

The article on the Fine Arts, in the 11th edition of the *Encyclopædia Britannica* (1910–11), by the English man of letters Sir Sidney Colvin, is one of the few attempts in English to deal with the subject in a detailed, systematic way. He proposed three main divisions: the first, into shaping, moving, and speaking arts; the second, into imitative and nonimitative arts; and the third, into serviceable and nonserviceable arts. This triple division expressed Colvin's belief that no one formula could adequately describe the manifold interrelations of the arts.

On the other hand, Max Dessoir, a leading German aesthetician in the first part of the 20th century, tried to combine several bases in one pattern. Space and time arts are arranged in two vertical columns, with sculpture, painting, architecture, and plastic arts under "space" and mimicry, poetry, music, and poetic arts under "time." A third parallel column contrasts the arts "of imitation and definite associations" with the "free-arts of indefinite associations." He commits the same error that many previous writers made in supposing that the space arts coincide

with the arts of rest and the time arts with the arts of movement and succession and that sculpture and painting are necessarily imitative (*i.e.*, representational). He did not recognize the extent to which the traditional arts changed, making new modes of classification necessary.

Instead of rectangular diagrams, Étienne Souriau, a French aesthetician of the mid-20th century, offered a wheel-shaped one. By means of this form, he showed how seven basic types of perceptible data (lines, volumes, colours, sounds, etc.) were developed into complex arts. Using concentric circles, he showed how each type of datum developed into a nonrepresentational and a representational art. Though no such diagram can offer a complete picture, Souriau presents a large number of interrelations in a simple pattern.

BIBLIOGRAPHY. ST. AUGUSTINE, *Confessions*, trans. by E.B. PUSEY, pp. 223–239 (1838), one of the earliest extant classifications of the arts, made in disapproving of them on moral and religious grounds; FRANCIS BACON, *De Augmentis Scientiarum*, an enlargement in Latin of *The Advancement of Learning*, bk. 2, ch. 1, vol. 4 of *The Works of Francis Bacon* (1858), a profound, far-reaching survey of the state of science and technology in the early 17th century, including a short classification of the arts; SIDNEY COLVIN, "Fine Arts," in *Encyclopædia Britannica*, 11th ed., vol. 10, pp. 355–375 (1910–11), one of the few attempts in English at a detailed, systematic classification of the arts on various grounds; MAX DESSOIR, *Ästhetik und allgemeine Kunstwissenschaft* (1906; Eng. trans. by S.A. EMERY, *Aesthetics and Theory of Art*, 1970), a system of the arts reduced to a short, neat pattern, by a leading German aesthetician; G.W.F. HEGEL, *Vorlesungen über die Aesthetik*, trans. by F.P.B. OSMASTON, *Philosophy of Fine Art: Introduction* (1920), a system that is remarkable for its cosmic breadth; IMMANUEL KANT, *Kritik der Urteilskraft*, part of this work trans. by J.C. MEREDITH as *Critique of Aesthetic Judgment* (1911), a pre-evolutionary empirical system, based on common sense and broadly tolerant toward the many manifestations of art in his time; THOMAS MUNRO, *The Arts and Their Interrelations*, rev. ed. (1967), a critical survey of the various classifications of the arts up to the mid-20th century, with reference to over 400 arts and types of art; *Oriental Aesthetics* (1965), on types and classifications of the arts in India, China, and Japan; ETIENNE SOURIAU, *La Correspondance des arts* (1947): a wheel-shaped diagram exhibits the system of the arts from a modern French point of view.

(Th.M.)

Arts, Criticism of the

Criticism of literature, of music, of the visual arts, or of any other of the arts can be a controversial enterprise. For one thing, disputes arise about the purpose and nature of the judgments made by critics; for another, disputes arise about the nature and properties of what it is that critics discuss—the works of art themselves; and for still another, disputes arise about the possibility of generalizing about *all* the arts, each of which differs significantly from the others in many respects.

Each of these disputes is really a complex cluster, involving nearly all of the persistent issues involved in the practice of criticism. Although this article cannot pursue all of these issues, it will attempt to provide an orientation that will facilitate their investigation.

It may be safely said that criticism in all the arts is concerned with the description and assessment of particular works. Although some hold that the critic's proper function is only the appraisal or evaluation of works of art, it is certain that nothing can be evaluated unless it is describable beforehand. Accuracy of description can in fact be so extremely difficult, particularly for complex or unfamiliar works and traditions, that some critics devote their efforts largely to matters of a descriptive sort.

It may also be said that all critics of the arts are concerned with the description and evaluation of works of art *as works of art*, even if they are more interested in moral, political, religious, ideological, or other considerations. For example, the moral criticism of works of art presupposes that the actual properties and features of a given work first may be fixed and then may be examined further according to moral considerations. Similarly, religious, political, or other considerations can only follow some relatively objective determination of what it is that is being examined. It is in this sense that criticism of the arts is primarily aesthetic. Although the objectivity of a description or an evaluation may be argued, as well as the propriety of concentrating on only the aesthetic aspects of a work, the central point is not open to dispute; *if* given works of art are to be appraised on any grounds, they must be independently describable beforehand. One cannot judge what one cannot identify and describe.

Primacy of aesthetic issues

Quarrels also arise about what may rightly be construed as the properties of works of art. For example, to say that a novel *expresses* a certain Gothic longing or that a painting *symbolizes* the end of feudalism or that a work of sculpture *represents* a bird in flight presupposes some theory of what a work of art is. The object cannot be described truthfully unless it is of a sort that can exhibit the properties ascribed, and quarrels often arise about what may rightly be construed as the properties of works of art as such. To see this is to see the sense in which descriptive statements are theory-laden. The theory of criticism and the theory of the nature of a work of art are largely aspects of the same question.

Provisionally, then, the criticism of works of art may be considered, at least minimally, as aesthetic criticism—that is, centred on the actual properties of the works considered. Correspondingly, appreciation of art may be said to be aesthetic when the art is savoured or enjoyed in terms of the properties that may be discriminated in it. Appreciation, in this sense of the term, may be informed by criticism, since both are focussed on the same properties. This point should be emphasized because it has been held by Tolstoy and others that a genuine appreciation of art must be a naïve, direct, or uninformed response. If serious thought and labour go into the creation of works of art, however, there is no reason why a similar effort will not be needed to appreciate or criticize them.

IDENTIFICATION, DESCRIPTION, AND INTERPRETATION

The crucial conceptual issues in criticism of the arts are what is meant by a work of art and how its properties may be ascertained. The difficulties involved in these issues are principally of two sorts. One concerns the identity and individuation of works of art. For example, different performances of the same piece of music may be perceived to differ from one another. A given piece may be transposed for different instruments, or it may be performed on instruments that have been modified since the date of composition, and performances by different artists will regularly exhibit noticeably different qualities. Nevertheless, it is normally considered one and the same piece of music as long as it is identified by reference to a particular score, even though aesthetically there may be more interest in the subtle variations in the performances than in what they have in common. Some critics hold that all distinct performances must be compatible with some ideal performance or that all admissible performances must correspond to the fundamental score, and deviations from it result in serious logical paradoxes. It does seem possible, however, to admit as instances of the same work performances so different from each other as to appear incompatible with any idealized performance.

The same conclusion may be drawn for all the arts that rely on a notational scheme. Variant versions of a poem, for example, may count as instances of the same poem, and analogous instances may be found in theatre, dance, film, and in view of the increasing importance of the blueprint, architecture. Analogies may be found in the plastic arts as well.

It is important to emphasize that an entire range of questions regarding the objectivity of criticism rests on puzzles respecting the referent of criticism. Both in describing and in evaluating particular works, it must be made clear whether different versions of the same work of art or several distinct works of art are being discussed. Identity may sometimes be established by detailed analysis, for example, by providing evidence on notational and

The referent of criticism

cultural grounds that what seemed to be different folk songs may be construed as variant versions of the same song.

The principal issues of criticism concern not the identification of works of art but their description and evaluation. It is not possible to segregate entirely what may be correctly said about a given work of art and what it is that individuates that work of art—that is, makes it a distinct entity within a class of related entities.

To illustrate this point, imagine that the central image of a given work may be construed in two radically different ways. Some of Anton Chekhov's plays, for example, may be construed as either comedies or tragedies, depending on whether the views of the author or those of the director Konstantin Stanislavsky are preferred. If the possibility of such competing views be admitted (even though the mere admission of them presupposes a certain theory of criticism), then any account of what a critic does must accommodate this possibility.

When critics say what a certain image means and their (defensible) accounts conflict with each other, it is clear that they cannot be *describing* the work at hand. It should be possible to confirm a description by an independent study of the object described. Obviously, it is not possible to confirm descriptions that are incompatible.

It might be argued that the differences in conflicting critical accounts are merely apparent, as a coin might be described as circular from one view and elliptical from another. To resolve such an apparent difference in a physical object like a coin, one could invoke some commonly accepted canon such as saying that when it is seen "under normal circumstances" the differences disappear. In criticism of the arts, however, there is no such common canon in terms of which the competing views may be sorted. Moreover, in some schools of criticism, such conflicting views would not be ruled out as impossible.

Distinction between description and interpretation

The solution is to distinguish between *describing* works of art and *interpreting* works of art: a critic's description may be true or false of the work in question, but his interpretation of the work can be only plausible or implausible. Each of several incompatible interpretations may be plausible, but they cannot all be true. In rendering an interpretation of a work of art, then, the critic must be imputing to it properties that cannot with certainty be found in it. This view of critical practice implies a theory of the nature of a work of art that allows some properties to be considered either truly in the work or only plausibly imputed to it.

A substantial body of criticism is intelligible only if the critics who purport to be describing given works—incorporating analysis, comparison, historical or biographical explanation, and the like—are, to some extent at least, interpreting those works. The enormous body of criticism of the greatest poetry, drama, and fiction shows how dissimilar the apparently descriptive efforts of critics may be. The mere existence of this vast body of diverse views would appear to refute the claim that interpretation is merely the unearthing of what is descriptively true of a work of art. It may include this but it must be more.

Interpretive criticism would be unintelligible without a counterpart theory of the nature of a work of art. The key to that theory lies in not confusing works of art with the physical objects associated with them. Physical objects having different physical properties cannot be the same object. As has been noted, however, works of art with different physical properties, and even critical aesthetic differences, may count as instances of the same work of art. This fact is most easily seen in literature, drama, music, and, to some extent, dance and architecture, arts in which the identity of a given work depends on some notational system. It is less easily seen in the visual arts, even though different tokens of the same work, as in etching, may be admitted there too. Clearly, then, works of art are individuated in ways that substantially depart from those of physical objects and in ways that vary from art to art.

A further consideration is that a work of art is a purposive system, whose internal organization may be seen to reflect the systematic decisions of the artist. Criticism explicates this purposive organization, and critics are sometimes obliged to impute a design to a work of art rather than merely to find it inhering in the work. Under those circumstances, the critic turns from description to interpretation. Thus, the very nature of art leads to interpretation as a legitimate, and even inescapable, practice of critics.

An even more decisive difference between physical objects and works of art lies in the sorts of properties that are normally attributed to them. For instance, *expressive* qualities may be assigned to works of art: a novel such as Flaubert's *Madame Bovary* may be said to express a certain "bourgeois consciousness." Or *symbolic* qualities may be assigned: the castle in Kafka's novel of that name has been said to symbolize divine redemption. Or, *representational* qualities may be assigned: Picasso's painting "Guernica" is called a representation of the horrors of war. Also, *meanings* may be assigned in various ways: in *Hamlet*, for example, the meaning of Laertes' exchanges with Polonius and Claudius is said to be in their contrast with Hamlet's self-doubt; and the meaning of Bigger Thomas' dilemma in Richard Wright's novel *Native Son* is said to derive from the plight of the Negro in America.

As has been noted, it is difficult to say whether properties such as these are to be found *in* works of arts or only may be imputed *to* them. Out of respect for the artist, critics may assume their own role is subsidiary—*i.e.*, that of identifying properties of a work that might not otherwise be appreciated. Because it cannot be said with certainty, however, whether expressive, symbolic, or representational qualities or meanings and the like are actually *in* works of art, criticism must go beyond the severer canons of description to those of interpretation. This issue of the autonomy of criticism has been debated in the works of T.S. Eliot, Oscar Wilde, and many others.

Thus, as has been shown, critics may well offer incompatible accounts that purport to describe the same work. Even in cases in which the identity of a work of art is closely associated with its physical properties, as a work of sculpture might be associated with a mass of cast bronze, pure description may be adequate only for its physical properties but not for the properties that may be ascribed to a work of art. If a line in a painting is called "humorous," it is not always clear whether the line is being described or interpreted. What is clear is that critical interpretation must conform to certain minimal constraints. It must be compatible with whatever is descriptively true of the work in question; any interpretation that is compatible only with what is descriptively false is inadmissible. Interpretation, therefore, depends on some indisputable range of critical description.

Constraints on interpretation

The limits of this range, however, are not easy to establish. To do so requires deciding which among competing critical practices is the correct one. Such a comparison of critical hypotheses leads to metacriticism—that is, to the evaluation of the critical norms themselves, an extremely difficult matter. Without becoming entangled in this problem, some pragmatic rules of critical practice may be laid down: it should be possible to formulate its canons, these canons should be used by a community of practitioners, they should be effective in confirming or denying relevant claims, and it should not be necessary to distort them to examine new works or works that were not anticipated when they were adopted.

These rules permit a number of critical approaches and, therefore, allow alternative and incompatible interpretations of given works of art. It would be difficult, however, to justify the restriction of critical practice to any highly specialized way of proceeding. In literary criticism, for example, it would be difficult to reject out of hand the legitimacy of many diverse but fruitful approaches, such as the archetypal criticism of the Canadian critic Northrop Frye or the Marxist criticism of the Hungarian statesman and writer György Lukács or the Freudian

criticism of the British psychiatrist Ernest Jones or the neo-Aristotelian criticism of the Chicago critic Ronald S. Crane or countless others.

An extreme view of criticism holds that the interpretation to be preferred is the one that maximizes the value of the work in question. This view, however, does not recognize the rigour and independence of criticism or its obvious analogies to other endeavours, such as science, that are concerned with claims to truth and validity.

The objectivity of critical practice may be conceded not only to description but also to interpretation. Since interpretation is concerned with plausibility rather than with truth, plural approaches to works of art may reasonably be tolerated. The appreciation of a given work may entail a canvass of all plausible ways of construing it. Moreover, different schools of criticism may prove variously fruitful for each of the arts or for the movements within them. A Freudian approach to music or architecture, for example, promises less than formalist approaches; without question, however, the Freudian approach would be more fruitful in literature than in architecture. To examine the diversity of tenable critical practices (and there are new ones all the time) is to doubt that all but those consistent with some supreme critical principle can be disqualified.

VALUE JUDGMENT IN CRITICISM

In addition to the identification, description, and interpretation of works of art, the problem of their evaluation has been the subject of a number of disputes. The issues are those of value theory in general: there seems little reason to suppose that value judgments of works of art differ significantly from those of conduct, for instance. Immanuel Kant held that aesthetic and moral judgments are of fundamentally different logical kinds, but he was chiefly concerned with taste (which, despite Kant, appears in the moral, as well as the aesthetic, domain, in judging such matters as tact, decency, and personal ideals) and he failed to consider the implications of professional criticism and connoisseurship.

Nature of values

Although all the basic issues of the nature of values are not within the scope of this article, two fundamental issues are vital to a survey of the theory of criticism. For one thing, expressing one's tastes, preferences, likes, and dislikes must be carefully distinguished from judging merit. And for another, the principal varieties of value judgments must be sorted out. Quarrels about the critic's appraisal and evaluation of works of art are linked to these issues.

There is no prevalent philosophical view regarding value judgments that can be formulated in a simple and straightforward way. The account that follows puts forward one viable thesis, which may clarify how disputes about values can or cannot be resolved in a domain dominated by considerations of taste.

Value judgments are such in virtue of their predicates —that is, what they affirm or deny about the subject at hand. The predicates themselves, however, are not inherently valuational or nonvaluational; they are construed either way on the basis of governing theories. For example, to judge that Peter is tubercular may constitute a value judgment if good health is accepted as a norm. If tuberculosis is not regarded as a normative concept, however, but as a purely biological phenomenon, the judgment remains factual though not valuative. Factual judgments may be assigned truth values—that is, they may be determined to be true or false. Value judgments, on the other hand, are judgments that entail reference to a norm, or standard of merit. Some value judgments may also be factual judgments as well, as in the case of the judgment about Peter's tuberculosis.

Statements about one's likes or dislikes—one's tastes, in short—are usually not considered normative statements but statements of fact. They concern an aspect of a person's disposition and behaviour.

In making value judgments, however, the person puts a value on things by judging them in accord with norms that usually lie outside his own tastes. Of course it is possible that the values he places depend entirely on his tastes—his likes, dislikes, preferences—but it is not necessary. Herein lies a crucial distinction, for value judgments that depend on personal tastes are strikingly different from those that do not. Value judgments that depend upon taste may be called appreciative judgments and those that do not may be called findings.

Findings differ from factual judgments only insofar as they are linked to standards of merit; otherwise they are alike. In principle, critical judgments of the merit of a work of art, like other value judgments, may be as rigorously objective and confirmable as judgments of fact. Logically, findings are judgments of fact, in that truth values may be assigned to them.

It should be emphasized that questions of the relativity of values, or of their variability, are not relevant here. The logical properties of findings are not affected by the nature of socially institutionalized values. Value judgments about beauty or fashion may well derive from the prevailing tastes of a community, but, as findings, they will be made in accordance with those norms and not with one's personal taste (if we disregard coincidence).

In contrast, appreciative judgments are based entirely on one's own tastes. The well-known Latin maxim *de gustibus non est disputandum*, "there is no disputing concerning taste," applies to appreciative judgments only; it does not bear at all on findings.

Distinguishing between these two fundamentally different kinds of value judgments permits some rational debate respecting the merit of a given work of art. To the extent that a critical tradition is standardized (as the standards of wine tasting or of dog breeding have been established), critical findings may be regarded as objective relative to such a tradition. (The entire system may be challenged, of course, but that is another matter.) But appreciative judgments cannot be objective in that way; they cannot be simply true or false. Appreciative judgments depend on personal tastes, which vary greatly among individuals, so that seemingly contradictory judgments are common. If these judgments were treated as findings, such contradictory judgments might be found to be jointly true, a logical impossibility. If such a contradiction were resolved by regarding each judgment as true relative to given taste, then appreciative judgments could not be distinguished from mere statements about one's tastes. Since this distinctive kind of value judgment is prominent in aesthetic criticism, appreciative judgments may be conceded much weaker confirmation than findings. In a finding, one holds that a given work has (or lacks) a certain merit; the matter can be decided by attention to relevant criteria and evidence, as factual matters are. In an appreciative judgment, one assigns a certain value to a work in accord with one's personal likes, dislikes, and preferences. In findings, the supporting reasons must be publicly compelling; in appreciative judgments, the supporting reasons need only be relevant and reasonable to a critical public. The public may attest to the coherence of an appreciative judgment and its supporting reasons, but, because of differences in taste, it is not bound to share that judgment, as it must in the case of findings.

The problem of conflicting judgments

Incompatible findings, like incompatible descriptions, are inadmissible. Seemingly incompatible appreciative judgments, however, are admissible insofar as they are coherent (in accord with informal canons of such judgments) and compatible with the actual properties of the given work. In the context of an academic tradition, judgments of beauty may well be findings; but, in the context of personal taste, judging beauty is rendering an appreciative judgment. One may (appreciatively) say that a certain woman is beautiful and offer supporting reasons that may seem forceful or not. But, if one claims, in the mode of findings, that a certain woman *is* beautiful relative to a particular tradition of values, the evidence will serve flatly to confirm or deny the claim.

Disputes may arise about judgments of both sorts, and there are procedures for appraising each type. The precept about the pointlessness of arguing about taste should

therefore be amended to say that the kind of rational dispute possible for findings is not possible for appreciative judgments, or judgments of taste. Nonetheless, rational dispute of a different sort is possible for appreciative judgments as well.

The two types of judgment—findings and appreciative judgments—cannot be segregated on the basis of their respective range of predicates; an assertion that something is beautiful, for example, may be construed as either type of judgment. The conditions under which relevant claims may be confirmed is the key factor in distinguishing between the two types.

Other aspects of value judgment

There are, of course, deeper questions about values than can be treated in this article. Especially pertinent is this question: are values discoverable in nature, or the real world, or can they be construed only as an expression of the interests of a particular community? If it were possible to prove the existence of "true" or "real" values, there would be no need to account for appreciative judgments; practicing critics would be concerned only with findings—that is, with making judgments that are in accord with those true values. In fact, however, no such true values have been proved, and the critic is chiefly concerned with appreciative judgments, in which his personal tastes are systematically articulated. In any culture there may be a number of critics operating at cross purposes, each imprinting his own distinctive taste on a community of enthusiasts. Revolutionary tendencies in taste appear, however, resulting in significant alterations in critical practice. Thus, the judgments of critics tend to be informal and variable; because of the logical properties of their appreciative judgments and the conventional nature of the norms that support their findings, it could not be otherwise.

These, then, are the principal conceptual issues bearing on the systematic practice of criticism of the arts. The critic's judgments may be either valuational or nonvaluational. With respect to the former—that is, his value judgments—findings must be distinguished from appreciative judgments; with respect to the latter, the nonvaluational judgments, descriptive judgments must be distinguished from interpretive judgments. Because appreciative and interpretive judgments do not allow truth values to be assigned to them in the way that findings and descriptions do, the critic must tolerate logically weak judgments at the heart of his enterprise. This tolerance, however, should not be misconstrued as a lack of rigour in applying critical canons. On the contrary, rigorous critical practice requires such tolerance.

VARIETIES OF CRITICISM

Internal and external criticism

Actual critical practice raises certain technical questions that tend to divide considerations that are internal from those that are external to aesthetic criticism—that is, those that bear on the work of art as such from those that involve ulterior appraisals or characterizations. In spite of disputes regarding the proper scope and orientation of criticism, the diverse schools of criticism exhibit broadly parallel practices in both the internal and the external considerations to which they address themselves. For example, Marxist critics such as György Lukács and Christopher Caudwell use the socioeconomic categories of their philosophy to analyze works of art as art, to characterize the artist's life, and to study the role of the work within the dynamics of social change. Clearly, it is not always easy to discriminate between internal and external criticism.

The issue here is conceptual; it is not open to ideological quarrel. For instance, it has been said that the ancient Greek dramatist Aeschylus in his trilogy the *Oresteia* was presenting an idealized version of emerging notions of political justice. This external interpretation presupposes an internal interpretation of the work that does not violate any canons of aesthetic criticism, or it would not be tenable. Precisely the same consideration applies to the attempt by the Freudian critic Ernest Jones to psychoanalyze Shakespeare on the basis of *Hamlet* or Freud's attempt to analyze Leonardo da Vinci from his drawings and paintings. The principle that the external and the internal criticism must match remains the same whether the criticism is concerned with libidinal conflicts as are the Freudians, with archetypes as are the followers of the Swiss psychologist Carl Gustav Jung, with class conflicts as are the Marxists, or with theological and moral resolutions of modern poetry as is the French Thomist philosopher Jacques Maritain. In the light of the pluralism of viewpoints that has already been shown inevitable, it is not surprising that internal and external criticism cannot be sharply opposed to each other. Although adherents of some particular approach may disagree, it is difficult to see how any one approach can be exclusively vindicated. In a very real sense, the preference for any given approach may be construed as an appreciative judgment in itself.

Advantages of pluralism

It is not at all necessary that a theory about some aspect of human society be true in order for it to be fruitful and defensible in criticism. In describing, interpreting, and evaluating a work, the critic requires only that the theory is relevant to it. For instance, the critic may appropriately characterize or appraise a work in terms of Marxist, Freudian, Jungian, or Thomist doctrines to the extent that the imagination of either the artist or the audience is informed by such doctrines. Such doctrines need only be recognizable and socially significant to be useful in criticism; scientifically valid theories, on the other hand, may be entirely uninstructive when applied to the description and interpretation of a work of art. False theories may be so rewarding in discussing particular works that they cannot be dismissed solely because they are not true. To understand Wordsworth in terms of some version of Platonism is not to subscribe to Platonism itself, and to read the *Oresteia* in Marxist terms need not presuppose that Aeschylus held similar sociological convictions. The truth, or at least the plausibility, of the descriptive, interpretive, and evaluative judgments of critics must be carefully distinguished from the truth of the doctrines advanced by them or by artists. The validity of Thomism, for instance, is an entirely separate issue from the validity of interpretations of Dante from the Thomist point of view.

Those critics who believe they subscribe to a science of values, whether it may be Freudian, Thomist, Marxist, or some other, would quarrel against such a use of diverse doctrines. Inasmuch as the foundations of their beliefs do not compel the belief of all others, however, the use of doctrines of doubtful validity in criticism must be tolerated.

A doctrine may be applied by a critic if it is compatible with his own practice of criticism and if it provides an account of the design of that work, especially those elements that seem to call for interpretation.

In sum, the discipline of criticism has been shown to exhibit significant rigour, despite the logical weaknesses of the judgments of interpretive criticism and the uncertainty of the doctrines it applies. Contributing to this rigour are the requirements that an interpretation not deny any descriptive elements; that it be plausible; and that it deal with the traditionally salient problems of the work—that is, the interpretive puzzles that obstruct the assignment of a coherent and comprehensive internal order to the work.

A final issue may serve to round out this account of the criticism of the arts. As has been seen, an interpretation must be compatible with what is descriptively true of a given work of art. It is sometimes supposed that both description and interpretation should be similarly constrained by historical and biographical considerations. In fact, some versions of this thesis hold that interpretations prove to be no more than description provided under relatively difficult conditions of discovery. In the historical thesis, the "meaning" (*i.e.*, the correct characterization) of a work of art is the one that accords with its critical reception in the culture in which it was produced. The biographical thesis holds that "meaning" is what accords with the artist's intention.

Historical and biographical criticism

A number of things may be said about both theses. For

one thing, the two theses may be construed as the same wherever the artist's intention is interpreted in terms of the conventions governing such works rather than in terms of his own avowals of what he intended. It is extremely difficult, however, to suppose that one and only one construction can be put on a given work, especially in complex societies in which artists often intentionally depart from academic or other conventions. The problem of plausible alternative interpretations haunts critical practice even when the problem is confined within historical limits, even though the elimination of such alternatives is often claimed to be an advantage of historical criticism.

Furthermore, plausible interpretations that are put forward long after the work of art is produced may also be construed as the work of historical criticism; the restriction of interpretation to the period in which the artist worked represents a somewhat arbitrary constraint on the practice of criticism. Some works of art attract critics and audiences over generations, or even ages, without requiring close attention to historical or biographical origins. The force of accurate historical criticism cannot be denied, but criticism that ignores the *evolving* historical reception of a work of art unjustifiably restricts the scope of criticism.

A historical hypothesis, particularly one concerned with cultural significance, bears a striking similarity to interpretive criticism; like interpretive criticism, history as a discipline must rely substantially on criteria of plausibility. It should be noted that the same arguments that apply to historical and biographical criticism also apply to criticism based on cultural anthropology or the history of ideas.

Historical misunderstandings and inaccuracy about a given work of art must be distinguished from the historically changing significance of that work. A Freudian interpretation of *Hamlet*, for example, cannot be dismissed solely because the Freudian system was unknown to Shakespeare. If audiences that share Shakespeare's cultural and linguistic traditions are deeply influenced by the Freudian outlook, then a Freudian reading of his work, if independently plausible, cannot be regarded as a historical mistake. Interpretations that are constrained by *special* historical and biographical considerations must be distinguished from those that are not. Interpretations of both sorts may be welcomed.

Intentional criticism

Further objections may be raised against biographical criticism that narrowly construes the artist's intention as what may be documented in conversation, letters, and the like. Quite often, there is simply no such documented knowledge of the artist's intention. Even when there is, it may prove vague and ambiguous or even irrelevant to the appreciation of the work. In any case, any interpretation based on a statement of the artist's intention is subject to precisely the same sort of confirmation that other interpretations would be.

Intentional criticism may be viewed as a form of historical criticism that assumes certain types and modes of artistic endeavour within a tradition (to which the artist's intentions are said to correspond).

Some critics opposing what the American critics W.K. Wimsatt and Monroe Beardsley called the "Intentional Fallacy" would not admit any criticism based on the artist's intention; they would rule it out on the grounds that it violates the proper aesthetic concern of the critic. In view of what has already been said in this article about the nature of a work of art and of its boundaries, however, intentional criticism may be viewed as simply another selective mode of critical practice, one that is by no means exclusively correct but not for that reason inadmissible.

In conclusion, then, the principal issues affecting critical practices in the arts may be said to be (1) the identity and individuation of works of art; (2) the nature and characteristic properties of works of art; (3) their description and interpretation; (4) value judgments about them: and (5) the admissible varieties of, and constraints upon, criticism of the arts.

BIBLIOGRAPHY. Perhaps the most comprehensive canvassing of the current philosophical literature respecting criticism of the arts is to be found in M.C. BEARDSLEY, *Aesthetics: Problems in the Philosophy of Criticism* (1958); and J. MARGOLIS, *The Language of Art and Art Criticism: Analytic Questions in Aesthetics* (1965). Each of these two books (with extensive bibliographies) proposes its own theory of criticism; the first reduces interpretation to description, while the second opposes such reduction. Of relatively recent theories of art bearing on the problems of criticism, the following are among the most penetrating: N. GOODMAN, *Languages of Art: An Approach to a Theory of Symbols* (1968), primarily addressed to notational problems in identifying works of art; R. WOLLHEIM, *Art and Its Objects* (1968), pursues the paradoxes of numerical identity regarding works of art; S.K. LANGER, *Feeling and Form* (1953), attempts a systematic ordering of the different arts in terms of symbolic form; and H. OSBORNE, *Aesthetics and Criticism* (1955), construes criticism primarily in evaluative terms and the work of art as the object of such practice. Recent anthologies of the most widely discussed papers include: W. ELTON (ed.), *Aesthetics and Language* (1954), a linguistically oriented attack on the Italian philosopher Benedetto Croce and on Idealist aesthetics; and J. MARGOLIS (ed.), *Philosophy Looks at the Arts: Contemporary Readings in Aesthetics* (1962).

(J.Ms.)

Arts, Fraudulence in the

The most common type of fraudulence in the arts is forgery—making a work or offering one for sale with the intent to defraud, usually by falsely attributing it to an artist whose works command high prices. Other fraudulent practices include plagiarism, the false presentation of another's work as one's own, and piracy, the unauthorized use of someone else's work, such as the publication of a book without permission of the author; both practices are generally in violation of copyright laws.

Types of fraudulence

Forgery most often occurs with works of painting, sculpture, decorative art, and literature; less often with music. Plagiarism is more difficult to prove as fraud, since the possibility of coincidence must be weighed against evidence of stealing. Piracy is more often a business than an artistic fraud; it frequently occurs in the publication of editions of foreign books in countries that have no copyright agreement with the nation in which the work was copyrighted. A stage production, the reproduction of a painting, the performance of a musical composition, and analogous practices of other kinds of works without authorization and royalty payments also fall into this category.

The fundamental consideration in determining forgery is "intent to deceive." The act of copying a painting or other work of art is in itself not forgery, nor is the creation of a work "in the style" of a recognized painter, composer, or writer or of a particular historical period. Forgery may be the act not of the creator himself but of the dealer who adds a fraudulent signature or in some way alters the appearance of a painting or manuscript. Restoration of a damaged painting or manuscript, however, is not considered forgery even if the restorer in his work creates a significant part of the total work. Misattributions may result either from honest errors in scholarship—as in the attribution of a work to a well known artist when the work was in fact done by a painter in his workshop, a pupil, or a later follower—or from a deliberate fraud.

Excluded from the category of literary forgeries is the copy made in good faith for purposes of study. In the matter of autographs, manuscripts in the handwriting of their authors, forgeries must be distinguished from facsimiles, copies made by lithography or other reproductive processes. Some early editions of Byron's work, for example, contained a facsimile of an autograph letter of the poet. If such facsimiles are detached from the volumes that they were intended to illustrate, they may deceive the unwary.

Motivations for fraudulence

The commonest motivation for fraudulence is monetary gain. Fraudulence is most likely to occur when the demand for a certain kind of work coincides with scarcity and thus raises the market prices. Unprincipled dealers

have encouraged technically skilled artists to create forgeries, occasionally guiding them to supply the precise demands of collectors or museums. This is by no means a modern phenomenon: in the 1st and 2nd centuries AD, sculptors working in Rome made replicas of Grecian works to satisfy the demands for the greatly admired Grecian sculpture of the preceding five centuries. These copies or adaptations apparently were not offered as contemporary work, but as booty from Greece at the extraordinarily high prices paid for such works in imperial Rome. Similar circumstances may account for the "discovery" of a manuscript or autograph by a dead author or composer, although many such finds are quite legitimate and have been authenticated.

The history of the arts reveals instances of persons who have used forgery either to gain recognition of their own craftsmanship or to enjoy deceiving the critics who had rejected their genuine work. A legend told about Michelangelo illustrates this point. At the age of 21, he carved in marble a small sleeping Eros, or Cupid, based on ancient Roman works that he admired. Some time later this carving was sold as an antique to the well-known collector Cardinal Riario, who prized it highly. When Michelangelo stepped forward and claimed the work as his own he won immediate fame as a young man who could rival the work of the greatly venerated ancient sculptors.

Two further motivations behind forgery must be noted: forged documents have been produced from time to time to exalt or malign some religion, political party, or race; and forgeries are sometimes created as a hoax. Some hoaxes are intended to confound or ridicule the experts; others are intended to parody or burlesque an artist or genre.

Three methods of forgery

There are basically three methods of producing a forgery: by an exact copy, by a composite of parts, and by a work done in the style of an artist or period and given a deliberately false attribution. These methods apply most directly to the visual arts but can be discerned in literature and music as well. (Ed.)

LITERARY FORGERY

Financial gain is the most common motive for literary forgery, the one responsible for the numerous forged autographs that appear on the market. The popularity of such authors as the Romantic poets Burns, Shelley, and Byron led to the fabrication of numerous forgeries of their autographs, some of which remain in circulation. These forgeries were usually made by men who had access to only one or two genuine specimens, which they began by tracing. Their forgeries are stiff, exaggeratedly uniform, and lacking in the fluency and spontaneity of genuine autographs.

Instances of literary forgery

Occasionally a forger appears with a certain specious glamour like Constantine Simonides (1824–67), a Greek adventurer who varied his trade in perfectly genuine manuscripts with the sale of strange concoctions of his own. Maj. George de Luna Byron, alias de Gibler, who claimed to be a natural son of Byron by a Spanish countess, successfully produced and disposed of large quantities of forgeries ascribed to his alleged father and to Shelley, Keats, and others. More commonplace is the Edinburgh forger A.H. ("Antique") Smith, who was responsible for forgeries of Robert Burns, Sir Walter Scott, Mary Stuart, and other persons from Scottish literature and history—a feat that ultimately earned him 12 months' imprisonment.

Particularly notorious was the case of the Wise forgeries. Thomas James Wise (1859–1937) was one of the most distinguished private book collectors on either side of the Atlantic, and his Ashley Library in London became a place of pilgrimage for scholars from Europe and the U.S. He constantly exposed piracies and forgeries and always denied that he was a dealer. The shock was accordingly the greater in 1934 when John W. Carter and Henry Graham Pollard published *An Enquiry Into the Nature of Certain Nineteenth Century Pamphlets*, proving that about 40 or 50 of these, commanding high prices, were forgeries, and that all could be traced to Wise. Subsequent research confirmed the finding of Carter and Pollard and indicted Wise for other and more serious offenses, including the sophistication of many of his own copies of early printed books with leaves stolen from copies in the British Museum.

No forgery to attain recognition is better known than the "Thomas Rowley" poems of Thomas Chatterton (1752–70), which the youthful author attempted to pass off as the work of a medieval cleric. These poems, which caused a scholarly feud for many years, were influential in the Gothic revival. Chatterton, however, enjoys a place in English letters as a creative genius in his own right. The more conventional forger William Henry Ireland (1777–1835) cheerfully manufactured Shakespearean documents until his forged "lost" tragedy *Vortigern and Rowena* was laughed off the stage at the Drury Lane Theatre, London, in 1796. More fortunate was Charles Bertram, who produced an account of Roman Britain by "Richard of Westminster," an imaginary monk. Bertram's dupe, the eccentric antiquary Dr. William Stukeley, identified the monk with the chronicler Richard of Cirencester, known to have resided at Westminster in the 14th century. Bertram's forgery (cunningly published in a volume containing the works of two genuine ancient authors, Gildas and Nennius) had an enormous influence upon historians of Roman Britain, lasting into the 20th century. Equally influential were the Ossianic poems of James Macpherson (1736–96), which influenced the early period of the Romantic movement. To what degree Macpherson's poems are to be regarded as spurious is not certain. Denounced in his own day they were possibly, as he claimed, based upon a genuine oral tradition of Scottish Gaelic poetry; but there can be little doubt that they were carefully edited and interpolated by their collector.

Among the forgers who have tried to make the experts look foolish is George Psalmanazar (1679?–1763). A Frenchman, he went to England where he pretended, with great success, to be a native of Formosa (Taiwan), and published a book about that island, which he had never visited. Another is William Lauder, who attempted to prove Milton guilty of plagiarism by quoting 17th-century poets who wrote in Latin, into whose works he had interpolated Latin translations from *Paradise Lost*. A forgery made as a joke but taken seriously was the "Ern Malley" poems, offered to an Australian magazine in 1944 as the work of a recently dead poet. Actually it was composed by two young soldiers who wished to ridicule certain aspects of contemporary poetry.

The pure fabrication is a kind of forgery that defies classification, often because there is no false attribution and the motives are difficult to ascertain. An example of this is the *Historia regum Britanniae* (*c.* 1135) of Geoffrey of Monmouth (d. 1155), a pseudo-historian who compounded stories from Celtic mythology and classical and biblical sources into a fictitious history of ancient Britain. The book became one of the most popular of the Middle Ages and was the basis for some Arthurian legends recounted in medieval romance and epic.

Detection of literary forgeries. The scientific examination of a forged document may demonstrate its spurious character by showing that the parchment, paper, or ink cannot belong to the period to which they pretend. A skillful forger takes care, however, to secure appropriate materials; and in any case, scientific examination will not avail against the contemporary forger, living in the same age as his victim. Accordingly, other tests must be employed.

Forgeries may be detected by the methods of examination formulated by Jean Mabillon in his great work *De re diplomatica* (1681), for determining the authenticity of a document by the writing and the style of the terminology. These techniques have developed during three centuries into the modern sciences of paleography and diplomatic, by which various scripts and formulas can be assigned to particular ages and localities, and effective comparison can be made between two examples of handwriting pur-

porting to come from the same pen. Thus it is possible to state that a particular document could not have been written at the date that it bears. In dealing with printed texts, analogous methods are employed.

Nevertheless, a forgery may pretend to be no more than a copy of a genuine original. It then becomes necessary to examine the language and style in which it is written and to look for anachronisms or for statements that conflict with known authorities. This is the method of textual criticism brilliantly employed by Richard Bentley in his *Dissertation upon the Epistles of Phalaris* (1699), which proved that these letters, far from being written by a Sicilian tyrant of the 6th century BC, were, in fact, the work of a Greek sophist of the 2nd century AD.

While the detection of the careful forger may require an expert, forged literary autographs can often be detected by anyone taking the trouble to compare them with an authentic example. Many collectors have been deceived by their own credulity, because they wished to believe that they were getting a good bargain and subconsciously suppressed their critical faculty. A classic case is that of the French forger Vrain-Denis Lucas, who sold a collection of forgeries including a letter of St. Mary Magdalene, written in French on paper made in France. (Ge.B.)

FORGERY IN THE VISUAL ARTS

Any art object—paintings, sculpture, jewelry, ceramics, fine furniture, and decorative pieces of all kinds—can be forged. The difficulty of forging, however, is as important as market price in determining what is forged. Probably fewer than 1 percent of stone sculptures are false because they require so much labour to make and their market is limited, but as many as 10 percent of modern French paintings on the market may be forgeries. The technical difficulties in making a convincing imitation of an ancient Greek vase are so great that forgeries are almost nonexistent. In contrast the forgery level of tiny archaic Greek and Cretan bronze statuettes, which are simple to cast, is possibly as high as 50 percent. A forger is most likely to succeed with a mediocre piece in the middle price range because such a piece probably will never be subjected to definitive examination. Although the price should be low enough to allay suspicion, the object can still yield a fair return for the effort expended by the forger.

The copy is the easiest forgery to make and is usually the easiest to detect. When a duplicate has appeared the problem is merely to determine which is the original and which is the copy. At least a dozen excellent replicas of Leonardo da Vinci's "Mona Lisa" exist, many of them by his students. Various owners of these copies have at various times claimed that they possess the original. The Louvre is satisfied that it owns the painting by Leonardo because close examination reveals slight changes in the composition underneath the outermost layer of paint, and because this painting has an unbroken record of ownership from the time that the artist painted it.

Copies

A monumental sculptural forgery was a copy based on a Greek bronze statuette of a warrior of 470 BC, only five inches high and located in the Antikenabteilung, Berlin. The forgers made an eight-foot-high reproduction of it in terra-cotta and offered it as an Etruscan masterpiece. The resemblance was noted by the experts, who thought it to be an example of an Etruscan artist borrowing a Greek design motif. In 1961, after it had been in the Metropolitan Museum of Art in New York for 40 years, an analysis was made of the black glaze that covered the figure. It was found that the glaze contained as a colouring agent manganese, which never was used for this purpose in ancient times. Finally, Alfredo Adolfo Fioravanti confessed that he was the sole survivor of the three forgers.

Fine examples of pottery and porcelain have always commanded high prices, which have, in turn, encouraged the making of forgeries and reproductions. Since many European factories tried to imitate Italian majolica during the 19th century when it was especially popular, forgeries are common. The work of Urbino, Castel Durante, Faenza, and Gubbio was copied freely, and, to a lesser extent, so were the wares of Orvieto and Florence. Most of these forgeries are not close enough to deceive a reasonably expert eye. Potters used natural deposits the impurities of which, for good or ill, often affected the final result; until recently it has been impossible to procure materials in a pure state. In all but a few isolated instances (some German stoneware reproductions, for example) the forger no longer has access to these original deposits and he has to imitate the effect of the impurities as best he can. Although the best forgeries are often remarkably close to the originals, they are not very numerous.

In the composite fraud, or *pastiche*, the forger combines copies of various parts of another artist's work to form a new composition and adds a few connecting elements of his own to make it a convincing presentation. This type of forgery is more difficult to detect than the copy. Such a combining of various elements from different pieces can be very deceptive, because a creative artist often borrows from his own work. In fact, the similarity of a figure or an object in a forgery to that in a well-known work of art often adds to the believability of the new creation.

Composition fraud

The Dutch forger Hans van Meegeren employed a combined composite and stylistic procedure when he created seven paintings between 1936 and 1942 based on the work of Jan Vermeer. In "Christ at Emmaus" he combined figures, heads, hands, plates, and a wine jar from various early genuine Vermeers; it was hailed as a masterpiece and the earliest known Vermeer. Ironically, Van Meegeren never was detected as a forger. At the end of World War II he was arrested for having sold a painting attributed to Vermeer to one of the enemy, and was accused of being a collaborator. He chose to reveal himself as a forger, which was a lesser offense, and proved his confession by painting another "Vermeer" while in prison.

A variation in composite forgery, quite common with inlaid French furniture, involves the use of parts from damaged but genuine pieces to create a single complete piece that may or may not resemble one of the pieces from which it has been made. These made-up pieces are still considered forgeries. In composites of archaeological material only one part may be ancient, the balance being made up to complete the object. The head of a small terra-cotta figure may be ancient, the body and limbs of modern workmanship. A single ancient element in a composite forgery will help to deceive the buyer.

Most difficult of all to detect is the forgery done in the style of a particular artist or age. If the forger is skillful and is able to absorb the attitudes, conventions, and techniques of the period, he can often create a very successful piece of duplicity.

Stylistic fraud

The work of the Italian Alceo Dossena belongs in this class. He very competently forged works that were acquired by collectors and museums throughout the world. From 1916 to 1928 he produced hundreds of forgeries created as original expressions of archaic Greek, medieval, and Renaissance sculptors.

A newly discovered type of art inevitably brings on a flood of forgeries. At the end of the 19th century, when the first small, attractive Tanagra figurines were found in Greece, the market very shortly was flooded with a myriad of fraudulent Tanagra terra-cotta statuettes. In the mid-20th century, African primitive art became very popular, and woodcarvers from Italy to Scandinavia responded to supply the demand. Later, a very early civilization was discovered in Turkey, and the few genuine Anatolian ceramic pieces that appeared on the market were followed immediately by very competent forgeries apparently made in the same location as the ancient pieces. The lack of knowledge about genuine pieces made detection extremely difficult.

Detection of forgeries in the visual arts. The key to detecting forgery of unique objects lies in the fact that

every object has within itself evidence of when and where it was made. The two main approaches, stylistic and technical analysis, are complementary and are best used together.

Stylistic analysis

Stylistic analysis is subjective: it rests on the astute eye of the art historian. Each artist has a style, a flair, a verve unique to himself, and this can be recognized. His style will undergo change throughout his career, and this, too, can be stylistically analyzed and documented from his known works. When an unknown work purporting to be by a certain artist is discovered, the art historian attempts to fit it into the overall body of works by this artist. The subject matter, the brushwork, the choice of colours, and the type of composition are all consistent elements in a given artist's production. Any variation immediately arouses suspicion. When the idiosyncrasies of an artist's brushwork are studied, a fraud can sometimes be detected in much the same way a handwriting forgery is proven. In ancient works, particularly in antiquities, the scholar must examine the iconography of a piece. Forgers rarely have the scholarly background to combine iconographic elements correctly, and their errors often betray them.

An object must also be studied for its purpose. Ancient works were made for functional purposes. A forger usually makes an attractive piece often inconsistent with that purpose. As they were used most ancient pieces developed signs of wear. These rubbed and worn areas should appear in logical places on the object.

Documentation is also an important area of investigation. The apparent authenticity of many spurious pieces is bolstered by false documents to attest to the point of origin, former owners, and expert opinions concerning the pieces. A careful examination of these records often detects the forgery.

The hardest deception to detect is usually one that has been made recently. The forgery is a product of the time in which it was made, and the forger is closer to current understanding of the artist or period forged. The forgery therefore is often more appealing than a genuine work of art. As a forgery ages, viewpoints and tastes shift, and there is a new basis of understanding. Consequently, a forgery rarely survives more than a generation.

Technical analysis

Technical analysis, an objective approach, rests on an arsenal of equipment and tests. The fundamental principle is the comparison of a suspected work with a genuine work of the same artist or period. The suspected piece must show the same pigments or materials used and comparable age deterioration. Inconsistencies automatically cause the piece to be suspect. Oil paintings dry out and develop a crackle, bronzes oxidize, and ancient glass buried in the ground develops iridescent layers. The microscope is the most useful basic tool: a close examination of the physical condition often will show if the aging is genuine or has been artificially induced. The type of tools used by the artist can be detected from an examination of their telltale traces.

Ultraviolet rays readily reveal additions or alterations to a painting, since the varnish layers and some of the paint layers fluoresce to different colours. Ultraviolet is also used in the examination of marble sculpture. Old marble develops a surface that will fluoresce to a yellow-greenish colour, whereas a modern piece or an old surface recently recut will fluoresce to a bright violet. Infrared rays can penetrate thin paint layers in an oil painting to reveal underpainting that may disclose an earlier painting on the same canvas, or perhaps a signature that has been painted out and covered by a more profitable one. X-rays are used to examine the internal structure of an object. A carved wooden Virgin supposedly of the 15th century but revealing modern machine-made nails deep inside is obviously a fraud. A forger usually works for the surface effect and is not concerned with the internal structures.

Sometimes it is necessary to remove small bits of materials from a work and subject them to various analyses. Chemical analysis is particularly valuable in determining the pigment used because many of the paints available to the modern forger were unknown in earlier times. Today titanium, a 20th-century product, is used to make the white pigment in most oil paints, whereas white lead was the element used in the time of Rembrandt. Many ancient colours were manufactured by grinding natural minerals such as lapis lazuli for blue and malachite for green. Today cheaper synthetic chemicals are used. Some chemical tests, however, require the removal of more ancient material than is desirable. In that event a speck as small as the head of a pin can be analyzed spectrographically. From the burning of a minute sample a photographic record of the spectrum of the light emitted is analyzed to reveal the elements present and their relative percentages.

The dating of an object by the study of radioactive decay of carbon-14 has had little application in the detection of art forgery because of the large quantities of material that must be destroyed. Thermoluminescent dating is based on the slight damage to all matter, including clays, by the faint nuclear radiation present in the earth. Magnetic dating of ceramic objects is based on the slow but perceptible shift of the earth's magnetic field over the centuries.

Considerations of aesthetics and risk. One may logically question the real meaning of the difference between a genuine and a spurious work of art when in many cases it requires such expert study to detect the difference between the two. Or to phrase it another way, what is the difference in value of a work of art that has been on view in a museum for 40 years, after it has been proved to be false? This is a somewhat philosophical point in that the object itself has not changed, only our opinion of it. Its monetary value has been reduced from that of a rare, expensive, original piece to that of an attractive but spurious imitation. Its aesthetic quality has become a real danger, as it is a perversion of the truth. The forgery presents a false understanding of the work of an artist or an ancient culture, one which has been perverted in its modern translation. To appreciate the work of ancient artists their work must be studied alone and not be diverted by forgeries, or one will be inexorably misguided.

Despite all the studies and technical tests available, forgeries will still be made. The 20th-century art forger is far better equipped and much more knowledgeable than his predecessor. The demand for rare works of art has increased, and he will attempt to supply them. In collecting, whether by the private collector or by a museum, there comes a point when, after all the studies and all the tests are conducted, a decision has to be made as to whether or not to purchase a piece in question. The element of risk can be minimized but not eliminated. At this point, the collector should be ready to back his opinion with the purchase price. In order to acquire great pieces, particularly from newly discovered and relatively unknown cultures, it is necessary to take a calculated chance. The collector who has never bought a forgery probably has never bought a great piece of art. (J.V.N.)

Arts, Practice and Profession of the

The practice of the arts goes back to the remote prehistory of mankind; the profession of the artist is of more recent origin. The oldest surviving works of art such as the cave paintings at Lascaux, France, and Altamira, Spain, dating from the late Paleolithic Period between 10,000 and 15,000 BC, were presumably made by men who never thought of themselves as artists. Though these works can be viewed as art today, it is probable that their creators were intent only on executing a magic ritual designed to aid them in the hunt.

At some point in the development and differentiation of human society, the professional artist emerged. The monumental buildings and stone carvings of ancient Egypt or Assyria and the intricately decorated pottery and elegant murals of Crete were undoubtedly done by trained and experienced craftsmen. They were no longer occasional practitioners of art, as the cave painters had been, but full professionals—*i.e.*, men skilled in a specialized occupation, practicing it full-time and probably earning all of their livelihood from it.

Professional and amateur artists. But even the relatively simple definition of a professional as a person receiving pay for carrying out a specialized occupation on a full-time basis is difficult to apply to the arts. In no other field do the categories of professional and amateur so overlap. One of the 20th century's major poets, Wallace Stevens, and one of its most innovative composers, Charles Ives, earned their living as insurance executives. By every criterion of proficiency and accomplishment, both deserve to be ranked as professional artists, yet in a real sense, both were amateurs. Similarly, it is difficult to classify Thomas Jefferson as a professional architect, even though he designed some of the most beautiful buildings of his time.

Historical and cultural dichotomies in the arts. The phenomenon of amateurism in the arts represents only one of the key problems in an attempt to discuss the professional artist. There is also the question as to whether the arts are professions, as distinct from crafts or skills. This aspect of the concept involves consideration of matters of the status or prestige of the arts and decisions on what constitutes proper preparation for careers in them. On these issues, attitudes have varied enormously from one art to another, from one historical period to another, and from one culture to another. Nearly everywhere and always, music, architecture, and poetry have been regarded as professions, while pottery making has been regarded as an art and granted the dignity of a profession only in some non-Western cultures.

Diverse evaluations of the arts

Since antiquity, there has been a continuing debate as to whether painting and sculpture demand skills of eye and hand alone or intellectual grasp and training as well. The painter has often spoken contemptuously of the sculptor, describing him as a mere stonecutter, and the sculptor, in turn, has looked at the painter as simply an illusionist and trickster.

The attempt to gain for some of the arts the status of learned or quasi-learned professions resulted in a distinction between "the fine arts" and "the applied arts," a distinction that has done harm to both. The notion that a painter has a profession, but a cabinetmaker or silversmith only a craft, helped to isolate the former from everyday life and to limit the creative enterprise of the latter. The gradual breakdown of the attitude that permitted such exclusive categories to be created and the general rejection of the false distinctions between art and utility may be among the most encouraging developments in the arts in recent times.

Of even greater importance has been the lessening of the separation that exists between the professional and the practitioner. The "cultural explosion" following World War II not only made the arts more readily accessible to the general public but also stimulated artistic activity in great numbers of people. Never have there been so many professional artists active in so many fields, and never have there been so many nonprofessional practitioners of the arts.

Preparation of the artist

Formal education for a profession in the arts is a relatively new development. The school of art or architecture, the conservatory of music, the academy of dramatic art, and the university's creative-writing program have emerged in modern times, some within the last generation or two. To most artists of the past it would have seemed incomprehensible that they should go to school to learn their profession. Neither would any of the great educational institutions before this century have thought it part of their function to teach artists. Indeed, serious doubts continue to be expressed as to whether academic schooling is the best training for most branches of the arts.

Formal instruction in the visual arts—painting, drawing, sculpture, and architecture, as well as the many arts of decoration and design—has the longest and most diversified history. A consideration of the patterns of development in these related fields will reveal the general directions of training in all the arts as well as many of the basic problems running throughout the history of art education.

THE VISUAL ARTS

The ideal of the universally trained artist

Throughout much of history, the insistence that the artist be learned in many fields has constituted a deliberate attempt to raise his status, to rank him as a practitioner of the liberal rather than the mechanical arts. The Roman architectural theorist Vitruvius (fl. 1st century BC) declared:

> [The architect] should be a man of letters, a skilful draughtsman, a mathematician, familiar with historical studies, a diligent student of philosophy. acquainted with music; not ignorant of medicine, learned in the responses of jurisconsults, familiar with astronomical calculations . . . (From *De Architectura*, F. Granger [tr.], Harvard University Press, 1962.)

Such a prescription represented the ideal of the universally trained artist, and, so far as is known, no institution existed in antiquity to provide this or any other kind of formal training in the arts.

The traditions of apprenticeship. Until the 16th century, when the earliest academies of the arts appeared, the artist acquired his skills mainly through various systems of apprenticeship. He learned his trade as he practiced it under the instruction and supervision of a master. Sometimes the apprenticeship was regulated by a craft guild. Typically, a boy was bound to a master at the age of 14 and served for 7 years. This system was in force throughout most of the Renaissance, and it was under such rules that Michelangelo entered the workshop of Ghirlandajo and Leonardo da Vinci that of Andrea del Verrocchio. In the 17th century, the beginning artist came to be considered a pupil rather than an apprentice. He lived and studied in the home of a master for an indefinite period and was free to leave when he felt he had learned enough.

Functioning of the systems. Whether as apprentice or more informally attached pupil, however, the young artist was trained on the job by his master. As an apprentice, he began by doing the most menial jobs: grinding the colours, cleaning the brushes, or preparing the wood panel or the plastered wall. Gradually, he was trusted

The student, from menial to master

with more responsible tasks, given instruction in the technique of the art itself, and allowed to paint in some of the decorative details of an altarpiece or fill in large neutral areas of a fresco. Finally, he might be assigned the subordinate figures or landscape background of a painting by the master. It is said that Leonardo as an apprentice painted so beautiful an angel in a "Baptism of Christ" by his master that the master resolved to renounce painting and devote himself to sculpture.

Strengths and weaknesses of the system. The training of an apprentice in a Renaissance workshop was not confined to a single art. The workshop of Antonio and Piero Pollaiuolo, perhaps the most active art establishment in Florence of the mid-1400s, accepted commissions in sculpture as well as in painting of all sorts. The graduate of such a workshop, then, if he had kept his eyes open and his hands busy, could have developed a wide range of artistic skills. The apprentice system, however, had serious weaknesses. In a good workshop run by a conscientious master, an apprentice could receive excellent training. Far too many apprentices, however, undoubtedly were condemned to years of repetitious drudgery, receiving little systematic instruction and, at best, being trained purely as craftsmen. Moreover, the guilds deliberately limited the number of apprentices.

Academies and the artistic elite. The founding of the first academies of art, in the late 16th and early 17th centuries, was a step forward. Although later such institutions became restrictive and rigid, they were designed to break the monopoly of the guilds, to regularize the training of artists, and to lift artists from the category of mere craftsmen by liberalizing their education.

The French Academy as model. The most famous and influential of all academies of art was the Académie Royale, commonly known as the French Academy, founded in 1648 in imitation of the Accademia di S. Luca, which had been set up in Rome in 1593. Under the patronage of Louis XIV's great minister, Jean-Baptiste Colbert, the French Academy by the 1660s had become a major force. Under the directorship of the painter-decorator Charles Le Brun after 1683, it exerted a virtual dictatorship over French art. Its success inspired the creation in other countries of official academies that aped its organization and program.

Curriculum and rewards. The curriculum of the French Academy, fixed under Colbert and Le Brun, centred around drawing. The student drew from the drawings of his professors, then from casts, and finally from life. In addition, he attended academic lectures, analyzing pictures from the royal collection. These discourses were designed to instill in the student certain aesthetic criteria and a fixed hierarchy of values in which subject matter played a leading role. In the scale, historical paintings were regarded as the noblest, still lifes as the meanest.

The academy's students competed for a series of prizes culminating in the Prix de Rome, a four-year scholarship in Rome that assured its holder a successful career at the top of his profession. Even those who won no prizes could anticipate a secure future in the service of the state or of individual patrons, for the steady production of uniformly trained and indoctrinated artists was of great importance to the regime.

Academicism as a negative force

The academy performed a great service in breaking the stranglehold of the guilds on the training of artists, in raising the standards of art instruction, and in improving the status of artists. On the other hand, it locked the artist into a closed system, made conformity a virtue, and treated individualism and originality of style as sins to be avoided at all costs. By standardizing methods of instruction, it also standardized the bases of critical judgment. By admitting only 200 students and thus creating a small artistic elite, it neglected the need for trained artists and designers in the decorative and applied arts. Academicism established above all the principle that the artist succeeded not through native genius but through a correctness of technique that could only be acquired through proper training.

The English Royal Academy. In England, a number of schools of art were established during the early 18th century, notably one founded by the painter and caricaturist William Hogarth. In the employment of female models, these schools went beyond anything yet attempted in France. It was not until 1768, however, that the patronage of the crown was obtained for a Royal Academy. By the end of the century, this academy had achieved immense prestige and influence, and a painter who could sign the coveted "R.A." after his name was certain of a prosperous career. The *Discourses* delivered over a period of 15 years by the painter Sir Joshua Reynolds, the academy's first president, remain the best statement of the academic philosophy.

As a teaching institution, however, the Royal Academy fell far short of its French prototype. The limitation to 40 on the number of academicians increased the social and economic desirability of membership but narrowed the scope of the academy's teaching functions. The restrictive curriculum and the discouragement of "eccentricity" of style were not calculated to foster true talent. Of the outstanding English artists of the early 19th century, only J.M.W. Turner was trained and supported by the Royal Academy. The painter-poet William Blake despised it, and landscapist John Constable became an R.A. only late in his career.

Counter movements: the applied arts and crafts. It was not only its self-perpetuating and oligarchical exclusiveness that provoked criticism of the Royal Academy. With the growing impact of the Industrial Revolution, the academy was attacked by reformers in and out of Parliament for its failures to encourage the applied arts and to remedy the growing shortage of trained artisans in such fields as china manufacturing, ornamental metalwork and plastering, and carving in wood and stone. Parliamentary hearings sharply critical of the Royal Academy led in 1837 to the establishment of a government School of Design and an accompanying museum.

Schools and museums of design. The School of Design and its branch schools were succeeded, after 1852, by a network of art schools under a government Department of Practical Art. By 1864 there were 90 such schools instructing about 16,000 students. The founding, in 1852, of the Victoria and Albert Museum, which came to have vast collections of design in all fields, was an important step forward in art education. This combination of schools and museums of applied art was soon imitated in many of the leading cities of Europe, especially in Austria, Germany, and The Netherlands. Despite attacks on the basic principle of separating schools for the applied arts from those for the fine arts, such schools continued to flourish in the 20th century. Most of them, however, modified their curricula to include such studies as art history and aesthetics.

Waning of academic dominance. In painting and sculpture, however, the academic idea lost some of its vitality and dominant influence in the 19th century. By the mid-18th century, the French Académie Royale was under attack from the philosophers of the Enlightenment, and in 1793, at the height of the Reign of Terror following the French Revolution, it was dissolved and its functions handed over to a Commune des Arts led by the painter Jacques-Louis David. The Institut de France, set up in 1795 to supervise the arts, revived the academy in everything but name. The academic establishment, under different forms, remained a powerful though no longer controlling force in the French art world. As the École Nationale Supérieure des Beaux-Arts, it continues today to train artists to compete for the Grand Prix de Rome.

Continued influence of the masters. Even in the heyday of the academy, the system of training the artist in the master's studio had continued to flourish. In 1771 the Irish painter James Barry estimated that 5,500 persons were receiving some kind of art instruction in Paris alone and that of these, 1,500 were being trained to work in such industrial enterprises as the Gobelin tapestry works. Thus most artists were still trained in the studios of established artists or in elementary technical institutes, such as an industrial school founded by Jean-Jacques Bachelier in 1762. France's dominant position in the decorative arts during the 18th and 19th centuries can be attributed in

large part to the effectiveness of the Bachelier school and similar training centres.

During the second half of the 19th century, the demand for training in painting and sculpture grew so great that large numbers of beginners congregated in such studios, or ateliers, as the famous Académie Suisse in Paris, where they painted from a model under the often cursory supervision of a well-known teacher.

Copying the old masters

Another training method became important during the 19th century. Much earlier, copying of frescoes such as those by Masaccio in the Brancacci Chapel in Florence had been a major source of instruction for later painters. With the opening to the public of such great museums as the Louvre, the practice of painting from the old masters again became a basic feature of the artist's training. Even so sophisticated a painter as Paul Cézanne was devoted to this method of teaching himself.

Synthesis of art and craft. Despite 19th-century advances in the formal training of artists in all fields, sharp criticisms of prevailing art education were made, notably by the critic John Ruskin and the poet-craftsman William Morris. They opposed the separation between training for the applied arts and education for the fine arts. Morris saw the division as creating a group of designers who turned out standardized patterns for machine-made objects and a group of fine artists who were constrained from producing things needed by people for an aesthetically pleasing environment in daily life.

As a direct result of Morris' teachings, a number of art schools were established in England to revive handicrafts and to bridge the gap between the applied and the fine arts. The most successful of these schools was the London Central School of Arts and Crafts, founded in 1896. After 1900, however, the leadership in the movement to reform art education passed from England to Germany, where there was a decisive change in emphasis. Contrary to Morris' rejection of the machine, an attempt was made to realize the aesthetic possibilities of machine-made objects and also to create a new architecture.

Impact of the Bauhaus. The major figures in 20th-century art education were the Germans Bruno Paul and Walter Gropius. It was Paul's strong conviction that art schools had a responsibility to artists and to society: to train artists in fields in which they could both earn a living and be socially useful. After World War I, he combined the Berlin Academy of Art with the School of Decorative Art. In a pamphlet on art education published in 1918, he declared that all students, whether they intended to become fine artists or applied artists, should receive basically the same training. He stated also that no one should be admitted to an art school without first having learned a trade in a workshop or trade school.

Walter Gropius, in his early career in Germany and his later work in the United States, exerted an incalculable influence not only on art education but also on the whole development of modern art and architecture. Already a well-known architect in 1914, he became principal of the Weimar School of Arts and Crafts. After service in World War I, he returned to Weimar and in 1919 founded the Staatliches Bauhaus ("the State Architecture House"), a school merging the Weimar art school with the arts and crafts school. In 1925 the Bauhaus was moved to Dessau.

Unison of arts and crafts

The Bauhaus ideal was to unite all arts and crafts to create a new architecture that comprised a living environment; to break down the false separation between the applied arts and the fine arts, between art and utility; and to train artists in the creative possibilities of machine design.

The Bauhaus curriculum. To these ends, the Bauhaus curriculum emphasized the use of different tools and materials, as well as academic instruction in geometry, principles of construction and design, and the history of art. Instruction was divided into three stages. The first, lasting for six months, covered an elementary survey of Bauhaus principles and methods. The second, taking three years, was the basic practical and academic course in which the student, in addition to the general training he received, was required to specialize in a trade under the supervision of a particular master. At the end of this course, the student had to pass one of the regular city trade examinations before, finally, he entered the third phase, *Baulehre* ("building instruction"), in which he took an active part in one of the Bauhaus' projects.

During its short life, which ended in 1933, the Bauhaus achieved remarkable results and assembled an extraordinary faculty that included such leaders and innovators as painter-photographer László Moholy-Nagy, architect Marcel Breuer, and painters Wassily Kandinsky and Paul Klee. It had created the ideal of a new type of art education and proved that it was workable. John Ruskin, as Slade Professor of Art at Oxford in the 1870s, had taken his students out to repair roads, but it remained for the Bauhaus to transform Ruskin's experiments into a coherent program.

Acceptance of the arts in higher education. Though the Bauhaus had no immediate successor, it affected the teaching of art in many schools in following decades. Such education achieved notable growth in university-based or university-sponsored schools of art, especially in the United States. Such schools attempt, in many instances, to combine a four-year academic education with studio work in drawing, painting, sculpture, and other media. Many offer specialized work in such fields as industrial design, book illustration, advertising art, and costume design. The graduates of these schools usually are granted bachelor's or master's of fine arts degrees. None of the schools, however, has attempted to realize the Bauhaus ideal of a student completely trained in both the fine and applied arts.

The same is true of schools of architecture, most of which are connected with universities. In these, the academic curriculum is generally more rigorous than in schools of art. A degree is usually granted after a five-year course, which includes considerable work in traditional liberal arts subjects. A number of schools offer special concentrations in city planning. Few if any, however, see architecture as Gropius did, as a discipline unifying all of the crafts.

THE OTHER ARTS

Music. Next to schools for the visual arts and architecture, the most widespread of contemporary schools for the arts are those for the training of musicians, whether composers or performers. Like the school of art, the school of music has a long history.

The Paris Conservatoire model. The first full-fledged music school of modern times was the Conservatoire de Musique, founded in Paris in 1795 by the revolutionary National Convention as a successor to the earlier École Royale de Chant et de Déclamation and Institut National de Musique. In 1797 it had 125 professors and 600 pupils. It has had a continuous and distinguished history to the present day.

Development of the music curriculum

The curriculum developed at the Paris Conservatoire has been followed with slight variations in schools of music elsewhere. Originally, classes in composition, harmony, singing, and instrumental performance were given. Later, classes in music history were added, and an increased emphasis was given to training in sight reading. Still later, instruction in aesthetics and musical analysis became part of the standard curriculum.

The success of the Paris Conservatoire and the greatly increased demand for trained musicians during the 19th century led to the creation of conservatories in major European and American cities. In the United States, the Boston Conservatory of Music was founded in 1867, the Peabody Conservatory in Baltimore in 1868, and, later, others in New York, Philadelphia, and elsewhere. Some of these schools have remained independent, whereas others have become part of universities.

Private and institutional study. The conservatories of music have not altogether supplanted the older system under which a student worked under a particular master, as Ludwig van Beethoven did under Joseph Haydn at the end of the 18th century. Such a famous teacher of composition as Nadia Boulanger attracted students from all over the world, and singers and instrumentalists often

prefer to attach themselves to the studio of a favourite teacher. Increasingly, however, the conservatories have absorbed the master's classes.

Literature. The idea that the college-bred writer is superior to the one who has not had a liberal arts training goes back at least as far as the Elizabethan Age, when Robert Greene, one of the so-called university wits, sneered at Shakespeare as an upstart crow. The notion that creative writing, as distinguished from the ancient discipline of rhetoric, is something that can be taught in an academic environment is a recent development.

In the United States, especially, many creative writing programs have developed in higher education, usually in conjunction with the appointment of a well-known writer in residence as a member of the faculty. The creative-writing student typically receives more broadly based, and less technical, training than the student at a school of art or music.

Theatre and dance. The training of dramatists has taken a direction somewhat different from that of other writers. It has been combined with practical work and experience in the crafts of the theatre.

Academic teaching and apprenticeship. The workshop set up at Harvard by George Pierce Baker and the Yale School of Drama, which he founded in 1925, served as models for later drama schools. In recent years, some university-based schools of theatre arts have developed very elaborate programs, with professional courses in scenic design, lighting, and direction, as well as in playwriting and acting. They often sponsor highly trained repertory companies that present new and often controversial plays as well as the classics.

Training the performer

There also exist separate schools for actors outside the university establishment. Among the best known of these is the Royal Academy of Dramatic Art in London, which has trained many successful actors. The Actors Studio in New York City has enrolled fledgling actors as well as established actors who wish to keep their skills sharp.

The old apprenticeship system remains more a vital factor in the training of actors than in any other of the performing arts. Particularly in countries in which repertory companies are well-established, as in England, France, Germany, and the Soviet Union, actors can learn and gain experience in their craft by progressing from walk-on roles to more demanding ones. Often the actor can start in a provincial repertory company and move to one of the national companies. For the experienced actor, the repertory company provides the opportunity to do a variety of roles, and to go from a major to a minor part from week to week, as a member of an integrated and continuing ensemble. The system goes back to the beginning of stable acting companies in the Europe of the 16th and 17th centuries, when actors might enroll as boys and live out their lives as members of the same company.

Formal education for the dance in modern times dates from the establishment by Louis XIV of the Académie Royale de Danse in 1661. In 1669, the Académie Royale de Musique was founded, and a school to train professional dancers was added in 1672. These institutions made Paris, and specifically the Paris Opéra, the world centre of ballet training and performance in the 19th century.

Formal demands of the dance. Training for the dance has made less headway in universities than that for other of the performing arts. A few colleges in the United States offer a fully developed dance curriculum, and some schools of fine arts include programs in dance, but the professional instruction of the dancer, whether in ballet or the modern dance, usually is carried on in the 19th-century tradition of teaching in schools associated with ballet companies or opera houses. It has changed little from the time when Edgar Degas painted the young dancers of the Paris Opéra at practice. With few exceptions, training for the dance has remained a relatively narrow and physically demanding regimen.

The technologically based arts. Relatively little attention has been paid to the development of professional curricula in photography. More than any other art, it has been treated as a hobby to be learned without formal instruction. Where it is taught, the focus is on photographic technique rather than on photography as an art. There are, however, signs of a growing acceptance of photography as an important and expressive art form, and it is now becoming part of the curriculum not simply of schools of journalism but of schools of fine arts as well.

The new arts of the 20th century—film, radio, and television—still depend largely upon people trained in the older arts. The foundation in recent decades of film institutes associated with universities, notably in New York state and California, has been a significant step. A few radio and television programs exist, sometimes as parts of a department of communications arts or outside academic settings. Most of the directors, actors, and writers in film and television either have developed in the theatre or the literary world or have grown up in the industry without formal instruction.

THE SELF-TAUGHT ARTIST

With all of the many systems and institutions for formal training in the arts that have come into being over the centuries, there always have been self-taught artists. This is especially true of writers, the overwhelming majority of whom, from Homer to the present day, have had no specific training in their art, and many of whom, in fact, like Shakespeare or George Bernard Shaw, had comparatively little schooling of any sort. They have learned their trade by studying other writers and life itself, and by proceeding from imitation to original creation. Many people have turned to writing after education for careers in other fields. Medicine alone has produced such outstanding writers as the Englishmen Sir Thomas Browne and W. Somerset Maugham, and the American William Carlos Williams.

Art without schooling

Self-trained artists have also achieved prominence in other fields, though far less frequently than in writing. The history of architecture, perhaps of all the arts the one that seems most to demand strict technical training, contains two spectacular instances of the self-trained professional. Sir Christopher Wren, among the greatest of English architects, was a mathematician and professor of astronomy at Oxford before he took up architecture. But whereas Wren was grounded in the principles of the exact sciences, Sir John Vanbrugh, the architect of Blenheim Palace, had been a soldier and a dramatist before he turned to architecture at the age of 35.

The completely self-trained professional artist is a rarity in painting and sculpture. More than any other kind of artist, the painter especially must learn from and with other painters. Although such painters as Paul Cézanne, Vincent Van Gogh, and Paul Gauguin were in many respects self-taught, they absorbed a great deal from studies of, and interactions with, their fellow artists. Occasionally a true "primitive" such as Henri Rousseau, unhampered by conventional instruction, has produced a style with extraordinary power and directness as well as naïveté.

TRAINING OUTSIDE THE WEST

In non-Western cultures also, professional training in the arts has had a long history. Much of it has been carried out under systems of apprenticeship similar to those found in the West. Both in the Orient and in Africa, the profession of the arts has often been a hereditary one, sometimes, as in the case of bronze casters and ceramics workers in China, with secret techniques passed on from one generation to another. Similarly, Japanese Nō and kabuki actors long passed their craft from father to son, with the aristocratic Nō being regarded for centuries as a secret tradition. In West Africa, an entire village frequently has specialized in the production of a particular kind or style of art object.

Oriental and African art practices

Education in the arts has also been diffused through written treatises. In China a number of practical manuals on painting are extant, the two most famous ones dating from the 17th century. In India there were noted teachers of arts and crafts as early as the 1st century. Most recently, art schools similar to those in the West have been founded in a number of Eastern countries, notably in

Japan, where a conscious attempt has been made to combine ancient traditions and modern styles. During the period of French colonial rule in Southeast Asia, an influential École des Beaux Arts was set up in Hanoi. In many primitive and folk societies, however, such arts as dance have been passed on by imitative learning.

Conditions of work in the arts

In no way can artists be stereotyped as shivering recluses, painfully pursuing their craft in dimly lit garrets; as well-fed hangers-on to the coattails and whims of the wealthy; or as irresponsible wastrels, lurking in the outskirts and subcellars of respectable society. The conditions of their work and life have been shaped in large measure by the regard of their society for the arts in general or for their art in particular. High regard has not always brought success or satisfaction, however, and artists have turned into many different avenues in search of tangible or other rewards for their art.

THE STATUS OF THE ARTIST

The social and intellectual status of artists has differed considerably from one field to another, from one culture to another, and from one historical period to another. They have been regarded as entertainers, artisans, seers and prophets, and, often, as dangerous cranks or misfits. The history of each of the arts has been marked by a determined effort on the part of its practitioners to raise their status and to be accepted as honoured members of their society.

Prehistory. In preliterate cultures, the poet preserved and transmitted the beliefs and traditions that gave the culture its sense of identity and purpose. Less an original creator than a storyteller and singer, he kept alive the works that had grown up by gradual accretion and refinement, and often he contributed to the process. The Homeric epics of ancient Greece probably developed in this way over generations, though in the form in which they have survived they almost certainly were shaped by one or more supreme geniuses.

The primitive bard

The primitive bard seems to have occupied an anomalous position, held in awe because of his seemingly divine powers but without a fixed place in the social hierarchy—existing as a dependent of a tribal ruler or as a wandering beggar. It is no accident that the Greeks represented Homer as blind, thereby symbolizing not only the poet's inward-directed vision but also his separation from ordinary men. The peculiar contradiction that poets have complained of bitterly, that their gifts are venerated but that they themselves are neglected, has its most famous statement in the couplet, "Seven cities warred for Homer being dead,/Who living had no roof to shroud his head," by the English poet Thomas Heywood.

Antiquity. In the great age of classical Greece and, later of Rome, the artist lost some of his legendary quality as seer, but he gained considerably in social acceptance.

Greek poets, sculptors, and designers. The skill of the dramatist, like that of the athlete, was tested in competition and rewarded by prizes. The bard gave way to the historically defined individual. Sophocles, in the fifth century before Christ, was no blind beggar but a respected citizen, a soldier, and politician, as well as a tragic poet. Above all, the intellectual role of the writer was recognized and his claim to respect was validated by the celebrated dictum of Aristotle that poetry is more philosophical than history. Aristotle's defense of poetry was perhaps a deliberate response to the celebrated attack by Plato in *The Republic* on the creative artist as a potential threat to the stability of the state.

Emergence of the known artist

In other fields, too, artists began at the same time to emerge from anonymity and to achieve social acceptance. The nameless artisans and stonecutters who erected the first crude Doric temples and carved the cult images that they housed were succeeded by renowned architects such as Ictinus (flourished 5th century BC) and Callicrates, and by master sculptors such as Phidias (flourished 475–430 BC), who supervised the rebuilding of the Athenian Acropolis. Phidias is alleged to have represented himself and the Athenian tyrant Pericles on the shield of Athena. Such self-glorification would have been beyond the imagination of earlier generations.

The great mass of Greek sculptors of the classical and Hellenistic periods, however, continued to be regarded as craftsmen, paid standard wages for a day's work or for a specific piece. To Plato, for example, sculptors were common workmen. Even the recognized masters were expected to turn their hands to whatever their patrons demanded.

Rome and service to the state. Under the late Roman Republic and the empire, the artist continued to enjoy a favoured status. The great Roman dramatist Terence (flourished 2nd century BC) began his career as a slave, but his achievements earned him freedom and admission to the leading intellectual circles of his time. The organizing genius of the Romans enlisted poets, architects, and sculptors in the service of the state. Gaius Maecenas (died 8 BC), the first of the wealthy patrons of the arts, encouraged and supported such poets as Virgil and Horace. Vast building and engineering projects throughout the empire gave employment and prestige to many architects.

This was the age, too, that saw the emergence of the art connoisseur and the tourist in search of cultural treasures. The esteem for artists in Rome is reflected in the eagerness with which Pliny the Elder sought out and recorded biographical information on the great artists of Greece. For the first time the artist was felt to merit the same attention as the statesman or soldier. A similar rise in the prestige of the writer was signalized by the founding of such great libraries as the one at Alexandria, devoted to preserving the literature of the past.

The musician of antiquity. Much is known about the musician in antiquity, although practically none of the music itself has survived. There is considerable testimony to show that music itself apparently was considered among the highest of human accomplishments; in fact, of divine origin. The legend of Marsyas, the human being who dared to challenge Apollo to a musical contest and was flayed for his pains, was a favorite subject of Hellenistic sculpture. The myth of Orpheus, whose playing on the lyre could move even inanimate things to wonder and delight, reveals the almost superstitious awe in which the Greeks held the powers of the musician. Musical theory, with its close relationship to mathematics, was regarded as a branch of philosophy. The philosopher Pythagoras (flourished *c.* 530 BC), who saw the whole universe as a harmony of the spheres, was only one of many who gave the highest intellectual ranking to the study of music. The special status given to music in antiquity continued into the Middle Ages, when music alone, of all the arts, was ranked among the seven branches of learning.

Music as the highest art

In Greece, there emerged for the first time the distinction between the gentleman amateur and the paid professional that was to play so large a role in the later history of the arts. Every educated Greek was expected to be able to play an instrument, to sing acceptably, and to discourse on the theory of harmony. On a much lower intellectual and social level were the professional entertainers who competed for prizes at great public concerts, who performed in the dramas, and who supplied the musical accompaniment for athletic games.

Actors, dancers, and rhetoricians. The distinction between the creative artist and the entertainer or interpreter, which continues to be made even today, seems already to have existed in ancient civilization. The accomplishments of the actor-dancer were admired and applauded, but, aside from the citizen-dancer of the Greek festivals of tragedy, he had a relatively low intellectual and social status. The names and other details of some of the famous actors of this period are known, but references to them are in a tone altogether different from references to a Phidias or a Virgil, and everything indicates that actors were regarded as belonging to an inferior class.

The lost art of persuasion

One art virtually unpracticed today, that of the orator or rhetorician seeking to persuade, by speech or writing and according to a detailed formulistic pattern, occupied an especially favoured place in antiquity. The principles

of the art were expounded in treatises by Aristotle, Quintilian, and others, and its greatest practitioners, Demosthenes among the Greeks and Cicero (first century before Christ) among the Romans, were accorded the same respect given to the poets. In the twilight of the Roman Empire, the young St. Augustine supported himself as a teacher of rhetoric. The prestige of rhetoric as a noble and useful art reached its highest point during the Renaissance, when every court had its master rhetoricians and orators.

The Dark and Middle Ages. With the collapse of the Roman Empire in the West in the 5th century, the professional artist virtually disappeared in Europe. Until the revival of Western culture under Charlemagne about 800, the practice of the arts was confined mainly to scattered monastic enclaves, which kept alive the traditions of a written literature and began to develop a new architectural style. Some of the arts, such as the written drama, were lost altogether, only to be revived later on from church ritual and folk ceremonies. The sophisticated poet, a product of the stable and assured civilization of antiquity, vanished from the scene to be succeeded by anonymous bards, such as the creator of the Anglo-Saxon *Beowulf*, who, as in Homeric days, put into final form the results of centuries of oral shaping of legend and history. Only in the Byzantine Empire and, after the 7th century, in the rapidly growing world of Islām, was the professional artist able to flourish.

The rich burgeoning of medieval civilization following the early 9th-century Carolingian renaissance produced a magnificent harvest in the arts, but for the most part the creators remain unknown. The superlatively beautiful so-called Book of Kells from 9th-century Ireland was decorated, page by page, by a monk or group of monks, who saw the task as their gift to God, their way of living their vocation. It is doubtful that they were conscious of themselves as artists or that they were so regarded by their fellows.

The builders and sculptors of the great Romanesque and Gothic churches were journeymen masons and carvers who worked under the driving direction of a forceful churchman, such as the remarkable Frenchmen Hugh of Semur, Abbot of Cluny from 1049 to 1109, and Abbot Suger, who built the Abbey Church of St. Denis from 1140 on. The radiant stained-glass windows of the Gothic cathedrals were made in the workshops of Chartres and other centres. Only rarely did a particular craftsman, such as the sculptor Giselbertus of Autun and the sculptor-decorator Nicholas of Verdun, emerge from anonymity.

The Renaissance and Baroque. An enormous increase in the prestige of the artist came about with the beginnings of the Renaissance in 14th-century Italy. The veneration for antiquity that so dominated intellectual life was in large measure a veneration for the arts of antiquity, for a life-style in which the written and spoken word, the visual image, the public monument, and those who created them were seemingly central elements.

Reverence for the artist

New stance of the poet. The crowning with laurel of the poet Petrarch at Rome in 1341 was a ceremony intended to establish a link with ancient civilization. Almost immediately after the death of Dante, the *Divine Comedy* became the object of an intense scholarly and critical study equal to that given the great epics of antiquity.

Throughout Italy, but especially in Florence, the humanist of the 15th century was dedicated to the purification and preservation of Latin as a living universal language. He gave to the profession of writer and scholar a distinction it had not had since the collapse of Rome nearly a millennium earlier. Men of letters were held in an esteem that—in the case of that shown the Dutch humanist Desiderius Erasmus—approached reverence.

Regnancy of the visual arts. The new Renaissance attitudes were most striking in the visual arts. The painter and architect Giorgio Vasari, in his *Lives of the Most Eminent Architects, Painters, and Sculptors* (1550), saw the development of the arts in Tuscany as the working out of a divine plan. According to Vasari, God sent Michelangelo to the world endowed with so great a universality of power in each art that he might be considered of a divine rather than human nature. A century earlier, no one would have considered artists deserving of extended biographical treatment.

The artist had fought for this new status, however, from Filippo Brunelleschi, who stoutly defended his independence as an architect from the meddling of the Florentine government, to Michelangelo, in his defiance of Pope Julius II. Leonardo resented bitterly the placing of painting among "the mechanical arts" and attempted to raise the status of painting by deliberately downgrading sculpture, which he called a sweaty and fatiguing job for workmen. Even after he had become a world-famous artist, Michelangelo felt it necessary to defend his social and intellectual position. Forbidding his nephew to address letters to him as "Michelangelo the Sculptor," he insisted he had never been a painter or sculptor such as those for whom it was a business.

Status and the academy

The first academies of fine art were founded not primarily as teaching institutions but as means of enhancing the standing of artists. Florence's Accademia del Disegno, founded by Vasari in 1563, was headed jointly by a prince and an artist—the Grand Duke Cosimo and Michelangelo. In 1564 the academy publicly demonstrated the honour being paid to artists in its elaborate funeral ceremonies for Michelangelo. Such leading Venetian artists as the painters Titian and Tintoretto and the architect Andrea Palladio were glad to apply for membership in the Florentine Academy, and its advice on the design of the Escorial Palace was requested by King Philip II of Spain.

Particularly in northern Europe, however, the average painter, as distinct from the outstanding genius, continued to be regarded as a craftsman throughout the 16th century. In 1590 the Guild of St. Luke in Haarlem included not only painters, wood-carvers, and goldsmiths but also printers, slate layers, plumbers, and lantern makers. This extreme situation was bitterly complained of by a leading Dutch painter and theorist of the period, but it illuminates the attitude toward painting still held by many.

In the 17th century, the intellectual and social status of the artist reached perhaps the highest level it has ever attained. Two of the greatest Baroque artists, the Flemish painter Peter Paul Rubens and the Italian sculptor Gian Lorenzo Bernini, lived like princes. Both were accepted in leading intellectual circles and were completely at home in this environment. The Spanish master Diego Velázquez enjoyed lifelong security as the favourite painter and friend of King Philip IV, who, despite the grumbling of many aristocrats, awarded him the Noble Order of Santiago.

Writers and performers. The change in the status of the writer during the Renaissance and Baroque periods was not nearly as spectacular. The poet and rhetorician were treated with respect, but it was still necessary for Sir Philip Sidney about 1581 to write *An Apologie for Poetrie* (first published in 1595), and the poet Edmund Spenser, like many poets of lesser stature, had to beg for patronage from powerful nobles. Shakespeare published his narrative poems with obsequious dedications to his patron, the Earl of Southampton.

Practitioners of such newer literary forms as the novella and the popular drama never achieved full social or intellectual acceptance in this period. The dramatist, in particular, linked as he was with the day-to-day commerce of the theatre, and often himself an actor, was considered simply as a hack writer. His plays were regarded lightly as literature, and when Ben Jonson dared to publish his plays as his *Workes* in 1616, he was jeered at for his pretensions. Actors, though they were loved and admired as entertainers, had escaped only recently from being classed as "rogues and vagabonds," and technically they were regarded as household servants of the nobility. An occasional actor, such as Edward Alleyn or Shakespeare, was able to attain the position of a gentleman if he was a manager as well or had powerful patrons.

The theatre as mere entertainment

Only in the France of Louis XIV did the dramatist at-

tain the status of an honoured man of letters, and then only by adhering to the rigidly defined neoclassical standards of dramaturgy. The drama, like all the arts, was closely integrated into the political structure, and powerful ministers of the crown carefully supervised the work of the playwright. Leading dramatists such as Jean Racine were victims of political intrigues, but if they survived them, they could look forward to the ultimate reward of election to the Académie Française. Molière, however, who was an actor and theatre manager as well as a dramatist, was regarded socially as a member of Louis's household.

Revolutionary impetus. The great social and political changes of the late 18th century, climaxing in 1789 in the French Revolution, were as decisive for the artists as for other groups of men. The emphasis on personal freedom and the desire to break loose from mind-forged manacles as well as social shackles were key elements in the Romantic movement that dominated the arts for almost 100 years. A wide gulf separated the attitudes of Haydn from those of Mozart, though the two were only a generation apart in age. Haydn was content to serve as music master for the Esterházy family in Hungary from 1760 to 1790. Mozart could easily have made a similar career, but he rebelled against being a servant to the Archbishop of Salzburg. He determined to earn his living as an independent musician, and for a time his career flourished. The day of the free-lance composer had not yet dawned, however, and he died early, in poverty and loneliness.

For the first time in history, under the impetus of the French Revolution, there emerged the phenomenon of the revolutionary artist committed to an active political role. The most conspicuous example was the Neoclassical painter Jacques-Louis David, who not only expressed the ideology of the Revolution in his works and organized its great public festivals but was a political leader and a friend and ally of the Revolutionary leaders Marat and Robespierre. The ambivalent attitude expressed in the 20th century toward political activity by artists was illustrated earlier when David was caught up in Robespierre's downfall in 1794. Unlike other of Robespierre's followers who were executed summarily, David, after a stay in prison, was pardoned and restored to favour as virtual dictator of the arts. A similar situation befell the Spanish painter Francisco Goya, who had partially cooperated with the French puppet government in Spain. When the Napoleonic armies were driven out in 1814, he regained his position as court painter. There may have been in both cases an unwillingness to dispense with the services of a great artist. In addition, however, there also may have been at work the feeling, expressed even in this present century, that the artist is not to be taken altogether seriously as a politician.

The artist as political activist

The developing setting of modern art. A characteristic feature of artistic activity in the 19th and 20th centuries is that no generalizations about the status of the artist can be made. Trends are divergent and often completely contradictory. On the one hand, the artist became one of the representatives of the acquisitive society, a successful businessman satisfying the demands of the market. Whether he was a man of genius, such as the English novelist Charles Dickens and the French novelist Honoré de Balzac, or a talented and industrious hack, he wrote for a vastly expanded audience created by mass literacy and growing leisure. The English writer Anthony Trollope, sitting in his club and turning out his fixed quota of words, finishing a novel one day and beginning another the next, was a perfect embodiment of the respectable, punctual, middle class writer.

Similarly, the official artist was recognized by the national academy and hung at the salon exhibitions. He created a standardized and approved product—whether portrait, landscape, or sentimental illustration—to meet the great demands of a newly rich clientele eager for culture but unsure of its tastes. The American portraitist John Singer Sargent not only answered completely the artistic needs of his upper class patrons but identified with them as a person. At this point the social distinction between patron and artist virtually has disappeared.

On the other hand, the 19th century was above all the period of the alienated artist, the deliberate exile from society. The tone was set early in the century by the English poets Lord Byron and Shelley, both born aristocrats, who flouted the standards and conventions of their class. The contempt for accepted social behaviour and the adoption of the pose of the outcast are seen at midcentury in the French poet Baudelaire and in the closing decades in the French painter Gauguin. *Épater la bourgeoisie*, "to dumbfound the middle class," became the slogan of a whole group of French Romantics. The doom-ridden artist propelling himself toward destruction by drink, drugs, or a furious excess of behaviour became a characteristic figure of modern times, from Edgar Allan Poe to Jackson Pollock and many "pop" singers of the 1960s and 1970s.

Emergence of the alienated artist

Somewhat related to this phenomenon was the distrust with which the middle class came to view artists, above all painters and musicians. This is especially true of attitudes toward the avant-garde artist, whose rejection of academic conventions within his own art makes him suspect as an enemy of society itself. Napoleon III's superintendent of fine arts summed up for all time the attitude of officialdom toward such artists when he expressed his displeasure and disgust with their work, characterizing them as democrats who do not change their linen and hope to put themselves over on the world.

Impact of scientific dominance. As science became a dominant force, the intellectual prestige of the artist declined. The role of the prophet continued to be played by such writers as Thomas Carlyle and John Ruskin, both of whom were skeptical of the benefits of science and technology. No creative artist since Goethe, however, has gained the intellectual respect accorded to scientists. Modern art has produced no men of universal interests and abilities to match such Renaissance geniuses as Leon Battista Alberti or Leonardo, whose work and thought carried them into virtually every area of human activity.

The ideological gap between scientists and artists, between "the two cultures," as the English novelist C.P. Snow has called them, has widened dangerously over the past century. A number of artists, however, attempted to incorporate into their own work some of the methodology of science and to gain for themselves the intellectual status of the scientist. In a famous essay of 1880, *The Experimental Novel*, Émile Zola argued for a literature governed by science and claimed for the novelist the function of a biologist of society. The French Postimpressionist painter Georges Seurat, who set for himself the reconciling of art and science, believed that properly applied scientific theory could replace intuition as the basis of art. In the 20th century, apologists of Cubism, though not its leading practitioners, saw in it the artistic expression of the fragmented world of modern physics. Recently, electronic music, created mainly by university-based composers, has provided a new union of technology and art.

New areas of respectability. The actor-manager David Garrick had helped to make the theatrical profession respectable, but during the early 19th century, actors and actresses, however applauded or financially successful, continued to be regarded by many as slightly disreputable. By the end of the century, however, the situation had so changed that in 1895 Queen Victoria knighted Henry Irving, the first actor to be so honoured. Such an accolade became almost commonplace in following years, and in both Europe and America the actor is now accorded considerable respect.

The new arts of the 20th century—the cinema, radio, television, and recording—have all produced their mass idols. The fantastic adulation lavished on film stars or pop singers, however, has often been accompanied by an openly or covertly expressed intellectual contempt. Of all the artists involved in the creation of a film, only the director seems so far to have achieved intellectual respectability. Such directors as the Italian Federico Fellini, the Swede Ingmar Bergman, and the Frenchman Jean-Luc Godard became subjects of a serious aesthetic discussion comparable to that focussed on the most important of contemporary writers or visual artists.

Artists of the new arts

In music, the last 100 years have featured the virtuoso performer, the pianist, the violinist, the soprano, or the conductor. The separation of composer from performer began early in the 19th century, and instead of a Bach, Mozart, or Beethoven performing his own works, there is the virtuoso who interprets the compositions of others. The most publicized musician of the 20th century and the one most widely admired for his intellectual gifts was not a composer but the conductor Arturo Toscanini. The famous pianist Ignacy Paderewski, when he served briefly as premier of Poland in 1919, became the first professional artist to head a national government. One of the most striking phenomena of the rock music of the 1950s and 1960s was the closing again of the gap between composer-lyricist and performer.

Another important development in this century was the growing activity of black artists and women artists to break down the social and intellectual discrimination that historically has been directed against them. There has been, as a result, not only increased public knowledge of the contributions made by both groups but also a greater understanding of the artist as an individual who is directly involved in—and in much of his work reflects—the problems and stresses of his society.

THE ARTIST'S LIVELIHOOD

Throughout history, the economic status of the artist has varied as widely as his social and intellectual status, though changes in the one have not necessarily paralleled changes in the other. Since conditions favouring one art may have been unpropitious for another, artists in different fields often did not experience the same measure of economic security at any given time. Similarly, though artistic activity in general has followed economic development, there have been periods of great prosperity during which artists have starved.

Forms of patronage. Until recently, artists in most fields were directly dependent upon patronage—whether governmental, church, or private—for their livelihood. They produced works specifically commissioned for a particular need or occasion or designed to appeal to the tastes of a well-defined group or known individual. The notion of an artist working to please himself and then attempting to sell his product on the open market, either directly or through an intermediary, is a comparatively modern one. In such fields as architecture and serious music the artist even now remains almost completely dependent on direct commissions.

Quality and patronage

The system of patronage has had a profound effect on the work of art itself. The idea that institutional sponsorship always produces bad works of art is refuted by the facts. The buildings on the Acropolis of Athens, the Gothic cathedrals throughout Europe, the Sistine Chapel frescoes in Rome, and the sculptures of the Benin kingdom of West Africa, for example, were all commissioned by a governmental or religious body. Artists working to express a shared system of ideas and beliefs for a community of which they are an integral part are likely also to share a common and stable style. The rapid shifts of style that characterized the arts in modern times reflect, to a certain extent, the new economic status of the artist as well as the present instability of artistic traditions.

The open marketplace. Nevertheless, many artists of the past have chafed at the loss of individual freedom entailed by institutional support. This was particularly true during the 16th and 17th centuries, when the intellectual and social status of the artist was improving. When artists gradually freed themselves from the tyranny of patronage, they often discovered that they had submitted to the equally confining tyranny of the marketplace. In 17th-century Holland, for the first time in the history of art, painters began to produce works to be sold at auction or in art markets. The dependence on commissions did not cease, but direct patronage was no longer the only source of the artist's income. Most of Rembrandt's work, for example, was probably done to order, but many of his surviving works, including more than 60 self-portraits, probably were done without immediate commission.

In the 19th century, a number of artists attempted to capitalize directly on their own work, not by selling individual paintings to particular buyers but by exhibiting them for a fee to a mass audience. The American artist Rembrandt Peale earned $9,000 from the showing of his painting "The Court of Death," which was seen by 32,000 people during a 13-month tour in 1820–21. At virtually the same time, the French painter Théodore Géricault was exhibiting his famous, "The Raft of the Medusa" throughout England and Ireland. In 1855, Gustave Courbet constructed his own Pavillon du Réalisme at the Universal Exposition in Paris, charging the public an entrance fee to view 50 of his paintings.

In the other arts, as well, the artist emerges as an individual entrepreneur from the 16th century. Alexander Pope was perhaps the first poet in history to earn a living entirely from the public sale of his work. The new commercial orientation of the writer was summed up in the famous aphorism of Samuel Johnson, "No man but a blockhead ever wrote, except for money."

Institutional patronage has never, even in modern times, lost its importance for the artist. Eugène Delacroix, the supreme French Romantic painter, accepted a number of commissions for large murals from the French government. One of the most celebrated paintings of the 20th century, the "Guernica" by Pablo Picasso, was done for the Spanish Pavilion at the Paris Exposition of 1937. Both Marc Chagall and Henri Matisse created masterpieces of religious art on commission.

Artists in the modern period have had, nevertheless, to appeal to the general public in order to survive. For those who succeeded, the rewards were great, and many artists, both academic and avant-garde, became wealthy. On the other hand, innumerable others have been driven to despair by lack of public recognition and support.

Governmental and other subsidies. Various attempts have been made to provide some kind of governmental subsidy for artists. Among the most conspicuous of these were the Works Projects Administration (WPA) programs for painters, writers, actors, and other artists supported by the United States government during the depression of the 1930s. These projects were attacked bitterly by some politicians and eventually discontinued.

Today, the principle of government support for the arts is widely accepted. Most European countries have state theatres and opera houses, and they support symphony orchestras, ballet companies, and other groups of artists. The British government grants sizable subsidies to the National Theatre and the Royal Shakespeare Company. In the United States, the federal government and some state governments have given financial aid to artists through such organizations as the National Endowment for the Arts and the New York State Council on the Arts. Universities and some private foundations have become important sources of economic support for the artist. Poets, painters, and composers in residence are now found in many universities, sometimes with teaching duties, sometimes free simply to create.

State-supported performing companies

Conditions outside the West. The social forms of non-Western cultures have varied so widely, from place to place and from period to period, that it is impossible to make any valid generalizations about the economic position of the artist in such cultures. At one end of the scale, in simple nomadic or agricultural communities, the artist hardly has existed as a specialized person. Such crafts as pottery making or weaving generally have been diffused throughout the community, sometimes limited to one sex or another. In the sophisticated and highly developed imperial, monarchial, or tribal societies of China, India, or Africa, on the other hand, the trained artist has always been regarded as a valued servant of the ruling or priestly group and has been integrated completely into the economic structure of the state. With the vast social and political upheavals in the Orient and in Africa in recent decades, a period of rapid change in the economic and social status of the artist has set in.

INTERACTIONS AMONG ARTISTS AND WITH THEIR PUBLICS

The mingling of artists working in the same or different mediums always has provided a leavening element for

their creative energies and imagination. Similarly, collective or collaborative work, criticism and appreciation, and national and international awards, as well as collective action for the benefit of the artistic community, have contributed to artistic life and work.

The artist's working environment. The act of artistic creation is usually a solitary one, whether carried out in an isolated cell or in a crowded room. Most artists, however, have sought the stimulus of some special kind of environment, generally one in which they could have regular interaction with their peers. Only rarely has an artist who is cut off from others, by necessity or choice, been able to produce great work. It has been suggested that the American poet Emily Dickinson might have developed her poetic gifts even more significantly if she had not been so isolated from other writers. The battles of wit between Shakespeare and Ben Jonson at London's Mermaid Tavern may be apocryphal, but they describe a situation typical of the literary life.

A deliberately and formally organized artistic environment has proved only rarely to be conducive to creative work. Art colonies, either specifically limited to artists or existing within Utopian communities, have tended to fall apart rather quickly. One of the longest lasting of these, the MacDowell Colony at Peterborough, New Hampshire, has endured mainly because it offers a pleasant and quiet summer retreat for the artist. Brook Farm in Massachusetts, which Nathaniel Hawthorne joined briefly in 1841, and the Helicon Home Colony in New Jersey, founded by Upton Sinclair, were both short-lived.

The university has come to play an important role as a fostering environment for the artist. The many temporary or permanent positions it offers have provided not only a measure of economic security for artists but also an intellectually stimulating setting. There is some feeling, however, that permanent immersion in an academic environment may insulate the artist too much, eventually depriving him of his vital sources of inspiration.

Centres and schools of artistic activity

Historically, most artists seem to have thrived best in a city that is the centre of vigorous political, economic, and intellectual activity and in which they could interact with other artists when and where they chose. Florence in the 15th century, London in the Elizabethan era, Vienna in the late 18th and early 19th centuries, and Paris from the Revolution until World War II were such places. The Café Guerbois in Paris was the scene of innumerable heated discussions in the 1860s and the 1870s between many of the leading painters and writers of the period. Such interchanges undoubtedly provided much creative impetus for their art.

Sometimes, artists brought together by similar views have mutually inspired each other and worked in tandem to develop new styles. This was true probably of Giorgione and Titian in Venice, and certainly of Georges Braque and Picasso during the elaboration of Cubism in the early 20th century. There have also been looser groupings of artists with common interests, such as the Impressionist painters who exhibited together from 1874 to 1886. More recently, such groups as the Dadaists of immediately after World War I and the Surrealists of the 1920s for a time united various artists of sometimes diverse tendencies.

Artists have on occasion, particularly during the 19th century, combined out of a sense of shared poverty and neglect to express a common contempt for accepted values. They have formed a separate society of their own, a "bohemia" characterized by deliberately outrageous costume and behaviour. The ultimate expression of the bohemian disdain for middle class conventions was the glorification of suicide, and young French bohemians actually founded a Suicide Club in 1846 as a gesture of defiance.

Social integration outside the West

Such bohemian excesses generally have been unknown in non-Western cultures. In societies where the role of the artist has been clearly defined and established by long tradition, the notion of the alienated artist would be virtually incomprehensible. Like the European craftsman of the Middle Ages, the non-Western artist has functioned not in a special environment set apart from his society but as a respected member of the community. Here again, of course, as in other aspects of the profession of the arts, the very recent period has begun to see a breakdown in traditional values and relationships.

Multiple creators. Related to the question of the artistic environment is that of group creativity. A collective approach has proved far less viable in the arts than in such fields as scientific research. In the performing arts, film, and architecture, however, cooperative activity has been not only possible but often necessary, although usually there is one guiding vision—that of the director or the chief architect, for example. Many great buildings, such as St. Peter's Basilica in Rome, represent the effort of a number of different architects. Almost always, however, these architects have been in charge successively rather than at the same time.

Collaboration

More successful in most arts has been the collaboration of two individuals. The Parthenon was the product of the architects Ictinus and Callicrates. Collaboration was a common procedure among Elizabethan dramatists, a most notable example being the works of Francis Beaumont and John Fletcher. A collaboration between composer and librettist, such as that between Mozart and Lorenzo da Ponte, created many great operas.

Art collectives have been organized, with varying degrees of success, in many of the Socialist or Communist states, particularly in the immediate post-Revolutionary periods. In such countries as China, North Vietnam, and Cuba, deliberate emphasis has been placed on "the democratization of art," an attack on the notion of art as the province of the individual genius, and an attempt to create a collective and anonymous art. Numerous political events, such as the 1968 student strike in France, stimulated collective activity in the production of propaganda posters and the organization of guerrilla-theatre companies that gave informal but impassioned performances usually on social or political themes.

Guilds and unions. Artists have also banded together for very practical purposes. During the later Middle Ages and the Renaissance, European artists, like all other craftsmen, were organized into guilds that looked after their economic interests and regulated trade procedures. The bronze workers of the great African kingdom of Benin, which flourished in the 16th century, also had their guild.

Attempts to organize creative artists into modern trade unions generally have failed. During the depression in the United States, artists' and writers' unions enjoyed a brief period of growth, and during the 1960s black artists and women artists formed their own groups. Performing artists, in contrast to creative artists, have formed strong unions that have been able to exert considerable pressure to better their economic situation. American Actors' Equity Association and British Actors' Equity Association are probably the best known of these unions, and there are similar organizations in radio and television and in the film industry. On an international scale, there have been various attempts to bring together artists for political or economic activity. International PEN (*P*oets and playwrights, *E*ssayists and editors, and *N*ovelists) is an organization of writers that has taken vigorous public positions on matters of concern to professional men and women of letters. Founded in 1921 and actively supported in its early days by such prominent figures as H.G. Wells, Bernard Shaw, Anatole France, and Thomas Mann, it includes today more than 8,000 writers from 58 countries.

Impacts of criticism and appreciation. Among the necessary conditions of work for most artists are public criticism and appreciation. Although artists often have pretended to be scornful of critics, generally they have flourished best in an atmosphere in which their work was understood and encouraged. Almost every important artistic movement of modern times has had its critical spokesman and defender. Conspicuous among such champions have been the Frenchmen Zola, for the Impressionists, and Guillaume Apollinaire, for the Cubists, as well as the American critic John Martin, for the modern dance movement.

Many creative artists have been discouraged, however, by lack of appreciation of their work. The great Baroque architect Francesco Borromini committed suicide at least partly because of critical neglect and attack. A legend that the English poet John Keats died because of savage criticism of *Endymion* is false, but Keats was affected seriously by the attacks. Cézanne, in his later years, was deeply hurt by what he thought was complete public disregard of his achievement.

National and international honours

Like individuals of distinction in other fields, artists have been singled out for awards of various sorts. The most prestigious of these honours is the Nobel Prize for Literature, which has been awarded annually since 1901. The prize has sometimes been refused, notably because of political pressure, but the writers chosen usually have regarded it as the climax of their careers. There is no comparable award in the other arts.

In the United States, the Pulitzer Prizes annually honour outstanding work in drama, fiction, poetry, and musical composition, as well as in scholarly and journalistic writings. The National Book Awards also honour literary work in the different genres.

In other countries, artists are given prizes or other marks of merit for distinguished achievement. The Prix Goncourt is the best known of French literary awards. Many creative and performing artists appear each year on the honours list in Great Britain, as recipients of knighthoods or other distinctions. In the Soviet Union, the title of Honoured Artist is conferred as a badge of accomplishment, and in Japan, actors are often honoured with such titles as National Living Treasure, indicating the prestige they have acquired.

Artists are also eligible for election to honorary societies, some of which are limited to the arts. The greatest tribute that can be paid to an artist or intellectual in France is elevation to membership in the Académie Française, the famous company of "immortals." In the United States, the National Institute of Arts and Letters constitutes the chief honorary society of the arts.

THE ROLES OF THE AMATEUR

Amateurism has always been an important factor in the development of the arts. In the oldest sense of the term, the "amateur of art" is simply the lover of art. He need not necessarily be a practitioner of any of the arts himself, functioning instead to encourage and support the arts in every way possible. What distinguishes this kind of amateurism from passive art appreciation is its active commitment. From its ranks come the students, the connoisseurs, and the patrons of art.

There is also a more common sense in which the term amateurism applies to the arts. There are vast numbers of people who, without special talent or extensive training, write, paint, or play musical instruments primarily for their own pleasure or as a leisure occupation. Often such amateurs band together in musical groups or theatrical companies that perform for themselves and their friends. The line of demarcation between amateurs of this kind and professionals is usually clear, although their economic contributions in the form of royalties are often important for playwrights. Few Sunday painters, unlike Gauguin, ever abandon their businesses and families to risk everything on their talents.

The idea of the gentleman artist

Another kind of amateurism, rare today, though historically it has been of great significance, goes back to an idea that appeared first in antiquity and acquired force during the Renaissance, namely that proficiency in an art, particularly music or poetry, is an attribute of the gentleman. Art is valued as an accomplishment of the educated man, but not as a profession.

Unlike the amateur who practices an art simply for his own enjoyment and basically is not concerned with how well or how badly he does it, the gentleman amateur aims at excellence. His ideal is the quality of *sprezzatura*, or effortless grace, described by Baldassare Castiglione in his *Courtier* (1528) as one of the chief characteristics of the Renaissance courtier.

Chinese culture always has been unique in considering painting as the special avocation of the noble amateur. The man of letters, the statesman, and the upper class gentleman have traditionally been expected to be proficient in painting, and especially in calligraphy. In India, too, training in the arts has been considered a necessary part of the education of members of the highest caste.

The amateur in all of these senses has made invaluable contributions to the preservation and dissemination of art. The devotee of art has encouraged and supported artists, has collected and handed on works of art, and has founded museums, libraries, and schools for the arts. Above all, he has set a standard of taste in every generation, sometimes a false or artificial one but one that often has raised the level of artistic performance. If the skilled amateur at times has introduced a measure of snobbism into the appreciation of the arts, he has compensated for this by his defense of art against those who have attacked it as immoral, dangerous, or frivolous. Most of all, however, artists are indebted to the millions of amateur practitioners of art who, having experienced its value for themselves, can respond to it as practiced on the highest professional level.

BIBLIOGRAPHY. There is no one book that satisfactorily covers all of the issues discussed in this article. There are, however, a number of excellent works that deal in detail with one or another phase of the subject. CARL ROEBUCK (ed.), *The Muses at Work: Arts, Crafts, and Professions in Ancient Greece and Rome* (1969), contains a mass of fascinating information. RUDOLF and MARGOT WITTKOWER, *Born Under Saturn: The Character and Conduct of Artists: A Documented History from Antiquity to the French Revolution* (1963), is an invaluable work. NIKOLAUS PEVSNER, *Academies of Art: Past and Present* (1940), is not only the standard book on its subject but also contains many penetrating observations on the profession of the arts generally. QUENTIN BELL, *The Schools of Design* (1963), adds much interesting and useful detail to Pevsner's book and explores some new ground. CESAR GRANA, *Modernity and its Discontents: French Society and the French Man of Letters in the Nineteenth Century* (1967), is a brilliant study that was originally published in 1964 as *Bohemian Versus Bourgeois*. Much information about the profession of the arts may also be found in books on the history of the various arts, such as the volumes in the "Pelican History of Art" series; or JOHN REWALD'S magnificent two books on *The History of Impressionism*, rev. ed. (1961), and *Post-Impressionism* (1962). DONALD DREW EGBERT, *Social Radicalism and the Arts: Western Europe* (1970), provides a very full treatment of the effect of radical thought on the arts from the French Revolution to the present.

(Si.T.)

Arts, Social and Economic Aspects of the

It is necessary to begin a sociological analysis of the arts by identifying the various social frameworks within which artistic activities have been conducted and the influences that these frameworks have had on the style and content of the arts, the levels of creative attainment, the mode of living of the artists, and the uses to which their art has been put by society.

This mode of analysis is not concerned, as the histories of the various arts are, with describing how the particular arts have historically evolved and what they have meant to their users. Rather, it is aimed at discerning the basic alternative patterns of organizing artistic activities and the consequences, for society and for the arts, of adopting one or another of them.

Most of the necessary knowledge for recognizing these patterns is still lacking or is ambiguous in its implications. Indeed, there is no generally accepted theoretical basis for encompassing all the arts in relation to all sociological variables in all types of societies, from the simplest to the most complex. There is, furthermore, hardly any other field in the whole area between the humanities and the social sciences as inviting to partisan sensibilities as the relationship between art and society. Any general statements about relationships between art and society must therefore be treated cautiously, not as established knowledge but as tentative hypotheses.

This article is divided into the following sections:

I. General considerations

THE FIELD OF ART

There are two possible ways to conceive of art sociologically. In the nonhistorical view, art must be conceived as that which is defined by a society, or an artistically relevant part thereof, as art. This could be called the "labelling" view. The work itself may or may not claim to be art; it is recognized as such by those with an authority to do so (in modern societies, by artists and art critics) or by anyone interested. This definition implies that art did not exist in preliterate societies until it was recognized by the moderns, since what now appears to be art has been treated mostly as religious or utilitarian artifacts in such societies. In the absence of the label art, imposed by later cultures, these objects are indeed only utilitarian or religious artifacts. Art arises merely in our perception of them, but does not exist in the intrinsic qualities of the objects themselves.

Historical conception of art

The second, historical view of art is based on the assumption that art is what survives a series of "tests" given to objects that function as art. When such an object is initially presented to the view of people other than its creator, it could be viewed as representing a "claim to art." When it is accepted by large numbers of people in a society or by its established elites or by other artists and art critics, it could be said to have become a popularly, or authoritatively, or professionally validated work of art. But the ultimate test of its artistic quality is whether it can transcend the boundaries of time and space and be accepted by other peoples in other areas.

The historical conception of art implies that art represents a universe with *some* shared characteristics that are everywhere recognizable as artistic (whether or not the concept of "art" is consciously acknowledged). Experimental psychological studies provide some support for this view. It has been found, for example, that traditional Japanese potters agree to a high degree with U.S. art students on the relative merits of a series of works of art shown to them. The agreement is closer than that between American art and nonart students. Thus, practitioners of art appear to agree across cultural boundaries on the quality of artistic attainments.

The agreement on what constitutes a work of art has the following characteristics:

1. It is partial. Each society and period has its own particular standards, as well as generally accepted criteria, by which it judges works of art. The patrons and publics of art (and even art critics) probably insist on these special standards to a greater extent than do the artists themselves. Hence, local criteria should have greater weight in judging works of art when the artistic enterprise is dominated by nonartists. This is one reason for the great fluctuations over time in the economic evaluations of particular works of art, for persons who are not artists usually determine these judgments.

2. The artistic consensus is hierarchical. When artists are left alone, they can, in the long run, roughly agree on the ranking of individual works of art. This happens even in quite egalitarian societies, such as the Australian Aborigines, where most men participate in artistic activities but differences in the quality of achievements and in individual capacities are recognized. The notion of a hierarchy of artistic qualities is therefore not a superimposition of a social hierarchy on artistic experiences.

3. The consensus on art has expandable boundaries. The artists of a society can incorporate works they have been unfamiliar with into their notion of the "field" of art, with a discriminating sensitivity as to their merits. The entrance of new claims to art generates efforts at evaluation, clashes of particularistic values, and the rise of artistic schools and movements. Such claims are ultimately tested in terms of what is considered to be the total structure of the field of art. In turn this structure evolves, by a process of self-testing, through the evaluations it gives to works claiming the right to enter it.

THE AESTHETIC FUNCTION

The nature of the system of art seems to derive from sustained experience with the practical problems of making objects or acts that perform the functions of art and from a sense, which craftsmanship seems to generate, for what transcends mere craftsmanship. A mid-20th-century survey in the United States has shown that craftsmanship by itself is more highly regarded, in judging works of art, by nonexperts than by artists and art scholars.

Art and craftsmanship

Since craftsmanship is a purposeful activity, it appears that the art public is more apt to judge art by some presumed purpose, while artists judge it in terms of what transcends any presumed purpose. If it is ultimately the consensus of artists that determines what is included in the field of art, artistic value must lie in something that is not recognized, even by the artists themselves, as "the purpose" of art.

It follows that works of art cannot be understood by the manifest functions they have been specifically intended to perform. Where they function most purely as works of art, they perform latent functions—unintended and unrecognized. If this observation is valid, art could be regarded as the generalized system of the society for the performance of unintended and unrecognized (but nevertheless needed) psychological and cultural functions. If these functions are effectively performed by other systems of the society, art can remain implicit in them. To the extent that other systems become explicit about the functions they perform and rationalize them to exclude everything that does not clearly contribute to their purpose, art has to emerge as an autonomous system.

The autonomy of art from the social forces that would control it derives, as an immediate consequence, from the structural requirements of good design peculiar only to art; and, ultimately, from the origin of the aesthetic function in the intuitive organization of unintended and unrecognized functions of an interrelated psychological and cultural nature. To the extent that art performs an aesthetic function, it is not subject to intentional social control. A variety of consequences follow from this conception of the aesthetic function:

1. If its very essence arises from performing unrecognized functions, art must be a less self-conscious, a less "rationalized," and indeed a less professionalized activity than any other in the cultural sphere.

2. Since it must be ready to perform unrecognized functions as they unpredictably arise, the system of the arts cannot be a specialized one, adapted to a particular set of circumstances. It must remain generalized, to some extent maladapted to the existing state of society, and able to function in a wide range of areas of ambiguity.

3. The survival over time, and perhaps the aesthetic quality, of works of art depends on how wide a range of unintended and unrecognized functions they can effectively perform. It is because they have a wide aesthet-

ic range, in this sense, that great works of art function for us even when it is not known exactly what they have meant for their producers, as is the case with prehistoric art. The latent functioning of a work of art is not dependent on the grasp of its intended meanings.

4. It could be argued that an effective organization of any unrecognized function constitutes the aesthetic aspect of the social or psychological system in which it is embedded. Thus, scholars could analyze successful works of art as diagrams of effectively constructed but hidden psychological processes occurring in personalities individually or collectively, and could discern how these diagrams are used, by artists and art consumers, to deal with otherwise raw and chaotic psychological processes. The diagrams may be seen as providing rehearsals for effective organization of these psychological processes or as suggesting alternative models for them or as providing focal points around which they can crystallize.

If aesthetic value depends on consciously unrecognized functions, does an explication of these functions erase the aesthetic experience (or prevent it from arising for those who will, in the future, be conscious of the functions the work of art presumably performs)? Not necessarily—if the work of art, after one of its functions has been explicated, can still function effectively in other unrecognized and unintended ways. The interpretation of art could be viewed as a struggle against its inexhaustibility, but the functions that have been fully explicated would seem to become more cognitive than aesthetic.

SOCIAL USES OF ART

Relation of art to other disciplines

While, to be artistically effective, art must function as art—fulfilling a great variety of unrecognized and unintended functions—it does not generally operate as "pure" art. First, it may overlap with other cultural systems—religion, philosophy, science, a secular ideology—and perform, in part, the more clearly identifiable functions of these systems. It is then shaped, to some degree, by the superimposed functions it performs as a part of those systems.

In general, art tends to become increasingly differentiated from other cultural systems in the course of social evolution. Yet in some periods a closer integration of art and some other cultural system may be sought. Thus, the system of science has, in most cases indirectly, affected much of modern visual art. It cannot be taken for granted that the most complete differentiation of art from other cultural systems is most conducive to its authenticity. Nor does a self-conscious "integration" of art with another cultural system enhance art, as is shown by the failure of Socialist Realism, tightly bound to Communist ideology. It could be inferred from the notion of the aesthetic function that an indirect, unintended mutual interaction between art and some other cultural system would be most stimulating to the arts.

Second, art may be used by various social agencies or groups to perform functions these agencies are interested in. Such use of art by social agencies structures the content and style of art and influences its level of creative attainment and its total repertoire of functions. Again, it is not to be taken for granted that it is necessarily disastrous for art to be used for extra-artistic purposes. On the one hand, by using art to fulfill their purposes, social agencies may restrict art's capacity to function as art. This seems likely to happen to the extent to which social agencies successfully limit art to performing any set of consciously recognized and intended purposes.

On the other hand, by using art for their own purposes, social agencies may also stretch art's limits in directions that artists might not otherwise have been inclined to explore, enhance certain of its expressive potentialities at the cost of others, and increase its capacity to communicate with contemporaries while perhaps reducing its ability to communicate transhistorically and cross-culturally. By being forced to struggle against purposes imposed from the outside, artists may become more aware of what is both peculiar and essential to art.

Like other symbolic systems, art can function as a means of attaining the purposes of any system of society. Thus in the economy, art can be used as a means for attaining or symbolizing the possession of wealth; but also as a critique of particular ways of using it. In the political system, it can encourage or condemn a particular distribution or use of power; and, in the community, as a means of reinforcing or protesting against the existing order of sensibilities, expectations, social rankings, and social distances. In an ideological system, it can operate to strengthen the hold of established values by filling the imagination with forms or content suggestive of these values—or to question them by presenting forms and content that are irreconcilable with existing values. But even if art "objectively" functions to promote particular social ends, it is not necessarily consciously employed to promote these ends.

Extra-artistic functions

None of these extra-artistic uses of art seems by necessity aesthetically superior to any other. What seems important is whether artists accept the legitimacy of the extra-artistic expectations directed to their work and incorporate them, unselfconsciously, into their own notion of the artistic task. If they do so, they should be able to produce good art regardless of the type of extra-artistic expectations imposed on it.

The critical question, nevertheless, in evaluating the aesthetic quality of works of art is whether they can resist or transcend the social uses to which they have been put by their makers and whether they retain their own character and transmit their own message even when manipulated to serve the purposes of their sponsors. An art that has not been subjected to manipulation during its making could well be deprived of a powerful stimulus for acquiring a "resistable" character, an artistic toughness that ensures its aesthetic survival.

THE COGNITIVE CHARACTER OF ART

To what extent do the particular social uses of art shape its content and style? To what extent do content and style, therefore, correctly reflect or distort the "objective" realities of the society in which they have been produced? Does use of art by a social agency or group necessarily imply a distortion, in its interests, of the reality that art may be presumed to reflect? Or can some groups (as, in the Marxist views, the "progressive" ones, which identify themselves with the direction of history) use art in their own interests without thereby forcing it to distort reality?

The most general response to these queries is probably that art reflects either subjective affirmations or subjective denials, symbolic invalidations, of the existing reality. It can therefore be read only as a record of the history of subjective attitudes toward objectively existing reality. The ways in which art has been used can be assumed to influence the subjective responses it will express. The subjective responses that exist in the environment in which art is produced but that are not "useful" to the groups or individuals that provide resources for art creation, or for the artists themselves, are less likely to be reflected in art. Yet, insofar as art necessarily performs unintended and unrecognized functions as well, it may reflect even the subjective responses that it is not useful to anyone involved in the artistic process to reflect. These responses may contradict the conscious intentions of the artist. Art is never an objective record, and it is never fully controlled by those who use it—or it ceases to be art.

Inherent subjectivity of art

The most significant art may well express both the most striking characteristics of objective social reality and the sense of what is most missed in it—reflections of reality as well as utopian denials of it. The significance of such art may arise from its discovery of ways to articulate these mutually contradictory subjective responses to social reality, without suppressing one in favour of the other. Cognitive distortions in art arise not from an introduction of subjective attitudes but from a denial of the ineradicable contradiction between existing "objective" realities and their possible "subjective" negations. Art distorts the totality of human experience, in any social setting, when it is biassed in favour of either "objective" recording or "subjective" expression.

Art reflects, or compensates for the deficiencies of, ob-

jective reality not only in its content but also in style. Even completely nonrepresentational arts therefore have a cognitive character, and subjective orientations to social reality can be inferred from them.

Easily swayed modes of art

Some arts lend themselves more easily to deliberate manipulation in the interest of consciously distorting the ways in which they reflect reality—whether in style or in content. Fiction, the theatre, painting, and sculpture are more vulnerable to such manipulation than music or lyrical poetry. Representational styles lend themselves more easily to manipulation than highly symbolic or completely nonrepresentational ones. Indeed, one reason for moving toward the latter styles, in modern societies, is the desire of artists to escape manipulation. The mass arts are particularly susceptible to imposed distortions. It is deliberate manipulation, rather than merely the use of art by social agencies and groups, that would appear to give rise to distortions in the way works of art reflect reality in its interrelated social and emotional aspects.

SOCIAL DYNAMICS OF ARTISTIC CREATIVITY

If art performs unintended and unrecognized functions, the creation of artistic values should be affected by the degree to which art is needed, in particular social settings or by particular individuals, to perform these functions. That is, for artistic creativity to become possible, there must be many psychic needs that are neither met by existing social arrangements nor can be consciously identified and purposefully dealt with by means of social policy.

Conditions favourable to artistic creativity arise when rapid changes in either the organization of society or in the emotions of its members produce a sharply sensed disjunction between personal emotion and objective social structure. But while the need for art increases during such periods, the possibility of creating it also depends on the availability of resources for creating art. The supply of such resources tends to be diminished in the phase of most intense action of periods of radical change. This phase occurs during rapid economic accumulation, technological transformation, the high points of religious (or secular ideological) reformations, and struggles for imperial consolidation, national liberation, or change of political system. Artistic creativity is enhanced when an increased social need for art coincides with an ample supply of resources for artistic production—thus before and after, but not during, the most intense phase of any cycle of technological, political, ideological, or communal change in the society. Activistic social movements are unlikely to be artistically creative, but they increase the need for art—after they have succeeded or failed to transform society.

Creativity and social resources

Conscious social policy can affect artistic creativity by supplying, or failing to supply, social resources for artistic production commensurate with the existing social need for art. Not all such resources, however, can be controlled at will—the supply of cultural symbolism, for example, depends on its existence in any social system in a form appealing to the imagination of artists. It does not depend on the immediate policies of governments, churches, or parties, although these institutions can, to a high degree, determine the allocation of economic resources to artistic activities. But while a deficiency of such resources may prevent the creation of works of art for which the potential exists in a society, economic resources cannot generate artistic values if the social need for art is not sufficiently intense, as during periods of general cultural quiescence and social complacency, when existing conditions are taken for granted by most members of a society (as in 18th-century Italy); if the creative people are too widely scattered in a large population or too isolated from each other by ethnic, ideological, class, or disciplinary barriers to attain a necessary density of interaction; if an appropriate social organization for producing art, particularly important for the large-scale arts and the film, is not established; or if the general symbolic design of a civilization is not sufficiently developed or is already too "completed" to sustain efforts at producing great artistic designs.

In modern societies, perhaps especially in the large nations, two threats to artistic creativity have emerged in the possible bureaucratic overorganization of the artistic enterprise, leaving too little space for the unintended and unrecognized in art, and the early popularization by the mass media of new artistic movements before they have had time to mature their contributions. Once artistic movements become widely popular, they tend to drop what they have been doing, since the modern cult of originality discourages a continued exploration of what others have become familiar with. Hence, what a style is potentially capable of may never be developed.

II. Artists and artistic cultures

SOCIAL ROLE OF THE ARTIST

The two main variables in defining the social role of the artist are that role's degree of specialization and the extent to which it is conceived as involving manual labour or some sort of "spiritual expression."

Variables in defining the artist's role

By their nature, all the literary arts involve less visible manual labour than the traditional visual arts, and the sculptor or painter has been generally more easily and closely assimilated to the traditions of skilled manual craftsmanship. The poet has tended to be associated with the realm of religious ceremony and, later on, with record keeping within or outside of the various church organizations. Thus, some of the prestige of literacy in traditional civilizations has attached to the poet's role. Yet it was originally literacy in the service of a god as well as an illiterate aristocracy, and there is still some tendency to expect writers, more than other artists, both to entertain the classes that have become their sponsors in place of the aristocracy and to serve a moral purpose. It is they, of all the artists, who are expected to be "the moral conscience" of society. But besides this clerical tradition, there is also the more anarchic one of vagabond poets, who live "beyond good and evil."

In music, he who composes a work is frequently—at least since the German composer Beethoven—perceived as partaking of a more "spiritual" role, and he who performs it, particularly in groups of performers, has been frequently seen as more of a "craftsman." In the theatre, the actor is a physical labourer insofar as he uses his own body, but, in performing his role, his body assumes and acts out "spiritual substances" originally alien, and possibly greatly superior, to it. This is one reason for the ambiguities in the social treatment of the actor, who, like the singer and the dancer, has been the most exalted and the most despised of artists.

Within the limits shaped by the nature of the particular artistic medium, the social role of artists has been affected by developments in the organization of society and its value system. The main evolutionary trend has been toward increasing professionalization of artistic roles. In the preliterate societies of a more egalitarian character, all adult members of a society (or all members of one sex, and a few of the other) may be engaged in activities of producing objects or performances that, in addition to their consciously intended functions, have some kind of aesthetic aspect (superfluous from a purely utilitarian point of view). But some individuals are recognized by their peers as more competent carvers, potters, or dancers, and their products or performances, though not superior in a utilitarian way, are more highly esteemed; their authors receive a superior compensation in prestige and, less frequently, in material valuables. Yet even the best of tribal artists are spare-time specialists who devote most of their time to meeting obligations incumbent on all members of their society of their own sex and age.

Full-time specialization

It is only with the development of a hierarchic type of social organization that, for male artists, full-time specialization becomes possible, if their society is both interested in art and sufficiently prosperous to sustain a demand for full-time specialists. Women tend to remain semispecialists or "folk" artists, and, the more professionalized the artistic enterprise, the lesser their part in it. In the primitive states or hierarchically organized chiefdoms is formed the main pattern that has governed artistic enterprise in classical civilizations: the division

between "high" and "low" art, the specialization of male artists, formalization of their training, patronage by clients, and general subordination of art to the politically ruling class and the religious establishments.

This pattern has occasionally been modified in mature preindustrial civilizations. The basic hierarchic pattern, however, has been radically challenged only in consequence of the Industrial Revolution and the rise of a civilization associated with it, in which aspirations to universal participation appear. This transition is still going on. But "high" art has already become detached from its almost exclusive dependence on the ruling elite. It is now visible, through the mass media, to almost everyone and is intensely experienced by a recently developed loose coalition of artists and intellectuals. This coalition is the primary audience, even for art that has been explicitly produced for other social classes. An example is the Mexican murals of the 1920s that were intended to revolutionize the proletariat but are appreciated mainly by a bourgeoisified intelligentsia. With respect to art, the socially dominant class tends to lose confidence in its own taste and to become "culturally" subordinate to this coalition. From a symbol of privilege, art changes into a symbol of emotional aliveness; hence, the boundary between "high" and "low" art becomes blurred. But the artistic enterprise itself remains highly stratified in accordance with the prestige granted the type of activity the artist engages in and his personal achievement in it. Women once again return to greater participation in the fully specialized production of the "creative" arts. As for the performing arts, women have either always possessed or regained at an earlier time fully specialized roles in them. This is especially true of the dance, except in those cases where religious asceticism or some comparable influence has eliminated them from the performing arts as well.

"Cult of the genius"

Historically, the most significant single illustration of the ways in which the value system of a society affects artistic roles is the Western "cult of the genius." It developed under the influence of the great achievements and the striking personalities of artists like Michelangelo and Leonardo da Vinci in the Renaissance—a civilization that generally placed a very high value on achievement and expression of individual personality. Comparably great achievements in less "individualistic" cultures have not produced any similarly powerful notions of genius. The cult of the genius had the long-term effects of assimilating all the creative, and at a later date even the performing, arts to the "spiritual expression" of poetry; legitimating the demand for creative autonomy on the part of the men whose genius has been perceived as transcending the dimensions of established custom; and, on the basis of the above two changes, transforming those arts previously treated as crafts (and organized in guilds, etc.) into a peculiar kind of free profession.

All professions are corporate bodies of practitioners in a skilled activity who are devoted to an ethical purpose superior to the mere pursuit of wealth, power, or pleasure for themselves. The professions set their own standards, determine admissions to them, and judge their own members accused of transgressions against the profession's ethical code. Modern artists constitute a peculiar profession in that they do all this without necessarily being organized into an association that encompasses all of its members (as the medieval guilds did) and without necessarily being held accountable to public authorities for its activities. The ethos of the artistic profession, as it has emerged in the West since the Renaissance, is opposed to both general organization and any kind of public accountability of artists. Even with the evaporation of the cult of genius, in the 20th century, the conception of the artist's role as that of a free professional has remained as the ideal expectation. There are evident tendencies, from the latter part of the 19th century on, toward a partial collectivization of the role of the professional artist—whether in artistic movements in which several artists interact in producing individual innovations that have something in common (as did the French Impressionist painters of the 1870s) or in artistic workshops in which several artists cooperate in producing the same, or the same type of, works of art (as in the Bauhaus school of design in Germany, 1919–33). Yet it is a collectivization of a free profession, not a return to the guild structures, that *some* artists of industrial societies are willing voluntarily to accept.

Even as a liberal profession, the artistic enterprise remains professionalized to a lesser extent than other recognized professions. The artists are *morally* a profession, but the degree to which they *economically* depend on it as their main source of income varies tremendously. Most professional artists, in modern societies, do not derive the bulk of their income from the direct exercise of their profession, particularly where they have to sell their products under conditions of a free market.

Professional incomes

Estimates made at the beginning of the 1970s suggest that no more than one-half of 1 percent of the professional painters and sculptors in Paris and in West Germany receive a regular and sufficient income from the sale of their works. Some arts have retained, even in the self-perceptions of the artists, the character of vocations rather than professions: it is still awkward to describe someone as a professional poet.

It is conceivable that, in the more affluent and leisurely societies predicted for the future on the basis of technological progress, well-trained amateurs might again, as in the past in China, begin producing art of respectable quality. The nature of the aesthetic function sets limits on the extent to which a professionalization of the artistic enterprise can be sustained without aesthetic loss.

ARTISTIC CULTURES

Artistic cultures are the various basic situations in which art is produced. Each such culture involves a distinct type of social organization of artistic activities that is associated with a distinguishable attitude of artists toward their work. Artistic cultures arise from artists' relationships with other artists, their publics, their means of earning a living, and agencies affecting artistic activity; from their involvements with cultural systems not specifically artistic; and from artists' technologies, shared emotions, and ideologies. Changes in any of these variables modify artistic cultures and give rise to new variants of them.

Once the artistically undifferentiated unity of the tribal society has come to an end, several variants of "traditional" and "modern" types of artistic cultures can be distinguished.

Traditional artistic cultures. At least seven highly distinct types of artistic cultures can be identified in traditional (preindustrial) societies.

The folk culture. Artists are nonspecialized members of their community of residence and closely involved with all of its activities. Their art deals with typical experiences, concerns, or needs of ordinary members of that community. The real-life references are, however, linked with elements of highly utopian imagination (folktales, in which an attitude critical of the existing reality is frequently expressed), abstract stylization (geometric ornamentation of utensils), or symbolizing lyricism (folk songs). The artist is one of the people, but living more powerfully in the imagination than the others. Artists create by following or elaborating on traditional patterns. Much art is produced spontaneously for oneself or in friendship or for communal enjoyment, rather than for pay.

The artisan culture. The artist is a specialist—possibly a member of a specialized collectivity such as a guild or a workshop set up by a state or a church—who works on order and for pay (or on command) only. He develops the pride of good craftsmanship and habits of regularity and reliability in his work. He does whatever style or content is required by his client without asking about his intentions. Whatever individual needs he expresses in his work, his conscious ideology is that he is a skilled worker who respects high standards of craftsmanship and produces to earn a living. He belongs, not permanently to his community, but temporarily to his client, wherever the latter may be located, and perhaps to his clan or guild of fellow artisans who share his craft ethic. To the extent

Specialized craftsmen

that his client is his local community, however, he becomes a "civic" artist, whose highest purpose is, on command, to celebrate his community, as in the cities of the Mediterranean civilizations. (In modern society, this culture survives most nearly, perhaps, among orchestral musicians.)

The clerical culture. The artist is very much a craftsman, but his craftsmanship is subordinated to a highly valued tradition of a literate civilization, which he is committed to serve and to defend by his work. By his association with this tradition, he gains in prestige, but he also acquires a moral responsibility which the pure craftsman is not bound by. He belongs to a moral community, not necessarily localized, that provides him with criteria for judging which works of art are worth making. In this can be discerned the potential beginnings of an artistic consciousness and of a critical attitude of the artist toward society and its artistic ideologies. Most of the time, the clerical artist (for example, the medieval manuscript illuminator) is submissive to the discipline of the moral community of which he is a part, but, in the conception of the artist as a civilized servant of a higher moral purpose, there is, at least, a potentiality of criticism of the organization to which he belongs.

The ecstatic culture. This is a general term suggested for situations in which some type of artistic creation—though it is usually more than merely artistic—occurs in the midst of a mediumistic trance performed for religious or magical purposes, during an orgiastic happening, as a consequence of a mystical experience, or even as an element of prophecy. Art, performing or literary, arises from emotionally intense experiences, "divine madnesses," which are perceived to have high symbolic significance but over which the individual (or, sometimes, the group) that has them imposes no critical controls. Traditions that generate ecstatic art creation, such as the Dionysian ritual (performed by followers of the cult of the god Dionysus) in ancient Greece or the poetry of Hebrew prophecy, usually arise in loosely structured societies (as do the mediumistic priest-doctors known as shamans) or in times of social crisis (as mystics and prophets are likely to do). The shaman tends to be conservative with respect to his society, the mystic apathetic, the prophet radically innovative. Numerically, these types constitute a small part of the artistic cultures of the well-ordered literate civilizations and are least important in the visual arts dependent on organized patronage. But they have been sources of revitalizing impulses for established traditions. In the ecstatic culture, the artist is a nonspecialist who opens up higher, or more truthful, realms of existence and transcends the norms of everyday life. Theories of "artistic inspiration" and of the artist as martyr (or scapegoat) arise from this culture and continue to be generated in it.

Sources of revitalization

The courtly culture. The artist, who may be an aristocratic poet or a craftsman of ordinary social standing, is directly dependent upon a secular royal court or a household of the high nobility (or, by extension, plutocracy). To some extent, he is even socially involved with this household as a vassal, royal favourite, or court artist. He therefore not only produces for but also spiritually identifies with the high aristocracy for which he works, without actually being a member of it. The artist is a man ennobled by his art; his art must therefore be permeated with "noble" attitudes: heroic exaltation, fashionable late-medieval despair, or refined Rococo or Rājput sensuousness. While this art, by glorifying the establishment, reinforces its privileges, it may, at the same time, educate its—and other people's—emotions in novel ways.

The gentlemanly culture. When men of high social standing and independent economic means become active in the production of art, a tradition of gentlemanly art may arise (as is exemplified in much of the calligraphy and landscape painting in historic China). Art tends to be contemplative, subjective, aestheticizing—but not consciously "ennobling," since artists already possess sufficient "nobility" (as courtly artists do not). The artist is a man of independence who observes and contemplates without desire (an attitude that has been influential in modern aesthetic philosophies, frequently produced by such men).

The vagabond culture. All the traditional types of artistic cultures presuppose a firm social location of the artist in relation to a community, except where the artist is a vagabond adventurer who roams the countryside producing or performing works of art—comical tricks, storytelling, lyrical songs (for example, the medieval minstrels or the 15th-century French poet François Villon). In origin, he may be an uprooted folk artist, who belongs only to temporary communities. He is neither an apprentice journeyman nor a gentleman (who may also travel widely) but an impecunious amateur master unconcerned with material gain. (Masterful amateurism in the arts has two sources: the gentleman and the vagabond.) In contrast to the ecstatic artist, the vagabond does not assume that his works possess any higher symbolic significance. They are plays of fancy that amuse the fancier and whoever cares to join him. Individual vagabond artists have probably always existed, but vagabond cultures can arise only in the fringe areas of cities (for example, a transitional zone between industrial and residential quarters) or where nomadic tribes like the gypsies travel over a settled countryside. Travelling theatrical groups exemplify both conditions. Whatever the effect of vagabond artists on society, they, like the ecstatic artists, tend to have a liberating effect on the arts in which they engage.

Modern artistic cultures. Several types of artistic cultures, in some cases anticipated in earlier periods, have come to a full development in industrial societies. Some older types have been transformed, and new ones evolved. In the advanced industrial societies, artistic cultures tend to become fluid—composed of overlapping and fluctuating elements, components of a mixed orientation rather than rigidly separated alternatives. Nevertheless, several types can be distinguished.

Artistic cultures in industrial societies

The genius culture. The product of a conjunction of the artisan, clerical, and courtly cultures, the cult of genius emerged in the early 16th century during the High Renaissance and became more fully developed in the age of Romanticism at the beginning of the 19th century. The artist conceives himself as the "unacknowledged legislator of the world" (in the words of the English poet Percy Bysshe Shelley), an autonomous, godlike creator of new orders of reality obedient only to his perceptions and the categories of his mind. He is superior to the specializations of the sciences and the crafts: he creates the unifying symbols of a developing civilization. He is self-confident, a proclaimer of new values rather than a critic of the established ones. Historically, perhaps the greatest significance of the genius has been in the legitimation he has provided for the developing conception of the professional artist.

The professional culture. The most essential characteristic of the artistic professional is that he himself chooses what to produce or perform. But, unlike the gentleman artist, the professional produces in order to sell. His art is the activity of a specialist competent in the techniques of expressing subjective perceptions. In the visual and the literary arts, the professional usually works in his own studio, at times of his own choice. In the performing arts —which are less "professionalized"—he is dependent on facilities provided for him by entrepreneurs and impresarios. He may have an agent who represents his economic interests in any case. But the essential point, in the artistic profession, is not the ownership of the means of production; it is the artist's sense that he can, and indeed must, depend upon his personal aesthetic sense. This is the predominant image of the writer in modern Western societies.

A sociologically important distinction can be made between private and public professionals. The first have originated in the gentlemanly culture, the second in the salon–coffeehouse–journal circuit of the 18th and 19th centuries, in which the enlightened aristocracy and the increasingly popular press joined forces in supporting a socially critical collectivity of middle class artists, journalists, and hangers-on. In this public culture, it was most important to be up to date and to respond to current is-

sues by one's wit. As this culture began to disintegrate, the distinction between private and public professionals was partly replaced by that between bohemian and radical avant-gardists.

The applied-arts culture. The old artisan tradition has continued in the modern applied arts (for example, industrial design, advertising). The artist is, however, not usually organized in guilds but, rather, is employed in a white-collar type of job by large business firms or governmental organizations, sometimes by "artistic firms," which, in their management, are not very different from other business firms. But while the applied artist is employed as a craftsman, his attitudes have been affected by the culture of professional art. He may therefore be a craftsman with aspirations to professionalism and may tend to perceive himself as failing to realize his artistic aspirations, regardless of financial success and social recognition. Applied artists with the self-conception of professionals provide one of the main supports for movements of radical criticism of contemporary society and culture.

White-collar artists

A development toward the applied arts may be occurring at present in such an established profession as architecture: the increasing costs over which he has little control, the various restraints over his activity (zoning codes, labour union regulations, and the like), and group pressures to which he must respond are tending to transform the architect into a high-level organizational craftsman. As their opportunities for being artistic professionals decline, architects tend to conceive of themselves increasingly in the image of social engineers—a trend noticeable also in the other arts.

The mass-arts culture. The notion of the mass arts implies that the artist communicates with his public through the mediation of some type of mechanical or electronic machinery; that he does not know even the kinds of people of whom his public will eventually consist and may be unfamiliar with the characteristic experiences of most of his actual public. Furthermore, the responses that he will get from his public will probably also be, in most cases, mediated either in a mechanical manner (statistics of sales) or by professional intermediaries (newspaper critics). The film, television, mass-periodical fiction, and recorded music represent the clearest cases of mass art. Insofar as the mass media deal with any art, they tend to assimilate it to a greater or lesser extent to the mass arts. Because of the conditions under which he operates, the mass artist lacks a sense of general standards—other than the purely technical ones of craftsmanship—by which to orient his artistic activity. Nor, since he is dependent on large, impersonal audiences, can he trust his own convictions to guide him. His typical solution is to cultivate an "image" that has proved to be popular with a mass audience and that, once established, is "forced" on him by his public. He becomes a victim of his own image, in the sense that he is trapped within its confines. He is an uncertain specialist in the symbolic manipulation of diffuse audiences.

Cultivation of a popular image

Avant-garde cultures. Another characteristically modern artistic culture is definable by two aspects: a principled sense of alienation from significant aspects of existing reality and a conscious commitment to overcoming the deficiencies of existing reality by artistic means of a completely novel character. One of the distinguishable types of this artistic culture is the bohemian avant-garde, which tends to be alienated from all rational and utilitarian aspects of social organization and cultural tradition and aims to create a new kind of exaggeratedly irrational art and, perhaps even more important, an irrational style of life (typical of this group is the French poet and critic Charles Baudelaire). Its behaviour centres on the ambivalent and the self-consciously paradoxical: a tradition of pursuit of the new, the cultivation of a pleasureless hedonism, the development of systems for the liberation of spontaneity. Another type of this culture is the radical (politically committed) avant-garde, which regards itself as alienated from "oppressive" and "exploitative" political and economic institutions and tries to create a new kind of art intended to undermine faith in these institutions and to provide a basis for their abolition or reconstruction (an example is the German poet and playwright Bertolt Brecht). These two avant-garde cultures overlap, and, over time, one may change into the other. The alienated type is more influential among artists when faith in ideological utopias declines generally in their society. Perhaps because of its tendency to limit itself to consciously recognized and intended purposes, the aesthetic achievements of the radical avant-garde (the "prophets") have been less significant, so far, than those of the alienated avant-garde (the "mystics").

More recently, a third type has emerged: the anti-artistic avant-garde, which is alienated from the very notion of art and its practice as heretofore conceived, even (or perhaps especially) in the other versions of the avant-garde culture. Art itself is perceived as "oppressive" and "exploitative," and the obligation of the artist (and of the art critic) is seen as the promotion of the "end of art"—its diffusion into a "life" of childlike impulsivity. The very coherence of art is felt to be an imposition of an arbitrary system on the immediacy of "aesthetic experiences," which are to be pursued with a self-conscious repudiation of any deliberate control.

All the avant-garde cultures can be seen as diverse outgrowths of the culture of genius, with which the peculiarly modern developments in the arts began. But the bohemian and radical version of the avant-garde culture are also reactions, by artists and aesthetically sensitized intellectuals, to the development of the modern industrial society—a society highly rationalized and, in spite of its ideology celebrating the "common people," continuingly stratified. The anti-artistic avant-garde appears to be a "shamanistic" reaction against the professionalization of art, and, like the mediumistic trances of traditional cultures, its efforts may prove to be a socially innocuous (or conserving) ritual that is perhaps psychologically refreshing.

Total-command cultures. Hitler's Germany and Stalin's Soviet Union still provide the best examples of what happens when a modern artistic enterprise is subordinated to a political ideology that has the monopoly of organized power in a society. Artists are forced back into clerical roles—with the difference that the moral responsibility for upholding an ideology is imposed on them, without its necessarily corresponding with their own convictions; and, even when it does correspond with their ideological views, it conflicts with the conception of the professional role that they, as modern artists, regard as their primary orientation within the sphere of art. An artistic enterprise can be effectively politicized, without losing most of its aesthetic qualities, only if artists are content with assuming the role of "clerics" illustrating, with appropriate technical means, the manuscripts of a political ideology, yet do so without limiting their imagination to service in its mission.

Politicalization of art

The scientific–technological culture. Partly under the influence of imaginative developments in science and technology and partly out of disillusionment with the avant-garde cultures of art, an artistic culture in which the artist is assimilated to the role of a scientific researcher has arisen. The artist is a strategist of concepts, a deviser of technical systems for others to build, and a manager who invents ways for workers to relate technological or natural processes to each other. His difference from the scientist is that he seeks not new understandings but new perceptions; his difference from the technological experimenter is that the systems constructed are expected to have no utility. They are frequently evanescent or self-destructive. This type of artistic culture requires large financial outlays and tends to result mainly in entertaining decorative effects. It is neutral with respect to the particular institutions of a society but tends to glorify the technological and economic achievements that enable it to sustain such works of art. Thus it is the equivalent, in a technological civilization, to the monumental art by which absolute monarchs had been glorified in the agricultural empires, such as ancient Egypt.

Movement cultures. Artistic situations that arise in spontaneous movements of a general cultural, rather than

specifically artistic or primarily political, character (such as youth movements) may generate an immediacy and intimacy of the relationship between producers and consumers of art that is rare anywhere else in modern societies. The effect on the arts is to simplify aesthetic structures and integrate them more closely with the experiences of the many. The arts most frequently involved are poetry, music, and some form of theatre. The movements themselves are not highly productive of enduring artistic achievements. Their main significance is in opening up large audiences to a sensitive responsiveness to art or to particular kinds of art—a sensitivity anesthetized by the mass arts.

Amateur art making. With the increase in leisure time, amateur art making has become increasingly popular in advanced industrial societies, as had amateur musical performances in the European upper and middle classes in the 16th and 17th centuries. This phenomenon contributes to the blurring of the traditional distinctions between producers and consumers of art and to the involvement of larger numbers of people in a more active manner with the artistic enterprise, strengthening the social anchoring of art in the modern society.

III. Economic support of the arts

ECONOMIC EVALUATION OF THE ARTS

Factors in the allocation of wealth to the arts

The economic evaluation of the arts in general is indicated either by the absolute amount of economic resources put into their production, acquisition, distribution, and consumption or by the relative share of the total income of an individual, group, or society that these allocations represent.

While the absolute size of expenditures may be determined more by the level of wealth than by the degree of interest in art, it yet has a significant effect on the artistic enterprise, perhaps especially on art collection and prices of artworks. When the absolute amount of funds available for the arts is very large, it produces the phenomenon of "cultural imperialism": it enables the powerful, whatever the degree of their interest in art or their own creative attainments, to dominate and overwhelm the cultural activities of the financially less well endowed, unless the latter remain isolated or protect themselves by consciously designed cultural policies.

The percentage of the income devoted to art, on the other hand, bears a closer relationship to interest in art, and it could therefore be expected to be more closely associated with the level of artistic creativity—which does not necessarily require large economic resources to sustain it. Some of the finest works of primitive art, for example, have been produced in places where life is economically precarious, such as the swampy areas of New Guinea. The percentage of wealth devoted to the arts tends to be greatest in economically comfortable societies that have passed their peak of economic expansion—Italy after the middle of the 14th century and Spain in the late 16th and 17th centuries, to cite two instances.

The economic valuation of art is also affected by the degree of its association with activities that are regarded as possessing great importance in a particular society. Actual importance of an activity can be measured, in economic terms, by the size of economic allocations for its pursuit. The closer art is integrated with the activities (typically, the economic, political, religious, and military) getting the major share of available funds, the larger tends to be its own share. In the advanced industrial societies, a major financial basis of contemporary arts is their integration with the growing leisure industry (as in the Broadway theatre or the arts in the mass media) and with education (as in the widespread employment of artists in schools and universities). It is partly for this reason that modern states tend to allocate larger sums for the support of the performing than of the object-making arts and for the dissemination than for the production of art objects.

To the extent that art itself is a prestigious activity, individuals, groups, cities, or whole societies may compete for supporting its most important living practitioners or acquiring the most famous works. This motive has probably been present, to some degree, in all elite-oriented societies, but its significance tends to increase in civilizations that have many centres rather than a single "imperial" one—in Renaissance Italy, in Germany before its unification, and in the modern world in general. Competition of would-be patrons for the prestige of living artists increases not only the economic allocations to art but also the freedom of "elite" artists. Modern state support for the performing arts, in particular, rests to a high degree on competition for internationally recognized cultural reputations.

The value of art as an investment of wealth, either for ensuring its preservation or for increasing it, grows in periods of social and political instability and currency fluctuation. Small-scale artworks made either of precious materials or by prestigious old masters become the safest investment in times of trouble. This has been an important motive for the collection of art by the rich in the Renaissance as well as in the 20th century. It is characteristic of this system that a high economic valuation of art does not necessarily correlate with the income received by living artists, since the object of speculative interest is the reputation of a master, who is frequently dead, rather than the aesthetic merits of the work itself. It is a system in which artists, instead of being supported by the rich in the pursuit of aesthetic values, support the rich in their pursuit of further enrichment, since an artist may endure a lifetime of poverty to produce works that then become tokens of steadily increasing worth. As a consequence, the system encourages capital accumulation rather than artistic creativity. It has little effect on the performing arts or literature but is currently a major source of discontent among practitioners of the visual arts.

Relation of achievement to value

Increases in the social status of artists and in the prices their works fetch on the market have, in the past, tended to follow increases in the creative attainments of an artistic tradition. Thus, in England, an increase in artistic creativity in the earlier part of the 18th century (as exemplified by the paintings and engravings of William Hogarth) was not followed by a significant increase in the social and economic status of some artists until the 1780s. During the late 19th century, however, when contemporary English art was admired above that of any other period or society and highly rewarded, it produced only minor achievements. Clearly, economic allocations do not guarantee artistic efflorescences, and inferior art may be ascribed high economic value. Great artistic achievements, nevertheless, appear to increase the economic value of art, though perhaps not immediately. While the economic value of particular objects of art depends in part on their historical significance, uniqueness, and fashion, the economic valuation of art itself is, in the long run, not altogether unrelated to the presence in a society of large numbers of aesthetically meritorious works.

SYSTEMS OF FINANCING ARTISTIC ACTIVITIES

The economic support of artistic activities can be provided by the artist himself, who derives his income from sources other than the rewards he receives for producing art, or it can be furnished by nonartists supplying the economic means for the artist to survive while he is making works of art.

Self-financing of artistic activities has always been, and still is, considerable. The gentlemanly type of artistic culture is wholly supported by artists of independent means. The writing of lyrical poetry has very generally been a leisure-time activity of persons deriving the bulk of their income from other sources. In modern times, self-financing is present when the artist survives from an activity that does not require him to produce works of art, or when his income from producing works of art is significantly lower than what he could earn by being employed in a legitimate alternative occupation accessible to him. The dance is heavily self-financed in the second sense.

Sponsorship of artistic activities may be said to occur when the artist draws upon the economic support of individuals or organizations that do not necessarily expect to get anything for themselves in return for it. They support the artist because they are committed to art for its

own sake or to a particular artist. In this specific sense, artistic activities may be sponsored by government agencies supporting art as a "social service" for the people, by private foundations, by individual sponsors, by relatives who support the artist while he is economically unsuccessful, or by friends and acquaintances whom an artist "sponges on." Sponsorship may thus be, in some cases, unintentional.

Financing outside of the market system

Self-financing and sponsorship are economically "abnormal" systems of financing the production of goods and services that potentially possess an economic value to people other than their producers. These modes of financing are found principally in the "cultural" activities, above all religion and art (but also in "ideological" politics), and they occur because artists are not treated as if they were engaged only in the production of economic values. They produce economic values, but there is also a "religious" aspect in their activity that requires to be supported for its own sake. If the arts were to be supported entirely by a market economy, this aspect might well disappear: art would then become purely a commodity.

The arrangements of economic support that have traditionally carried the main burden of sustaining artistic activities are the three types of normal economic systems into which the arts may be integrated like any other productive activity: the exchange, command, and market economies.

The exchange economy. An artist in the exchange economy produces for a customer familiar to him who, in turn, directly or through a series of similar exchanges, provides him with a desired good or service of equivalent value. The transaction between the producer and consumer is, ideally, a ritualized exchange of gifts, and, in addition to providing the goods that each needs, it reinforces their social relationship. This type of economy prevails in the egalitarian type of preliterate societies and in the folk type of artistic cultures. In more advanced societies, this becomes a minor part of the economic support structure of the arts; it tends to be limited to the private circle of artists and their friends. The economic rewards to artists within this system are small, fairly continuous, and not greatly differentiated in magnitude.

The command economy. The artist in the command economy depends on a consumer—an individual or organization—of superior status who has extracted a great deal of wealth from the producers in the economy and can distribute it, perhaps within the boundaries established by tradition, as he sees fit. This economic system is dominant in a range of societies extending from the Kwakiutl Indians of the northwest coast of North America through the classical absolutist monarchies to modern totalitarian states. Usually, however, it does not completely displace elements of other economic systems. In this system, the artist depends for his support on relatively few patrons, who are far more powerful and socially resourceful than he is. He may be well rewarded by them, but he must produce works that will be regarded as possessing high value—usually both aesthetic and economic —by his patron. He is paid well if he produces economically valuable aesthetic goods and services. (A significant exception to this principle has been built into the situation of women in the performing arts: in male-dominated societies, they tended to be well paid if they performed sexual as well as artistic services.) Before the modern age, all artists who produced expensive works of art were supported by economies of this type. Even today, architecture—to the extent that it is an art—and the large-scale "technological" arts are supported in this manner.

Patron systems

The market economy. In the market economy, many artists compete for the favour of numerous customers not greatly differing in their purchasing power and not personally known to artists. Since artists are not familiar with their customers, their products become either acts of self-expression or of appeal to an image, an abstract stereotype, of the "average customer." In reality, market economies in the arts only approach this condition to varying degrees: some publics are known to their artists, and there are always elements of the command economy limiting the operations of market economies. There are always economic or political elites or powerful business and political organizations, at whose command, to varying degrees, artists must be in order to achieve "success" even in market economies. And in the modern system of art trade, the mass media have assumed the character of a command element in a market system. To be able to compete for numerous potential buyers, artists must first ingratiate themselves into the favour of a relatively few taste makers in positions of power within the system of mass communications. The more centralized this system is, the more of a command character it acquires.

In a pure case of market economy, the artist's freedom is great, but his rewards are highly unpredictable and uneven; his uncertainty and sense of alienation from his public is a natural consequence. In market economies, the arts are particularly dependent on support through the economically "abnormal" systems of self-financing and sponsorship. These systems typically provide the economic basis for radically new departures in the arts in market economies. They also subsidize the established arts when their costs are too high to be supported by the market (symphony orchestras, for example).

Competition for the "best"

When there are several basically independent command economies in adjoining areas, all interested in art, they are likely to compete with each other for possessing the "best" living artists (as well as the works of the most prestigious dead masters). This competition is apt to favour artistic creativity in a way that pure market economies, concerned with the production of the most usable rather than the most perfect, seem to be less capable of. First of all, pure market economies are hard put to concentrate sufficiently large economic resources to finance expensive artistic achievements (except where they can be immediately "consumed" by large numbers of people, such as in film making). Beyond that, the expectation, typical of command economies, that the artist will produce the most perfect object he is capable of producing may actually increase his motivation (and consequently his capacity) for doing so. Market economies do not hold forth any such expectation. No longer economically supported, expectations of the artist's commitment to excellence in a market economy come to depend mainly on the professional integrity of the artist.

It seems probable that a given allocation of funds to artistic activities can be more directly translated into high artistic achievements in command economies than in market economies—provided, however, that the command economy, in addition to insisting that an artist produce the most perfect, also permits him to do what he is best at. It is in the latter respect that the command economies of modern totalitarian states have fallen short: they have prescribed for their artists a manner of working in which the latter could not do their best work. Mass-media "command economies" may also work to that effect.

Market economies are potentially more capable than command economies of integrating art into the private life of ordinary members of society, and not only into the life-style of the elite. But market economies seem less capable, by themselves, of generating high artistic achievements (as well as producing artistic public environments). There is, therefore, likely to be an increasing demand for art in market economies but a reduction in the quality of what is being produced. There may be other, quite powerful stimuli to artistic creativity in societies with market-type economies, including the creative entrepreneurs who succeed in joining the market mechanism to an artistic purpose. But the impersonal workings of the economic system of the market itself appear to interfere with the accumulation of the "creative capital" while encouraging its dissemination.

THE ART MARKET

The art market is a complex system, with roots in preliterate societies and historical civilizations, by means of which artistic activities are organized as profit-making enterprises. Expectably, this system is most fully developed in capitalist economies, but, since economic enter-

prises generally have to take profitability into account, even in state-managed economies, the art market has some degree of existence wherever art is treated as an economic good that is offered, for a price, on a market.

The operations of the art market are determined both by the general dynamics of market systems and by the peculiar character of art as a commodity.

Sellers' options

People buy art for various reasons. But the organizations that specialize in selling art (or also in producing it for sale, as theatrical companies) are built in most cases on one of two assumptions about the motivations that propel people into spending their money on art. There is an elite market that sells reputation and a popular market that sells entertainment.

Selling entertainment. The popular market provides art for customers who seek primarily entertainment. It must, therefore, adjust to the prevailing conceptions of what is entertainment or shape such conceptions to correspond with what it is capable of providing. It conducts market research into audience preferences, but it also manipulates these preferences by spreading the impression, through its publicity agents and the mass media of communication, that entertainment is what the popular art market dispenses: not only its finished productions but the whole behaviour of the people involved with them is "entertaining." The artist must "sell" not only his art but also his behaviour outside of the art system. The implicit aim is absorbing everything that appears to the mass audience to be entertainment into the ambience of the popular art market—by transmuting the entertaining aspects of life into salable works of art, by associating entertaining people who are not artists with the popular art market, and so on.

Conversely, whatever cannot be regarded as entertaining tends to be forced out of the works of art or artistic performances handled by this system. It puts a premium on "slickness," the glittering or sensational packaging, and discounts both high seriousness and unique sensibility, unless they can be seen as "entertaining." Its influence spreads even beyond the arts it deals with, affecting the character of art that people highly exposed, from their early years, to this system produce and consume even when they operate outside of it.

Selling reputation. If the popular market sells entertainment (an important means of overcoming sensory deprivation), the elite market sells reputation (an important resource for legitimating high social status or aspiration). It is, therefore, involved only with customers concerned with reputation. Such customers may be individuals or organizations. While the "masses" are mainly involved with the popular market, organizations, including states, tend to be more closely linked with the elite market. This market attunes itself to the prevailing hierarchies of artistic reputation, but it also reinforces these hierarchies by spreading the news of the high prices (or prizes) fetched by the works of art handled by it, by encouraging competition among buyers (or supporters) of unique art objects, and by subsidizing the work of scholars and critics that is likely to draw the attention of purchasing elite groups to their goods, increasing their cultural reputation.

Transforming cultural significance into economic value

The elite market has a monopoly of the "measuring rods" used to transform cultural significance into economic value. For the buyers, these scales of measurement indicate the degree of their "cultivation." If impresarios in the popular market have the role of tastemakers (as well as organizers of a complex set of productive activities in the performing arts), dealers in the elite market operate as cultivation makers, cultivation being economically definable as the rate at which cultural reputations are paid for. Art sellers for the elite do not create the reputations, but they prosper by increasing the price of acquiring cultivation.

On the living artist, the elite market has the effect of encouraging him to produce a reputation that, highly paid for, identifies the purchaser as a person of cultivation. The artist's works must be the opposite of what the popular market deals with—they must *not* be entertaining but rather culturally "significant" (in accordance with current conceptions of cultural significance). In the 20th century, cultural significance is regarded as virtually equivalent to being innovative.

Interaction of popular and elite markets. Markets that are oriented to elites but deal in mechanically reproduced multiples, such as the publishing of "serious" (as contrasted to "popular") books, represent a special case in between elite and popular markets. The objects they deal in are not inherently "entertaining," and yet the cultural significance an individual object is seen to possess does not lend itself, when the object is multiplied many times over, to being transmuted into inflated prices on the market for reputations. Publishing costs have become so high that any published book, unless subsidized, must enter a popular or semipopular market. The transformation of book publishing into an industry oriented to a fully popular market has been encouraged by the paperback revolution and the profitability of motion-picture rights for both publishers and writers. A peculiarity of the book market is that it has developed semicaptive publics, in the form of book clubs, which the other arts have not been as successful in organizing.

The motion-picture industry is in the popular market. So are all the "spectacular" arts, such as the opera and the ballet, insofar as they are economically dependent on a market—even though their markets have been, by tradition, smaller and more selective than those of the cinema. The smaller and more select a market of the popular type is, the more important seems to be the influence of professional critics on it. And the more influential the critics, the more closely does a popular market approximate an elite market.

Relation of selling to quality

As the history of the opera and the ballet indicate, it is not to be assumed that a market concerned more with selling entertainment than with selling reputation does not permit the production of high artistic values. Even though a public is presumed to be spending its money for entertainment, entertainment is not necessarily what the artists think they are selling—one reason for the alienation of the artist from his public. The great impresario in the popular market is the one (such as Sergey Diaghilev) who arranges for artists to sell their best art to a public convinced it is getting glorious entertainment. Pioneering in new forms of entertainment may both change notions of entertainment and produce objects that will enter the elite market. It is not primarily by the objects produced but, rather, by the manner of their economic operation that one may distinguish between the popular and the elite market in the arts.

Popular and elite markets are not wholly separate. Prices of paintings by old masters in the elite market tend to be increased by their pleasing appearance and are usually reduced when they depict inelegant scenes of suffering. The elite market operates most purely, in terms of reputations, when art museums are involved. Conversely, any "respectable" popular market uses (and manufactures) reputations to increase the economic value of its product. Only anonymous entertainment—by "nameless" artists—can constitute a purely popular market.

The popular market, by treating art as entertainment, imposes on consumers' contact with art the expectation of fleeting experiences and of the absence of any cultural significance transcending them. The elite market imposes the expectation of enduring values and of the presence of the highest kind of significance. In both cases, the market exercises an influence over the definitions of art held by the art consumer (and even by the artist, to the extent he is governed by his market situation rather than other elements of the artistic role). The effectiveness of the influence depends on the degree to which market considerations alone govern artistic experiences and activities.

In both the popular and the elite markets, contrary to the usual dynamics of the marketplace, increases in the number of artists and in the amount of their production, relative to the size of the demand for their work, do not necessarily reduce the prices of works of art. In modern societies, these trends produce a focussing of attention on a few (who receive very high rewards) and the neglect of the rest of art producers, many of whom may be only slightly inferior (or not inferior at all) to the "stars."

Publicity in the mass media, which both the popular and the elite markets manipulate and benefit from, reinforces this tendency by promoting celebrity cults. The objects of these cults may be intrinsically meritorious or not, but the cult, in either case, destroys proportionality between merit and reward. Mass media tend to promote in the arts a phenomenon similar to the medieval cult of sacred relics. Current profitability of investments in art objects rests, perhaps mainly, on a cult of this sort.

Artists' unions

Trade unions of artists—a recent phenomenon—are important mainly in the popular art market. They establish lower limits for the incomes of working artists but also increase the cost of full-scale artistic productions, particularly in the performing arts. In effect, they seek to eliminate the need for the performing artists to finance their art by accepting an income less than commensurate with what they could get from an alternative occupation. But the increases in costs of artistic performances render the performing arts more dependent on sponsorship systems. Neither the European theatre nor symphony orchestras anywhere could survive in a perfect market system. While increasing the economic security of employed artists, artistic trade unions tend also to promote the unemployment or the underemployment of the performing artists and the growth of a "serious amateur" system (for example, the off-off-Broadway theatre and other experimental fringe theatres), which, in addition to developing a style alternative to that of the professional theatre, may also nurture fresh talent and feed it into the professional system. Artists working for the elite market have been less concerned with establishing trade unions. They either survive as celebrities—or fail to survive.

Marginal phenomena. In addition to the two major types of art markets, one can distinguish two currently marginal phenomena: traditional (that is, noneconomic) elements in the art market, such as ideological commitments to particular types of art or group commitments to particular artists, and the various "little" markets, at present increasingly numerous in Western societies, in which art is sold not exclusively, or not mainly, for profit and which may indeed be partly financed by proprietors or participants from income not derived from the sale of art or through their own unpaid services (little magazines, artists' cooperatives, the U.S. "underground" cinema at its beginnings). Little markets may be individual or cooperative, expert or amateurish, and built on the most varying motives. While their cultural role may be important, particularly in nurturing difficult artistic innovations, the little markets collectively cover only a minor part of the art market. If they become economically successful, they tend to be incorporated into one of the two major systems of art trade.

Incorporation of traditional elements into art markets

The "traditional" elements are usually incorporated into one of the three types of art markets and limit the intrinsic logic of their operation. In the elite markets, nation states impose restrictions on the export of historically significant works of art; all respectable book publishers print a certain number of worthy books they expect to be altogether unprofitable. In the popular markets, traditional criteria establish limits of "proper" and "improper" entertainment (performances of avant-garde musical works, for example, are consistently less profitable, both in Europe and the United States, than those featuring more traditional ones). On the little markets, which tend to lack economic staying power, commitments to an identifiable tradition exert a stabilizing effect.

REMUNERATION OF ARTISTS AND PROTECTION OF THEIR RIGHTS

Methods of remunerating artists depend on whether they are involuntarily bound (serf artists) or, with their own consent, are attached (palace artists) to a consumer or organization that uses their works, or are free to sell them on the market.

Bound artists are provided with subsistence by their lords; attached artists receive regular salaries (which may be high in the case of palace favourites and academicians) and additional bonuses for particular successful works of art. Freedom to sell on a market may be unlimited, as in modern societies, or it may be conditional on membership in a socially recognized group of producers (the medieval guild system). To the extent that it approaches a perfect market (numerous artists of approximately equal artistic reputation competing for numerous customers of approximately equal purchasing power), the economic transaction takes the form of a sale; in command economics it is more usually a commission. In guild systems, the association of producers may itself transact the sale or at least regulate the conditions of sale, by its members, of their products. In a dealer system, which was known in classical antiquity but (in the visual arts) has developed most fully since the 17th century (in the Netherlands) and the 19th (in France), a group of commercial intermediaries—dealers and artist's agents—has stepped in between individual artists and individual purchasers. Their task is to introduce the one to the other and conduct the economic transaction in accordance with the practices of good business. (Some art dealers and their literary equivalents—writers' agents—have operated also as patrons and even sponsors of young artists.)

Methods of payment

In market systems, methods of remunerating artists depend on the traditional cultural reputation of the art they practice, the degree to which the artists' rights of authorship are legally recognized in an economically consequential manner, and the technological requirements for transacting the sale of an artwork.

When the traditional cultural reputation of an art is high, the artists who engage in it, while not necessarily highly rewarded in economic terms, tend to acquire a moral right to a socially recognized authorship of their works. Their names are affixed to the works they have produced; these are no longer products of anonymous craftsmen or works signed by the supervisors of art workshops, as were lacquerworks from the imperial workshops of China.

The conception of individual authorship began developing in Greece around 700 BC and in China more than 1,000 years later. It was known in the medieval West and India but remained undeveloped in the Byzantine civilization. This conception is directly dependent on the development of a professional or gentlemanly or genius type of artistic culture. Indirectly, it is supported by a strong stress on individualistic values in a cultural tradition, but, as in eastern Asia, the notion of authorship could arise even in the absence of any strong commitment to individualism.

The notion of a legally protected intellectual property of an art creator in his work, which he retains even after he has sold his work to a user, presupposes a conception of authorship but extends beyond it. Historically, it is a much later development. It began in the West in the late Middle Ages and has been encouraged by technological inventions facilitating the reproduction of works of art (before book printing, possession of a manuscript implied the right to reproduce it); the growth of a competitive market in such reproductions, which needed to be regulated (the most prominent motive in the early phases of the copyright law was the desire to protect the economic interests of the book publishers, rather than the intellectual rights of the authors); and the image of the artist as a man of genius who may sell, like other producers, the works of his labour but retains a right to the spiritual substance, uniquely his own, that he has invested in them. What the copyright and unfair-competition laws protect are tangible contributions to a product that remain identifiably individual. The artist has a legal right only to what he has worked out; the law protects the labour of elaboration, not the idea or intuition. Yet, once the notion of a legally protected intellectual ownership has taken root, it tends to become self-perpetuating, even in the absence of the conditions that have favoured its development.

Implication of intellectual ownership

The retention of a moral right in the artistic product provides the rationale for an author's sharing in the income that the buyer derives from the use of his work and from the appreciation of its value over time. The logic of this system has been worked out most fully in the publishing and the mass-communications industries (radio,

the film, and television). In the visual arts, efforts are still being made to extend the economic implications of the recognition of the author's moral right to his work by developing a model contract for the sale of a work of art that will not only guarantee to the artist control over the reproduction of his work (which he may claim even now, by registering his works for copyright protection or stipulating at the time of the sale that he retains this right) but also provide for his share in any profits from the resale of his work.

The contemporary copyright system guarantees to the writers covered by it that their incomes will be proportional to the current economic value of their works (the total income from their sale). The visual artists' income, on the other hand, is unrelated to the current economic value of their works, once these have been sold (except indirectly, as the prices of the works they will sell in the future are affected by appreciation or depreciation of the works sold earlier). Thus, there is a disproportionality in the effects of the law on the relationship between the artist and his product in literature and the visual arts.

In the performing arts, unless the performance is recorded, the artist cannot be guaranteed any direct economic benefits from being recognized as the author of his performance. The performance "vanishes" after it is completed. It is only what is being performed (the text, choreography, musical composition), and not the performance itself, that can be protected by custom or the law. There is thus a difference between the legal rights of performing and "producing" artists in their art, and this difference may well affect their overall social status and self-esteem.

Legal rights in the mass arts

The development of the mass-arts industry has made it possible for performing artists to enjoy the benefits of legal protection of their continued "intellectual possession" of their performances, if they have been made to be recorded and can be reproduced. Recordings of live performances have remained unprotected and frequently "pirated" or reproduced without permission. In 1971, however, a convention was signed by 53 countries prohibiting international piracy of musical recordings, and individual countries are developing legislation to control its domestic variants. If only in the mass-arts industry, the situation of performing artists has been made similar to that of such "producing" artists as writers and composers, who receive royalties on their past work. The performers in a film continue to receive a set rate of payment from each showing of that film and residuals from reruns on television. While in this way they have a sort of continuing property right in their performances, as specified in their contract, performers have no moral right of authorship that would permit them to control the manner in which their work is presented to the public (as writers of books do). This right is usually vested in the film director, and even then, only if it is specifically assured to him in his contract.

Whether the legal protection of artistic property has in fact encouraged the production of high-quality art appears debatable: the system does not distinguish between high- and low-quality products. The operation of the legal-protection systems in the arts must be judged by the degree to which it helps artists both to earn an income and to derive self-respect from their work. It must, however, also be judged by inquiring whether its provisions result in larger benefits to the artists collectively or to the sellers of their works collectively.

ART COLLECTING

Art collecting and the building of architectural ensembles, such as churches and palaces, which can be regarded as immobile "art collections," have probably provided the most important source of income for the major visual artists, particularly in command economies. Once artworks enter a collection, however, they tend to stay there for long periods of time, potentially reducing the space and the demand for the works of later artists. There is thus a certain ambiguity in the attitude of artists toward art collections and museums, particularly in societies that possess well-stocked ones, such as Italy or, by now, the United States. Museums that tend to "enshrine" artists are in this respect worse, from the living artist's point of view, than private collections, which get reshuffled every once in a while—a process encouraged, at all times, by defeats in war, social upheavals, economic troubles, and, in modern societies, by high inheritance taxes. In contemporary societies, collecting by nonartistic organizations—governmental agencies, business firms, universities—seems likely to become increasingly important. This would mean a greater incorporation of art into real-life (as contrasted with museum) environments. As an encouragement for living artists, collecting seems to be most effective when any particular collection is intended to be temporary: that is, when it is established, exhibited, and then dispersed to make room for a different one.

Relations between museums and living artists

Purposeful collecting of works of art is most eagerly pursued in periods of great affluence and a reduction of the creative drive—in the Hellenistic age (323–30 BC), in ancient Rome, and in 18th-century Europe. The relationship between art collecting and political power has been more ambiguous. On the one hand, the powerful have liked to surround themselves with the grandeur emanated by an "overpowering" collection of art. On the other hand, states have compensated for their loss of power by cultivating an image of their cultural grandeur and refinement; art collections serve this purpose, too. But art collecting is also an appropriate response to great outbursts of creativity that have occurred in the past. And it establishes reservoirs from which later artistic efflorescences will, in part, be fed: art collections, if open to the public, provide a place for young artists to study their craft and for people in general to develop an interest in the arts.

Collecting of the art of the past may be encouraged by a lack, or loss, of faith in the creative accomplishments of living artists; by the proved prestige of the works of the past (important when the newly rich collector has neither taste nor understanding to judge by himself); and, particularly in contemporary society, by the profitability of economic investments in famous works of art. It is estimated that art prices in general multiplied some ten times from the early 1950s to the beginning of the 1970s.

The recent rise in art prices

Private art collecting on a smaller scale has been developing in the middle classes since the beginning of the modern age. Currently it shades off into "temporary collections" of multiples from the popular market, such as musical records or posters used to decorate student rooms. Attitudes derived from this practice are spreading even into sophisticated responses to art (*e.g.*, conceptions of the social function of museums).

FRAUDULENCE IN THE ARTS

Fraudulence is misrepresentation of authorship, usually for financial gain but sometimes for more complex reasons of a psychological or ideological nature. The sale of a copy of a unique work of art claiming to be the original and the sale of an original work claiming to be a previously unknown product of a famous master or of a highly valued anonymous tradition are typical instances of fraudulence. From an aesthetic point of view, a good falsification may be preferable to a mediocre original, and it would seem to "corrupt" the immediate aesthetic experience of amateur art consumers less than authentic but poor art presumably does. But a falsification distorts the evidence used for constructing an understanding of what "has really happened" in the past and for formulating sophisticated criteria of aesthetic judgment.

As an economic phenomenon, fraudulence represents primarily an assault on the elite market. On the one hand, it may reduce the funds available for buying authentic works of art; on the other, it tends to discredit the system of buying reputations. Yet it appears, in the modern world, not to have had much of either effect. Perhaps the most enduring sociological significance of fraudulence in the arts is that it has encouraged economic investment in the fraudulence-control system—art scholarship, gallery and museum expertise, and so forth. Beyond its intellectual reasons for existence, art scholarship has justified itself economically as art policing.

IV. Social control of art

Little art, except perhaps in the "intimate" genres such as lyrical poetry, can have been created, until the latter part of the 19th century, without some degree of social control—that is, influence exerted by nonartists—over its creation. The influence has varied greatly in degree, in the groups and agencies exerting control, and in the means used.

TYPES OF REGULATION

Six basic types of social control of art can be distinguished: (1) suppressive censorship by agencies in total control of channels of possible expression (the "medieval system"); (2) product specification by a relatively few customers, each of whom is not in total control of channels of artistic expression (the "Renaissance system"); (3) administrative restriction of the artist's access to his potential audience without a complete withdrawal of his opportunity to communicate and without destruction of his works ("enlightened censorship"); (4) organizational incorporation of artists into either nonartistic institutions, such as churches or business firms, artistic groups under the authority of nonartistic agencies, such as the academy under the French king Louis XIV (reigned 1643–1715), or state artists' unions (the "organizational system"); (5) expression of preferences of taste by large numbers of individual art consumers not differing greatly in the power to command and to purchase (the "democratic system"); and (6) criticism by experts specializing in sustained analysis and evaluation of individual works of art (the "intellectual system").

Censorship compared with criticism. Of the six modes of control, censorship is the most severe and least sensitive to the aesthetic merits of works of art. Art is on principle judged in terms extrinsic to artistic values and subordinated to explicitly utilitarian considerations of political, religious, or "moral" character. Criticism, at the other extreme, at least uses the means of imagination, rather than of power, to control products of the imagination and mediates between artists and groups of users of art (however small) whose standards particular critics articulate. Thus, criticism helps to relate artists to the subcultures in which their work is most responsively consumed and to reveal the character of these subcultures to their own members. At best, criticism expands the artist's experience in areas relevant to his understanding of how art operates in the minds of people and increases the consciousness of the community to which the critic "speaks." At the same time, the artist can avoid being influenced by critical interpretations (at the risk of not learning what they reveal) by the simple decision not to read the reviews. Scientific research into empirically demonstrable effects of particular kinds of art on particular types of personalities, under specified conditions, can be treated as a newly evolved element of artistic criticism.

Benefits derived from criticism

Censorship of the arts has been typically justified by "clerical" or "civic" conceptions of art—the view that art has a moral obligation to defend a cultural tradition higher than art itself or a civic obligation to celebrate the community that supports the artist. The first view is usually espoused by various ideological elites, but the second can be quite popular and widely supported, even in a democracy. The clerical conception of art also generally implies the assumption that art has a great power to corrupt or to save. It is, indeed, this tendency to overestimate the power of art that leads to demands for censorship. The civic attitude toward art presupposes merely a tendency to suppress anything that offends local self-esteem.

Whatever the conception of art, censorship becomes "necessary" only when an established clerical or civic view of art is powerfully challenged by other artistic cultures—the ecstatic, the vagabond, the genius, the professional, or the avant-garde. It is perhaps from such challenges to civic and clerical assumptions by ecstatic (Dionysian) or emerging professional types of artists that the first explicit philosophical defense of artistic censorship, by the philosopher Plato, emerged in classical Athens. A conflict between two clerical cultures, the Catholic and the Protestant, together with the invention of the printing press (which made literature more "dangerous"), led to the great development of formal, organized religious and political censorship in 16th-century Europe. Censorship declined, especially in the Anglo-Saxon countries, in the 18th century, with the establishment of religious tolerance and in conjunction with the displacement of clerical by professional conceptions of the writer.

Targets of censorship. Censorship has been mainly directed against the ideological (stated or implied views) or depictive (represented scenes) content of the arts, thus primarily against the arts in which content is more important—literature, the theatre, and the visual arts (including the film and, to a lesser degree, photography). But whole types of art have been outlawed. The ancient Spartans expunged music and dance, as well as poetry, on the grounds that they might promote effeminacy and license in a population that had to be hardened for heroic militarism. Early Christianity suppressed the theatre and fictional literature of the Greco-Roman civilization. Muslims, Calvinists, and in some periods the Byzantine iconoclasts outlawed religious visual art.

Suppression of content

While, in general, secular states have been concerned only with the content of art, ideological organizations have been sensitive, especially in 20th-century totalitarian systems, to the attitudes and values suggested also in style. It was primarily by stylistic characteristics that "degenerate" art was defined in Nazi Germany. Totalitarian movements have not only prohibited some styles but have also prescribed others for their artists to work in (for example, Socialist Realism in the Soviet Union between the 1930s and the 1950s).

The 17th-century absolutist state also perceived the value implications of artistic styles, but (like the medieval Catholic Church in its approach to the visual arts) it relied more on the techniques of product specification—patronage, by a royal court, and promotion, by an official art academy—rather than on prohibition, enforced by police power, against working in particular styles and having works in these styles exposed, in some manner, to artists' customers. As a mode of control, product specification is more congenial to artistic creativity than is censorship; and 17th-century France sustained creative attainments of a high order, even in the visual arts in which the court specified its demands most insistently. But it achieved still more in dramatic literature, over which the court had a less direct influence.

In the 20th century, the large economic organizations that have come to dominate the mass arts have acquired a capacity to exercise a private kind of censorship by depriving artists of their means of work. In the "image" industries, the reason for such blacklisting, as in the U.S. film industry after World War II, has tended to be the political image of the artist rather than either the style or the content of the work he was proposing or had done in the past. In the democratic societies, private watchdog and pressure groups are likely to be more effective in imposing their demands for censorship on the mass-arts industries or on the business firms whose advertising sustains them financially than in influencing governmental agencies. The newer mass media are, because of their dependence on public licensing (television stations), more vulnerable to governmental pressures than the traditional arts.

Self-censorship

Self-censorship by artistic enterprises (for example, the movie rating system of the U.S. film industry) has developed largely in response to the influences private pressure groups have brought to bear on the culture industries, by threatening their mass sales. A different variety of self-censorship is practiced by art museums when they ban types of art with contents that are not congenial to the economic or political interests of the business leaders who usually control their boards of trustees, or that seem capable of causing libel suits, or that appear to conflict too sharply with the traditional conceptions of what art museums should exhibit.

In neither of these two situations does "censorship" completely prevent public exposition of the works censored or terminate the public career of the artist con-

cerned. These cases thus do not represent true, suppressive censorship but, rather, a system of limiting the public's opportunities for viewing certain types of art. Prohibition of the sale of certain types of art to juveniles also represents restrictive censorship. In respect to the arts, the Western democracies have by now virtually abandoned suppressive censorship in favour of the restrictive.

In the U.S.S.R., there have been some trends after the death of Joseph Stalin (1953) toward a transformation of the system of suppressive censorship into a de facto system of administrative restriction: allowing for privileged exhibitions of modernistic art in scientific institutes, showings of avant-garde foreign films to select circles (partly specialists and partly political elite), publication in small editions or in recondite journals. But a somewhat relaxed suppressive censorship is still in operation. China has a completely suppressive system.

In contrast to the censorship practiced by the ideological organizations, style is usually of no concern to the economic interest and private pressure groups endeavouring to subject art, or what is presented as art, to censorship either by pressuring the mass-arts industries and large artistic enterprises or by demanding action by government agencies (in the United States, most frequently on grounds of "obscenity").

CONDITIONS FOR SOCIAL CONTROL

Factors in the susceptibility to restraints

In general, the arts seem to be most susceptible to social control when artists are dependent on a relatively few important consumers or on a great mass audience of a fairly homogeneous social character, and when their works are either very expensive "uniques" or highly profitable "multiples." The susceptibility of artists to social control thus depends, to some extent, on the kinds of art they choose to produce. This susceptibility tends to decline when there is a differentiated, heterogeneous public with political institutions permitting a free expression of individual choices and an inexpensive access to a wide range of works of art. If access to art is provided at public expense, however, artists again become susceptible to social control—this time by the intermediaries staffing the cultural organizations, such as museums and state publishing houses, that determine which artists and which works will be exposed to the public.

Art is least susceptible to social control when it is sponsored and financially supported by other artists, who acquire their income in some manner other than through the sale of their works (for example, through teaching). The institutionalization of the professional conception of art is perhaps, in the long run, the most reliable defense, from within the artistic enterprise, against deliberate manipulation of the arts by social agencies. But a purely professional tradition of art is so inoffensive as to appear dehumanized, and artists themselves may seek to overthrow it, opening themselves up to deliberate manipulation by those (frequently political movements) they align with to achieve this goal.

IMPLICATIONS OF SOCIAL CONTROL

The issue of censorship and other kinds of deliberate manipulation of art has ultimately to be dealt with in terms of moral and political assumptions about human nature and the proper character of the artistic enterprise, not primarily in terms of the effects of these policies on artistic creativity. The effects of social restraints, or their absence, on artistic creativity seem, in any case, somewhat ambiguous. In general, no direct relationship seems to exist between the degree of personal freedom enjoyed by the artist and the aesthetic quality of his work. The tolerance and cultivation of the art patrons in Italy during the 17th and 18th centuries did not prevent a decline in creativity. On the other hand, a general cultural repressiveness does not always preclude an artistic efflorescence: the period of the most intense activity of the Spanish Inquisition in the 16th and 17th centuries coincided with El Siglo de Oro (The Golden Age), one of Spain's most important periods of artistic creativity.

Freedom, however, may have become a necessary—though not sufficient—condition for artistic creativity in industrial societies. Artists, particularly those who have been affected by artistic developments in the West since the Renaissance, have come to expect creative freedom and cannot help but feel illegitimately constricted in its absence. Their personalities are no longer sufficiently congruent with an authoritarian structure of external controls, as the personalities of medieval artists may have been, to be able to produce aesthetically significant work when subjected to such controls. By abolishing artistic freedom, both the Soviet Union and Nazi Germany destroyed flourishing artistic movements and proved unable to generate aesthetically valid substitutes for them. But a relaxation of earlier rigid controls may be more conducive to artistic creativity than the maximum of freedom, because under restrictive controls an unspent tension accumulates, which is then available to be released in an explosion of creative activity when pressures are relaxed. Under complete external freedom, such energy may never accumulate; unless the artists possess an extraordinary degree of self-discipline, their energies tend to be immediately used up through a variety of outlets.

Effect of easing controls

What seems to be specifically fatal to artistic creativity is not social control of the arts but an imposition, whether by outsiders or indeed by the artists themselves, of a completely intentional conception of the artistic enterprise: that is, its successful limitation to the expression of any set of recognized and intended functions.

If there is to be any social control over the arts, which many artists would dispute, its least objectionable form would seem to be one limited to a combination of expressions of preference by large numbers of interested art users with analysis and reasoned evaluation by art critics and scholars. The two modes of control in conjunction balance each other's biases and increase the range of options available to artists. These controls can be dismissed from consideration only if it is assumed that art is totally irrelevant even to the people most interested in it (other than the artists themselves). Art would then have to be treated as either a private affair of the artists or as pure entertainment without any cultural significance.

V. The arts and religion

In both preliterate societies and historic civilizations, the arts have frequently, but not always, had a close relationship with religion. In the past, this relationship has tended to be less direct when art objects were being produced by women, such as the pottery of the Pueblo Indians of the southwestern United States. Women, who have rarely been the religious specialists of their societies, have mostly produced an art of decorated utilitarian artifacts or of personal intimate expression, in either case not characterized by high cultural symbolism. Men have been more frequently disposed, or constrained, to justify their aesthetic interests by relating them to a metaphysical purpose. In effect, this means that men have had more reasons, in most preliterate and historical societies, for making art than women did.

SOCIAL RELATIONSHIPS

Interaction of art and religion. An explanation for the frequently close relationship between art and religion may be found in the areas in which they are similar or overlap. In both art and religion, there is much concern with the basic needs of the imagination and with a valid perception of subtle qualities of experience, and there is no binding requirement that they provide references to demonstrable fact for their insights (as there is in science). The similarity means that the arts and religion might, in part, operate as functional substitutes for each other: the more successfully one system functions, the less need for the other, and the less successfully, the more need. This may be one reason for the modern growth of interest in the arts, especially among the intelligentsia and the alienated of the middle class.

Religious and artistic similarities

Religion, however, tends to be more dependent than the arts on those aspects of culture that are communal, in-

volved with abstract ideas, and concerned with standards of conduct. It must provide guidelines for action that whole communities (as well as individual persons) could live with. While the arts can perform such "religious" functions, they can also survive quite well without performing them: inherently, the arts have a less direct, less intentional, less "responsible" relationship to social action than does religion. In their specifically aesthetic essence, the arts are more private, more individualizing, less binding than religion. There is more play than obligation in the arts. The opposite is true of religion. Popular interest in the arts tends to decline, and interest in religion to increase, during life-threatening historical crises, such as the Black Death of 1348–50 in Europe or destructive wars. Interest in art frequently increases after such periods. Religion is more of a crisis-management phenomenon, art that of postcrisis integration.

The impact of art on its consumers is likely to be magnified by its association with religion or even, in the absence of any formal association with organized churches, by its perception in terms appropriate to religious experiences. If close alliance between the arts and religion means that they are "used" by religion, the arts become collective liturgies, providing sensuous elements to increase the hold of a religious doctrine over the more private aspects of human experience. If, on the other hand, the arts "interact" with religion, if artists can have an influence on the development of religious orientations (instead of merely being "guided" by them), religion might acquire some of the characteristics of an art—become less systematized, more private, less dogmatic in its claims, more individualizing in the experiences it permits. The medieval Catholic Church, by and large, "used" the arts, while the Asian religions—other than Confucianism—tended to "interact" with the arts. In classical Greece, the arts became so emancipated from religion that they can be said to have "used" it, with more enduring benefits for the arts than for religion.

Separation of religion from art. A sharp separation of religion from the arts, such as tended to occur during the Protestant Reformation, promotes the rise of a rationalized, "disenchanted" religious world view and an anarchically romantic tradition of the arts. Like the Reformers, religions generally have been willing to accept some kinds of music and of literature and have varied mainly in their attitudes toward the visual and the "bodily" arts—the dance and the theatre. Attitudes toward the religious significance of the materially existent underlie this variation. But religions have also varied in the degree to which they made use of, or interacted with, the arts. "Aesthetically deprived" religions lose one sort of appeal to potential adherents and, perhaps especially in times of widespread discontent and cultural crisis, do not compete well for popular support with religions that possess more powerful aesthetic (or mythological) resources. Soviet explanations of the survival of religion in the U.S.S.R. stress increasingly its aesthetic aspect —a problem for Marxist ideologists, who are beginning to perceive a lack of this element in their own system of faith.

Effect of separating art from religion

A religion or a secular ideology without the arts loses one type of symbolic resource for its perpetuation and a possible source of modification of its doctrine. In addition, the arts represent one possible way of testing human significance of various aspects of the message of a religion or secular ideology. Do they survive, when artistically treated, without the support of enforcement by the established authorities of a church (or party)? It has been suggested that some ideological and religious concepts failed to be retained in the popular consciousness because they never received an effective artistic elaboration.

For the arts, a complete separation from religion or secular ideology means, on the one hand, a release from the obligation to serve a tradition regarded as superior to art itself and from its various efforts at social control —including censorship—over artistic expression. On the other hand, the separation of art from religion or ideology means: (1) the loss of a symbolic resource that either can be used directly in art creation or that stimulates artistic creativity indirectly by "disturbing" the imagination of artists; (2) the loss of one type of opportunity to create art that is both appreciatively used by large numbers of people and regarded as significant by them; and (3) the loss of a type of patronage that has historically been more continuously interested in the arts (other than literature), in times good and bad, than any other and that has tended to exhibit more concern even for the aesthetic merits of art than did the two most important types of patrons—the high bourgeoisie and the secular state—that followed the virtual demise of church patronage.

A preoccupation with patronage, however, has not always governed the behaviour of artists. Even though painters could expect to lose their most important kind of patronage if the iconoclastic Protestant Reformation succeeded, a surprising number of them supported the Reformation. Historically, literature has been least dependent on religious patronage; music (because of its almost ubiquitous linkage with ritual), perhaps most.

Attitudes toward patronage

AESTHETIC INFLUENCES

Influence of kinds of religion. A strong influence of doctrinal religion over the artistic enterprise disposes it toward a "clerical" conception of its task: upholding of a cultural tradition regarded as higher than art itself. It also tends to eliminate women from roles, except auxiliary, in the artistic enterprise—as in organized religion. But the *mystical* streak of religious experience has frequently influenced the artistic enterprise in a generally liberating direction, producing an ecstatic type of artistic culture. Any kind of direct religious influence on the arts tends to give them a more consciously symbolic character, but the doctrinal religions tend to impose on them an authoritarian rigidity (for example, the Romanesque style current in Europe from the 11th to the 12th centuries), whereas the mystical religions produce tendencies toward a more fluid style that could be interpreted as more egalitarian (Buddhist wall paintings at Ajantā in Mahārāshtra State, India). Mystical religions may also open the arts more equally to both sexes, as it did for such women mystic writers of the late Middle Ages as the English Julian of Norwich and the Italian St. Catherine of Siena.

Feeling-oriented religions like Buddhism tend to produce preferences, in the personalities influenced by such religions, for sensuous styles of art; belief-oriented religions like Calvinism favour austerity in art styles.

Confucianism has also tended to favour austerity, but the Chinese Confucian gentlemen painters drew most of their artistic inspiration from Taoism and variants of Buddhism. Perceptual tendencies may persist even after the religious tradition that has shaped them is no longer consciously adhered to.

Changes in the religious system have, in strongly religious periods, provided impulses for subsequent artistic changes. Periods of increased artistic creativity have frequently followed those of intense religious struggle—conversions of nations, great heretical movements, successes or failures of popular reformations, even iconoclasm. But this is not an effect peculiar to religious changes: other types of intense social action have also preceded artistic efflorescences. A more specifically religious influence on artistic creativity is suggested in the historic tendency for artistic efflorescences to occur after periods of great religious creativity. This suggests that the arts benefit from a partial secularization of intensely religious traditions or that religious efflorescences shape symbolic or emotional resources that are most usable for artistic expression when they have aged ("mellowed") somewhat but have not been completely discarded from the living experience of a people. Expirations of previously potent religious traditions, as of Buddhism in India, have coincided with declines in artistic creativity.

The modern secular equivalents of religion have generally been quite inferior to it in their effects on the arts. This may be partly because most of the "secular religions" of 19th-century origin have been rationalistic, pur-

Inferior influence of secular "religions"

posive ideologies with little mythological content to disturb and stimulate the artistic imagination. In fact, artists have been most affected by the drama of events (or "theatre") brought into being by secular religions, rather than by their "mythology."

A great many modern artists have been willing to let themselves be influenced by the secular ideologies or by the more ancient religious traditions of their own civilization or by religions of cultures alien and exotic to them. The latter two influences have generally been aesthetically more auspicious than the former, but most artists do not experience even these influences with sufficient intensity to be "disturbed" by them and tend to exploit, almost at random, their more superficial characteristics.

Art's shaping role in religion. It would be difficult to demonstrate that developments in the sphere of art have had any independent effects on religion. Throughout much of history, art has not been sufficiently independent from religion to be perceived as a "cause" of religious developments. More likely, it may have given focus, a tangible concreteness, a dramatic shape, a memorable melody, to abstract religious notions or shapeless feeling states and provided means for celebrating and transmitting them—rather than initiating the experiences and the notions themselves.

It seems likely that the cultural attitudes of the growing number of alienated intelligentsia of the West are greatly affected by its artistic culture. The conception of the "revolution" as espoused by the New Left has, in many ways, been a "surrealistic" one ("all power to the imagination," etc.). Fascism, too, has been considered by some observers to be an aesthetic phenomenon almost as much as a political one. It is, in any case, through the shaping of fantasy dispositions—congenial modes of perception—that art can influence the development of general value orientations, which in turn dispose people to favour particular religious or political ideologies, when choice between alternatives is possible.

The impact of fantasy

Yet the shaping of fantasy dispositions is not a foolproof method of manipulation, particularly in modern societies: it may provoke a subjective rejection of overly insistent attempts to influence—an anarchic response to the rigid authoritarianism of the "classical" styles or, conversely, a demand for new dogmas and rituals in response to more ambiguity, suggested by the arts, than an individual can live with in his own life.

VI. Technology, science, and the arts

INFLUENCE OF TECHNOLOGY ON ART

To varying degrees, the arts depend on technological evolution for the very techniques used to create works of art —music considerably, literature least, and architecture most of all. The cinema has been made possible only by recent technological developments.

The arts also depend on technology for the dissemination of the creative product. Book printing has made possible the development of a mass reading public, which in turn has facilitated the rise of new literary genres, such as the novel. Modern techniques rendered objects of visual art mechanically reproducible, hence perceived and treated as less "unique" than they had been in the past. The film is a peculiar art in that the technique of production and the technique of dissemination immediately imply each other, both having been produced by the same technological development.

Beyond these direct technological influences on the arts, there is an indirect one, mediated through the effects that particular technologies have on the imagination of artists or of larger populations.

Effect on content. Generally, the arts do not mirror, in any direct manner, the technological developments occurring in the society in which they have been produced. In their contents, the visual arts are more likely to touch upon the consequences of technological developments that have become intimately familiar (for example, the artifacts represented in still-life painting) but are not necessarily its objectively most important result; or perhaps upon the more vividly visible agents of technological development (such as draft animals, machines, or electronic processes) rather than on the whole system of technology or the basic principles underlying it.

In other words, the arts focus on those aspects of technology that "grasp the senses." Thus, they frequently dwell on technological innovations in a very early stage of their development, then let them drop as subjects for artistic concern after they have become fully developed, attained a dominant role in the economy, and are taken for granted emotionally.

But it is also what technological change has eliminated or does not permit to exist that can grasp the artists' imagination; they will then be concerned with what they miss in a particular technological system and will depict, perhaps, the opposite of what they see as existing in it. It has been found that in preliterate societies where the house shape is circular, straight lines are preferred in art style and that, conversely, where the house type is rectangular, art styles tend toward the curved line. This finding suggests either that art supplies what is most lacking in the technological environment or that one art must provide what another art does not.

Art as a celebration of the absent

Technological developments may both suggest new contents for art and encourage the elimination of old ones. Thus, the invention of photography has virtually eliminated the need for realistic portraiture.

Effect on style. In the development of styles of art, technological factors appear to be more important than they are in the choice of subject matter. Certain styles have been made possible only by particular technological developments (electronic music). In other cases, technological developments (new types of paints) have converged with new scientific theories (in optics) and perhaps psychological changes (the decline of middle class democratic militance) to produce a particular style, such as Impressionism in French painting.

In still other cases, a style may be regarded as a symbolic projection of psychological attitudes inherently linked with a technological process. It has been argued that tendencies toward more geometric styles of visual art have emerged in connection with both of the major technological transformations of society—the agricultural and the industrial revolutions, while periods that have preceded these transformations have favoured more "realistic" styles (*e.g.*, Paleolithic cave paintings and the figurative arts of urban pre-industrial civilizations). A possible explanation of the linkage of the technological revolutions with more abstract styles of art may be the alienation from nature or a sense of mastery over it suggested by the geometric styles. Through them man imposes "his own" type of order on nature, where no such geometricism can be found. This attitude is also implied by the great technological transformations through which man has objectively increased his control over the forces of nature.

This process could have started in the imagination of artists inventing the notion of mastery over nature as a dream; in the attitudes of the people or of the religious, economic, or political leaders, reflected in both technological and artistic changes; or in the process of technological transformation, which, by its success, led to a widespread sense of mastery, projected into artistic style.

Industrial mastery and style

In the industrial transition the apparent sequence has been change in popular or elite attitudes, encouraged by the Protestant Reformation; speeding up of technological changes; and the rise of geometric styles of visual art. Music has "lagged behind" the technological transition even more than have the visual arts, but literature may, in certain respects, have anticipated it.

Thus, it could be argued that the poetry of courtly love and of religious affective mysticism of the later Middle Ages suggested an attitude of mastery over nature (over sexual impulses, limits of time and space). Even if this interpretation were accepted, however, it could not be concluded that literature is necessarily a more sensitive indicator of underlying psychological changes than the other arts. It may be in periods in which the other arts are heavily dependent upon organized patronage and a guild organization, and literature is comparatively free of such encumbrances, that it registers psychological changes

more sensitively and at an earlier date. Technology, in this perspective, appears not as the "ultimate" determinant of artistic expression but as an aspect of basic psychological and cultural change—an aspect that became crucial at a certain point.

The interest of artists in science appears to have been greatest on the threshold of the Industrial Revolution, in the 17th century, and toward its end—when technological developments, particularly in the field of electronics, have altered the material basis of advanced societies in the second half of the 20th century. In between, artists, especially writers, tended to be repelled by technology and its effects on people and the environment (and by the science they associated with these effects).

In the latter part of the 20th century, the attitude of repulsion still tends to hold with respect to the machine technology, but a distinction is made between it and the electronic (and cybernetic) technology, which is viewed more optimistically. Electronic technology, by the miracles of its circuitry that exhibits an almost human responsiveness, is expected to overcome the chasm between the "mechanical" and the "spiritual" that the Industrial Revolution had deepened.

Changes in the character of science during the 20th century, its recognition of the principles of relativity and indeterminacy and of the importance of the researcher's subjectivity, have contributed much to the revived appeal of science to artists and to their high expectations with respect to the technology based on this kind of science. In the 20th century, psychoanalysis and several perspectives in the social sciences have also been influential in the arts.

The response of the arts to science

In the long run, it is likely that the artists' response to the sciences and technologies of advanced industrial societies will follow the usual logic of the workings of the artistic imagination. That is, scientific technology should influence the arts through the artists' choices between affirming it and modelling their own work after it or repudiating it and concentrating on what it cannot recognize or suppresses or, if left to itself, would tend to destroy. The power, mathematical clarity, and systematic nature of the sciences and technologies may produce an artistic response in the form of sensuous, amorphous styles, carrying suggestions of impotence, of mysticism, of unique experiences.

There is no reason to anticipate that, in the long run, artists will be overwhelmed by science and assimilated into its mode of operation. Indeed, the more science and technology develop, the more they may be subjectively taken for granted, the more imagination may be captured by what science and technology cannot encompass, and the more an art that has not been overwhelmed will be needed. Artists tend to be overwhelmed by a great increase in the technical possibilities of expression only when they have no reason of their own—a mode of perception, a value commitment—to express anything in particular.

Effect on creativity. An essentially descriptive science may influence artistic creativity favourably when it fuses with an older tradition of an artistic craft, as anatomical and optical research vitalized painting in the Italian Renaissance. But a highly abstract science, removed in its formulations from directly perceivable realities, seems to be of most benefit to artists when they permit their imaginations to be stimulated by the general atmosphere of scientific discovery, of the revision of concepts about the nature of reality, or of new perceptions, rather than when artists have set out to apply scientific principles consciously to their work. Even an incorrect interpretation of scientific models by artists can be artistically productive (and perhaps scientifically suggestive).

OTHER ASPECTS OF THE RELATIONSHIP

Effect of art on the social sciences

To what extent the arts can influence the sciences is still uncertain. If "visual thinking" precedes conceptual thought, or if there is a basic background element common to both visual and conceptual thought, changes in perceptions that art either reflects or stimulates may generate responses in conceptual theorizing and, in this manner, affect developments in science as well as in philosophy. But it is on social and psychological theory and on the perceived shape of history that developments in the arts may be expected to have the strongest effect.

The association of artists with technology, especially in the visual arts and architecture, has been far closer and more durable than it has been with science, and the requirements and achievements of artists have often led to technological discoveries. Literary artists, on the other hand, have, particularly in the periods of great scientific discovery, such as the 17th century, been influenced more by science than by technology.

It might seem that the new technologies of the mass media of communication, by permitting more pervasive dissemination of particular works of art throughout society, are likely to increase the impact of art on people's personalities and modes of existence. But the mass media may also have the opposite effect: by making of art a commonplace occurrence that is taken for granted but does not generate an enduring emotional response, by assimilating it more completely to "entertainment," the mass media may decrease the effects of works of art on people and, indeed, on the artists themselves and on their aesthetic experiences.

At the same time, the media may be increasing the psychological impact of nonartistic events, particularly those that resist being assimilated to entertainment, such as wars in a foreign country, which were easier to take for granted before the electronic media became fully developed. This has led to tendencies to substitute, especially in the visual arts, the structures of events or of social systems for aesthetic structures (for example, an art exhibition consisting of photographs of slum buildings and landlords' names).

While it is debatable whether the mass media have enhanced the impact of art, they have certainly increased the social status of the performing artists (and tend to transform all artists whom they capture into performers).

VII. Aesthetic education

The broad and narrow views of aesthetic education

In the broad sense, aesthetic education refers to everything that art is, or may be, used for in the education of nonartists. In the narrower sense, aesthetic education is the developing of a sensitivity to aesthetic qualities and works of art and of an understanding of the criteria by which some works of art are regarded, by artists and art critics, as possessing more highly valued aesthetic qualities than others. Aesthetic education could hardly avoid, but it does not need to be limited to, what is implied in the term's narrower meaning. Approaches to aesthetic education vary mainly in how they conceive of its "broader" responsibilities.

As soon as art is created and exposed to others, it always educates, whether effectively or not, in some way. A study could well be made of the implicit philosophies of aesthetic education, inherent in the manner in which art is used and particularly in the manner in which the growing individual is exposed to it, of the preliterate societies in which the role of an art educator—as distinguished from the practicing artists—does not exist.

BASIC CONCEPTIONS

The formal development of aesthetic education, like the formalization of all education, has occurred in the classical civilizations. In the Western tradition, four basic conceptions of aesthetic education for the nonartist have been sociologically most important, although in practice they frequently overlap.

Didactic. The didactic theory regards art as a means for shaping a particular type of personality (the view of the Greek philosopher Plato). Modern notions of proletarian, black, or feminine "consciousness raising" by means of art, insofar as they presuppose that art is to be used for developing an attitude specified in advance, represent variants of the didactic approach to aesthetic education. But even when the goal is developing a particular type of aesthetic taste (as, for example, a taste for the "classical" styles or for "modern" art), a philosophy of education is didactic, albeit in a more subtle way. The didactic theory implies that if art does not do the task as-

signed to it, it has either no place in education or a subordinate one; and it may lead to justifying censorship of the arts, "to protect the innocent from corruption." This view of aesthetic education is most congruent with the "clerical" conception of art.

Therapeutic. The therapeutic theory views art as the supplier, for individuals or groups, of experiences that everyday life in society fails to provide but that are assumed to be necessary for a "whole" and "healthy" existence. In a highly rationalized society, art supplies or reveals the irrational, supplementing or confronting reason and duty with spontaneity and sensuousness. Or, in a more sophisticated conception, art reconnects reason with sensuousness, which had first to be separated from each other, for man's self-awareness to advance itself.

Since this philosophy of art as therapy developed in an early phase of the Industrial Revolution, it usually conceives the deficiencies of society in terms of what was becoming suppressed then—needs for emotional expression —or what was promised ideologically but has not been adequately delivered in reality even in the most modernized societies, such as equality and participation. But what appear to be increasingly missed in the advanced industrial societies are credible designs for the symbolic coherence of life; a sense for experiences and objects that resist being used up and are immune to planned obsolescence. The therapeutic function of aesthetic education may be changing accordingly.

Changes in the therapeutic function since the Industrial Revolution

The objective of a "therapeutic" aesthetic education is to use art to bring out the missing elements and either to promote their integration with the existing state of affairs or to overthrow the latter. The task may be conceived as "sociotherapeutic" or "psychotherapeutic"—overcoming the deficiencies of a whole civilization or those of an individual personality. In contrast to the didactic approach, only the initial problem and the general direction of the effort, but not the final solution—a specified type of personality or society—are presupposed. Artworks can be judged, in a general way, by the degree to which they fulfill the therapeutic task set to art by the character of the society or the stage of the evolution of civilization contemporaneous with it. But no artwork can be in principle excluded from aesthetic education, since any work may be "therapeutic" for someone.

Developmental. The developmental theory aims at making it possible for anyone to choose from the realm of art whatever he needs to develop his unique potentialities. The evolution of society has not given rise to any particular type of need that art should be meeting in a given social context. The task of aesthetic education is, perhaps, to increase the range of exposure to art so that every individual will choose on the basis of a more complete knowledge, more intelligently, how to develop his own self aesthetically.

This is a liberating educational philosophy, particularly in a tradition dominated by didactic approaches. But it has three unintended effects: (1) Since it puts the emphasis on what a person gets from a work of art for himself, it destroys the reason for trying to understand the work of art in itself and the ways it has functioned for other people, including its author. (2) While this approach permits individual experiences and descriptions of such experiences, it eliminates the basis for a more generalized critical evaluation of works of art. (3) By its emphasis solely on the individual's aesthetic experience, it eliminates the need for art. What have the works of art got that "aesthetic experiences" on a crowded street or in one's dreamworld do not give?

The developmental approach applied to children

The developmental approach is most applicable to the aesthetic education of children, where it is provided with a sense of direction by the psychologists' notion of the stages of intellectual and perceptual development of the personality, each offering distinctive possibilities and limits to aesthetic education. In the aesthetic education of adults, however, by implying that neither art nor the society nor history are particularly important as compared with a person's "experiences," this approach defines itself as a luxury object, likely to appeal to a social group that is prosperous but impotent to shape its destiny; and it needs to be balanced by various other kinds of aesthetic education.

Culture-critical education. The purpose of another form of aesthetic education is criticism of culture, in the broad, anthropological sense, through analysis of concrete works of art and of their functions in the life histories of individuals and in the historical existence of societies (and particular groups within them). This culture-critical approach differs from the therapeutic in that it is based less on the personal feelings and cast of mind of the educator and anchored more in the empirical study of culture history and of people's relationships to the symbolic expression of their experiences. It considers art in the context of all human experience, not just in the narrow social setting of an individual perceiver of art (as the developmental theory necessarily does). It is not concerned with recapitulating human experiences in the technical detail of historical monographs. Instead, it is involved with the recognition of patterns in which experiences are "fitted together"—externally influenced, intuitively structured, and their qualities and meanings interpreted to affect later experiences.

Aesthetic education as culture criticism is concerned with producing an ability to make aesthetic judgments that are founded on the knowledge of the ways in which whole civilizations, as well as everything involved with them, have been working. An analytical understanding of parts and of particular relationships is encouraged to grow into a capacity to perceive and evaluate the overall connectedness of a civilization.

Aesthetic education as culture analysis is a method that can be adequately used only with adults; but it can be placed at the very centre of the education of adults, including college students. Its purpose is not to produce art critics but, rather, persons more competent of judging civilizations, including their own, on the basis of an increasing understanding of what they have done, or failed to do, to human sensibilities.

SUPPLEMENTARY APPROACHES

The culture-critical approach to aesthetic education is predominantly analytical. It needs to be supplemented, for most people, by practice in the making of works of art. The writing and performing of dramatic works permit an exploration of the potentialities of social interaction and its limits, which a person has either had no experience with in his own life and yet senses as potentially significant or which he has experienced in an "incomplete" manner and whose full logic and his own design for interpreting it he wishes to work out. Other kinds of literature seem to have a similar role in aesthetic education. Music and dance clarify the dynamic rhythms in terms of which personal experiences and the character of civilizations are perceived, while the visual arts crystallize images of the emotional qualities these experiences and civilizations are sensed to possess. The film provides a potential basis for integrating the functions that literature, music, and the visual arts have in aesthetic education, but the separate experience of these arts provides a clearer understanding of such functions.

Architecture, with its commitment to relating dispositions of the imagination to the practical exigencies of life —and therefore to social policy—in a viable overall design of aesthetic merit, deserves, perhaps, a central place in aesthetic education that has not been recognized in any large-scale educational system. It may have a particularly important role in the education of those who refuse to recognize the linkages of their imaginations with the requirements of actuality.

The importance of aesthetic education beyond purely artistic considerations

It would appear to be arbitrary and self-defeating to limit aesthetic education entirely to considering the work of art in its isolation. It also must give some attention to the ways in which societies organize, or fail to organize, themselves to build aesthetically adequate whole environments (physical, social, and even "spiritual"). It must demonstrate how individuals can demand and, by their own political actions and spending patterns, support the building of such environments. A complete program of aesthetic education should include a consideration of the

costs of building and tearing down (or maintaining) aesthetically inadequate environments as compared with the costs of building environments capable of adequately performing a great many cultural functions for the people inhabiting them. And it must teach the techniques of social action for insisting effectively that the kind of aesthetic environment needed is provided.

The importance of immediate contact with practicing artists in the aesthetic education of nonartists is not primarily in the teaching of the technical skills of making art, which the practicing artists are not necessarily superior to "art educators" in transmitting. What good practicing artists can provide for aesthetic education is the demonstration of how "aesthetic structures" (meaningful connections between disparate elements of experience) arise from skilled labour under the constant judgment of a personal sensibility. Good artists also reveal in workaday practice how the nature of a subject, a design, a genre evolves in the process of elaborating its implications and simultaneously develops intrinsic requirements of its own, a set of "norms," a "logic," that the artist cannot disregard without diminishing his creative attainment. In this way, practicing artists transmit a sobering sense for what is required of creators by the inner logic of their works.

The role of the art critic in aesthetic education is to clarify the criteria by which he judges the aesthetic fitness of works of art and distinguishes between artistic successes and failures. The critic should be distinguished from the art interpreter, who explicates the meanings that a work of art has for him. The aesthetic philosopher's most productive role in aesthetic education would be to compare, in some systematic manner, the criteria of the critics, the meanings of the interpreters, and the intentions and the practices of the artists of various societies. In practice, the aesthetic philosophers mainly study each other. Partly for this reason, a role in aesthetic education has been opening up for the sociologists and psychologists of art, who are concerned with how art actually functions in the life of societies and personalities.

Since different individuals are likely to benefit most from different aspects of aesthetic education, it would seem to be a mistake to have a single model of aesthetic education for everyone.

VIII. Preservation and dissemination of art

THE NATURE OF ART PRESERVATION

Art preservation in preliterate societies

Even in preliterate societies, not all art is created for the occasion of its use and then abandoned. First of all, the basic design of the work of art survives in the collective memory of the tribe, or of its more artistically inclined members, and can be reproduced from this recollection, frequently with creative modifications. This principle of preservation operates most clearly in oral literature, but it gives continuity also to the other arts, both performing and objectifying. And it is not limited to preliterate societies.

Art objects may also be preserved either for their utility or for their religious significance. Cave paintings have been continuously "refreshed"—that is, restored by overpainting—over long periods of time by the Australian Aborigines to retain the benefit of their magical effectiveness.

Even before the rise of literate civilizations, art collecting had become a symbolic exhibition of wealth and power. Forms of writing, which made easier the collection and preservation of literature, probably also were developed, in the classical civilizations, for their utility in economic management, the pursuit of religiously significant activities such as astronomy, and the more effective exercise of political power. But once traditions of collecting works of art and of literacy have evolved, they have tended to acquire a degree of autonomy from the purposes they may originally have been associated with. Systems of musical notation have evolved later than literacy and without any significant economic or political motives to necessitate their development; it was encouraged, however, by a religious need to stabilize the liturgical uses of music. Systems of dance notation have been produced for purely artistic purposes. Systems of photographic, sound, and motion recording have been provided by the progress of modern technology. The development of these systems has been propelled more by curiosity than by the anticipation of the great profits they eventually proved capable of producing.

Collections of manuscripts existed in the ancient world, and a system of state and school libraries was established in Rome. But a network of public libraries has evolved only since the middle of the 19th century. The notion of a collection of books has not been as closely associated with the aristocracy as that of a collection of works of visual art: the chief connection of libraries has been with scholarship and its practical applications (in preaching, in administration, and, in modern times, in self-advancement through education).

Art collecting in the industrial age

The nature of art collecting has also changed in the age of industrialization and the democratic revolutions that started in the second half of the 18th century. Art collections, which previously had been possessions of the monarchy, privileged classes, and the church and (except for the visible part of church art) were rarely opened to the public, became, in most cases, public museums.

The traditional association of high art and art collecting with class privilege has led some of the revolutionaries and avant-gardists of the 19th and 20th centuries to conclude that the establishment of a democratic culture requires the destruction of the monuments to an aristocratic culture collected in the museums—and of the museums themselves as repositories of that type of culture.

Not only art museums but also symphony orchestras and even the theatre (in contrast to Elizabethan times, 1568–1603) have, in Western societies, little attraction for the working and lower middle classes. A study made in France in the 1960s found that 1 percent of museum attenders were agricultural labourers, 4 percent industrial workers, 5 percent artisans and tradesmen, the rest white-collar workers and higher social classes. In eastern Europe, where there is more of a tradition of high culture being in alliance or, indeed, in secret emotional conspiracy with the people (an attitude of the folk culture that has been retained), working class attendance at performances or exhibitions of high culture is higher. But even though it is encouraged by government, party, and trade-union agencies (and indirectly by the monotony of much of the officially sponsored "popular" culture), interest in high culture is still stratified by class.

This lack of interest by manual labourers in art poses a contradiction. Works of art, by whomever they have been sponsored or collected, have always been produced by craftsmen who surpassed mere craftsmanship. They represent a conjunction of craftsmanship and sensibility of the men and women who have been in the vital centre of their own times, working and imagining. If there is a monument to the immortality of manual labour, it is a museum of art.

Museums of modern art

Museums devoted to contemporary art have developed only in the 20th century. Instead of preserving what has survived repeated tests of critical judgment over the ages, museums of contemporary art delve into the flux of ongoing artistic developments, at best endeavouring to sort them out into intelligible patterns and to enlighten the public's consciousness of its own times. Frequently, however, such museums have become powerful trend setters for the fashionable, producing an ephemeral new "movement" each year and becoming, in effect, adjuncts of the mass media of communication rather than seekers for the surviving values of art. In the 1960s, there developed demands that contemporary-art museums be conceived of as "houses of controversy"—where anything arousing concern of contemporary artists could be exhibited, whether it is art in the traditional sense or not. There are tendencies toward differentiation between two types of art museums: one engaged in controversy and the other a repository of art-historical collections whose holdings are critically evaluated for their aesthetic merit. There also seems to be an increasing need for museums in which all the arts of a period or a historic group could be shown together, to reveal the overall cultural atmosphere of the

period or group and the interconnections of its arts, placed within their sociological context.

To preserve artworks implies the desire not to deprive future generations of the kinds of human experiences that the circumstances of the past and present have generated and the future may no longer be able to produce. Possession of what one is not able to produce stretches the mind in ways that, in the absence of these possessions, could not even be imagined. By not preserving works of art, a society would lose much of its awareness of the limits of its own imagination and would tend to treat its present modes of existence and of aspiration as though they were absolute.

Unselective preservation of everything that has claimed to be art would, however, very quickly overload the depositories of culture. A decision to preserve therefore implies a criterion of selection to determine what is worth preserving. Such criteria may be the aesthetic merit of the work of art or its historical significance for a nation, a church, a political movement, or a family lineage. Preserving samples of the "popular culture"—presumably lacking in aesthetic merit but representative of the character of a period—is also justifiable. Since judgments of aesthetic merit are revised and possibly improved over long historical periods, "accidental" preservation of works that have not been judged by their contemporaries to possess aesthetic merit can also become important.

The greater part of the art produced by the preliterate societies and historic civilizations has been lost due to neglect and historical misfortune. Only 12 percent of the tragedies said to have been written by Aeschylus, Sophocles, and Euripides in Greece during the 5th century BC have survived. Of the period that the Chinese traditionally regard as representing the historical peak of their painting—the T'ang (AD 618–907)—hardly any paintings have been preserved. Many works of art have been intentionally destroyed by organizations or individuals (for example, medieval peasants burning classical marble statues for lime to fertilize their fields). Among the major social organizations, the churches have probably done more for the preservation of works of art than any other, but they have also destroyed art in religious wars and campaigns for the eradication of heresy. States have both protected and destroyed. Business organizations, on the other hand, rank among the major destroyers of architectural monuments, particularly in contemporary societies. Only by governmental regulation can the popular market, whether capitalist or Socialist, be restrained from destroying unique works of art to build parking lots.

Destruction of art

SYSTEMS OF DISSEMINATION

At least seven types of systems through which artistic products are disseminated to art consumers may be identified. These systems differ in the manner in which contact with art is established and the attitude with which it is approached.

1. Ritualistic systems. Art is incorporated into the conduct of special, repetitive occasions and presented as an integral part of them (for example, church services and political rituals in which particular kinds of music are performed). Highly specific types of art receive wide exposure on an occasional basis. An air of the extraordinary, of festivity, is attached to these types of art. The modern opera has inherited some of the trappings of the ritualistic system. Certain avant-garde occasions may approach it. So do art festivals, by breaking with the routine of permanent museum collections or environments, which gives art the character of being taken for granted.

2. Environmental systems. Art is incorporated into the organization of the everyday, stable environment visible to everyone in the normal course of his life. Architectural works, landscaping, public monuments, and private libraries are cases in point. Transmitted in this way, art influences the perceptual expectations of most everyone, but it tends to be taken for granted, to become "invisible." In modern societies, economic organizations and governmental agencies are primarily responsible for the dissemination of art (bad as well as good) through this system. Governments could, indeed, do more for aesthetic education by controlling the environmental system than through their hold over aesthetic education in the schools.

3. The utilitarian system. Art is incorporated into the small, usually portable objects of everyday use, from eating utensils to automobile designs. In its effects, this system is comparable to the environmental system. But it is industry, rather than the government, that is in a strategic position to affect art's distribution through the utilitarian system.

Art in everyday utilitarian objects

4. The art-trade system. Art objects are produced for and sold on the market specialized for goods of their nature. Depending on their cost, they may appeal to a "mass" or a "class" public but, in any case to those possessed of a purchasing power they can devote to objects of no material utility and who have a tradition of buying such objects. In practice, the system of trade in the objects of fine art tends most frequently to become oriented to economically privileged groups. The market for music records and tapes is, however, creating a tradition of buying art objects even among the underprivileged. The book trade, particularly after the development of the paperback in 19th-century Germany, is oriented to a broader section of the population than is the art trade; it tends to divide into an elite-oriented and a popular component, but the two overlap.

5. The mass-entertainment system. Artworks are constantly exposed, at low cost, to large audiences, but not as a stable and integral part of their everyday environment (as in the environmental and utilitarian systems) nor with an attitude of the extraordinary attaching to it (as in the ritualistic system). The ubiquity of exposure, the fleetingness of the occasions of exposure, and the general atmosphere of fun and games surrounding the operations of this system have the effect of obliterating the unique significance of any particular object of art. Everything processed through the mass-entertainment system tends to become like everything else.

6. The educational system. This is the concern not only of schools but also of modern museums and libraries. Works of art are collected and disseminated with an educational intent—in schools potentially to everyone in the right age groups, in museums and libraries to those who choose to make use of the education offered. Museums, however, have not been fully assimilated to the educational system. In the United States, they are still not regarded, in their claims for public support (or for an automatic tax exemption by virtue of their status), as quite equivalent to schools. There are also notable tendencies in the latter half of the 20th century to incorporate museums into the mass-entertainment system. On the other hand, a politically controlled system of "mass entertainment," as in totalitarian states, is in fact heavily "educational," in a didactic manner. The street theatre of the "counterculture" is also intended to be educational.

The educational system typically lacks the power inherent in environmental or utilitarian systems and the intensity characteristic of ritualistic systems. Possibly for these reasons, the art disseminated through the educational system tends to acquire connotations of what in the upper middle class of Western societies used to be perceived as "femininity"—a refined irrelevance to the world of affairs. The possession of "real life" power by the large art museums constitutes one of their educational advantages over art teaching in the schools, where the art teacher is still frequently treated as an inferior type of educator.

7. Movement systems. There are indications that a new system of dissemination of art may be emerging in the youth movement and perhaps other popular movements of a basically "cultural" (rather than traditional "political" or "economic") character that have become a feature of advanced industrial societies. Any particular movement system is temporary, but, while it lasts, it generates an intense audience response to certain kinds of art, and the audience may even be drawn into the collective production of works of art. The dividing line between producer and consumer of artworks becomes attenuated. Art can be consumed without waiting for a set

occasion, but its consumption always has an aura of rebellious celebration attaching to it. If movement systems are successful, however, they tend to be assimilated into mass-entertainment systems—revitalizing them, but losing their own vitality.

While all known societies produce (and therefore presumably need) some kind of art, not all their individual members use art or exhibit any kind of response to it, even when it is offered to them at no cost and in an environment that is not intimidating. Therefore, all societies have some system, or a combination of systems, for the dissemination of works of art, but not all of their members are involved with such systems. While art-dissemination systems might aim at a universal exposure to works of art, they cannot be blamed for not generating a universal response to art.

The sources of the responsiveness to art lie partly outside of the whole artistic enterprise, in the structures of individual personalities and in their experiences in confronting social systems and historical processes. In this sense, an individual's contact with art starts not with society's systems of art dissemination but with the character of his existence.

BIBLIOGRAPHY

Anthologies: On the visual arts in preliterate societies, see CAROL F. JOPLING (ed.), *Art and Aesthetics in Primitive Societies: A Critical Anthology* (1971), an important reader. On the arts in historic societies, MILTON C. ALBRECHT, JAMES H. BARNETT, and MASON GRIFF (eds.), *The Sociology of Art and Literature* (1970), has very extensive coverage and bibliographies. The best overview of the sociology of literature is LEO LOWENTHAL, "Literature and Sociology," in JAMES THORPE (ed.), *Relations of Literary Study: Essays on Interdisciplinary Contributions*, pp. 89–110 (1967).

Art and society: ROBERT ESCARPIT, *Sociology of Literature* (1970); I.C. JARVIE, *Movies and Society* (British title, *Towards a Sociology of the Cinema*, 1970); and ALPHONS SILBERMANN, *Wovon lebt die Musik?* (1957; Eng. trans., *The Sociology of Music*, 1963), provide overall analyses of the social organization of particular arts. CESAR GRANA, *Bohemian versus Bourgeois: French Society and the French Man of Letters in the Nineteenth Century* (1964); FRANCIS HASKELL, *Patrons and Painters: A Study in the Relations Between Italian Art and Society in the Age of the Baroque* (1963); BARRINGTON KAYE, *The Development of the Architectural Profession in Britain: A Sociological Study* (1960); HARRISON C. and CYNTHIA A. WHITE, *Canvases and Careers: Institutional Change in the French Painting World* (1965), are studies of changes in the social role of particular types of artists. An account of a social setting in the performing arts (the Broadway theatre) is SAMUEL W. LITTLE and ARTHUR CANTOR, *The Playmakers* (1971).

Basic works on social elements in the style and content of the arts: WALTER ABELL, *The Collective Dream in Art: A Psycho-Historical Theory of Culture Based on Relations Between the Arts, Psychology and the Social Sciences* (1957); PIERRE FRANCASTEL, *La Réalité figurative: éléments structurels de sociologie de l'art* (1965); ARNOLD HAUSER, *Sozialgeschichte der Kunst und Literatur*, 2 vol. (1953; Eng. trans. of vol. 1, *The Social History of Art*, 2 vol., 1957); VYTAUTAS KAVOLIS, *Artistic Expression: A Sociological Analysis* (1968); ALAN LOMAX, *Folk Song Style and Culture* (1968); LEO LOWENTHAL, *Literature and the Image of Man: Sociological Studies of the European Drama and Novel, 1600–1900* (1957); RENATO POGGIOLI, *Teoria dell'arte d'avanguardia* (1962; Eng. trans., *The Theory of the Avant-Garde*, 1968); PITIRIM A. SOROKIN, *Social and Cultural Dynamics*, vol. 1, *Fluctuation of Forms of Art* (1937); and MAX WEBER, *The Rational and Social Foundations of Music* ed. by D. MARTINDALE, J. RIEDEL, and G. NEUWIRTH (Eng. trans. 1958). Important studies of particular historic cases are LUCIEN GOLDMANN, *Le Dieu caché: étude sur la vision tragique dans les Pensées de Pascal et dans le théâtre de Racine* (1956; Eng. trans., *The Hidden God: A Study of Tragic Vision in the Pensées of Pascal and the Tragedies of Racine*, 1964); and PHILIP E. SLATER, *The Glory of Hera: Greek Mythology and the Greek Family* (1968).

Social conditions of artistic creativity have been studied in VYTAUTAS KAVOLIS, *History on Art's Side: Social Dynamics in Artistic Efflorescences* (1972); and A.L. KROEBER, *Configurations of Culture Growth* (1944). Influences of art on society are theorized in HUGH DALZIEL DUNCAN, *Communication and Social Order* (1962); and RADHAKAMAL MUKERJEE, *The Social Function of Art* (1948). VICTOR W. TURNER, *The Ritual Process: Structure and Anti-Structure* (1969), provides a framework for analyzing the social effects of the performing arts. For a survey of some empirical findings, see JOSEPH T. KLAPPER, *The Effects of Mass Communication* (1960).

Art and economics: There is no basic overall inquiry into the role of economics in the development of art. Good historical studies of art collecting are FRANCIS HENRY TAYLOR, *The Taste of Angels: A History of Art Collecting from Rameses to Napoleon* (1948); and NEILS VON HOLST, *Künstler, Sammler, Publikum* (1960; Eng. trans., *Creators, Collectors, Connoisseurs: The Anatomy of Artistic Taste from Antiquity to the Present Day*, 1967). For trends in art prices, see GERALD REITLINGER, *The Economics of Taste*, 3 vol. (1961–70); and GERALDINE KEENE, *Money and Art: A Study Based on the Times-Sotheby Index* (1971). On economic support of contemporary arts in the United States, see WILLIAM J. BAUMOL and WILLIAM G. BOWEN, *Performing Arts: The Economic Dilemma* (1966); and WILLIAM JACKSON LORD, *How Authors Make a Living: An Analysis of Free Lance Writers' Incomes, 1953–1957* (1962). In nine west European nations, see FREDERICK DORIAN, *Commitment to Culture: Art Patronage in Europe, Its Significance for America* (1964). On the development and current status of legal rights of artists, see BRUCE W. BUGBEE, *Genesis of American Patent and Copyright Law* (1967); BORIS I. GOROKHOFF, *Publishing in the U.S.S.R.* (1959); GEORGE HAVEN PUTNAM, *Books and Their Makers During the Middle Ages*, vol. 2 (1897); HOWARD WALLS, *The Copyright Handbook of Fine and Applied Arts* (1963).

Art and Politics: There is no reliable survey of relationships between art and politics. Good examples of monographic studies of particular historic cases include: HUGH DALZIEL DUNCAN, *Culture and Democracy: The Struggle for Form in Society and Architecture in Chicago and the Middle West During the Life and Times of Louis H. Sullivan* (1965); DONALD DREW EGBERT, *Social Radicalism and the Arts, Western Europe: A Cultural History from the French Revolution to 1968* (1970); JAMES A. LEITH, *The Idea of Art As Propaganda in France, 1750–1799* (1965); GEORGE LACHMANN MOSSE (ed.), *Nazi Culture: Intellectual, Cultural, and Social Life in the Third Reich* (Eng. trans. 1966); JAMES L. PEACOCK, *Rites of Modernization: Symbolic and Social Aspects of Indonesian Proletarian Drama* (1968); HAROLD SWAYZE, *Political Control of Literature in the USSR, 1946–1959* (1962).

Art and religion: Relationships between religion and the various arts are comprehensively surveyed in GERARDUS VAN DER LEEUW, *Vom Heiligen in der Kunst* (1957; Eng. trans., *Sacred and Profane Beauty: The Holy in Art*, 1963). For sociological studies of religion and the visual arts, see the works of Abell, Francastel, Kavolis, and Sorokin listed above. Of numerous historical studies, G.G. COULTON, *Art and the Reformation*, 2nd ed. (1953); and JEAN GIMPEL, *Les Batisseurs de cathédrales* (1958; Eng. trans., *The Cathedral Builders*, 1961), are concerned with the effects of religion in organizing the arts, while HELEN GARDNER, *Religion and Literature* (1971); and ANDRE MALRAUX, *La Métamorphose des dieux* (1957; Eng. trans., *The Metamorphosis of the Gods* 1964), with the "spirit" of religion in art.

Art, technology, and science: A historical survey is provided in CYRIL STANLEY SMITH, "Art, Technology, and Science: Notes on their Historical Interaction," *Technology and Culture*, 11:493–549 (1970). On the impact of contemporary science and technology on the visual arts, JACK BURNHAM, *Beyond Modern Sculpture: The Effects of Science and Technology on the Sculpture of This Century* (1968), is more imaginative, but less balanced, than C.H. WADDINGTON, *Behind Appearance: A Study of the Relations Between Painting and the Natural Sciences in This Century* (1969). On the influence of science on poetry, see DOUGLAS BUSH, *Science and English Poetry: A Historical Sketch, 1590–1950* (1950); and MARJORIE NICOLSON, *Science and Imagination* (1956). A mythology substituting electronic technology for the spirit of religion has been elaborated in MARSHALL MCLUHAN, *Understanding Media: The Extensions of Man* (1964).

Art and education: The most influential recent prescriptions for aesthetic education have been JOHN DEWEY, *Art As Experience* (1934); and HERBERT EDWARD READ, *Education Through Art* (1943). For psychological studies of perception and imagination in art, see RUDOLF ARNHEIM, *Visual Thinking* (1969); and ANTON EHRENZWEIG, *The Hidden Order of Art: A Study in the Psychology of Artistic Imagination* (1967). The utopian and the analytical dimensions of aesthetic philosophy may be illustrated by HERBERT MARCUSE, *Eros and Civilization: A Philosophical Inquiry into Freud* (1962); and RALPH A. SMITH (ed.), *Aesthetic Concepts and Education* (1970). See also *The Journal of Aesthetic Education* (quarterly).

(V.Ka.)

Arts, Style in the

Definitions of "style"

Like much of the vocabulary of aesthetics, the word "style" resists straightforward definition. The word may point to little more than a mode or form of artistic production; or it can designate traits regarded simply as aids in the task of dating, grouping, and attributing works of art; it can imply skill, grace, or some other sort of excellence; it can mean a manner sanctioned by a standard; it refers to a mode, form, manner, tone, theme, subject, or quality—or a combination of such—that is felt to be characteristic enough to evoke a person, a group, a class, a nation, a place, a period, or a civilization; often also the reference is to features that are said to express an outlook, a doctrine, or a program. As a rule, even in the most carefully controlled context, several meanings will be present; and the tidy meanings will tend to bloom, or decay, into the untidy. Thus, although "sonata style," strictly constructed, should point only to a mode of musical production, in fact it will usually suggest a Classical outlook, the European 18th century, and perhaps the compositions of Haydn. Although to a field archaeologist "Late Helladic III" may designate merely a device for classifying pots of the ancient Greek city of Mycenae, in many imaginations the phrase is apt to inspire a vision of an entire culture, or perhaps of the legendary King Agamemnon bleeding in his bath after being murdered by his wife, as related in Aeschylus' tragedy.

The resulting confusion in thinking and talking about art is often deplored. One art historian likens style to a rainbow, a phenomenon of perception governed by the coincidence of certain physical conditions, which vanishes in the attempt to approach it. Another scholar takes the view that an adequate theory of style awaits a deeper knowledge of the principles of form construction and expression and a unified social theory comprising the practical means of life as well as emotional behaviour.

Such comments have not, however, had much effect; the majority of artists, critics, historians, and ordinary appreciators have continued to employ, loosely but confidently, the familiar term. And this persistence is not indefensible. Rainbows, after all, do exist; the chaser who fails to catch one demonstrates nothing except a mistake about their mode of existence. Also, in talking about art one can always cite the principle, first enunciated by Aristotle, that every study has its own degree of certainty and that a well-educated man will not ask for an unsuitable degree.

With that principle as a point of departure, this article will undertake to expand and combine the several meanings of "style" into a discussion of the inner nature, the varieties, and the dynamics of the phenomenon as it manifests itself in all the arts. (By "dynamics" will be meant the patterns of movement and change that are the concern of style-conscious historians and biographers.) Although the expression of personal opinions will be unavoidable, an effort will be made to present the current state of each question as that state was manifest in the 1970s and to stick closely to accepted usage; the aim will be mostly to discover what the commonly used terms actually mean and only occasionally to suggest what they ought to mean. The whole discussion will be on the level of a general theoretical introduction; material from the history of art and the history of aesthetics will appear only in the form of examples intended to provide clarification and some historical perspective. For full treatment see also RELATED ENTRIES under ARTS, STYLE IN THE, in the *Ready Reference and Index*.

This article is divided into the following sections:

I. The nature of style

General suppositions

It is easy to suppose that present notions about the nature of style are as old as the human ability to perceive differences, and a sampling of reasonably ancient cultural activity can seem to confirm the supposition. Much of the history of Chinese painting, for example, seems unthinkable without something like a modern critical apparatus for sorting out the dynastic periods, the local schools, and the copiers of venerated masters. It is almost impossible to imagine that the ancient Greeks were not thinking of style when they noted the differences between Doric and Ionic orders in architecture. The way in which ancient Athenians contrasted the "rational" sound of the stringed cithara and the "irrational" reed-pipe wail of the aulos suggests the distinction between classical and romantic styles that was made in the 19th century, and the parodies of the tragic dramatist Euripides by the Athenian comic playwright Aristophanes imply modern conceptions of a personal style. Much of what is now called stylistics seems to have existed already in the long succession of ancient Greek and Latin treatises on rhetoric. In sum, examples from both East and West can seem to support the assumption that there has always been something that may be called style.

INVENTION AND DISCOVERY

That "seem," however, needs very heavy emphasis, for some unexpected facts lie below the surface of the sort of sampling that has just been cited—facts that are open to more than one interpretation, but certainly not wide open.

Historical background. The admirer of Chinese painting who consults the old texts on the subject will find illuminating accounts of brushwork and much wisdom about the creative process but practically no discussion of style in the full modern sense of the word. In Indian aesthetics since ancient times, the doctrine of *rasa* (Sanskrit: "essence") has been used in reference to the flavour or sentiment of works of art and to the modes of affective response to them, but not to what is properly called style. In the West, ancient writers on art exhibit a similar and finally rather enigmatic failure ever to focus squarely on the subject. Linguistic evidence, while inconclusive, suggests that in the Greco-Roman world there was no word that meant quite what is now generally meant by "style."

Vitruvius, the Roman authority on architecture, writing sometime during the 1st century BC about the Doric, Ionic, Corinthian, and Tuscan orders, avoided even the Latin word *ordo* ("arrangement") and contented himself with *opus* ("work") and *genus* ("kind"). The Greek traveller Pausanias, writing about the visual arts in the 2nd century AD, used *kataskeuē* ("device" or "method of fit-

ting out") and *ergasia* ("work"). Among writers on literature and rhetoric a parallel tendency is apparent. Speaking of the style of an author, Aristotle was likely to refer simply to *lexis* ("speech" or "word"), and he was also likely to be talking merely about lucidity. The unidentified Greek critic known as Demetrius, writing probably in the Hellenistic era, used *charaktēr* ("quality" or "mark"), but the noun carried overtones from the verb meaning merely to scratch or engrave. The anonymous Latin text called the *Ad Herennium*, dating from around 85 BC, used *figura* ("figure"). A generation later Cicero used an arsenal of terms that included, with greatly varying degrees of precision, *figura*, *color*, *habitus* ("condition," "character"), *dictio* ("diction"), *elocutio* ("elocution," in a very general sense), and *genus*.

"Style" and *stilus*

Only in Late Latin does *stilus*, the word for the sharp-pointed instrument for writing, usually on wax, begin to mean also a manner of writing, as "pen" now does in such expressions as "a fluent pen" and "an acid pen"; and even here modern readers must be alert, for the derivation of English "style" from *stilus* does not prove that *stilus* always meant "style." The Latin term was reserved entirely for discussions of writing and speaking and usually for treatises on rhetoric; moreover, it seems to have implied little more than style in the sense of a skill or grace, and of a manner sanctioned by a standard. Apparently an author or orator in the closing years of the Roman Empire, in the 5th century AD, could have a periodic, loose, effective, ineffective, elevated, elegant, plain, high, middle, or low *stilus* but only very exceptionally, if ever, an idiosyncratic *stilus* that expressed a personality. And, again apparently, an architect, painter, sculptor, or musician could not have a *stilus* at all.

No important change in the usage thus established can be detected during the European Middle Ages. Words that suggest a kind, category, or mode of artistic production continued to be used in contexts in which a modern critic or historian might think in terms of a characteristic or expressive manner, or style. In architecture and the other visual arts, *opus* continued to be favoured; the French Gothic style of building was called Opus Francigenum, and English-style embroidery was know on the Continent simply as Opus Anglicanum. In music, the stylistic change apparent at the beginning of the 14th century, especially in France, was referred to as a new art: Ars Nova. The Latin *stilus*—and eventually its derivatives in other languages—was used only for talking about writing and speaking, and normally in the old rhetoricians' sense of a nonpersonal style sanctioned by a standard. When Dante (*Purgatorio*, xxiv) refers to the *dolce stil nuovo* ("sweet new style") that appeared in Italian poetry at the end of the 13th century, he stresses the importance not of the authors' personalities but of making the manner suit the matter and the occasion. The Host in Chaucer's *Canterbury Tales*, of the late 14th century, has this sense in mind when he addresses the Clerk of Oxford, in the prologue to the latter's tale:

> Your termes, your colours, and your figures,
> Kepe hem in stoor till so be ye endyte
> Heigh style, as whan that men to kinges wryte.
> Speketh so pleyn at this tyme, I yow preye,
> That we may understonde what ye seye.

In Renaissance Italy a shift in attitudes is apparent. Giorgio Vasari, for instance, in his widely influential *Lives of the Most Eminent Italian Painters, Sculptors and Architects* . . . (first edition in 1550, enlarged edition in 1568), built up a fairly consistent terminology on the basis of the word *maniera* ("manner"); his *maniera tedesca* ("German manner") refers to Gothic architecture, *buona maniera greca antica* ("good antique Greek manner") to ancient classical architecture, *maniera vecchia* ("old manner") to Byzantine or Byzantine-influenced painting, and *maniera moderna* to Renaissance architecture and painting. The *stilus* of the rhetoricians, *stile* in Italian, was still, however, reserved for literature. Not until around 1600 did musicians use such expressions as *stile moderno* and *stile rappresentativo*, and *stile* in criticism of the visual arts came still later.

In Britain, the equivalent extension of usage does not occur until the 18th century; the *Oxford English Dictionary* gives 1706 for the earliest reference to "style" in painting and 1728 for the earliest application of the term to music. Concerning the earliest English application to architecture there is some disagreement involving connotations, but a case has been made for a passage in Henry Fielding's novel *Tom Jones*, written in 1749: "The Gothic style of building could produce nothing nobler than Mr. Allworthy's house."

Earliest English usage of "style"

After that there was an era of the refinement of labels. A sharpened distinction between the art of ancient Greece and that of Rome began to be made in the 1760s. The division of British medieval architecture into Norman, Early English, Decorated, and Perpendicular styles dates from 1817. The term "roman" (Romanesque), referring to the architecture of western Europe before the Gothic, appeared in French criticism around 1820. Around 1850, "Rococo," after a career in slang, became a serious term for the fanciful style of the 18th century. The idea of the Renaissance as a cultural period, and not just an artistic movement, became fully-fledged around 1860. Definitions of the post-Renaissance styles of Mannerism and the Baroque were elaborated in the late 19th century. By the early 20th century, journalists were applying their own coinages to the styles discernible in modern painting and poetry.

Contemporary thought. The interpretation of the centuries-old mass of mostly semantic data on style is difficult and, for many people, exasperating. How is it possible to reconcile seemingly adequate perceptions of style throughout history with the long lack of adequate terms for it? How can the apparently adequate term, *stilus* or a derivative, be reconciled with inadequate perception of what it now connotes? Assuming that Chaucer's pilgrims reached their destination, what did the Host, familiar as he was with the figures and the high style of the rhetoricians, think when he was confronted by the Frenchness of Canterbury Cathedral?

Retrospective interpretations

Some historians have taken the easy course of assuming that when their ancestors used such words as "kind," or "work," or "speech" in certain contexts they somehow actually meant not what such words normally meant but what is now meant by "style." When *stilus* or a derivative was used, according to these historians, it somehow actually meant not what the rhetoricians meant but what is now meant in references to the composer Igor Stravinsky's or the novelist Ernest Hemingway's personal style. More rigorous minds have decided that style, viewed in the perspective of linguistic and general cultural history, is a will-o'-the-wisp. The majority of scholars, however, to judge from published essays, are reluctant to tamper with the evidence or to indulge themselves in a comfortable skepticism. They might therefore agree with the position that will be adopted in this article, which is that style in the arts is to a considerable extent a discovery, and to a large extent an invention, of a surprisingly late date.

Like many another cultural invention-discovery, style had a basis in human behaviour, but the distance between an ordinary ability to recognize things and what is meant by style in the arts is about as great as the distance between ordinary human memory and what is meant by history. Again like many another invention-discovery, style had a long phase during which some important levers and gears were already in place and more or less functioning. But the main job of assembling and powering the apparatus has been done since the end of the Middle Ages. Contributing to this development were Renaissance ideas of the importance of the individual personality, as opposed to medieval collectivism; 18th-century ideas of order and taxonomy in the natural sciences; and 19th-century ideas of biology, history, and, of course, aesthetics, all of which provided analogues for stylistic perceptions. The inventing and discovering are still going on, with much help from the experiments of artists and from such disciplines as archaeology, anthropology, psychology, sociology, and linguistics.

To talk of the nature of style in these terms is to raise some difficult philosophical questions, ranging from those

Philosophical questions on the nature of style

posed by ancient thinkers down to those of recent logicians. For although in practical affairs it may be willingly granted that every invention is to some extent also a discovery and that every discovery involves some invention, the fact is that the word "invention" implies one sort of being and the word "discovery" quite another sort. Moreover, by a curious reversal of what happens in many inquiries, the philosophical questions that are thus raised for art critics, historians, and appreciators tend to be less pressing in regard to style as a concept or a collective noun than to style as it is actually experienced. People speculate calmly, if at all, about the nature of their comprehensive stylistic assumptions and become heated about the alleged reality or unreality of the style of the 19th-century French sculptor Rodin or of the *style galant* in 18th-century music or of the style of the Renaissance.

Can anything useful be said in this realm? Certainly any attempt to deal thoroughly with the issues would lead far beyond the scope of this article and deep into problems for which professional philosophers have not yet found accepted solutions. But it seems legitimate to confront antistyle "realists" with the suggestion that a style is no less real, or no more unreal, than a work of art, which is also a kind of invention-discovery, and to add that this degree of certainty is all that a well-tutored man should expect. Works of art can be, among other things, physical objects, imaginary objects, enduring possibilities, realized possibilities, sensible phenomena, insensible phenomena, sheer processes, and even, according to respectable opinion, transcendental entities. They can also have—and this is important to the argument—what has been called an emergent mode of existence and might be called a "do it yourself" mode; a picture, for instance, emerges from the blobs of pigment on a canvas when the viewer steps back and perhaps squints, and a symphony emerges from blobs of sound in the same way. All these modes of existence, and the emergent in particular, can be found among styles. Rodin's style emerges when a sufficient number of his works are contemplated from a certain psychic distance, and it is also a bronze entity in one of his statues of Balzac. The *style galant* emerges from compositions by Bach's sons, and it is also in a single Mozart serenade, which itself exists on paper, in performances, and, above all, as an enduring possibility. The Renaissance style, according to the scholar Arnold Hauser, "is at once more and less than what has actually been expressed in the works of the Renaissance masters. It is something like a musical theme of which only variations are known." In short, it is probably most usefully thought of as having an emergent mode of existence.

All this might be summarized by remarking that the process of invention and discovery that produced the general notion of style over a period of centuries is constantly being recapitulated by individuals, sometimes over a period very brief indeed, for particular styles. From this, one might hastily conclude that practically anyone can invent-discover what will pass unchallenged as a style; and anyone acquainted with modern art scholarship and art publicity must grant that there is a measure of truth in the conclusion. But in the long run, of course, there are certain limits to what can pass as style, just as there are certain limits to what can pass as a work of art; eventually opinion accumulates to the effect that the invention-discovery in question does not work well enough, or is simply not important enough, to qualify for the standard label. The annals of archaeology in Latin America and the eastern Mediterranean are strewn with styles that broke down, often after extensive repairs by their inventors. And, in fact, the world's major accepted styles turn out on examination to have more rigour and clarity in their nature than might be supposed. They have a number of recurring features that can be extracted and combined so as to constitute a working model of style, a sort of metastyle, that can be used for dealing critically with new labels.

PRINCIPAL ASPECTS OF STYLE

These recurring features can be grouped and considered under the headings of value aspects, poietic (or creative) aspects, morphological (or formal) aspects, metaphorical aspects, polar aspects, and measurable aspects. The word "aspect" is preferable to "feature" or "element" or some other possibility, for it must be kept in mind that a style is an invention-discovery with several modes of existence. Moreover, in each instance, what is being talked about is likely to be affected by the different viewpoints of producers, consumers, historians, critics, and other observers.

Value aspects. The first group on the list is logically defective, since all the other aspects have value aspects, but it is important enough to merit some separate preliminary treatment. That styles are regarded as desirable is evident from common usage. Merely to say that an artist, a work, or a period has style is to judge him or it favourably; merely to use "style" in preference to such words as "manner" or "fashion" is to imply value; even to say that a thing is in a poor style is often to suggest that it does not have enough style. And that styles are actually worthwhile is difficult to doubt. They provide the art appreciator with the pleasure of recognizing somebody or something, a pleasure that is certainly among the basic ones of human existence: witness the popularity of handbooks that tell how to distinguish Tang from Sung styles in Chinese art or Louis Quinze from Louis Seize in French art. Styles provide the artist with the pleasure of being recognized, and they do so without the self-display of a signature. They are like codes; in the language of information theory, they help obtain an invariant output from a variable input, and nearly all art history, which is a comparatively recent phenomenon, and much criticism makes use of them. They also have many less evident sorts of value. They function as the signs and, to some extent, as the agents of integration in individual artists, groups of artists, and sometimes whole cultures; they are brakes on alienation. They are appetizing and preservative, like spices; they have saved from oblivion a number of great minds whose ideas have lost their fascination. To cite only a few examples from British critical and historical literature, it is hard to imagine anyone still reading much of Dr. Samuel Johnson, Edward Gibbon, Thomas Babington Macaulay, Thomas Carlyle, or John Ruskin for content alone.

Evidence from common usage

These positive aspects are accompanied, of course, by some negative ones, and the latter have been worrying critics increasingly during recent decades. Since styles stress similarities and work partly as codes, they tend to blur differences and to simplify excessively; they encourage many viewers to see, for example, merely "a Picasso" or "Cubism" where one ought to see the rich uniqueness of a painting. The pleasure of being recognized, and the money that may come with it, can encourage some artists to develop a mere trademark. Successful period styles of the past may foster, as they did among 19th-century European architects, an absurd amount of eclecticism and fancy-dress historicism. Successful current styles can generate an equally absurd amount of imitation among artists. The difficulty of defining specific styles and style in general creates serious problems in art history, which will be discussed in the last section of this article.

Negative aspects

Do these negative aspects outweigh the positive? The majority opinion is clearly that they do not, for there is no prospect of a return to the supposed innocence of the centuries before the massive, intricate, dangerous, useful invention-discovery got up steam.

Creative aspects. One of the complaints, however, is very legitimate: it is that people who talk about style do so too often from the viewpoint of an appreciator. The same complaint can be made about art discussions in general; a good deal is heard, for instance, about disinterested contemplation, which is fair enough from an appreciator's viewpoint but close to wild calumny from an artist's viewpoint. The hardworking men who built the Parthenon were certainly not disinterested in any usual way, nor were John Milton in writing *Paradise Lost*, Michelangelo in painting the frescoes for the Sistine Chapel, Richard Wagner in composing the opera *Tristan und Isolde*, and Leo Tolstoy in creating *War and Peace*, and what they were doing can scarcely be called contempla-

tion. It was rather what the Greeks called *poiēsis* ("creation," or simply "making").

Style, then, has what can be called poietic aspects; the adjective brushes jargon but lacks the Romantic connotations of "creative" and the matter-of-factness of such an alternative as "productive." The existence of these aspects can be posited etymologically, with the risk inherent in arguing from dead metaphors; *stilus*, as has been noted, originally meant a writing instrument; and such near equivalents for "style" as "manner" (Latin *manuarius*, "of the hand") and "fashion" (Latin *facere*, "to make") also have clearly poietic pedigrees. Moreover, in some contexts "style" still means little more than a mode of artistic production.

But here an attempt to sharpen common usage seems called for, since a style in its poietic aspects is not the whole of an act of making. It is only the part of the act that represents a deviation from a norm and that, as such, is apparent enough to offer the pleasure of recognition. The norm may be provided by a more inclusive style, by a tradition, by material conditions, or by some other frame of reference within which artists work. It may also be assumed, more or less arbitrarily, by observers. Thus the personal style of the 17th-century Flemish painter Peter Paul Rubens is not, poetically speaking, the whole of his way of applying paint to canvas but merely that part of his way that constitutes a recognizable deviation from a norm—the Baroque style—in which he worked. The Baroque, to continue the illustration, is not the whole of the Baroque painters' ways of applying paint to canvas but merely the part of their ways that constitutes a recognizable deviation from another norm, the general style that prevailed in European painting from roughly the middle of the 15th century to the end of the 19th, though in many histories of art it is instead assumed to be the High Renaissance style as exemplified by Raphael.

The role of norms

One can conclude that style is dependent on originality and the will to exercise it. But much depends also on the norm. In the first place, many norms are imposed, sometimes by accepted authority, sometimes by social pressure, and most often by unawareness of an alternative; the average Western composer, for instance, between Bach in the 18th century and Schoenberg in the 20th, seems to have regarded the tonal-style norm—the organization of tones and chords in a composition in relation to a keynote—as something like a law of nature. In the second place, certain norms contain fewer variables than others and therefore offer fewer opportunities for deviation; a Byzantine mosaicist had no possibility of developing a marked personal style. And, finally, there are the supernorms constituted by each art, by artistic materials, by languages, and by much else; at this level the number of variables may be decisive. Traditional sculpture offers fewer variables than painting and hence has yielded a much smaller number of styles. Granite offers fewer variables than bronze and hence has what might be called a lower yield in terms of style. Specialists in stylistics—the branch of linguistics that studies the variables in a language and their manipulation—have noted that one of the secrets of the 20th-century Welsh poet Dylan Thomas's strongly personal style was his discovery of unsuspected variables in English: thus where the norm had seemed to insist on nouns of temporal, or linear, measurement he could write "All the sun long," "A grief ago," and "farmyards away." In "Spelt from Sibyl's Leaves," the 19th-century English priest Gerard Manley Hopkins showed a comparable talent for finding possibilities of deviation:

> Earnest, earthless, equal, attuneable, vaulty, voluminous . . . stupendous
> Evening strains to be time's vast, womb-of-all, home-of-all, hearse-of-all night.

Formal aspects. Much of the above might have been put under the heading of the morphological—or "formal," if certain connotations are ignored—aspects of style, and much that is traditionally morphological is equally poietic. The form of a work of art can be regarded as the record left behind by the making process; this idea, implicit in ancient rhetoricians' descriptions of prose and poetry (*e.g.*, as laboured), has been prominent in modern criticism since the appearance in the 1950s of such process-emphasizing accomplishments as Action painting, in which the brush strokes and textures may be regarded as a record of the creation of the work; aleatoric music, in which the notes or sounds are selected by chance; and Brutalist architecture, the sort that leaves the concrete raw and plank marked.

The making process, however, involves the whole work, whereas form may be regarded as excluding content and including only shape, volume, space, structure, pattern, organization, texture, rhythm, imagery, emphasis, balance, and the like. This separation is often denounced by careful critics, and a successful work of art, when contemplated in a properly focussed and expanded state of awareness, does indeed present itself with form and content organically tangled. But there is little likelihood that art appreciation suffers when things are untangled for discussion, since most persons are quite capable of distinguishing between the critical analysis of a work and actual aesthetic experience. So it seems safe to accept common usage concerning "form" and then to agree with commentators who have been assuming for centuries that style has purely morphological aspects—without joining them in assuming that it has practically no other aspects.

Separating form and content

Immediately an apparently drastic shift in emphasis occurs, from one of variables and deviations to one of repetitions and conformity. In fact, style can be reasonably, if incompletely, defined as constant formal elements and their combinations, with content excluded except in certain circumstances. But the shift in emphasis is obviously just a result of the play of aspects. A style is always generated by the manipulation of available variables in such a way as to yield a recognizable deviation from a given or an assumed norm. If, however, the deviation is to be recognized as something more than an accident or a solitary impulse, it must be repeated, either identically or in a recognizable variation. It must become understandable, which a unique event—an accident—cannot be.

Thus a style is always, when perceived from what can be called the poietic stance, rather surprising; the Baroque norm and the English-language norm do not lead to any expectation of Rubens' fleshly swirl and Thomas' "A grief ago." But thus also a style is always, when perceived from the morphological stance, rather familiar; what was unexpected in terms of the act of making becomes expected in terms of form. Again the illustration can be continued above the level of personal style: the energized masses found in Baroque painting of the 17th century are constant in their deviation from the balance of High Renaissance paintings of the 16th century. In sum, an artist, or a group of artists, is obliged by the nature of style to move freely into constraint, and heretically into orthodoxy.

Metaphorical aspects. Hence certain styles are commonly said to be "characteristic," or "expressive." An aesthetic deviation, repeated sufficiently, may become converted into a form and yield recognition pleasure. The result may fairly be described as a manifestation of personality. The flame shapes in El Greco's paintings may be thought of as a handwriting, Bach's driving rhythms as a gait, Proust's long sentences as a voice; and usually no harm is done to understanding.

Such metaphors, however, along with the words "characteristic" and "expressive," can become whimsical or misleading in many situations. Moreover, the stylistic aspects in question are best perceived in depth and in the aggregate by noticing that nearly every style is itself a metaphor, functionally speaking. It implies, as Aristotle said a good metaphor does, an intuitive perception of the similarity in dissimilars. It works, as an ordinary simile does, by seizing striking likenesses and neglecting differences; to see that the 18th-century English poet William Cowper wrote in a Miltonic style resembles, as process, seeing that Robert Burns's sweetheart was "like a red red rose." There is a substitution of a part for a whole, as in synecdoche; in many eyes a pointed arch and a flying buttress are enough to evoke the Gothic style, and for many ears a single chord can summon up Beethoven.

Similarity in dissimilars

Most importantly, in nearly every stylistic context, and not just in those involving personal and "characteristic" styles, there are two sections, like the two sections in the comparing process of metaphor; these can be thought of as the "window" and the "view." In the simplest situations the view through the window of the style is of an individual artist, or of a well-defined group; the 19th-century French poet Stéphane Mallarmé may be sensed through his repetition of the word *azur*, and the contemporaneous group of Impressionist painters that surrounded Claude Monet are recognizable through their deviant, flickering brushwork. The situation, however, is seldom quite that simple. Through Mallarmé's style as well as through Impressionism the view may be of a doctrine or a program; in other situations it may be of a class, a nation, a place, a period. There are styles that bear a functional resemblance to myths, if the latter are thought of as communal metaphors. The view that looms through the symmetrical frontality of the rigidly posed figures in ancient Egyptian sculpture is of an entire culture, a culture that is dramatically different from the one that looms through the asymmetrical twist, the contrapposto, of figures in Italian Renaissance statues.

These remarks have to be qualified, for if common usage is accepted there are styles that seem to have no metaphorical aspects, that are practically opaque. Possible examples are procedural styles in general: those described by the ancient rhetoricians, those associated with the fixed forms of music and poetry, those that are just simplifications, often geometrical, of natural forms.

Polar aspects. Common usage also provides evidence for the existence of certain structural or self-defining tendencies in style that can be grouped under a single heading as polar aspects. These have long been noticed; Hellenistic and Roman literary critics have a lot to say about the flowery, redundant oratorical prose known as Asiatic, which is presented as the diametrical opposite of the plain, economical Attic. The invention or discovery of such polarities did not get seriously under way, however, until the 18th century in western Europe; and most of it has been accomplished, mainly by German thinkers and largely in the visual arts, since the late 1800s.

Among the great number of such contrasting pairs that could be mentioned are haptic–optic (*i.e.*, oriented to the sense of touch as opposed to sight orientation), idealistic–naturalistic, multifarious–unitary, closed–open, linear–painterly, and many more. It will be noticed that the trend is toward all-inclusive world styles, or at least toward constantly recurring stylistic features, and that the emphasis is strongly on morphological aspects. This emphasis, although open to the usual objections to "formalism," has compensated handsomely, in terms of instrumental value, for the sometimes naïve scientism and general overconfidence implicit in the labelling. Indeed, it is not an exaggeration to say that the best visual-art criticism and history published since World War I could not have been written without the help of polar analysis of form.

Applicability of polarization

But pairs like the rather abstruse ones mentioned are not the whole story. Any style, including the familiar established ones, may be polarized; the 19th-century French painter Delacroix's Romantic style may be paired with his older contemporary Ingres' Neoclassical style, the Gothic with the Renaissance, the French with the English, the Christian with the Islāmic, the Eastern with the Western. Each member of each pair is defined in terms of what the other member is not; each is at once the deviant from the other and the norm for the other. Often in such pairs the forms are not seriously analyzed; mere diametrical opposition, as in traditional political parties, is felt to be enough. This peculiarity may be especially evident in connection with a modern style, which is always polar to begin with and which may stay that way until in its turn it begins to cease to be modern. Only then may historians have a good chance to cut through the partisan propaganda, get at the constant forms, and decide if the style is internally consistent enough to merit a label of its own and a place in the parade that began some 40,000 years ago.

Measurable aspects. The historian who undertakes such a task is not likely to approach the constant forms with a yardstick, for in general the measurable aspects of style are not very highly considered by artists and art critics. But such aspects do exist.

The differences between Doric and Ionic orders in classical architecture are not only in the abacuses and volutes that decorate the columns and their capitals but also in proportions and in the number of flutes on a column. The 20th-century French architect Le Corbusier performed his subtle manipulation of architectural variables with the help of a system of proportion, which he called the *modulor*, based on the human figure. Sculpture styles were influenced for centuries by the canon (now lost) of Polyclitus, a Greek sculptor of the 5th century BC who believed that "the beautiful comes about little by little, through many numbers." In a portrait in the Mannerist style of mid-16th-century Italy, much of what makes it Mannerist may be a matter of how long the body is. Some of Hogarth's pictures can be analyzed in terms of what he called "the line of beauty," obtainable by winding a "precise serpentine line around the figure of a cone." Painters of the 20th century have revived the interest Renaissance artists had in the proportion (about 8:13) known as the golden section. An important part of the stylistic difference between a movie director of around 1930 and one of around 1970 may be discovered by simply noting the smaller number of camera shots and sequences used by the latter. Styles in poetry can be specified, often with surprising results, by counts of images, rhymes, run-on lines, and metrical variations; and such methods are accurate enough to help date Shakespeare's plays. Prose styles are, for certain modern linguists, a matter of the statistical averaging of the use of certain words, performed with the help of a computer. That musical styles have measurable aspects has been clear, of course, since at least the time of Pythagoras, who discovered in the 6th century BC the relationship of musical intervals to the lengths of strings; and the fact has become freshly clear under the impact of 20th-century science and technology. Computers have become standard equipment for many composers; synthesizers have become generators of styles translatable into mathematics; Beethoven's poietic deviations from a norm have turned out to be quantifiable in somewhat the same way as the unforeseeables studied by information theorists.

Qualifications on quantification

Some qualifications are in order. The analysis of a style is not the same as the experience of a style: the whole of a work of art is certainly not the sum of its measurable parts. While it may be true that under certain conditions quantity turns into quality, it does not follow that every quality can be quantified; and certain conditions—Beethoven's genius, for instance—remain to plague the quantifier. But all this does not alter the fact that styles do have certain measurable aspects. Nor does it excuse the neglect of these aspects by some art appreciators, critics, and historians. Perhaps the remedy both for the shortcomings of the quantity-minded and for the attitude of the quality-minded will eventually be found in interdisciplinary work on aesthetic problems.

II. The varieties of style

Since it is part of the nature of style to provide recognition pleasure, and since this pleasure is usually accompanied by an irrepressible impulse to name, one can suppose that unlabelled styles are rare. Would that they were not, an archaeologist may say; would that there were an opportunity to classify works of art scientifically and to substitute numbers or New Latin labels for such misnomers as "Gothic" (which is unrelated to the Goths) and "Cubist" (which has little to do with cubes). Actually, however, the downright mistaken or merely derisive labels are neither very numerous nor very misleading; to anybody who knows enough to be interested, "Gothic" is likely to mean something like "Medieval West European III," and "Cubist" something like "genus, partly abstract; species, Picasso–Braque 1907–14." And if the majority of style names are not scientifically descriptive, they do as a rule offer adequate clues not

only to the thing being talked about but also to the class, or classes, to which the thing belongs. In other words, the familiar nomenclature, although accumulated apparently haphazardly through the centuries, has taxonomic—more precisely, typological—implications. To speak of Rembrandt's style is not only to refer to certain poietic deviations from a norm and to certain recurring formal elements; it is also to imply the existence of a personal variety of style plus a more general sort that includes the personal variety. To speak of a realistic style, or of one of its several polar opposites, is to imply a different variety and a correspondingly different general sort.

When such implications are grouped, they yield some 13 varieties of style in the arts. (The "some" is inserted here to allow for reasonable differences of opinion as to where the dividing lines should be drawn.) These 13 varieties are clearly of two general sorts, which emerge from two types of "view" beyond the metaphorical "windows" that styles create in a sufficiently knowledgeable imagination. The first general sort, to which Rembrandt's style belongs, affords views that focus on single cultures; the second sort, to which a realistic style may belong, affords views that cut across cultures. It will be noticed that a given style may move from one category to another; more will be said later about this mobility. But most styles are reasonably stable, and for the moment it is convenient to assume that the others have certain recognizable home categories. Even a slightly unstable classification can stiffen discussion.

Two types of "view"

SINGLE-CULTURE VARIETIES

Single-culture styles are usually inhabited, so to speak. They usually evoke, more or less in the foreground of the contemplating imagination, either a person, a school, a social class, an ethnic division, a regional community, a nation, an ecological division, a religious community, or the generations that constitute a period. Rembrandt's style usually evokes the bulb-nosed, sad-eyed person known through dozens of remarkably self-searching self-portraits; the Venetian style usually evokes the 16th-century masters Giorgione, Titian, Tintoretto, and Veronese; each style in African sculpture usually evokes a tribe; and so on down the list. Single-culture styles are therefore frequently said to be "characteristic," or "expressive," of a particular people; and in this context these familiar terms of interpretative art criticism may seem to triumph over the mild objection raised earlier, in the discussion of the general metaphorical aspects of style. In fact, these adjectives, and also the noun "people," raise some awkward problems even here.

Personal styles. No variety of style seems, at first thought, quite as vividly, specifically, indubitably inhabited as the personal variety. Quoting the celebrated and seldom-read *Discours sur le style* (1753), by the Comte de Buffon, and neglecting his qualifying remarks, many appreciators assume confidently that "the style is the man himself." In a somewhat modified form, the same assumption can be found as far back as the 1st century in the Stoic moralizing of the Roman philosopher Seneca. In a somewhat pseudoscientific form it has produced some disturbingly glib psychoanalysis of works of art. In its plebian form it has led to such suppositions as that the flame shapes in El Greco's paintings are evidence of astigmatism, the long sentences in Proust's novels evidence of asthma, the rhetoric of Liszt's piano pieces evidence of Gypsy blood, and the right angles of Mies van der Rohe's architecture evidence of a subtle totalitarianism. The notion may be said to have reached one of the peaks of its career in 1935 in the earnest excogitation of the literary scholar Caroline Spurgeon; after counting and sorting Shakespeare's images, she concluded that the poet was

Style and the man

> a compactly well-built man, probably on the slight side, extraordinarily well coordinated, lithe and nimble of body, quick and accurate of eye . . . probably fair-skinned and of a fresh color, which in youth came and went easily . . . very sensitive to dirt and evil smells . . . gentle, kindly, honest, brave and true.

She also saw, through the obviously wide-open window of the personal style, a man who at 35 had "probably experienced heartburn as a result of acidity."

It is easy to call this sort of interpretation wrong and not easy to explain exactly why it is wrong. After all, everyone indulges in it to a degree. Miss Spurgeon, of course, went a bit too far; she was neglectful of complexity and of the possible differences between a dramatist and his personages. But her counting and sorting of images was a valuable and influential piece of research; it demonstrated, in an irrefutable way, the existence of some of the deviations and constants that make up Shakespeare's personal style. If the person who is certainly recognizable in this personal style is not quite the Stratford man himself, who is he?

When the question is asked about a large enough number of personal styles, a tentative answer may emerge. The style, it appears, is not the man himself but the artist himself—mostly, at least. Naturally, the artist is to a considerable extent the man; he has much of the latter's native capacities, acquired skills, secret drives, and painful defects. But the artist is a professional role, a programmatic personage, a cultural configuration, a persona; in sum, he is a remarkably, often deliberately, synthetic personality. Further, he is conditioned by much besides the man himself and notably by the work of other artists. To put all this another way, every personal style is in part sheer performance, and every artist as such is in a sense (not a pejorative one) a performer. Mies the man went on living in his relatively old-fashioned Chicago apartment, while Mies the artist was "performing" with gleaming right angles in the tall apartment buildings he designed for Chicago's fashionable Lake Shore Drive; Mozart the man disliked flute music, while Mozart the artist "performed" by composing flute music; Petrarch himself philandered, while Petrarch the poet "performed" as a faithful worshipper from afar of the idealized Laura.

The person and the performer

Hence, in the opinion of many modern critics, the once-popular problem of personal stylistic sincerity is meaningless; to pose it is to mistake art for life. Hence also the distinction that is often made between creative personal styles and performing personal (or group) styles should not be too categorical. Although a dramatic text, a musical score, or a notated ballet may seem to constitute a norm that offers a very small number of variables, in practice a competent actor, musician, dancer, conductor, or director usually manages to produce enough deviations to have an easily recognizable personal style. No opera-record collector is likely to confuse an interpretation by the intensely dramatic soprano Maria Callas with one of the same role by the serenely lyrical soprano Renata Tebaldi; and ballet literature suggests that the ethereal 19th-century ballerina Marie Taglioni was as different from her rival the sensuous Fanny Elssler as the 19th-century Italian operas of Vincenzo Bellini were from those of his contemporary Gaetano Donizetti. Moreover, an interpreter has about the same choice as a creator among the more inclusive styles that can always be recognized simultaneously with a personal one; he can be modern, traditional, Classical, Romantic, Baroque, or whatever. And finally, if he tries to be as faithful as possible to his text, the result will approach another personal "performing" style, that of the artist who composed the work. To succeed in producing *Phèdre* exactly as it was conceived would be to play the player Jean Racine.

These remarks should not be interpreted as a complete denial of the presence of "the man himself" behind a personal style—into the polar opposite of Miss Spurgeon's error. Since the artist is partly conditioned by the man, so, of course, is the style; and stylistic evidence can often be made to match biographical information in an enlightening way. Friends of Mies noticed in his manners and dress a certain fastidiousness and a love of good material that reminded them of his architecture. The reported simplicity, honesty, and modesty of Haydn are an agreeable match for qualities in his musical style. Most readers probably sense an authentic personality, a real voice, behind the sprung rhythm and breathless rush of the verse of Hopkins. Also, some quite successful methods of sty-

listic analysis apparently depend on a strict correspondence between the manner and the man himself; a fascinating example is the technique for attributing paintings, developed by the Italian art critic Giovanni Morelli in the 19th century, which assumes that the touch of a particular master can best be detected in unimportant details, such as the ears in a portrait, that were presumably painted without taking much thought.

None of the counter-evidence, however, seriously shakes the argument that the person in a personal style is mostly the artist as such, and some of it does not stand up very well under scrutiny. Fastidiousness, simplicity, and vehemence do not become meaningful in this context until they are given energy and focus by the artist; and the telltale details used for attributing paintings may have about as much aesthetic interest as fingerprints.

School styles. When artists are considered as a stylistic group, or school, all the problems raised by personal styles reappear in new guises in the company of other problems; and one of the more nettling of the latter is the precise meaning of "school." For there is no denying that this part of the apparatus of criticism has got badly out of hand since its invention and discovery in the 18th century (largely by the pioneer Italian archaeologist Luigi Lanzi). Art critics, historians, and especially painting-museum curators have acquired the habit of using the term as an elegant variation for what usually turns out to be merely a country of residence; thus J.M.W. Turner is said to be a painter of the British school and Thomas Eakins of the American school. Sometimes the geographical designation is narrowed, with a commensurate gain in stylistic information; thus Mantegna is said to belong to the North Italian school and Perugino to the Umbrian school. The gain, however, may be in confusion; the division between the so-called Northern and Southern Sung schools of Chinese painting, for example, has been called the most misleading and arbitrary in art history. Sometimes geography is abandoned for a general stylistic designation; thus the 18th-century French painter Jean-Baptiste Chardin is said to belong to the Realist school. Sometimes the stylistic designation is narrowed drastically, and then a gallery visitor may be confronted by a brass plaque attributing a 15th-century Florentine painting to the school of Fra Angelico, for instance; this can mean that documents point to the studio or to a follower of Fra Angelico; or that the picture is an ancient, and therefore respectable, copy; or that it looks rather like a genuine Fra Angelico without his customary quality—the unstated premise being that all pictures by Fra Angelico are first class.

The meaning of "school"

The situation is regrettable not only because one word is being forced to do things other words can do better but also because "school" has its own work to do. Musicologists can profitably use the term to talk about the centres of musical activity that existed in the 12th century at such places as Paris, Compostela, Padua, and Winchester; or about the late-16th-century amateur "academy" known as the Florentine Camerata, in which the monodic style that led to opera was fostered; or about the group of composers of atonal music that surrounded Arnold Schoenberg in 20th-century Vienna. Painting historians must refer to the Tours school of Carolingian miniaturists, the Shen Chou school of 15th-century Chinese ink artists, the Barbizon school of 19th-century French landscape painters. Literary historians must consider such schools of poetry as those of the 16th-century French Pléiade, the English Lake poets of around 1800, the Tokyo (then Edo) haiku masters of the 17th and 18th centuries, the American Imagists of around 1914. Even architectural historians, who tend to think in large units, have to take account of such phenomena as the Burlington group of Palladianists in 18th-century London, the Glasgow School in the 19th century, the slightly later Chicago School, and so on. Each of these examples, and of the hundreds of others that could be cited, involves a well-defined and usually not large geographical area, a relatively short time span, and a relatively small number of artists working in a describable shared style; here are the essential requirements for using the term "school" profitably. Of course, a curator, in announcing that Turner is of the British school, may really intend to commit his museum to the proposition that a nationally shared painting style has been perceptible in Great Britain down through the centuries. Such is not usually the intention, however, and when it is, it should be made explicit.

The confusion is worth dwelling on because in many works of art a school style, defined as the shared style of a relatively small number of artists, is as striking as a personal style. It is a "window" that affords a "view" inhabited by a synthetic personality, a programmatic personage, almost (but not quite) vivid enough to justify thinking in terms of something like an overartist, as some German philosophers have. Moreover, in the interaction between a personal style and a school style, there is a model, manageable for study, of the complex relations that emerge when several styles are found together in a given work. The personal style of John Donne, the 17th-century English poet of the Metaphysical school, is recognizable in the dense, macabre imagery, the sometimes violently wrenched metre, and the self-dramatizing switch of the following lines from his "Nocturnall upon St. Lucies Day, being the shortest day":

Interaction of artist and school

> The world's whole sap is sunke:
> The generalle balme th' hydroptique earth hath drunke,
> Whither, as to the beds-feet, life is shrunke,
> Dead and enterr'd; yet all these seeme to laugh,
> Compar'd with mee who am their epitaph.

At the same time, the style of the Metaphysical school is apparent in the rather conversational tone, the compact syntax, and the use of extravagant poetic conceits. Deviations and a norm solicit attention, and the solicitations will multiply if the recognition process is continued into the maze of styles—the Elizabethan, the Jacobean, the English, the religious, the aristocratic, the Mannerist, the formal, the haptic, etc.—which a sufficiently subtle and patient critic may discover in Donne's poetry. The common reader, in Dr. Johnson's sense, can be excusably irritated at a certain point by the game of hide-and-seek between the different and the same, the self and the other. But, in fact, such simultaneous recognitions are normal in the actual experience of art; and they are no more mysterious than recognizing, with confidence and usually without being able to say exactly why, that a given face is of an individual, a family, a region, a nation, and a race—is at once itself and not itself.

Social styles. On a scale of recognizability, many critics would probably put social styles—those associated with a particular class or section of society—directly after personal and school styles, at least when much of the art of the centuries before the Industrial Revolution is being considered. Even an untrained appreciator can sense courtly styles in the intricate fixed forms of troubadour verse, the stiff etiquette of a Louis XIV portrait, and the languors of medieval Japan's *Tale of Genji*, by Murasaki Shikibu; bourgeois styles in the solid forms of 17th-century Dutch still-lifes, the uncomplicated rhythm and harmony of a Protestant hymn, and the matter-of-fact, 18th-century English prose of Daniel Defoe; and peasant or proletarian styles—often more accurately described as traditions—in songs, carvings, and embroidery. In the 20th century such clear-cut social styles have become less and less noticeable, partly because class distinctions have become much less evident in the technologically more advanced nations. Also, artists have ceased to know for whom they work, the art market having replaced, except on special occasions that are most frequent for architects, the old system of direct commissioning by patrons. Nevertheless, a sophisticated, or merely mischievous, critic can point to contemporary social styles; some evoke the established families, others the new millionaires. A number are related to young people, who since the 1960s have exhibited many of the economic and cultural characteristics of a separate class. Politicians in all countries throughout the 20th century have occasionally attempted, sometimes on a totalitarian scale, to impose on artists one of the old courtly or bourgeois styles; and a few dictators, notably Hitler and Mussolini, have temporarily revived an imperial-court style with the par-

Tradition and class distinction

venu touch, familiar to art historians in such outsized forms as those of Darius's palace at Persepolis in ancient Persia and Napoleon's church (originally temple) of the Madeleine in Paris.

Here two concessions seem called for. The first is that in talking about social styles it is often impossible, even for the purpose of cold analysis, to keep morphological aspects separate from content. The second is that throughout history the artist as such has been remarkably, sometimes depressingly, available for the "expression" or "characterization" of a social stratum other than that of the man himself. Perhaps the artist as such—shaman, bard, craftsman, entertainer, 19th-century demiurge, 20th-century iconoclast—has been rather more of a performer than has already been suggested.

Ethnic styles. Like social styles, ethnic styles have become less noticeable in the modern era. Their formerly high level of recognizability, their complex morphological aspects, and their surprising persistence over long periods have made them, however, favourite subjects for study among both archaeologists and aestheticians. Good examples are plentiful in the Indian arts of North America; the sculpture, painting, and music of black Africa; the pottery of the ancient Middle East and east Asia; and the surviving decorated objects, mostly metalwork, of the so-called barbarian peoples who moved across Asia and Europe between roughly the 6th century BC and the time of Charlemagne, at the end of the 8th century AD. In some instances scholars have been able to trace the borrowing of motifs; the Germanic animal styles of the migration period, for example, show the influence of Roman figurative art and Mediterranean ribbon ornament. But the borrowed motif is invariably transformed by a repeated deviation into one of the morphological constants of the borrowing tribe, and the reasons for this enduring assimilative capacity are not well understood. The notion of a physically inherited stylistic disposition has long since been discredited, and archetypes in a collective unconscious, as postulated by the 20th-century Swiss psychologist Carl Jung, have been dismissed by the majority of professional historians. Among the more attractive theories are some that point to analogies with the inertia and the assimilative capacity of a language; yet even these seem inadequate before such a fact as that the Eskimo ethnic style has lasted for about two millennia. Another attractive theory links the lack of stylistic change to a general lack of history—or at least to a general lack of awareness of history. But if this theory is plausible in a North American or an African context, it is much less so in the context of the Asian and European migrating peoples, who managed to pass through an immense amount of history without making important changes in the design of their crowns, buckles, and other useful objects.

Theories of stylistic disposition

Regional and national styles. The problem of stylistic stability re-appears in the consideration of regional and national styles, which are partly just ethnic styles that have settled down. But they are always more than that. The high—and polar—recognizability of Oriental and Occidental styles cannot be satisfactorily accounted for by references to ancient tribes and by linguistic analogies; nor can the long preoccupation in the Mediterranean basin with human forms; the long preoccupation in northern Europe with animal, zoomorphic, fantastic, symbolic, and abstract forms; the rigidity of Egyptian pictorial and sculptural forms during some 3,000 years; the persistently emotional, romantic, and expressionist tendencies in German music, painting, and literature; the French emphasis on structure in architecture, painting, and poetry; the English linear and decorative tendency that runs through medieval miniature painting, Perpendicular Gothic architecture, the drawings of William Blake, and Art Nouveau. Common sense, of course, is needed in thinking about such styles; the theorizer who sets out to show that all French art is rational and all German art emotional will be in trouble immediately. Also, a certain vagueness is often suitable, for the distinctive features of a regional or national style may be of the sort better described as qualities than as morphological aspects. Recurring differences, however, finally add up to recognizability, and a quality hard to define can be strongly felt.

Climate and landscape were formerly popular as explanations for regional and national styles (for all styles, as a matter of fact); Gothic architecture was supposed to have emerged in northern Europe because of the many forests. Evocations of some kind of permanent national outlook were also frequent; Russian musical styles were thought to be inhabited by a Slav soul. Such ideas are now perhaps too much out of fashion; it is not quite unthinkable that an English stone carver's affection for linear pattern was encouraged by the frequent absence of bright, shadow-casting sunlight in England and that the symmetry of much French architecture and painting corresponds to the average Frenchman's enduring attachment to order. But eventually, of course, an explanation must include an entire regional or national culture and environment and at the same time take note of the fact that an art may have an existence of its own. To neglect this latter possibility would be to repeat on a large scale Miss Spurgeon's confusion of men with writers.

Ecological styles. A subvariety of the regional variety is perhaps distinct enough to be classed separately as the ecological: here, that is, the style in question evokes in fairly specific ways the relationship of human organisms to their environment. Here also there are likely to be strong polarities; typical contrasting pairs are urban–rural, mountain–plain, hunting–farming, inland–seaboard, nomadic–sedentary, capital–provincial (in some ways), and (at least in comic strips and science fiction) earth–space. Such styles are most recognizable in architecture, painting, and the making of such useful objects as furniture, tools, and weapons. But they may be recognized more distantly in the dance, in music, and in poetry: the imagery of the Parisian poet Charles Baudelaire is urban; that of the New England farmer-poet Robert Frost is rural; while Homer's is seaboard, at least in the *Odyssey*. It is probable, too, that a well-defined ecological pattern affects in subtle respects the appreciation of foreign styles and hence the emergence of new local ones; psychologists have found that the Zulus of South Africa, for instance, who live in a "circular culture" of windowless round huts and meandering paths, are relatively immune to visual illusions seen by people who have been conditioned by the right-angled, straight-perspective, so-called carpentered world of European and American cities.

Influence on appreciation

Religious styles. Conditioning also undoubtedly affects recognition of religious styles. The problem of hard-to-define "qualities" that contribute to recognizability, mentioned above in connection with regional and national styles, also returns here to vex a conscientious historian. So does the problem of the separation of form and content, plus the false problem of the sincerity of the artist as such—of the artist as mere "performer." Strictly speaking, in terms of forms and their combinations, one must grant that a vast number of profoundly moving works of religious art are not recognizably in religious styles. One can plausibly argue, for example, that there has been no religious style at all in Western painting since about the 15th century; later painters of religious subjects, such as Van Eyck, Raphael, Rubens, and their successors, painted the Virgin much as they painted their wives and mistresses. A similar point can be made about Western post-Renaissance music; Bach's sacred works sound much like his secular ones, and Giuseppe Verdi's magnificent *Requiem* (1874) has sounded to many ears like his operas. Even in the European Middle Ages and in the worlds of the great Eastern religions, the evidence is not always clear; the style that seems to yearn toward God in the 13th-century Gothic cathedral at Chartres, France, served also for town halls and ivory combs.

The point, of course, should not be exaggerated, partly because other styles often make use of borrowed forms and principally because many religious stylistic elements do exist in their own right, even though their secular ancestry can sometimes be traced. In architecture, examples of religious style can be seen in the basilican plan

Style conditioned by content

of Christian churches, the cosmic-mountain form of Hindu temples, the rectangular and cruciform plans of mosques, the needle shape of the minaret; in music, the single vocal line and free rhythm of Gregorian chant, the florid melody of Islāmic chant; in painting, the free brushwork of Zen Buddhists, the abstract arabesques of Islām, the nonillusionistic kinds of pictorial space favoured by medieval Christians. But when the list of such elements is completed, the fact still remains that the average appreciator recognizes a religious style primarily because it is tinged by long association with religious texts, ritual, and iconography. In brief, it has for him a quality that seems to emanate from content.

Period styles. A style belonging to one of the single-culture varieties may be divided, conventionally or arbitrarily, into periods. Beethoven's personal style is usually split into early, middle, and late; the ethnic style of the migrating Germanic peoples may be referred to as Animal I, II, and III. The adjective "period" is often reserved, however, for a distinct variety of style: the one in which the metaphorical "windows" afford "views" inhabited by generations whose cultural and other activities appear to constitute definable units of history. Familiar examples are the Gothic period style, the Renaissance, and, in general, all styles that bear the names of rulers or dynasties: the Victorian style, the Carolingian, the Sung. Frequently the period style is itself "periodized," the Gothic is Early and Late, the Renaissance is Early and High. The issues raised by periodization of all sorts will be discussed in the last section of this article (see below *III. The dynamics of style*). But period styles have their place in this part the classification, for they are clearly, often emphatically, of the single-culture sort.

CROSS-CULTURAL VARIETIES

Uninhabited, unmetaphorical styles

Cross-cultural styles are usually uninhabited, in contrast to personal styles. They do not, in any event, call up into the foreground of the appreciator's imagination a John Donne, a Metaphysical school of versifiers, a Murasaki Shikibu in an ancient Japanese court, a Germanic tribe on the march, a succession of English stone carvers expressing their Englishness, a Baudelaire in an urban twilight, a medieval monk singing for God, or a group of eminent Victorians. In a sense, then, cross-cultural styles are relatively unmetaphorical; they tend to focus attention on themselves. They have modes of existence that lie outside of history, and they often are not so much aesthetic terms as general-utility adjectives: almost anything, and not just works of art, can be "classical," for instance, or "organic," or "abstract." Cross-cultural styles in art, however, are by no means without implications; they can evoke outlooks, contexts, methods, and professions.

Classical and Romantic styles

Outlook styles. Any style, of course, can be said to express an outlook or an attitude along with whatever else it expresses. Michelangelo's personal style expresses the outlook of Michelangelo; the Biedermeier style in furniture and decoration expresses the outlook of the German and Austrian middle classes between the Congress of Vienna in 1814–15 and the Revolution of 1848. Certain cross-cultural styles, however, can be said to specialize in general outlooks and attitudes that recur everywhere in all arts in all eras. There is a Classical style—a deviation toward clear, logical, nobly impersonal, carefully proportioned forms—that is recognizable not only in works that are ordinarily labelled "Classical" or "Neoclassical," such as the sculpture of the Parthenon of 5th-century-BC Athens and the plays of Pierre Corneille of 17th-century France, but also in the 13th-century sculpture of Reims Cathedral, the 20th-century Symbolist poetry of Paul Valéry, the 18th-century English portraits of Sir Joshua Reynolds, a Japanese screen, a Chinese vase, and some buildings on Fifth Avenue in New York City. There is a Romantic style—a deviation toward restless, alogical, nobly personal, intensely expressive forms—that is recognizable not only in works of the Romantic period of the early 19th century, such as the music of Frédéric Chopin or a poem by Heinrich Heine, but also in the Italian baroque architecture of Francesco Borromini, the fantasy painting of Paul Klee, Shakespeare's *King Lear*, a Hindu stone relief, a Hellenistic mosaic, and an avant-garde dancer. The same sort of thing can be said about such styles as the realistic, the fantastic, the expressionistic, and the idealistic, each of which implies an attitude toward life and the world. And perhaps the list should be rounded out with the academic style, into which the other outlook styles tend to sink when they are reduced to a set of teachable rules.

Since these styles cross every aesthetic, geographical, or temporal frontier, embrace common human attitudes, and exhibit strong polar aspects, they have tempted many critics into an effort to arrange them all into two contrasting groups: the classical and the romantic, the conservative and the liberal, the idealistic (here the classical joins forces with the romantic) and the realistic, the rational and the emotional, and so on. Such arrangements have the advantage of breaking up traditional divisions and freshening awareness along with the disadvantage of not exhausting the evidence.

Contextual styles. At first glance the outlook styles may seem capable of annexing the contextual, which include the traditional genres and kinds of art—such styles as the tragic, the comic, the satiric, the pastoral, the heroic, and the melodramatic. But here the outlooks, when they exist, are at one or two removes from those of real life and the real world. A tragic style evokes not a death in the family but a work by Sophocles, Shakespeare, or some other playwright; a pastoral style evokes not herdsmen in the Alps but swains in a mythical Arcadia; a heroic couplet evokes not a brave warrior but the practice of John Dryden and others of using units of two rhyming lines of iambic pentameter in their "heroic" drama. Moreover, when the context—the genre, or kind of art—is not literary, the contextual style may evoke nothing that can properly be called an outlook. The operatic style in Verdi's *Requiem*, cited above, is a contextual style; so is the landscape style, with its hints of land, horizon, and sky, that is sometimes recognizable, like a ghost from Dutch paintings of the 17th century, in modern abstract paintings. So are the sculptural styles recognizable in the bizarre 20th-century architecture of the Spaniard Antonio Gaudí, the painterly styles in the Italian baroque sculpture of Gian Lorenzo Bernini and in certain Cubist sculpture of the 20th century, the musical styles of the poetry of Edgar Allan Poe and Alfred Lord Tennyson.

Procedural styles. Procedural cross-cultural styles are similar to but not quite the same as the contextual. For the term "procedural" is here meant to refer to ways of making art, to varieties of *poiēsis*, that may be shared by several arts and, in fact, are often shared by all. Hence, when the point of view is that of appreciators, procedural styles are commonly called "formalistic." Familiar examples of such styles are the mimetic, the representational, the naturalistic, the abstract, the geometric, the organic, the linear, the optical, the haptical (or tactile), and the plastic; some of these can be regarded, not always profitably, as subvarieties of others, and all of them can be regarded as members of polar pairs.

Formalistic members of polar pairs

Traditionally, certain procedural styles are associated with certain arts, but they need not be. Mimetic, or representational, styles, for example, are most often associated with painting and sculpture (*e.g.*, Gilbert Stuart's lifelike 18th-century portraits of George Washington or a Sumerian animal statue of the 3rd millennium BC), but they can also be recognized in the resemblance of Frank Lloyd Wright's mid-20th-century Guggenheim Museum to a snail, in the similarities of Nikolay Rimsky-Korsakov's musical composition *The Flight of the Bumble Bee* to the buzzing of a bee, and in Tennyson's frequently quoted lines in *The Princess*:

> The moan of doves in immemorial elms,
> And murmuring of innumerable bees . . .

which employ onomatopoeia, the use of words that actually sound like what the words represent.

Similarly, linear styles can be recognized not only in such obvious places as a line engraving by the 16th-century German master Albrecht Dürer or in the linear pat-

terns of Plateresque ornament of 16th-century Spain but also in the vocal line of an Italian Renaissance madrigal or in a modern building by the American architectural firm of Skidmore, Owings, & Merrill.

Traditionally also certain procedural styles are associated with certain cross-cultural outlook styles, but again they need not be. Mimetic styles are accompanied by Classical in the serene 17th-century landscapes of Nicolas Poussin, by Romantic in the turbulent 19th-century seascapes of Turner, by Realistic in Caravaggio's works of 16th-century Italy; by fantastic in the 20th-century Surrealistic compositions of René Magritte, and by Expressionistic in the tortured figures of Matthias Grünewald's Isenheim Altarpiece of the early 16th century. Abstract styles in 20th-century painting are accompanied by Classical in Piet Mondrian's use of pure lines and rectilinear shapes, by Romantic in Wassily Kandinsky's watercolours of his Blaue Reiter period, by Realistic (of a sort) in Frank Stella's striped, "objective" works, by the fantastic in Yves Tanguy's Surrealistic vistas, and by Expressionistic in Willem de Kooning's often violent canvases. The point is worth some emphasis, for even the most careful critic is likely to slip into the error of assuming that the classical, the romantic, and especially the realistic styles call for eternally fixed methods of production.

Professional styles. When the context of a contextual style or the procedure of a procedural style is derived from somewhere outside the arts in a sufficiently recognizable way or form, the result may be called—at the risk of some confusion—a professional style. Every artist, of course, has a professional style insofar as he is indeed an artist. But the critical occasions for talking about an "art" style in a meaningful fashion are rare; they are likely to arise only when an emphatic distinction is needed between two levels of artistry or when, as during the 19th-century English Aesthetic movement, artists and allied nonartists are waging war against alleged Philistines. On the other hand, artistic styles derived from nonartistic professions have never been rare and have recently been plentiful. An engineering style is easily recognizable in Roman, Gothic, and modern architecture and also in several kinds of modern sculpture and painting. Many novelists, from the beginning of the genre, have borrowed the styles of historians, and many the styles of journalists; directors of fictional films have worked in documentary styles, composers of modern music in the styles of experimental science and electronic-age technology. Occasionally the stylistic trend among 20th-century artists toward outside professions has been noticeable enough to lead a few observers, always promptly challenged by others, to conclude that the traditional arts were running low on unmanipulated variables.

Styles from non-artistic professions

III. The dynamics of style

This article has considered styles more or less as a panorama in which all the features are contemporaneous with each other and with the appreciator. The approach, to borrow a term from modern linguistics, has been largely "synchronic"; and such an approach has evident advantages. It gives an explicator a chance to classify, to structuralize, without worrying overmuch about the randomness of history. More importantly, it corresponds in a sense with an appreciator's actual experience of works of art, which is, of course, always synchronic, always in the present; experientially speaking, the Gothic style of the 13th century is not a second older than the style of Skidmore, Owings, & Merrill of the 20th. The historical, or diachronic, approach can offer, however, its own set of advantages. Facts and speculation concerning styles as they occur or change over a period of time can have the same sort of value as political or military history, and in addition they can contribute greatly to the recognition pleasure that is basic in an appreciation of styles.

Difficulties of stylistic history

The pleasure, it should be said right away, is normally accompanied by some peculiarly daunting doubts. Like all history, stylistic history is at once a branch of knowledge that tries to explain significant past events, a chronological record of such events, and somehow the past events themselves, in all their intractable uniqueness. But whereas the members of the trinity can usually be kept reasonably distinct in political or military history, they can usually be found in a state of oneness in stylistic history; the beginning of the Renaissance style, for instance, is notoriously a blend of theoretical explanation, selective records, and such "events" as surviving paintings, poems, and buildings. Also, whereas elections and battles have their fixed times and places, many styles do not; romanticism can leave the ahistorical limbo of cross-cultural styles to become the single-culture 19th-century Romanticism and then suddenly materialize, to some historians, as a phase of late Greco-Roman single-culture Classicism. In sum, the emergent mode of existence to which styles are disposed may make impossible a clean distinction between conceptions and historical facts and may expose the most conscientious of art historians to the charge of merely manoeuvring with private abstractions.

Another difficulty, which was glanced at in connection with the measurable in style, can be mentioned again here. It is the familiar one of overspecialized interpretations presented as general theory. Much of the terminology and nearly all of the chronological framework for the history of style are inventions of specialists in the study of the visual arts. Fortunately, the terminology and the framework can be adapted, with the help of some stretched meanings, to the study of music and literature. In what follows, a strong possibility of visual-art bias should be kept in mind during the discussion, which will concern origins, diffusion, and change and duration of art styles.

HISTORICAL ORIGINS

The question of the origins of styles has already been raised. From an appreciator's strictly synchronic point of view, to raise such a question is often to be irrelevant, or to get into a round of tautologies and to confuse the merely relational with the causal. The origins of the courtly style, of the Eskimo style, and of personal styles are by definition courts, Eskimo, and artists, respectively. There is something to be said, however, for the elaborated tautology as a form of analysis and also for the fact that adding the space-time of history makes a difference: it is one thing to point to an emphasis on order in the French national style and another thing to account for the advent of the Gothic style at the abbey of Saint-Denis in 1140. Moreover, art historians do not usually mean anything as determinative as a cause when they refer to the origins of a style; they merely mean a set of conditioning historical factors. And when they disagree they usually do so over the relative importance to be assigned to one of four sorts of factors: the politico-economic, the cultural, the technical, and the artistic.

The relational and the causal

Politico-economic factors. The most evident sort is the politico-economic. If the ancient Greeks had lost the Persian Wars in the 5th century BC, the columns of the temples on the Acropolis would probably be taller. If the Great Depression in the United States had begun earlier, the Empire State Building and other skyscrapers in New York of the 1920s and 1930s would probably have been shorter. The styles of Chinese blue and white porcelain were perceptibly influenced by export possibilities. Films are an industry as well as an art. The Italian Renaissance cannot be fully understood without references to the personality cults of monarchs, petty tyrants, and usurping mercenary leaders, to the capital accumulated in the bank of the Medici family of Florence and the coffers of the Vatican, to the expansion of international trade, and to the loosening of feudal ties. Such examples, along with more subtle ones, can be multiplied into a solidly factual kind of stylistic history.

Cultural factors. Nothing quite so solid is likely to come out of a consideration of contributing cultural factors; here one is obliged to weigh such imponderables as changes in manners, morals, psychologies, philosophies, and that pervasive sensibility system known as "the spirit of the age" and then to try to match these changes with the arrival times and the formal elements of presumably new styles. Thus it can be argued that the new period

The question of the "spirit of the age"

style gradually apparent at the close of the Greco-Roman era—the lack of naturalism, for instance, in painting—reflects Christian otherworldliness. Similarly, it might be claimed that the exuberantly enumerative prose style of the French satirist François Rabelais has roots in the widespread 16th-century zest for learning and discovery. To take still another example, the development of the orchestral crescendo in the middle of the 18th century, principally at Mannheim, Germany, has been said to reflect a new kind of human self-assertion, one destined for importance in all the arts with the arrival of 19th-century Romanticism.

Technical factors. The presence of politico-economic or of cultural factors need not, of course, rule out the technical sort, and examples of the latter are plentiful. The stylistic change from 14th-century to 15th-century European painting coincides with a new utilization, although not the invention, of the oil technique. The refinement of volumes and of implied movement in Renaissance bronze sculpture is linked to a new skill in casting techniques acquired in the making of artillery. Chopin's personal style and significant improvements in the piano both date from the 1830s. Sometimes the technical factors are partly disguised by a change of material; the Doric order in architecture is a wood style in stone. Sometimes, too, the technical factors must be understood in a large sense that embraces the functional, and they may then be accompanied by moralizing; thus, some 20th-century architects have maintained that it is "honesty" to let a building reveal its construction and use. Usually more than one set of technical factors can be discovered; a poet's style that mixes true rhyme with eye rhyme (similarity only of spellings) has origins—rather remote—both in ancient oral mnemonics and in the silent reading fostered by printing.

Artistic factors. Explanations of stylistic origins involving politico-economic, cultural, and technical factors tend to have in common the defect of not providing very exclusive matchings of formal elements with supposed sources. Many times and places have had ambitious princes and accumulated capital equal to those of 16th-century Italy without producing anything like the smoky style, the sfumato, of Leonardo da Vinci's paintings, or the clarity and solemnity of Bramante's architecture. If a lack of naturalism goes well with early Christian otherworldliness, it also seems to go somehow with the reputed thisworldliness of the 20th century. If the perfected piano can be matched with the smooth 19th-century compositions of Chopin, it can also be matched with the staccato 20th-century music of Béla Bartók. To be sure, these are only contributing factors, not specific causes. Even so, the versatility of the factors mentioned usually leads an art historian to add some relatively direct, purely artistic factors and eventually to postulate a group of ancestors and influential cousins for a given style. Thus Leonardo's style is said to be derived partly from his early master Verrocchio's, early Christian from ancient Roman and Syrian, Chopin's from the styles of other Polish pianists and from the Irish-born John Field. Art historians of this persuasion do not, as is sometimes alleged, reject the hypothesis that an artist may think up a style partly on his own; they merely regard it as lying outside the concerns of scholarship.

Matching causes and effects

Here another difficulty in the writing of stylistic history has to be mentioned. In which painting did Leonardo's personal style become his own and not Verrocchio's? At what date did the early Christian style cease to be Roman and Syrian? Questions of this sort, if pressed far enough, can raise the suspicion that a discussion supposedly about the origins of a certain style is actually about the arbitrary periodization of a more inclusive style.

DIFFUSION

The factor of place in diffusion

Periodization is always, although the fact is not always made clear by periodizers, a spatiotemporal operation; it poses questions of where as well as of when. The Gothic period can be said, if dates are used with convenient recklessness, to end around 1420 in Italy, around 1530 in France, and a generation later in England. Moreover, the "where" may be not only a point in geographical space but also a zone in the imaginary space constituted by any classification of the arts. The Italian Renaissance can be said to begin in painting around 1300 with Giotto; in poetry around 1330 with Petrarch; in architecture around 1420 with Brunelleschi; and in music around 1525 with madrigal composers, or perhaps around 1600 with Monteverdi. In sum, staggered dates, distinct localities, and the separation of the arts combine to involve the student of period styles in a complex problem of assumed or alleged correspondences and sometimes in unexpected variants of the problem of stylistic origins.

Correspondences in real space. Like their colleagues in other branches of cultural history, art historians sometimes are obliged to choose between diffusionism and theories of spontaneous development; the striking similarity between a motif on a Chinese bronze and one on an Aztec temple, for instance, may be attributed to prehistoric migration, to analogous stages of civilization, or to chance. Normally, however, and for good reasons, art historians rely on diffusion from a creative centre in their attempts to explain stylistic correspondences in even widely separated areas; and they rely on it almost exclusively in discussing period styles. It is fairly easy to trace the movement of Andrea Palladio's style from the buildings he designed in Vicenza, Italy, in the 16th century to Inigo Jones's Banqueting House in London in the 17th century, of opera buffa from Naples to Vienna in the 18th century, or of Cubism from Paris to Prague and New York in the 20th century. A difficulty in this sort of history is that diffusion implies receptivity, and stylistic receptivity implies at least a degree of spontaneous development.

Correspondences in the arts. There are a number of problems in attempts to deal with stylistic correspondences in different arts. One of the most common is the difficulty of making a distinction between a period style and a period of time when the same label is used for both —and perhaps for each in more than one sense. Thus, a historian who refers to Baroque music without explanation may mean that the music in question has certain stylistic affinities with the theatricality of Bernini's sculpture, with the full-blooded movement and illusionism of Pietro da Cortona's painting, with the undulations of Borromini's architecture, and with the cadences of Sir Thomas Browne's prose; instead, or also, he may mean, as many musicologists would, that the music carries the technical eramark of a basso continuo part; again he may mean that the music evokes the manners, public life, science, and general culture of "the Age of the Baroque"; and finally he may mean nothing more than that the piece was composed in the 17th century. If he does mean that the music has stylistic affinities with Baroque sculpture, painting, architecture, and prose, then other difficulties appear. He must manage to translate each art into the others, construct a convincing historical pattern, and explain the correspondences.

Problems and ambiguities of correspondences

Nevertheless, there is considerable agreement among art historians that such correspondences do exist—not in every period but often enough to merit attention. In addition to those of the Baroque, which are frequently cited, one can mention those between musical and visual-art proportions during the Renaissance, those among nearly all the arts during the Gothic period, and those among painting, sculpture, architecture, and music during the 20th century. Persuasive arguments for correspondences between art and other disciplines have been advanced, notably in a comparison of Gothic architecture with scholasticism, the contemporaneous church-oriented philosophy, and by several commentators in comparisons of Leibniz's highly complex but integrated philosophy to Baroque art.

CHANGE AND DURATION

The already mentioned problem of distinguishing between the origins of a distinct style and the periodization of a more inclusive one complicates every discussion of stylistic change and duration. It can be argued that whenever a style moves into a new period or phase it becomes

a new style; and a few modern historians have drawn the conclusion that the concept of style should be kept out of art history and be reserved for synchronic structuring and critical analysis. They feel that one can usefully take a cross section of Baroque, for example, and study it horizontally, out of time, but that to talk about the historical antecedents of Baroque, or about phases of Baroque, is to fall into logical contradiction. Such historians, however, are very much a minority. Most of their colleagues are committed not only to stylistic change and duration but also, if often only implicitly, to various theories about supposedly typical stages in the stylistic historical process.

Cyclical theories. In the preface to his *Lives*, Vasari remarked that the arts, like human beings, "are born, grow up, become old, and die." Four centuries later, the infinitely more knowledgeable and sophisticated art historian Henri Focillon entitled an essay on style *The Life of Forms in Art* (1934). André Malraux, in his *Voices of Silence* (1951), refers to

> these imaginary super-artists we call styles, each of which has an obscure birth, an adventurous life, including both triumphs and surrenders to the lure of the gaudy or the meretricious, a death-agony and a resurrection.

References to the "maturity" or the "decay" of styles are part of nearly everybody's art criticism. In sum, the biological metaphor for style has become commonplace. But it once was a serious theory of the historical process, and as such it perhaps still deserves some denunciation for having been frequently both a misrepresentation of facts and a source of prejudice against estimable works of art —Hellenistic, late Gothic, Mannerist, Baroque, and so on —which were believed to belong to the "decadent" part of "the life cycle" of a style.

In an effort to get closer to the observed course of events, some historians have favoured, in whole or in part, a cyclical theory that pictures each major single-culture style as going through the same irreversible series of cross-cultural styles, which is usually given as archaic, classic, baroque, impressionist, and archaistic. Thus the first, or archaic, phase of the Graeco-Roman cycle is supposed to correspond with the first phase of the Gothic and of the Renaissance cycles; and one can speak of third-phase baroque Greek, third-phase baroque Gothic, even third-phase baroque Baroque. The theory has some fascination, and occasionally it works well enough to shed light on the actual historical behaviour of styles. But often it works only because one has been careful to start the cycle in the right place, and far too often it does not work at all.

Dialectical theories. The notion that history is a pendulum, with left inevitably followed by right, occurs to everyone, and it is especially likely to occur to art historians because of the polar aspects of style. Sometimes the pendulum is imagined as swinging forever between cross-cultural outlook styles: classical then romantic, idealistic then realistic. Historians who are inclined to feel that outlook styles are too vague and too laden with value implications may favour the idea of swings between cross-cultural procedural styles: mimetic then abstract, organic then geometric. The influential theory devised by the Swiss art historian Heinrich Wölfflin (1864–1945) postulates an elaborate dialectic involving pairs such as linear–painterly and closed–open. A theory devised by the German critic Paul Frankl (1878–1962) combines a movement between styles of being and becoming with a cyclical development through preclassic, classic, and post-classic stages. Another theory, devised by the Austrian scholar Alois Riegl (1858–1905), postulates cycles of evolution within a long swing across the centuries from an early haptic to a later optic phase. All these models of the stylistic historical process break down eventually, but they can provide useful categories for organizing the flux of artistic events.

The pendulum notion of history

Sequential theories. Historians who refuse to believe that styles are haunted by destiny may be willing to grant that within short periods and mostly in terms of technique something that looks like a preordained evolution can occur. Thus it is possible to discern in Gothic architecture a predictable movement toward lighter construction, in Early Renaissance painting a movement toward a desired illusionism, in 16th-century European music a movement toward the tonal system that emerged in the following century. But beyond this concession, such historians are likely to rely on simple sequences devoid of any trace of determinism. Their works often consist of a sequence of biographies of artists and a sequence of centuries. Do such methods suggest mere chronicling rather than history? Perhaps partly to answer such a question, a theory advanced by the contemporary American historian James S. Ackerman presents stylistic change as a "process" of a sort, although not one that is preordained; art history is envisaged as a series of steps away from the past, but not toward the future. "Each step," Ackerman says, "for the artist who takes it, is final and definitive; he cannot consciously make a transition to a succeeding step, for if he visualizes something he regards as preferable to what he is doing, he presumably will proceed to do it. . . ."

Satiation theories. Why does the artist take a step away from the past? A common explanation is that he, or his audience, has become overly familiar with the prevailing style. The phenomenon is similar to what psychologists call semantic satiation—the loss of meaningfulness in repeated words. According to one theory, stylistic satiation is hastened by comparison; thus when much was changing at the beginning of the 20th century, many painters felt that their old styles were intolerably familiar. According to another theory, satiation is always merely temporary. To revert to part of the biological metaphor, styles are born, but they never really die.

BIBLIOGRAPHY

Theoretical surveys: An excellent critical résumé of early 20th-century speculation, with emphasis on the visual arts, is M. SCHAPIRO, "Style," in A.L. KROEBER (ed.), *Anthropology Today* (1953). J.S. ACKERMAN, "Theory of Style," *Journal of Aesthetics and Art Criticism*, 20:227–237 (1962), stresses relational values and offers a lucid critique of evolutionary notions. R.L. SCRANTON, *Aesthetic Aspects of Ancient Art* (1964), analyzes in sharp detail the structure of style and applies his conclusions to specific works, including literature. HERBERT READ, in the introduction to *The Styles of European Art* (1965), emphasizes the psychological aspects of the subject. RENE WELLEK and AUSTIN WARREN, *Theory of Literature*, 3rd rev. ed. (1966), have much to say about style in passing, from the standpoint of Anglo-American New Criticism. GEORGE KUBLER, *The Shape of Time* (1962), wages brilliant war on conventional art history and presents a formal substitute for the concept of style. BRUCE ALLSOPP, *Style in the Visual Arts* (1956), reviews the history of the concept and stresses the allegedly damaging effects of style on contemporary artistic activity.

Special studies: ERWIN PANOFSKY, *Renaissance and Renascences in Western Art*, 2nd ed., 2 vol. (1965), examines the idea of rebirth in Italy and discusses the significance of medieval renascences; his *Meaning in the Visual Arts* (1955), although focussed on iconography, has extensive reflections on style; his *Gothic Architecture and Scholasticism* (1951) is a study in correspondence. ETIENNE SOURIAU, *La Correspondance des Arts* (1947), presents a basis for comparative aesthetics. WYLIE SYPHER, *Four Stages of Renaissance Style* (1955) and *Rococo to Cubism in Art and Literature* (1960), make good use of stylistic polarities in an analysis of painting, sculpture, architecture, and literature. RUDOLF WITTKOWER, *Architectural Principles in the Age of Humanism*, 3rd ed. rev. (1962), deals in depth with problems of symbolism, optics, and harmony in Renaissance buildings. NIKOLAUS PEVSNER, *The Englishness of English Art* (1956), offers one of the few instances of a serious historian taking the idea of a national style seriously. G.M.A. GRUBE, *The Greek and Roman Critics* (1965), discusses stylistic theories from Homer to the 3rd century AD. WALTER WIORA, *Die vier Weltalter der Musik* (1961; Eng. trans., *The Four Ages of Music*, 1965), presents a panorama of the world's musical styles from ancient times to the 20th century.

Classical studies: FRANZ BOAS, *Primitive Art* (1927, new ed., 1962); H. FOCILLON, *Vie des formes* (1934; Eng. trans., *The Life of Forms in Art*, 2nd ed., 1948); P. FRANKL, *Das System der Kunstwissenschaft* (1938); A. RIEGL, *Stilfragen: Grundlegungen zu einer Geschichte der Ornamentik* (1893; 2nd ed., 1923); HEINRICH WOLFFLIN, *Renaissance und Barock* (1888; Eng. trans., *Renaissance and Baroque*, 1964); *Die klassische Kunst* (1899; Eng. trans., *Classic Art*, 1952, reprinted 1968);

and *Kunstgeschichtliche Grundbegriffe* (1915; Eng. trans., *Principles of Art History*, 1932).

Bibliographies: Useful short lists of theoretical works on style may be found in the above-mentioned publications of Schapiro and Scranton. Longer lists, mixed with other material, may be found in those of Panofsky, Sypher, and Wellek and Warren.

(R.McMu.)

Asceticism

Asceticism, in religion, is the practice of the denial of physical or psychological desires in order to attain a spiritual ideal or goal. The term and its cognates are derived from the Greek verb *askeō*, which originally meant to manufacture technically or artistically and later to exercise or to train. The noun *askēsis* means "exercise" and "training." Hardly any religion has been without at least traces or some features of asceticism. In the history of religions and of civilization, the extent to which the practice of asceticism has enabled men to develop their inner (spiritual) powers over their instinctive urges and the influences of the external world has been notable. The practitioners of asceticism believe that the ascetic person has access to powers that uphold moral standards and enliven spirituality.

The origins of asceticism. *Asceticism in athletics, intellectual endeavours, ethics, and technological endeavours.* The origins of asceticism lie in man's attempts to achieve various ultimate goals or ideals: development of the "whole" person, human creativity, ideas, the "self," or skills demanding technical proficiency. Athletic *askēsis*, involving the ideal of bodily fitness and excellence, was developed to ensure the highest possible degree of physical fitness in an athlete. Among the ancient Greeks, athletes preparing for physical contests (*e.g.*, the Olympic Games) disciplined their bodies by abstaining from various normal pleasures and by enduring difficult physical tests. In order to achieve a high proficiency in the skills of warfare, warriors also adopted various ascetical practices. The ancient Israelites, for example, abstained from sexual intercourse before going into battle.

Goals of asceticism

As values other than those concerned with physical proficiency were developed, the concept expressed by *askēsis* and its cognates was applied to other ideals—*e.g.*, mental facility, moral vitality, and spiritual ability. The ideal of training for a physical goal was converted to that of attaining wisdom or mental prowess by developing and training intellectual faculties. Among the Greeks such training of the intellect led to the pedagogical system of the Sophists—itinerant teachers, writers, and lecturers of the 5th and 4th centuries BC who instructed in return for fees. Another change in the concept of *askēsis* occurred in ancient Greece when the notion of such training was applied to the realm of ethics in the ideal of the sage who is able to act freely to choose or refuse a desired object or an act of physical pleasure. This kind of *askēsis*, involving training the will against a life of sensual pleasure, was exemplified by the Stoics (ancient Greek philosophers who advocated the control of the emotions by reason). The goal of such moral and volitional asceticism was viewed as enhancement of the dignity of man. These ideas reveal the various shades of meaning of the word *askēsis*. They range from the negatively oriented, in which the object of *askēsis* is the avoidance of evil, the suppression of vicious tendencies, or the moderation of excessive passions, to positively oriented trends, in which the object is the strengthening of the virtues that perfect moral and spiritual life and that enable one to cultivate inner powers.

The view that one ought to deny one's lower desires—understood as sensuous, or bodily—in contrast with one's spiritual desires and virtuous aspirations, became a central principle in ethical thought. Plato believed that it is necessary to suppress bodily desires so that the soul can be free to search for knowledge. This view was also propounded by Plotinus, a Greek philosopher of the 3rd century AD and one of the founders of Neoplatonism, a philosophy concerned with hierarchical levels of reality. The Stoics, among whom asceticism was primarily a discipline to achieve control over the promptings of the emotions, upheld the dignity of human nature and the wise man's necessary imperturbability, which they believed would become possible through the suppression of the affective, or appetitive, part of man. In a similar manner, the value of asceticism in strengthening man's will and his deeper spiritual powers has been a part of many religions and philosophies throughout history. The 19th-century German philosopher Arthur Schopenhauer, for example, advocated a type of asceticism that annihilates the will to live; his fellow countryman and earlier contemporary philosopher Immanuel Kant held to a moral asceticism for the cultivation of virtue according to the maxims of the Stoics. In 20th-century society, in the face of criticism that the mechanical, commercial, and technological equipment of modern life—with a momentum and enticement and stimuli of the senses all its own—has enslaved men, critics, such as the Roman Catholic theologian Romano Guardini, have advocated asceticism as a means of rescuing human existence. Man, having lost his identity because of the effects of the growing technological process upon him, must once more renounce the world in order to regain his spiritual position. And, according to Arnold Gehlin, the possibilities that the spiritual discipline of asceticism offers are to be understood as important aids in humanization.

Asceticism in modern societies

Asceticism in religion. The concept of *askēsis* as a means of achieving various spiritual goals was also applied to religion, in which it assumed a significant position. Many factors were operative in the rise and cultivation of religious asceticism: the fear of hostile influences from the demons; the view that one must be in a state of ritual purity as a necessary condition for entering into communion with the supernatural; the desire to invite the attention of divine or sacred beings to the self-denial being practiced by their suppliants; the idea of earning pity, compassion, and salvation by merit because of self-inflicted acts of ascetical practices; the sense of guilt and sin that prompts the need for atonement; the view that asceticism is a means to gain access to supernatural powers; and the power of dualistic concepts that have been at the source of efforts to free the spiritual part of man from the defilement of the body and physically oriented living. Among the higher religions (*e.g.*, Hinduism, Buddhism, and Christianity), still other factors became significant in the rise and cultivation of asceticism. These include the realization of the transitoriness of earthly life, which prompts a desire to anchor one's hope in otherworldliness, and the reaction against secularization that is often coupled with a belief that spirituality can best be preserved by simplifying one's mode of life.

Types of religious asceticism. Though the demarcation lines seldom can be drawn clearly and many elements mingle and overlap, certain types of asceticism are still distinguishable: ritual, disciplinary (physical and moral), and mystical. According to an agelong idea that has dominated primitive religions, engagement in the profane world is believed to be the antithesis of a relationship to the sacred realm, a relationship that can be recovered by ritual sacrifices. Survivals of ritual asceticism (*e.g.*, fasting) are reflected in many of the higher religions.

Disciplinary asceticism, with its goal of training the soul, is graphically depicted in various techniques aimed at accomplishing this goal. The methods of *yoga* (a Hindu psychological–physical meditation system) consist of injunctions involving the regulation of breathing, posture, sitting, and meditation. In Buddhism this system is further developed into what is known as the Eightfold Path, a kind of guide to moral or righteous living that may be practiced by both monks and laymen. In Christianity, the spiritual exercises taught by St. Ignatius of Loyola, the 16th-century founder of the Roman Catholic monastic order known as the Jesuits, are designed to actuate the will toward the pursuit of moral and spiritual perfection. Hyperasceticism (excessive disciplinary asceticism), in its ultimate goal, goes beyond the training of the soul and ends in the ultimate annihilation of the body so that the soul may become free. This stems either

Influence of dualistic ideas

from metaphysical dualism, which separates the material from the spiritual (*e.g.*, the body from the soul) into sharply contrasted realities, or from quasi-dualistic views. Metaphysical dualism is contained in the thought of Plotinus, in Neoplatonism, and in Gnosticism, a Christian movement that taught that matter is evil and the spirit good. It is also found in the teachings of Marcion, a 2nd-century Christian who founded his own church, and Mani, a 3rd-century founder of a dualistic religion that bears his name. Quasi-dualistic ideas that produce a hatred of the body are found, for example, in Syrian Christian asceticism, which pressed relentlessly toward a life of mortification, along with an insatiable longing for the accomplishment of extravagant aims. Turning farther toward the East, one finds that Siddhārtha Gautama, the 6th–5th-century-BC founder of Buddhism, rejected asceticism, but some Buddhists have practiced disciplinary asceticism. An extreme example is found in the legend of Hui-k'o, a student of the 6th-century Japanese Zen Buddhist guru (teacher) Bodhidharma, who cut off his arm in the presence of the master to demonstrate the sincerity of his desire to study the *dharma* (law) with Bodhidharma. Gorakhnāth, medieval founder of the Hindu order of religious ascetics, the Kānphaṭa Yogis, belonged to the tradition common to both Hinduism and Buddhism of the 84 *mahasiddhas*, or "great perfect ones," who acquired magical powers through the practice of rigorous forms of spiritual discipline.

An extreme form of dying to the world is practiced by some members of Jainism in India who, in their attempts to reach sainthood, starve themselves to death.

The goal of mystical asceticism is union with the divine —the mystical experience. By means of dying to the world, of extinguishing the self and the will, and by traversing through various stages in the purification of the soul, one climbs up the ladder of mystical ascent toward the divine union. Among the Syrian Christians, who greatly influenced Ṣūfism, an Islāmic form of mysticism, mystical asceticism is graphically described in a work by Stephanos bar Ṣūdailē, 5th–6th-century monk from Edessa, entitled *Hierotheos* ("Holy God").

For Christians, still another type of asceticism, stemming from the desire to experience the sufferings of Christ, was exemplified by the emergence in the Middle Ages of the beggar-monks. Devotion to Christ and his sufferings has enabled these monks (and others) to enter into the experience of Christ's sorrows with new insights, such as finding a Christ in all who suffer. In this instance, asceticism has taken on a new meaning—*i.e.*, to serve Christ by becoming united with all whose lives are filled with pain and sorrow and by entering the service of compassion and redemption.

Forms of religious asceticism. *Celibacy and denial of material goods.* In all strictly ascetic movements, celibacy has been regarded as the first commandment (see also CELIBACY). Virgins and celibates emerged among the earliest Christian communities and came to occupy a prominent status. Among the earliest Mesopotamian Christian communities, only the celibates were accepted as full members of the church, and in some religions only celibates are permitted to be priests (*e.g.*, Aztec religion and Roman Catholicism). Abdication of worldly goods is another fundamental principle. In monastic communities there has been a strong trend toward this ideal. In Christian monasticism this ideal was enacted in its most radical form by Alexander Akoimetos, a founder of monasteries in Mesopotamia (died *c.* 430). Centuries before the activities of the medieval Western Christian monk St. Francis of Assisi, Alexander betrothed himself to poverty, and, through his disciples he expanded his influence in Eastern Christian monasteries. These monks lived from the alms they begged but did not allow the gifts to accumulate and create a housekeeping problem, as occurred among some Western monastic orders, such as the Franciscans. In the East, wandering Hindu ascetics and Buddhist monks also live according to regulations that prescribe a denial of worldly goods.

Abstinence and fasting. Abstinence and fasting are by far the most common of all ascetic practices. Among the primitive peoples, it originated, in part, because of a belief that taking food is dangerous, for demonic forces may enter the body while one is eating. Further, some foods regarded as especially dangerous were to be avoided. Fasting connected with religious festivals has very ancient roots (see also DIETARY LAWS AND CUSTOMS). In ancient Greek religion, rejection of meat appeared particularly among the Orphics, a mystical, vegetarian cult; in the cult of Dionysus, the orgiastic god of wine; and among the Pythagoreans, a mystical, numerological cult. Among a number of churches the most important period of fasting in the liturgical year is the 40 days before Easter (Lent), and among Muslims the most important period of fasting is the month of Ramadān. The ordinary fasting cycles, however, did not satisfy the needs of ascetics, who therefore created their own traditions. Among Jewish-Christian circles and Gnostic movements, various regulations regarding the use of vegetarian food were established, and Manichaean monks won general admiration for the intensity of their fasting achievements. Christian authors write of their ruthless and unrelenting fasting, and, between their own monks and the Manichaeans, only the Syrian ascetical virtuosos could offer competition in the practice of asceticism. Everything that could reduce sleep and make the resultant short period of rest as troublesome as possible was tried by Syrian ascetics. In their monasteries Syrian monks tied ropes around their abdomens and were then hung in an awkard position, and some were tied to standing posts.

Personal hygiene and limitation of location. Personal hygiene also fell under condemnation among ascetics. In the dust of the deserts—where many ascetics made their abodes—and in the blaze of the Oriental sunshine, the abdication of washing was equated with a form of asceticism that was painful to the body. With respect to the prohibition against washing, the Persian prophet Mani seems to have been influenced by those ascetic figures who had been seen since ancient times in India, walking around with their long hair hanging in wild abandonment and dressed in filthy rags, never cutting their fingernails and allowing dirt and dust to accumulate on their bodies. Another ascetic practice, the reduction of movement, was especially popular among the Syrian monks, who were fond of complete seclusion in a cell. The practice of restriction in regard to contact with human beings culminated in solitary confinement in wildernesses, cliffs, frontier areas of the desert, and mountains. In general, any settled dwelling place has been unacceptable to the ascetic mentality, as noted in ascetical movements in many religions.

Psychological and pain-producing asceticism. Psychological forms of asceticism have also been developed. A technique of pain-causing introspection was used by Buddhist ascetics in connection with their practices for meditation. The Syrian Christian theologian St. Ephraem Syrus counselled the monks that meditation on guilt, sin, death, and punishment—*i.e.*, the pre-enactment of the moment before the Eternal Judge—must be carried out with such ardour that the inner life becomes a burning lava that produces an upheaval of the soul and torment of the heart. Syrian monks striving for higher goals created a psychological atmosphere in which continued fear and dread, methodically cultivated, were expected to produce continual tears. Nothing less than extreme self-mortification satisfied the ascetic virtuosos.

Role of meditation

Pain-producing asceticism has appeared in many forms. A popular custom was to undergo certain physically exhausting or painful exercises. The phenomena of cold and heat provided opportunities for such experiences. The Hindu fakirs (ascetics) of India provide most remarkable examples of those seeking painful forms of asceticism. In the earliest examples of such radical forms of self-mortification that appeared in India, the ascetic stared at the sun until he went blind or held up his arms above the head until they withered. Syrian Christian monasticism was also inventive in regard to forms of self-torture. A highly regarded custom involved the use of iron devices, such as girdles or chains, placed around the loins, neck, hands, and feet and often hidden under

garments. Pain-producing forms of asceticism include self-laceration, particularly castration, and flagellation (whipping), which emerged as a mass movement in Italy and Germany during the Middle Ages and is still practiced in parts of Mexico and the southwestern United States.

Variations of asceticism in world religions. *Primitive and ancient religions.* In the primitive religions, asceticism in the form of seclusion, physical discipline, and the quality and quantity of food prescribed has played an important role in connection with the puberty rites and rituals of admission to the tribal community. Isolation for shorter or longer periods of time and other acts of asceticism have been imposed on medicine men, since severe self-discipline is regarded as the chief way leading to the control of occult powers. Isolation was and is practiced by young men about to achieve the status of manhood in the Blackfoot and other Indian tribes of the northwestern United States. In connection with important occasions, such as funerals and war, taboos (negative restrictive injunctions) involving abstinence from certain food and cohabitation were imposed. For the priests and chiefs these were much stricter. In Hellenistic culture (*c.* 300 BC–*c.* AD 300), asceticism in the form of fasting and refraining from sexual intercourse was practiced by communities of a religiomystical character, including the Orphics and Pythagoreans. A new impetus and fresh approach to ascetic practices (including emasculation) came with the expansion of the Oriental mystery religions (such as the cult of the Great Mother) in the Mediterranean area.

Eastern religions. In India, in the late Vedic period (*c.* 1500 BC–*c.* 200 BC), the ascetic use of *tapas* ("heat," or austerity) became associated with meditation and *yoga*, inspired by the idea that *tapas* kills sin. These practices were embedded in the Brahmanic (ritualistic Hindu) religion in the *Upaniṣads* (philosophical treatises), and this view of *tapas* gained in importance among the Yogas and the Jainas, adherents of a religion of austerity that broke away from Brahmanic Hinduism. According to Jainism, liberation becomes possible only when all passions have been exterminated. Under the influences of such ascetic views and practices in India, Siddhārtha Gautama himself (see above) underwent the experiences of bodily self-mortification in order to obtain spiritual benefits; but since his expectations were not fulfilled, he abandoned them. But his basic tenet, which held that suffering lies in causal relation with desires, promoted asceticism in Buddhism. The portrait of the Buddhist monk as depicted in the *Vinaya* (a collection of monastic regulations) is of one who avoids extreme asceticism in his self-discipline. The kind of monasticism that developed in Hinduism during the medieval period also was moderate. Asceticism generally has no significant place in the indigenous religions of China (Confucianism and Taoism) and Japan (Shintō). Only the priests in Confucianism practiced discipline and abstinence from certain foods during certain periods, and some movements within Taoism observed similar rules. Shintō in Japan, however, does include ascetics.

Western religions. Judaism, because of its view that God created the world and that the world (including man) is good, is nonascetic in character and includes only certain ascetic features, such as fasting for strengthening the efficacy of prayer and for gaining merit. Though some saw a proof of the holiness of life in some ascetic practices, a fully developed ascetical system of life has remained foreign to Jewish thought, and ascetic trends could, therefore, appear only on the periphery of Judaism. Such undercurrents rose to surface among the Essenes, a monastic sect associated with the Dead Sea Scrolls, who represented a kind of religious order practicing celibacy, poverty, and obedience. The archaeological discovery (1940s) of their community at Qumrān (near the Dead Sea in an area that was a part of Jordan) has thrown new light on such movements in Judaism.

In Zoroastrianism (founded by the Persian prophet Zoroaster, 7th century BC) there is officially no place for asceticism. In the Avesta, the sacred scriptures of Zoroastrianism, fasting and mortification are forbidden, but ascetics were not entirely absent even in Persia.

Significance for Christianity

In Christianity all of the types of asceticism have found realization. In the Gospels asceticism is never mentioned, but the theme of following the historical Christ gave asceticism a point of departure. An ascetic view of the Christian life is found in the First Letter of Paul to the Corinthians in his use of the image of the spiritual athlete who must constantly discipline and train himself in order to win the race. Abstinence, fasts, and vigils in general characterized the lives of the early Christians, but some ramifications of developing Christianity became radically ascetic. Some of these movements, such as the Encratites (an early ascetic sect), a primitive form of Syrian Christianity, and the followers of Marcion, played important roles in the history of early Christianity. During the first centuries ascetics stayed in their communities, assumed their role in the life of the church, and centred their views of asceticism on martyrdom and celibacy. Toward the end of the 3rd century, monasticism originated in Mesopotamia and Egypt and secured its permanent form in cenobitism (communal monasticism). After the establishment of Christianity as the official religion of the Roman Empire (after AD 313), monasticism was given a new impetus and spread all over the Western world. In Roman Catholicism new orders were founded on a large scale. Though asceticism was rejected by the leaders of the Protestant Reformation, certain forms of asceticism did emerge in Calvinism, Puritanism, Pietism, early Methodism, and the Oxford Movement (an Anglican movement of the 19th century espousing earlier ecclesiastical ideals). Related to asceticism is the Protestant work ethic, which consists of a radical requirement of accomplishment symbolized in achievement in one's profession and, at the same time, demanding strict renunciation of the enjoyment of material gains acquired legitimately.

Islām in its beginnings knew only fasting, which was obligatory in the month of Ramaḍān. Monasticism is rejected in the Qur'ān (the Islāmic sacred scripture). Yet ascetic forces among Christians in Syria and Mesopotamia, vigorous and conspicuous, were able to exercise their influence and were assimilated by Islām in the ascetic movement known as *zuhd* (self-denial) and later in that of Ṣūfism, a mystical movement that arose in the 8th century and incorporated ascetic ideals and methods.

BIBLIOGRAPHY. JAMES HASTINGS (ed.), "Asceticism," in the *Encyclopaedia of Religion and Ethics*, vol. 2 (1910); and "Askese," in the *Reallexikon für Antike und Christentum*, vol. 1 (1950), are two summary articles, the latter in German. OSCAR HARDMAN, *The Ideals of Asceticism* (1924), presents a treatment of wider scope. EDMOND DEMAITRE, *Fakirs et yogis des Indes* (1936; Eng. trans., *The Yogis of India*, 1937), offers a matter-of-fact treatment of the phenomenon. For Buddhist asceticism, the best work is G.C.A. EVOLA, *La dottrina del risveglio* (1943; Eng. trans., *The Doctrine of Awakening*, 1951); for Platonism, I.G. WHITCHURCH, *The Philosophical Bases of Asceticism in the Platonic Writings and in Pre-Platonic Tradition* (1923), is still usable. F. MARTINEZ, *L'Ascétisme chrétien pendant les trois premiers siècles de l'Église* (1913), presents a comprehensive account of Christian asceticism in early centuries, which may be supplemented by OWEN CHADWICK (ed.), *Western Asceticism* (1958), unfolding the phenomenon through the translation of selected classical original records. A. VOOBUS, *History of Asceticism in the Syrian Orient*, 2 vol. (1958–60), based on manuscript research, deals with the autochthonous origin of Syrian monasticism and its development in Syria, Mesopotamia, and Persia. For the later history of Christian asceticism, the best treatment is LOUIS GOUGAUD, *Dévotions et pratiques ascétiques du moyen âge* (1925; Eng. trans., *Devotional and Ascetic Practices in the Middle Ages*, 1927).

(A.V.)

Aschelminthes

The phylum Aschelminthes (also known as Nemathelminthes) comprises a diverse group of invertebrate animals. Adults possess a space—the pseudocoel—between the gut and the body wall, have bilateral symmetry (*i.e.*, a plane through the centre of the body divides it into mir-

ror-image halves), and lack division of the body into segments.

Many aschelminths are less than one millimetre (0.04 inch) long; some are less than half that length. The smallest forms, in fact, are no larger than certain protozoans, with which they were confused by early microscopists. The bodies of aschelminths, however, contain several complete organ systems and thus are more complex than the protozoans, which lack comparable organs.

The group contains about 17,000 described species, a large number of which are common in salt water or freshwater. Many are of economic importance as parasites in man and domestic animals. Adults are generally of academic interest because they demonstrate eutely; *i.e.*, they tend to be composed of a fixed number of cells.

GENERAL FEATURES

Size range and diversity of structure. Six classes of Aschelminthes are recognized: Nematoda, Rotifera, Gastrotricha, Kinorhyncha (or Echinodera), Nematomorpha (or Gordiacea), and Priapulida.

Nematodes, also called eelworms, pinworms, threadworms, and roundworms, range in length from about one millimetre (about 0.04 inch) to more than 20 centimetres (about eight inches), and their elongated bodies tend to be pointed at both ends. Rotifera, so-called wheel animalcules, are microscopic in size, usually from 100 to 500 microns (about 0.004 to 0.02 inch) long, and typically have a ciliated (*i.e.*, with ever-moving hairlike structures) disk at the anterior, or front, end. Gastrotrichs and kinorhynchs are minute, wormlike forms. Gastrotrichs are ciliated on the ventral, or lower, side. The kinorhynch has a spiny ringed body and a retractable head. Nematomorphs, or hairworms, are thin, elongated animals and attain lengths exceeding 80 centimetres (about 30 inches). The outer layer (cuticle) is thick and tough. Priapulids are warty and superficially (externally) ringed, or segmented; the largest are about eight centimetres (about three inches) long.

Distribution and abundance. Nematoda, the largest class, comprises some 13,000 species. Free-living species occur in salt water and freshwater and in sand and soil; parasitic forms are found in animals and plants throughout the world. Most Rotifera, numbering about 1,800 species, are free-living forms in both freshwater and salt water.

The Gastrotricha number about 1,800 species and live in salt water and freshwater. The Kinorhyncha, which includes about 100 known species, is a marine group. Members of the Nematomorpha, containing 250 to 300 species, are parasitic in arthropods (*e.g.*, insects, spiders, centipedes, and crabs) as juveniles and free-living in salt water or freshwater as adults. Priapulida, which numbers less than ten species, is a salt-water group.

NATURAL HISTORY

Reproduction and development. Most aschelminth species either have separate sexes or are hermaphrodites (*i.e.*, possessing functional reproductive organs of both sexes) derived from males or females.

The eggs are fertilized inside the female, but development usually takes place outside the female's body. Sperm are injected by male rotifers through the female body wall. In nematodes, sperm are injected through the female genital pore (vulva) with the assistance of the copulatory spicules (needlelike structures) of the male (see Figure 2). Copulation in kinorhynchs presumably involves setae, or bristles, on the male copulatory organ. Gastrotrichs are mainly hermaphroditic. Male nematomorphs deposit sperm near the female cloaca (*i.e.*, a cavity that functions as both a reproductive and an excretory duct); the sperm move through the cloaca before entering a storage sac called the seminal receptacle. In some rotifers and nematodes the eggs hatch into larvae within the female; the larvae then move to the outside.

The embryonic development of aschelminths, although peculiar in several ways, is basically determinate and spiral—that is, the early divisions of the fertilized egg produce cells called blastomeres that form definite organs or tissues in the adult, and certain parts (spindle axes) of the dividing egg are oriented in a definite way. It is therefore possible to identify each blastomere and to determine its final form in the adult.

During embryonic development a hollow ball of cells, a coeloblastula, is produced, whose central space, the blastocoel, forms the adult pseudocoel, in which lie the internal organs. Early in development, cell division ceases, except in the reproductive organs, so that the number of cells in the adult of a species is more or less constant. Even in adult rotifers and nematodes, whose tissues usually consist of masses of cytoplasm containing nuclei rather than individual cells with one nucleus each, the number of nuclei remains constant.

Larval development

Larval development involves periodic shedding (molting) of the cuticle in kinorhynchs, nematodes, nematomorphs, and priapulids. The external, or superficial, segments of newly hatched kinorhynch larvae are either lacking or indistinct; during molting, which occurs at least five times, the number of external segments increases, and associated modifications of the cuticle occur until the adult form is attained.

Molting in the larger nematodes is controlled by a mechanism involving an organic substance called a molting hormone and specialized cells in the nervous system called neurosecretory cells. Four molts occur between the four larval stages and the adult stage; in some parasitic nematodes one or two molts occur before the egg hatches. Larvae of most free-living nematodes differ from adults only in size and the absence of sex organs and sex characteristics. The larvae of many parasitic nematodes, on the other hand, differ markedly from the adults. These differences, apparently associated with the parasitic mode of life, usually involve only the head and the esophagus.

The nematomorph larva, free-living in water at the time of hatching, is small and divided into two regions—presoma and trunk. Within a short time it enters the body of the host arthropod—usually an insect but sometimes a centipede, a millipede, or a crab in the case of the marine nematomorph *Nectonema*. The larva grows in the body cavity of the host, gradually losing certain larval structures associated with feeding and derived from the presoma (proboscis and stylets); after several weeks or months, the larva leaves the host and molts to form a lethargic adult that is free-living in or near water. Only males in search of females actually swim.

Priapulids hatch as tiny larvae enclosed in plates derived from the cuticle. A series of circular spines at the front end is followed by a narrow neck; both regions can be withdrawn into the lorica, a thick, hard covering. The last circle of spines in larvae of *Halicryptus* serves as an outlet for gland cells resembling the adhesive tubes of gastrotrichs. Larvae of the genus *Priapulus* possess lateral tactile spines resembling lateral antennae found in rotifers and a terminal foot similar to that in rotifers. The internal structure of the larvae resembles that of the adults. Priapulid larvae apparently live and feed on the ocean bottom for about two years before shedding the lorica; they molt throughout their lives.

Behaviour and ecology. *Habitat.* Free-living aschelminths are aquatic animals; the aquatic medium, however, may occupy only a tiny crevice in soil or sand. Rotifers are abundant in freshwaters everywhere; a few live in brackish water or the sea. Gastrotrichs live primarily in freshwater, although there are also a few marine forms. Kinorhynchs are wholly marine; nematomorphs, except for the marine genus *Nectonema*, live only in freshwater. Nematodes occur in virtually every aquatic habitat, including vinegar; priapulids are marine.

Locomotion. Most aschelminths remain close to the substrate, defined here as the ground or the surface of an object with which an organism associates, when moving. Some rotifers have a terminal posterior foot that is elongated and stalklike; the foot serves to attach the animal permanently. In other rotifers the foot is shorter and is used either to grasp objects as the animal creeps or, in the swimming forms, as a rudder. Gastrotrichs glide across a substrate on cilia; kinorhynchs move by protruding the head, locking it in the substrate by the

scalids, or hooked spines, and pulling the rest of the body forward. Nematodes usually move in a way similar to that of snakes—*i.e.*, by waves of contraction that move down the body; they can also move or remain stationary by using an adhesive cement produced by the caudal glands. Priapulids bury themselves in the soft bottom mud of the sea at depths as great as 500 metres (over 1,600 feet).

Food. Aschelminths generally feed on small particles, such as bacteria, protozoans, and organic detritus; but many nematodes and rotifers and all priapulids are carnivorous and can kill and ingest larger animals. Digestion is believed to be extracellular (*i.e.*, occurring outside the cells) in the forepart of the gut, with absorption taking place in the hindpart; in some rotifers and nematodes, however, intracellular digestion may occur.

Adaptations to dry conditions. Many aschelminths live in temporary pools and have evolved eggs that are resistant to drying and other means of surviving dry conditions. Some rotifers can survive desiccation for three to four years then become active again when placed in water. Some bdelloids (rotifer order Bdelloidea) secrete a protective cyst. Others produce three types of eggs, of which a thick-shelled dormant type can survive desiccation and low temperatures for months; such eggs invariably produce females. The gastrotrich order Chaetonatoidea produces two types of eggs, one of which is dormant and resistant to desiccation. Nematode eggs are covered by a protein membrane that occasionally has a heavily sculptured appearance; in some cases it contains chitin, a tough carbohydrate substance that strengthens the case. The egg shells may have lids through which the young hatch or, particularly in some mermithids, so-called byssus threads by which the eggs become attached to plants. In many groups of nematodes, particularly parasitic forms, only one type of egg is normally produced; it is highly resistant to desiccation and to the action of chemicals.

Resistance of rotifers

Parasitic and free-living nematodes. Larvae of parasitic nematodes are either free-living or parasitic in a wide range of intermediate hosts: annelid worms, arthropods, mollusks, vertebrates of all types, and plants. Some species have parasitic larvae and free-living adults. Adults also occur in a wide range of hosts, which may be infected by eating nematode eggs or larvae; in some cases, the larvae penetrate the host's skin. In the medically important filariids the larvae enter the bloodstream of their vertebrate host, from which they may be sucked by blood-sucking insects. In the insect host further development takes place before the larvae are injected into another vertebrate host, in which they grow to adulthood. The free-living larvae of many plant-parasitic nematodes first attack the roots of the host plant; they remain attached as adults on the outer surface of the root or penetrate the plant tissues, through which they may migrate.

FORM AND FUNCTION

External structure. *General characteristics.* Separation of the head as a distinct body part is seldom apparent in aschelminths. The body is usually elongated; some rotifers, however, are nearly spherical. Spines, scales, and setae (bristles) of various kinds occur on the body surface. Gastrotrichs are almost invariably wormlike, with an expanded head region; the body bears cilia, particularly on the head lobe and along the ventral surface. The kinorhynch body, relatively constant in diameter, is superficially divided into segments and bears a series of regularly arranged spines.

Nematodes and nematomorphs are usually wormlike; some of the free-living marine nematodes may be conspicuously ringed and bear many long setae; a few have rows of ventral stiltlike bristles on which they move.

The warty body of the priapulids is divided into the presoma and a longer annulate (ringed) trunk irregularly covered by small spines and papillae (fingerlike projections). The anterior tip of the body is modified as a retractable, spined, barrel-shaped structure (proboscis).

The head and related structures. The anterior end of an aschelminth, although called a head, does not usually form a distinct one. In rotifers it is typically broad, with the mouth on a so-called apical field, which is centrally located, nonciliated, and surrounded by the corona (a ciliated region; see Figure 1). The apical field usually

The corona of rotifers

From L. Hyman, *The Invertebrates.* (1959); used by permission of McGraw-Hill Book Co.

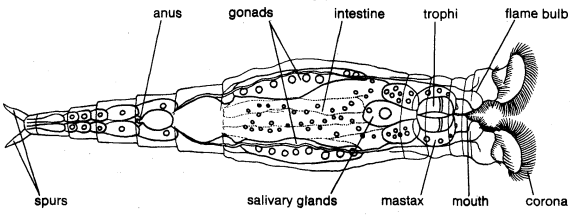

Figure 1: Body plan of rotifer (*Philodina roseola*).

bears a series of sensory hairs and the ducts of the retrocerebral organ, which is of uncertain function. The shape of the corona varies with its function. The cilia are frequently fused to form cirri (tentacle-like organs), membranelles (flat plates), and other complex structures; such structures, however, may be entirely lacking. In general the corona is an organ of locomotion; it is reduced in sessile (nonmoving) and creeping forms, but the former may use it to produce water currents for passing food into the mouth.

The anterior end of nematomorphs, called the calotte, is usually white and bordered posteriorly by a ring of dark pigment. The mouth is terminal or ventral within the calotte but may be totally lacking in the adults of some species.

Kinorhynchs are virtually the only aschelminths with a more or less definite head. It can be withdrawn into the anterior region by muscles attached to the outer surface of the esophagus or pharynx. The roughly spherical head includes the first of the 13 or 14 external segments and bears a central terminal mouth and five to seven circles of scalids (hooked spines) that may bear bristles. The mouth is on the tip of an extendable mouth cone armed with spines called oral styles; there may be other spines on the mouth cone.

Posterior to the head in some kinorhynchs is a region divided into 14 or 16 plates, or placids, which close over the anterior end when the head is retracted. Other kinorhynchs have eight or ten slight thickenings that can be withdrawn with the head.

The gastrotrich head is typically a swollen lobelike region with one or two pairs of red pigment spots; sometimes with one or two pairs of palps, or tentacles, on each lobe; and with long tufts of head cilia, particularly in chaetonotids, that probably act as sense organs. The chaetonid head also contains paired ciliated pits. The circular mouth opening is usually surrounded by bristles or hooks derived from the lining of the mouth cavity.

The nematode head typically bears a central, terminal mouth surrounded by a series of sense organs that are probably tactile (*i.e.*, pertaining to touch) and a pair of lateral sensory structures called amphids. The latter are characteristic features of nematodes. The mouth opening may be bounded either by a fringe derived from the cuticle supported by 12 rods (rugae), or by two, three, or six muscular lips; in some species, the mouth is rather large and permanently open. Basically the sense organs form three circles: an internal circle of six organs bordering the mouth opening, an intermediate circle of six organs, and an outer circle of four. The last two circles in some groups unite to form one circle of ten, in which the components of the original circles can be distinguished.

In other groups, the intermediate circle apparently is lacking, and only an outer circle of four remains. The sense organs of the head, other than the amphids, are often hairlike in free-living marine species and papillose, or fingerlike, in parasitic species and in those inhabiting the soil. The lateral amphids, of uncertain function, may be spiral-shaped grooves in the cuticle, pocket-like and elongated from front to back, or—in parasitic species—papillose.

A hypothetical primitive nematode head has been described as having the mouth bounded by six lips with two papillae—one related to the inner lips, the other to the intermediate lips—plus an outer circle of four additional papillae. From such a hypothetical arrangement other lip and sense organ arrangements could have been derived. Although such speculation is of some value, the marked similarity between the circular, rugae-bordered mouth openings of some members of the order Chromodorida and the mouth of many gastrotrichs suggests that the earliest nematodes did not possess lips.

The cheilostome and esophostome

The nematode mouth opens into a buccal cavity, or cheilostome, lined by cuticle similar to that covering the outer surface of the body. The anterior region of the esophagus may also form a chamber, the esophostome. Toothlike structures of various sizes and number may develop from the walls of the cheilostome and esophagus; spear-like structures in the esophagus are characteristic of certain nematodes parasitic in plants and insects.

The mouth in the Priapulida opens in the centre of the retractable proboscis and is surrounded by spines arranged in concentric five-membered groups.

The tail. Most aschelminths, except kinorhynchs, have a tail, frequently with structures that may aid in locomotion, may enable the animal to attach to a substrate, or—in males—may function during mating. In rotifers this tail is called a foot; it may be divided at the tip to form spurs (see Figure 1) or toes, at the ends of which pedal glands extrude an adhesive cement. Similarly, the tail of chaetonotoid gastrotrichs has tubes that produce an adhesive substance; in the gastrotrich order Macrodyasoidea, as many as 250 such tubes and associated adhesive glands occur over the entire body. In kinorhynchs, which have no true tail, a pair of similar adhesive tubes occurs in the ventral surface.

Many free-living nematodes, particularly marine forms, have a pore on the tail through which a cement substance produced by three internal caudal (tail) glands is extruded (see Figure 2); several rows of pores of uncertain function are found along the body of many, largely marine groups. In many species, particularly parasitic ones and those inhabiting the soil, the cuticle of the male tail is expanded into thin lateral sheets called caudal alae. Priapulids have no true tail, although one or two hollow caudal appendages of uncertain function occur in two species. The posterior end of the body also bears the anus and two urogenital (excretory and reproductive) pores.

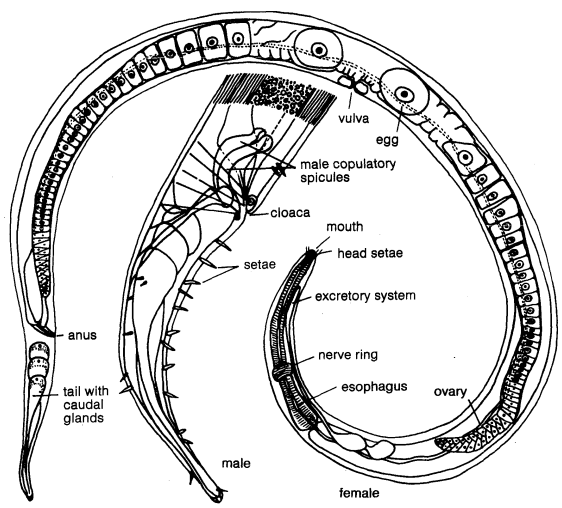

Figure 2: Body plan of nematode (*Axonolaimus paraspinosus*). General view of a female and the tail of a male.

Body structure. *The first tube: the cuticle.* The body of all aschelminths can be considered a series of tubes, one within the other. The outermost tube consists of the epidermis ("skin") and the cuticle. The cuticle may form rings; in rotifers, however, it forms thick plates, and in kinorhynchs it forms external segments. The gastrotrich cuticle is covered with spines, and that of various nematodes bears structures such as hooks, rings, and bristles.

Cuticle structures and modifications

The cuticle is derived from and attached to the underlying syncytial epidermis—*i.e.*, epidermis without cell walls. This epidermis, structurally simple in rotifers and gastrotrichs, bulges in nematodes into the pseudocoel to form three or four longitudinal ridges, or chords, which are dorsal, ventral, and lateral in position. In kinorhynchs the chords are dorsal and lateral; in nematomorphs they are dorsal and ventral.

The cuticle of large nematodes may have as many as eight layers. Some small species have several layers with complex systems of rings, rods, and articulatory ("hingeing") processes. Generally, the cuticle appears to consist of three layers: an outer cortical layer, a middle plastic matrix layer, and an inner basal layer.

The surface of the nematode cuticle is usually marked by transverse grooves (striations) and may appear to be covered by dots and lines that indicate the presence of rings or rods within the cuticle. They do not open to or project from the surface. Four structural types of cuticle occur in the adult. In one type, hardened cortical and basal layers are separated by the usually plastic, sometimes fluid, matrix layer; through the middle layer pass rigid columns connecting the cortical with the basal layer. The second type of cuticle consists of transverse rings, or annules, of rigid material separated by narrow regions of more flexible material. The rigid annules have overlapping edges or a series of comblike processes that extend from one annule to another. The third type of cuticle has several distinct layers of crossing, spiraling fibres that form a flexible lattice, which usually consists of an annular cortical layer and a median, matrix layer that is soft and easily deformed. The fourth type of cuticle is very thin, with no distinguishing features other than striations and dots.

The cuticle of nematomorphs consists of an outer homogeneous layer and an inner layer that may have as many as 45 fibrous laminations. The most conspicuous feature of the cuticle in many species is the irregular pattern of wartlike processes, or areoles, projecting from the outer surface. In priapulids the cuticle has two layers: an outer homogeneous layer and a thicker, laminated inner layer.

The cuticle in rotifers, gastrotrichs, and kinorhynchs is thin; little else is known of its structure except that it contains no chitin. In kinorhynchs the cuticle forms overlapping annular segments. In rotifers it is yellowish in colour and often ringed and, in some species, forms the lorica, consisting of one or more plates; this structure may often be conspicuously marked with grooves, striations, tubercles (knoblike projections), or spines. The gastrotrich cuticle is typically covered by scales, which, at the posterior end of the body, frequently bear curved, sometimes multipronged spines.

The second tube: the musculature. The muscles form the next tube of the body. In rotifers, gastrotrichs, and kinorhynchs, they consist of a number of enucleate—*i.e.*, cells without nuclei—circular muscles running transversely around the body. Typically, another system of nucleate muscles runs longitudinally. This longitudinal system, least modified in gastrotrichs, is most extensive along the ventral surface. In kinorhynchs, the longitudinal muscles correspond to the external segmentation. Rotifers have a large number of single muscles, but they are not arranged to form a system. In nematodes and nematomorphs, only longitudinal muscles occur. Two muscle layers occur in priapulids; the longitudinal muscles apparently control the proboscis, but there are also circular muscles in that region.

The third tube: the digestive system. The third tube, the pseudocoelom, is poorly developed in rotifers, gastrotrichs, and nematomorphs but is extensive and fluid-filled in nematodes and kinorhynchs. The large body cavity of priapulids probably does not constitute a pseudocoelom.

The innermost tube of aschelminths, the digestive tract, extends the length of the body and, toward the anterior end, is always swollen and muscular. In gastrotrichs,

Adaptations of the digestive system

kinorhynchs, and nematodes, the mouth leads into a short, often elaborate buccal (mouth) cavity, followed by the swollen muscular region variously called an esophagus, pharynx, or mastax. This region consists of a mass of radial muscles, through the middle of which runs a triradiate (Y-shaped), cuticle-lined space, or lumen. In some kinorhynchs, however, the lumen may be round or flattened. In nematodes with a triradiate lumen, one arm is always midventral; it is middorsal in kinorhynchs and some gastrotrichs (macrodyasoids) but ventral in others (chaetonotoids). In certain nematodes and gastrotrichs, the esophagus forms muscular bulbs; in some nematodes the bulbs have valves. Gland cells, or salivary cells, occur on the outer surface of the esophagus in kinorhynchs and gastrotrichs. Three similar groups of cells are buried within the nematode esophagus and empty by ducts into the lumen. In kinorhynchs the esophagus has an epithelial cell layer below the lining; the latter is derived from the cuticle.

In rotifers, the mouth is often on the ventral side. It may lead either directly to the esophagus, or mastax, or indirectly through a ciliated buccal tube. The mastax is usually a muscular organ, and the arrangement of the muscles may be complex, with an internal chewing apparatus made up of several cuticle-derived structures—trophi—that are characteristic of the different groups of rotifers. Usually, a pair of salivary glands empties anterior to the trophi. The esophagus is swollen anteriorly into a stomach. The intestinal wall, which is not lined with cuticle, consists of one layer of granular cells, which may bear cilia. The posterior end may terminate in a rectum.

The esophagus of priapulids differs from that of other aschelminths in having both circular and longitudinal muscles covered externally by a thin layer of longitudinal muscles and internally by an epidermis and a spiny cuticle. The esophagus leads into a nonmuscular intestine.

The nematomorph digestive tract is simple; both sexes have a cloaca, and there is frequently no mouth. The anterior part of the gut usually is a solid rod of cells, presumably representing the esophagus; the intestine, a small, simple tube, may be an excretory organ.

Functional features. *Water balance and excretion.* Aschelminths have no special respiratory or circulatory systems. Water balance and excretion are carried out by tubes closed at one end; at the other end they empty into the posterior end of the gut. This arrangement prevails in most rotifers, some gastrotrichs (order Chaetonotoidea), and all kinorhynchs. In priapulids the tubes are connected to the ducts of the gonads, forming excretory organs called protonephridia; these do not occur in nematodes and nematomorphs. The protonephridia in rotifers and gastrotrichs have flame bulbs, cup-shaped organs into the lumen of which project cilia. In kinorhynchs and priapulids the flame bulbs are replaced by solenocytes, long tubular cells with one whiplike hair, or flagellum. In priapulids, several large clusters of solenocytes close to the gonads are supported by mesenteries, or sheets of cells, within the body cavity.

In most marine nematodes water balance and some excretion are performed by one large ventral gland cell, the renette (see Figure 2). In most soil, freshwater, and parasitic species, however, these functions are performed by lateral tubes buried in the lateral cords of the epidermis. Both systems empty to the exterior through an anterior, ventral pore. A definite excretory system is lacking in all nematomorphs, some rotifers, and some nematodes.

Reproductive system. The reproductive system is relatively simple. The ovaries and testes are often double in both sexes, but most rotifers and some nematodes have one gonad. The male and female sex cells in rotifers and most gastrotrichs empty through the cloaca; kinorhynchs have terminal lateral gonopores, or reproductive openings, in each sex. In nematodes the sperm leave by the subterminal cloaca in most males, and in most females the eggs leave via an opening at about the middle of the body (Figure 2). The tail of male nematodes usually has files of sensory papillae, setae, or rays and a pair of copulatory, rodlike spicules (Figure 2). In some groups, caudal alae, which assist in copulation, may develop around the cloacal region. A pair of small porelike sense organs (phasmids) occur on the tail of some nematodes.

Components of the nervous system

Nervous system. The aschelminth nervous system is relatively simple. It consists of an anterior nerve mass or nerve ring and a series of major longitudinal and numerous smaller nerves. There are two major ventral nerves in rotifers; a pair of similar lateral nerves in gastrotrichs; a single indistinct ventral nerve in kinorhynchs; a midventral nerve cord in nematomorphs; and one ventral nerve in priapulids. The remainder of the priapulid nervous system is closely associated with the epidermis. In nematodes nerves extend anteriorly from a nerve ring that passes around the esophagus (see Figure 2); posteriorly are a middorsal nerve, a midventral nerve, and from one to three pairs of lateral nerves.

EVOLUTION

On largely structural evidence—since there is no fossil record—the Rotifera appear to be rather primitive animals that evolved more or less directly from the Turbellaria, a class of flatworms (phylum Platyhelminthes). The strongest evidence is provided by developmental similarities of the two groups and by the presence of virtually identical protonephridia in rotifers and in certain turbellaria.

The Gastrotricha are considered by some authorities to be related to rotifers because of the form of the body musculature and, in some species, the presence of protonephridia with flame cells. These features are common to most aschelminth groups, however; gastrotrichs resemble nematodes—to which they are probably most closely related—in the structure of esophagus and the digestive tract and in the presence of cuticular spines and bristles; in addition, the gastrotrichs have an organ similar to the adhesive tube found in some marine nematodes. Many of these resemblances, however, may be only structural similarities and thus may have no evolutionary significance. It is doubtful that gastrotrichs are a natural group since the location of the esophageal lumen of members of the order Macrodyasoidea differs from that of other gastrotrichs and nematodes (see above *Tubular structure*). In addition, the Macrodyasoidea have pores that lead from the lumen of the esophagus to the exterior, and they lack protonephridia.

Both Kinorhyncha and Rotifera have been considered as relatives of arthropods or as links between arthropods and annelids, largely because of their segmentation and the addition, during development, of segments anterior to the terminal segment of the body. The segmentation is only superficially similar, however, since in kinorhynchs it develops from the cuticle inward, and in annelids and arthropods it starts in the mesoderm and develops outward.

In contrast, the similarities between kinorhynchs and other aschelminths are extensive: no true coelom, protonephridia with flame cells, a close association between the nervous system and epidermis, presence of adhesive tubes and copulatory spicules, and similar form of the esophagus. On the basis of these similarities, kinorhynchs are generally considered relatives of rotifers, gastrotrichs, and nematodes.

Nematodes are generally regarded as pseudocoelomate aschelminths. The only strong evidence against such a relationship is the absence of protonephridia. Nematodes, elongated cylinder-shaped animals, have longitudinal muscles that move the body in a snakelike fashion. The "skeleton" of a nematode is the pseudocoelomic fluid, which is under pressure. The esophagus, an efficient anterior pump, sucks food into the gut against the pressure of the fluid in the pseudocoelom. The absence in nematodes of flame cells and solenocytes may be attributable to the fact that cilia and flagella probably cannot function in the presence of such internal pressure. Because mechanical problems are imposed on nematodes by the structural nature of the body, most of the features characteristic of nematodes are functionally interrelated. Any animal that evolved such a unique body would nec-

essarily have such complex morphological features. It is therefore difficult to determine phylogenetic relationships on the basis of structural features. Even the triradiate esophageal lumen common to most aschelminths is not necessarily indicative of a relationship among the various groups; it happens to be the most simple and efficient shape for a lumen.

Although the taxonomic position of the nematomorphs is somewhat complicated by the unique nature of their digestive system, the free-living larvae have certain structural similarities to the kinorhynchs, and the nematomorphs are more easily accommodated within the aschelminths than elsewhere. The relationship of the Priapulida to other groups is even more uncertain, since it has not yet been definitely established that it is a pseudocoelomate group. Although treated here as aschelminths for convenience, the priapulids are probably more appropriately treated as a distinct phylum.

Aschelminthes thus can be considered a grouping of convenience. None of its subgroups is clearly derived from other members, and all are at about the same organizational level. Aschelminthes are important, nevertheless, in demonstrating the morphological problems involved in acquiring a body cavity and an anus; they also reveal the limitations that solutions to such problems can impose on the design of the invertebrate body.

CLASSIFICATION

Distinguishing taxonomic features. The classification used here is based on *The Invertebrates*, by L.H. Hyman, still an excellent survey of the Aschelminthes, although published in 1951. According to this system, the Aschelminthes are considered a phylum and each of the six groups a class, although Priapulida could justifiably be considered an independent phylum. Structural similarities allow the inclusion of Rotifera, Gastrotricha, Kinorhyncha, and Nematoda within the phylum, although some authorities are hesitant about such a grouping. The taxonomy of Aschelminthes presents difficulties that have not been fully resolved.

Annotated classification. The classification of Rotifera, Gastrotricha, and Kinorhyncha used here is basically unchanged from that of Hyman; that of the Nematoda has been rearranged.

PHYLUM ASCHELMINTHES

Many-celled, bilaterally symmetrical, unsegmented, invertebrate animals with a pseudocoel between the gut and the body wall; about 17,000 known species; many forms aquatic; often parasitic; mostly wormlike, generally microscopic or very small; no circulatory or respiratory organs; nervous system usually consists of anterior ganglia and longitudinal nerve cords; reproductive system simple.

Class Rotifera

Microscopic and aquatic; anterior corona (area of cilia surrounding anterior end); internal jaws or trophi (a set of small, hardened jaws); about 1,800 species.

Order Seisonacea or Seisonidea. Marine, epizoic (*i.e.*, living on or in another animal but not parasitic); elongated forms; corona poorly developed; sexes similar in appearance; gonads paired.

Order Bdelloidea. Swimming or creeping; retractable anterior end; males unknown; 2 germovitellaria (organs that produce ova and yolk cells separately); mastax (esophagus) ramate (stout with large platelike unci, or toothlike structures).

Order Monogononta. Swimming or nonmoving (sessile); 1 germovitellarium; males small with 1 testis; mastax not ramate.

Class Gastrotricha

Microscopic, aquatic; without corona; cilia on body, particularly on ventral surface; adhesive tubes present; no trophi or mastax; about 1,800 known species.

Order Macrodyasoidea. Elongated marine forms; adhesive tubes full length of body; no protonephridia (excretory organs).

Order Chaetonotoidea. Mostly fusiform (spindle-shaped) freshwater forms; 2 to 4 pairs of adhesive tubes posteriorly; protonephridia present.

Class Kinorhyncha (Echinodera)

Microscopic, marine forms; 13 or 14 external segments (zonites); head retractable; protonephridia present; about 100 known species; orders used below correspond to Hyman's informal groups.

Order Heterorhages. Closing apparatus of 3rd external segment without a definite dorsal plate; relatively spiny.

Order Homalorhages. Closing apparatus of 3rd external segment with a definite dorsal and 3 ventral plates; relatively less spiny.

Class Priapulida

Small to medium-sized (to about 8 cm, or 3 in.), warty marine forms with superficial rings and a retractile proboscis (structure at anterior end); 2 genera; *Priapulus* and *Halicryptus;* few species.

Class Nematomorpha (Gordiacea) (hairworms)

Very long and thin, no rings on cuticle ("skin"); juveniles parasitic in arthropods; adults free-living in seawater and freshwater; about 250 to 300 species.

Order Gordioidea. Freshwater forms, without body bristles; larvae parasitic in terrestrial or aquatic arthropods; pseudocoel reduced.

Order Nectonematoidea. Open-sea dwelling; double row of bristles on body; larvae parasitic in Crustacea; pseudocoel not reduced.

Class Nematoda

Largest and most diverse aschelminth class; about 13,000 known species; classification below recognizes 18 orders in 3 groups that should be treated as subclasses in a formal classification; the first 2 groups comprise what are often called the Adenophorea (or Aphasmidia); the 3rd group is often called Secernentea (or Phasmidia).

Group 1 (Adenophorea [Aphasmidia])

Amphids (lateral sense organs at head region) generally obvious, pocket-like, below the cuticle surface, typically opening through a horizontal slit; excretory system a ventral cell; cuticle with cross spiral fibres, rarely with strong annulations (rings); sense organs surrounding mouth, typically setae (bristles); body setae and caudal glands common; no phasmids (porelike sense organs); some species parasitic.

Order Enoplida. Marine, free-living; buccal (mouth) cavity (esophostome) surrounded by esophageal tissue; caudal glands usually present.

Order Oncholaimida. Marine, free-living; large cuplike buccal cavity not surrounded by tissue, usually contains large teeth; caudal glands usually present.

Order Dorylaimida. In freshwater or soil; rarely marine or plant parasites; papillae (fingerlike projections) at head region; buccal cavity large and toothed or with spear-shaped structure in esophagus; caudal glands usually absent.

Order Mermithida. Smooth, filiform (threadlike); either larvae parasitic in insects and adults free-living in soil or water or adults parasitic in insects and larvae free-living; intestine modified for food storage; no anus.

Order Trichurida. Parasitic in vertebrates; body usually thin anteriorly; mouth minute; esophagus reduced; stichosomes (internal glandular columns) present; 1 male spicule (needlelike structure used in copulation); larval buccal cavity with spear-shaped structure.

Order Dioctophymatida. Parasitic in vertebrates; larval buccal cavity with spear-shaped structure; 1 long spicule and a terminal sucker-like organ in male.

Group 2 (Adenophorea [Aphasmidia])

Free-living, typically small marine forms, occasionally found in soil and freshwater; amphids open grooves in cuticle, forming spirals, circles; excretory system a ventral cell; cuticle frequently ringed; body setae common; caudal glands present; no phasmids.

Order Araeolaimida. Amphids spiral or looplike; sense organs of head region usually in 3 circles; cuticle simple, sometimes ringed.

Order Monhysterida. Amphids typically circular; sense organs of head region generally in 2 circles; cuticle sometimes ringed.

Order Chromadorida. Sense organs of head region in 2 or 3 circles; amphids simple or multispiral, sometimes reniform (bean-shaped); cuticle always heavily ornamented, complex in some genera.

Order Desmodorida. Wholly marine; amphids spiral or crook-shaped; cuticle strongly annulate; locomotory setae in 1 subgroup (Draconematina).

Group 3 (Secernentea [Phasmidia])

Typically in freshwater and soil or parasitic in wide range of vertebrates, invertebrates, and plants; amphids rarely obvious.

often papillate; excretory system consists of lateral canals; cuticle superficially structureless; no body setae; phasmids present; no caudal glands.

Order Rhabditida. Most free-living, some parasitic; buccal cavity well-developed; posterior, valved esophageal bulb present; 2 spicules in male.

Order Rhabdiasida. No definite esophageal bulb; complex life history, with reproduction occurring in parasitic and free-living stages; parasitic stages hermaphroditic (both sex organs on 1 animal) or parthenogenetic (reproduction without fertilization); free-living stage may be bisexual.

Order Oxyurida. Typically small; valvulated posterior bulb, at least in larvae; males with one or no spicules; larvae like miniature adults; species are parasites mainly of terrestrial hosts, invertebrates and vertebrates, including man.

Order Strongylida. Mouth large without lips but frequently with cuticular leafs (corona); males with broad caudal alae (sheets of cuticle) supported by rays; life histories variable, usually direct (no intermediate host); parasites of mammals, rarely of birds or reptiles.

Order Ascaridida. Three prominent lips; buccal cavity not obvious; no posterior esophageal bulb in adults; life history usually indirect (*i.e.*, with an intermediate host or hosts); parasites of vertebrates.

Order Spirurida. Typically 2 lateral lips; esophagus muscular anteriorly, glandular posteriorly, without bulb; life history indirect; parasites of vertebrates.

Order Dracunculida. No lips or buccal cavity; esophagus as in Spirurida; vulva (female genital pore) usually nonfunctional; male spicules filiform; life history indirect; parasites of vertebrates.

Order Filariida. Long and thin, without lips; buccal cavity minute or lacking; esophagus muscular anteriorly, glandular posteriorly, without bulb; vulva anterior; young hatch from egg outside or inside the female; life history frequently involves removal of young organisms (microfilaria) from host's blood by blood-sucking insect; parasites of vertebrates except fish.

WAGLER (eds.), *Die Tierwelt der Nord- und Ostsee* (1929).

(W.G.I.)

Ash'arī, al-

Abū al-Ḥasan al-Ash'arī was a famous Muslim theologian, Arabic in language and culture, who founded a theological school that later claimed as members such celebrated authors as al-Ghazālī (died AH 505 [AD 1111] —AH denotes dates according to the Muslim calendar) and Ibn Khaldūn (died AH 808 [1406]).

He was born about AH 260 (AD 873/874) in the city of Basra, at that time one of the centres of intellectual ferment in Iraq, which, in turn, was the centre of the Muslim world and the seat of a world civilization. It is generally agreed that he belonged to the family of the celebrated Companion of the Prophet Abū Mūsā al-Ash'arī (died AH 42 [AD 662/663]), though some theologians opposed to his ideas contest the claim. Since this would have made him by birth a member of the Arab-Muslim aristocracy of the period, he must have received a careful education. A contemporary recorded that the wealth of al-Ash'arī's family permitted him to devote himself entirely to research and study.

Early work

His works, especially the first part of *Maqālāt al-Islāmīyīn* ("Theological Opinions of the Muslims"), and the accounts of later historians record that al-Ash'arī very early joined the school of the great theologians of that time, the Mu'tazilites. He became the favourite disciple of Abū 'Alī al-Jubbā'ī (died AH 303 [AD 915/916]), head of the Mu'tazilites of Basra in the final decades of the 3rd century AH (late 9th and early 10th centuries AD).

Despite the lacunae in the documentation concerning these theologians, certain characteristic traits of their culture and social position can be singled out. Anxious to mark the originality of Islām in contrast to all dualist doctrines and in contrast to Christianity and Judaism as interpreted by the Qur'ān, the Mu'tazilites concentrated their efforts on underlining the absolute transcendence of the one God. To accomplish this they drew principally from their own Arab-Muslim tradition and remained relatively impervious to the foreign cultures (especially Greek and Iranian) that invaded Baghdad from the beginning of the 3rd century AH. But the Arab-Muslim culture was not popular: during the period of al-Ash'arī's studies, the rupture between the intellectual elite of Mu'tazilite theologians and the common people was all but complete.

A disciple of al-Ash'arī describes that period of his master's life in this way: "Al-Ash'arī was a disciple of Jubbā'ī. He faithfully went to hear him and take lessons from him, never leaving him for all of 40 years. In the sessions devoted to controversy, he showed his gift for argumentation and was bold in confronting his adversary; but he was not gifted for writing. When he took up a pen, at times he never finished, and at times what he wrote was not satisfactory."

That testimony, at least in its negative aspect, should be corrected by what Ibn 'Asākir reports: "His works are very well organized, the expressions and the developments are very exact." In any case, it was during that period of his life that al-Ash'arī, the brilliant and faithful disciple of the Mu'tazilites, undertook the composition of a work in which he gathered the opinions of the diverse schools on the principal points of Muslim theology. That work, the first volume of the current edition of the *Maqālāt*, is valuable for what it records of Mu'tazilite doctrines. It remains one of the most important sources for retracing the history of the beginnings of Muslim theology.

At the same period al-Ash'arī composed *Risālah ilā ahl ath-thaghr* ("Treatise for the Men of the Frontier") for the Muslims of Bāb al-Abwāb (Derbent, between the Caucasus and the Caspian). The occasion was the renewed interest of the central administration in the security of the northern frontier of the empire.

Later, at the age of 40 (*c.* AH 300 [AD 912/913]), when he had become a specialist in theology and was well known for his oral controversies and his written works, al-Ash'arī quit his master al-Jubbā'ī and abandoned Mu'tazilite doctrine. This conversion was spectacular. It made al-Ash'arī the focus of attention of Basra for some time and merited a certain number of accounts, which, though impossible to confirm in their details, are certainly correct in their general lines. What happened was apparently this: following a crisis of conscience, accompanied, perhaps, by dreams, al-Ash'arī saw clearly the limits of Mu'tazilism and was led back to a closer attachment to the sources of Muslim faith, the Qur'ān (Islāmic scripture) and the *Sunnah* (tradition). Reading texts of his master, al-Jubbā'ī, it is possible to ascertain the defects that may have struck al-Ash'arī. In those texts al-Jubbā'ī seems to have no particular audience in mind, nor does he try to convince; he only demonstrates. It appears that, for him, the reality of God as well as that of man has been so sterilized and desiccated that it has become little more than matter for rational manipulation.

Later ideas and works

Al-Ash'arī, more conscious than all others of these limits and of the premature desiccation of Mu'tazilite theology, did not hesitate to proclaim his new faith publicly. Certain reports even speak of him dramatically declaring his new stand in the middle of the Friday prayer in the Cathedral Mosque of Basra. From that day, the former Mu'tazilite started combatting his colleagues of yesterday. He even attacked his old master, refuting his arguments in speech and writing. It was then, perhaps, that he took up again his first work, the *Maqālāt*, to add to the objective exposition rectifications more conformable to his new beliefs. In this same period, he composed the

work that marks clearly his break with the Mu'tazilite school: the *Kitāb al-Luma'* ("The Luminous Book").

It was not until his former master Abū 'Alī al-Jubbā'ī died at Basra in AH 303 (AD 915) that al-Ash'arī decided to make Baghdad his centre. Arriving in the capital, he soon became aware of the importance assumed by a group of faithful of the *Sunnah*, the disciples of Ibn Ḥanbal. Their leader, al-Barbahārī, was a dynamic person with a touch of the demagogue. Al-Ash'arī visited him to explain his doctrinal views, insisting on the fact that his previous theological formation enabled him to attack the Mu'tazilites with their own weapons thus making his treatises models of apologetic in support of the truth. The response was disappointing: there was no encouragement, no approval, no acceptance into the ranks of the Ḥanbalites. Al-Barbahārī curtly replied that he had no interest in any of this; he had only one master—Ibn Ḥanbal.

It must have been after that interview that al-Ash'arī composed, or perhaps put the last touches to, one of his most famous treatises, the *Ibānah 'an uṣūl ad-diyānah*, ("Statement on the Principles of the Religion"), which contains some passages venerating the memory of Ibn Ḥanbal.

In the years that followed, al-Ash'arī, now installed in Baghdad, began to group around himself his first disciples. Focussing his theological reflection on certain positions of the mystic al-Muḥāsibī (died AH 243 [AD 857]) and of two theologians, Ibn Kullāb (died *c.* AH 250 [AD 864/865]) and Qalanisī (died *c.* AH 300 [AD 912/13]), al-Ash'arī laid the bases for a new school of theology distinct from both the Mu'tazilites and the Ḥanbalites. His three best known disciples were al-Bāhilī, aṣ-Ṣu'lūkī, and Ibn Mujāhid, all of whom transmitted the doctrines of their master to what later became the flourishing school of Khorāsān.

Al-Ash'arī died sometime around AH 320 (AD 932/933) but most probably in AH 324 (AD 935/936). He was buried at the southwest of the city in a place called the Wharf of the Water Jars. A mausoleum erected over his tomb was later destroyed by fanatic Ḥanbalites.

The opposition that was first aroused by al-Ash'arī himself through his spectacular conversion continued to assail his disciples, but through constant dialogue with their opponents they slowly disentangled the main lines of doctrine that became the stamp of the Ash'arite school.

BIBLIOGRAPHY. M. ALLARD, *Le Problème des attributs divins dans la doctrine d'al-As'ari et de ses premiers grands disciples* (1966), is a complete study of the life and works of al-Ash'arī, including an exposition of his conception of God. An indispensable work for those who wish to read al-Ash'arī is R.J. MCCARTHY (ed.), *The Theology of al-Ash'ari* (1953), containing the texts of two of his theological treatises along with their English translation. Three appendixes give in translation the writing of Arab authors on the life and work of al-Ash'arī, and a fourth gives the main elements of his credo. W.M. WATT, *Islamic Philosophy and Theology* (1962), serves to situate al-Ash'arī in the chronological development of Muslim thought. A.J. ARBERRY, "Al-Ash'arī's Tract on Faith," *BSOAS*, 19:160–162 (1957), is a learned note showing how a short treatise of al-Ash'arī was handed down among the traditionists.

(M.A.Al.)

Ashurbanipal

Ashurbanipal was the last of the great kings of Assyria and collector of a great library at Nineveh. He reigned from 668 to 627 BC.

The life of this vigorous ruler of an empire ranging initially from the Persian Gulf to Cilicia, Syria, and Egypt can be largely reconstructed from his autobiographical annals and royal correspondence. His father, Esarhaddon, appointed him crown prince of Assyria in May 672 BC with the intention of averting dynastic struggles. Shamash-shum-ukin, a son of equal status by another wife, was appointed crown prince of Babylonia. Probably due to the influential queen mother Naqi'a-Zakutu, Ashurbanipal was given responsibility earlier.

Ashurbanipal was involved in administration and versed in the problems of controlling the northern hill tribes.

By courtesy of the trustees of the British Museum

His tutors were Nabu-shar-usur, a general, and Nabu-ahi-eriba, who interested him in history and literature. Like few Mesopotamian kings before him, he mastered all scribal and priestly knowledge and was able to read Sumerian and obscure Akkadian scripts and languages. His athletic powers were shown in hunting, archery, and horsemanship. Though there is little evidence of his experience on the actual battlefield, there is no reason to doubt Ashurbanipal's claim that his father favoured him for his bravery and intelligence.

He soon shouldered heavy responsibilities, having to command the court and nobles. No governor or prefect was appointed without consulting him, and he had authority over many state building projects. His reports to his father showed such qualities of statesmanship that he was left in charge of all affairs while his father was en route to Egypt. When Esarhaddon died at Harran in December 669 BC, Ashurbanipal transferred full power to himself without incident. The queen mother exacted an oath of allegiance from both family and courtiers.

Ashurbanipal's reign

Ashurbanipal's first concern was to quell a revolution in Egypt, where Taharqa (Tarku; biblical Tirhaka), an Egyptian king, had invaded the Nile Delta and won support. Swift Assyrian military action enforced his withdrawal, and Ashurbanipal appointed local princes supported by Assyrian garrisons. Some of the princes intrigued with Taharqa, and the Assyrians deported them to Nineveh. Keeping to his plan to have native administrators, Ashurbanipal chose Necho I as supreme ruler of the delta and made a treaty with him. Further pressure from Taharqa's successor Tanutamon (Tandamane) led to another Assyrian intervention in 664–663, when the Assyrians seized control of Memphis and sacked Thebes. When Necho died in 663, Ashurbanipal held to his policy and accepted the succession of another local ruler, Psamtik (Psammetichus I); he was rewarded by a peace that enabled him to campaign elsewhere. In 654 BC the Assyrian garrisons were expelled from Egypt, but trade continued so that this loss resulted in little weakening of his position.

He next turned to the Phoenician city of Tyre, which had supported both Egyptian and Lydian bids for independence. A successful siege of Tyre led to the resubmission of the rulers of Syria and Cilicia and to a request for Assyrian help from Gyges of Lydia against Cimme-

rian intruders. Because Lydian mercenaries had assisted Egypt, this help was refused. A swift display of military might against the Mannaeans and an alliance with Madyes, the Scythian chief, repulsed Cimmerian advances and left Ashurbanipal free to attend to Babylonia, his southern neighbour.

Ashurbanipal had confirmed his half-brother Shamash-shum-ukin as local ruler of Babylonia, but with restricted powers. Assyrian garrisons and officials there continued to report to the Assyrian king, and he continued to appoint governors both in the Sea-lands (Persian Gulf) and Ur. Babylonians petitioned him direct and received land grants. For 16 years, relations with his brother were peaceful. When Tept-Humban, a usurper in Elam, entered Assyrian territory and was killed, the Assyrian action was primarily in support of the Elamite princes Humbanigash and Tammaritu, who were given specific regions in Elam with no attempt at direct Assyrian rule. Ashurbanipal's actions probably aimed also to assist his own brother, whom he still trusted. Ashurbanipal received a deputation of Babylonians about this time, and he punished the Gambulu tribe for complicity in the Elamite affair.

Shamash-shum-ukin's long stay in Babylon had imbued him with the traditional local spirit of nationalism and resistance. He may have interpreted his brother's policy of appeasement as weakness and as an opportunity for him to increase his own status. In any event, he contrived a coalition with other outlying peoples of the Assyrian Empire—Phoenicia, Judah, Elam, Egypt, Lydia, and the Arab and Chaldean tribesmen; and had these groups risen simultaneously Assyria would have fallen. When Ashurbanipal discovered the plots, he appealed directly to the Babylonians and perhaps tested their loyalty by imposing a special tax; only upon their refusal did he take military action. He seemed to move in ways that avoided direct danger to his brother, and he worked more through siege warfare than through direct action; the Babylonian Chronicle records that for three years "the war went on and there were perpetual clashes." Elam, suffering from internal dissension, was unable to help the rebels; and gradually, through starvation, the Arabs who had retreated into Babylon deserted as the famine became intense. Shamash-shum-ukin committed suicide in his burning palace in 648 BC. Ashurbanipal's own feelings toward the city are shown by his work of restoration and by his appointment of a Chaldean noble, Kandalanu, as his viceroy there.

Ashurbanipal had to take further action to quell the rebellion. Raiding the Arab tribes, he defeated the Nabataean Uate and his allies and isolated the Qadar tribe. The struggle with Elam was harder; war there dragged on until 639 BC, when the Assyrians sacked Susa. That year Ashurbanipal celebrated his triumph; he had "the whole world" under his sway, and four captive kings drew his chariot in the procession.

The military action required to maintain order must not overshadow Ashurbanipal's ability as an administrator. The empire prospered economically despite the threatened closure of the northern and eastern trade routes due to Lydian and Median expansions. Unfortunately, the sources are too scanty to follow his reign after 631 BC. Ashurbanipal's death is nowhere recorded, but it seems that he followed his father's precedent in bringing his sons Ashur-etel-ilani and Sin-shar-ishkun into coregency, each with a separately defined authority. It is no indictment of his rule that his empire fell within two decades after his death; this was due to external pressures rather than to internal strife.

Personality and significance

Ashurbanipal was a person of religious zeal. He rebuilt or adorned most of the major shrines of Assyria and Babylonia, paying particular attention to the "House of Succession" and the Ishtar Temple at Nineveh. Many of his actions were guided by the omen reports, in which he took a personal and informed interest. He celebrated the New Year Festival, and one of his reliefs, showing him dining in a garden with his queen Ashur-sharrat, may illustrate this event. His younger brothers were priests in Haran and Ashur.

Ashurbanipal's outstanding contribution resulted from his academic interests. He assembled in Nineveh the first systematically collected and catalogued library in the ancient Near East (of which 20,720 Assyrian tablets and fragments are now in the British Museum). At royal command, scribes searched out and collected or copied texts of every genre from temple libraries. These were added to the basic collection of tablets culled from Ashur, Calah, and Nineveh itself. The major group includes omen texts based on observations of events; on the behaviour and features of men, animals, and plants; and on the motions of the sun, moon, planets, and stars. Lexicographical texts list in dictionary form Sumerian, Akkadian, and other words, all essential to the scribal educational system. He collected many incantations, prayers, rituals, fables, proverbs, and other "canonical" and "extracanonical" texts. The traditional Mesopotamian epics such as the stories of Creation, Gilgamesh, Irra, Etana, and Anzu have survived mainly due to their preservation in his library. The presence of handbooks, scientific texts, and some folk tales (*The Poor Man of Nippur* was a precursor of one of the *Thousand and One Nights* tales of Baghdad) show that this library, of which only a fraction of the clay tablets has survived, was more than a mere reference library geared to the needs of diviners and others responsible for the King's spiritual security; it covered the whole range of Ashurbanipal's personal literary interests, and many works bear the royal mark of ownership in their colophons.

The King was patron of the arts; he adorned his new and restored palaces at Nineveh with sculptures depicting the main historical and ceremonial events of his long reign. The style shows a remarkable development over that of his predecessors, and many bas-reliefs have an epic quality unparalleled in the ancient world, which may well be due to the influence of this active and vigorous personality.

Asia

Asia is more a geographical term than a homogeneous continent. The most diverse of all continents, it extends over a latitudinal range of 92° from north to south, has the greatest range of land height of any continent, is subject to climates ranging from Arctic to tropical, and produces the most varied forms of vegetation and animal life in consequence. Similarly, its patterns of human adaptation range from the life-styles of the nomads of Arabia and Central Asia to those of the crowded cities of the Yangtze Basin and the Gangetic Plain.

Asia has to be described mainly in superlatives. It is the largest of the continents, occupying 30 percent of the world's land area, with a mainland area of approximately 17,000,000 square miles (44,000,000 square kilometres). While to the east the Pacific Ocean forms its natural boundary, the chains of islands that include the component territories of Japan, Taiwan, the Philippines, and Indonesia also form part of Asia. To the west the boundary is more difficult to define but is generally regarded as running southward along the eastern foot of the Ural Mountains, after which it turns approximately southwestward to the northern shore of the Caspian Sea, from where it again runs generally southwestward to the Caucasus Mountains, which form the boundary until the Black Sea is reached; from the Black Sea, the coast of Asia Minor and the Mediterranean coast of the Levant

form Asia's western limits, after which the boundary runs south across the Isthmus of Suez and along the coast of the Arabian Peninsula.

Asia is the most populous of the continents. Its population, in the early 1970s, was estimated to be 2,164,000,000, representing more than half the human race. The continent includes the two most populous countries in the world—China and India—in addition to Japan and Indonesia, each of which has a population of more than 100,000,000; among non-Asian states these last two countries are surpassed in numbers only by the populations of the Soviet Union (the territory of which also extends into Asia) and the United States. In the 20th century the population of Asia has been growing faster than the world average, its growth rate in the early 1970s being a little more than 2 percent a year. Despite the general awareness in Asia, especially in the most populous countries, of the need for some regulation of this growth, it appears that—barring some unexpected breakthrough in technology that would make large-scale limitation of population possible—the population of Asia may well reach 3,800,000,000 by the year 2000.

Origin of the name Asia

The name Asia is very ancient, and its origin in antiquity has been variously explained. The Greeks used it to designate the lands situated to the east of their homeland. It is also believed that the name may be derived from the Assyrian word *asu*, meaning "east." Another possible explanation is that it was originally a local name given to the plains of Ephesus and gradually extended to include Anatolia (contemporary Asia Minor) and the rest of the continent.

Geological development has resulted in a configuration that includes the Arabian massif (mountainous mass) and the plains of Iraq; the mountain belts of Turkey, Iran, and Afghanistan; the great Himalayan mountain chain stretching from Afghanistan to the Burmese peninsula; the Indo-Pakistan subcontinent; Central Asia; the vast Siberian lowlands extending from the Urals to the Pacific; and the great island chains that sweep in arcs from Japan to Indonesia.

As a result of this configuration, Asia's population is unevenly distributed. Thus, while there has been a concentration of population on the Arabian plains and river valleys, in the Indo-Pakistan subcontinent, in Central Asia, and especially China, and to some extent in the Pacific borderlands and on the islands, there are vast areas with a low density of population.

Siberia, which represents approximately one-third of the land area of Asia, has an estimated population of fewer than ten persons per square mile (four persons per square kilometre), compared with the average density of 180 persons per square mile in the rest of Asia.

The mountain systems of Central Asia not only have provided the great rivers with water from their melting snows but also have formed a natural barrier that has made the movement of peoples possible only through mountain passes. As a result the historic movement of population has been broadly from the arid zones of Central Asia through the mountain passes into the Indo-Pakistan subcontinent. Another movement has been from China through Southeast Asia to modern Indonesia and Malaysia. There has also been movement from the Arabian Peninsula and from India across the Bay of Bengal into Indonesia and Malaysia. The Japanese people and, to a lesser extent, the Chinese have remained ethnologically more homogeneous than the populations of other Asian countries.

Asia's religious heritage

Asia has been the birthplace of all the great world religions, including Buddhism, Christianity, Hinduism, Islām, Judaism, Sikhism, Taoism, and Zoroastrianism. Of these, only Christianity moved westward; it subsequently exerted little influence, in its religious aspects, on Asia, although many Asian countries have Christian minorities. Buddhism has had a greater impact outside its birthplace in India and is prevalent in various forms in China, Korea, Japan, the Southeast Asian countries, and Sri Lanka (formerly Ceylon). Islām has spread out of Arabia eastward to Afghanistan, Pakistan, and India, and thence to Malaysia and Indonesia, as well as west and south to several areas of Africa. Hinduism, basically a non-proselytizing religion, has been mostly confined to the Indian subcontinent.

Before the major industrial revolution that occurred in the 18th and 19th centuries, most of the principal technical achievements began in Asia. Three millennia before Christ, Asians knew the arts of cooking and pottery and the use of fire for the smelting of ores. They had already progressed from the nomadic stage to the established life of cultivators, using irrigation and practicing crop rotation. They had learned to domesticate animals and had invented the wheel, the harness, the saddle, and the chariot. They had begun to use a form of paper and had developed elaborate scripts. Familiar with wood carving, stonecutting, and the casting of metals, they have left monuments of stone and metal that to this day evoke admiration and astonishment. They used the art of calculation, including the decimal system, and employed means of measurement. Various indigenous systems of medicine were developed, which have stood the test of time and are still in use. In ancient times major Asian empire-states arose, employing intricate systems of laws and regulations and delegating power and authority to institutions of government at various levels.

In the 15th century, Asia's material advance was envied by people in Europe. The port of Venice was hailed as Europe's window to the East. The fabled prosperity of Asia prompted the movement of adventurous spirits from Western nations to Asia and led to the eventual conquest of many Asian countries. The Western impact on the civilizations of these Asian countries, on their mental attitudes, and on the development of their political institutions and economic systems can only be referred to briefly here. Even though almost all Asian countries have attained their independence, the era of European conquest and colonization has left an indelible mark on much of Asia. The Asian countries received many benefits by way of the establishment of an infrastructure, a system of posts and telegraphs, a railway and road network, ports and harbours, public health systems, modernized educational systems, and also the rudiments of an apparatus of modern government—civil, judicial, and military—and ideas for publishing newspapers and magazines. On the other hand, there was little progress in industrialization. The effect of the neglect of industrial development during these years of colonization is still noticeable in commercial relations among Asian countries. Broadly, it may be said that the role of the Asian countries—with the exception of Japan, which did not feel the impact of conquest and colonization—was that of primary producers exporting their products to the metropolitan countries, where they were turned into finished products and re-exported back to the Asian countries. Today, as a result, most Asian countries have economies that are non-complementary; recent efforts at the international and regional levels to produce greater economic integration and coordination among Asian countries have not entirely succeeded.

The impact of the West

In addition to this factor, the lack of any ethnic, religious, or cultural homogeneity among the Asian peoples has made it difficult for a common Asian political consciousness to arise. In the struggle for independence most of the Asian countries developed a political philosophy favouring nationalism. Furthermore, since achieving independence, many Asian countries seem to have lost the unifying force of emergent nationalism and are groping to find a substitute for it. Even the doctrine of nonalignment, which seemed to be common to several Asian countries, has lost its impetus, and in the early 1970s the centre of interest in this direction appeared to have moved from Asia to Africa.

In the economic field, Asian countries are caught between two conflicting forces. On the one hand, the need to ensure improved levels of living has led to a desire to move toward orderly and planned economic and social development. On the other hand, in many countries there has been a long tradition of other-worldliness and austerity. This conflict of forces may produce a new philosophy of economic development in Asia that will reconcile the

need for material progress with the imperative of not abandoning spiritual and religious values.

Asia's entry into the nuclear age

The political forces that are emerging in Asia cannot be ignored. China has begun to play an important role in world affairs; it is as yet the only nuclear power in Asia. Japan has emerged as one of the great industrial nations of the world and clearly has the capability to develop into a nuclear power, although the Japanese, in the light of their own experience at the end of World War II, have accepted a constitution renouncing war as a sovereign right of the nation and abjuring the threat or use of force as a means of settling international disputes. India perhaps has the technology to become a nuclear power, but to do so would involve such an enormous sacrifice of resources needed for economic development that it is doubtful whether it will be done.

The recent political history of the continent is to some extent the result of the political vacuum created by the withdrawal of the colonial powers from Asia. In the early 1970s the disturbed political situation at one end of the continent, in the Middle East, and at the other end the equally confused and dangerous political situation in the countries of Indochina formerly under French administration provided two illustrations of this fact. The difficulties that have persisted between India and Pakistan since their independence in 1947 and between Indonesia and Malaysia between 1963 and 1968 are clearly part of the same pattern.

With a new awakening of political consciousness, with a new spirit of regional cooperation, and with a new urge at the grassroots level for the improvement of living standards, there are positive factors at work that should make possible a resurgence of Asia in the coming decades. The rate of population growth constitutes the only negative factor. Several Asian countries have shown, however, that even under existing circumstances great progress can be made in the limitation of population growth. If this trend were to become more general and widespread, the chance that Asia will enter the 21st century economically stronger and socially better developed would be correspondingly increased. (This article covers the general physical and human geography of Asia. For historical aspects, see COLONIALISM and INNER ASIA, HISTORY OF, as well as historical articles on individual nations. There are separate articles on the major geographical features of Asia, as well as on Asian nations and major Asian cities. ELEMENTS AND PROCESSES IN THE MAKING OF THE CONTINENT

Platforms, shields, and geosynclines. Asia consists, in part, of several platforms that have been subjected to almost no folding since the Precambrian Era, which lasted from 4,600,000,000 to 570,000,000 years ago. It also consists of vast regions of folding, formed later in various periods or ages, that originated in geosynclines (large and generally linear troughs that gradually subsided over long periods of time and subsequently became filled with thick accumulations of sediments). Contemporary geosyncline systems, still not consolidated by folding, join the shores of the Asian mainland to the Malay Archipelago, underlie bordering seas such as the Sea of Japan and the Sea of Okhotsk, and extend to the island arcs of the Pacific Ocean.

The four continental platforms

The principal continental platforms of Asia are the Siberian Platform in the north, the Chinese Platform in the east, the Indian Platform in the south, and the Arabian Platform in the southwest. Those parts of the platforms where the Precambrian crystalline bedrock is not covered by a sedimentary deposit are called shields; almost all the shield areas were dry land during the last 500,000,000 years and include the Aldan Shield in Eastern Siberia, the North Chinese Shield, the Indian Shield in peninsular India, and a large part of the Arabian Shield. In addition, the Russian Platform has played an important role in the geological history of western Asia. Along its western edge, the folded structures of the Urals and of Kazakhstan were formed at the end of the Paleozoic Era (which lasted from 570,000,000 to 225,000,000 years ago).

Endogenetic and exogenetic forces. Two forces have been at work to mold the Asian continent into its present configuration. On the one hand are the endogenetic forces, which represent vertical or lateral forces originating deep within the Earth and that produce fissures in the Earth's crust through which magma, or molten rock, wells up in the form of lava or forms intrusive bodies; when it solidifies, this rock, basalt, is described as igneous (solidified from the molten state). Exogenetic forces, on the other hand, represent those endless processes of erosion and sedimentation that take place on the surface, where rocks are subjected to weathering and denudation. Associated with these two forces is a principle of equilibrium called isostasy, which represents a theoretical balance maintained between large sections of the Earth's crust, which act as though they were floating on a denser underlying layer. In maintaining this balance, less dense material rises vertically while denser material sinks downward.

The mountain-building process. Mountain building, or orogenesis, is the result of folding or thrusting, which occurs when thousands of feet of sediment accumulate in geosynclines, causing them to sink deeper, thus either activating, or interacting with, vertical or lateral endogenetic forces. In this way the geosynclines themselves, representing zones of structural weakness between crustal blocks or platforms, are folded upward into new mountain systems—a process associated with the upwelling of granitic magma and the deformation of metamorphic rock (rock that has been altered in composition, texture, or internal structure as a result of heat and pressure).

THE TERRITORIAL FORMATION OF ASIA

Blocks and zones of folding

As a result of folding, the intrusion of granite, the swelling of the Earth's crust in response to pressures, the isostatic uplifting (uplifting caused by equal pressure on all sides) of mountains, and the drying up of marine basins that lay in the geosynclinal regions between the continental platforms, ancient blocks of the Earth's crust and weaker zones of folding were united to form the Asian continent. From the formerly inundated geosynclines,

several belts of folding—including the Alpine–Himalayan belt—were formed in the Late Paleozoic Era, the Mesozoic Era (from 225,000,000 to 65,000,000 years ago), and the Cenozoic Era (which is dated from 65,000,000 years ago to the present time).

The composition of the continental platforms. *The Siberian Platform.* Greatly deformed schists (metamorphic rocks containing micaceous minerals), gneisses (rocks in which bands rich in granular minerals alternate with bands containing schistose materials), and granites of the Precambrian form the basement of the Siberian Platform. Extending between the river basins of the Yenisey and the Lena, it surfaces within the boundaries of the Aldan Shield, north of the Stanovoy Mountains, and the Anabar Massif (mountainous mass), west of the Lena River and south of the Arctic. In other areas the crystalline bedrock is overlain almost horizontally by sedimentary rock, including marine and salt lagoon deposits from the Cambrian Period (from 570,000,000 to 500,000,000 years ago), marine deposits from the Ordovician Period (from 500,000,000 to 430,000,000 years ago) and the Silurian Period (from 430,000,000 to 395,000,000 years ago), as well as deposits from the Permian Period (from 280,000,000 to 225,000,000 years ago) containing strata of coal. In the western part of the platform, primarily along the edges and in the centre of the broad Tungus syncline (a basin formed by a downward bend of rock strata), east of the Yenisey River, the Paleozoic strata are cut by numerous intrusive sills (layers) of a dark, fine-grained, basaltic rock known as trap-rock, locally associated with copper and nickel ores and volcanic pipes (cylindrical veins of volcanic origin) containing diamond-bearing kimberlite (an ultrabasic rock of a subcrustal origin). In the southern part of the platform, the lower layers of the sedimentary cover consist of thick layers of Precambrian marine sediments analogous to the Sinian System in China. They were slightly disturbed at the time of the Baikal folding, which occurred at the end of the Precambrian and during the Cambrian Period. Along the northern and eastern edges of the platform, there is widespread distribution of coal-bearing deposits from the Jurassic Period (from 190,000,000 to 136,000,000 years ago) and the Cretaceous Period (from 136,000,000 to 65,000,000 years ago). Mesozoic sedimentary series reach particularly great thickness in the depressions of the Vilyuy River and in the depression near the Verkhoyansk Mountains, which run parallel to the Lena River, both areas containing deposits of fuel gas.

The Chinese Platform. The Chinese Platform consists of four separate massifs—the North Chinese, the South

Chinese, the Tarim, and the Tibetan—which probably constituted a single platform in the Precambrian. This platform appears to have broken up at the beginning of the Paleozoic Era, at which time geosynclinal downwarps were formed between the separated blocks. As a result of the folding that took place in these downwarps during the Paleozoic and Mesozoic eras, mountain ranges arose, including the Kunlun and the Tsinling (both in China). The Precambrian bedrock is exposed on the surface primarily within the boundaries of the North Chinese massif, which contains large deposits of ferruginous (iron-bearing) quartzite.

The four Chinese massifs

During the Silurian Period and the Devonian Period (from 395,000,000 to 345,000,000 years ago), the southern part of the platform—as well as almost all of it during the later part of the Cretaceous Period—was subjected to folding and faulting deformations that were considerably more intense than those experienced by platforms elsewhere in the world. These deformations were accompanied by intrusions of ore-bearing granite.

The sedimentary rocks overlying the folded bedrock (basement) of the Chinese Platform represent, for the most part, marine sediments of the Precambrian and Lower Paleozoic (Cambrian, Ordovician, and Silurian) eras; marine and continental deposits from the Devonian, Carboniferous (from 345,000,000 to 280,000,000 years ago), and Permian periods, some of which are coal-bearing; and thick layers of rocks of the Mesozoic Era, as well as layers from the Cenozoic Era in some of the depressions. Among the Mesozoic deposits there is an abundance of red fragmented rocks that were formed when the prevailing climate was hot and dry. The sedimentary cover is thickest in the synclines of the Ordos Desert region of Inner Mongolia, of the Chinese province of Szechwan, and of the Lower Huang Ho, as well as in the Mesozoic downwarp of southeastern Korea.

The Arabian Platform. The Arabian Platform, like the Indian Platform, is usually considered to have formed a part of the continent of Gondwana, which began to split apart during the Paleozoic Era. Gondwana is believed to have included Africa, Australia, South America, and possibly Antarctica, and the two platforms do have much in common with these continents. The ancient basement of Arabia is composed of Precambrian crystalline rocks, which crop out in the western part of the peninsula as the Arabian Shield. To the north and east the bedrock is buried under thick layers of horizontal or only slightly disturbed Paleozoic rocks; these are mainly sediments from the Jurassic and Cretaceous periods and from the earlier part of the Cenozoic Era. These sediments strata lie within the bounds of the Mesopotamian downwarp, which occurs in the Persian Gulf region; here the bedrock has sunk to a depth of about two and a half miles and contains large amounts of petroleum.

The crystalline bedrock

The Indian Platform. The Indian Platform covers a large part of peninsular India and Sri Lanka. It consists of a Precambrian crystalline shield in which broad grabens (blocks that have been downthrown along faults in the rock on either side) along the Godāvari River and along the Dāmodar River farther to the northeast are overlain by horizontal deposits of the Gondwana system. These were laid down between early Carboniferous and late Jurassic time. The Deccan Plateau, which forms the backbone of peninsular India, is itself overlain by basaltic lavas (traprock from the Late Cretaceous Period and the Early Cenozoic Era). Along the edges of the platform the bedrock is covered by marine deposits from the Jurassic, Cretaceous, and Tertiary (from 65,000,000 to 2,500,000 years ago) periods; in the Gulf of Cambay region, off the west coast of India, these contain petroleum deposits. To the north, the bedrock lies under Cenozoic deposits that reach their greatest thickness in the northern part of the Ganges River Basin, in the marginal downwarp at the foot of the Himalayas, and in the Indus Basin. Deposits of gas and petroleum are associated with the Cenozoic marine and continental sediments, while the Precambrian rocks of the shield contain iron and manganese ores. A small Precambrian outcrop, the Shillong Plateau massif, occupies the eastern part of the platform.

Mountain folding. *The Late Precambrian and the Paleozoic eras.* Those Asian zones that were folded during the Late Precambrian and Early Paleozoic eras consist of various kinds of weakly and strongly metamorphosed volcanic and sedimentary rocks. They are cut by intrusions of granite, granodiorite (a quartz-bearing rock formed at great depth), gabbro (a coarse-grained, dark igneous rock), diabase (a rock of basaltic composition), and serpentinous ultrabasic rocks (*i.e.*, igneous rocks containing less than 45 percent of silica). Deposits of gold, copper, tungsten, polymetallic (*i.e.*, containing many metals), and other ores are associated with these rocks in many areas.

Regions of Late Precambrian and Early Paleozoic folding border the Siberian Platform to the west and south. They compose the Yenisey Ridge, the Eastern and Western Sayan ranges, the Kuznetsk Alatau, the higher (alpine) part of the Soviet Altai, the Mongolian Altai, and a considerable part of the Khangay and Tannu-Ola ranges. Caledonian folding—which is to say, folding that took place during the Caledonian (*i.e.*, Silurian–Devonian) orogeny (mountain-building process)—is also found in the Taymyr Peninsula and on the Severnaya Zemlya Islands, in central Kazakhstan, in the northern chains of the Tien Shan, in the Kunlun Range, and in southeastern China. In the portion of the Caledonian orogeny that occurred during the Devonian Period, a number of large depressions were formed. These included the Kuznetsk and Minusinsk basins and the depressions in the central part of Tuva. Large reserves of coal are concentrated in the deposits laid down in these regions in the Carboniferous and Permian periods.

Areas of depression

The fold structures of the Hercynian orogeny were formed as the result of tectonic activity (movements of the Earth's crust) that occurred during the Middle Paleozoic (Devonian) and Late Paleozoic (Carboniferous and Permian) eras; these constitute a broad arc traversing the central part of the continent. The Hercynian fold struc-

tures have a northeasterly and southerly trend between the Russian and Siberian platforms, and a northwest trend in Kazakhstan, along the Salair Ridge, and in the southern Altai; run east to west in the Tien Shan, Kunlun, and Tsinling ranges; and run northeast in northeastern China. According to geophysical data, the Hercynian fold system of the Urals, covered toward the south by a horizontal layer of Mesozoic and Cenozoic deposits, is joined with the Tien Shan. In addition, a branch proceeds from it which passes through the Mangyshlak Peninsula toward the Donets Basin.

A considerable area of the original Paleozoic fold zones was levelled by erosion and subsequently sank, forming large depressions that were filled to an overall depth of between one and four miles with virtually undisturbed marine and continental sediments of the Mesozoic and Cenozoic eras. Associated with these depressions are the vast West Siberian Plain; the Turgay Downwarp, located to the east of the southern Urals; the Turan Platform in the Amu Darya and Syr Darya basins; the depressions of Lake Balkhash and of the lower course of the I-li Ho (river); the Dzungarian Basin; the Fergana and Turfan depressions; the Tsaidam Basin; the Tungliao or Manchurian lowlands in the Sungari River Basin; and others. Only the intermontane depressions, those of Fergana and Turfan, were affected by slight folding; in the other depressions the strata lie almost horizontal. Deposits of petroleum and gas are found in almost all these depressions, from Western Siberia to the Tsaidam Basin and Manchurian Plain in China.

Mesozoic folding zones

The Mesozoic Era. The belt of Mesozoic folding includes northeastern Siberia (the Verkhoyansk and Chersk ranges), the Sikhote-Alin Range in the Amur region, a large part of Indochina, and possibly the Trans-Himalayas. Folded structures, intersected by numerous granite intrusions, were formed in all these areas as a result of the crumpling of thick layers of geosynclinal deposits of the Permian, Triassic (from 225,000,000 to 190,000,000 years ago), Jurassic, and Early Cretaceous periods. Associated with these folding belts are gold, tin, and polymetallic ores. Moderately large blocks—such as the Kolyma, Indosinian, and other massifs, which resemble the Precambrian or Paleozoic platforms in their structure—are enclosed between the branches of the broad Mesozoic folding zones.

Mesozoic folding and the upwelling of magma (molten rock) also affected adjacent areas, such as the Hercynian mountain zone of Mongolia and the Transbaikalia, the Caledonian zone of South China, and a considerable part of the Chinese Platform. Deposits of tungsten, tin, mercury, and other metals are found in these areas.

The Cenozoic Era. During the Early Cenozoic Era, a volcanic belt was formed that extends from the Chukotsk Peninsula and the shores of the Sea of Okhotsk through the eastern slopes of the Sikhote-Alin Range, in South Korea, to the southeast coast of China. It runs approximately along the border of the Mesozoic and Cenozoic fold zones. This volcanic belt is composed of massive accumulations of basaltic, andesitic, and acidic lavas dating from the Cretaceous and Early Tertiary periods, with many granite intrusions. It would seem that a series of volcanoes extended through this belt in a long arc, resembling the volcanic island chains of East Asia.

The two Cenozoic fold belts

Areas of Cenozoic folding are confined to two zones—the Alpine–Himalayan belt that traverses Asia from west to east, and the Pacific Ocean belt that runs through the island arcs to unite with the Alpine–Himalayan belt in Indonesia. The Alpine–Himalayan belt was essentially formed on the site of the extensive Tethys Geosyncline. This geosynclinal ocean, the remains of which are to be seen in the Mediterranean and Black seas and in the marine basins of Indonesia, divided two distinct continents—Gondwanaland and Angara, or Angarida—during the Paleozoic, Mesozoic, and Early Cenozoic eras. In the Alpine–Himalayan belt itself there may be distinguished two—and in places three—curving folded mountain ranges; at times these are close together, and at times they diverge. These ranges represent slabs or blocks that were overthrust onto one another or onto the edges of the neighbouring platforms, forming gigantic and complex anticlines (convex folds). The internal parts of their folded structures were sometimes already formed during the Mesozoic Era from Mesozoic and Paleozoic sediments that had accumulated in the Tethys Geosyncline, while some slopes and foothills were formed of Tertiary deposits as a result of less violent folding. The thick sand–clay strata of the Cenozoic Era, which accumulated at the base of the mountains and in depressions in front of them, often contain gas and petroleum.

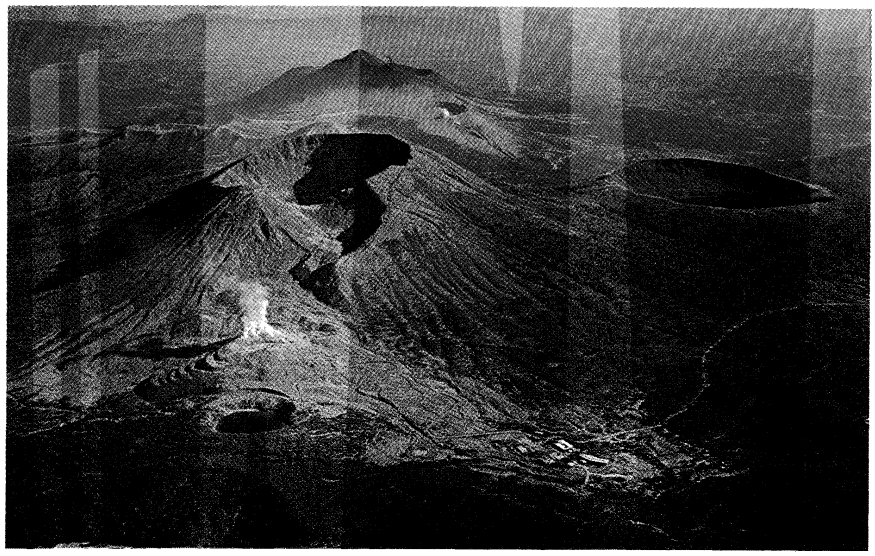
Northern and southern anticlinoria

The northern series of alpine anticlinoria (*i.e.*, series of anticlines and synclines so arranged that together they form a general arch or anticline) is formed by the Greater Caucasus Mountains between the Black and Caspian seas; the Turkmen–Khorasan ranges east of the Caspian; and the Safīd Kūh Selseleh-ye (Paropamisus), Pamir, Gissar, and Alai ranges. West of this system of ranges runs still another series of folded structures, separated from the first series by deep troughs. These consist of the Pontic Mountains, the Lesser Caucasus, and the Elburz Mountains. In the related depressions—the Black Sea, the Kolkhida (Rion) and Kura-Aras Lowland, and the South Caspian basin—are concentrated layers, from three to six miles thick, of Cenozoic deposits, which are folded along the edges of the depressions. The southern series of anticlinoria is composed of the ranges of the Tavr, Zagros, Makran and Soleymān mountains, the Hindu Kush, and the Himalayas. Between the northern and southern series of folded mountain ranges are situated the massifs of Menderes and Kirshekhir in Turkey, and the central Iranian massif. The small Georgian block occupies a similar position between the Greater and Lesser Caucasus. All these massifs represent regions consolidated by Precambrian or Paleozoic folding, with surface outcrops of bedrock in some places; in others, the bedrock is covered by weakly folded sedimentary deposits of the Paleozoic, Mesozoic, and Cenozoic periods.

The youngest geosyncline system

Mountain folding in progress. In the folded ranges of Burma, Malaysia, and Indonesia there occurs a transition from the belt of alpine folding—formed on the site of geosynclines that were already landlocked and drained—to a contemporary geosyncline system in which folding is not yet complete. This system, the youngest, occupies the area between the Asian continent itself and the Pacific Ocean and includes the folded systems of the Koryaken Range; the Kamchatka Peninsula; Sakhalin Island; Borneo; Celebes Island; the archipelagoes of the Komandorskiye (Commander), Aleutian, and Kuril islands; and the islands of Japan, the Ryukyus, Taiwan, the Philippines, the Moluccas, and the Sundas. Within its structure, geoanticlinal uplifts, consisting of island arcs and mountainous peninsulas, may be distinguished, as well as intermontane troughs, the contemporary geosynclinal downwarps of the seas bordering Asia, and deep-sea trenches on the periphery of the Pacific and Indian oceans. The axial parts of the folded ranges and island arcs in this zone are usually composed of Mesozoic and Upper Paleozoic deposits; they are cut by recent (Tertiary) intrusions and are crowned with a series of active volcanoes. The Tertiary deposits of the intermontane troughs attain great thickness and contain petroleum deposits, such as those of Sakhalin, Japan, and Indonesia; they were folded during the Miocene Epoch (from 26,000,000 to 7,000,000 years ago) and the Pliocene Epoch (from 7,000,000 to 2,500,000 years ago). In some places there are folds in the deposits sedimented in the Quaternary Period (which began 2,500,000 years ago), and as a result of large and recent fractures, Cenozoic lavas consisting of basalts and andesites cover vast areas of the island regions of East Asia.

The Alpine–Himalayan belt and, in particular, the Pacific Ocean belt are both characterized by the active tectonic processes peculiar to geosynclinal systems. A comparatively rapid horizontal shifting of different parts of the Earth's crust at a speed of between one-quarter and three-quarters of an inch a year is taking place, according to geodetic measurements taken in Japan and Tadzhikistan. Also characteristic is intensive vertical movement. This occurs in the form of the uplifting of geoanticlines,



Kirishima Range on Kyushu, Japan's southernmost island; it includes several active volcanoes.
Kokunai Jigyo Kouku

accompanied by the sinking of neighbouring depressions and strong seismic activity. Disturbances of the isostatic equilibrium are concentrated in zones where the contrasting nature of the vertical movement is the most clearly manifest. The foci of earthquake shocks are not confined only to those fractures that rupture the Earth's crust but include also the deeply buried zones of folding that are associated with fractures. These zones are tilted from the deepwater trenches of the Indian and Pacific oceans toward the Asian continent at angles of from 20° to 70°. The sources of the earthquake shocks lie from 10 to 450 miles deep (about 150 miles deep in the Hindu Kush region). The characteristic movement originating from these foci is overthrust folding and upthrusting, and it indicates extreme compression of the Earth's crust. It is assumed that along the deep fractures there occurs an overthrusting of the island arcs onto the floor of the Pacific Ocean, an underthrusting of the Indian Platform under the Himalayas, and an analogous movement along the buckled edges of all the other outlying downwarps and deep-sea trenches. A considerable thickening of the Earth's crust is taking place in the high mountain regions of Central Asia and the Himalayas; here the Earth's crust is up to 40 or 50 miles thick, as opposed to 20 to 25 miles thick on the low plains and flatlands. This thickening may also be related to the lateral compression that is folding the Cenozoic strata.

Foci of earthquake shocks

THE PATTERN OF ASIA'S PALEOGEOGRAPHIC DEVELOPMENT

The Precambrian era. Although, on the crystalline shields of Asia, rocks may be found that are known to have been formed 3,000,000,000 years ago, an adequate description of the paleogeography of the continent—that is to say, of its geography in different eras and periods of geological time—can be given only for the last 1,000,000,000 years. At the beginning of this period, primitive forms of animal and plant life appeared, primarily as algae, when the vast marine basins of the Precambrian covered the geosynclinal regions of the Urals, the Tien Shan, the Altai, the Western Sayans, and South China, as well as the southern parts of the Siberian Platform and the entire Iranian Massif. At that time continental sediments, including glacial deposits, accumulated over a considerable part of the Chinese Platform, while regions of erosion where detrital material was removed were represented by the shields.

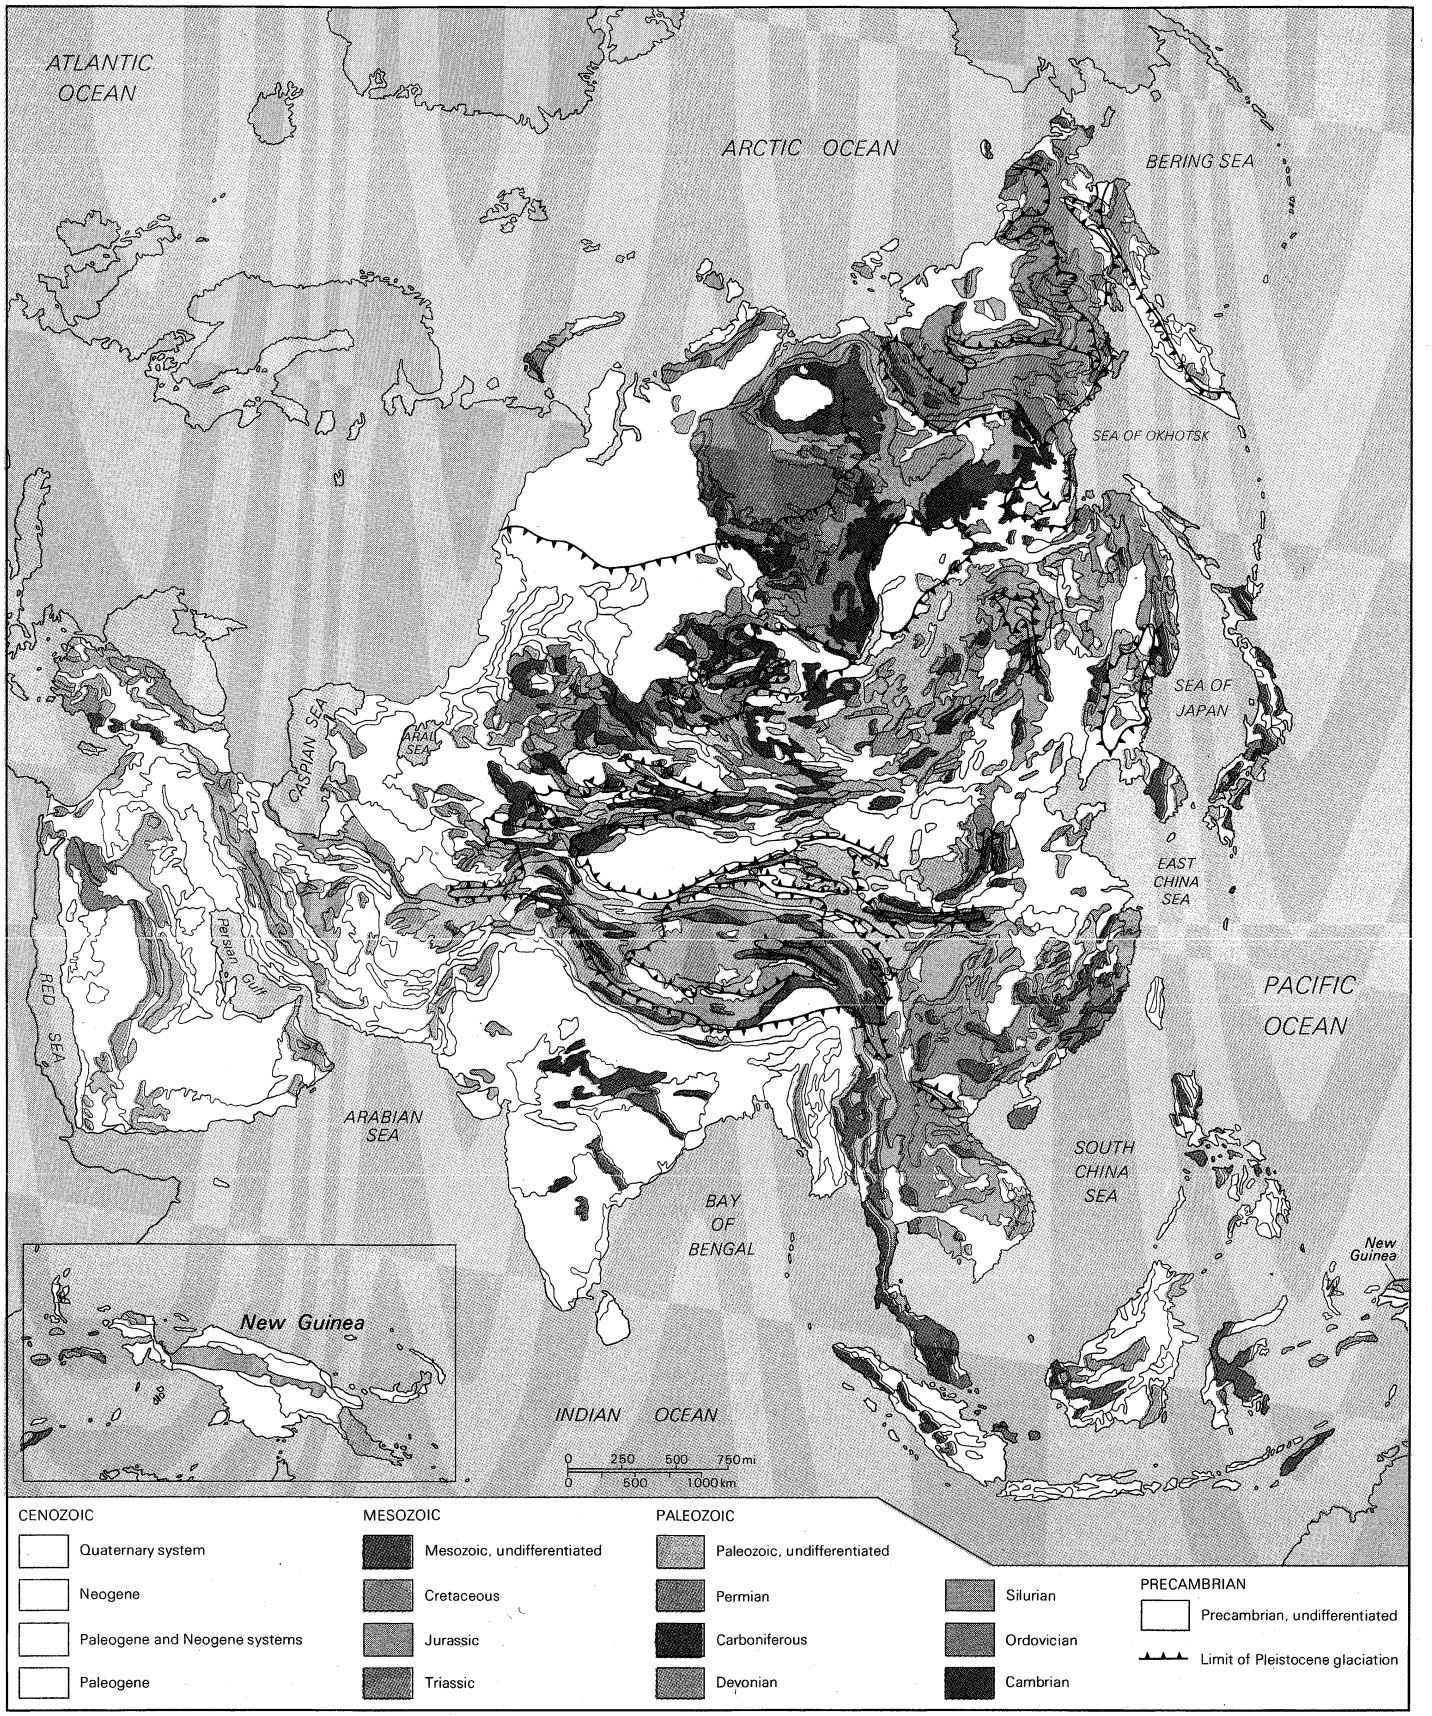
Asian seas of the Precambrian

The Cambrian and Ordovician periods. During the Early Cambrian Period, the seas began to transgress, covering almost all of the Siberian Platform, a large part of the Chinese Platform, and the northern parts of the Arabian and Indian platforms. The transgression reached its maximum extent in the middle of the Cambrian Period, and the seas began to recede during the Late Cambrian, particularly from the Siberian Platform. But the sea advanced again during the Early Ordovician Period, covering almost the entire area of the Chinese Platform. The Cambrian and Ordovician deposits on the platforms were primarily limestone, but there were also red sand–clay rocks. Deposits of rock salt were associated with the sand–clay rocks in the southern part of the Siberian Platform, in the northwestern part of the Indian Platform, and in the eastern part of the Arabian Platform. Such deposits, and the nature of the marine animal life, indicate that these three platforms were situated in a hot climatic zone; judging from the paleomagnetic data, the Equator then passed through the southern part of the Siberian Platform.

The Silurian Period. The seas receded during the course of the Silurian Period; red sediments and evaporites (sediments formed as a result of evaporation) continued to be laid down in the western half of the Siberian Platform and in other areas. At the end of the Silurian Period and in the course of the Devonian Period, all the platforms were uplifted and became dry land, except for some of the marginal areas and freshwater basins. Meanwhile, during the Cambrian, Ordovician, and Silurian periods, marine sandy-clayey and carbonate sediments, tuffs (rocks formed of compacted volcanic fragments), and lavas continued to be deposited in the geosynclines that separated the Russian, Siberian, and Chinese platforms from each other, as well as from Gondwanaland. The basins, which were separated from each other by islands, gradually dried up as the result of the Baikal and Caledonian folding; these included the basins of the Sayans, a considerable part of the Altai, the Khangarulsk, Tannu-Ola, central Kazakhstan, Kunlun, and South China. Large land areas were also subjected to volcanic activity.

The Devonian, Carboniferous, and Permian periods. The paleogeography of the Late Devonian, Carboniferous, and Permian periods is somewhat similar. In place of the present continent of Asia there existed, as before, the separate, small continental blocks of the three northern platforms, with the enormous continent of Gondwanaland to the south of them. Carbonaceous, detrital, and volcanic rocks continued to be deposited in the seas of the geosynclines separating these blocks. Calcareous sediments were also characteristic of the seas covering the massifs of Iran and Turkey, part of the Siberian Platform during the Devonian Period, and the southern half of the Chinese Platform in the Carboniferous Period. But the area of the marine geosynclinal basins was greatly reduced as a result of subsequent Hercynian folding. The basins between the Russian, Siberian, and Chinese platforms almost disappeared toward the middle of the Permian Period, at which time the area of present-day Mongolia and Western Siberia dried up. Coal-bearing strata

Virtual disappearance of the landlocked basins



Geological structure of Asia and (inset) New Guinea.

that accumulated during the Late Carboniferous and Early Permian periods on the Indian, Chinese, and Siberian platforms and in the intermontane Kuznetsk, Minusinsk, and Tuva basins provide evidence that a humid climate then prevailed. In India these strata are underlain by glacial deposits of the Carboniferous Period.

The Triassic and Jurassic periods. From the beginning of the Triassic Period, the northern platforms, together with the folded mountain ranges from the Paleozoic Era,

formed a large continent embracing three-quarters of modern Eurasia. At the same time Gondwanaland split up into several giant blocks, separated from each other by a series of basins, some of which broadened and formed the Indian Ocean. The geosynclinal basins of the Mesozoic Era survived in the Tethys Sea, in Northeastern Siberia, in the Amur region, in Indochina, and in the belt of island arcs located in East and Southeast Asia. Shallow seas or coal-bearing freshwater basins and swamps, especially numerous during the Jurassic Period, at times covered the lowlands of Western Siberia, the Turansk Plain, the Iranian Massif, and the Ordos Desert and Szechwan Basin.

The Cretaceous Period and the Cenozoic Era. Toward the middle of the Cretaceous Period, the areas of Mesozoic folding—located in what are now the Verkhoyanski Mountains, Sikhote-Alin, and Indochina—dried up, while in the course of the Late Cretaceous Period and the Early Cenozoic Era a rapid reduction in the size of the Tethys Sea took place. Finally, toward the beginning of the Early Cenozoic Era, folding in the Himalayas united India with the remainder of the continent, and Asia acquired approximately the outlines it has today. The island arcs and the basins of the marginal seas were shaped at the same time.

The joining of India and Asia

The Cretaceous Period and the Cenozoic Era were marked by mighty volcanic phenomena throughout East Asia. The Pliocene Epoch and Quaternary Period were times of vigorous tectonic movements that not only led to the uplifting of folded mountain ranges in the Alpine–Himalayan belt and in the island arcs but also rejuvenated the relief of the ancient folded mountains of the Urals, the Tien Shan, the Altai, the Sayans, and other ranges. Today an active belt of contemporary seismic activity stretches from the Hindu Kush through the Tien Shan, Mongolia, and the Baikal region to the Sea of Okhotsk.

Contemporary developments. The paleoclimatic and paleomagnetic data indicate that considerable shifting was taking place—in relation to the North and South poles as well as to each other—of those blocks from which the Eurasian continent was gradually formed. During the course of the early and middle periods of the Paleozoic Era, a considerable rapprochement (bringing together) of the Russian and Siberian platforms occurred. In the Late Carboniferous and Permian periods the Indian Platform was situated much closer to the South Pole and was partially subjected to glaciation. The Siberian Platform, on the other hand, was at that time located in the northern humid zone; in the Triassic Period the North Pole evidently lay at its northeastern edge. At the end of the Paleozoic Era the Tethys Sea was several times broader than the belt of folding that was formed within it in the course of the Mesozoic and Cenozoic eras. There are indications of the drift of the island arcs toward the shores of the Pacific Ocean and of the spreading of the bottoms of the marginal seas, such as the Sea of Japan and others, which originally developed and deepened in the middle of the Mesozoic Era. (P.N.K.)

II. Physical geography

RELIEF

Asia is the highest of the continents and contains the sharpest relief. The highest peak in the world, Mt. Everest, which is 29,028 feet (8,848 metres) high; the lowest place on the Earth's land surface, the Dead Sea, which is 1,296 feet (395 metres) below sea level; and the world's deepest continental trough, occupied by Lake Baikal, which is 5,315 feet (1,620 metres) deep and whose bottom lies at 4,250 feet (1,295 metres) below sea level, are all located in Asia.

Asia is also the most extensive of the continents. The farthest terminal points of the Asian mainland are Cape Chelyuskin in the Soviet Union (77°43′ N) to the north; the tip of the Malay Peninsula, Cape Piai, or Bulus (01°16′ N), to the south; Cape Baba in Turkey (26°04′ E) to the west; and Cape Dezhnyova, or East Cape (169°40′ W), also in the Soviet Union, overlooking the Bering Strait, to the east. The shores of Asia are washed by the Arctic Ocean on the north, the Pacific Ocean on the east, the Indian Ocean and the marginal seas of the Indian and Pacific oceans on the south, and by the seas of the Atlantic Ocean—the Mediterranean, the Aegean, the Sea of Marmara, the Black Sea, and the Azov Sea—as well as by the landlocked Caspian Sea, on the west.

The continent's extremities

Asia is separated from Australia to the southeast by the mingled waters of the Indian and Pacific oceans, and from North America on the northeast by the Bering Strait. The Isthmus of Suez unites Asia with Africa, and it is generally agreed that the Suez Canal forms the border between them.

The boundary between Asia and Europe is a historical–cultural concept that has changed more than once and is only as a matter of agreement tied to a specific borderline. The most convenient geographic boundary is a line drawn along the eastern base of the Urals, then turning west along the Emba River to the Caspian Sea; west of the Caspian, the boundary follows the Manych River and the Kerch Strait to the Black Sea. From a statistical–economic point of view, the boundary is taken to run along those political–administrative borders of the republics and *oblasti* of the Soviet Union that most closely approximate this line, which is to say, along the eastern borders of the Komi Autonomous Soviet Socialist Republic; the *oblasti* of Arkhangelsk, Sverdlovsk, and Chelyabinsk; the western border of the Kazakh S.S.R.; and along the northern borders of the *kraya* (territories) of Stavropol and Krasnodar. Some authorities consider, however, that the boundary runs along the border between the Russian Soviet Federated Socialist Republic and the Transcaucasian republics (the Georgian S.S.R. and the Azerbaijan S.S.R.).

The area of mainland Asia, including the Caucasian isthmus, amounts to about 16,750,000 square miles (43,400,000 square kilometres), of which the peninsulas—Asia Minor to the west; the Arabian Peninsula, peninsular India, Indochina, and the Malay Peninsula to the south; Korea, Kamchatka, and the Chukotsk Peninsula to the east; Taymyr and Yamal to the north—make up about 3,000,000 square miles.

The islands—Cyprus, Sri Lanka, the Andamans, the Malay Archipelago, the Philippines, Hainan, Taiwan, the Ryukyus, Japan, the Kurils, Sakhalin, Wrangel Island, the New Siberian Islands, and Severnaya Zemlya—account for another 770,000 square miles.

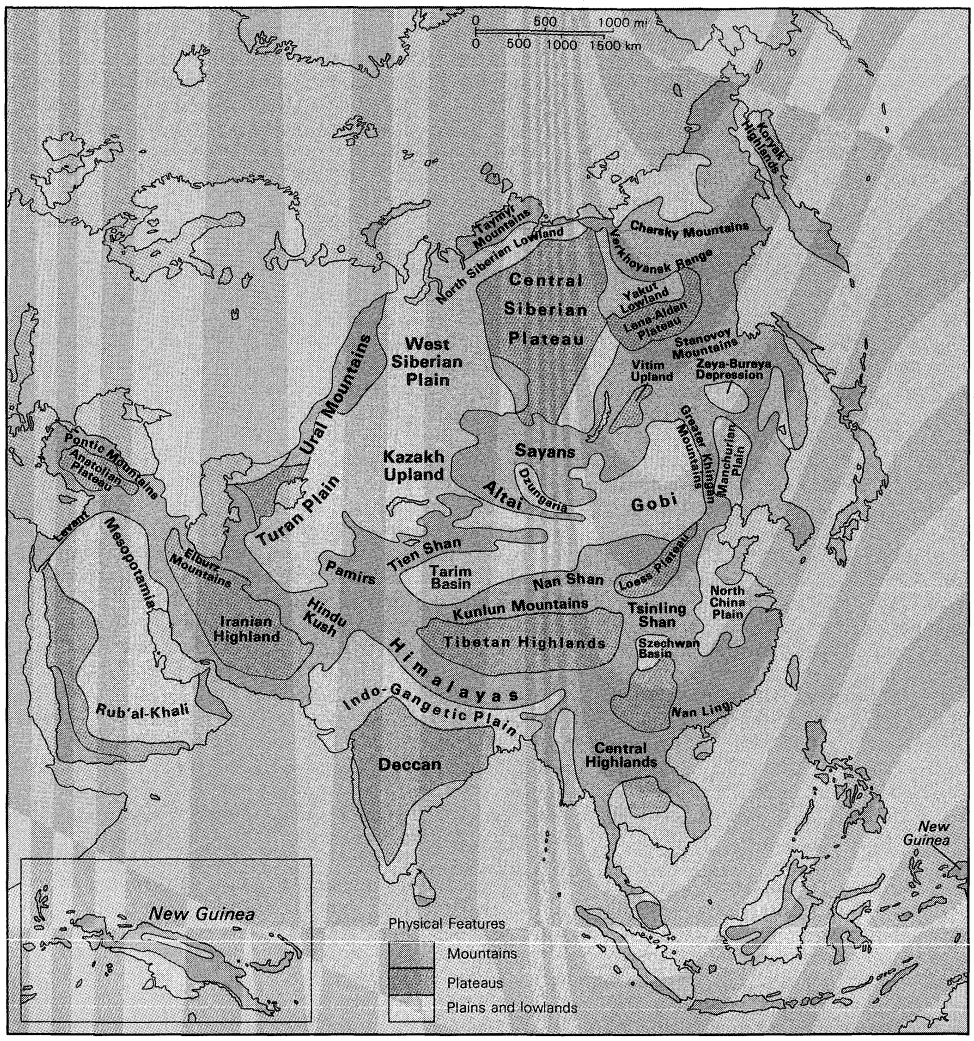
Asia's coastline is, variously, high and mountainous; low and alluvial; terraced as the result of the land being uplifted; or "drowned," where the land has subsided. The specific features of the coastline in some areas—especially in the east and southeast—are the result of active volcanism; of thermal abrasion (resulting from a combination of action by sea breakers and of thawing) by the subterranean fossilized ice (consisting of fossil ice, subsurface ice, and ice-formed rock), as in northeastern Siberia; and coral building, as in the south-southeastern area.

A characteristic of the surface of Asia is the predominance of mountains and plateaus, which form about three-quarters of the total area. The highest mountains and plateaus occur in Central Asia (Mongolia, Dzungaria, the Kashgar region, and Tibet) and Middle Asia (Turkmenia, Uzbekistan, Tadzhikistan, Kirgiziya, and Kazakhstan), which are also characterized by the vastness of their interior drainage basins.

Asia's mountain ranges

The mountain belts. The mountains are grouped in two large belts. One extends from the Chukchi Peninsula at the eastern extremity of Asia through the Kolyma Highlands, the Dzhugdzhur Mountains, and the Stanovoy Mountains to the mountains of Southern Siberia (the Stanovoy Uplands, the Sayans, and the Altai) and to the Tien Shan and Gissar-Alai. The Chersk and Verkhoyansk ranges are the Western spurs of this belt.

The second belt, in the west, runs in a latitudinal direction and includes the West Asian highlands, the Pamirs, Karakoram, the Tibetan Highlands, and the Himalayas; it then turns to the south and southeast, running through the Arakan Mountains to the islands of the Malay Ar-



Physiographic regions of Asia.

chipelago. A generally latitudinal branch springs from it in the Pamirs region and runs eastward through the Kunlun, Nan Shan, and Tsinling mountains. The western part of the second mountain belt consists, for a considerable distance, of two series of mountain chains that converge in dense knots in the highlands of Armenia, in the Pamirs, and in the southeast of the Tibetan Highlands; the two chains then diverge to encompass the interior plateaus—the highlands of Asia Minor together with the Anatolian Plateau, and the Iranian and Tibetan highlands. At the margins of the highlands the mountain chains change direction abruptly in the congested mountain knots, but in the intervening areas they curve in flowing arcs.

Along the edges of the Central Asian plateaus extend the elongated mountain chains of the Greater Khingan, T'ai-hang Shan, and the Sino-Tibetan ranges. The Khingan–Bureya mountains (Bureya and Lesser Khingan mountains) demarcate the Zeya-Bureya Depression; the Manchurian–Korean mountains and the Sikhote-Alin ranges separate the plains of the Amur–Sungari, the Lake Khanka lowland, and the Manchurian Plain. The coastal ranges in the southeast consist of the Nan Ling (South China) and Annam mountains. In the east, the Koryak Highlands rise in the northern section of the Kamchatka–Koryak arc; in its southern portion they form the Central Range (Sredinny Khrebet) of Kamchatka. The marginal seas of the Pacific Ocean are bordered by the East Asian islands, which form the line of arcs that also extends partly onto the continent, running from Borneo to Taiwan, through the Ryukyu Islands to Korea, from Honshu to Sakhalin, and from the Kuril Islands to Kamchatka.

The plains and lowlands. Low plains occupy approximately a quarter of Asia, particularly the vast West Siberian and Turan plains of the interior. The remaining lowlands are distributed either in the maritime regions, such as Northern Siberia, the Yana-Indigirka lowland, Kolyma, and the Chinese coastal mainland, or in the piedmont depressions of Mesopotamia, the Indo-Gangetic Plain, and mainland Southeast Asia. In addition, there are the intermontane plains of Kashgaria, Dzungaria, Tsaidam, and Fergana and the plateaus of middle Siberia and the Gobi. The plateaus inside Tibet, the Tien Shan, and the Pamirs lie at altitudes as high as 12,000 feet. Many ranges in Middle and Central Asia reach elevations of 21,000 to 24,000 feet, but in other mountain chains and massifs they rarely exceed 12,000 feet. To the south of the zone of piedmont depressions, partially occupied by seas—the Arabian Sea, the Bay of Bengal, the Gulf of Oman, the Persian Gulf, and, in the Mediterranean, the Cyprus Basin—lie extensive tablelands and plateaus, including the Deccan Plateau in India and the Syrian–Arabian Plateau in the west; these are enclosed by marginal mountain ranges, such as the Western Ghāts in India; the Oman, Ḥaḍramawt, Yemen, and Hejaz mountains on the Arabian Peninsula; and the Lebanon and Anti-Lebanon mountains in the Levant. In Central Siberia are the isolated and uplifted Putorana Mountains and, situated to the north of them, the Byrrangas Mountains.

The distribution of plains and lowlands

The islands. A large part of the islands of Asia are mountainous. The highlands of Sri Lanka rise to 8,279 feet (2,524 metres), Mt. Kinabalu in Malaysia reaches 13,451 feet (4,101 metres), Fujiyama on the Japanese island of Honshu has an altitude of 12,385 feet (3,776

Dhaulāgiri, in the Great Himalayas, Nepal, rising to a height of 26,810 feet.
Bernhaut—FPG

metres), and many volcanoes of Sumatra, Java, and Mindanao reach 10,000 feet. The Kuril–Kamchatka island arc, which extends onto the Kamchatka Peninsula, comprises the Vostochny (East) volcanic range. Especially high is the Klyuchevsk group of volcanoes, where the highest active volcano in Asia—Klyuchevskaya Sopka—rises 15,580 feet (4,750 metres).

Geologic and climatic influences. Mesozoic and Alpine foldings created boundaries between basic types of mountains over vast areas of Asia. The contemporary relief of Asia was molded primarily under the influences of: (1) ancient processes of planation (levelling); (2) larger vertical movements of the surface during the later Tertiary and Quaternary periods; and (3) severe erosive dissection of the edges of the uplifted highlands with the accompanying accumulation of alluvium in low-lying troughs, which were either settling downward or being uplifted more slowly than the adjoining heights.

Forces shaping Asia's relief

The interior parts of the uplifted highlands, and the plateaus and tablelands of peninsular India, Arabia, Syria, and Eastern Siberia, which are relatively low-lying but composed of resistant rock, have largely preserved their ancient peneplaned (levelled) surfaces. Particularly spectacular uplifting occurred in Central Asia, where for the last 30,000,000 years the amplitude of this uplift of the mountain ranges of Tibet, the Pamirs, and the Himalayas has exceeded 13,000 feet. The eastern margin, meanwhile, underwent subsidences of up to 2,300 feet. Uplifting as a result of fractures at great depths, of which the Kopet-Dag and Ferghan mountains provide examples, and of folding over a large radius, of which examples may be seen in the Tien Shan and Gissar-Alai, played a large role.

Erosional dissection transformed many ancient plateaus into mountainous regions. Majestic gorges were carved into the highlands of the western Pamirs and southeastern Tibet; the Himalayas, the Kunluns, the Sayans, the Stanovoye Highlands, the Cherski Mountains, and the marginal ranges of the West Asian highlands were deeply cut by the rivers, creating deep superimposed gorges and canyons. In many areas, and especially in those regions with dry climates, erosion clearly exposed the structural forms, including rock layers of different erosional resistance.

Vast areas of Middle, Central, and East Asia, particularly in the Huang Ho Basin, are covered with loess (a loamy unstratified deposit formed by the wind or by glacial meltwater deposition). There are broad expanses of badlands, eolian (wind-produced) relief, and karst topography (limestone terrain associated with vertical and underground drainage), and features associated with ancient glaciation.

Eolian relief

The mantle of Quaternary glaciation embraced northwestern Asia only to 60° N. East of the Khatanga River, which flows from Siberia into the Arctic Ocean, only isolated glaciation of the mantle debris and of the mountains occurred because of the extremely dry climate that existed in the northeast even at that time. The high mountain regions experienced mainly mountain glaciation. There are traces of several periods during which the glaciers advanced—periods separated by warmer interglacial epochs. Glaciation continues in many of the mountainous areas and on the Severnaya Zemlya archipelago. Karakoram, the Pamirs, the Tien Shan, the Himalayas, and the eastern Hindu Kush are noted for the immensity of their contemporary glaciers.

There is an enormous area of permafrost in northern Asia that extends to lower latitudes than in any other part of the world. Little snowfall occurs, due to the aridity, and deep freezing of the soil takes place.

Several lowlands, primarily coastal plains, are covered with marine sediments as the result of recent advances of seas, such as the Caspian and the northern seas.

Volcanism added broad lava plateaus and chains of young volcanic cones to the relief of Asia. Ancient lavas and intrusions of magma, exposed by later erosion, cover the terraced plateaus of peninsular India and Central Siberia. Extensive zones of young volcanic relief and contemporary volcanism, however, are confined to the unstable arcs of the East Asian islands, together with Kamchatka, the Philippines, and the Greater and Lesser Sunda Islands.

Volcanic zones

Recent volcanism is also characteristic of the West Asian highlands, the Caucasus, Mongolia, the Manchurian–Korean mountains, and the Syrian-Arabian Plateau. In historic times eruptions have also occurred in the interior of the continent in the Lesser Khingan Mountains and the Anyuy highlands.

The regions of Asia. In geographical literature the practice of dividing Asia into large regions, each grouping together a number of countries, is common. These divisions usually consist of North Asia, including Siberia and the northeastern edges of the continent; East Asia, including the continental part of the southern Soviet Far East, the East Asian islands, Korea, and eastern and

Bololo Canyon, north of Kābul, Afghanistan. The Hindu Kush mountains are visible in the background.
Harrison Forman

northeastern China; Central Asia, including the Tibetan Highlands, Dzungaria and Kashgaria in the Sinkiang Uighur Autonomous Region, Inner Mongolia, the Gobi, and the Sino-Tibetan ranges; Middle Asia, including the Turanian Plain, the Pamirs, the Gissar-Alai and the Tien Shan; South Asia, including the Philippine and the Malay archipelagoes, Indochina and the Indian Peninsula, the Indo-Gangetic Plain, and the Himalayas; and West Asia, including the West Asian highlands (Asia Minor, Armenia, and Iran), the Levant, and the Arabian Peninsula. On occasion, the Philippines, the Malay Archipelago, and the Indochina peninsula, instead of being considered as part of South Asia, are grouped separately as Southeast Asia; the Arabian Peninsula and the Levant are also sometimes grouped together separately as Southwest Asia.

North Asia. The North Asia region includes platform plains, plateaus, and folded mountain ranges. Frost weathering and permafrost have influenced relief.

Northeast Siberia

In Northeast Siberia are found faulted and folded mountains of moderate height, such as the Verkhoyansk, Chersk, and Okhotsk-Chaun mountain arcs, formed of Mesozoic structures rejuvenated by neo-tectonic uplifting; the Koryak Mountains, formed of Cenozoic structures, are also in this region. Volcanic activity took place in these areas during the Cenozoic Era. Some plateaus are found in the areas of the ancient massifs, such as the Kolyma massif. Traces of several former centres of mountain glaciers remain, as well as traces of lowland originally covered by the sea, such as the New Siberian Islands. The Aldan Plateau—an ancient peneplain resting on the underlying platform that sometimes outcrops on the surface as the Aldan Shield—is located in the region. Traces of ancient glaciation are also to be distinguished.

The North Siberian plains consist of the Middle Siberian Tableland and the Lena–Vilyuy lowlands, which are platform plateaus and stratified plains that were uplifted in the Cenozoic Era. They are composed of terraced and dissected mesas with exposed horizontal volcanic intrusions; plains formed from uplifted Precambrian blocks; a young uplifted mesa, dissected at the edges and partly covered with traprock (Putorana Mountains); and the peripheral North Siberian lowland, covered with its original marine deposits.

The West Siberian Plain is stratified and is composed of Early Cenozoic sediments deposited over thicknesses of Mesozoic material, in addition to folded bedrock that is Hercynian in the west and Caledonian in the east. The northern part was earlier subjected to several periods of glaciation; in the south the predominant deposits are those laid down by glacier streams, as well as alluvial deposits.

In the northern part of the region are the mountains and islands of the Asian Arctic. The archipelago of Severnaya Zemlya is formed of fragments of fractured Paleozoic folded structures. Throughout the region vigorous contemporary glaciation has occurred.

East Asia. Mountains and plains are characteristic of the northern part of continental East Asia. The main features in the northern region include the Khingan–Burein mountains; the Sikhote-Alin ranges of Khabarovsk and Primorsky *kraya* (territories) in the Soviet Union; the Manchurian–Korean highlands running along North Korea's border with China; the East Korean range of the Korean Peninsula; the Zeya-Buryea Depression of Amur *oblast* in the Soviet Union; the Liao Ho in Liaoning Province, China; the Manchurian Plain and the North China Plain; and the Amur and Sungari rivers and the Lake Khanka lowlands. Most of these features were formed by folding, faulting, or broad zonal subsidence. The mountains are separated by alluvial lowlands in areas where recent subsidence has occurred.

The mountains of southeastern China were formed from Precambrian and Caledonian remnants of the Chinese Platform by folding and faulting that occurred during the Mesozoic and Cenozoic eras. The mountain ranges are numerous, are of low or moderate altitude, and occupy most of the surface area, leaving only small, irregular-shaped plains.

The East Asian islands

The islands off the coast of East Asia and the Kamchatka Peninsula are related formations. The Ryukyu Islands, Japan, Sakhalin, and the Kuril Islands are fragments, uplifted in varying degrees, of the Ryukyu–Korean, Honshu–Sakhalin, and Kuril–Kamchatka mountain-island arcs. Dating from the Mesozoic and Cenozoic eras, these arcs have complex knots at their junctions, represented by the topography of Kyushu and Hokkaido. The mountains are of low or moderate height and are formed of folded and faulted blocks; some volcanic mountains and small alluvial lowlands are also to be found.

Kamchatka is a mountainous peninsula, formed from fragments of the Kamchatka–Koryakskaya and Kurilo–Kamchatskaya arcs, which occur in parallel ranges. The young folds enclose rigid ancient structures. Cenozoic (including contemporary) volcanism is pronounced. Vast plains exist that are composed of alluvia with volcanic ashes.

Central Asia and South Siberia. Central Asia consists of mountains, plateaus, and tablelands formed from fragments of the Siberian and Chinese platforms, peripherally surrounded by a folded area formed in the Paleozoic and Mesozoic eras.

The mountains of Southern Siberia and Mongolia were formed by renewed uplift of old faulted and folded blocks; ranges are separated by intermontane troughs. The alpine mountains—the Altai, the Mongolian Altai,

and the Sayano–Tuvan and Stanovoy highlands—are particularly noticeable. They have clearly defined features resulting from ancient glaciation; contemporary glaciation is also very active.

The Central Asian plains and tablelands include the Takla Makan Desert, the Gobi, and the Ordos Desert. Relief features vary from surfaces levelled by erosion in the Mesozoic and Cenozoic eras to stratified plateaus with low mountains, eroded plateaus on which loess had accumulated, and vast sandy deserts covered with windborne alluvium and lacustrine deposits.

Alpine Asia—sometimes known as High Asia—includes the Pamirs and the eastern Hindu Kush, the Kunlun Mountains, the Tien Shan, the Gissar-Alai Mountains, the Tibetan Highlands, the Karakoram Range, and the Himalayas.

The Pamirs and the eastern Hindu Kush are sharply uplifted mountains dissected into ridges and gorges in the west. There is thick glacial cover; alpine deserts occur on the plateaus.

The Kunlun Mountains, the Tien Shan, and the Gissar-Alai Mountains belong to an alpine region that was formed from folded structures of Paleozoic age. There are glaciers that are of impressive size centred in this alpine region.

The Tibetan Highlands

The Tibetan Highlands represent a fractured alpine zone in which Mesozoic and Cenozoic structures that surround an older mass in the centre have experienced more recent uplifting. Some of the highlands are covered with detrital desert; elsewhere in this region, alpine highlands are dissected by erosion or are covered with glaciers.

The Karakoram Range and the Himalayas include the highest mountains in the world; they were formed by uplifting that took place in a zone of Cenozoic folds and Mesozoic partially folded areas containing outcrops of the ancient bedrock. Contemporary glaciation is vigorous.

South Asia. South Asia, in the limited sense of the term, consists of peninsular India and Sri Lanka (formerly Ceylon) and the Indo-Gangetic Plain.

Peninsular India and Sri Lanka are formed of platform plateaus and tablelands uplifted in the Mesozoic and Cenozoic eras and subjected to humid climate erosion ever since. Tablelands with uplifted margins and terraced and dissected plateaus with lava mantles or intrusions may be distinguished.

The Indo-Gangetic Plain is formed from the combined alluvial plains of the Indus, Ganges, and Brahmaputra rivers, which lie in a deep marginal depression running north of and parallel to the main range of the Himalayas. It is an area of immature subsidence, in which thick accumulations of earlier marine sediments and later continental deposits that washed down from the mountains have been transformed into sandy deserts in the western arid region.

Southeast Asia. Southeast Asia comprises the Indochina Peninsula and the islands and peninsulas to the southeast of the Asian continent.

Indochina

The mainland consists of the western mountain area and the central and eastern mountains and plains. The western mountain area of Burma is a zone of Cenozoic folding. Mountains of medium altitude are formed of folded blocks that decrease in size and altitude to the south; the valleys are alluvial and broaden out to the south. The central and eastern region of Thailand and North and South Vietnam is characterized by mountains of low and moderate height that have been moderately fractured. The region is one of Mesozoic structures surrounding an ancient mass known as the Cambodian saucer, with which are associated plateaus and lowlands filled with accumulated alluvial deposits.

Archipelagoes border the southeastern margin of Asia, consisting mainly of island arcs with which peninsulas are associated. The island arcs are bordered by very deep oceanic trenches. These arcs are characteristically very unstable and are volcanically active.

The Indian Ocean arcs—the island chains of Sumatra, Java, and the Lesser Sunda Islands—consist of fragments of alpine folds formed from materials of different ages. Cenozoic and contemporary volcanic activity is manifest, and volcanic mountains as well as alluvial lowlands may be distinguished.

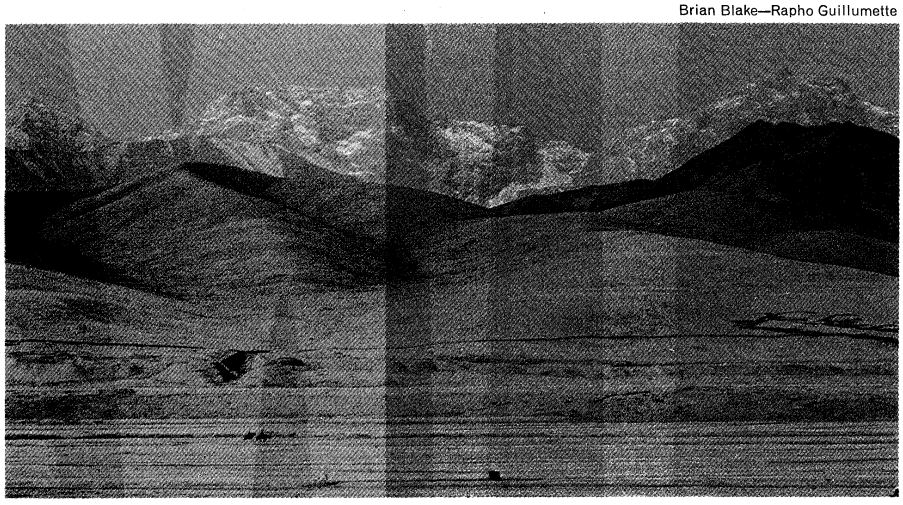
Borneo and the Malay Peninsula are formed from fractured continental land situated at the junction of the Alpine–Himalayan and East Asiatic geosynclinal regions; contemporary volcanism is absent. The mountains are composed of folded and faulted blocks; the lowlands are alluvial.

The Pacific Ocean island arcs, including Celebes, the Moluccas, the Philippine Islands, and Taiwan, are fragments of folded alpine structures that were built up by volcanic products during the Cenozoic Era. Volcanic activity and the building of coral reefs continue. Mountain areas of moderate height, volcanic ranges, alluvial lowlands, and coral reef islets may all be distinguished.

Middle Asia. Middle Asia includes the plains and hills lying between the Caspian Sea to the west and Lake Balkhash to the east.

The area between the Caspian and Lake Balkhash is composed of flat plains on continental platforms of folded Paleozoic and Mesozoic bedrock. Individual uplifted portions form low rounded hills (*melkosopochniks*) in the Kazakh region; low mountains on the Mangyshlak and Krasnovodsk peninsulas of the Caspian Sea; and mesas (isolated hills with level summits and steeply sloping sides) in areas of earlier marine sedimentation, such as the Ustyurt Plateau and the Kara-Kum Desert. Thick accumulations of alluvium have been transported by the wind, forming sandy deserts in the south. Original marine and lacustrine sediments adjoin the shores of the Caspian and Aral seas and Lake Balkhash.

Brian Blake—Rapho Guillumette



The Ch'lang-t'ang plain of northern Tibet, bordered by the Kunlun Mountains.

West Asia. West Asia includes the highlands of Asia Minor, and the Armenian and Iranian highlands.

The highlands of Asia Minor—the Pontic mountain system that parallels the Black Sea, and the Tavr and Anatolian tablelands—are areas of severe fragmentation, heightened erosional dissection, and isolated occurrences of volcanism.

The Armenian Highlands

The Armenian Highlands, which include the Little Caucasus and the Kurd mountains, are severely fragmented. Recent uplifting, in the form of a knot of mountain arcs, took place during a period of vigorous volcanism that occurred in the Cenozoic Era.

The Iranian Highlands represent a combination of mountain arcs (in the north, the Elburz and Turkmen-Khorasan mountains, the Safīd Kūh Selseleh-ye, and the western Hindu Kush; in the south, the Zagros, Makran, Soleymān, and Kirthar mountains), together with the tablelands of the interior, and the Central Iranian, Eastern Iranian, and Central Afghanistan mountains. There are isolated Cenozoic volcanoes, a predominance of accumulated remnants resulting from ancient erosion, and saline and sandy deserts in the depressions and on the tablelands.

Southwest Asia. Southwest Asia, like much of southern Asia, is made up of an ancient platform—the northern fragments of Gondwanaland—in which sloping plains occur in the marginal downwarps. Its principal components are the Arabian Peninsula and Mesopotamia.

The Arabian Peninsula is a tilted platform, highest along the Red Sea, on which the stratified plains have undergone erosion under arid conditions. Block tablelands with uplifted margins, Cenozoic lava plateaus, stratified plains, and cuestas (long, low ridges with a steep face on one side and a long gentle slope on the other) may all be distinguished. Ancient marine sands and alluvia, resulting from previous subsidence and sedimentation, now take the form of sandy deserts.

Mesopotamia consists of the Tigris and Euphrates floodplains and of the deltas from Baghdad to the Persian Gulf. The original lowland is covered with late Cenozoic and Quaternary sedimentation; the elevated plain, on the other hand, has been dissected by erosion and denudation under the continental conditions prevailing in the Late Cenozoic Era.

CLIMATE

Air masses and wind patterns. The enormous expanse of Asia and the abundance of mountain barriers and inland depressions have resulted in great differences in existing conditions of solar radiation, atmospheric circulation, and climate as a whole. A continental climate, associated with large landmasses and characterized by an extreme annual range of temperature, prevails over a large part of Asia. Air reaching Asia from the Atlantic Ocean, after passing over Europe or Africa, has had time to be transformed into continental air. As a result of the prevalent easterly movement of the air masses, as well as the isolating effect of the marginal mountain ranges, the influence of sea air from the Pacific Ocean extends only to the eastern edge of Asia. From the north, Arctic air has unimpeded access into the continent. In the south, tropical and equatorial air masses predominate, but their penetration to the centre of Asia is restricted by the ridges of the latitudinal belt of highlands; in the winter months—November through March—such penetration is further impeded by the density of the cold air masses over the interior.

The continental climate

The contrast between the strong heating of the landmasses in the summer months from May to September and the chilling in winter produces sharp seasonal variations in the atmospheric circulation and also enhances the role of local centres of atmospheric activity. Winter chilling of the Asian landmass develops a persistent high-pressure winter anticyclone over Siberia, Mongolia, and Tibet, which is normally centred southwest of Lake Baikal. Within the zone of the anticyclone there is relatively little strong air movement in protected basins and lowlands, but strong winds may affect the higher mountains and passes. The anticyclone is fed by subsiding upper air, by bursts of Arctic air flowing in from the north, and by the persistent westerly air drift that accompanies the gusty cyclonic low-pressure cells operating within the Northern Hemisphere cyclonic storm system. Drifts of cold, dry air move eastward and southward out of the continent, affecting eastern and southern Asia during the winter. Only a few of the winter cyclonic lows moving eastward out of Europe carry clear across Asia, but they do bring greater periodic change in weather in Western Siberia than is typical in Central Siberia. The zone of lowest temperature—the so-called cold pole—is found in the northeast, near Verhoyansk, where temperatures as low as −90° F (−68° C) are recorded. The outward drift of winter air creates a sharp temperature anomaly on Asia's eastern margin, where the climate is colder than the characteristic average for each given latitude. But episodic intrusions of oceanic air from the east and southeast moderate this anomaly, so that temperatures are not as severe here as in the centre of the anticyclone.

The polar front

The zone where the temperate and tropical air masses are in contact—called the polar front—shifts southward in winter. This movement is caused by a displacement, in the same direction, of the entire system of atmospheric circulation—a displacement resulting from the powerful climatic influence exerted by the chilled continent. The winter rainy season in the southern parts of the West Asian highlands, which is characteristic of the Mediterranean climate, is associated with this southerly movement of the polar front. In the more northerly areas of West and Middle Asia, the effect of cyclonic action is particularly strong in the spring, causing the maximum in annual precipitation to occur at this season. In summer, the polar front shifts northward, causing cyclonic rains in the mountains of Southern Siberia. In West, Middle, and Central Asia, a hot, dry, dusty, continental tropical wind blows at this time. Over the basin of the Indus River the heating creates a low-pressure area, known as the South Asian (or Iranian) low. The southern monsoon (a rain-bearing wind) advances along its southern edge, bringing copious rainfall to peninsular India, the southern Himalayas, and mainland Southeast Asia. Farther to the west the hot, dry air of North Africa and the katabatic (downward) current of air from Europe, blowing from the northwest, sweep in the direction of this low-pressure area. The aridity of the desert–tropical climate of Arabia and Pakistan is related to this phenomenon.

In eastern Asia the Pacific Ocean polar front creates atmospheric disturbances during the summer. From the warm sectors of cyclones moving westward through this region, the warm and moist summer monsoon blows toward the continent. Becoming chilled as it passes over cold ocean currents, this air brings fogs and drizzling rains. To the south of 38° N, where the warm Kuroshio (Japan) Current approaches the coast of Japan, the summer monsoon brings protracted rains and high humidity; together with high temperatures, this creates a hothouse atmosphere.

The summer period over China is a time of variable air movement out of the South Pacific. If that drift is strong and the summer continental low-pressure zone is marked, a strong summer monsoon may carry moisture well into Mongolia. If neither the drift nor the continental low is strong, the China summer monsoon may fail, falter over eastern China, or cause irregular weather patterns that may threaten China proper with crop failure.

Typhoons and monsoons

Tropical cyclones, or typhoons, occur along the East Asian weather fronts throughout the year but are most severe during the autumn months. These typhoons are accompanied by very strong winds and torrential rains so heavy that the maximum precipitation from the typhoons locally may exceed the total amounts received during the normal summer monsoons.

In winter the Pacific Ocean polar front is driven back to tropical latitudes by a steady drift of cold, dry Siberian air. On the East Asian islands the effect of the winter continental monsoon is tempered by the surrounding seas. In passing over them, it becomes warmed and saturated with moisture; then waters the northwestern slopes

of the island arcs. Occasionally, however, strong bursts of cold air carry cold spells as far south as Hong Kong and Manila.

In winter, continental tropical air prevails in subequatorial Asia; in summer it is replaced by equatorial ocean air. The winter season's dry and warm winds, directed toward the equatorial low-pressure axis, are analogous to trade winds but simultaneously act as the South Asian continental monsoon. The dry spring that follows changes abruptly and dramatically into the rainy summer with the onset of the monsoon. The summer monsoon brings enormous amounts of rain (up to about 25 inches in a month). Over the areas of Asia close to the Equator —southern Sri Lanka, Malaysia, and the Greater Sunda Islands—equatorial air prevails continuously, accompanied by even temperatures and abundant rainfall at all seasons. The Lesser Sunda Islands have a subequatorial monsoon climate; their wet and dry seasons are regulated by the calendar rhythm of the Southern Hemisphere, which is characterized by a wet summer from November to February and a dry winter from June to October.

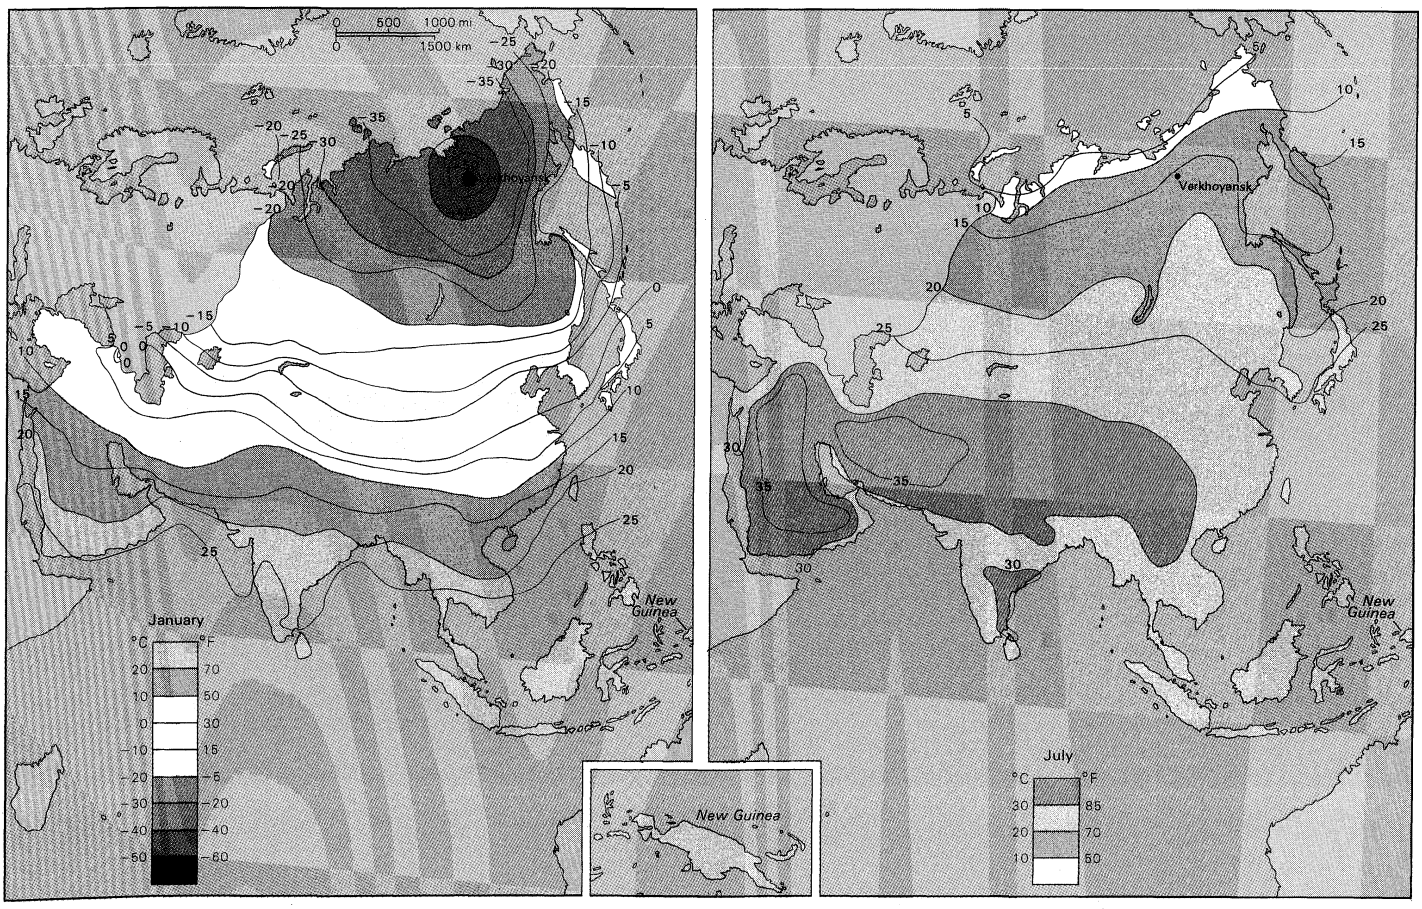
The influence of topography. Differences between the climatic conditions of the various regions of Asia are determined to a considerable degree by topography. Different altitudinal climatic zones are most clearly defined on the southern slopes of the Himalayas, where they vary from the subequatorial and tropical climates of the foothills, at the lowest levels, to the snowy climate of the peaks, at the highest altitudes. The degree of exposure also plays a large role—the different orientation of the opposite slopes of the ridges in relation to compass directions and to the prevailing winds. The sunny southern slopes differ from the shady northern ones, and windward slopes exposed to moist ocean winds differ from leeward slopes, which, lying in the wind (and rain) shadow, are necessarily drier. In addition to the physical isolation of the leeward slopes from the moisture-laden winds, the foehn effect is also found here. This occurs when a strong wind traverses a mountain range and is deflected downward as a warm, dry, gusty, erratic wind. Contrasts of climate resulting from exposure are manifested clearly in the Himalayas, the Elburz Mountains, Japan, Taiwan, the Philippines, the Tien Shan, the Transbaikalia, and many other places.

The foehn effect

The isolating barrier effect of the relief on the climate appears clearly in the West Asian highlands and in Central Asia. In these regions the surrounding mountains isolate the tablelands of the interior from the moisture-laden winds. The massiveness of the interior highlands is also a significant factor; it favours the formation of local anticyclones over them during the cold months of the year.

During the winter season some of the cyclonic storms that move eastward through the Mediterranean Basin are deflected south of the Tibetan Highlands, crossing northern India and southwestern China and then turning northeastward to return to the northern cyclic path. Such storms do not often bring winter rain, but they create short periods of cloudy, cool, or gusty weather and bring snow to the higher mountain ranges.

Temperature. The average January temperature over a considerable part of Siberia is below −4° F (−20° C), and in the Verkhoyansk region it reaches −58° F (−50° C). Along the coastal areas, the proximity of the Pacific Ocean moderates the temperatures to from 23° F to 5° F (−5° C to −15° C). The January isotherm (a line connecting points of equal temperature) of 32° F (0° C) passes through Samarkand, Peking, and the island of Honshu. An isotherm of 68° F (20° C) is traced along the Tropic of Cancer and one of 77° F (25° C) along the Equator. In July, when the average temperature is 86° F (30° C), the maximum temperatures are found in West Asia and in the Thar and Takla Makan deserts. The 68° F (20° C) isotherm moves as far as 55° to 60° N, but near the cool Pacific Ocean it bends to the south. Along the northern coasts of Asia the average temperature in July is below 50° F (10° C), which is typical for a tundra



Average temperatures for January and July in degrees Celsius for Asia.

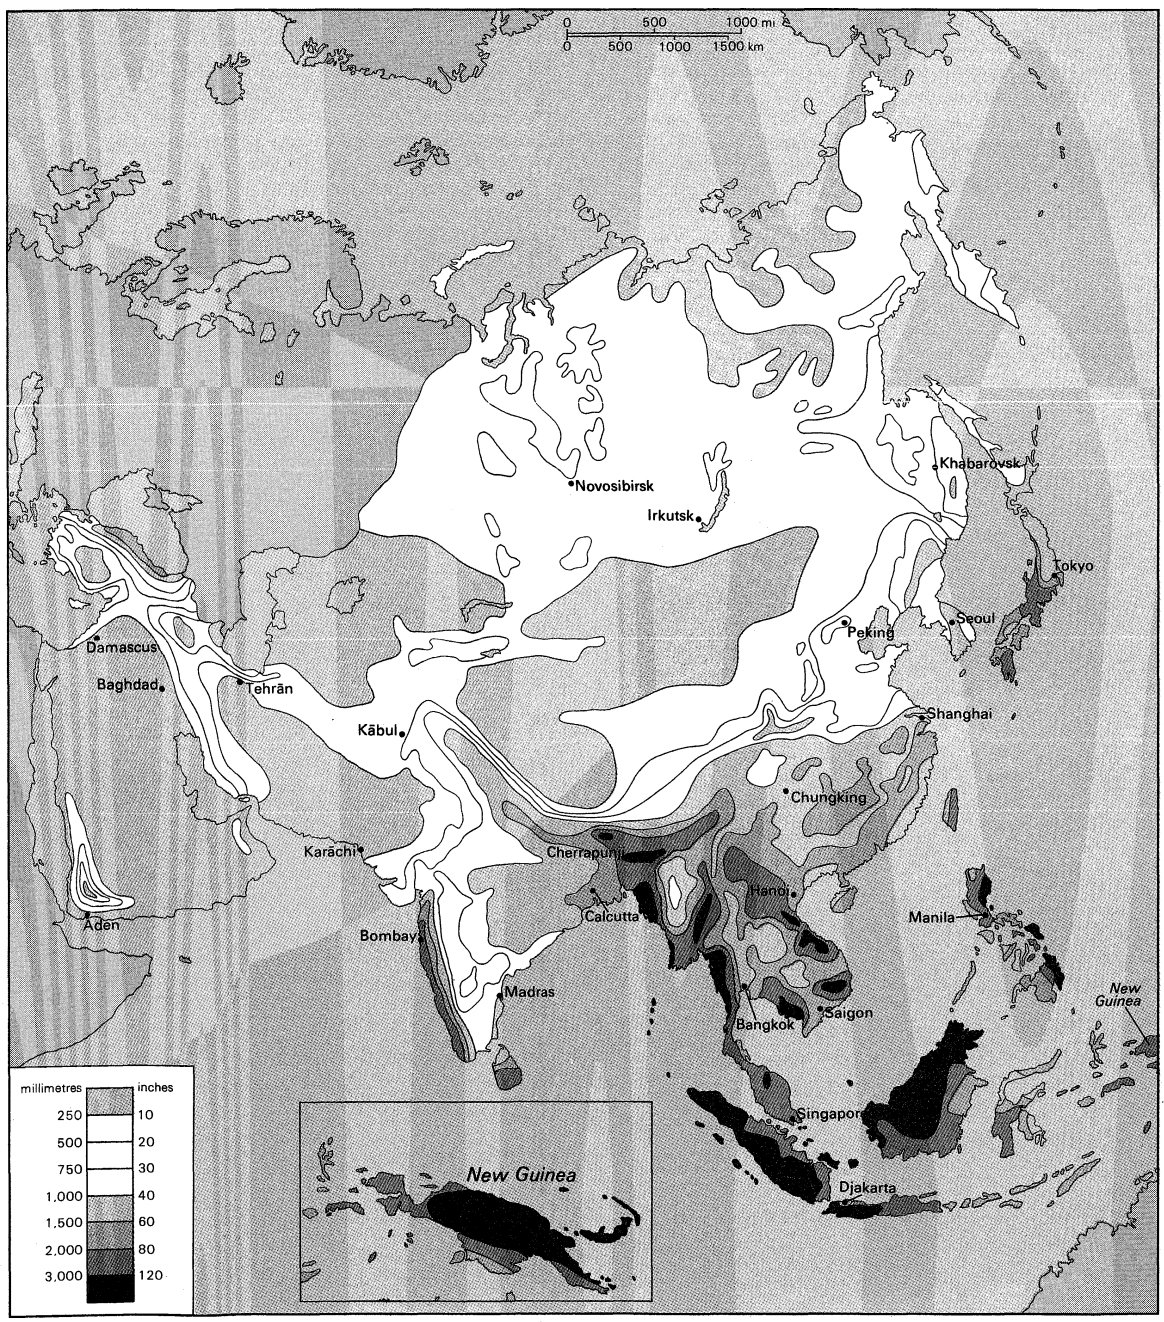
climate. The greatest amplitude in annual temperature range occurs near the "cold pole," which has surprisingly warm summers; the annual range may exceed 175° F (97° C).

Rainfall. Annual rainfall in the equatorial belt is approximately 80 inches; it is 80 to 120 inches and more (300 to 500 inches in places) on the windward maritime slopes in South and East Asia. In Cherrapunji (Meghalaya) 900 inches of rain fell in seven months in 1891. Precipitation is less than 40 inches on the lee slopes of the subequatorial regions. In the subtropical and temperate monsoon climates there is adequate rainfall, amounting to about 24 to 40 inches. Precipitation is less than ten inches in Eastern Siberia and averages six to eight inches (but may be less than four inches in some places) in the deserts of West, Middle, and Central Asia.

Climatic regions. The distribution pattern of rainfall throughout the year is varied. Relatively uniform moisture is characteristic of the Asian equatorial zone. Maximum summer precipitation and minimum winter precipitation are the rule in the subequatorial zones and in other regions with monsoon climates, as well as in those areas where there is summer movement of the fronts—the polar front in the mountains of Southern Siberia and the Arctic front in the sub-Arctic regions. Wet winters and dry summers are typical of the Mediterranean climatic region in West Asia, where precipitation is associated with the winter activity of the polar front. This polar front activity, accompanied by maximum precipitation, occurs in the spring in the interior parts of the West Asian highlands. Summer and winter precipitation merges in some parts of Asia. In the Kolkhida climate, the summer rains—brought by the northwesterly Atlantic air currents—merge with the cyclonic Mediterranean winter rains. In some areas of Japan and eastern China there is uniform precipitation when, in addition to the summer monsoon, the winter monsoon brings moisture.

As the aggregate result of these various meteorological patterns, the following types of climate may be distinguished in Asia: the tundra climate (associated with the cold, treeless plains of the Arctic lowlands of Asia); the cold, sharply continental climate of Eastern Siberia; the cold, moderately humid Western Siberian climate; the humid, subtropical Kolkhida climate; the desert climate

Types of climate



Average annual precipitation for Asia.

of the temperate zone; the Mediterranean subtropical climate of the western edge of West Asia; the subtropical desert climate; the mountain-steppe highland subtropical climate of West and Central Asia; the alpine desert climate; the climate of the Eastern Pamirs, Karakoram Mountains, and Tibetan Highlands; the climate of the tropical deserts; the temperate monsoon climate of the Soviet part of the Far East, and northern parts of Japan and East China; the subtropical monsoon climate of Southern Japan and of Southeastern China; the subequatorial monsoon climate of South Asia, eastern Java, and the Lesser Sunda Islands; and the equatorial climate of the Greater Sunda Islands.

Many climatic variants can be distinguished that are associated with such local topographical features as the degree of exposure of the slopes, the protective effect of the mountains, and altitudinal zonality, with temperatures dropping as the altitude increases. Low temperatures, however, are also found in low hollows where cold air stagnates or on coasts where air is chilled by cold ocean currents. The mountain climates, evidently, represent variants of those climates that are determined by latitude. All the various features of the types of climate mentioned exert a strong influence on other natural conditions, as well as on the landscape as a whole.

Urban climate. Distinctive variations of climatic characteristics result from the cultural and economic activities of human society. One example of this is provided by the microclimates associated with the cities and with large industrial complexes. The emission by the cities of quantities of dust and gases produces alterations of temperatures and changes in wind patterns. Such conditions are characteristic, for example, of Tokyo and the industrial region of northern Kyushu in Japan, of Calcutta and the industrial area of the northeastern part of peninsular India, and of the industrial regions of the Kuznetsk Basin in the Soviet Union.

DRAINAGE

Rivers. Asia is a land of great rivers. The Ob, the Irtysh, the Yenisey with the Angara, the Lena (with the waters of the Aldan and the Vilyuy), the Yana, the Indigirka, and the Kolyma rivers all flow into the Arctic Ocean. Among rivers draining into the Pacific Ocean are the Anadyr, the Amur (combined with the Sungari and the Ussuri), the Huang Ho, the Yangtze, the Hsi, the Song Hol, the Mekong, and the Chao Phraya. The Salween, the Irrawaddy, the Brahmaputra, the Ganges, the Godavari, the Krishna, and the Indus flow into the Indian Ocean, as also does the Shatt al-Arab, which is the confluence of the Tigris and Euphrates rivers. Only small mountain rivers flow from Asia into the Caspian, the Sea of Azov, the Black Sea, and the Mediterranean. The Amu Darya, the Syr Darya, the I-li, the Chu, the Tarim, the Gilmend, and the Tedzhen rivers empty into vast interior basins. Some of these rivers end in lakes, some end in dry deltas in the sands or salt marshes, and some flow into oases, where all the water is used to irrigate fields or else it evaporates.

Rivers of the Pacific

All the Siberian rivers freeze over in the winter, and some freeze to the bottom. In spring widespread flooding occurs. These rivers are important communication routes, being used by boats during the summer and as roads for sleighs in winter; they also teem with fish.

In the dry regions, where drainage is landlocked, the only large rivers are temporary ones fed by snow and glacier water in the mountains; they reach their peak water levels in summer. Rivers that are not fed by mountain runoff have little water; their levels vary sharply, and periodically or occasionally they dry up. The rivers of the monsoon climate regions reach their maximum volume in summer and are utilized for irrigating the rice fields. The Asian rivers in the vicinity of the Mediterranean that are not fed by mountain snows grow shallow in summer and sometimes even dry up. In the equatorial regions, however, the rivers are perennially full of water.

Lakes. The lakes of Asia are numerous, varying considerably in size and origin. The largest of them—the Caspian and Aral seas—are the remains of larger seas that existed here previously. Lakes Baikal, Issyk-Kul, and Khubsugul, the Dead Sea, and others lie in tectonic depressions. The basins of Lakes Van, Sevan, and Rezaïyeh (Rezaïe) are, furthermore, encircled by lava, and Lake Telets was gouged out by ancient glaciation. A number of lakes were formed as the result of landslides (Lake Sarez in the Pamirs); karst processes (the lakes of western Tavr, in Turkey); or the formation of lava dams (Tsin Bokhu in Northeast China, and several lakes in the Kuril Islands). In the volcanic regions of the eastern Asian islands, in the Philippines, and in the Malay Archipelago, lakes have formed in craters and calderas. The subArctic has a particularly large number of lakes; in addition to lakes formed as a result of permafrost and subsidence, there are also ancient glacial moraine lakes. Many lagunal lakes occur along low coastlines.

The Ganges River winds through the fertile plain east of Delhi, in northern India.
Harrison Forman

The lakes in the internal drainage basins—such as Koko Nor, Tuz, and others—are usually saline. Lake Balkhash has freshwater in the west and brackish water in the east. Lakes through which rivers flow are freshwater and regulate the flow of the rivers that issue from them or flow into them; examples of these are Lake Baikal, associated with the Angara River; Lake Khanka (the Sungacha and Ussuri rivers); Tung-t'ing Hu and P'o-yang Hu (the Yangtze River); and Tonle Sap (the Mekong). Large reservoirs have also been created by the construction of hydroelectric stations.

Subterranean water. In arid regions, subterranean water is often the only source of water supply. Large accumulations are known to exist in artesian basins and beneath the dipping plains at the foot of mountains; these are associated with the extensive oases of Middle Asia, Kashgaria, and many other regions.

SOILS

The soils of Asia are distinctly marked by the combined effects of climate, topography, hydrology, organic nature, and the economic activities of man. The horizontal zonality of the climate, the drainage conditions, the existing plant and animal life, and agriculture are each related to the considerable meridional extension of Asia, which is accompanied, of course, by a horizontal zonality of the soil cover, which is especially clearly defined in the plains of the continental sector.

M. Gifford—De Wys Inc.

The Arctic zone. In the Arctic, where glacial and Arctic deserts predominate, the processes of soil building are manifested only in rudimentary form. The soils here are saturated and are low in humus. The sub-Arctic north of Asia is occupied by a timberless zone of tundra vegetation. Beneath the tundras, specifically tundra-type soils are formed, which are characterized by poor drainage (associated with the proximity of permafrost) and only a short period in which the decomposition of organic substances is possible. This results in the accumulation of undecomposed organic residues in the form of particles of peat. The poor drainage creates an oxygen-free medium in which the bluish substance known as gley is formed. Thus, peaty-gley soils are most characteristic of the tundra. There are widespread occurrence of movement by mud glaciers; heaving of the ground because of frost; settling or caving in of the ground from thawing; and the formation of stone rings around central areas of debris in bouldery regions.

The forest tundra. Farther south stretches the transitional belt of the forest tundra, where tundra and sparse forest alternate with regularity. Here tundra soils alternate with the soils of the taiga (the cold, swampy forested region to the south of the tundra, characterized by very low temperatures). The soils below the frozen taiga are called cryogenic (*i.e.*, having very low temperatures). In the mountainous regions the peaty-gley soils are replaced by mountain tundra and weakly developed, often embryonic soils of detritus and stony fragments.

The forest zone. The forest zone occupies the largest part of the temperate zone. Characteristic of soil formation in the forest zone is the leaching process. The forest leaves and needles that fall, together with dead remains of the sparse grass cover, are subjected to decomposition by organic acids in the litter of the forest floor; the duration of the summer season and the amount of precipitation are sufficient for complete decomposition of the soluble soil components; the soil solutions transport them and leach them into deeper soil horizons (layers). The undecomposed quartz grains remain in the upper horizon, which is therefore infertile; this layer resembles light-gray ashes, which is the reason soils of this type are called podzols ("under ashes"). The various subzones of the forest zone are subjected to different degrees of leaching. A dense, rusty-brown horizon of wash-down (deposition in an underlying layer of soil) underlies the podzolic portion of the soil profile (vertical section of the soil); its colour is related to the accumulation of iron and aluminum oxides. This layer, called orstein, or iron pan, is impervious to water and contributes to the self-swamping of the taiga forests. East of the Yenisey River, where the forest zone for its entire breadth is in the grip of permafrost, soil drainage (and consequently the leaching process) is made more difficult; the transfer of substances is complicated by freezing and thawing, and therefore the typical podzols are replaced by specific cryogenic taiga soils. Marshes and bog-type soils are widely distributed over a considerable part of the taiga subzones.

The leaching process

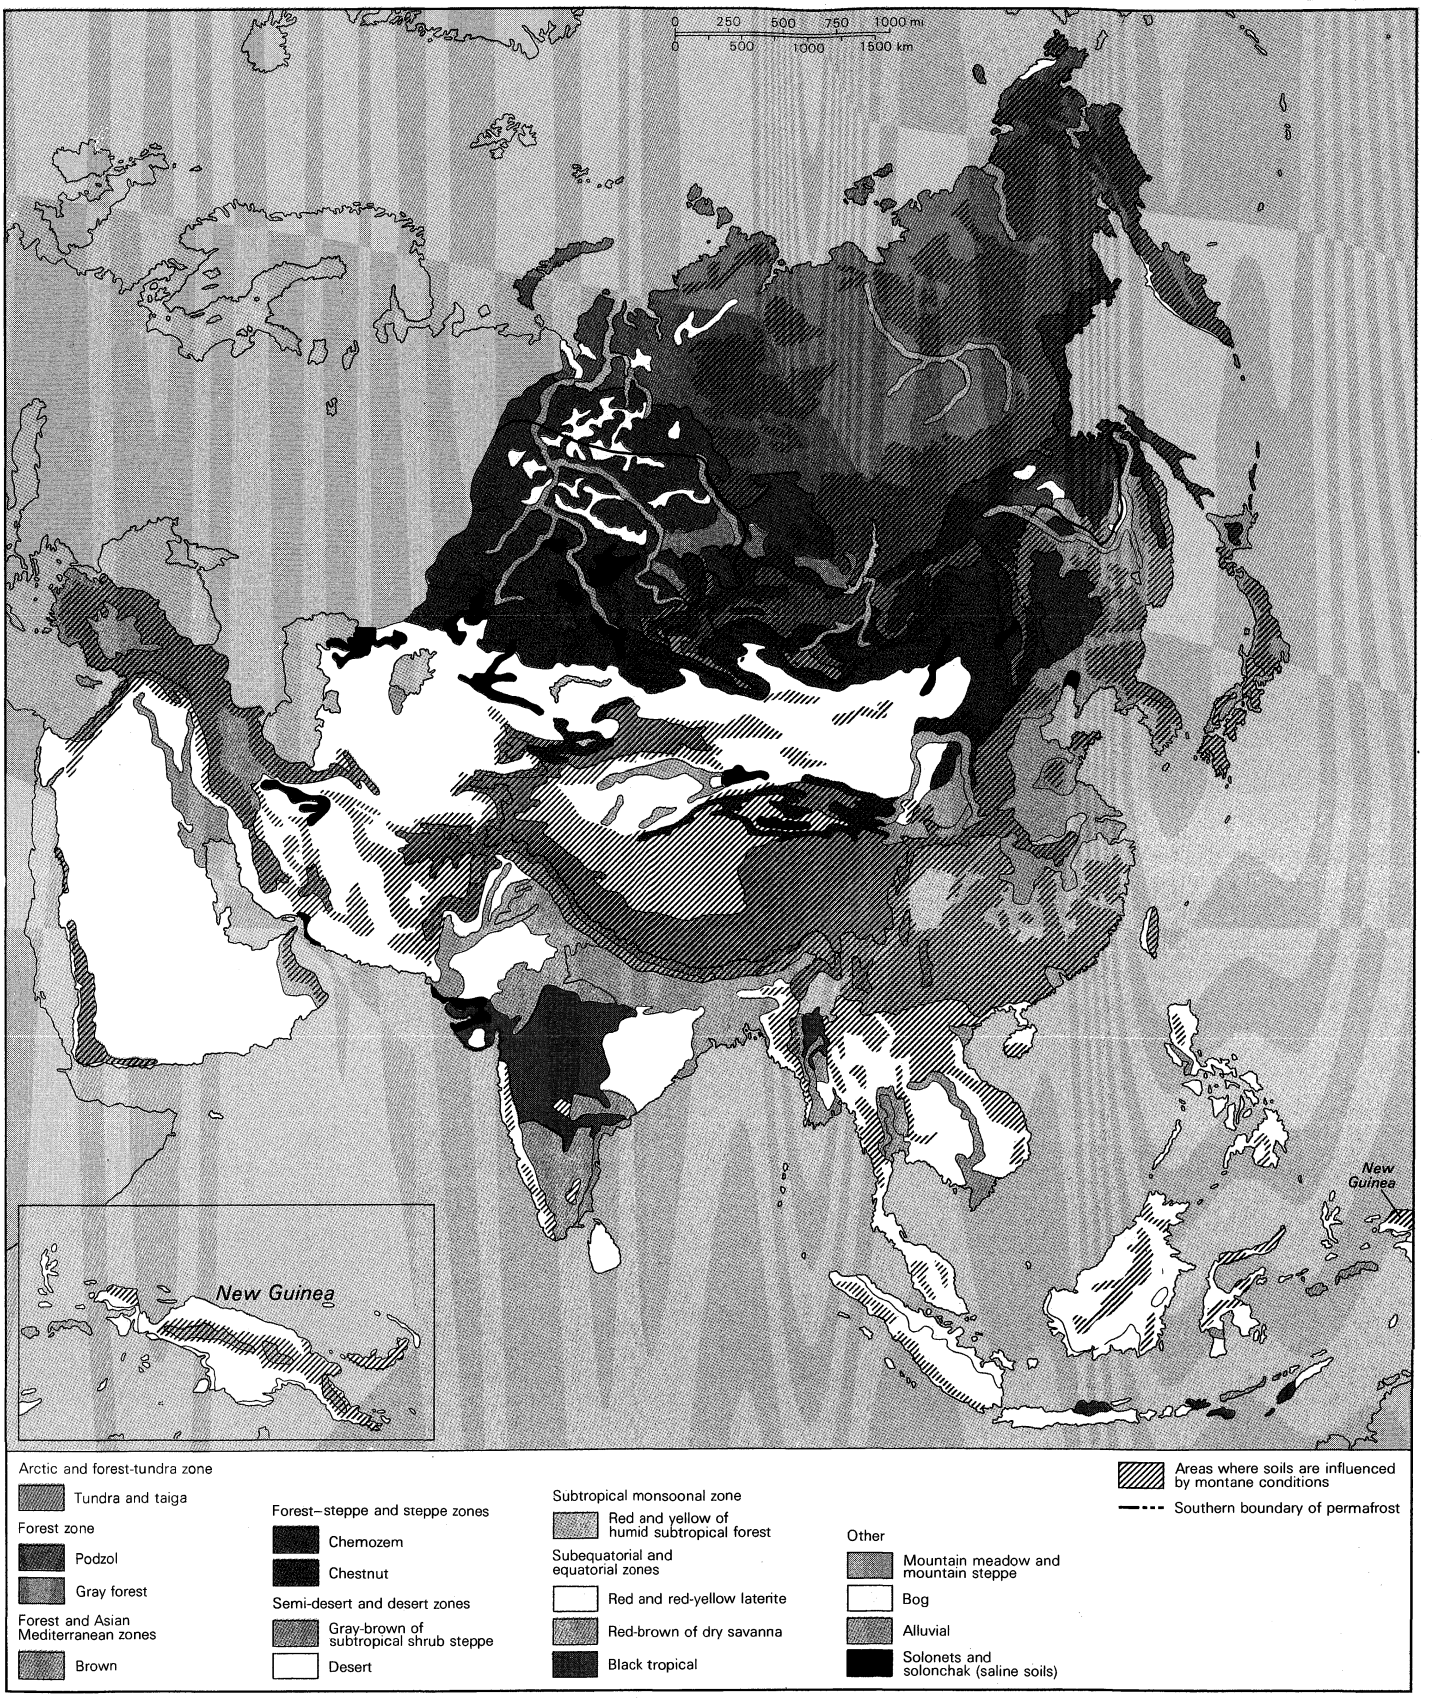
The deciduous forest subzones of Asia form two distinct areas. In Western Siberia there are small-leafed, primarily birch or aspen, forests on gray forest soils. They are more gray in colour than the podzols because of the greater amount of organic substances—such as tree leaves and a more abundant grass cover—feeding these soils. This explains their higher content of humus, as well as their greater fertility. The second section of the deciduous forest subzone has survived in the Far East, stretching from the Lesser Khingan Mountains in the north to the Japanese island of Honshu; in this subzone abundant warmth and moisture intensify chemical weathering, and iron oxides accumulate even in the surface soil horizons. In this manner brown forest soils, known as forest burozems, are formed.

The forest-steppe and steppe. Soil cover in the forest-steppe region is formed when the ratio of precipitation to evaporation is in equilibrium and as the leaching process of the wet season alternates with the upward flow of the soil solutions during the dry period. Under these conditions, with abundant organic material resulting from the dense vegetation, intensive accumulation of humus takes place in the soil, and dark-coloured soils are formed that are the most fertile in all of Asia; known as chernozems, they are the most fertile as well as the thickest of the forest-steppe and mixed grass subzones. Characteristic of the wooded-meadow plains of the Amur Basin (the "Amur prairies") are meadow soils that are dark, semi-boggy, and often composed of blue gley. In the drier steppes, where vegetation is sparse, the amount of humus is reduced and the content of unleached mineral salts is increased; transport of the dissolved salts to the surface by the upward flow of soil solutions is also intensified. Associated with this process is a bleaching and salinization of the soil. The drier steppes thus form a transitional zone from the shallow southern chernozems to the chestnut soils. Broad expanses of the forest-steppe and steppe are under cultivation and serve as rich granaries for the cultivation of grain crops. Severe wind erosion occurs during the hot, dry seasons. In many areas impoverishment of the soil has also developed as the result of surface washout and gully erosion, despite preventive efforts.

Soils rich in humus

Semidesert and desert. Through inner Kazakhstan and Mongolia stretches a zone of semidesert, and through Middle Asia, Dzungaria, Takla Makan, and Inner Mongolia a belt of temperate zone deserts. A belt of subtropical deserts extends through the Levant, the Iranian highlands, and the southern edge of Middle Asia. Beneath the semideserts, with their mosaic of desert and arid-steppe vegetation, light-chestnut and light-brown semidesert soils form; these are low in humus but contain an abundance of strongly alkaline soil. Beneath the deserts, where the supply of organic substances, as well as the humus content, is extremely low, gray-brown soils form in the temperate zone; gray desert soils (sierozems) form in the arid subtropics. Here there is a great deal of saline soil, and agriculture is possible only with the use of irrigation, which is feasible in the infrequent oases, where specific cultivated types of sierozems have formed.

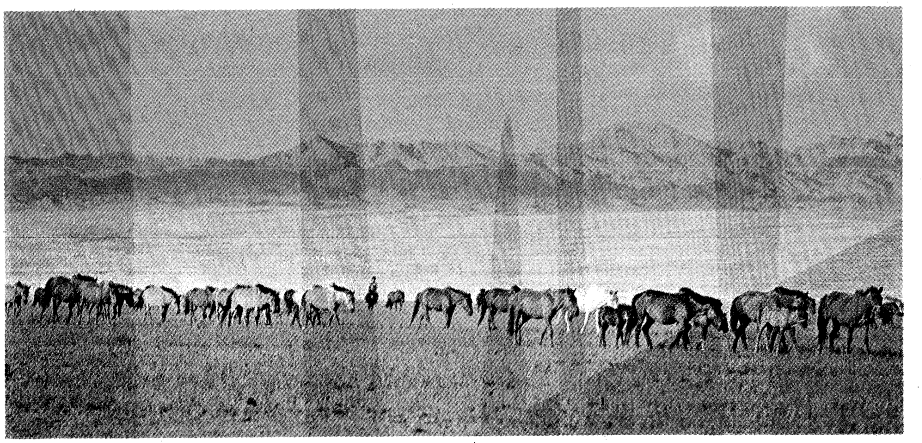
Only in western Asia is the tropical desert zone clearly defined. Here broad expanses are characterized by embryonic soils and desert crusts, as well as by blowing sands.



Soils of Asia.

The Asian Mediterranean. In the maritime areas of the Asiatic Mediterranean—Asia Minor and the Levant—xerophytic vegetation (vegetation structurally adapted to exist with very little water) of the Mediterranean scrub-woodland types, known as maquis (evergreen), shiblyak (an association of bushes and scrub characteristic of the Balkan Peninsula in Europe), and frigana (low-growing, prickly, and cushion-like bushes), is prevalent. The predominant soils under such vegetation are brown; they have accumulated iron as a result of the intense chemical weathering during the wet Mediterranean winter and of the upward flow of soil solutions dur-

Iron-bearing soils



Horses grazing on the steppe grass in the southern region of the Gobi. The Altai Mountains In the background form the southwestern boundary for the desert.
Paolo Koch—Rapho Guillumette

ing the dry summer. Frigana vegetation, characterized by thorn bushes, is widely represented in the West Asian semidesert highlands. Here soils have developed that are transitional between the brown soils and the sierozems.

The subtropical monsoonal regions. Typical of the monsoon subtropics are the evergreen forests of the southern portion of the Korean Peninsula, of southwestern Japan, and of southeastern China. Intensive chemical weathering during the simultaneously warm and wet summer monsoon season results—as it also does in the more southerly torrid zones—in the decomposition and carrying away from the soil of many minerals, the accumulation of residual iron and aluminum oxides, and the consequent predominance of red and yellow soils as well as of podzolized soils. Agriculture, with the irrigation of rice fields, is especially widespread on the alluvial soils of the plains, which have been cultivated continuously by farmers for thousands of years. Terracing of the slopes is a widely applied practice.

The subequatorial and equatorial regions. The subequatorial zones of Asia are covered by savannas (grassy parklands) and dry-tropical deciduous forests, primarily situated in the rain shadow on the leeward slopes, and by wet-tropical evergreen forests on the rainy windward slopes facing the sea. Intensive leaching followed by evaporation is characteristic of these soils. Under the wet tropical forests, red-yellow lateritic (leached and hardened iron-bearing) soils predominate; beneath the savannas and dry tropical forests there are red lateritic soils that change, with increasing aridity, to red-brown and desert brown soils. Beneath the dry savannas of peninsular India there are unique black soils called regurs that are thought to be developed from basalt country rock.

Charles Lenars—Atlas

Tropical vegetation surrounding fertile rice paddies on the island of Java, Indonesia. The active volcano Gunung Merapi rises above the clouds in the background.

In the equatorial zone (southern Malaysia and the Greater Sunda Islands), typical tropical rain forests have developed. In southwestern Sri Lanka and in Java they have been almost entirely replaced by an agricultural landscape in which mountain slopes and hills are covered with plantations of tea, coconut palms, and rubber trees. The soils are lateritic and are red-yellow or brick-red, with marginal degrees of laterization.

In the valleys of the subequatorial and equatorial zones, alluvial soils predominate; they have been developed by thousands of years of cultivation and irrigation of the rice fields. Artificial terracing of the slopes is practiced on a very large scale in the mountainous regions, both for purposes of irrigation and in order to prevent soil erosion.

The mountains. In the mountains, zones of different soil types are found at different altitudes. As a rule they are skeletal, underdeveloped soils, clearly reflecting the differences in rock structure and origin and in the degree of exposure of the slopes. The boundaries of the vertical zones become higher from north to south; the number of zones increases. Mountain soils also correspond to the different vegetation zones occurring at different altitudes. Under the mountain forests of the northern portion of the temperate zone are mountain-podzolic soils. Mountain variants of the gray forest soils and taiga-cryogenic soils have also developed; above the tree line they are replaced by mountain-tundra soils. Mountain chernozem and mountain chestnut soils develop beneath the mountain steppes in the southern part of the temperate zone; brown mountain-forest soils are found in the wetter regions; beneath the alpine and subalpine meadows the soils are of the mountain-meadow type. Mountain red podzolized, yellow earth, and other lateritic soils are predominant in the wet areas of the lower latitudes; in the dry areas mountain brown and gray-brown soils, as well as mountain gray soils, occur. The alpine steppe and desert soils of Central Asia have a number of distinctive characteristics.

Underdeveloped mountain soils

The correlation of the vertical soil zones and of the landscape zones varies with the whole spectrum of vertical zonality. A zone of forest, followed higher up by meadows, with snow cover at the highest altitudes, is characteristic of the western maritime regions. On lower slopes in the western Caucasus, for example, broadleafed mountain forests occur on brown mountain-forest soils; above these are coniferous forests on mountain podzolic soils, followed by stunted trees, followed in turn

by subalpine and alpine meadows on mountain-meadow soils, while near the highest ridges perennial snow and glaciers are found. Associations of desert, steppe, meadowland, and snow zones are widespread in the interior of Asia and sometimes include mountain-forest zones. Thus, characteristic of the Tien Shan, for example, is the predominance of mountain-desert and semidesert landscapes, which occur in association with gray-brown and brown mountain soils in the foothills of the ranges, while higher up are mountain steppes associated with mountain chestnut soils and mountain chernozems. Under parts of the mountain forest-steppe and the mountain forests, the soils are podzolized. Above the stunted forest zone in the maritime sector, mountain-meadow soils occur beneath the meadows, but here, too, a distinctive snowy type of landscape occurs in the vicinity of the ridges.

Typical of the mountains of Eastern Siberia are the taiga-tundra spectra that occur in vertical zones; thus, mountain taiga on taiga-cryogenic soils is followed by a zone of dwarfed trees, followed by mountain tundra, and then finally by bald peaks.

In eastern Asia, the subalpine and alpine meadow zones with mountain-meadow soils usually disappear; instead, mountain-forest landscape extends as far up as the vicinity of the crests and is succeeded only by a zone of stunted trees. The spectra of the alpine regions of South Asia (the Himalayas) are distinguished by the most complex variety of vegetation and soil types. (Y.K.Y.)

III. Vegetation and animal life

VEGETATION

In Asia an immense range of vegetation is found, resulting from the continent's wide diversity of latitude, altitude, and climate. Natural conditions, however, are not entirely responsible for the associations of trees, plants, and grasses of Asia; natural landscapes have been transformed by 80 centuries of farming.

The geographic pattern of vegetation. *North Asia.* The natural landscape has been least affected by man in sparsely populated North Asia. Vast plains, continentality, and the nearness of the Arctic Ocean explain the presence here of a zone of tundra—cold, treeless plains with permanently frozen subsoil—similar to that found in the western Soviet Union and in Canada. In more flourishing parts the tundra has a discontinuous covering of lichens, mosses, sedges, rushes, some grasses, cushions of bilberries, and dwarf trees of willow and birch; in the far north, lichens grow on favourable hillsides. Thanks to the greater number of hours of daylight during the summer solstice in June, when the Arctic Circle receives the same amount of light energy as the tropics, the tundra at this season is covered with bright flowers. Nevertheless, climate conditions are extreme; in Severnaya Zemlya, along the Arctic coast, thawing begins in May and frosts begin in August, although in some years frosts may occur at night throughout the short summer. The soil never thaws below a depth of two or three feet; consequently, hollows are badly drained and turn into peat bogs. Windy conditions speed up evaporation, and the frozen soil cannot absorb water to compensate for this, so that surface drought often allows wind erosion and the transport of sediments deposited by annual riverine floods.

The tundra

The tundra belt extends still farther south on higher ground. In the Arctic Urals tundra begins at about 3,000 feet, but at latitude 53° N it begins at 4,250 feet. Tundra extends over large areas of the Cherski, Verkkoyanski, and the Kamchatka mountains.

The taiga

The taiga zone—a belt of coniferous forest—begins south of the tundra, after a transitional zone of "wooded tundra" and forest galleries, found along streams between the tundra-covered watersheds. Taiga, although essentially coniferous, is mixed with hardy deciduous trees such as aspen and birch; there are sections of grass and shrub steppe in the drier zones. Larches account for 37 percent of the Siberian forest, which covers 2,700,000 square miles; pines cover 24 percent and spruce 4 percent. The geographic distribution of particular types of vegetation is determined chiefly by climate. Spruce, for example, unable to survive temperatures below −36° F (−38° C), is not found east of the Yenisey River. The taiga has a thin undergrowth of cranberries and bilberries, and there are numerous extensive peat bogs.

In Soviet Asia broadleaf deciduous forest does not extend eastward beyond the Yenisey River, where it gives way to the coniferous forests of Central Siberia, reappearing in Eastern Siberia near the Okhotsk Sea; here poplars, birches, and alders are numerous, as well as various conifers and larches. Forests around the Ussuri River include maples, ashes, walnut, elms, and lindens, in addition to species already mentioned. In the direction of China, as described below, the landscape becomes transitional.

South of the Siberian forest, the zone of prairie (continuous herbaceous cover) is not uninterrupted; forest frequently gives way to steppe (discontinuous cover).

Tibet, which is chiefly dry and cold, has a scattered vegetation of halophilic bushes (bushes flourishing in a salty environment) and Artemisia's tufts.

The Far East. In the Far East, the monsoon climate brings hot and rainy summers, giving rise to a great variety of temperate and tropical vegetation. China has the most varied vegetation of any country in the world, with about 15,000 species, excluding mushrooms and mosses. Far Eastern forests are fascinating to botanists because of the variety of their plant life; many trees have large, bright evergreen leaves, and there is a dense undergrowth with abundant creepers.

Japan has 68 percent of its area under forest, whereas China is almost entirely deforested, although sizable tracts remain untouched in the remote, rugged regions and many small areas have been reforested. The reason for this is that Japanese scenery was traditionally respected, and strict forestry regulations were severely enforced. The best examples of Far Eastern forest are found in Japan; for example, in the Kii Peninsula. Conifers are the principal species used for reforestation in Japan's policy of restoring its forests in order to meet the industrial need for wood.

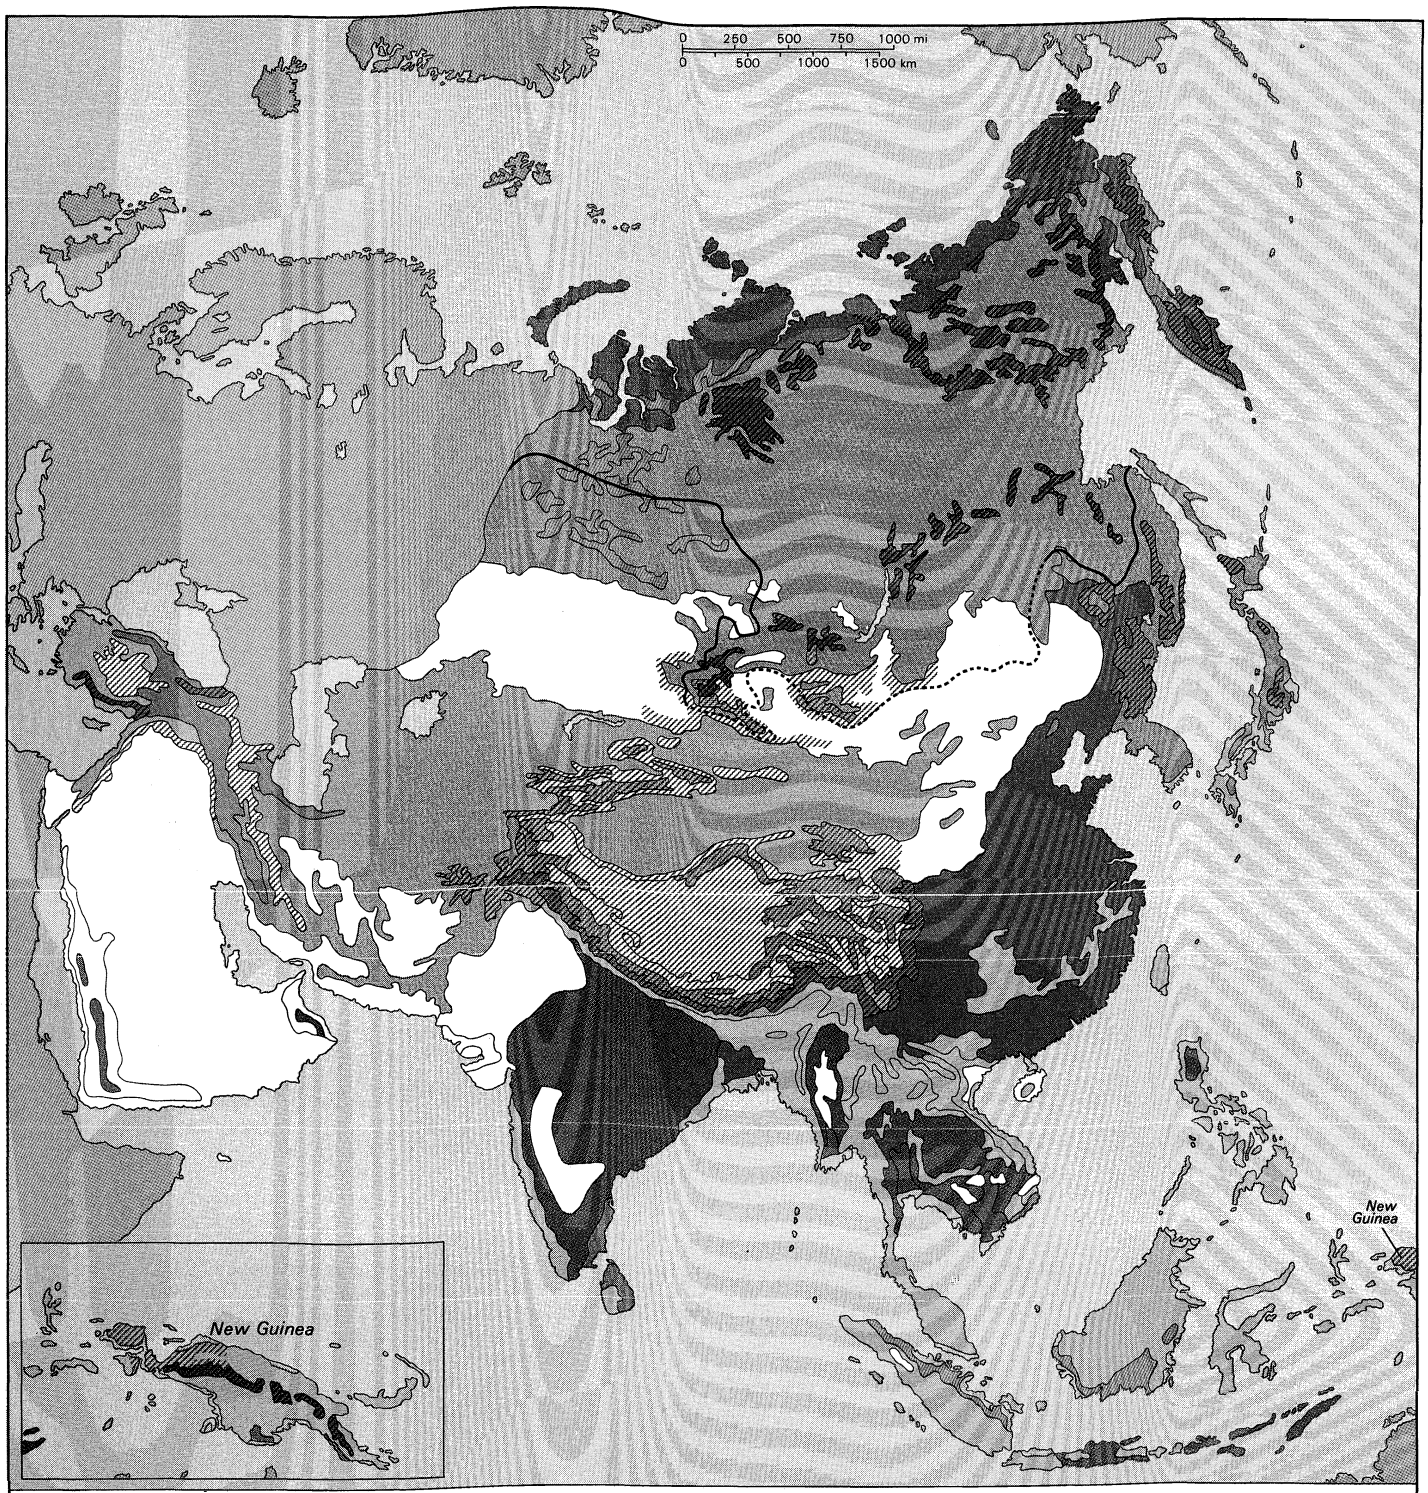
North of the Yangtze River, much of China was covered by primeval deciduous forest, most of which has been removed through farming. South of the Yangtze the "true" Chinese forest was prevalent before 1800. A wild growth of trees and shrubs survives, however, throughout the cultivated areas, and park-like tree growth and stands of bamboo are widespread. The "true" forest included 60 different genera of tall trees, including—among the temperate genera—oak and maple, linden, chestnut, hornbeam, and a species of hickory. Tropical genera included magnolia, the tulip tree, the camphor tree, the Spanish cedar, liquid ambar (a tropical tree of China), catalpa, and lianas (vines). A variety of conifers of both hemispheres was also to be found, and in the mountains of eastern Szechwan there grew a rare and ancient Chinese conifer, the metasequoia. Palm trees are found throughout South China and South Korea as well as in the southern half of Japan; many varieties of bamboo are also found in these regions.

The "true" Chinese forest

The Peking government is proceeding energetically with a program of reforestation. The new forests, however, consisting largely of pines, do not resemble the primeval Chinese forest.

South Asia. The wettest parts of peninsular India, such as the Western Ghāts, and of Southeast Asia have magnificent forests noteworthy for the variety of their plant life. The culturally controlled forests of Java and Sumatra alone include over 3,000 species of trees. The variety of tropical vegetation is accentuated by the diversity of influences, such as that of altitude upon climate. Temperate pines are found in Sumatra and in the Philippines, where eucalyptus also thrives; oaks occur in the mountains of New Guinea; and austral *Podocarpus* (evergreen trees with a pulpy fruit) in the eastern Himalayas. In the seasonal monsoonal climatic zone of central Indonesia, Thailand, Burma, and southern India, the teak forest thrives as an open park-like cover with little underbrush.

A notable feature of South Asian vegetation is the Dip-



Vegetation zones of Asia.

Taiga vegetation growing on the Siberian Lowland of south central Siberia.
Sovfoto

terocarpacea family (yielding aromatic oils and resins), which is here represented by more than 500 species. Mangrove thrives in muddy deltas along the South Asian coastline. In the southernmost areas, the bogs on the land-side edges of the mangrove swamps abound with the semi-aquatic nipa palm, the leaf fronds of which are widely used for thatching.

Hevea brasiliensis, the most successful rubber plant, is found in tropical Southeast Asia, where it was introduced from South America in the 1870s; it is particularly important in plantations in Malaysia and Indonesia.

Primeval evergreen rain forest remains in a few parts of South Asia. Secondary forest, which develops where temporary clearings have been made in the original forest, covers a much larger area. In drier tropical areas, secondary forest is deciduous; where the dry season is particularly long, park forest, with trees spaced at wide intervals, is found, as in the "sal" (East Indian hardwood) forests of India. Extensive fires in such areas have resulted in a herbaceous landscape, as in the cogonales (areas of coarse tall grasses, used for thatching) of the Philippines.

Mountain vegetation

In the higher mountains of Southeast Asia the cooler humid tropical climate gives rise to deciduous and coniferous temperate forest at altitudes of between about 4,250 feet and 10,000 feet. Above this level, low forests of plants, mostly shrubs of the heath family, are often found. Diverse types of trees grow in the mountain forests of the region. The Arakan Mountains of Burma, for example, are covered with a thick mantle of little bamboos. In the eastern Himalayas sal is intermingled with *Castanopsis* (a small genus of nut-bearing trees) and pines. Above these are found forests of shrubs and trees of the laurel family and, higher still, oaks and conifers; between about 10,000 feet and 13,000 feet, forests of firs occur. The central Himalayas present strikingly beautiful landscapes in the following upward succession: dry sal forest; pine forest; cedars, spruces, pines, and oaks; firs, birches, and tall rhododendrons; above 13,000 feet, bushes of rhododendrons, together with junipers; above 16,000 feet, perpetual snows.

West Asia. In western Asia naturally wild vegetation no longer occurs in clearly defined zones but is dispersed in small areas. The region is predominantly arid: desert-like depressions such as the Kyzylkum in the Kazakh and Uzbek regions of the Soviet Union and the Rubʿ al-Khali (Empty Quarter) of the Arabian Peninsula contrast with the moist, well-forested mountains that lie between them. Three climatic zones, however, characterize western Asia: a continental climate in the northern regions; a dry zone, except where northerly winds bring moisture to the mountains, to the south; and a Mediterranean climate along the western edges.

A few examples of the variety of vegetation associated with these climatic zones may be cited. In the valleys of the dead rivers of the Kara-Kum Desert grows a strange tree, the saxaul, which is oddly shaped, gnarled, and leafless; between the galleries of saxauls the desert is interspersed at very wide intervals with bushes and tufts of grass. A fringe of steppe covers the area between the Fertile Crescent (which sweeps in an arc from the Tigris–Euphrates Valley to the Mediterranean) and the north and west of the Syrian Desert. With more than 2,000 species of plants—more than in the whole of the Sahara—the borders of the latter desert are noteworthy for their floral variety. The moist northern slopes of the Pontic Mountains in northern Turkey are covered by magnificent forests of beeches and conifers, with an undergrowth of tall cherrylowels, hollies, and creepers. This type of forest is also found in Georgia and on the northern slopes of the Elburz Mountains in Iran. Along the Mediterranean border of Asia the vegetation is similar to that in other parts of the Mediterranean region: holm oak (an evergreen oak), Aleppo pine (characteristic of the city of Aleppo), cistus, mastic tree (which yields mastic, used as a chewing gum), and other species are found in landscapes of thick underbrush and open scrubland.

"Pontic" forest

Man and vegetation. *Vegetation in traditional civilization.* Asia's indigenous vegetation has provided many edible products, such as stone fruits, citrus fruits, bananas, mangoes, soybeans, and tea; building materials, such as wood, bamboo, and thatch; cotton and straw for clothing; bamboo, widely used in the making of utensils; and the bark of the paper mulberry, used for making bark cloth and paper. In addition, silkworms are fed upon mulberry leaves; lacquer is made from *Rhus vernicifera* (lacquer tree); and a multitude of other items are obtained from plants, including a styptic for stopping hemorrhage, an anti-asthmatic agent made from mahuang (a plant yielding ephedrine), and a fine fibre, extensively used in weaving, derived from ramie, a plant of the nettle family.

Similarly, the forested areas of Southeast Asia provide the sparse population with a wide variety of products: firewood; timber for construction; foodstuffs from a variety of trees, plants, and fungi, including sago, taro (a plant with an edible, starchy, tuberous rootstock), and mushroom; scented resins from sandalwood and eaglewood (an East Indian tree with soft resinous wood); and dyes from a variety of tubers. Probably the irrigated cultivation of taro and rice began in Southeast Asia.

Wheat is indigenous to the humid hill margins of western Asia; it still grows spontaneously in the hilly fringes of Asia Minor. Cherry, peach, and pistachio trees, as well as vines, were domesticated in the mountains of western Asia. The large acorn cups from the forests of *Quercus aegilops*—a species of oak, in western Asia Minor—are valued for the abundant tannin they contain.

Commercial forestry. China and the Indian subcontinent, with their enormous populations, are today poor in timber resources. The best resources of timber for building and for paper manufacture are in Siberia. Japan produces about 1,600,000,000 cubic feet of timber annually from its controlled forests. The tropical and equatorial forests of South Asia are difficult to exploit; because of the diversity of species found in these forests, commercially valuable trees are mixed with a majority that is of no economic value. Some deciduous forests, however, are of commercial interest since they are more homogeneous and consist of good quality trees. Included in this category are the forests of teak, sal, and ironwood. Such forests are important in the Burmese economy, timber being among the more important exports. The countries of Indochina, as well as Thailand, Malaysia, and the Philippines, are covered with extensive forests, but only a small fraction of their timber resources are commercially exploited. As in Burma, teak is the most valuable wood, but much of the remaining natural

Timber

timber is of low quality and not easily marketable. It is, nevertheless, increasingly being recognized that the forests of these countries form potentially valuable resources. Malaysia, in particular, is encouraging the development of forestry, and although overshadowed by rubber and tin, forestry is one of the most important Malaysian industries. In western Asia, Turkey has launched a program to increase production from its forests and thus reduce lumber imports. (P.Gu./Ed.)

ANIMAL LIFE

The Himalayas, stretching from east to west, form a barrier largely preventing the movement of animals southward or northward. Thus, Asia north of the Himalayas, with parts of western Asia and most of the Far East, belongs to the Palearctic (literally "ancient Arctic") zoogeographical region. Asia south of the Himalayas is called the Oriental, or Indian, Region. The boundary dividing these zones east and west of the Himalayas is not well marked, however, as there the mountain chains often have a north–south trend facilitating migration of animals between them.

The Palearctic Region. A distinction can be made between the animal life of the tundra in the north and that of the adjacent taiga farther south; the taiga in turn merges into the steppes, which have their own distinctive forms of animal life. The tundra subsoil is frozen throughout the year; hence, burrowing animals cannot live there, and, as the tundra is partly free from snow only during the short summer, conditions for life are poor. Most animals, including reindeer, Arctic hare, Arctic fox, and wolf, live here in summer only and migrate in autumn, but the lemmings (small rodents of circumpolar distribution) stay, feeding on the herbage buried beneath the snow. Hibernation is impossible, for the short summer does not allow the necessary accumulation of food reserve in the body.

During the summer, birds are numerous but they also desert the tundra in winter, except for such birds as the willow grouse and the ptarmigan, which live in tunnels in the snow, feeding on berries and leaves. Many species of waders, such as the gray plover, the sanderling, and several kinds of sandpipers, migrate to the tundra and breed there in the summers, feeding principally on the mosquitoes in the wet areas. Mosquitoes are also the staple food of passerine birds (true perching birds), such as the snow bunting and the Lapland bunting. Gyrfalcons (a subgenus of large Arctic falcons), rough-legged buzzards, and skuas (large, dark-coloured rapacious birds of northern seas) prey on these smaller birds and on lemmings. Several kinds of geese and ducks, Arctic tern, and three species of divers occupy the moist parts.

The taiga fauna

The taiga fauna is much richer than that of the tundra. The taiga is the haunt of brown bear, wolf, glutton (a kind of wolverine), otter, ermine, sable, lynx, elk, forest reindeer, hare, and several kinds of squirrel. Birds include various kinds of grouse and woodpecker, pine grosbeak, crossbill, siskin, redpoll, red-spotted bluethroat, rubythroat, redwing, fieldfare (a medium-sized thrush), nutcracker, Siberian jay, and many others. Wading birds include the terek sandpiper, which frequents marshes and pools.

The rivers of North Asia are inhabited by many common freshwater fishes and by several kinds of sturgeons, including the sterlet. Lake Baikal has a peculiar animal life, including many native species of sponges, worms, and crustaceans and a native species of seal.

The animal life of the steppes differs as much from that of the taiga as that of the tundra. It includes many burrowing rodents, such as jerboas, marmots, and piping hares, and, among larger animals, large numbers of antelope. The steppes were the original home of the northern cattle (*Bos taurus*), the horse, and probably the Bactrian (two-humped) camel; it is doubtful that any of these remain as truly wild animals. Typical birds are bustards, quails, sand grouse, and the red-legged hobby. Hoopoes and rollers are common locally, and bee eaters and the common sand martin nest along riverbanks. Waterfowl inhabit the reed beds of the great rivers, as do locusts, which migrate in almost unbelievably large numbers, devastating crops.

Wild sheep and goats live in the mountains and on the plateau to the north of the Himalayas. Tibet is the home of the wild yak, which is in great danger of extermination, although the domesticated yak survives.

The eastern part of the region, comprising Northeast and eastern China, has several peculiar kinds of deer. The Siberian tiger, originally native to southeastern Siberia, Manchuria, and Korea, has spread southward through eastern China into all of Southeast Asia and northern India. The giant panda inhabits the lower mountain margin of China bordering Tibet; the lesser panda is a Himalayan animal. Associated with the wastelands of the higher Himalayas is a legendary form of higher animal life—the yeti, or "Abominable Snowman." Some species of animals are peculiar to Japan, including a monkey related to the tailless Barbary ape of Gibraltar.

The large rivers of China have a rich fish life, among which *Psephurus gladius* (paddlefish) from the Yangtze and Huang Ho is of interest, as it is one of the two survivors of an otherwise extinct family, the other remnant of which is the paddlefish of North America. Another freshwater animal is the giant salamander, found in Japanese waters. Southeast Asia and southern China are the home of most of the carp family, from which the various forms of goldfish are derived.

The animal life of Asia Minor is much like that of other Mediterranean countries, but that of Israel, Syria, and Arabia also includes an African element, such as a species of coney and—in Lake Tiberias and the Dead Sea—fishes of the African genus *Tilapia* (the Nile perch). The donkey may have been domesticated in Southwest Asia, and the dromedary (one-humped) camel was originally native to the drier portions of Transcaspia.

The Oriental Region. The greater part of the Oriental Region is tropical. The northwestern part is dry and partly desert, so that animal life is chiefly confined to the forms related to those of the dry parts of the Ethiopian and Palearctic regions. Elsewhere, monkeys are common. Apes are found only in tropical rain forests—being represented by gibbons in Assam, Burma, the southeastern peninsula, and the Greater Sunda Islands—whereas the orangutan is restricted to Sumatra and Borneo, where it is in danger of extermination.

Large game animals

The Asiatic distribution of the African lion is now confined to the Gir Forest of the Kāthiāwār Peninsula in India, where it is protected, but a few specimens may still occur in southeast Iran. The tiger is now found from the Himalayas to Sumatra, Java, and Bali, but not in Borneo or Sri Lanka. Panthers range all over the region, except in Sumatra. Civets and mongooses are numerous. Among badgers, the ratel lives in the hilly districts of peninsular India and is even to be seen as far west as Israel. Jackals are plentiful in India; the striped hyena is confined to drier parts. Both are absent from the east.

Flying and ordinary squirrels are common in woodlands; the gaur (a large wild ox) is found in India and Burma, the banteng (the Malayan wild ox) in Burma and south to Borneo and Java, but not in Sumatra.

The most common antelope is the black buck, found in open brush-covered wild areas and cultivated plains all over India, except on the Malabār Coast; the nilgai, or blue bull, and the chousingha (a four-horned antelope of northern India) occupy hilly regions south of the Himalayas. Species of deer include musk deer in the pine zone of Kashmir, Nepal, and Sikkim; sambar deer practically over the whole region; and barking deer ranging northward into southernmost China.

Chevrotains (very small, hornless, deerlike ruminants) are typical, and wild pigs are also widely distributed. The Indian one-horned rhinoceros is protected and confined to Nepal and Assam; the Javanese rhinoceros is now restricted to Malaya, southern Sumatra, and western Java; the two-horned rhinoceros ranges from Burma to Sumatra. The Indian tapir lives in dense forests in southern Tenasserim, Malaya, and Sumatra. The Indian elephant is found throughout the region. Scaly anteaters, or pangolins—also found in Africa—are characteristic. The

tropical cattle (*Bos indicus*), known as Zeku or Brahman cattle and recognizable by its shoulder humps, was domesticated in India, as was the water buffalo, which is now distributed from Egypt to central China and the Philippines.

Birds

Game birds are important. The Indian peacock is to be seen throughout India, whereas another species of peacock (*Pavo muticus*) is restricted to Java. Numerous species of pheasants live in the forests of Burma, Thailand, Indochina, Malaya, Sumatra, and Borneo. Jungle fowl are unique to the Oriental Region and are the source of all domesticated chickens. Pigeons occur in great variety, but the number of species of parrots is small as compared with that of other tropical regions. Water and wood kingfishers are represented by many species. Hornbills show their greatest development in the Oriental Region. The Indian hoopoe is common in India but is only a migratory bird in the southeastern part of the region. Among cuckoos the brain-fever bird —an Asian hawk cuckoo that takes its name from the suggested effect of its repetitious cry—is well-known. Eagles, osprey, falcons, hawks, kites, and buzzards all occur; in the western part vultures are numerous and are found even in towns. The forests are inhabited by many species of woodpeckers. The barbets (loud-voiced tropical birds) are characteristic, the best known being the coppersmith bird. Bee eaters and rollers are common in India, but whereas the former can be found as far as the Malay Archipelago and beyond, rollers are absent in the southeast except in Celebes and beyond. The passerine birds are very numerous. The house crow, the Indian grackle, and the common mynah are familiar birds in India. Drongos (Old World passerines, usually black with hooked bills), flycatchers, bulbuls, tailorbirds, orioles, and many others are widely distributed, and broadbills are typical birds. Among the herons the white cattle egret is common all over the region, whereas spoonbills, cranes, and gulls are almost confined to the western part.

Of the crocodiles, the gavial (which has long slender jaws and a soft, inflatable nose tip) is restricted to the large rivers of northern India; a species of an allied genus is found in Sumatra and Borneo; and the mugger (the common freshwater crocodile) and the estuarine crocodile have a wider distribution. Freshwater turtles and land tortoises are well represented. Lizards are numerous, and flying lizards are also typical of the region. Chameleons are chiefly African, but one species is found in peninsular India and Sri Lanka. Snakes are numerous, among them the poisonous krait, cobra, and Russell's viper. Frogs and toads are abundant.

The freshwater fish life of the Oriental Region is rich. The carp and catfish families have many native genera and species. The labyrinth fishes (so named for a labyrinthine outpocketing of the gill chamber that permits them to take oxygen from air as well as water), to which the climbing perch and the gourami belong, are characteristic of the fish life of the region, as are spiny eels.

Insects, arachnoids (scorpions, spiders, and mites), mollusks, and other invertebrates inhabit this region in great numbers. Large bird-winged butterflies, allied to the well-represented swallowtails, are typical. Almost all known families of scorpions are present. Among land shells the absence of Helicidae (a family of land snails having lungs), common in the Palearctic Region, is noteworthy. Their place is taken by other forms, such as *Hemiplecta*, and by land mollusks having horny or shelly plates on their posterior dorsal surfaces. (L.F.deB.)

IV. Natural resources

MINERAL RESOURCES

Continental immensity and geological diversity explain the mineral wealth of Asia, which includes reserves of almost every important mineral. Abundant reserves of coal, oil, natural gas, and uranium, iron, bauxite, and other ores are either being exploited or await development; much wealth also remains to be surveyed. Difficulty of access, however, sometimes constitutes a barrier to exploitation.

Mineral fuels. *Coal.* Asia has enormous reserves of coal, amounting to almost 60 percent of the world total, but they are unevenly distributed. The largest reserves are found in China and in the Asian part of the Soviet Union; Taiwan, Japan, North Korea, South Korea, North Vietnam, Indonesia, and India have smaller but economically important reserves. Burma, Thailand, South Vietnam, Malaysia, and the Philippines have only insignificant amounts of poor coal. In Southwest Asia both Turkey and Afghanistan have small economic reserves.

Coalfields

Chinese coal reserves are estimated at over 1,100,000,000,000 tons and are chiefly high-grade coals. Every province has at least one coalfield, but the largest reserves are in Shansi and Shensi in the north. Szechwan, Shantung, and the Northeast (Fu-shun, in Liaoning Province) are old producing regions with good reserves, and a coal-mining region with large reserves has been developed in central Anhwei, north of the Yangtze River. Mines in Ningsia and Kansu supply northern industrial plants, but their reserves are not clearly known. The long-known reserves in western Hopeh are now being exploited.

In the Soviet Union the known coal reserves are tremendous, but the extent and quality of Siberian deposits are not yet fully known. The reserves exceed 1,700,000,000,000 tons, of which roughly 400,000,000,000 are relatively poor in grade; there are about 150 fields being worked, but as new economic developments occur the regional mining picture shifts somewhat according to quality of coal and cost of transport. The Moscow Basin brown coals and the higher quality coals of the Donets Basin of the eastern Ukraine continue to be important in the west, and the Vorkuta field west of the Urals and south of the Arctic coast will help supply the western zone. The Ural Mountains are not rich in coal, but there are scattered small fields of lower grade coals. The Karaganda fields in Kazakhstan in the southeast have huge deposits, but the coal has proven to be high in ash; and mining there is not now expanding since newer sources of better coals exist in Western Siberia. The new Ekibastuz field, north of the main Karaganda fields, is a new producer of high-quality coal.

Well over 90 percent of the known coal supplies of the Soviet Union lie in Siberia. The Kuznetsk Basin in Southwestern Siberia was the second ranking producer in the early 1970s, after the Donets Basin, and has large reserves. The Minusinsk Basin in the central region of Western Siberia, the Kansk region to the north along the Trans-Siberian Railway, the Cheremkhovo area west of Lake Baikal, and the Bureya Basin in the southeast are the major areas of production. Many smaller deposits are worked to supply local regions, such as the small and scattered fields north of Vladivostok, on Sakhalin Island, or in the hilly valleys of southeasternmost Turkistan.

Petroleum and natural gas. At least 60 percent of the world's known oil and gas reserves are also in Asia; the proportion may prove higher with the continued exploration of Siberia and the seas of southeastern Asia. Many of the island chains bordering eastern Asia have geological formations favouring petroleum accumulation, and oil fields are in production in Sumatra, Java, and Borneo. In the early 1970s, western Asia had the largest known oil reserves, located in Iran, Iraq, and the Persian Gulf area of Arabia. Other regions in Southwest Asia have only small amounts of oil, and known petroleum reserves on the Indian subcontinent are small.

Burma is the only oil-producing area on the mainland of Southeast Asia, although offshore waters may yield production after further exploration. The Philippines has not become a producing region, and the petroleum production of Japan is rather small. Korea appears to have slight prospect of production, but China is believed to have several modest oil-producing fields in Szechwan, Kansu, Sinkiang, and the Northeast. The Tsaidam Basin in northwestern Tsinghai Province may become a producing region, but information is scant. Some oil has been produced regularly from oil shales found in the Northeast, and natural gas is exploited in Szechwan.

In the Soviet Union, Siberia is expected to rival South-

The Soviet oil and gas fields

west Asia in the production of oil and natural gas. The old producing fields lay in the southern Volga Basin and in the margins of the Caucasus Mountains; the Volga Basin is the region in which many of the newer fields were in production in the early 1970s. The flanks of the Ural Mountains have a number of large oil fields and small gas fields. The northern Volga Basin, along the western flank of the Ural Mountains, contains the leading producing regions for oil. Major gas fields are located in the northeastern Ukraine south of Kharkov and in the Carpathian foothills of the western Ukraine. Uzen, on the Mangyshlak Peninsula on the eastern shore of the Caspian Sea, is a major gas-producing field that also yields oil. Another major field is that of Gazli in the Kyzyl Kum Desert south of the Aral Sea, and the rich gas field in the northern Ob River Basin at Berezovo indicates that the whole Ob Basin may yield natural gas. In the Lena River Basin, north of Yakutsk, there are large proven gas reserves.

Uranium. Reserves of uranium ore are found in Asia's ancient crystalline rocks. The Soviet Union, China, and India all have their own supplies of uranium. The Soviet Union, in particular, has rich ore fields in Kirgizia, between Osh and Tuya Muyun. Chinese uranium resources are probably located in northern Sinkiang and southern Hunan.

Metallic ores. *Iron.* All portions of Asia have deposits of iron ore, although not every political state has its own private supply. South Korea, South Vietnam, Taiwan, Sri Lanka, and several smaller countries in Southwest Asia appear to have only small iron-ore supplies. Japan has far less than needed by its large iron and steel industry and depends largely on imported supplies. The Philippines has much more ore than needed by its small industrial needs and is an ore exporter. Malaysia also exports considerable volume. Thailand, Burma, and Pakistan have fair amounts of relatively low-grade ores, and North Vietnam and Turkey have good ores in substantial volume. Indonesia and India both have large deposits of good iron ores that are reasonably distributed.

Although formerly regarded as deficient in iron ores, China contains huge quantities of varying grades of ores that are widely distributed and often located close to coal supplies. Regional centres of ore mining, smelting, and fabrication are located at An-shan, southern area of the Northeast; near Peking; in southern Anhwei, west of Shanghai; in central China, east of Wu-han; in southern Inner Mongolia, north of Pao-t'ou; in central western Kansu; and on Hainan Tao (Hainan Island), off the south coast. Large iron ore deposits also occur near Chungking in Szechwan. Iron ore in small local volumes is widely located in Kweichow and Yunnan in the Southwest.

The Soviet Union formerly depended largely on iron ore from the Krivoy Rog and Kerch basins of the southern Ukraine, but huge deposits of magnetic ore have been found near Belgorod. Iron ore has long been extracted from the Ural Mountains, and further deposits have been found at and near Magnitogorsk in the Southern Urals. There appears to be an unlimited supply of low-grade ore in the Kustanay Basin east of the Southern Urals in southwestern Siberia. A major iron ore range, at Kachkanar, west of the Northern Urals, contains low-grade ores. Large deposits of medium-grade iron ore have been found northwest of Lake Baikal, close to the Cherenkhovo coal deposits. Smaller deposits have been located in the Murmansk Peninsula and at several locations in Eastern Siberia.

Ferroalloy metals. Asian resources of nickel are not extensive. There is a notable Soviet nickel ore field at Norilsk (in Northern Siberia); Indonesia also possesses reserves. Those in Burma have not been fully surveyed.

Asian countries with reserves of chromium include Turkey, the Philippines, India, Iran, Pakistan, and Cyprus; reserves are also found in Soviet Asia. Chinese reserves are unknown.

Manganese is found in abundance. The Soviet Union has large reserves in Central Asia and in Siberia, and India also possesses large quantities. Chinese reserves are considerable, but those of Japan are limited.

China has exceptionally large reserves of tungsten, especially in southern China. Tungsten reserves of Soviet Asia are also important, as are those of molybdenum.

Copper, tin, and zinc

Nonferrous base metals. Asia is not richly endowed with copper ore. In Soviet Asia the principal fields are Almalyk (southeast of Tashkent), Dzhezkazgan (west of Karaganda), Kounrad (Lake Balkhash), and in the Kuznetsk Basin. Japan's widespread copper ore reserves are of medium importance, and the Philippines have limited reserves. The extent of China's reserves is not known, but deposits are located in Kansu, Hopei, Anhwei, and Hupeh. Turkey, Israel, India, and North and South Korea have small reserves.

Significant reserves of tin exist along a north–south axis running from southwestern China through the Malay Peninsula to Indonesia. Thailand, Burma, North Vietnam, Laos, and Yunnan Province in China also have deposits of tin. Soviet Asia has substantial reserves in Transbaikal and also in the Sikhote-Alin Range.

Soviet Asia's lead and zinc reserves—the largest in Asia—are located in the Kuznetsk Basin and in central and eastern Kazakhstan. China also has abundant reserves of zinc and lead ores, and North Korea has important lead resources.

Asia has enormous reserves of bauxite. In Soviet Asia, bauxite fields are located in Kazakhstan and in the Sayan Mountains. There are also large reserves in India, Indonesia, the Philippines, and Malaysia, as well as significant reserves in China.

Important quantities of mercury occur in south central China and in the Soviet regions of the Ukraine and Siberia. Magnesite is common in Asia. There are large reserves of antimony in central China; Turkey and Thailand also have substantial reserves.

Gold and silver

Precious metals. Many Asian countries have produced gold from alluvial stream deposits in past centuries, and some continue to do so. Small volumes of alluvial gold are produced in Burma, Cambodia, and Indonesia, and the headwaters of the Yangtze River in the Tibetan border region yield some gold. India formerly was a large producer of gold from lode mines, but the best ores appear to have been exhausted. Japan, North and South Korea, Taiwan, and the Philippines have significant gold-ore reserves, and Malaysia periodically produces gold from small lode mines.

The Soviet Union has produced gold from lode mines in the Central Ural Mountains for centuries, and in the 19th century there were several gold rushes to work alluvial stream deposits in Siberia on the Lena and Yenisey rivers. In the early 1970s Soviet gold production was rising, and lodes were worked in several Siberian locations, centring on the upper reaches of the Kolmya River and in the hill and mountain country surrounding Yakutsk. The lode opened up at Auezov in eastern Kazakhstan, south of Semipalatinsk, may allow the Soviet Union to threaten South Africa in rank as a gold producer.

Platinum is mined near Norilsk in the Central Siberian Plateau in Northern Siberia. Silver is not abundant.

Nonmetallic deposits. Reserves of asbestos are very localized; it is abundant in China, South Korea, and in Soviet Asia. Mica is abundant in Soviet Asia and is also found in important quantities in India. Asia has abundant reserves of rock salt; the hills and "glaciers" of salt in southern Iran are unexploitable, however, under present conditions. Reserves of sulfur and gypsum are abundant in Central and West Asia. Japan has large reserves of sulfur. In North Vietnam phosphates are obtainable from sedimentary fields and from apatite. The Soviet Union has large deposits of phosphates in the Mangyshlak Peninsula on the eastern shore of the Caspian Sea and other scattered deposits of lesser value. Diamonds are insignificant in India but are produced in east central Siberia.

WATER RESOURCES

Asia's water resources constitute a vast potential, both for generating hydroelectricity and for irrigation. In the arid parts of the continent, water is primarily useful for irrigation.

Siberian hydroelectric power

Siberian rivers have an excellent hydroelectric potential, for when dammed they provide low falls with an enormous volume of flow. Extreme cold and low winter water levels, however, hinder their exploitation. Thanks to abundant precipitation and great differences in water level, the Soviet Far East has an immense potential for hydroelectricity, although the remoteness of Eastern Siberia discourages industrialization.

Japan, a country of high man-made waterfalls but relatively small volumes of water flow, has already harnessed almost all its rivers that have a hydroelectric potential; this potential, however, is increased by heavy rains, particularly in summer.

The waterpower potential of northern China is extremely limited because the flow of the Huang Ho and other northern rivers is erratic, and all carry heavy volumes of silt. The hydroelectric potential of China south of the Tsinling Mountains, however, is great. The Yangtze River has a considerable waterpower potential, particularly near I-ch'ang, although this site would be expensive to develop.

The hydroelectric potential in the Indian subcontinent is subject to regional variations. The Western Ghāts, which slope down abruptly to the western maritime plains, permit high waterfalls; unfortunately, the rivulets that rise on the summit have an insignificant volume of winter flow. Rivers of the eastern slope of the Deccan, such as the Mahānadi and the Godāvari, lend themselves to the construction of dams with low falls and great volumes of flow, as also do the Himalayan rivers entering the Ganges Plain. The Himalayan ranges offer rich possibilities for the utilization of high waterfalls for generating hydroelectricity, but in winter their waters are very low, and most of the sites would be expensive to develop.

BIOLOGICAL RESOURCES

Widely varying climatic conditions, particularly in the distribution of rainfall, have produced terrains in Asia ranging from tundra and desert to forest and alluvial plain, each supporting its appropriate plant cover, on which, in turn, typical animals and birds subsist. The Arctic north of the continent and large areas of the central mountain massif—known as "the roof of the world"—are practically uninhabitable. In addition, even where there is water—and nowhere is water conservation pursued more carefully than in Asia—there are still many areas of undrained swamp. Much else is desert. By far the greater part of Asia remains uncultivated. Prime resources are the extraordinarily intensive agriculture made possible by irrigation of the alluvial soils of the great river deltas and courses; the forests, with commercially valuable species of trees; the flocks of sheep and goats supported by Asia's semi-arid deserts and grasslands; and the produce of the intensively fished surrounding seas of South and East Asia.

Timber resources. Much of Northern Siberia, south of the Arctic Circle, is covered by coniferous and mixed forest, which is commercially exploitable. The great deciduous forests of northeast India, Burma, Thailand, and Malaysia contain teak and other important hardwoods, as well as bamboo. Mangrove forests line the waters of the Ganges and Irrawaddy deltas and many small stretches of coast along the Malay Peninsula, Indonesia, and the Philippines. But in the Indian subcontinent lowland, forest has yielded place to cultivated land, as a result of population expansion; agriculture has similarly reduced the natural forest areas of China to insignificance, except in northern Manchuria. Japan, on the other hand, is relatively heavily forested in relation to its area and population, although much of the present cover is planted forest. More than half of the Philippines still carries heavy forest, but good commercial forests cover only one-third of the country. These forests produce valuable hardwoods and the soft "Philippine mahogany."

Resources for agriculture and animal husbandry. *Crops.* In Soviet Asia, the black-earth belt across Southern Siberia is cultivated with grain crops, of which wheat is the most important, as also are areas of the Soviet Central Asian republics. Grain crops, chiefly wheat, are cultivated in North China—where soybeans are also grown—and in Japan. Intensive use of water resources from wells, as well as from irrigated rivers, has enabled grain crops to be raised in Iraq, Iran, Pakistan, and northern India. The great staple of South Asia is rice. It is the chief food crop of Japan, South China, Taiwan, Southeast Asia, the Indonesian islands, the Philippines, Burma, Sri Lanka, and parts of India and Pakistan, and is found in Iran, southwestern Asia, and elsewhere.

Of plantation crops, rubber, from a Brazilian plant imported in the 19th century, is cultivated in Malaysia and Indonesia and also in India and Sri Lanka. Tea is grown on commercial plantations in the uplands of northern India and Sri Lanka for export and in China and Soviet Asia on small holdings for domestic consumption. Sugarcane is harvested in Java, the Philippines, India, and Central Asia; and tobacco is grown widely, notably in Turkey, Soviet Asia, China, and Indonesia. Citrus fruit is produced in the Mediterranean lands, in the Soviet Central Asian republics, and in China and Japan. Date palms are cultivated, particularly in Arabia. Licorice is grown in Turkey. Asia is also a producer of opium from the poppy.

Livestock. The uncultivated steppe lands and deserts of Central Asia and Mongolia support flocks of sheep and goats. Semi-nomadic pastoralism is the rule there, as it is in parts of Afghanistan, Pakistan, Iran, and Arabia. In Central Asia, the horse and the yak are the riding animal and the beast of burden, respectively; in Arabia, the camel is both. Cattle are raised in agricultural areas. Hides, wool, and other animal products are important

economically. Reindeer herds are kept in the northern tundra of Siberia, where they feed on mosses and shrubs. In Siberia, valuable furbearing animals have long been hunted. In India, Burma, and Thailand elephants still work as draft animals in the lumbering industry; particularly in Southeast Asia, the water buffalo is an important draft animal as well as a milk and butter producer. Angora goats are herded in Anatolian Turkey to provide the silky mohair for which they are noted. Silkworms are reared for silk in China, Japan, India, and Soviet Central Asia.

Game birds. North of the Himalayas, such game birds as ptarmigan, grouse, plover, and various kinds of waterfowl are found. South of the Himalayas, pigeons, pheasants, and other game birds are taken. Various kinds of hawk and falcon, trained to hunt, have their habitat in Arabia and other parts of Asia.

Seafood. In addition to fish and other sea creatures, various kinds of crab and shrimp are intensively fished off the coasts of China, Japan, and Southeast Asia. The sturgeon, prized for caviar, is fished commercially, particularly in the Caspian Sea and the rivers of Siberia.

(P.Gu.)

V. Human resources

A discussion of Asia and its peoples cannot entirely exclude other parts of the Old World when the origins of man, his ethnic divergence, and his migrational wanderings, or the evolution and historic development of his linguistic and culture systems are considered. The relatively modern division of the largest of the continents into Europe and Asia derives from arbitrary decisions made by peoples living in the western part of the peninsula of Europe; this division has only minor significance in relation to the historic patterns of human occupation of the continent. The ethnic and linguistic diversity of Asia is greater than that of any other continent, because it represents ethnic types and linguistic systems that have evolved in separated regional homelands, as well as repeated patterns of modification and intermixture, resulting from both peaceful and militant migrations. Ethnically and linguistically, some territories have become highly diversified mosaics in which there are mixed and overlapping elements.

EVOLUTION OF THE ETHNIC PATTERN

The three major racial stocks

Original racial stocks. The peoples of Asia include all the three major racial stocks of *Homo sapiens*—Congoid (Negroid), Caucasoid, and Mongoloid. The view is here taken that Congoid racial stocks derived from tropical origins in the zone extending from Africa eastward through the Indonesian Archipelago. It would, however, appear that to the east of Africa their original numbers were insufficient to ensure that they become the predominant element among the populations of South and Southeast Asia. The contrary belief that Congoid groups east of Africa originated in Africa leads to the conclusion that the migrating Congoids scattered out very thinly to the eastward and were able to contribute only to the skin pigmentation of South India and part of Southeast Asia. Whatever their origin, Congoid racial stocks at no time seem to have penetrated deeply into the Asian mainland. At the present time they constitute an element in ethnic stocks only in the southern peninsular fringes of Asia. The view here taken is that the Caucasoid racial stocks derive from a western Eurasian racial hearth, or region of origin, that also includes North Africa, and that Mongoloid racial stocks derive from an eastern Eurasian racial hearth. A very simplified view of the history of man in Eurasia, then, is that the western zone of the continent came to be populated primarily by the Caucasoid, or white, ethnic groups; that the eastern zone was populated primarily by the Mongoloid, or yellow, ethnic groups; and that the southern fringes of the continent were lightly occupied in early time by the Congoid, or black, ethnic groups. This pattern was apparently derived from the evolutionary beginnings of *Homo sapiens* possibly about 40,000 years ago, out of predecessor racial stocks, since the basic differentiation of the human species predates both modern man and the last glacial era. In considering modern man in Asia we cannot speak of distinct races in any definite way, as repeated migrational movements since the last glacial era have resulted in such intermixed racial stocks that the modern Asian cannot be racially defined. While it is possible to give a general description of an Indian, a Chinese, or a European, this can be done only in terms that connote ultimate regional origin in the broadest sense. In discussing Asian ethnology, therefore, we cannot refer to races but only to ethnic groups that speak particular languages and that have particular cultural characteristics. Thus, a Hunan Chinese from central China may be compared to a Czech from central Europe, or a Japanese from the southern island of Kyushu may be compared to an Iranian from southern Iran. All four belong to the single species but show marked differences in physique, language, and culture. It is, nevertheless, convenient to stereotype Chinese, Japanese, Czechs, and Iranians as members of "geographic races," meaning members of normally separated breeding populations.

Prehistoric migrations

Ancient migratory movements. The two primary prehistoric centres from which migrations over the continent took place were Southwest Asia and a region comprising the Mongolian plateaus and North China.

From prehistoric to historic times, possibly beginning as early as 30,000 years ago, movements from Southwest Asia continued toward Europe and into Central Asia; significant movements also took place into India. There were probably small divergent migrational movements in other directions that became swallowed up in later patterns of mixing. The Greeks were one of the late groups moving westward, about 2100 to 1900 BC, as were the Aryans who moved east to invade India from 1600 to 1500 BC. Mongoloid migrational movements have always been primarily toward Southeast Asia.

Important Mongoloid components, however, also moved westward through Central Asia toward the European peninsula. Such movements must have begun as early as 10,000 years ago, but they continued into the Christian Era as Mongols pushed Turkic peoples westward, setting off additional displacements of such peoples as the Finns and the Magyars. These westward Mongoloid movements also produced, over a period of time, much mixing of early Caucasoid and Mongoloid stocks in Central and West Asia. Northern Eurasia continued to be inhabited chiefly by thinly distributed residual elements of very early eastern Asian stocks, although some fairly late northward movements of Turkic peoples did take place.

There have been many small-stream movements away from the main trends, and these have often complicated the ethnic picture of any one region. At least one prehistoric Caucasoid movement penetrated East Asia and today is represented by the historic aboriginal population of Japan known as the Ainu. A countermovement out of India by a nomadic ethnic stock about AD 1000 contributed the Gypsy strain now so widespread in Europe.

Prehistoric countermovements along the China coast carried early Mongoloid migrants of Southeast Asia northward again into southern Korea and Japan, to leaven the later Mongoloid and Ainu stocks, from all three of which modern Japanese are derived. Similar northward drifts of early Mongoloid Indonesians account for a significant share of the ethnic ancestry of the population of the Philippines. Within the broad zone of Central Asia, prehistoric and historic movements have often retraced older migratory routes, creating overlapping and fragmented distributions of stocks that have yielded the many ethnic groups found there today. Secondary and tertiary intermixing of many of these regionally derived ethnic groupings has resulted in the emergence of regionally and physically distinct ethnic groups. Thus, the Uzbeks may originally have derived from a Mongoloid stock; some of them migrated westward to near the Volga River at an early date, then moved southward to become intermixed with Caucasoid-derived stocks. Uzbeks are now widely distributed in Central Asia and show considerable physical and linguistic variation.

Modern movements of peoples. Within historic time the aggressive expansion of particular ethnic groups has

The mixture of ethnic groups

either driven weaker groups away from their territory or has resulted in the newcomers' assuming control of the territory and reducing the older inhabitants to the status of ethnic minorities. Some of these weaker ethnic stocks eventually became so diluted by intermixture as virtually to lose their identity. In some instances a new and variant ethnic stock with a different dialect resulted from the mixing. Some areas are now given over to distinct enclaves occupied by several diverse ethnic stocks, each following its own way of life. Thus, in Southeast Asia, from the riverine and coastal lowlands to the higher mountain uplands, different ethnic stocks have been migrating southward to become resident in separate altitudinal layers, one above the other. Some of this migrational movement in Southeast Asia is as late as the 19th century, but it has been going on for thousands of years. Within what are now India and Pakistan the general trend, for many centuries, has been eastward and southward, producing very discontinuous patterns. Discontinuity also characterizes the ethnic patterns in Central and Southwest Asia.

Militant campaigns of Arabs spread Islām and Arab political structures out of Arabia westward into Africa and Spain and eastward through the Levant into Asia Minor, Transcaspia, and India. Beginning in the 7th century AD and lasting until the 16th century, these efforts spread Arab ethnic elements widely in Southwest Asia and northern Africa.

Within recent times, movements of Caucasoid European Russians eastward along the Central Asian routes of exploration, and the penetration of the oceanic fringes of South and East Asia by Caucasoid western Europeans, have carried Caucasoids to all parts of the Eurasian continent. This has resulted in an interbreeding that has produced many local and variant mixtures. Since the 17th century, intermarriage between Europeans and indigenous Asians has produced many mixtures, including the Anglo-Indians of India and the Burghers of Sri Lanka. Intermarriage between Chinese men and local women has produced many hybrid strains in Indonesia, Malaysia, Thailand, and the Philippines. The introduction of American white and black soldiers to East and Southeast Asia, during and after World War II, has further complicated the ethnic mosaic in China, Korea, Japan, Vietnam, and the Philippines. Such modern racial mixings are often viewed apart from the historic patterns of migration and racial mixing, but essentially they form a part of them.

POPULATION DISTRIBUTION AND REGIONAL ECOLOGY

Life-styles in the 18th century

The background. Around 1750 the distribution of ethnic groups was relatively easy to describe. The whole of northern Eurasia was rather lightly populated by diverse ethnic groups of Paleo-Asiatic, Tungusic, and Turkic peoples who engaged in hunting, collecting, fishing, or herding; some groups, such as the Samoyed, Yakut, and Chukchi, had somewhat distinctive single economies or had economies that were seasonally mixed. Central Asia, Tibet, and Mongolia formed a mixed zone dominated by nomadic pastoralism, but the lower plateaus and lowlands were sprinkled with agricultural oases in which towns and villages were occupied by sedentary crop growers. Population was relatively light; mountain regions were occupied only in summer, but there were locally dense populations centred on such large oases as Tashkent, Samarkand, Kashgar, and Urumchi, with smaller groupings around lesser sources of water. The Buriat Mongols and the Kirgiz were pastoral, whereas the Tadzhiks, Uighurs, and Uzbeks were sedentary oasis dwellers. Southwest Asia was then inhabited by Iranian, Arab, and Turkish peoples, with a scattering of minority ethnic stocks, practicing either traditional pastoralism or the agricultural economy of the oasis. Population was concentrated around cultivable areas, water resources, or grass pastures.

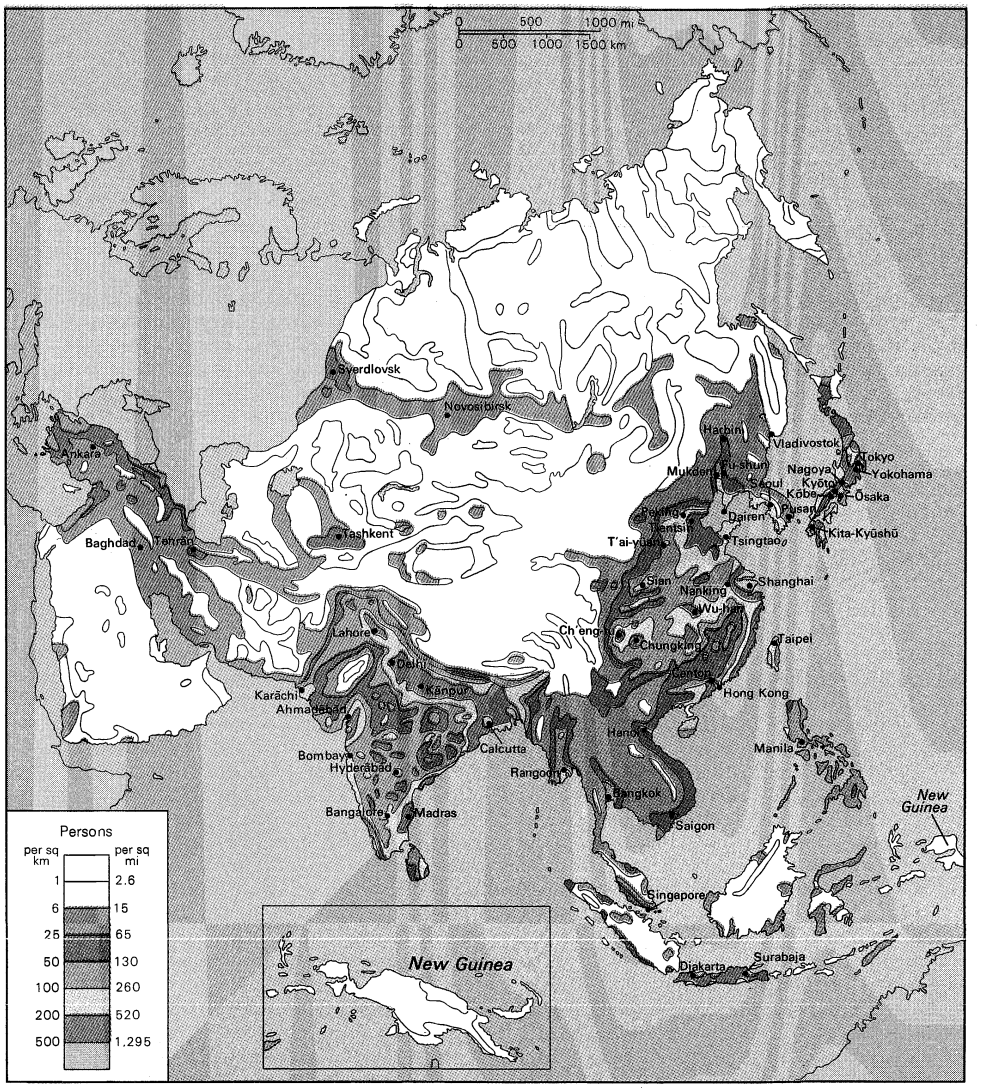
South and East Asia showed a more complex dual set of patterns. The largest components consisted of the highly civilized lowland populations, long settled on their land and engaged in sedentary agriculture and handicraft manufacturing. Market towns and cities were scattered over the countryside, and many small port towns dotted the seacoasts. Population density was heaviest in the best agricultural lowlands, which had also been occupied the longest, such as the North China Plain, southern Japan, coastal Vietnam, and the Ganges Valley.

Lesser components included the many diverse ethnic groups scattered in wet deltaic lowlands such as those of the Ganges, Irrawaddy, Chao Phraya, and Mekong rivers; the central plain of Luzon Island in the Philippines; and the north coast of Sumatra. Groups were also scattered throughout most of the hill and lower mountain country. Their living systems varied from simple hunting and collecting economies to more complex systems in which, apart from shifting cultivation (the shifting of cultivation to new land after a crop has been raised), hunting and collecting are also practiced. Generally these lesser areas had small populations scattered in hamlets or village settlements sustained by subsistence economies; only a little handicraft manufacturing took place, and trade was confined to minor products. The Nāga of northeast India, the upland Karen of Burma, and the Miao of Laos exemplified this life-style. Toward the end of the 18th century, European colonial efforts were beginning to shape the production systems of eastern Eurasia to conform to patterns of integrated world trade. The supplying of Europe with raw materials, which was to characterize the early 20th century, was also begun at this time.

The pattern of ethnic distribution. By the early 1970s, great changes had taken place in both the ethnic patterns and the associated life-styles in Asia. The divisions that prevailed in the 18th century were dissolving as the Soviet Union and China extended their economic and political control over Siberia and Central Asia, as the former colonial lands of South Asia established political independence, and as some of the component territories of the old Ottoman Empire were reshaped into the modern nations of Southwest Asia. Many of the hundreds of small ethnic groups were being absorbed into the populations of nation-states, many old languages were declining, and many formerly distinctive living systems were remaining in existence only as remnants or artificially preserved societies. The expansion of dominant ethnic groups was steadily restricting the territory available for older, simpler societies; and aspects of modern economic development were replacing the earlier systems. It is possible, still, to identify the region in which the Yukaghir formerly lived as a separate culture group in Eastern Siberia, but—for the few hundred Yukaghir who remain—political absorption, modernizing acculturation, and internal social decay have made the classic description of the group largely a historic one. Many former horse-riding, tent-dwelling, sheep-herding Kara Kirgiz today ride tractors on Soviet state grain farms, live in permanent villages, and speak Russian in public. Some men of the Chotanāgpur hill region of eastern India, who formerly engaged in hunting and practiced shifting cultivation, today work in the steel mills of Jamshedpur. The remnant Ainu of northern Japan today are gathered into "cultural villages" where their continued woodcarving and bear dances attract a flow of tourists from southern Japan.

Social changes of the 20th century

Contemporary developments. Population densities have everywhere increased, and planned programs of modernized agriculture, mineral exploitation, and industrialization are bringing cultural change. Some of the small ethnic groups are dying out, but larger groups have often accepted change and are again increasing in numbers. In South and East Asia, increasing lowland populations are pressing hard upon the available land as population densities exceed 2,000 persons per square mile. In Central Asia, both Chinese and Russian settlement programs are moving peoples from heavily populated regions into frontier zones, in order to develop both agricultural and industrial resources. In Southern Siberia the Soviet settlement program has spread a thick wedge of European Russians and assorted ethnic minorities eastward to the Pacific and northward along every river valley to the Arctic Ocean. As a result, the Paleosiberian ethnic remnants are being submerged and absorbed. Old trading posts, oasis towns, and the few old cities of South-



Population density of Asia.

ern Siberia and Soviet Central Asia are being developed into modern industrial centres; these are linked to modern transport systems by which raw materials and manufactured products flow back to the European regions. Most new cities are populated largely by European Russians, with the former Asian ethnic stocks remaining chiefly in the rural areas. The modernization of Southwestern Asia, through the renascence of Turkey and the impact of petroleum exploitation on the Arabian Peninsula, has altered many of the old patterns of ethnic groupings in these areas. A further alteration of the historic pattern came in 1948 with the creation of the State of Israel, to which over 1,000,000 Jews from Europe, North America, and the Middle East had migrated by the early 1970s.

Urbanism

Urbanism is becoming very marked in some parts of Asia, thus heightening regional contrasts in population densities. Japan, with about 70 percent of the population living in urban areas, is the most highly urbanized country in eastern Asia. Israel, in western Asia, is more than 80 percent urban. Elsewhere, the urban population varies from 20 to 35 percent of the total, although this percentage is rising as industrialization proceeds. Some cities are becoming among the largest in the world, and many of the newer cities resemble those of the West in terms of population, buildings, facilities, and congestion.

Ecological factors. Agriculture remains the mainstay of the Asian population, and more than 70 percent of Chinese, Indonesians, and Indians are engaged in agriculture and animal husbandry. Although marginal lands in many parts of southern and eastern Asia have been brought under cultivation, and many former pastoral ranges in Southwest and Central Asia are now irrigated, the broad ecologic factors touched upon above continue to give rise to zonal distinctions in population and economic activity. Parts of South and East Asia can support dense populations. Favoured localities in the southwest —for example, in Turkey and northern Iran—support large populations. In Southwest and Central Asia in general, however, agricultural productivity and population density vary markedly with the regional pattern of rainfall or the availability of water from humid highlands nearby. In the Soviet sector the older pastoral nomadism has been transformed into organized transhumance (seasonal migration of stock between lowlands and mountains); in consequence, the formerly nomadic families are now permanently resident in villages, and only herders accompany the flocks and herds. Northern Asia remains a semi-developed frontier region with short-season crop growing in favoured southern localities, even though breeding of newer varieties has extended agriculture northward. The Arctic fringe is being developed on the basis of mineral resource exploitation, but only in particular localities. Siberia remains lightly populated, with the population grouped around local centres.

The importance of water

The pattern of ethnic language distribution. A language map always tends to reflect past conditions because speech systems are constantly undergoing change.

In the past, language maps for the Eurasian continent have often shown eight languages—Turkic, Slavic, Tungusic, Chinese, Tibeto-Burman, Indo-Aryan, Iranian, and Mongol—almost blanketing the main portion of Asia and leaving other languages predominating only on peninsular appendages, island fringes, and in small pockets. Except for the large eastward expansion of the Slavic group, the map reflects distributional patterns that prevailed in the 18th century. At that time, by far the largest language groups, by number of speakers, were the Chinese and Indo-Aryan, but the Tungusic languages were probably used over wider areas. In recent times many of the small ethnic-group languages have, for practical purposes, been dying out, to be preserved only by professional linguists. The Tungusic group shows this decrease in usage, in spite of the Soviet practice of publishing books and newspapers in regional languages and the encouragement given to the preservation of the more important ethnic languages. Russian is now the dominant public language throughout the Soviet Union, and in the Asian territories it is spoken by large numbers of non-Slavic inhabitants. Similarly, Mandarin Chinese is expanding in China at the expense of local languages and dialects. In India, however, local languages are not losing ground, and language has become a territorial political issue. Meanwhile, the Indian Parliament continued, in the early 1970s, to debate in English. In Indonesia, which has many local languages and dialects, Bahasa Indonesia (the national language) has not yet spread throughout the Indonesian state. English remains the most commonly spoken single language in the Philippines, despite the adoption of a national Pilipino language.

The loss of small ethnic languages

Whereas many languages are dying out, as ethnic groups disappear or become merged into larger groups, some ethnic populations are increasing in numbers, thus increasing the relative importance of their languages. The large increase in the population of China now means that Mandarin Chinese is the world's leading language by number of speakers. The marked increases in population in Japan and the Indonesian island of Java mean that Japanese and Javanese rank much higher on the list of languages, by speakers, than they formerly did. Similarly, Western Hindi, spoken in northern India, is one of the larger languages by number of speakers. Though many of the Paleosiberian (Paleo-Asiatic) languages are dying out as their ethnic users decline in numbers, the Uzbeks and the Tadzhiks, for example, have adjusted to Russian control and are again increasing in numbers, forming significant ethnic components of the Soviet Union, with the result that their languages are being maintained. It appears that many ancient languages spoken in Asia have disappeared within the last millennium and that others have been greatly modified by linguistic change.

Regional situations have sometimes produced multiple and overlapping language patterns. Around some of the old Central Asian oases and in Southern Siberia, migrants from Russia and exiled ethnic groups have created ethnically mixed regional populations. A comparable pattern may be discerned in Chinese Central Asia. Such large cities as Manila, Singapore, and Bombay show complex linguistic patterns. As European Russians have moved into the new cities in Transcaspia and Western Siberia, Russian has become the language of the cities; the older languages have been confined chiefly to the countryside.

FORMS OF ETHNIC ADMINISTRATION

Imperial administration. The older forms of administration, by which political states controlled adjacent and frontier ethnic groups, generally used local native leaders, who normally were given honorific subordinate titles and made responsible for the orderly control of their territories. The Chinese Empire sometimes entered into treaty-like agreements with subordinate states on its periphery and either subsidized the non-Chinese states or exacted tribute as a token of subordinate or feudatory status. The British in India and Burma, the Dutch in Indonesia, and the French in Indochina developed systems of frontier agencies that employed resident officials to supervise local leaders, who exercised autonomy over what amounted to ethnolinguistic groups. The Thai maintained their control of Siam (now Thailand) as a buffer state between the French and British regions but in their northern area maintained the older form of control through native leaders. Beyond the reach of these larger imperial states simpler ethnic groups maintained their local sovereignty under the rule of chiefs, shamans, or clan leaders, sometimes forming limited confederations.

Multi-ethnic states. The development of modern forms of political administration among Asian states has produced some distinctive regional patterns. The Soviet Union was the first state to organize administrative districts on an ethnolinguistic basis. There are about 100 separate ethnic groups publicly recognized in the Soviet Union, as well as some minority groups never identified, and about 60 of these are represented by political administrative territories at major or minor levels. China under the Communist regime has adapted this system and has modified the Imperial political structure in regions containing ethnic or linguistic minorities—primarily in South and Southwest China, Northwest China, and Central Asia. In the Soviet Union such ethnic territorialism is relatively fixed and stable, but in China there continue to be changes in spatial arrangements of autonomous regions as various pressures are exerted, for not all minorities have yet been given internal territorial autonomy.

Ethnolinguistic political units

In India, with several hundred languages and many varieties of ethnic groupings, ethnolinguistic recognition is made only at the state level. Several of the political states of the Indian Union are now bounded by linguistic limits. Many minorities are not recognized at present, and the question of spatial ethnic and linguistic autonomy has given rise to considerable unrest within the Indian Union. The former northeastern Nāga tribal agency, however, has become a full state on the basis of its cultural unity. In Pakistan the tribal and frontier agencies formed during British Indian rule are still preserved; in these agencies, spatial autonomy derives from the ethnolinguistic situation. Burma has still not resolved the problems of integrating ethnic minorities into a modern political structure, and in the early 1970s several upland ethnic minority groups were expressing militant opposition to the forms of limited territorial autonomy offered by the government. Throughout the rest of Southeast Asia, except for Malaysia, ethnic minorities have received virtually no formal recognition, and each country is adopting different means of integrating its minorities.

Malaysia is a multi-ethnic state in which Malays total just less than half the total population; Chinese total just over one-third; and Indians, Pakistanis, and tribal groups almost equally split the remainder. The constitution makes no recognition of the plural ethnic composition; Malay is the official language; Islām is a state religion (although religious freedom is guaranteed); and the head of state must be a Malay. Quasi-legal political parties, however, represent ethnic groupings, and there are—in practice—many ways in which all ethnic elements are represented.

In Southwest Asia, minor populations exist in most political states without formal recognition of their status, the minority position deriving from ethnic, linguistic, or religious factors. Only in Saudi Arabia and Yemen (Aden) is there homogeneity in the three elements. Lebanon is ethnically and linguistically Arabic, but its population is almost equally divided between Christians and Muslims. Israel has a sizable Arab minority, and Iran is only half Persian in ethnic and linguistic terms. Most other states in Southwest Asia have comparable ethnic conditions.

VI. Political geography

HISTORICAL DEVELOPMENT

The Pre-European era. The first sophisticated organization of space, people, and cultural systems is customarily attributed to ancient Southwest Asia. In the earliest times there emerged the concept of a normal political state ruled by a god-king to whom all resources belonged and who held total power over the human population. Whereas some early states were city-states, the long-term

Ancient state systems

trend was toward the spatial state that included rural hinterlands. States rose and fell in the ancient Orient as the conceptual system spread both westward into the Mediterranean Basin, as well as into the peninsula of Europe, and eastward into India and China. Historically, Indian political systems dominated South and Southeast Asia, Chinese systems controlled East Asia, and variations on the original model continued in Southwest Asia, while steadily changing variations developed new patterns in the Mediterranean Basin and the European peninsula.

At the end of the 15th century, at the time of Vasco da Gama's voyage to India (which signalled the dawn of European influence in Asia), the situation on the continent was approximately as follows: East Asian systems were relatively stable; the political situation in Southeast Asia was in a state of flux, as several states were in decay, and Islāmic political missionaries from Arabia had not yet succeeded in consolidating their influence; South Asia was similarly in a state of flux as the Mughal Empire struggled to achieve spatial hegemony over the Indian subcontinent; Southwest Asian political systems were experiencing a period of readjustment as the Turkic peoples penetrated the region and began to assume control; Central Asia was experiencing the last phase of the expansion of the Mongols, as well as the spread of Islām; no formal political states had so far evolved in the Siberian zone.

The evolution of European contact. The evolution of Europe's political relationship with Asia may be conveniently divided into two phases. The earlier phase that characterized the modern political geography of Asia was one in which some of the states of the European peninsula were able to introduce political controls into the unstable parts of the remainder of the Eurasian continent. The second, and more recent, phase has been characterized by the withdrawal of these controls from the whole of the southern zone, despite the fact that varying economic and political links remain operative. In the northern zone, however, where at an earlier stage no political states were in existence, the current phase is marked by the integration of the territory into the Soviet Union, a state centred on the eastern part of the European peninsula.

Trade and politics

South and East Asia. The earliest European contacts with parts of southern and eastern Asia aimed at trade in the exotic products of the East; Europeans used their seapower to establish control over the trade routes. The European countries fought each other for the monopoly of the Eastern trade and established trading posts ("factories") at various points extending from Persia to South China and to the East Indies. The Portuguese, who were the first to arrive in India (1498), Malaya (1511), and southern China (1514), began to trade with these areas and established the first European trading posts there. The Dutch and the British followed not long after and the French and the Danes a little later. By 1700 the coasts of southern and southeastern Asia were dotted with European-controlled trade ports. Gradually these ports became points of territorial expansion, as Europeans increasingly intervened in the hinterlands so as to extend their control over production and trade. Some areas, such as Burma, Thailand, and Vietnam, were of little trading interest to the Europeans, and others, such as China, Korea, and Japan, declined to deal with the Europeans freely. By 1700 Portuguese power was in decline and the primary division of trading territories resulted from wars between the Dutch, English, and French, the Eastern conflicts often mirroring those in Europe itself. As a result, the Indies became a Dutch preserve, India became a British zone, and Spain held the Philippines. Only in the latter had the Christianizing of Asians as well as the acquisition of territory been an initial objective.

Political settlements in Europe after the conclusion of the Napoleonic Wars (1815) affected Southeast Asia. The Indies became totally Dutch, Britain acquired control over Malaya, and France gave up its claims to large territories in India in favour of Britain. The trading companies of The Netherlands and Great Britain ceased to operate in 1798 and 1858, respectively, and territorial political administration was assumed by the two governments. France returned to Southeast Asia somewhat later, taking over weak political states unable to resist encroachment, in order to establish power in Indochina. During the 19th century the United Kingdom took over Burma by stages, finally annexing it to India, and eventually assuming political control over a portion of western Borneo never effectively occupied by The Netherlands. The United States took over the Philippines from the Spanish in 1898. The German effort to gain control over the Chinese Shantung Peninsula was thwarted by other European powers, so that Germany had to be content with a long-term lease on the territory of the city of Tsingtao in southern Shantung, and a railroad-building concession. Germany did, however, become a political power in the Pacific islands in the late 19th century. During the last half of the 19th century, European countries pressured China into granting small holdings, called treaty ports, which were guaranteed by treaties, and these dotted the China coast and extended up the Yangtze Valley as far inland as Chungking in West China.

Thailand (then called Siam) remained free from political encroachment, and both Korea and Japan spurned all European effort to establish trade or to obtain political privilege. Late in the 19th century, however, Japan began its own political expansion, first in the form of establishing a sphere of influence, and then by conquest, taking over the Kuril Islands to the north and the Ryukyu Islands to the south, in 1875, and gained Korea and Taiwan in 1895. In 1905 Japan obtained southern Sakhalin and then gradually gained control of Manchuria, finally establishing the puppet state of Manchoukuo there in 1932. The expansion of the Turkish Ottoman Empire in Asia Minor left much of Arabia outside organized political control, and numerous small sheikhdoms continued to exist independently around oases in southern Arabia and along the Persian Gulf.

Japanese expansion

Central Asia. In AD 1400 the pastoral empire of the Golden Horde ruled all of Central Asia and much of eastern European Russia. During the 15th and 16th centuries Russian agricultural colonization spread eastward, and the exploitation of furs and forest timber products began; by the end of the 16th century, Russian explorers had crossed the Urals. In 1639 the first Russian explorer reached the Pacific Ocean at the Sea of Okhotsk, and in 1650 the Russians and the Chinese reached their first impasse over the control of trade and territory in the Amur River Valley. As in Siberia there were only small and fragmented ethnic territories lacking formal political organization, Russian political control was rapidly and easily achieved there. Expansion east of the Caspian Sea, however, proceeded more slowly, and it took until the end of the 19th century to bring the many Islāmic pastoral societies under control and to extend Russia's boundaries to the frontiers of Persia and Afghanistan in the south and to China in the Central Asian zone.

THE CONTEMPORARY PATTERN

The end of colonialism. During the late 19th and early 20th centuries the European powers were educating Asian peoples in methods of modern political administration and economic development. Political and cultural nationalisms gained in strength after 1900, focussing on traditional culture systems in the various regions. Political independence came to parts of southwestern Asia between 1920 and 1926, after the collapse of the Ottoman Empire, as a result of a deliberately planned separation of various ethnic groups. Conflicts and changes continued in Southwest Asia as the century progressed, heightened by the setting up of the State of Israel in 1948.

The Japanese defeat of Western military power in Southeast Asia in 1942 gave an enormous psychological stimulus to movements for political independence even during the Japanese occupation, and each colonial ruler was faced with demands for the end of colonial status as World War II ended.

The United States in 1935 had promised the Philippines

Independence of colonial states

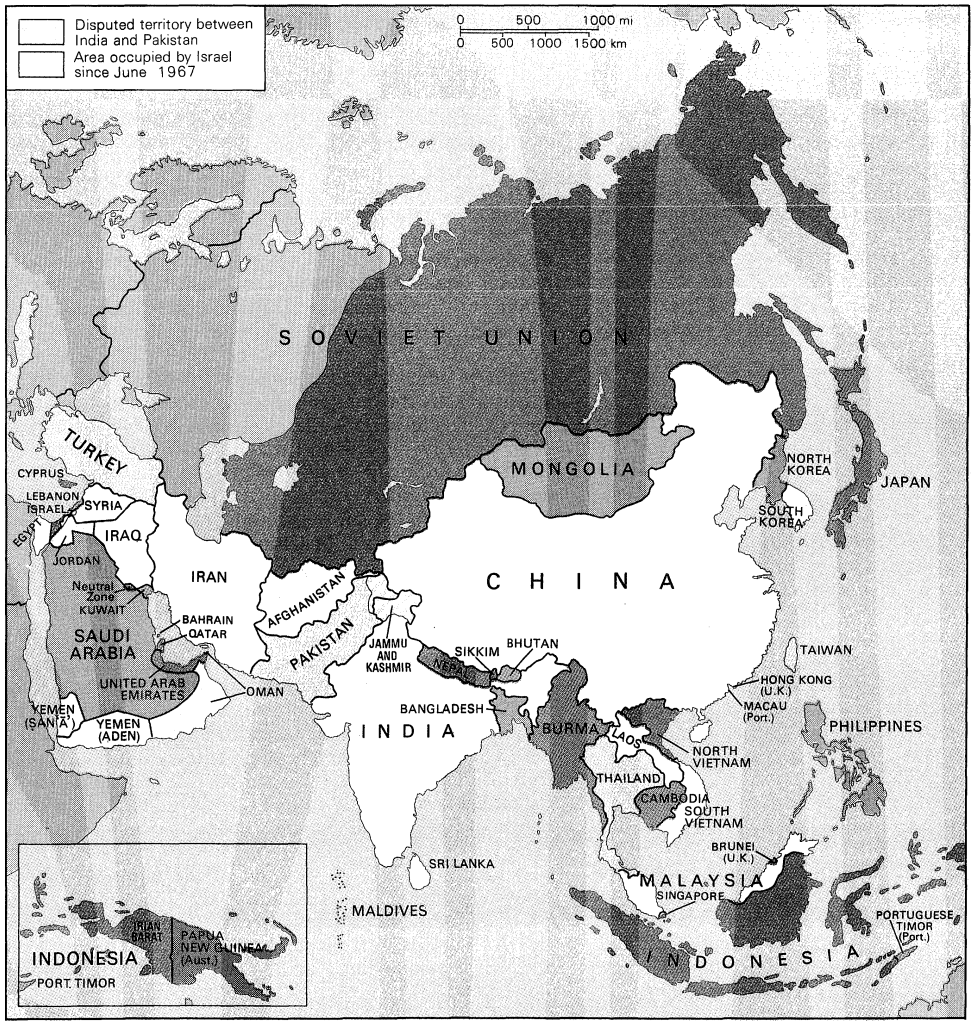
independence in 1945; this promise was fulfilled in 1946, after World War II, and this first release from externally administered status in the East was the forerunner of other moves. Political independence came to India and Pakistan in 1947; Ceylon (now Sri Lanka) and Burma in 1948; Indonesia in 1949; Cambodia in 1954; nominally to Vietnam in 1954; also nominally to Laos in 1954; and to Malaya in 1957, with the Borneo colonies being added in 1963 to form the Federation of Malaysia. Singapore withdrew from Malaysia to become an independent state in 1965. By the early 1970s the British crown colony of Hong Kong, Portuguese Timor, and Portuguese Macau remained as the only European colonial holdings in Asia. Meanwhile, the Soviet Union was able to avoid the charge of imperialism in Central Asia and Siberia because territories there were given the status of nominally autonomous republics within the framework of a federal union.

Problems of Asian nationalism. Three major conflicts occurred after World War II in which Western powers and their allies, Asian or other, were drawn into conflict with Communist-supported Asian forces. The first of these was the French war in Indochina (1946 to 1954), which ended with the withdrawal of the French and the nominal independence of the component territories of the region. The second was the Korean War (1950 to 1953), in which North Korean troops, later supported by the Communist Chinese, invaded South Korea, whose government was supported by United Nations forces; the result was a perpetuation of the division of the country into North and South by a cease-fire agreement. The third conflict was the war in South Vietnam, in which the United States supported the South Vietnamese government against Communist-backed guerrilla forces; fighting later spread to Laos and Cambodia.

By the beginning of the 1970s, Asian nationalism had recovered internal political and cultural control from the Western powers in all the larger countries of Asia, except in the Asian part of the Soviet Union. Within the Soviet Union, Russian strength had been sufficient to prevent outright rebellion, although the flight of some pastoral ethnic groups had continued back and forth across the boundary between the Soviet Union and China. Political independence had been much more completely achieved than had economic independence or social and economic advancement. Internal stability was also sometimes threatened by regional or ethnic imbalances, as in East Pakistan (now known as Bangladesh). Japan emerged as the most ethnically unified nation-state in Asia, and its great economic development from 1945 to the early 1970s resulted in relative internal stability. Elsewhere in Asia, political and cultural conditions were everywhere in flux, as nationalistic groups, ethnic minorities, and political parties strove for the attainment of different objectives and as different nation-states attempted to pursue their national interests. Contrasts between traditional rural societies and modern urban industrial populations raise new kinds of problems. The establishment of the People's Republic of China in 1949 represented one of the major political developments of the century in Asia and is fraught with long-term consequences for South and Southeast Asia. In Southwest Asia the Arab–Israeli conflict threatens to create worldwide repercussions if the conflicting interests cannot be reconciled.

Problems after independence

Continuing European linguistic influences. Europe has imprinted many permanent marks upon Asian cultures.



Political divisions of Asia.

Perhaps this is most noticeable in the continued use of European languages. Russian, English, and French are the dominant languages used, but German, Spanish, Dutch, and Portuguese are also employed in particular regions. Thus, German ethnic minorities in Soviet Central Asia continue to use German; older Filipinos speak Spanish; Indonesians use Dutch; and Portuguese is employed in Macau, Timor, and former Portuguese India. Vietnam, Cambodia, and Laos utilize French as a lingua franca, and French is taught in many schools. Dutch was the lingua franca of the educated class in Indonesia and is still taught in some schools. Pilipino is the official language of the Philippines, while English serves as a lingua franca and is taught throughout the schools. In Malaysia, India, and Hong Kong, English has an official status, is taught in schools, is spoken widely among the educated classes, and is the language of parliamentary debate. In parts of Southwest Asia, French and English are commonly spoken languages and are often taught in schools. Within Soviet Central Asia and Siberia, Russian is becoming more widely used and is the only common language. English, the most widely used non-Asian language, is a lingua franca throughout East, South, and Southwest Asia. (Jo.E.S.)

VII. Resource development

Factors in resource development

The utilization of Asia's natural resources has depended, to a large extent, not only on the development of technology but also on political circumstances. Thus, until the end of World War II and the beginning of the process of decolonization in Asia, most Asian countries were not free to develop their own natural resources independently and without reference to the economic interest of a metropolitan power. Cultural attitudes also affect the utilization of resources. To give but one example, cattle, which are a source of immense wealth in many developed countries, are a drain on scarce resources in India, where cultural taboos prohibit the slaughter of cattle either for purposes of food or for the conservation of resources when the animals are no longer productive.

The value of natural resources also varies with the prevailing technology. For example, with the application of new technology to the production of cereals, the same area of land can give greatly increased production. The application of modern technology has also produced improvement in many other areas, such as in Japan for the production of silk or of cultured pearls. Technology may also make it possible to exploit mineral wealth that was previously unusable because of problems of accessibility or of juxtaposition of other minerals.

INDUSTRIES

Mining. Asia produces a variety of minerals. Many of these are mineral fuels, such as coal and petroleum. The largest Asian producer of coal is the People's Republic of China, followed by Soviet Asia, India, North Korea, and Japan. Smaller quantities of coal are produced in a number of other countries. The Arab countries of Southwest Asia are among the principal producers of petroleum in the world. The biggest producer among the Asian countries is Iran, which is responsible for more than one-fifth of the total Asian production. Indonesia comes next, followed by Soviet Asia, China, India, and Brunei; some other countries produce much smaller quantities. Efforts are also being made to undertake offshore prospecting on a systematic basis. The biggest producer of natural gas is Soviet Asia, followed by Pakistan, Iran, Japan, Afghanistan, and Taiwan.

The largest producers of iron ore and ores for ferroalloys are China, Soviet Asia, India, and North Korea. Together, these four account for some 90 percent of the total production of the region. The People's Republic of China and India are among the ten major world producers of manganese ore and between them account for some 85 percent of Asia's total output. Asia's biggest producer of chromite is the Philippines, followed by Turkey, India, Iran, and Japan. There is also some production of tungsten in China and both North and South Korea and nickel in Indonesia. Soviet Asia was expected to become a major producer of many of the ferroalloys during the 1970s.

Asia is one of the world's main producers of tin-in-concentrates (tin ore that has been partially processed to increase the concentration of tin), providing some 59 percent of the world's total production. Malaysia alone accounts for some 55 percent of Asia's production, and Thailand has replaced Indonesia as the second largest Asian producer with some 16 percent. There is also considerable production of copper ore in the Philippines, Japan, and China.

The bauxite produced in Asia represents only a small part of total world production, although production in Soviet Asia is expected to increase during the 1970s. Development of the eastern Siberian gold mines has given Soviet Asia a leading position in the world's production of gold. The region, however, accounts for a third of the world's production of sulfur, principally from Japan and China; and more than three-fifths of the world's production of graphite, from Korea (North and South) and China.

Heavy industry and engineering. Despite the fact that the continent has such a variety of mineral resources, metallurgical industries have not been well developed, except in Japan and in Soviet Asia during the 1970s. The major producers of steel in the region are Japan, China, and India; Soviet Asia may rival both China and India by 1980. Japan, China, and India are also the major steel consumers, although the consumption of steel is increasing in Soviet Asia, Pakistan, and the Philippines, and Hong Kong is one of the main consumers on a per capita basis. Japan, China, and India are also the region's leading producers of metallurgical coke. It is to be expected that other countries will begin to establish steel plants and that the production of steel will continue to grow in Japan, China, and India.

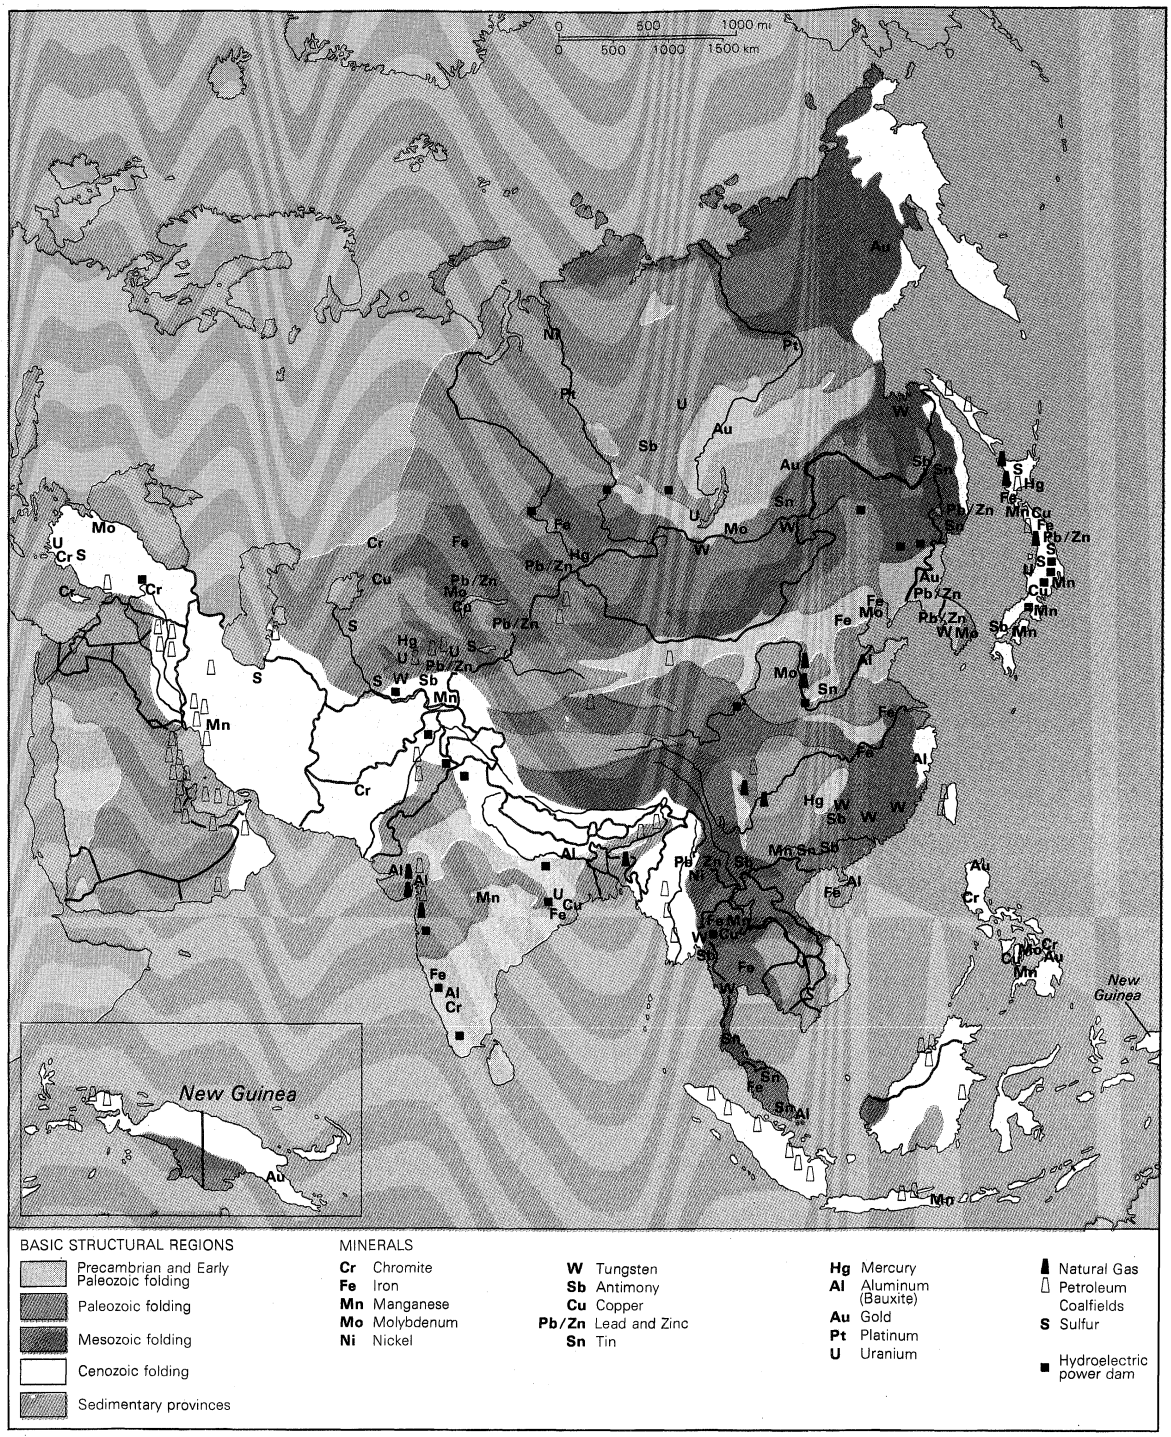
The production of aluminum is concentrated in four countries—Japan, Soviet Asia, India, and Taiwan. Japan accounts for over half of the total output of aluminum in the region. India is developing its aluminum production and has a relatively well-developed aluminum industry. There is also some production of copper, zinc, lead, and tin in Asia, with Japan leading in the production of zinc and lead and Malaysia in the production of tin. Japan is the leading consumer of tin, followed by India and China.

Asia's engineering industries

Japan produces every variety of engineering goods, from tankers and locomotives to miniaturized electronic equipment. In the postwar era, India has also gradually diversified its engineering industries and now produces heavy capital goods (machines and tools used in the production of other goods), various items of industrial machinery, prime movers (engines and other sources of motive power) and boilers, diesel engines, sewing machines, machine tools, agricultural machinery, and all kinds of electrical equipment. India also produces radio receivers, metal manufactures of various kinds, railway rolling stock, automobiles, bicycles, and precision instruments. The People's Republic of China also made considerable progress in the field of engineering industries during the 1950s and 1960s. Other Asian countries have concentrated on the production of durable consumer goods.

Chemical and petrochemical industries. The consumption of nitrogenous and phosphatic fertilizers has greatly increased in Asia and is certain to increase much more in the future as additional countries use the advanced techniques and improved seeds that have now become available. The major consumers of fertilizers, on a per acre basis of arable land, have been Japan, Taiwan, and South Korea. Because of their vast size, India and China, where the use of fertilizers is rapidly increasing, are, in absolute terms, among the major consumers. In production, Japan accounts for close to 55 percent of the output of nitrogenous fertilizers in Asia excluding the People's Republic of China. India has greatly increased its production, especially of ammonium sulfate, and has also experimented with fertilizers having a much higher nitrogen content, such as urea. Production of phosphatic fertilizers is also increasing.

Asia also produces and consumes basic chemicals, such



Basic structural regions and principal mineral and hydroelectric sites of Asia.

as caustic soda, soda ash, and sulfuric acid; Japan is the leading producer of these, followed by China and India.

The consumption of pulp and paper throughout the continent is growing steadily and is bound to increase with improved levels of living. The major consumers are Japan and India, and the major producers are China, Japan, and Indonesia.

Various surveys undertaken under the auspices of the United Nation's Economic Commission for Asia and the Far East (ECAFE) have shown that there is considerable scope for the manufacture of petrochemical products in Asia. At the Second Asian Conference on Industrialization (1970), a program for developing the petrochemical industry was initiated; this program included proposals to close the annual gap between prospective demand and capacity, estimated in terms of ethylene at about 500,000 tons. It was also recommended that more countries should manufacture machinery and equipment for the fabrication of plastics. An increase in the production of synthetic fibres, especially polyester, was also considered important.

The expanding textile industry

Manufacturing and textiles. The textile industries, particularly cotton, have expanded greatly in Asia since World War II. Japan and India have become the world's largest exporters of cotton textiles, and China, Taiwan, Pakistan, and Hong Kong have also entered the international market. The industry produces cotton yarn, cloth, and finished garments. There is also some production of wool (both yarn and woven fabrics) in the region. Here again, Japan, China, and India are the main producers and consumers; Japan is Asia's chief producer of woollen fabrics. Japan and India have also become major producers of woven rayon and acetate fabrics. Japan has also turned to noncellulose synthetic fibres, especially nylon,

acrylic, and polyester fibres. In the early 1970s Japan was second only to the United States in the production of these fibres and fabrics.

Industrial development in the region has made significant progress in relative terms, but it must be recognized that, in absolute terms, progress has been very limited; in relation to its size and vast population, the contribution of Asia to total world industrial output has been small. There is, however, a discernible trend toward a transition from light to heavy industry in many countries of the region, the development of Soviet Asia is dramatic, and it is likely that the continent will have an increasing share of world production in the final decades of the 20th century.

Timber, fisheries, and animal husbandry. Logs are exported from the Philippines, Malaysia, Indonesia, Thailand, and Burma to industrialized and timber-deficient countries, especially Japan. Thailand and Burma produce special varieties of timber such as teak. Thai teak is also exported to Europe.

Soviet Asia has an enormous forest area estimated at more than 500,000,000 hectares (1,250,000,000 acres). Present annual fellings in Soviet Asia are estimated at around 120,000,000 cubic metres (4,250,000,000 cubic feet), while natural losses of mature and overmature forests are estimated to be close to three times the present removals. Average yields of timber are 150 to 200 cubic metres per hectare (2,150 to 2,850 cubic feet per acre). The wood ranges from pine around the Bratsk area to a mixture of pine, larch, aspen, birch, and other species in the region south of Lake Baikal. Logging and transport operations are highly mechanized and have been facilitated by a road-building program.

Bamboos are an important component of wet evergreen, moist deciduous, and dry deciduous forests in the tropical parts of southeastern Asia, principally in Burma, Cambodia, Sri Lanka, India, Indonesia, Laos, Malaya, New Guinea, Pakistan, the Philippines, Thailand, and Vietnam. At higher altitudes and in temperate climates in Asia, as in Bhutan, China, Japan, and Nepal, many of the genera found in tropical parts are represented by different species, and other genera are common in China and Japan. In this connection, it is interesting to note that pure bamboo forests are common on slopes where temporary cultivation has been carried on in Burma, Bangladesh, and other parts of Asia.

Asia has a considerable potential for increased development of its fisheries. Japan has shown how far afield a well-organized fishing fleet can go in search of fish. In general, the problems of the fishing industry stem from lack of adequate capital and advanced technology, which tend to restrict fishing to coastal and offshore areas and make it difficult to extend the fishing to the deep seas. Because of a lack of refrigerated transport and storage, there are also the problems of preserving fish after the catch and of transporting the catches to centres of consumption. In some countries freshwater fish are also an important addition to the diet of the local people, and the raising of fish in culturally controlled ponds is important in southern China, Indonesia, and the Philippines. While the dairy industry is important in a few countries such as India, Pakistan, Soviet Asia, and Turkey, there is not much large-scale development of beef-cattle farming; Soviet Asia, however, is developing such patterns. Both China and Japan are discarding their traditional taboos against the use of milk products, and both countries have growing urban dairy industries. Only in areas where there are communities of overseas Chinese—in Singapore, for example—has an attempt been made to raise swine outside China, which probably leads the world in pork production. The poultry industry has made rapid strides during recent years, and the production of both eggs and broiling chicken has gathered considerable momentum. In the case of poultry, availability of feed is one of the major limiting factors for the further growth and development of the industry. Straw, obtained from the rice crop, is the primary fodder for livestock in southern Asia. Cattle feed is usually supplemented by concentrates, such as oil cake.

The raising of livestock

The raising of sheep and goats for meat and wool is especially important in Afghanistan, Pakistan, and southern Soviet Asia, and these animals are also raised in practically all the other countries of Asia. The sheep population of Southeast Asia is small.

In spite of the large number of cattle and sheep in the region, the hides and skins industry has not been adequately developed. Technological problems in connection with both the flaying of skins and their curing remain to be overcome.

Handicrafts. Traditional cottage industries and handicrafts continue to play an important role in the economies of all Asian countries. They not only constitute an important manufacturing activity in themselves but are almost the only available means of providing additional employment and of raising the level of living for both rural and urban populations. In view of the growing world market for the products of traditional Asian cottage industries and for Asian handicrafts, there is room for considerable expansion, especially in standardizing production and in marketing products in the advanced countries.

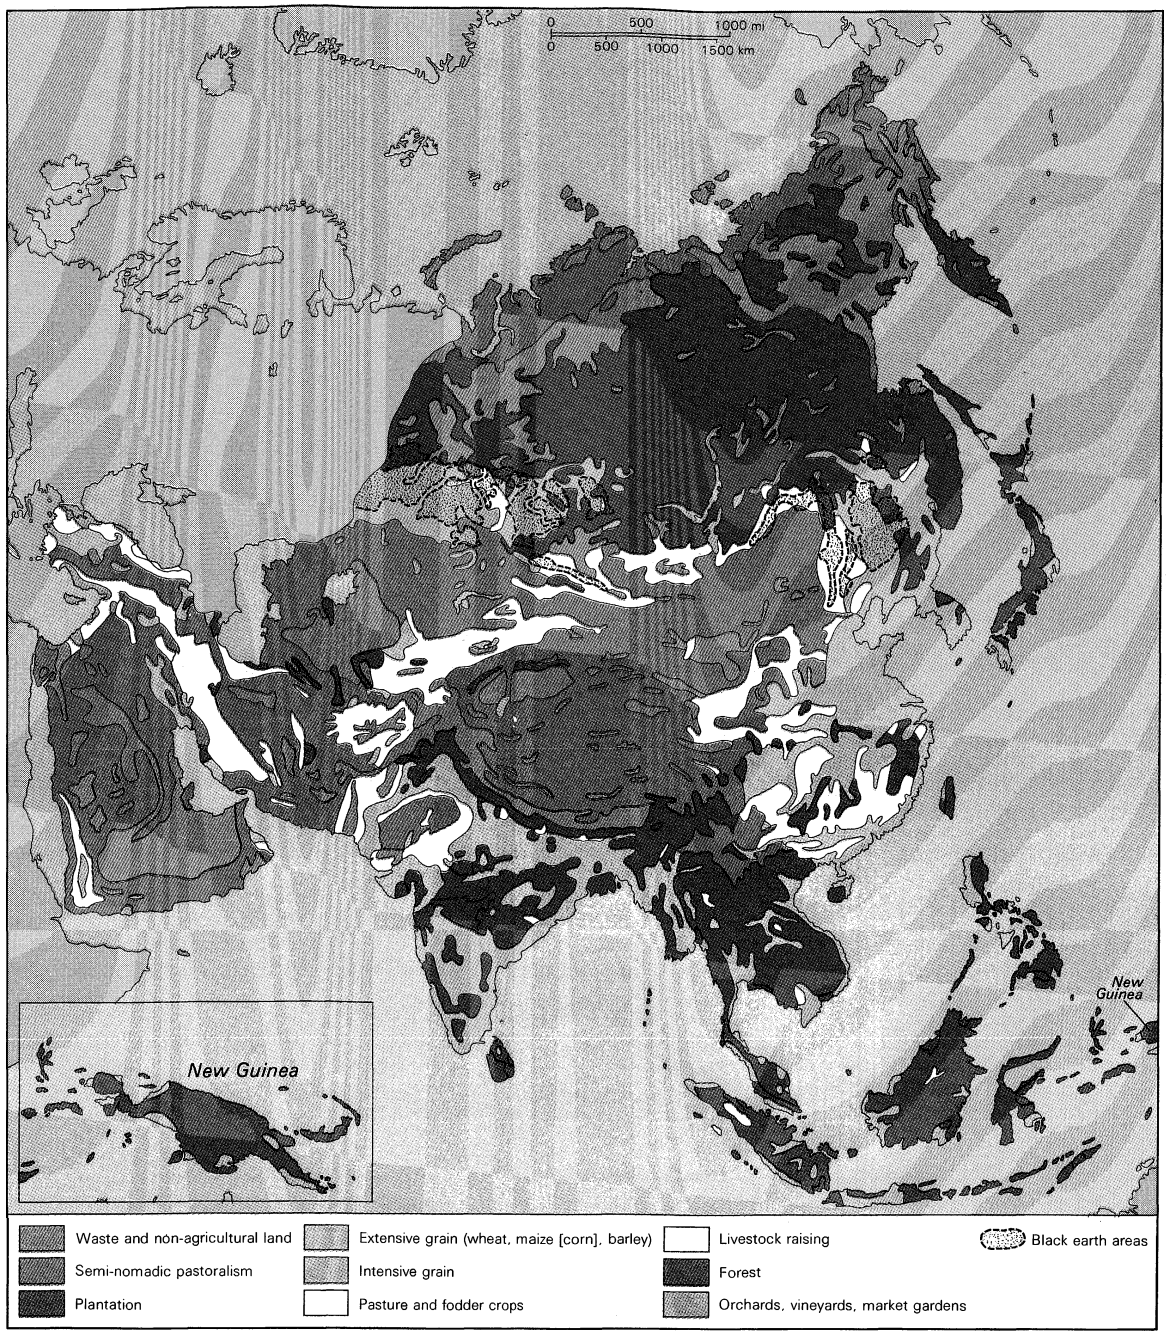
Other industries. Asian countries are at different stages in developing their pharmaceutical industries. The progress of the industry in Japan is comparable to that achieved in western Europe and the United States. Great progress has also been made in India and, in some respects, in Pakistan, but these two countries have still not reached the stage of being self-supporting in technology, raw materials, or equipment. China has begun to develop an industry based on a distinctive blending of Occidental and native pharmaceutical manufacturing. In most of the other countries, the pharmaceutical industry is only a processing industry based on basic drugs, imported in bulk, which are then marketed as capsules, tablets, and injectibles. It must also be remembered that in many Asian countries traditional medicinal products and treatments are still popular, especially in rural areas.

International tourism has developed to such an extent that by the early 1970s some 3,000,000 tourists annually were visiting Asian countries. The most visited places, in order of popularity in the year 1970–71, were Hong Kong, Japan, Thailand, Taiwan, Singapore, India, and Pakistan. Hong Kong and Singapore each have a big entrepôt trade and attract visitors primarily because they are duty-free ports. In the early 1970s, with the gradual lifting of the "bamboo curtain," it was anticipated that tourism in China would increase substantially as the decade progressed. There is considerable scope for further development of tourism in Asian countries, for many of them possess ancient monuments and natural attractions of great beauty. Unfortunately, many of these interesting places are not easily accessible, and the departments of tourism have often been unable either to organize or actively to promote tourism. In 1970 it was decided to establish the International Tourism Organization, as an intergovernmental agency. This institution is expected to provide greater technical assistance in the future to countries with specific plans to develop tourism.

The importance of tourism

POWER

The consumption and generation of electricity in Asia practically doubled during the 1960s. Even so, the per capita consumption of power in Asia is very small compared with the world average, amounting to less than 300 kilowatt-hours per capita, compared with a world average of between 1,000 and 3,000 kilowatt-hours in western Europe and more than 6,000 kilowatt-hours in North America. Japan is the biggest producer of power in Asia, and its generation capacity amounts to a little more than half the region's total. The annual electricity output by public utilities and similar bodies in the Asian countries belonging to the United Nations Economic Commission for Asia and the Far East (ECAFE) amounted to some 597,000,000,000 kilowatt-hours in 1970. Of this total, three-fourths was produced by thermal power and a quarter by hydroelectric power. Both types of production have progressed rapidly in Soviet Asia, which may rank close to Japan in total production by 1980.



Agricultural regions of Asia.

Thermal and hydroelectric power

Thermal power has, indeed, become the most important source of supply among the various types of electric power generated in the region. There is an increasing tendency to operate thermal power stations for meeting the regular demand and to build—or plan—hydroelectric power stations to serve during peak demand periods. In countries such as Afghanistan and Nepal, however, hydroelectric power generation is several times greater than the generation of thermal power. This is explained by the fact that, because these are landlocked countries, the imported fuel needed to supply thermal plants is expensive.

Nuclear power plants are being developed in a number of countries. Japan completed its first atomic power plant in 1967, with a capacity of 160 megawatts (a megawatt equals 1,000,000 watts), and is constructing more and more such plants, with a total capacity of some 2,400 megawatts. The capacity is expected to reach 6,000 megawatts by 1975. India commissioned its first nuclear power station at Tarapur in early 1969 with a capacity of 380 megawatts, and two more atomic power plants, each with a 400-megawatt capacity, are in the construction and planning stage. Pakistan has constructed a 137-megawatt nuclear power plant in Karachi. Taiwan is planning to have a 500-megawatt nuclear power station in operation by 1975. Other countries—the Philippines, South Korea, and Thailand—also have nuclear power plants either in the planning stage or under construction.

In the construction of steam thermal power stations, there is an increasing tendency toward a larger unit capacity operating at very high pressure and temperature. Japan has two small geothermal plants (which employ the heat of the Earth's interior) and is the only Asian country to use them. Small gas-turbine generating stations have also been installed in many countries. Pakistan has been using natural gas from the Sui gas field for both thermal and gas-turbine generation.

AGRICULTURE, IRRIGATION, AND LAND USE

High-yielding cereals

The most important development in Asian agriculture during recent years is the evolution of new high-yielding strains of cereals. This development is now being utilized in several Asian countries and is likely to have a marked

influence on the yield per acre of cereals during the 1970s and 1980s. Rice is, of course, the staple food crop among Asian countries. Asia produces some 60 percent of the total production of rice in the world. Except in Afghanistan, Soviet Asia, and Malaysia, rice occupies the greatest land area as a single crop. In Afghanistan and Siberia wheat is the dominant crop, while in Malaysia rubber occupies the greatest land area, with rice coming second. The total percentage of land under rice cultivation, as compared to total arable land, is highest in South Vietnam, Taiwan, and Thailand; it varies between 25 percent and 50 percent in most Asian countries.

In spite of the fact that the region is a major rice-producing area, several countries (among them Sri Lanka and Indonesia) are not self-sufficient in rice. Thailand, Burma, and Cambodia are exporters of rice, and South Vietnam was also an exporter until 1965. After rice, wheat is grown extensively in India, Pakistan, Iran, Turkey, Soviet Asia, northern China, Korea, and Japan. Barley and oats are also grown in these countries. Maize (corn) is grown in Soviet Asia, India, Pakistan, Afghanistan, Indonesia, and the Philippines. India, China, Pakistan, and Soviet Asia also grow sorghum and millet.

Asia produces several plantation crops, of which the most important are rubber, tea, coconuts, sugarcane, and pineapples. The major producers of rubber are Malaysia, Indonesia, India, Thailand, and Sri Lanka. India and Sri Lanka predominate in plantation tea production, and China, Taiwan, and Japan produce several types of tea on small holdings. Coconuts are an important crop in the Philippines, Indonesia, Sri Lanka, and India. India, the world's leader in sugarcane production, produces for domestic use only, whereas the Philippines, Indonesia, and Taiwan produce both for domestic consumption and export. The Philippines, Taiwan, and Malaysia produce pineapples, which are canned for export.

The continent produces a variety of tropical and subtropical fruit, mainly for domestic consumption. Transport facilities, where available, can be used only for limited distances. In view of the climatic conditions and the past lack of refrigerated transport, consumption is seasonal and is confined to areas close to centres of production. Among the main varieties of fruit produced are bananas, mangoes, apples, oranges, pineapples, several varieties of citrus fruit, papayas, and some specialities such as mangosteen (a dark reddish-brown fruit) and durian (a large oval fruit with a prickly rind, a soft pulp, and a peculiar odour). Taiwan, the Philippines, and Malaysia export bananas to Japan.

Except in a few countries, canning of surplus fruit has been developed only to a limited extent. In view of the tremendous potential for the production of fruit, there is vast scope for increased canning for export, whether of such fruits as mangoes and pineapples or of fruit juices from apples, oranges, or pineapples. The fruit canning industry has markedly increased in Taiwan.

The same factors affect the production of vegetables. Vegetables are produced mainly for local consumption, and only tubers can be transported over distances and stored for a period of time. In Taiwan, successful efforts have been made in the canning of mushrooms and asparagus, both of which are becoming leading exports.

Methods of irrigation

The traditional method of irrigation in Asia is by gravity water flow. The water from upstream storage reservoirs or diversion dams is carried through canals to field distributaries. The fields adjoin one another, and the water is able to flow from one field to the next; it may, however, take some time for the water to move across the terraced fields back to the canal system. The disadvantages of this system include the loss of water by evaporation and seepage and the possibility that the continuously flowing water will carry with it soil nutrients, fertilizers, and pesticides. In Japan and Taiwan, water is moved by small electric pumps, which operate continuously during the growing seasons.

In the early 1970s more attention was being given to the use of underground water by lift. The use of ordinary pumps as well as of deep-bore well turbine pumps is becoming more common, especially in India, Pakistan, and Iran. Such irrigation avoids some of the disadvantages of flow irrigation and allows for easier drainage.

Of the crops cultivated in the region, rice, sugarcane, and, in Soviet Asia, sugar beets need the most water. Cereals other than rice, legumes, and root crops can be grown even on rain-fed land. A survey of Asian agriculture undertaken under the auspices of the Asian Development Bank in 1968 quotes a figure of approximately 20 percent of the arable area under cereals as being served by irrigation. The availability of an assured source of water supply is an important element in the new technology, which also requires the use of fertilizer in conjunction with the improved cereal seeds that have been developed. Huge irrigation projects in Southern Siberia and southwestern Soviet Asia are rapidly altering traditional agricultural patterns.

VIII. Asian commerce

Several centuries before the Christian Era, Asian countries had commercial relations among themselves as well as with the countries of the West. In the earliest days, nomad tribes carried on this trade over considerable distances, using barter as the medium of exchange. Particularly important in such trade were fine textiles, silk, gold and other metals, various precious and semiprecious stones, and spices and aromatic products. There was a considerable expansion of trade during the Greek era around the 4th century BC, by which time various land routes had been well established connecting Greece, via Asia Minor, with the northwestern part of the Indian subcontinent. A further development of land and sea routes, especially to South India, occurred during Roman times. This East–West trade flourished in the first four centuries AD but was subject to considerable vicissitudes in later centuries. During this period there was also a great expansion of trade to Southeast Asia and to China through what are now Malaysia and Cambodia.

Ancient trade patterns

After Spain, in the 15th century, became interested in discovering a direct sea route to Asia—an interest that led to the discovery of the Western Hemisphere—the era of the great circumnavigators arrived in the 16th century. Portugal was one of the first countries to dream of establishing a monopoly over the lucrative spice trade with Asia. The Dutch and the British started similar enterprises at the turn of the 17th century, each country establishing its own East India company. The British began by centring their activities on the Indian subcontinent and extended their interest in due course to Burma, Ceylon (now Sri Lanka), and present-day Malaysia. The Dutch first concentrated on Ceylon but later expanded into and concentrated on Southeast Asia. The French were able to establish only minor footholds on the Indian subcontinent, but their 19th-century penetration of Indochina was more successful. Spain was content with the control it had established over the Philippines. In the course of time, the trading companies developed into colonial empires.

The export trade of Asia was formed by these historical circumstances. In the days before the East India companies, the products of Asia were those demanding the exploitation of human skills, such as silk and textiles, and such precious commodities as spices and aromatic products, which depend especially upon climatic and soil conditions and careful human labour.

The colonial trading system

With the development of the East India companies and the further assumption of colonial rule, a new pattern of trade emerged. Generally speaking, the colonial countries became the exporters of raw materials and imported the finished products from their metropolitan rulers. During this period, tea and tobacco also entered into international trade, and jute became a monopoly product of the Indian subcontinent. Until the end of the 19th century, Japan had trading relations mainly with Korea and China and generally remained somewhat aloof from world trade. China was the first country of Asia to have any significant trade relations with the Western Hemisphere; these were especially with the United States.

The latter half of the 19th century and the early part of the 20th constituted the heyday of colonial rule. By the

first decade of the 20th century, Japan had emerged as a major military and naval power and gradually developed into an important trading partner with the rest of the world. The era that followed was that of the colonies' struggle for political independence, which reached its climax immediately after World War II. Fifteen years after World War II the great British, French, and Dutch empires had virtually ceased to exist in Asia.

As a result of the achievement of independence by the former colonies, the emergence of the People's Republic of China, and the development of Japan into one of the major producing and trading countries of the world, the old established patterns of trade have changed considerably. Most of the newly independent countries are planning their economic and social development and have tried—with varying degrees of success—to diversify their production and to develop new industries, even if they cannot wholly overcome the handicaps of the colonial past.

TRANSPORTATION

Reference has already been made to the main transport systems that linked Asia and the Western world. Until the 19th century, the land, or caravan, routes, supplemented by oceangoing vessels, were predominant. In the latter half of the 19th century there was a major shift to seagoing vessels. Rail transport has begun to play a progressively more important role, mainly in the internal movement of passengers within individual states and in the transport of heavier goods over longer distances. Concurrently, there has been a considerable development of ports and harbours, linked to their hinterlands by rail and road. Air transport is also proving to be not only the speediest but often the cheapest means of transport, especially for costly items of relatively small weight and bulk. Air transport plays a particularly important role in landlocked countries—such as Afghanistan, Nepal, and Laos—and in the opening up of relatively inaccessible areas.

Means of internal transport

Within Asian countries, animal transport still remains the main means for the local transport of goods from one village to another or from the villages to a central marketplace. The animals, used for plowing during the cropping season, are also used for transport of goods at other times. The diesel truck, however, is now rapidly replacing draft animals for internal traffic, and there is a simultaneous development of roads and highways in most countries. In the 1960s and early 1970s, an attempt was being made, with international backing and cooperation, to establish an Asian highway network. When this project is completed, there will be a direct road link from Istanbul, in Turkey, to Singapore, and to Saigon, in South Vietnam.

Inland navigation is important in certain countries; a good river and canal system is capable of carrying goods and passengers at small cost over considerable distances. Among the countries having a well-developed inland water transport system are Bangladesh, Burma, Thailand, the former Indochina countries, and China. There are also great riverine ports such as Calcutta, Rangoon (Burma), Bangkok (Thailand), and Saigon; oceangoing ships can navigate the Mekong River to inland ports such as Phnom Penh (Cambodia) and can sail up the Yangtze River to Wu-han (China). Ultimately, it might be possible to connect even Laos with the sea by an extension of inland navigation facilities on the Mekong. The Yangtze, Sungari, and Hsi rivers of China provide a wide network of routes for motorized barges, supplementing traditional water transport.

For the movement of petroleum products, there has been some development of pipelines, especially in West Asia and western and southwestern Soviet Asia. Pipelines have considerable advantages, such as economy and speed, but they also have the disadvantage of being subject to political vicissitudes when they cross international boundaries. Meanwhile, there has been a considerable development of ever larger oil tankers, which, through economies of scale, can compete with the most efficient pipelines and can also effect point to point delivery.

INTERNAL TRADE

In view of the division of labour that existed between the colonial countries and the metropolitan powers in colonial days, it is not surprising that the economies of the newly independent countries of Asia are more competitive than complementary. In the case of certain countries, such as the Philippines, Sri Lanka, India, Afghanistan, Iran, and Pakistan, their intraregional exports in recent years amounted only to 4 to 15 percent of their total exports. On the import side, Iran, Afghanistan, Taiwan, South Korea, the Philippines, and India imported less than 10 percent of their requirements from other developing Asian countries. Japan, the most developed of Asian countries, exported about 35 percent of its products to developing ECAFE countries and received from them 23 percent of its imports.

Competitive economies

Asia is the biggest producer of rice in the world; rice is indeed one of the most important commodities of intraregional trade, and it is the most important export item of such countries as Burma, Thailand, and Cambodia.

There has been an effort on the part of Asian countries to improve their trading position by joining in commodity agreements. Malaysia, for example, is a member of the International Tin and Rubber Agreement. Other Asian countries are members of the International Sugar Agreement. Sri Lanka, India, Indonesia, and Pakistan have set up an International Tea Committee. The Asian Coconut Community was established in 1968, with Sri Lanka, India, Indonesia, Malaysia, the Philippines, Singapore, and Thailand participating. Most recently, there has been an effort to set up an Asian Pepper Board. Participation in these commodity agreements is not designed so much to promote intraregional trade as to help stabilize prices of primary products produced in Asia that enter into world trade.

The People's Republic of China was one of the main trading partners of the Socialist bloc of countries in Europe, especially the Soviet Union, in the early days after the revolution. China is now increasingly seeking trade contacts with other Asian countries. In many cases trade agreements between China and other Asian countries are in the form of barter agreements. China's most important trading partners in Asia have been countries such as Burma, Cambodia, Sri Lanka, India, Indonesia, Japan, Malaysia, Pakistan, and Singapore.

In 1958 a special effort was made to promote intraregional trade by the establishment, under the auspices of ECAFE, of intraregional trade talks. In the early 1970s, efforts were being made to establish an Asian Clearing Union, as a first step toward more ambitious regional and sub-regional monetary co-operation.

There has been little effort at trade integration on a regional or subregional basis in Asia. In this respect Asia lags behind Latin America and, to some extent, Africa. Trade between India and Pakistan, which could be of great mutual benefit, is virtually nonexistent because of the state of political relations between the two countries.

Many Asian countries are engaged in the process of diversifying their internal production. Their goal is frequently self-sufficiency rather than specialization and division of labour among a number of countries. As Asian countries increasingly become industrialized, however, and as they make greater use of their individual natural advantages, trade among the countries of the region could become more complementary.

EXTERNAL TRADE

The external trade of Asian countries has been considerably affected by the political ties that existed in colonial times, when important trade connections were established and when a certain trade pattern developed that proved convenient for both trading partners to continue. This convenience extended even to payments arrangements; the former British colonies were part of the sterling area, while the former French colonies found the franc a convenient medium of exchange. In addition, a system of Commonwealth preferences existed within the sterling area.

Several factors tended to interfere with this pattern in the 1960s. First, the European Economic Community (EEC) was formed, with its new system of preferences. Second, Japan was rapidly becoming a major producer of both consumer and capital goods and a major market for the commodities exported from other Asian countries. Third, the People's Republic of China began to take increasing interest in trade outside the Socialist bloc.

Major export items

The main items exported from the developing countries of Asia were rubber, tea, crude petroleum and petroleum products, rice, sugar, copra, coconut oil and palm oil, cotton and cotton fabrics, jute and jute fabrics, tin-in-concentrates, tobacco, wood products, iron ore, wool, and hides and skins. Spices, which were such an important part of the trade with the West in earlier centuries, now form a very small part of the total exports.

Since the major exports of the developing countries of Asia are still primary products, both their volume and price depend upon external demand, which fluctuates according to the level of industrial activity in the advanced countries. As a result, there are fluctuations both in the volume and price of the primary products exported. Further, there has been a tendency on the part of the advanced countries to replace some of these primary products in part by synthetic products, such as synthetic rubber and nylon and polyester fabrics. The developing countries are faced, therefore, with the problem that, even when they are able to increase their volume of exports, there is no corresponding increase in the value of their exports. In addition, the price of the consumer and capital goods exported by the advanced countries to the developing countries has been steadily rising. The establishment of the United Nations Conference on Trade and Development (UNCTAD), with a permanent secretariat in Geneva, is a response to the recognized need for an international agency to deal with some of these major problems of the developing countries and to help promote their trade with the advanced countries.

The main imports

The main imports of the developing countries have been machinery and transport equipment (including trucks, automobiles, and tractors); other manufactured goods; chemicals, including fertilizers; food, beverages, and tobacco, especially cigarettes; mineral fuels; and oils and fats. There has been a decline in British exports to the sterling bloc countries of Asia in the postwar period. The major trading partners of France in Asia have been the countries of Indochina, while The Netherlands trades mainly with Indonesia. West Germany has developed considerable trade with Asia in the postwar period.

Since 1959, the Soviet Union has increased its trade with Asian countries, especially Burma, Ceylon (now Sri Lanka), India, and Indonesia, which have been pursuing a neutralist foreign policy and have accepted economic aid from the Soviet Union as well.

The United States has been the biggest provider of economic aid to many Asian countries in the postwar period; there has also been a concurrent increase in trade between the United States and Asian countries. The dominant Asian trading partner of the United States is Japan; Hong Kong is next, followed by Taiwan and South Korea, after which come India, the Philippines, Indonesia, Pakistan, and Thailand.

In its efforts to trade with countries outside the Communist bloc, the People's Republic of China has increased its trade with countries such as the United Kingdom, Australia, Canada, and France; it has also entered into a series of trade agreements with Japan. Trade between China and the United States came to a virtual standstill in 1950, when the United States imposed an embargo on hundreds of commodities; while the ban continues to apply to traffic in certain strategic goods, in 1971 it was lifted for other commodities. As a result, it is to be expected that, in the course of the 1970s, the United States will become a significant trading partner of China. China has also been trying to extend its trade relations with the newly independent countries in Africa.

During this century, petroleum has become an important part of the trade of countries of West Asia with the rest of the world. Iran and the Arab countries and sheikhdoms are among the chief beneficiaries of this trade. Originally, the Western powers had considerable economic superiority, which they used to negotiate terms that were less advantageous to the producing countries. The producing countries, in their turn, began to work closely together to protect their common interest; recent negotiations, resulting in much better terms for the producing countries, have shown the strength of the Organization of the Petroleum Exporting Countries (formed in 1960).

COMMERCIAL PROSPECTS

Asia, with three-fifths of the world's population, has today a disproportionately small share of the world's trade. The trade between the People's Republic of China and the rest of the world is just beginning to grow and—with the lifting of the United States embargo on trade in most commodities—China is likely to have an increasing share of Asian trade. Japan has embarked on a period of growth that may be expected to continue. India is rapidly becoming a major industrial producer. Meanwhile, thanks to the Green Revolution (*i.e.*, the spectacular increase in agricultural yields due to advances in technology), the production of cereals—especially rice in Asia—almost doubled during the latter part of the 1960s. While much of this increased production will be needed to feed the millions of hungry mouths in Asia itself and may reduce the interregional trade in rice, it will also make it possible for Asian countries to make greater efforts toward industrialization and diversification.

The Green Revolution

The trade of Asia with the rest of the world, in percentage terms, is bound to increase in the final quarter of the 20th century. Similarly, trade among Asian countries is also bound to grow. It is likely, however, that there will be a marked change in the pattern of trade, with Asia exporting more finished and semifinished goods as well as raw materials, and also competing with the West in exporting certain types of manufactured products. Even so, there will still be a range of sophisticated products, such as intercontinental aircraft and high-speed computers, which most Asian countries will still find it necessary to import. (C.V.N.)

IX. Demographic patterns

PRESENT POPULATION PATTERNS

Size of population. Asia, covering about a third of the total land area of the world, had a population of about 2,164,000,000, or just over half the world total, in the early 1970s. Asia includes the two countries that in 1971 had the largest populations in the world—the People's Republic of China, with an estimated population of about 732,000,000, and India, with a population of about 550,000,000; these two countries alone had populations that together were estimated to comprise more than a third of the world's people.

Age and sex composition. The age structure of Asia's population, particularly in the developing countries, is predominantly young. Roughly 40 percent of the population is under 15 years of age; about 55 percent is between 15 and 59 years old; and about 5 percent is 60 years old or older. One consequence of this is that the number of dependents—particularly children—is disproportionately large in relation to the number of gainfully employed adults. Another is that, in view of the present high birth rate, the age structure favours large additions in the future to the massive population already in existence.

In nearly all countries of the world, more male than female babies are born. In advanced industrialized countries, where maternal mortality is low and where baby girls receive as much care as baby boys, the male death rates are higher than female death rates at every stage of life; the numerical excess of males at birth is, in consequence, gradually reduced until females outnumber males in the older age groups.

Some Asian countries, particularly India and Sri Lanka, as well as Pakistan and a few predominantly Muslim countries, have a high sex ratio—*i.e.*, the number of males per thousand females—in the sense that males

outnumber females in all age groups, even though in a few categories of the population females predominate at birth. This unusual sex ratio has led to some controversy as to the reasons for it. In some countries, current social attitudes are held to be responsible for the differential mortality rates of the sexes after birth. Early marriages —if not quite child marriages—increase the initial balance in favour of males; the reason for this is the relatively high mortality rate of mothers in childbirth.

Density and distribution. Although it is difficult to generalize about a continent as vast as Asia, certain common features and trends can be mentioned. At the outset it may be pointed out that Japan, which is modernized and Westernized, and Israel, which is virtually a European enclave on Asian soil, are the two best known exceptions to many generalizations.

Regions of high population densities

While Asia and Europe are the two most densely populated continents, Asia is slightly more overcrowded than Europe. The density in Asia is 127 persons per square mile, while that in Europe is 114. The density in North and South America is 28 and 35, respectively, while the comparable figures for Africa and Oceania are 30 and 5. In the United States the density per square mile is about 57, but it is 1,089 in Taiwan and 728 in Japan. The densities of India and Pakistan are about 434 and 318, respectively, while the newly created nation of Bangladesh (formerly East Pakistan) has a population density of 1,361. Kerala state in India has 1,420 persons per square mile, and West Bengal has about 1,310. The island of Java in Indonesia has about 1,365 persons per square mile. The density of China, however, is only about 200 per square mile.

Migration to towns and cities. The distribution of Asia's population has traditionally followed a pattern of dense settlement in river valleys, where soil was fertile because of perennial irrigation, and where double-cropping (the harvesting of two crops a year) sustained large numbers. Today this traditional pattern is still in existence, despite the emergence of another pattern, represented by the attraction of large and congested industrialized cities such as Tokyo, Calcutta, Bombay, Shanghai, and Tientsin—cities to which the underemployed rural population often migrates. The depressed rural economy, the periodic failure of the monsoon, and the near-famine conditions that result have contributed to the continual drift of population to the towns and cities; often, however, the shortage of available jobs results in many unskilled village farmers, who come to the city in search of work, ending up in slums rather than as operators of factory machines.

While haphazard, unplanned urbanization is proceeding in many Asian countries, the population in general remains predominantly (about 70 percent) rural, except in Japan, Taiwan, Israel, and the Philippines.

FUTURE TRENDS

The two variables that determine future trends in the size of population are the birth rate and death rate. The factors affecting the behaviour of these two variables, including birth control, may therefore be examined before indicating possible trends in the size of population.

Birth rates. The world average birth rate during the last half of the 1960s was estimated at about 34 per thousand persons. Africa has the highest birth rate, with 46 per thousand. Asia comes second, with a rate of about 38 per thousand. Within Asia, the birth rates range from 51 per thousand in Pakistan, 49 in Jordan, and 42 in Malaysia to 39 in India, 32 in China, 29 in Ceylon (now Sri Lanka), 27 in Lebanon, and 27 in Soviet Asia. During the 1960s the birth rate was 42 per thousand in West Asia, compared with 33 in East Asia.

Several Asian countries, aware of demographic trends and their adverse effect on economic growth and social progress, have embarked on official birth control programs, which have met with varying degrees of success. Japan's program has perhaps been the most effective. In operation since World War II, it includes well-publicized family-planning services, legalized abortion, and the provision of all forms of contraceptive devices. Programs in China, South Korea, Taiwan, India, and Sri Lanka offer family-planning services, birth-control clinics, vasectomies, and contraceptives (including intra-uterine devices). The Soviet Union has an ambivalent population control policy, and birth rates in Soviet Asia continue to be relatively high. The Southeast and Southwest Asian countries lag behind in formal programs, but public consciousness and basic planning were growing in the early 1970s. It is not yet clear whether or not methods of birth control will be successful in the short term, but the long term effect is expected to show important decreases in the birth rate.

Death rates. A falling death rate and its corollary, a rising life expectancy, are due in a large measure to man's increasing control over disease. The death rate in northwestern Europe and the Soviet Union is less than 10 per thousand persons, whereas the rates in Asia are relatively high—about 20 to 35 per thousand in Nepal and Burma, 20 in Malaysia, about 17 in China, 14 in India, about 12 in Soviet Asia, about 8 in Sri Lanka, and 7 in Japan and Thailand. Medical and public health facilities have a long way to go in much of Southwest Asia, India, Pakistan, and Indonesia before they will equal European standards, but as they improve, the Asian rates will drop still further.

Infant mortality rate

The infant mortality rate—a sensitive index of the standard of living and of the cultural milieu—is also declining in many countries. Compared with an infant mortality rate of between 20 to 35 per thousand live births in northwestern Europe, Canada, and the United States, the rates in Asian countries have dropped, particularly since 1940, to 139 per thousand in India and 125 in Indonesia, 50 in Sri Lanka, 50 in China, 12 in Japan, 21 in Taiwan, and 23 in Israel. The rates in Burma and the Philippines are about 150 and 67, respectively. The present rates offer room for considerable reduction, but it must be remembered that in some parts of Asia they were between 150 and 200 as late as 1940.

Population growth. With the population of most Asian countries increasing at a rate of between 2.5 and 3.5 percent per year, Asians are increasing at a faster rate than Europeans; this was not so during the 18th and 19th centuries. The increase has been caused by the belated health revolution, bringing a dramatic decline in the death rate and particularly in the infant mortality rate. Since, moreover, Asia's population is a young one, the potential for future growth is great.

A declining death rate and a high and slowly declining, if not stationary, birth rate mean that the survival rate is high, yielding huge net annual additions to the population. The population of India, for instance, increased by more than 78,000,000 during the decade from 1951 to 1961 and added some 108,000,000 between 1961 and 1971.

Population projections

At the current rate of increase, according to one estimate, Asia will add another 1,000,000,000 in the decade from 1970 to 1980. By AD 2000, according to one projection, Asia may have more than 60 percent of the total world population, which by then would have doubled to about 7,000,000,000. If Asia reaches 4,000,000,000 to 4,500,000,000 by AD 2000, it is difficult to see how it can afford this enormous increase in the light of its present depressed standards of living and its current rate of economic development; indeed, it is highly questionable whether so many people could exist on the basis of projected available resources. The projections of astounding growth, however, do not account for present and future programs of population control. It may be said that the course of future events in Asia depends primarily on the response made to the challenge posed by the problem of overpopulation. (S.Ch.)

BIBLIOGRAPHY. The works cited below represent only a fraction of the extant literature on Asia, the purpose being to provide a highly selective reading list that bears on some of the topics dealt with in the article itself. Additional references to further literature on a large number of special topics may be found in these works. For a detailed description of the land and people of Asia, see GEORGE B. CRESSEY, *Asia's Lands and Peoples: A Geography of One-Third of the Earth and Two-*

thirds of Its People, 3rd ed. (1963); FRANK M. LeBAR, GERALD C. HICKEY, and JOHN K. MUSGRAVE, *Ethnic Groups of Mainland Southeast Asia* (1964); БОРИС ФЕДОРОВИЧ ДОБРЫНИН *et al., Зарубежная Азия; физическая география* (1956); and *Общий обзор* in *Советский Союз* (1972). Works treating the influence of geographical conditions on political, social, cultural, and economic conditions include: J.E. SPENCER and WILLIAM L. THOMAS, *Asia, East by South: A Cultural Geography,* 2nd ed. (1971); and C.A. FISHER, *South-east Asia: A Social, Economic and Political Geography,* 2nd ed. (1966). OWEN LATTIMORE (ed.), *Silks, Spices and Empire: Asia Seen Through the Eyes of Its Discoverers* (1968), is a readable survey of early travel accounts. For more specialized treatment of specific aspects of some Asian countries, the following works may be consulted: GEORGE B. CRESSEY, *Land of the 500 Million* (1955); KENNETH S. LATOURETTE, *The Chinese: Their History and Culture,* 3rd ed. rev. (1946); ARTHUR L. BASHAM, *The Wonder That Was India: A Study of the History and Culture of the Indian Sub-Continent Before the Coming of the Muslims,* rev. ed. (1963); JAWAHARLAL NEHRU, *The Discovery of India,* 4th ed. (1956); RUTH BENEDICT, *The Chrysanthemum and the Sword: Patterns of Japanese Culture* (1946, reprinted 1967); and GEORGE B. SANSOM, *Japan: A Short Cultural History,* rev. ed. (1943, reprinted 1962). For Eastern religion and philosophy, see KENNETH P. LANDON, *Southeast Asia: Crossroad of Religions* (1949, reprinted 1969); SUKUMAR DUTT, *Buddhism in East Asia: An Outline of Buddhism in the History and Culture of the Peoples of East Asia* (1966); S. RADHAKRISHNAN, *Eastern Religions and Western Thought* (1959) and *The Hindu View of Life* (1957); and JOSEPH M. KITAGAWA, *Religions of the East,* enl. ed. (1968). Works dealing with the varied impact of major European nations upon the peoples of Asia include: K.M. PANIKKAR, *Asia and Western Dominance: A Survey of the Vasco da Gama Epoch of Asian History, 1498–1945* (1953); EDWIN O. REISCHAUER, JOHN K. FAIRBANK, and ALBERT M. CRAIG, *East Asia: The Modern Transformation* (1965); GEORGE B. SANSOM, *The Western World and Japan* (1950); and NORMAN JACOBS, *The Origin of Modern Capitalism in Eastern Asia* (1958). The rise and development of nationalist movements in Asia is dealt with in JAN M. ROMEIN, *Das Jahrhundert asiens: Geschichte des modern asiatischen Nationalismus* (1958; Eng. trans., *The Asian Century: A History of Modern Nationalism in Asia,* 1962); PHILIP WARREN THAYER and WILLIAM T. PHILLIPS (eds.), *Nationalism and Progress in Free Asia* (1956); WILLIAM MACMAHON BALL, *Nationalism and Communism in East Asia,* 2nd ed. rev. (1956); and WILLIAM L. HOLLAND (ed.), *Asian Nationalism and the West* (1953).

Geological history: JOHN W. GREGORY, *The Structure of Asia* (1929); KURT LEUCHS, *Geologie von Asien,* vol. 1, 2 pt. (1935–37); SSU-KUANG LI, *The Geology of China* (1939); JAPAN, GEOLOGICAL SURVEY, *Geology and Mineral Resources of Japan,* 2nd ed. (1960); MASAO MINATO, MASAO GORAI, and MITSUO HUNAHASHI (eds.), *The Geologic Developments of the Japanese Islands* (1965); RAYMOND FURON, *Introduction à la géologie et à l'hydrogeologie de la Turquie* (1953); JOVAN STOCKLIN, "Structural History and Tectonics of Iran: A Review," *Bull. Am. Assoc. Petrol. Geol.,* 52:1229–1258 (1968); AUGUSTO GANSSER, *Geology of Himalayas* (1964); P.V. RAO, "Geology and Mineral Resources of India," *Int. Geol. Congr.,* 22nd session, New Delhi (1964); REINOUT VAN BEMMELEN, *The Geology of Indonesia,* 2 vol. (1949); F.A. VENINGMEINESZ, "Indonesian Archipelago: A Geophysical Study," *Bull. Geol. Soc. Am.,* 65:143–164 (1954); B.M. GOZON, "Geology of the Philippine Islands," *Petrol. Engr.,* 33:B64–66, 69 (1961).

Physical geography: General works include: PIERRE GOUROU, *L'Asie* (1953); R.R. RAWSON and W.G. EAST, *Asia* (1966); RAOUL BLANCHARD, *Asie occidentale,* and FERNAND GRENARD, *Haute Asie* (1929); J. SION, *Asie de moussouns,* 2 vol. (1928–29); and R.R. RAWSON, *The Monsoon Lands of Asia* (1964). Representative photographs of the Asian landscape are presented in MARTIN HURLIMANN, *Asien: Bilder seiner Landschaften* (1956; Eng. trans., *Asia: 289 Pictures in Photogravure,* 1957). The geomorphology of Asia is treated in FRITZ MACHATSCHEK, *Das Relief der Erde,* 2 vol. (1955).

Flora and fauna: L.S. BERG, *Natural Regions of the U.S.S.R.* (1950; Eng. trans. from the 2nd Russian ed., 1938); H.G. CHAMPION, *A Preliminary Survey of the Forest Types of India and Burma* (1936); PHILIP J. DARLINGTON, *Zoogeography* (1957); *Flore générale de l'Indochine,* 7 vol. (1905–52); GUSTAV FOCHLER-HAUKE, "Das Waldkleid un die Pflanzenbezirke Süd-Chinas," *Mitt. Geogr. Ges. Wien,* 78:158–178 (1935); *Forestry in Japan,* issued by the Tokyo Forestry Agency (1964); BUNZO HAYATA, "General Aspects of the Flora of Japan . . .," in *Scientific Japan, Past and Present,* pp. 77–104 (1926); P. LEGRIS, *La Végétation de l'Inde* (1963); LIOU HO, *Lauracées de Chine et d'Indochine* (1934); PAUL MAURAND, *L'Indochine forestière* (1943); F.J. ORMELING, *The Timor Problem* (1955); JULES VIDAL, *La Végétation du Laos* (1956); E.H. WALKER, "The Plants of China and Their Usefulness to Man," *A. Rep. Smithson. Instn.,* pp. 325–361 (1943); WANG CHI-WU, *The Forests of China* (1961); R.O. WHYTE, "The Phytogeographical Zones of Palestine," *Geogrl. Rev.,* 40:600–614 (1950).

Natural resources: E.A. ACKERMAN, *Japan's Natural Resources and Their Relation to Japan's Economic Future* (1953); VIOLET CONOLLY, *Beyond the Urals: Economic Developments in Soviet Asia* (1967); J.A. HODGKINS, *Soviet Power: Energy Resources, Production and Potentials* (1961); M.S. KRISHNAN, *Geology of India and Burma,* 5th ed. (1968); P.E. LYDOLPH and THEODORE SHABAD, "The Oil and Gas Industries in the U.S.S.R.," *Ann. Ass. Am. Geogr.,* 50:461–486 (1960); A.A. MINC, "Geographische Probleme der Ausnutzung der natürlichen Ressourcen in der UdSSR," *Petermanns Geog. Mitt.,* 114:21–28 (1970); "Natural Resources in Malaysia and Singapore," in B.C. STONE (ed.), *Proceedings of the 2nd Symposium* (Kuala Lumpur, 1969); D.B. SHIMKIN, *Minerals: A Key to Soviet Power* (1953) and *The Soviet Mineral-Fuels Industries, 1928–1958: A Statistical Survey* (1963); WANG KUNG-PING, "Mineral Resources of China, with Special Reference to the Nonferrous Metals, *Geogrl. Rev.,* 34:621–635 (1944); R.O. WHYTE, *Grasslands of the Monsoon* (1968) and *Land, Livestock, and Human Nutrition in India* (1968).

Human resources and political geography: W.G. EAST and O.H.K. SPATE, *The Changing Map of Asia,* 4th ed. (1961), is a general political geography; and ALISTAIR LAMB, *Asian Frontiers: Studies in a Continuing Problem* (1968), concentrates on the problem of political frontiers. GUY WINT (ed.), *Asia Handbook* (1969), is a current events summary and detailed fact book dealing with the continent. C.G.F. SIMKIN, *The Traditional Trade of Asia* (1968), discusses the history of the growth of trade between the Occident and the Asian regional zone, often with considerable geographic materials included. W.B. FISHER, *The Middle East: A Physical, Social, and Regional Geography,* 5th ed. (1964), provides the most complete coverage of southwestern Asia; and GEORGE B. CRESSEY, *Crossroads: Land and Life in Southwest Asia* (1960), is somewhat more thematic in its coverage. J.E. SPENCER and W.L. THOMAS, *Asia, East by South: A Cultural Geography,* 2nd ed. (1971), is a full-scale geography dealing with the region from Pakistan through Japan; whereas C.A. FISHER, *South-East Asia: A Social, Economic, and Political Geography,* 2nd ed. (1966); and DONALD W. FRYER, *Emerging Southeast Asia: A Study in Growth and Stagnation* (1970), deal in more detail with the mainland of Southeast Asia and Indonesia–Philippines. RICHARD A. BUTWELL, *Southeast Asia Today—and Tomorrow: Problems of Political Development,* 2nd ed. (1969), concentrates on the problems of political nationalism in the former colonial countries. P.E. LYDOLPH, *Geography of the U.S.S.R.,* 2nd ed. (1970), is a full-scale geography of the whole of the Soviet lands, including Central Asia and Siberia. W.H. PARKER, *An Historical Geography of Russia* (1968), concentrates on the historical geography and expansion of the Soviet political state. EDWARD ALLWORTH (ed.), *Central Asia: A Century of Russian Rule* (1967), is a political-historical study of Russian control of Central Asia; and LAWRENCE KRADER, *Peoples of Central Asia* (1963), is primarily concerned with the historic ethnic groupings of Central Asia.

Resource development: For the continent as a whole, the basic, most authoritative, and up-to-date sources of economic data and information are the publications of the United Nations Economic Commission for Asia and the Far East (ECAFE) and certain other intergovernmental organizations. The *Economic Survey of Asia and the Far East,* prepared and published annually by ECAFE, is the most comprehensive account of the economic situation in the continent as a whole. A multi-disciplinary analysis of the problems of underdevelopment, development, and planning for development in Asian countries will be found in GUNNAR MYRDAL, *Asian Drama: An Inquiry into the Poverty of Nations,* 3 vol. (1968); the countries covered include Burma, Sri Lanka, Cambodia, Laos, Indonesia, Malaysia, Thailand, and Pakistan, but most of the work is devoted to India. The following studies in ECAFE's "Mineral Resources Development Series" may be particularly mentioned in respect to mining and industries: *Mining Developments in Asia and the Far East* (annual); *Mining Developments in Asia and the Far East: A Twenty-Year Review, 1945–1965* (1967); *Lignite Resources of Asia and the Far East: Their Exploration, Exploitation and Utilization* (1956); *Copper, Lead and Zinc Ore Resources of Asia and the Far East* (1960); *Bauxite Ore Resources and Aluminum Industry of Asia and the Far East* (1962); *Tin Ore Resources*

of Asia and Australia (1964); *Mineral Raw Material Resources for the Fertilizer Industry in Asia and the Far East* (1967). Data on mineral resources of China may be found in K.P. WANG, "The Mineral Resource Base of Communist China," in U.S. CONGRESS, JOINT ECONOMIC COMMITTEE, *An Economic Profile of Mainland China*, vol. 1 (1967). ECAFE's studies relating to industries include *Asian Industrial Development News* (annual); *Industrial Development in Asia and the Far East* (1965); *Development Prospects of Basic Chemical and Allied Industries in Asia and the Far East* (1963); and *Industrial Developments in Asia and the Far East: Selected Documents Presented to the Asian Conference in Industrialization*, 4 vol. (1966). Works dealing with industries in China include CHOH-MING LI (ed.), *Industrial Development in Communist China* (1964); FREDERICK M. CONE, *Chinese Industrial Growth: Brief Studies of Selected Investment Areas* (1968); BARRY M. RICHMAN, *Industrial Society in Communist China* (1969); and YUAN-LI WU, *The Steel Industry in Communist China* (1965). The role of small industries in the development effort is discussed in "Modernization of Small Industries in Asia," *Economic Bulletin for Asia and the Far East*, 11:24–40 (1960); and CARL RISKIN, "Small Industry and the Chinese Model of Development," *China Quarterly*, 46:245–273 (1971).

ECAFE's publications relating to the development of power resources include: *Electric Power in Asia and the Far East* (annual); *Proceedings of the Regional Seminar on Energy Resources and Electric Power Development* (1962); and *The Role and Application of Electric Power in the Industrialization of Asia and the Far East* (1965). Projections of future energy requirements are made in the development plans of many countries, but the NATIONAL COUNCIL OF APPLIED ECONOMIC RESEARCH, *Demand for Energy in India, 1960–1975* (1960), may be cited as an early example of non-official estimates. Material relating to the power industry in China includes: YUAN-LI WU, *Economic Development and the Use of Energy Resources in Communist China* (1963); JOHN ASHTON, "Development of Electric Energy Resources in Communist China," in U.S. CONGRESS, JOINT ECONOMIC COMMITTEE, *An Economic Profile of Mainland China*, vol. 1 (1967); and ROBERT CARRIN, *Power Industry in Communist China* (1969). Possibilities and the potential of nuclear power development are discussed in the *Reports* (1959–60) of the Preliminary Assistance Missions sent to several Asian countries by the International Atomic Energy Agency. A list of civilian power reactors in operation or under construction with all pertinent technical data may be found in the INTERNATIONAL ATOMIC ENERGY AGENCY, *Power and Research Reactors in Member States* (published twice a year).

Agriculture: Two among the several publications of the Food and Agriculture Organization of the United Nations (FAO) are: *The State of Food and Agriculture* and *FAO Rice Report* (both published annually). The ASIAN DEVELOPMENT BANK, *Asian Agricultural Survey*, 2 vol. (1968), is another recent comprehensive survey covering most of the continent. A succinct account of Asian agriculture may be found in COLIN CLARK, "Agriculture in Asia," *Pacific Community*, 4: 283–294 (1970); and the ways to improve its contribution to the economy are discussed in "Strategies for Agricultural Growth," *Economic Survey of Asia and the Far East, 1969*, pt. 1A (1970). The agricultural situation in China is described in J.L. BUCK, O.L. DAWSON, and YUAN-LI WU, *Food and Agriculture in Communist China* (1966). The growth in cereals output and its economic and social impact may be found in LESTER R. BROWN, "The Agricultural Revolution in India," *Foreign Affairs*, 46:688–698 (1968); SAM-CHUNG HSIEH, "New Outlook for Asian Agriculture," *International Development Review*, 10:6–9 (1968); UNITED STATES DEPARTMENT OF AGRICULTURE, *Taiwan's Agricultural Development: Its Relevance for Developing Countries Today* (1968); NORMAN E. BORLAUG, "The Green Revolution: For Bread or Peace?" *Bull. Atom. Scient.* (1971).

Commerce: (*Transport*): The status and problems of transport in Asian countries and its role in their economic development is exhaustively dealt with in "Transport Development," *Economic Bulletin for Asia and the Far East*, vol. 11, no. 3 (1960). The Asian Highway Project, designed to connect the capitals and seaports of Asian countries, is described by M.S. AHMAD, "The Asian Highway," *ibid.*, 19:45–48 (1968). Despite its status as a major mode of transport in the rural areas of most Asian countries, not much literature is available on animal transport; the INDIAN PLANNING COMMISSION, *Role of Bullock Carts and Trucks in Rural Transport: Case Studies* (1963), is most valuable. WILFRED OWEN, *Distance and Development: Transport and Communications in India* (1968), is an excellent treatment of the subject for India, as are VICTOR D. LIPPIT, "Development of Transportation in Communist China," *China Quarterly*, 27:101–119 (1966); and YUAN-LI WU, *The Spatial Economy of Communist China: A Study on Industrial Location and Transportation* (1967). (*Trade*): A historical perspective of Asian trade from its remote beginnings may be found in C.G.F. SIMKIN, *The Traditional Trade of Asia* (1968). J.C. VAN LEUR, *Indonesian Trade and Society: Essays in Asian Social and Economic History* (1955), includes a sociological interpretation of early Asian trade. B.G. GHATE, *Asia's Trade* (1948), is a descriptive account of the situation up to the early 1940s; and ALFRED K. HO, *The Far East in World Trade: Developments and Growth Since 1945* (1967), brings the general survey up to 1960. Purely descriptive literature for recent periods is scanty, and what is cited hereafter is more analytical. Among several studies prepared by ECAFE, the following may be particularly mentioned: "Asia's Trade with Western Europe, with Special Reference to the Common Market," *Economic Survey of Asia and the Far East, 1962*, pt. 1 (1963); "Foreign Trade of ECAFE Primary Producing Countries," *Economic Survey of Asia and the Far East, 1959*, pt. 2 (1960); "Trade Between Developing ECAFE Countries and Centrally-Planned Economies," *Economic Bulletin for Asia and the Far East*, 15:16–51 (1964); and "Intra-Regional Trade As Growth Strategy," *Economic Survey of Asia and the Far East, 1969*, pt. 1B (1970). SEIJI NAYA, "The Commodity Pattern and Export Performance of Developing Asian Countries to the Developed Areas," *Economic Development and Cultural Change*, 15: 420–437 (1967), is comprehensive and analytical. Material relating to the foreign trade of China includes: PAULINE LEWIN, *The Foreign Trade of Communist China: Its Impact on the Free World* (1964); and ALEXANDER ECKSTEIN, *Communist China's Economic Growth and Foreign Trade: Implications for U.S. Policy* (1966).

Demographic patterns: GEORG BORGSTROM, *The Hungry Planet: The Modern World at the Edge of Famine* (1965); S. CHANDRASEKHAR, *India's Population: Facts, Problem and Policy* (1967), *Hungry People and Empty Lands*, 3rd ed. (1954), *Population and Planned Parenthood in India*, 2nd ed. (1961), *Communist China Today*, 4th rev. ed. (1964), *Asia's Population Problems* (1967), and *Infant Mortality, Population Growth and Family Planning in India* (1972); C.D. COWAN (ed.), *The Economic Development of Southeast Asia* (1964); KINGSLEY DAVIS, *The Population of India and Pakistan* (1951); PHILIP M. HAUSER (ed.), *Urbanization in Asia and the Far East* (1957); PING-TI HO, *Studies on the Population of China, 1368–1953* (1959); JACQUES M. MAY, *The Ecology of Malnutrition in the Far and Near East* (1961); POLITICAL AND ECONOMIC PLANNING (PEP), *World Population and Resources* (1955); JOHN ROBBINS, *Too Many Asians* (1959); EDGAR SNOW, *The Other Side of the River: Red China Today* (1962); JOSEPH E. SPENCER, *Asia, East by South: A Cultural Geography* (1954); MORRIS B. ULLMAN, *Cities of Mainland China: 1953 and 1958* (1960); United Nations, DEPARTMENT OF ECONOMIC AND SOCIAL AFFAIRS, *Report on the World Social Situation* (1957–), and *The Future Growth of World Population* (1958); and C.K. YANG, *A Chinese Village in Early Communist Transition* (1959).

(C.V.N./P.N.K./Y.K.Y./P.Gu./L.F.deB./Jo.E.S.)

Asia Minor, Religions of

The religions of Asia Minor consist of the beliefs and practices of the ancient peoples and civilizations of the Anatolian Peninsula (modern Turkey), Soviet Armenia, Syria, and north Mesopotamia, including the Hattians, Hittites, Hurrians, Assyrian colonists, Urartians, Phrygians, and Luwians.

SOURCES OF KNOWLEDGE

Until comparatively recent times, the pre-Christian religions of Asia Minor were known only through the works of classical writers, supplemented by coins and the monuments reported by travellers. For the Greeks and Romans, Asia Minor was above all the home of the religion of Cybele, the Great Mother of the cult centred in Phrygian Pessinus. A monument such as the colossal, but much weathered, figure of a Hittite goddess carved high up on the slopes of Mt. Sipylus was of necessity ascribed by the 2nd-century-AD Greek traveller and geographer Pausanias to the Mother of the Gods (a title of Cybele), since no other ancient Anatolian goddess was known to him.

In the 19th century a series of inscriptions renewed interest in the ancient civilization of Asia Minor, and in the 20th century systematic excavations provided his-

torians and archaeologists with vital new facts. The discovery of the royal archives of the Hittites at Boğazköy (ancient Hattusas) in 1907 made available for the first time a mass of indigenous literary evidence for an Anatolian civilization, a civilization belonging to the 2nd millennium BC, before the arrival of the Phrygians. Because of the discovery of these clay tablets, the religion of the Hittites necessarily predominates in any account of the religions of Asia Minor. Later Hittite history has been further clarified by the decipherment of the Hittite hieroglyphic inscriptions on monuments dating for the most part from the early centuries of the 1st millennium BC, after the downfall of Hattusas. For the same period, the cuneiform inscriptions of the kingdom of Urartu in the region of Lake Van contain some information on the religion of that area, though they are mostly concerned with other matters.

The Hittite records at Boğazköy give abundant evidence for a state religious cult. Religious ideals, for instance, are revealed in the prayers offered by various members of royalty and all important state matters, including royal decrees and treaties, were referred to certain deities. The clay tablets testify to a unification of religion and the state, for the state and monarchy were placed under the protection of national deities at the ancient capital of Hattusas.

The clay tablets of Assyrian commercial colonists found at Kültepe, Alişar, and Boğazköy belong to the period immediately preceding the rise of the kingdom of Hattusas, but they contain little information bearing on the life of the indigenous population. For all earlier periods, scholars are dependent on the inarticulate data of archaeology—isolated finds, the interpretation of which leaves a large element of uncertainty.

PREHISTORIC PERIODS

The earliest evidence of religious beliefs has come to light at the mound of Çatal Hüyük, to the south of modern Konya. Here in four seasons of excavations (1961–65), James Mellaart discovered remains of a Neolithic village of mud-brick houses, many of which could be identified as shrines. They are dated by radiocarbon to *c.* 6500–5800 BC (calculated with a half-life of 5,730). Huge figures of goddesses in the posture of giving birth, leopards, and the heads of bulls and rams are modelled in high relief on the walls of some of these shrines. Others contain frescoes showing elaborate scenes such as the hunting of deer and aurochs, or vultures devouring headless human corpses. A series of stone and terracotta statuettes found in these shrines represent a female figure, sometimes accompanied by leopards and, from the earlier levels of excavation, a male either bearded and seated on a bull or youthful and riding a leopard. The main deity of these Neolithic people was evidently a goddess, a mistress of animals, with whom were associated both a son and a consort. Her character is vividly shown by a schist plaque carved to represent two scenes, a sacred marriage and a mother with child. The dead appear to have been excarnated in a mortuary outside the village by exposure to vultures, as shown in the painting, before being buried under the platforms in the houses.

Cults of goddesses

At Hacilar, near Lake Burdur, a somewhat later culture was unearthed by the same excavator, and here again were found statuettes of goddesses associated with felines; but, as in the later levels at Çatal Hüyük, the son or consort is absent.

Entirely different and far removed in time and place are the discoveries at Alaca Hüyük and Horoztepe in northern Anatolia. Here, dating from the latter half of the 3rd millennium BC (*c.* 2400–2200), were found royal tombs richly furnished with artifacts in bronze and precious metals. Beside the heads of skeletons lay female figurines; one such figure found in a grave at Horoztepe represents a mother nursing her child. Many of the objects found in these graves must have had ritual significance. At Horoztepe a bronze sistrum, or rattle, was found. But the outstanding feature of the graves at both sites is the occurrence of bronze standards, which may have been carried on poles. They are open-work objects of circular or occasionally rhomboid form and are adorned with figures of animals (bulls, stags, and, in one instance, felines), birds, flowers, and swastikas and other geometrical patterns. Other standards, consisting of simple statuettes of stags or bulls, also occur.

The archaeological finds of central Anatolia follow immediately after the period of these royal tombs from the Pontic region. Kültepe, near Kayseri, became in the 19th century BC the centre of the Assyrian trading outposts (*kārum*) already mentioned; but from the mound itself, from a level just prior to the foundation of the Assyrian colonies, have come a series of remarkable statuettes. The majority of these are abstract, disk-shaped idols without limbs; many of them have two, three, or even four heads, and others bear on their chests small male figures in relief, in one case accompanied by a lion. There can be little doubt that here again is a representation of a divine family—a mother goddess with consort and child or children. From a level at Boğazköy contemporary with Kültepe comes a limestone mold of a "mistress of animals," a nude goddess standing on a pair of felines and holding aloft an animal in either hand. Molds for a pair of figures, a bearded god and a goddess—the god carries various weapons or emblems, the goddess in most instances holds a baby—have been found at several sites at a somewhat later level.

Though the Old Assyrian tablets are concerned exclusively with commercial matters, the seal impressions that they bear contain a new and elaborate system of religious symbolism (iconography) that later reached its maturity under the Hittites. Here a whole pantheon of deities, some recognizably Mesopotamian, others native Anatolian, are distinguished by such features as dress, attendant animals, weapons, actions, and attitudes. Among them are several weather gods, all associated with a bull, but distinguished in various ways; the weather is depicted in the form of rain falling above the god. A bull alone, carrying an enigmatic pyramid upon its back, sometimes surmounted by a bird, is a particularly common motif and probably symbolizes a weather god. Other deities are a war god holding various weapons, a hunting god holding a bird or hare, a god in a horse-drawn chariot, another in a wagon drawn by boars, a goddess enthroned and surrounded by animals, a nude goddess, and several composite beings. On many seals the deity—and especially the bull with the pyramid—are shown receiving ritual offerings.

RELIGIONS OF THE HITTITES, HATTIANS, AND HURRIANS

An interval of only a few decades separates the end of the Assyrian colony period from the earliest records of the kingdom of Hatti, and for the next five centuries (*c.* 1700–1200 BC) the history of Asia Minor is well documented. The texts reveal a country inhabited by a number of distinct peoples. The Hittites in the centre, the Luwians in the south and west, and the Palaians in the north were speakers of related Indo-European languages. In the southeast were the Hurrians, comparatively late arrivals from the region of Lake Urmia. The Hattians, whose language appears to have become extinct, were most probably the earliest inhabitants of the kingdom of Hatti itself.

Each of these nations had its own pantheon, and individual cult centres had their own names for deities. The result is a bewildering number of divine names, and even when a deity is denoted not by a name but by a logogram (sign or signs standing for a word) to indicate weather god, sun god, moon god, etc., it seems that the deity of each city was regarded by the Hittite theologians as a distinct personality. There are even special weather gods, such as the weather god of the lightning, the weather god of the clouds, the weather god of the rain, the weather god of the palace, the weather god of the royal person, the weather god of the sceptre, and the weather god of the army, each again conceived as a separate personality. These were probably only manifestations or

Types of gods

aspects of a single deity, and this is reflected to some extent in the iconography, the pattern of religious symbolism, in which, as in the preceding period, there is a well-defined and limited number of divine types. Shrines are distributed widely throughout the country.

The pantheon. The most widely worshipped deity of Hittite Anatolia was clearly the weather god, as befits a country dependent on rain for its fertility; and under the title "weather god of Hatti" he became the chief deity of the official pantheon, a great figure who bestowed kingship, brought victory in war, and probably represented the nation in its dealings with foreign powers. Thus the treaty with Egypt is said to be "for the purpose of making eternal the relations which the sun-god [of Egypt] and the weather-god [of Hatti] have established for the Land of Egypt and the Land of Hatti." His name in Luwian, and probably also in Hittite, was Tarhun (Tarhund); in Hattic he was called Taru, and in Hurrian, Teshub. He is associated with the sacred bull and appears on monuments either attended by a pair of divine bulls or driving over mountains in a chariot drawn by bulls. In the cult itself Tarhun may even have been represented by a bull. Often, deities were represented by a symbol on clubs and other weapons. An example is the rock carving of a sword deity in Yazılıkaya (Inscribed Rock) near Boğazköy. A human head tops the hilt, which is carved in the form of four crouching lions.

As Tarhun's spouse, the great goddess of the city of Arinna was exalted as patroness of the state. (Arinna has not been located, but it was situated somewhere in the heartland of the Hittite kingdom, within a day's journey of the capital.) Her name in Hattic was Wurusemu, but the Hittites worshipped her under the epithet Arinnitti. She is always called a sun goddess, and sun disks appear as emblems in her cult, but there are indications that she may originally have had chthonic, or underworld, characteristics. As "sun goddess of the earth" she might be identified with Lelwani, the ruler of the netherworld. The king and queen were her high priest and priestess.

The weather god of another city, Nerik, was regarded as the son of this supreme pair, and they had daughters named Mezzulla and Hulla and a granddaughter, Zintuhi. Telipinu was another son of the weather god and had similar attributes. He was a central figure in the Hittite myths.

Solar and lunar deities

There was also a male sun god, distinct from the sun goddess of Arinna, a special form of whom was the "sun god in the water," probably the sun as reflected in the waters of a lake. His name in Hittite was Istanu, borrowed from the Hattic Estan (Luwian Tiwat, Hurrian Shimegi). There was also a moon god (Hittite and Luwian Arma, Hurrian Kushuh), but he plays little part in the texts. In the iconography, the sun god was represented in the robes of the king, whose title was "My Sun"; the moon god was shown as a winged figure with a crescent on his helmet, sometimes standing on a lion. According to official theology there also existed a sun god or goddess of the underworld. In this place resided the sun on its journey from west to east during the night.

The god who is known from the Kültepe seals as the god of hunting appears frequently on Hittite monuments; he holds a bird and a hare, as at Kültepe, and he stands on a stag as his sacred animal. From descriptions of the statues it appears that this is the deity denoted in the texts by the logogram KAL, perhaps to be read Tuwata, later Ruwata, Runda. The war god also appears, though his Hittite name is concealed behind the logographic name ZABABA, the name of the Mesopotamian war god. His Hattic name was Wurunkatti, his Hurrian counterpart Astabi. His Hattic name meant "King of the land."

The Hittite goddess of love and war is similarly disguised under the logogram of the Babylonian ISHTAR; she was evidently much revered and was the special protectress of Hattusilis III. Her Hurrian name was Shaushka. As a warrior goddess she was represented as a winged figure standing on a lion with a peculiar robe gathered at the knees and accompanied by doves and two female attendants.

There was a mother goddess, Hannahanna "the grandmother," closely associated with birth, creation, and destiny, but the theologians appear to have regarded her as a minor deity.

It is impossible to enumerate the lesser deities, many of whom are mere names to scholars. Among them were deities of many mountains, rivers, and springs, and the spirits of past kings and queens who had "become gods" at death. Demons are conspicuous by their absence; sickness and misfortune were ascribed either to sorcery or to divine retribution.

During the later years of the Hittite kingdom, the state cult came under strong Hurrian influence. The sun goddess of Arinna and the weather god of Nerik were identified with the Hurrian queen of the gods, Hebat, and her son, Sharruma; and at a holy place near the capital (now named Yazilikaya), where a rocky outcrop forming a natural open chamber was adorned with a series of 64 bas-reliefs that represented the national pantheon, every identifiable deity bears a Hurrian name, written in Hittite hieroglyphs. The central group is recognizable as the family of the sun goddess, but she is named Hepatu, her son Sharruma. They both stand on felines, she, perhaps, on a lion or lioness, and he on a panther. The Hittites had here already begun a process of assimilation.

Gods and men. The gods were imagined to have their own lives, though also needing the service of their worshippers, who in turn were dependent on the gods for their well-being. They lived in their temples, where they had to be fed, clothed, washed, and entertained. Part of their time, however, might be spent in heaven or in roaming the sea or the mountains. They might withdraw in anger and so cause life on earth to wither and cease. One of the most characteristic rituals of the Hittites was the invocation by which a god who had absented himself was induced to return and attend to his duties by a combination of prayer and magic.

The relation between man and god resembled that between servant and master. "If a servant has committed an offence and confesses his guilt before his master, his master may do with him whatever he pleases; but because he has confessed his guilt . . . his master's spirit is appeased and he will not call that servant to account." Confession and expiation form the main theme of the extant royal prayers.

Divination. Divination, through which the cause of divine displeasure was ascertained, was of three kinds: augury (divination by flight of birds), haruspicy (divination by examining the entrails of sacred animals), and dice throwing, arts said to be practiced respectively by the "bird-watcher," the seer, and the "old woman." The omens, as interpreted by these experts, were either favourable or unfavourable, and would give a yes or no answer according to the sense of the question put to them. In this way, by a lengthy process of elimination, it was possible to determine the precise offence that required expiation. Divination was a science inherited by the Hittites from the Babylonian seers. Signs of the peoples' fate were thought to be sent by the gods, manifested in unusual occurrences. Haruspicy, as noted, was one of the most popular practices of divination. The liver and viscera of the sacrificial victim were examined, and according to their configuration it was decided whether the omen was favourable or unfavourable. Records of these practices have survived in large numbers, but they are also among the worst written of the Hittite tablets.

Sacrifices and festivals

The cult. The proper conduct for temple personnel was laid down in a tablet of instructions that gives some insight into the organization of a temple. Divine vengeance is threatened against those who misappropriate food or drink brought for sacrifice, who admit unclean animals or unauthorized persons into the temples, who purloin vessels or implements belonging to the god, who

fail to celebrate festivals at the proper time, and who desert their posts to spend the night with their wives.

Many extant texts consist of descriptions of festivals in which the king or queen is the chief officiant. These festivals were numerous, but their names are largely unintelligible. Many of them were seasonal. The preliminary details, such as the robing of the king and his entry into the temple, accompanied by various dignitaries and by musicians playing their instruments, differed little from one festival to another. Owing to the very large number of fragmentary texts, it has not yet been possible to discern special characteristics of the festivals. They invariably culminated in libations and frequently in a cultic meal. One such festival lasted 38 days and involved celebrations in a dozen different cities.

Burial customs. The tablets from Boğazköy have yielded much information about the burial practices of the Hittites. One tablet tells of a burial ritual for a king or queen that lasted 13 days and in which the body was cremated. In the usual Hittite fashion, the body was initially burned and the fire extinguished with potable liquids. The bones were then dipped in oil or fat and wrapped in cloth. A feast followed their placement on a stool in a stone chamber. Although cremations were practiced to a great extent, burial of the body in an earthen grave was not uncommon. In 1952 Kurt Bittel excavated a site near Yazılıkaya close to a natural rock outcrop. The site contained 72 burials, 50 of which were cremations. There was no indication to show that cremations were exclusively the right of the elite.

Mythology. In Anatolia itself myth seems to have remained on a rather primitive level and is mainly to be found embedded in magical or ritual texts. Writings of this type constituted a large portion of Hittite literature and indicate the prevalance of both black and white magic. Myths were consequently associated with magical rituals aimed at curing diseases, ensuring good fortune, dispersing evil spirits, and the like.

A particularly well-attested type of myth occurs in connection with the invocation of an absent god and tells how the god once disappeared and caused a blight on earth, how he was sought and found, and eventually returned to restore life and vigour. In one such myth the weather god withdraws in anger and the search is conducted by the sun god (whose messenger is an eagle), the father of the weather god, his grandfather, and his grandmother Hannahanna. In another, it is Telipinu who is angry, and the gods who search are the sun god, the weather god, and Hannahanna, the grandfather being omitted. In both these versions, the missing god is found by a bee sent forth by Hannahanna. In another similar story, the sun god and Telipinu are both missing, not from anger, but because they have been seized by "Torpor," which has paralyzed nature. In yet another version, the weather god of Nerik is said to have gone down to the netherworld through a hole in the ground, apparently the hole from which the river Marassantiya (modern Kızıl Irmak) gushed forth, which suggests that this weather god may really have been a god of the underground waters.

Another myth, the "Slaying of the Dragon," connected with the Hattian city Nerik, was apparently recited at a great annual Spring festival called Purulli. It tells how the weather god fought the dragon and was at first defeated, but subsequently, by means of a ruse (of which there are two quite distinct versions), succeeded in getting the better of him and killing him. The ritual associated with this tale has not been identified but its primitive character establishes it as folklore.

Other mythological tales of Hittite and Hattian deities existed, but they are too fragmentarily preserved to give any connected story.

The elaborate epic of the struggle against Ullikummi, and the *Theogony,* though written in Hittite, are Hurrian in origin and refer to Hurrian and even Mesopotamian deities. The *Theogony* tells of the struggle for kingship among the gods. Alalu, after holding the kingship for nine years, was defeated by Anu (the Babylonian sky god) and went down to the netherworld. Anu in his turn, after nine years, gave way to Kumarbi, a Hurrian god, and went up to heaven. Eventually the weather god Teshub was born, and though the god KAL apparently reigned for a period, and the end of the tale is lost, it is certain that Teshub was the final victor, for there are many allusions to the "former gods" who were banished to the netherworld by him. The conception itself derives from Babylonia.

The "Song of Ullikummi" tells of a plot by Kumarbi to depose Teshub from his supremacy by begetting a monstrous stone as champion. Ullikummi, the stone monster, grows in the sea, which reaches his waist, while his head touches the sky; he stands on the shoulder of Upelluri, an Atlas figure who carries heaven and earth. Teshub is warned of the danger and goes out to battle in his chariot drawn by bulls, but he fails and appeals for help to Ea (Babylonian god of wisdom). The latter orders the "former gods" to produce the ancient tool by which heaven and earth had once been cut apart (the only surviving hint of a Hittite creation myth), and with this he severs Ullikummi from the giant and so destroys his power. Again the end is lost, but it is certain that the final victory went to Teshub.

RELIGIONS OF SUCCESSOR STATES

When Hattusas fell, *c.* 1180 BC, the Luwians moved eastward and southward into Cappadocia, Cilicia, and North Syria. Here they formed a number of small successor kingdoms. Shortly afterward the Phrygians crossed the Bosporus from Thrace and occupied the centre of the Anatolian plateau, cutting off in the extreme southwest a remnant of the Luwian people, who became known as the Lycians and maintained their reverence for the Luwian gods Tarhun, Runda, Arma, and Santa into classical times.

The East Luwians, whose rulers used the Hittite hieroglyphic script to record their deeds, worshipped these same deities; but their chief goddess was Kubaba, who hardly appears in the archives of Hattusas except as the local goddess of Carchemish in Syria. Her prominence was due to political factors, for Carchemish was then the leading Hittite city.

The traditional Hittite iconography survived, but was gradually permeated by Aramaic and Assyrian influences. Orthostats (stone slabs set at the base of a wall) from Malatya on the Euphrates show Tarhun in his bull-drawn chariot receiving libations from a king dressed in his traditional robes, and there is a relief showing his battle with the dragon. At Carchemish was found a representation of the winged moon god with the sun god, both standing on a single lion. Kubaba on a stela appears enthroned, the throne resting on a lion. Runda (the Hittite Tuwata or KAL) is regularly symbolized by a stag's head or antler.

Urartu. In the far east of Anatolia, the Hurrian nation formed around Lake Van a new kingdom, which rose to considerable power, *c.* 900–600 BC. With few exceptions, the cuneiform inscriptions of this kingdom of Urartu are historical and reveal nothing of its religion, except the names of deities. The national god was Haldi, and he is associated with a weather god, Tesheba, a sun goddess, Shiwini (compare Hurrian Teshub and Shimegi), and a goddess, Bagbartu (or Bagmashtu). Haldi is represented standing on a lion, Tesheba on a bull, Shiwini as a goddess holding a winged sun disk above her head. The cult was practiced not only in temples (one of which is shown in detail on an Assyrian relief) but also in front of rock-hewn niches in the form of gates through which the deity was probably believed to manifest himself.

The Phrygians. Little would be known of the religion of the Phrygians but for the fact that in 204 BC the Roman Senate, on the instructions of the priests, who had consulted the Sibylline books, had the sacred black stone of the Phrygian mother goddess, Cybele, or Cybebe, transported from Pessinus, together with her priests, and installed in a temple on the Palatine. As a

Cybele

result, there is much information about the cult and its mythology, though it must be remembered that during 200 years of Persian rule Anatolia had been exposed to many alien influences from the east, which may have affected this cult.

The high priest of Cybele was given the name of Attis, and—at least in later times—she was attended by a band of fanatical devotees called *galli*, whose orgiastic dancing, at the climax of which they castrated themselves in their ecstasy, was notorious.

The cult myth of these rites told how Cybele (known at Pessinus as Agdistis, from Mt. Agdos in the vicinity) loved a beautiful youth named Attis. According to the earliest version, Attis was killed, as was the Syrian Adonis, by a boar. All later versions, however, refer to wild revelry and castration. Agdistis is a bisexual monster who is trapped by Bacchus and castrated; Attis is betrothed to a daughter of Midas (or Gallus, the king of Pessinus); the wedding guests are driven mad by Cybele, and first Gallus, then Attis, castrates himself, the latter as he lies beneath a pine tree; in one version Attis is turned into a pine tree. A poem by Catullus describes how a young Greek wanderer named Attis was caught up in the revels and sacrificed his virility, only to be prostrated later with remorse. The "Phrygian rites" introduced into Rome by Claudius included the ceremonious felling of a pine tree to represent the dead youth and its transport in procession to the temple. Still later, the taurobolium (sacrifice of a bull) and the belief in the resurrection of Attis were added to the cult.

How much of this myth belonged to the original cult of the Phrygian mother goddess is questionable. Herodotus, in describing the celebration of the rites by the legendary Scythian sage Anacharsis, mentions only that he did so in a grove, that he carried a timbrel (a small hand drum or tambourine), and fastened images about his person. There is no suggestion of orgiastic rites.

In Asia Minor itself, the cult of Cybele is marked by carved rock facades with niches or by rock-hewn thrones, on which the statue would be set; in front of these, the rites were celebrated in the open air. Cybele was a goddess of the mountains, out of which she was believed to manifest herself to her devotees. Representations of the goddess show her in her niche, sometimes flanked by lions, draped in a long garment and wearing a high polos (cylindrical crown or headdress) or with bared breasts and flanked by musicians. Her name and her association with the lion cannot be separated from the Hittite Kubaba, whose cult had spread from Carchemish to the borders of Phrygia; but the process by which this matronly figure was transformed into the Mountain Mother of the Phrygians can only be surmised.

The goddess Ma of Comana, despite her name (Mother), was regarded at least by the Romans as a deity distinct from Cybele and identified with the war goddess Bellona. Her relationship to the ancient Hittite-Hurrian goddess Hebat of Kummanni (=Comana) remains obscure, for there is no evidence that the latter was a goddess of war.

The god Men, who appears on numerous monuments of the Hellenistic period, was an equestrian moon god, later identified with Attis and with the Thracian Sabazius. He is basically the Persian moon god Mao, as (Artemis) Anaitis is the Persian Anahita.

SUMMARY

Asia Minor shows a remarkable continuity in its worship. From the Neolithic Age, for 6,000 years, the population venerated a divine pair, mother goddess and weather god, the former in association with the lion, the latter with the bull; a divine son, associated with the panther; and a god of hunting whose symbolic animal was the stag. To the ancients, for whom the essence of a thing lay in its name, this continuity was less obvious than it is today. The many names under which the deities were known at different times and places appear to us of less significance, in a religious sense, than the constancy of the types.

Asian Peoples and Cultures

Asia, a geographical term defining a major continent, is characterized by too little or too much: too little precipitation or too much; too many people or too few; too much central government control, or not enough to foster grass roots development; overindulgence or undernourishment; Playboy clubs coupled with poverty; Nobel Prize winners and massive illiteracy.

Asian diversity

Asia contains most physical varieties of modern man: Mongoloids, Caucasoids, Australoids, blacks, Negritos, and mixtures of all these.

Linguistically, Asia also embraces most major non-African language families: Indo-European, Uralic-Altaic, Sino-Tibetan, Austro-Asiatic (including Munda, or Kolarian), Dravidian, Tai-Kadai, Malayo-Polynesian.

Buddhism, Confucianism, Hinduism, Islām, Judaism, and Christianity have competed ideologically and politically. Shamanism, a belief in demons and ancestral spirits reached by the medium of diviners called shamans, and also localized nature worship of various types overlie the major religions, partly because widespread illiteracy among the people denies them access to religious literature.

Geography and ecology vary as much as the people, ranging from the highest mountains on Earth to the almost sea-level deltas of South and Southeast Asia, and from the Central Asian steppes and deserts to the north, where forest steppelands blend into taiga.

ASIAN CULTURAL TYPES

Common characteristics. All Asian nations have moved toward some sort of industrialization or economic diversification, but most peoples live at agricultural subsistence levels in peasant and tribal milieus. Such societies have attributes and attitudes 180° from those of the pluralistic, industrialized, highly specialized, multi-institutional societies of the West. Five major factors deserve consideration:

1. Illiteracy and linguistic diversity. Most Asians cannot read and write, and literacy constitutes an important tool in any people's cultural tool kit. Even if all Asians could read and write, linguistic diversity would still foster divisiveness. Usually, language and ethnic group tend to coincide, and regional linguistic affiliations are major cohesive factors.

2. Basic food production. Most Asians spend most of their time engaged in basic food production, either agriculture or herding, or combinations of the two. An interesting correlation appears to exist between the percentage of illiterates and the percentage of agriculturists and herders in Asian societies.

3. Lack of mobility. Emphasis on the group rather than on the individual results in a relative lack of social, eco-

nomic, and political mobility in Asian societies, the most intensive manifestation being the Hindu caste system.

Rural orientation

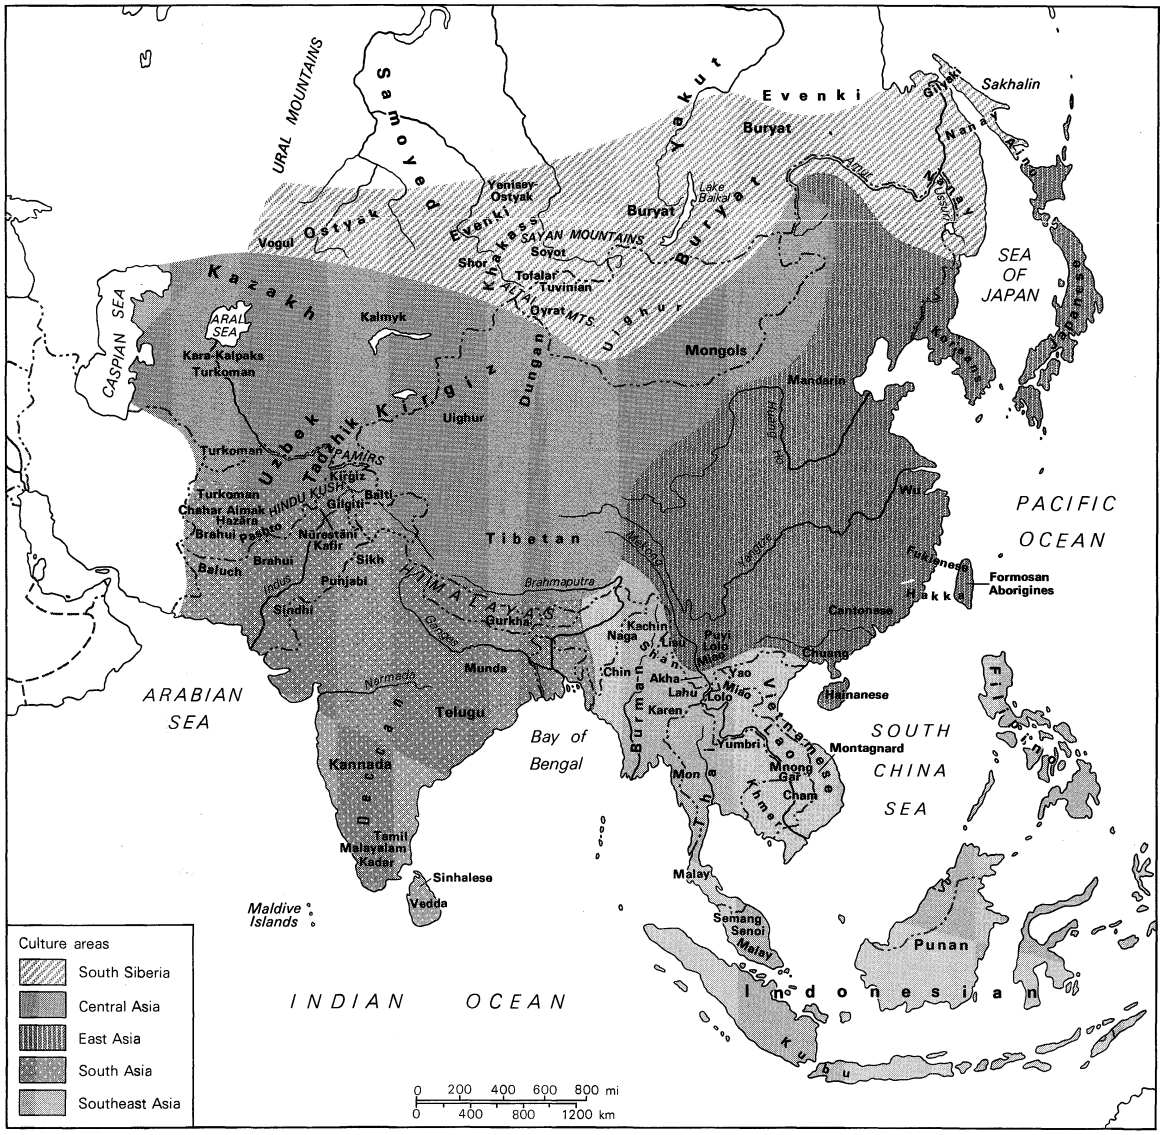
Endogamous marriage patterns dominate—that is, persons marry strictly within their group or class. Even exogamous peoples—peoples requiring marriage outside the group—usually select mates within a tightly defined set of alternatives. Economically, men and women usually follow the occupations of their parents; politically, people are born into statuses of leaders or followers (only on rare occasions have peasants become kings and vice versa). Lack of mobility helps hold people to the land and perpetuates existing leadership patterns, both essential in the survival economic patterns of Asia—in contrast to the surplus economic situation in the West. When the individual (or his family group) moves to the city, he often remains rural oriented, even though urban based. Even nomads, in spite of physical migration, lack fundamental mobility, for they move along the same routes from year to year.

4. Absence of adolescence. In Western societies, adolescence is primarily a time of learning, away from the family, in order to prepare the individual for entrance into an ultraspecialized, multi-institutional situation. In Asian society, however, the individual usually lives in a generalized, uni-institutional society: the extended family and other structured, hierarchal tribal units. Socialization of the Asian child takes place inside the family, and the child becomes an adult almost overnight, with a full range of social, economic, and political responsibilities. While the father–mother generation (the present) forms the economic unit, the grandparents (the past) teach the children (the future) about their history, customs, and values. Economic roles are usually learned from parents and older brothers and sisters. The gradual introduction of formal educational systems based on literacy has affected these patterns in varying degrees, however, and young urban literates now often reject the idea of having respect for age.

5. Kinship in place of government. Few central governments in Asia can replace the network of reciprocal social, economic, and political rights and obligations that are currently vested in kin units. In the past, outsiders have come to the rural area to extract taxes, rents, slaves, conscripts for armies, and women for harems. Peasants continue to resist penetration into their areas, often using passive resistance; tribesmen and nomads usually resist violently.

The concept of ecological time also forms an important pattern, in which people adjust to the annual cycle of nature unencumbered by the artificial time units established to control and limit Western economic and noneconomic activities.

All the attributes sketchily discussed above tend to perpetuate an "inward-looking" society in which men and women are born into a "set of answers." In the pluralistic, ultraspecialized, developed world of the West, men and women are born into a "set of questions," or an "outward-looking" society.



Distribution of Asian peoples and cultures.

General settlement patterns. Among other factors, ecology, technology, and historical accident influence settlement patterns and crystallize Asian peoples into two general categories, sedentary and nonsedentary. Interactional patterns include linked networks between sedentary villages, towns, and cities and their relationships with nomads, semi-nomads, and semi-sedentary groups. Numbers of peoples in Asian Siberia still support themselves by hunting, trapping, fishing, and logging, travelling with the season. Fishing villages abound in all Asian areas having access to such large bodies of water as oceans, lakes, rivers, and inlets. Pockets of hunters and gatherers still roam the hills and forests of South and Southeast Asia.

Sedentary patterns

Two sedentary patterns exist: the linear type is common wherever villages and towns string out along major rivers that usually serve as highways; the nuclear type is more common in drier and mountainous areas and grew in response to needs for water and defense, with several villages clustering about a town and several clusters of village–town nuclei hovering around cities.

Villages are usually self-sufficient subsistence units but obtain many commodities and all luxuries from either town bazaars, travelling peddlers, or nomadic traders. (Some villages, though, will have small bazaars catering to local, daily needs.)

Towns generally occur wherever several major trails intersect, usually near a large river, oasis, or other major source of water. For the villages, the town usually constitutes the commercial, administrative, and communications centre. Often villagers bring raw materials, local craft products, and agricultural produce to town bazaars by donkey, horse, camel, or human back, or by boat if on a waterway. Goods are shipped from the town by truck, camel, oxcart, or donkey or, again, by boat if waterways form a major part of the transportation network.

The town bazaar (often held only one or two days a week) also acts as a disseminator of news, but cheap transistor radios have brought about a revolution in communications. Most villages have at least one, and even nomads move from pastureland to pastureland with battery-powered radios blasting away.

Full-time specialists in the towns (relatively few exist in villages), such as ironworkers, carpenters, weavers, dyers, tailors, shoemakers, masons, general storekeepers, butchers, bakers, bicycle repairmen, automotive repairmen, and caravansary owners, generally live above their shops (or near them) in the bazaar; in other words, a unity of occupation and residence is the pattern for most Asian towns. Also in the towns are the headquarters of lower grade civil servants and quasi-military police, representing the state. Often absentee landowners live in the town.

Where main commercial routes have met and permitted easy access to the outside world, cities have sprung up. The city, therefore, is a major commercial, administrative, and communications centre, linking the interior with the outside world. Large guildlike groups of specialists live in separate sections of the bazaar in the "old city." Individual artisans—and, more recently, factories—produce items for export and for sale in the town bazaars. In addition, more and more groups migrate seasonally to towns and cities to take advantage of new job opportunities brought about by post-World War II development processes. Some remain in the cities to make Asia's urban problems annually grow more acute.

To handle the growing administrative problems, "new cities" spring up alongside the "old," often separated by a river. Government officials, the growing entrepreneurial class, foreign diplomats, and development technicians usually live and work in the new city, while the bazaar and the bulk of the population remain in the old. Elected (or appointed) parliaments sit in the capitals and sometimes the provincial centres, and courts administer justice based on myriad legal codes. Most Asian peoples, however, prefer to have as little contact with government officials as possible.

Sedentary farmers are agriculturists who live permanently in the same village and leave only when forced to or in order to accept a better farming opportunity. Semi-sedentary farmers are either agriculturists who own enough livestock to be moved in the summer to highland pastures or agriculturists who move to the fields at harvest time and live in portable huts.

Nomadism

Nomads are herdsmen who move as a group from summer to winter pasturages and back again. Steppe and desert nomads often move great horizontal distances; nomads near mountains usually move vertically to alpine grasslands in the summer and plains grasslands in the winter. Few nomads move constantly—only seasonally.

Semi-nomads are herdsmen who practice some agriculture. A sizable part (more than 50 percent) of a semi-nomadic group will move with the livestock to summer pasturages, while the remainder tend crops in the winter headquarters. Their movements, primarily vertical, usually cover much shorter distances than those of true nomads. (Seasonal nomadism or semi-nomadism, it may be noted, is also called transhumance.)

Throughout history, competition for land between sedentary and nonsedentary peoples has caused nomads, voluntarily or involuntarily, to evolve into semi-nomads or semi-sedentary peoples but seldom fully sedentary unless under duress. Most nomads and semi-nomads have many functional, symbiotic relationships with villagers along their routes of migration. Livestock furnishes meat, dairy products, and wool, which the nomads often trade for grains, vegetables, fruits, and nuts. Moneylending becomes a major economic activity of wealthier nomads. Even landowning village farmers often need extra cash for such life-cycle ceremonies as birth, circumcision, marriage, and death: nomads happily lend money at exorbitant rates. Some farmers also purchase trade goods from nomads on credit. Unable to repay, the farmer sometimes loses his land and becomes a tenant to the nomads, who then collect annual rents as they pass through the village.

Often, nomadic groups have traditional grazing rights in lands owned by specific villages. While grazing on the grain stubble, their flocks deposit vast quantities of dung, later plowed under to replace nitrogen lost in the soil. Animal dung remains a primary source of fuel, as well as fertilizer. In the Soviet Union, however, planners in the 1930s considered the nomads parasites and either collectivized or eliminated them, thus in the process eliminating the natural fertilization. This is one reason why the attempted cultivation and exploitation of the "virgin lands" of Kazakhstan has yet to succeed.

Intelligently conceived, vigorously implemented, long-range programs to supplement land reclamation and improved agricultural practices would benefit both nomads and villagers, but the elimination of the economically valuable—and maligned—goat would probably not improve the situation.

ASIAN CULTURE AREAS

Within each area of Asia, different peoples and their patterns can be identified, described, and classified together in many ways. The following represents simply one of many useful classifications.

Southern Siberia. Located south of the circumpolar culture area and east of the Ural Mountains, southern Siberia lies in a transitional area in which tundra or treeless plain becomes taiga or swampy coniferous forest. Farther south, the taiga blends into a forest steppe with alternating stands of trees and open, seasonal grasslands. Summers, except in the extreme south, are too short to permit agriculture; spring floods often inundate the taiga. Farther north are the Altai (Kirgiz) and Sayan (Kazakh) mountains, which abut Central Asia in the west and the Mongolian People's Republic in the east. Farther east are the mixed broadleaf forests of the Amur–Ussuri valleys, with hot summers and severe winters. The Pacific maritime coast and Sakhalin Island complete the geographic picture. The northeastern region of China (formerly called Manchuria) sits to the south.

Mongoloids of Siberia

The indigenous populations are primarily Mongoloid racially, although generally they are outnumbered in most areas by Russian, Ukrainian, and Belorussian immigrants. The aborigines still live mainly in separate,

virtually endogamous villages, though many groups (including reindeer herders) have been collectivized by the Soviets. They speak several languages and dialects of the Uralic-Altaic family, among them Samoyedic, Tungusic, Mongolian, and Yakut (or other Turkic dialects).

The main economic pursuits include small-scale reindeer herding (seven to ten reindeer per herd, small when compared to groups farther north), hunting (deer, elk, squirrel), trapping (sable, fox), and fishing. Traditionally, the inhabitants have lived either in longhouses and semi-subterranean huts in permanent villages or in conical, bark-covered tepees at temporary campsites and, for transportation, have used canoes, rowboats, skis and snowshoes, sleds drawn by reindeer or dogs, and, in the east, horses. Many aborigines now work in mines and other Siberian industrial projects.

Most aboriginal groups are small. The 80,000 Evenki (Tungusic-speaking reindeer herders), for example, live and wander in an area about the size of the continental United States.

Central Asia. Central Asia extends from western Manchuria to the Caspian Sea, along the grasslands, mountains, and plateaus of Inner and Outer Mongolia, Tibet, the Central Asian Muslim republics of the U.S.S.R. (Kirgiziya, Tajikistan, Uzbekistan, Kazakhstan, and Turkmenistan), and Afghanistan north of the watershed of the mountain range of the Hindu Kush. An interesting man-made boundary, the Great Wall of China, exists in the east. Altitudes and local ecology vary considerably from region to region and even within regions. The western Turkistan deserts and steppes lie close to sea level, whereas the upland Mongolian steppes often exceed 5,000 feet (1,500 metres) above sea level. Basically, Central Asia is an arid zone that has inland drainage and a continental climate.

Mongoloids of Central Asia

Racially, all Central Asians are Mongoloid variations, more Caucasoid to the west (Slavic) and southwest (Mediterranean subvariant). Most speak Uralic-Altaic languages—usually Turkic dialects but also Mongolian. Other language families include Sino-Tibetan (Tibetan in Tibet and Chinese near the eastern and southern borderlands) and Indo-European (Tajiki and Dari Persian). Cyrillic has replaced the Arabic script in Soviet Central Asia and Mongolian in Mongolia. Inner-Mongolians now use streamlined Chinese characters, but Tibetans, though under great pressure from the Chinese, cling to their own traditional script.

Islām pressed into Central Asia early in the 8th century AD, culminating in the Arab sack of Samarkand in 712. Most people as far east as Outer Mongolia and south into Chinese Sinkiang became Sunnī Muslims, constituting the main orthodox school of Islām, but pockets of Ismā'īlīs, who consider the Aga Khan as their leader, live scattered in such mountainous areas as the Pamirs and the Hindu Kush. Buddhism centring on teachers known as lamas and heavily laden with animistic and shamanistic beliefs and practices dominates Tibet and neighbouring parts of Mongolia and China. Anti-religious drives by the Communists of the U.S.S.R. and China have been only partly successful.

Often called the belt of "pastoral nomadism," Central Asia also includes sizable sedentary agriculturists, usually existing in the loose-knit symbiotic system described earlier, with modifications wherever Communism has introduced collectivization of herds and land. Political ties are largely kin oriented, and a loosely stratified class system exists along with a hereditary nobility. Slavery was common until the Russians and British virtually wiped it out in the 19th century. Mongol nomadic patterns dominate: groups move year-round, more horizontally than vertically, but within well-defined territories; there are comparatively few fixed economic centres (bazaars and towns).

Local ecology greatly influences livestock distribution. Fundamentally, sheep and goats are mountain animals (though sheep prove to be less adaptable than goats and tend to flounder in snow); cattle and camels appear more numerously in transitional forest steppes and semideserts. Yak and yak–bovine hybrids become important in the Pamirs and the higher mountains of Sinkiang, Mongolia, and Tibet. Donkeys and mules are found mainly in the west, where Central Asia nudges the Middle East. Horses, prestige animals throughout Central Asia, are ridden, and sometimes their milk is drunk, often as *kumys* (fermented mare's milk).

South Asia. South Asia includes the territories of southern Afghanistan, Pakistan, India, Nepal, Sikkim, Bhutan, Bangladesh, Sri Lanka (formerly Ceylon), and the Maldive Islands. From the permanent glaciers of the highest mountains on Earth to the lush hilly jungles of Sri Lanka, and from the barren deserts of Afghanistan to the intricate delta networks of the Brahmaputra River of Bangladesh, four major geographic features dominate the South Asian landscape: the Himalayas, the Indo–Gangetic Plains, the Deccan, and the Indian Ocean. All these centre in India, itself divided by the Narmada River into two major ecological north–south zones. The seasonal monsoonal winds play important roles in most South Asian ecosystems, each monsoon having two phases—the northeast monsoon (January to February cold; March to mid-June hot) and the southwest monsoon (mid-June to mid-September rain; mid-September through December ebbing monsoon).

Caucasoid and Mongoloid in South Asia

India is the easternmost wing of the Caucasoid racial region; Mongoloid influences, however, occur in areas bordering Central Asia, especially in central and northern Afghanistan, Pakistan, Kashmir, Nepal, Sikkim, and Bhutan, in northeastern India, and in eastern Bangladesh. Darker skins occur as one moves south and southeast toward India.

In India, particularly in the south, the higher castes usually have lighter skins than do the lower or peasant castes. In the central hills of India live small bands of Negrito-like hunters and gatherers. The few hundred surviving unmixed indigenous hunters and gatherers of Sri Lanka are primarily Caucasoid but with some Australoid characteristics. Some Mongoloid-looking peoples live over 4,000 feet (1,200 metres) above sea level, but basically, the people of Sri Lanka are dark-skinned, slender Caucasoids. Two interesting Caucasoid subvarieties occur in Punjab (India), Nūrestān (Afghanistan), and Chitrāl (Pakistan): the Nūrestāni and the Kafirs of Chitral, who speak Kafiri dialects of Indo-European, have a high frequency of blond characteristics (almost one-third of the population), and the Punjabi-speaking Sikhs are usually deemed the hairiest people in the world.

Four great language families embrace all the dialects spoken in South Asia: Indo-European (mainly north of the Narmada River and across the whole range of South Asia), Dravidian (mainly south of the Narmada River), Sino-Tibetan (on the northeastern borders), and Austro-Asiatic, including Munda, (some hill tribes of India and Bangladesh). In India itself, the geographical and cultural heart of South Asia, over 500,000,000 people speak 14 official languages, divided into about 80 principal dialects and about 550 subdialects. English still functions as the lingua franca for the intelligentsia of India, Pakistan, Bangladesh, and Sri Lanka.

Sanskrit influences most regional languages in India; all with written traditions are written in Devanāgarī or related scripts derived from Sanskrit—except for Tamil, a distinctive script, and Urdu, which uses the Perso-Arabic script, as do the Indo-European languages of Afghanistan and Pakistan.

Hinduism, Islām, and other religions

Hinduism and elements of caste permeate most of the South Asian cultural scene. The Indian government has outlawed caste, but, like racial discrimination elsewhere, caste refuses to be effectively cowed by legislation. Islām, basically an egalitarian religion, entered the Indian subcontinent in the early 8th century AD. Mass conversions to Islām mainly involved "untouchables" and low-caste Hindus; the Muslim elite grew out of the conquering Islāmic armies. Change of religion, however, did not automatically change economic, political, or social status, and caste elements remain strong among Muslim groups in India, Bangladesh, and Pakistani Punjab and Sind. Occupational caste names refer to local groups, and, although men often freely change occupational and politi-

cal affiliations, endogamy is still the pattern, and social status remains largely group oriented.

The several other religions in South Asia include over 10,000,000 Christians scattered in India, Pakistan, and Sri Lanka (about 120,000 are Anglo-Indian), forty percent of them Roman Catholics; about 200,000 urban, commercially and industrially oriented Parsis (Zoroastrians), about half of them living in Bombay and about 90 percent of them literate; about 2,000,000 Jains, also largely in Bombay; and about 10,000,000 Buddhists, almost wholly in Sri Lanka (India, where Buddhism began, has only a few hundred thousand Buddhists).

Although regional, particularly linguistic, units may be politically strong in India, the extended family usually forms the most important socio-economic unit; all contribute to the extended family and are supported by it. Mountaineers and hillsmen, found in the extreme east and west of South Asia and in the central hills of India, are usually tribal. Most rural peoples are governed by village, camp, caste, or tribal councils.

Wheat and rice are the major crops, but barley, millet, maize, gram, tea, coconuts, rubber, jute, cotton, fruits, and nuts are cultivated where soils and climate permit. India has about one-half (not the better half) of the world's cattle, a ratio of 80 cattle for every 100 persons. Most South Asians drink milk and use dairy products; only the Hindus prohibit the consumption of meat. Water buffalo occur in all wetter areas; some are found as far north as northern Afghanistan. Sheep provide many essentials for the peoples of the Northwest Frontier Province and Baluchistan of Pakistan and Afghanistan; half of India's sheep are concentrated in Madras and the southern Deccan, which have insufficient pasturelands to support cattle. Goats are ubiquitous. Donkeys, mules, and camels live mainly in the northwestern regions of South Asia. Elephants, more romantic than visible, occur mainly in the forests and jungles of northern and northeastern India, Bangladesh, and Sri Lanka. Fishing is important everywhere except in the extreme north and northwest.

The Orissa–Bihār–Bengal triangle in east India provides all the ingredients necessary to support large-scale industrial developments; the only other Asian area equal in potential is Manchuria. Several industrial complexes sprawl across north India.

East Asia. Asia owes debts to China, the dynamic high-cultural centre of East Asia, which has been both innovator and synthesizer. All three East Asian nations—China, Korea, and Japan—have north–south cultural and ecological divisions, although the mountainous islands of Japan and equally mountainous peninsula of Korea tend to be more homogeneous than sprawling China, with perhaps 800,000,000 people, including about 20,000,000 hill peoples in South China common with Southeast Asia.

China as the cultural centre of East Asia

North China, more level than the south, has a relatively dry climate and is influenced by the proximity of western steppes and deserts; the windblown and alluvial soil makes extensive cultivation of wheat possible, along with some soybean and kaoliang (grain sorghum). South China, the predominately rice- and tea-growing area, begins about halfway between the Huang Ho and Yangtze rivers, with the Yangtze Basin being the transitional area of wheat and wet-rice production. In mountainous Korea the 45,000,000 people are squeezed into the narrow coastal plains and fertile inland river valleys, which constitute only about one-fifth of the land area. Similarly, in the 3,350 mountainous islands of Japan, the little cultivable land has to be efficiently farmed. Japan's climate, though generally mild and temperate, has climatic and latitudinal ranges almost identical to those from chilly Maine to humid Georgia.

Mongoloids in East Asia

Physically, East Asians are essentially variations of the Mongoloid. The North Chinese are generally taller and exhibit more Mongoloid traits than southerners. Near China's southern borders live a number of important non-Chinese minorities, such as Miao, Lolo or Yi, Puyi, Shan, Tai, and Mon-Khmer. Other important minority groups in China include Kazakh (and other Turkic speakers), Dungan (Hui) or Tunya, Koreans, Chuang, and Uighur; over 500,000 Japanese live in the north, especially in Manchuria.

Koreans, more homogeneous than either the Chinese (Koreans are shorter) or Japanese (Koreans are taller), have assimilated practically all minority groups. The Japanese are the hairiest Mongoloids, partly because of racial mixture with the modified Caucasoid Ainu, possibly the aborigines of Japan but today relegated to Hokkaido and other islands off south Siberia.

Linguistically, China presents a rather diverse face. At least six (some specialists list as many as nine) dialects of the Sino-Tibetan language family are spoken by the Han or Chinese proper: Mandarin (the major dialect), Cantonese, Wu, Fukienese, Hakka, and Hainanese. Although spoken dialects are usually mutually unintelligible, the 40,000 Chinese characters are common to all dialects; and, to be considered literate, an individual should know at least 5,000. Korean has a phonetic script called Han'gŭl or Ŏnmun, using modified Chinese characters. Japanese apparently relates to Korean. The script consists of Chinese characters and a syllabary (*kana*) of Japanese origin. The Ryukyuan language of the northern Ryukyus is similar to Japanese, but Okinawan (in the southern Ryukyu Islands) is not mutually intelligible with Japanese. Culturally, Okinawa leans toward China, as well as Japan. A popular saying is: "China is our father, Japan our mother."

Philosophies and religions of East Asia

Although exposed to all major (and many minor) religions, China remains most greatly influenced by Confucianism, Taoism, and various schools of Buddhism. Throughout history, Chinese rulers encouraged the ideals of Confucianism most helpful to the maintenance of state power, currently disguised as the *Quotations from Chairman Mao Tse-tung*. Ancestor worship and seasonal animistic rites relating to the agricultural cycle have also continued to be widespread in China. The indigenous religion of Korea, Chondo-gyo, consists of several interlocking, seemingly contradictory elements, combining monotheism, shamanism, animism, Confucianism, and Buddhism. About 4,000,000 Koreans practice Buddhism, and about 2,000,000 are Christians. Shintō, Japan's indigenous religion, has been without state sanction since 1945 but remains an important politico-religious force, with at least 40,000,000 adherents. The 65,000,000 Japanese Buddhists usually also practice some sort of Shintō.

In each East Asia cultural zone, cultural traits vary from north to south. For example, in drier north China, wheelbarrows and two-wheeled carts drawn by oxen, donkeys, or horses replace the sedan chairs and river and canal boats of the subtropical, wetter south; water buffalo exist in both areas, but the North Chinese use oxen more extensively for cultivating land; famine has always been more prevalent in the north. The People's Republic has perpetuated at least as much as it has modified in Chinese culture. The family retains its importance, and the village council continues to exist in the communes. The philosophical base of government exhibits familiar patterns, peasants continue to be peasants, and the political hierarchy exists within a framework of divinely sanctioned (Maoist) authority.

World War II divided homogeneous Korea politically into North and South Korea, and, although the southern elite wear Western-style clothing and northerners wear Mao jackets, village culture remains relatively the same. Outside the official government level, local, often kin-oriented political parties control the rural areas in both North and South Korea. The North Korean land reforms of 1946 distributed 56 percent of all farmland to peasants, and another law guaranteed private ownership of small farms; thus few collective farms exist. North Korea has become more highly industrialized.

Japan, a zone of homogeneous cultural blend (like Korea), has embraced much that is Chinese (often filtered through Korea). But Japan is, of course, one of the most industrialized nations in the world, with 90 percent literacy. This modernization began in the late 19th century and resulted in Japanese uniqueness and contrasting patterns: devotion to the emperor coupled with democracy, sumo wrestling and baseball, modern business and indus-

trial giants (*zaibatsu*) combined with the *on-oyabun* (loyalty of client to company, or worker to company). As in most East Asia, though, family and a stratified social system remain strong in Japan, and often political parties and unions reflect these patterns.

Southeast Asia. Southeast Asia—which includes Burma, Thailand, Laos, North and South Vietnam, Cambodia, Malaysia, Indonesia, and the Philippines—has served as a north–south funnel for peoples and cultures for thousands of years, resulting in a hodgepodge of linguistic and ethnic groups. Important influences have flowed from both China and India. Two major geographic worlds exist: the mainland and the archipelagoes of Indonesia and the Philippines. In both, thriving empires and tribes of hunters and gatherers, intensive wet-rice agriculture (at times with elaborate terracing), and slash-and-burn horticulture exist. Plow agriculture is practically nonexistent; the hoe and digging stick are common. Besides the main staple of rice, crops include tea, coffee, maize, opium, cinchona (for quinine), rubber, coconuts, palm oil, sugarcane, tobacco, cotton, teak, and hemp.

Seamanship and navigation reach high peaks of technical perfection in the open seas, especially around Malaysia, Indonesia, and the Philippines. Fishing is an important economic institution. For all Southeast Asians (except Muslims) the pig is important in the diet. All eat chicken. The water buffalo (seldom milked) is the most common animal used to prepare fields for agriculture.

Australoids and Mongoloids of Southeast Asia

Physically, most Southeast Asian peoples are either Australoid or Mongoloid, with significant variations within each group. Australoids include the Negritos of the Philippines, the Semang of Malaysia, the Andamanese, and some Cambodian groups. Possibly several hunters and gatherers represent remnants of the earliest Mongoloids, including the Yumbri (northeast Thailand and Laos), Punan (Borneo), Sakai or Senoi (south of the Semang River), and Kubu (Sumatra). Intermediate Mongoloids include the Thais, Mon (Burma), Malay, Lao, Vietnamese, Cambodians, Filipinos, and Indonesians. The Mongoloid Miao (China, Vietnam, Laos, Thailand) apparently have some Caucasoid admixture. The Burman are physically the most Mongoloid (Burman, an ethnic designation, should not be confused with Burmese, the citizens of Burma). The Thai, Burman, Khmer, and lowland Vietnamese constitute about 75 percent of the mainland population. Since at least the 3rd century BC, Chinese have been moving into Southeast Asia; the more than 20,000,000 now in the area are primarily urban labourers, professionals, merchants, and traders.

Traditionally, anthropologists have classified Southeast Asians in such linguistic categories as Sino-Tibetan (Chinese dialects, Tibeto-Burman, Karen, Miao-Yao), Tai-Kadai (Tai and Kadai, the latter spoken mainly on southern Hainan Island and along the Yunnan–Vietnam border), Austro-Asiatic (widespread in Cambodia and the two Vietnams and including Mon-Khmer, Viet Muong, Senoi-Semang), and Malayo-Polynesian (in Malaysia, Singapore, and Indonesia and among the Cham of South Vietnam and Cambodia).

Various religions pockmark the cultural landscape, with Buddhism either dominant or subtly influencing all others. Varieties of Buddhism are widely practiced in Burma, Thailand, Laos, Cambodia, and Vietnam. Islām, with strong Hindu elements, is strong in Indonesia, Malaysia, Singapore, Mindanao, and other southern Philippine islands. Almost all mountain tribes practice animism and ancestor worship to a certain degree (some to the exclusion of other religions) and have extensive pantheons of nature spirits and supernatural beings. Magic is common, and various categories of shamans, healers, and diviners flourish among both sexes. Roman Catholicism is strong in Malaysia, Singapore, and the Philippines.

Extensive empires developed under Indian impact in the early centuries AD, but today only a few petty princely states survive as legacies.

The village remains the key unit of culture. (Even in North Vietnam, certain tribal groups are permitted to retain their identity, though their leaders are officially linked to the central government.)

ORIGIN AND DEVELOPMENT OF ASIAN PEOPLES AND CULTURES

Paleoanthropological record. Once considered by Charles Darwin and others as the cradle of mankind, Asia, given the present evidence, must relinquish the bassinet to Africa south of the Sahara. Nevertheless, many important prehominid and hominid paleontological finds have been made.

The Asian continent was undoubtedly the scene of a large-scale dispersal of early members of the natural order to which man belongs, the Primates. It is, for instance, the home of the only surviving genus (*Tarsius*) of the tarsiers, small nocturnal primates (about the size of newborn kittens), now confined to the Philippines, Borneo, the Celebes (Sulawesi), and Sumatra, the fossil remains of which are of great importance in the study of man's remote ancestry. Fossils of extinct apes, belonging to the widespread genus *Dryopithecus*, have been recovered from the Siwālik foothills of the Himalayas and are believed to be broadly ancestral to the African apes the chimpanzee and gorilla, though the Asian species may not be the actual ancestral forms. More important are the rare fossils of the genus *Ramapithecus* from the same locality, which appear to be near the ancestral lineage of man and are classified as early Hominidae. From South China the large fossil primate teeth and jaws named *Gigantopithecus* are thought to represent an eastern gorilla-like derivative of *Dryopithecus*.

Primate and hominid remains

Although there is no convincing evidence of Asian fossils of equivalent age and morphology to the African apemen called *Australopithecus*, there is a good fossil record from East Asia of hominid remains classified as *Homo erectus*, which lived in the Pleistocene Epoch, some 200,000 to 500,000 years ago. The most ancient specimens come from Java (first found in 1891 and then named *Pithecanthropus*), and an important group of middle Pleistocene fossils was discovered at Chou-k'ou-tien near Peking (recognized in 1927 and then named *Sinanthropus*); many other forms have since been found. This species, *Homo erectus*, which appears to have been ancestral to modern man, is believed to have walked fully erect, since the thighbones from Java are practically indistinguishable from those of modern man. The skull, however, was very different and enclosed a brain that averaged 1,000 cubic centimetres (the average for modern man is some 1,400 cubic centimetres); it was long and low so that its greatest breadth was as far down as the level of the ears, and the heavy jaws lacked a chin. The fossils found near Peking came from cave deposits and were associated with tools of bone and stone, as well as with hearths.

In late Pleistocene deposits of less than 100,000 years were found important fossils that many authors consider to represent diverse varieties of the modern species, *Homo sapiens*, primarily Australoid and Mongoloid. One probable Australoid skull from Niah Cave, Borneo, dates from about 40,000 years ago, the oldest specimen of *Homo sapiens* yet discovered.

Early *Homo sapiens*

Cultural origins. The earliest traces of human activity in Asia are associated with the fossil man known as *Sinanthropus* found at Chou-k'ou-tien near Peking. Hearths, roughly chipped stone implements, and other crude tools that were found with him are distinct in shape and method of manufacture from the hand axes characteristic of the Lower Paleolithic in Europe, but they are of comparable antiquity, perhaps 400,000 years old. Middle Paleolithic (100,000–30,000 BC) finds occur sporadically in Central Asia and China; scattered Upper Paleolithic (30,000–12,000 BC) sites are found in Afghanistan, China, Japan, Java, the Philippines, and possibly the southern Celebes. In southern Siberia were found traces of a flint- and bone-using culture with pressure-flaked flint points and bone harpoon heads but without the developed cave art of Europe. These cultures are perhaps 10,000 or 15,000 years old. Later, the stone tools of East and Central Asia included many tiny parallel-sided blades with little secondary trimming, intended for mounting in series. These "microliths" also echo the

European and North African development. The microlithic cultures lasted long, for in Siberia, Mongolia, and Manchuria they are often found combined with Neolithic elements in the shape of polished or partly polished stone axes, crude handmade pots with rounded or pointed bottoms, and small triangular arrowheads. With the advent of pottery and stone polishing, probably about 3000 BC, these semisedentary hunting and fishing cultures moved closer to a Neolithic technology.

This northern belt of cultures reaches to the sea in Kamchatka. To the south lies the cradle of the high bronze culture of protohistoric China, based on the easy agriculture of the Huang Ho Valley. The Neolithic cultures that preceded the Bronze Age in this area were much more advanced than the Mongolian Neolithic, and their origins seem to have owed nothing to it. The southernmost zone, comprising South China, Indochina, and the great islands of Southeast Asia, also possessed a distinct prebronze tradition. Excavations in Indochina have produced small chipped-stone tools unlike anything found in the north, as well as individual kinds of stone axes, polished only on the edge, and some rough pottery with impressed decoration. The use of stone in the southern zone continued into historical times, as it did in Japan, which had no share in the early spread of bronze metallurgy, but evidence indicates early Japanese pottery (*c.* 10,000 BC) that possibly predates previous known finds.

In South Asia the typical chipped-stone tools associated with the Paleolithic Period have been found widely distributed. In the north of India some of these are associated with river terraces corresponding with glacial and interglacial periods. Hunting, food-gathering Mesolithic peoples of South Asia, who used microliths to point and barb their arrows and as knives and scrapers, were as widespread as their Paleolithic predecessors. In forest areas, this cultural stage with its use of microliths persisted to the early centuries AD or even later. In the valley of the Son River and the Mahādeo hills and at Singhanpur, rock paintings, physically associated with microliths, have been compared with Paleolithic paintings in Europe; actually the majority are of the early historic period, and none is earlier than 1000 BC. The Neolithic Period in South Asia is the hardest to determine, depending mainly on the advance in agriculture to make its evidence apparent. Digging-stick cultivators would show no change in material possessions from those of the Mesolithic food gatherers. Hoe cultivation, possibly with terracing, needs stone hoes; and slash-and-burn cultivation needs axes. By far the greater number of ground and polished stone axes have been found in the east and south of India. The small amount of copper found at some stone-ax sites in India hardly justifies the cultures as being classed as Chalcolithic, or copper- or bronze-using.

Neolithic Period

The origins, development, and spread of food production, which marked the Neolithic Period, are complicated, and new evidence challenges the priority of the Middle East. Evidence from Āq Kupruk in north Afghanistan indicates the presence of domesticated sheep and goats about 8000 BC and of cattle about 6000 BC. Sickle blades, pecked stone hoes, chisels, hand mills, and pounders suggest at least the collection and preparation of wild grains. Possibly the zone of this animal domestication and grain collection spread along a latitude of 30° to 40° N, at an average altitude of 2,500 feet (750 metres) above sea level, from the northern Hindu Kush to Anatolia and the Aegean. In addition, in the Spirit Cave of north Thailand was found evidence of the cultivation of vegetables, beans, and water chestnuts; if the estimated date of these findings, 10,000 BC, is accurate, then they represent the world's earliest known horticulture. A possible date of 9000 BC for slash-and-burn horticulture on Taiwan adds to the evidence of the birth of cultivation in Asia. Throughout East and Southeast Asia by about 2500 BC, people were cultivating millet, buckwheat, beans, and probably rice, though those on the coasts largely depended on the sea for their livelihood, as attested by large shellfish middens. The South Chinese and Southeast Asians early developed maritime skills, and by about 2500 BC sea trade possibly extended as far west as Bengal.

Early civilizations. Chinese urban civilization began with the Shang or Yin dynasty (*c.* 1766–*c.* 1122 BC) and continued under the Chou (*c.* 1122–221 BC), who marched in from the west, absorbed much from the Shang, and developed the Chinese social and cultural patterns still recognized today. Confucius (551–479 BC) lived during this period. Iron arrived about 500 BC and was cast into plows (the stone hoe previously dominated) and into weapons. In India, Indo-European-speaking tribes, commonly referred to as Aryans, began their invasions from the west about 1700 BC, which contributed to the destruction of the Indus Valley (Harappan; *c.* 2300–1700 BC) Bronze Age civilization. The centuries following witnessed several immigrations, culminating in the entry of the Vedic Aryans in the 14th to 12th centuries BC. Iron probably was introduced in the 7th or 6th century BC. The Vedic period came to a close at the end of the 6th century BC, to be succeeded by a plethora of dynasties and states, briefly united under the Mauryan Empire of Aśoka the Great (*c.* 265–*c.* 238 BC).

With urban civilizations firmly established, several patterns developed that became recurrent through time. Asian urban society had—and still has—an economy based primarily on agriculture. Control of water for irrigation and the upkeep and spread of the intensive canal and drainage systems fostered the growth of authoritarian governments with varying degrees of despotism. Periodically, invasions from the steppes and deserts of Mongolia and Central Asia overthrew existing dynasties, and then the conquerors in turn were culturally conquered by the fallen civilizations. Empires expanded and fell, and others rose in a continual process of political fusion and fission. A charismatic tribal ruler would unite tribes into a confederation and then spread his political mantle as far as military power, diplomatic duplicity, and sexual alliances could carry him. With the death of the charismatic leader, the empire he created usually began to break up; at times, fission began even before his death.

Invasions and rise and fall of empires

A few such individuals left lasting monuments—or ruins—on the social, political, and cultural landscape. Alexander the Great smashed through Afghanistan, moved unsuccessfully into Central Asia, and down to the Punjab in the 4th century BC. Hellenism resulted; Greco-Bactrian and Indo-Greek kingdoms rose and fell; some lasted well into the 1st century BC. More important, Buddhism mingled with Greco-Roman humanism, ideologically and artistically, and spread along the Silk Route, which stretched from ancient Cathay to Greece and Rome. The Silk Route was a highway of culture, as well as commerce.

In the 13th century AD, Genghis Khan and his Mongol army left great ruins in their wake but also revitalized the eastern Islāmic world. Timur in the 14th century destroyed much while fostering a Central Asian cultural renaissance. China received cultural stimulation from its perennial conflicts with the nomads beyond the Great Wall, a symbol of the borderland rivalries existing all over Asia.

European contacts and modern developments. Political insecurity, particularly after the Turco-Mongol invasions, broke up the Silk Route and led European navigators around the South African cape in search of new routes to the East.

Beginning in the early 19th century, European imperialism began to replace Asian imperialism. Tsarist Russia drove to the Pacific Ocean, conquering the marginal hunter-fishermen of Siberia and the ancient and sophisticated but jaded Muslim khanates of Central Asia; after the Russian Revolution, Communists replaced the tsarists. The British rapidly gained control of the Indian subcontinent; the French moved into Indochina; the Dutch occupied the East Indies; the Spanish ruled the Philippines until the United States took over after the Spanish-American War and thus intruded into the Asian scene, to remain there until the present. China, culturally satisfied but politically introvert, feebly resisted the capitulations. Japan moved slowly from its self-imposed isolation and

then rapidly to imperialism, which culminated in its military defeat in World War II and subsequent economic revival.

The European imperialists split Asia into either colonies or zones of influence. Even those few nations (such as Afghanistan and Thailand) that continued to remain independent had their external boundaries drawn by imperialists.

Modern Asian states and territories

Empires need bookkeepers, and the Europeans in Asia trained large numbers of local personnel, gradually permitting them at least limited entrance into their political, economic, and, to a lesser extent, social worlds. The bookkeepers, exposed for varying periods of time to the ideological, political, and economic models of their masters, began to adopt them, often unconsciously, as their own. The ideals of individual freedom and economic well-being led to Asian nationalism and, particularly after World War II, brought about political independence, and the internal imperialist replaced the foreign imperialist. Asian leaders, having adopted the political and economic models of the West, tend to think in Western terms and react like their Western counterparts when faced with internal problems. Regional autonomy and tribalism are anathema to most Asian leaders, and they insist on the rights of the individual and his obligations to the state under various brands of democracy and Socialism. They forget, however, that when European boundary-hardening exercises settled down after World War I, most European nations were based on reasonably uniform linguistic units. Rarely, however, do linguistic units in Asia coincide with national boundaries, which are legacies of European imperialism. In addition, the reciprocal rights and obligations between government and governed that theoretically dominate Western political processes occur at the kinship, tribal, and regionally oriented level in Asian society. Few Asian governments can even begin to replace the delicate networks woven by these kin systems.

Modern Asian governments range from Socialistic (People's Republic of China) to constitutional monarchies (Afghanistan), developing democracies (India) to transient military dictatorships (Pakistan), but, in most cases, whatever their form, they involve the masses of the people only minimally.

The rising demands for Asian regionalism, the creation of autonomous units within federations, are often either ignored or suppressed by central government in the name of "national integrity." The successful creation of Bangladesh in 1971 after the Pakistani military regime attempted to crush a movement for regional autonomy is a classic example. Such demands will probably increase. Even in Soviet Central Asia, cries for Tadzhik power, Uzbek power, and so on are getting louder and stronger. Perhaps only three Asian nations have recognized the utility of linguistic and tribal semi-autonomous units inside their national boundaries: India, China, and North Vietnam.

When—and if—foreign military adventures end in Asia, meaningful international economic blocs may develop and permit the Asian nations to present a unified economic front to the more developed Western world.

BIBLIOGRAPHY. The works of CARLETON S. COON, *The Story of Man*, 2nd rev. ed. (1962), *The Origin of Races* (1962), and *The Living Races of Man*, with E.E. HUNT, JR. (1965), probably offer the best surveys of fossil man and the development and distribution of modern Asian physical types, although controversy exists over some of Coon's conclusions. Two classic Asian geographies are L.D. STAMP, *Asia: A Regional and Economic Geography*, 12th ed. (1967), and GEORGE B. CRESSEY, *Asia's Lands and Peoples*, 3rd ed. (1963). A good regional study is HARRY ROBINSON, *Monsoon Asia* (1966). Few archaeological works exist on Asia in general, but many specific studies have been written. Several works, however, do have important survey materials, including GRAHAME CLARK, *World Prehistory*, 2nd ed. (1969); J. HAWKES, *History of Mankind: Prehistory*, vol. 1, pt. 1; LEONARD WOOLLEY, *History of Mankind: The Beginnings of Civilization*, vol. 1, pt. 2 (1963). FRANCOIS BORDES, *La Paléolithique dans le monde* (1968; Eng. trans., *The Old Stone Age*, 1968), admirably outlines the early periods in Asia. The socio-political processes and ecologic patterns that led to the development and repeated rise and fall of authoritarian regimes in Asia is ably detailed in K.A. WITTFOGEL, *Oriental Despotism* (1957). Another monumental work is GUNNAR MYRDAL, *Asian Drama*, 3 vol. (1968), which evaluates past and potential development. For general reading and easy reference, D.N. WILBER (ed.), *The Nations of Asia* (1966), is indispensable. Finally, RALPH LINTON, *The Tree of Culture* (1955), remains a basic work on Asian cultural patterns.

(L.Du.)

Asians, Prehistoric

The traditional picture of Asia as the cradle of mankind provided the impetus for Western scholars to search this part of the world for the vestiges of man's biological and cultural beginnings. The romanticism of this notion has been tempered by scientific discoveries indicating that man had inhabited Europe and Africa as long as Asia, but Asia was nonetheless important in its broad spectrum of climatic zones, from Arctic to temperate and tropical, its mountain ranges and grassland steppes, its inland seas and Arctic tundra, plus other ecological settings to which prehistoric and modern man had to adapt both biologically and culturally. Since the formation of the present geological features of Asia during the period of mountain-building activity in the Middle Tertiary (about 35,000,000 BP [Before Present]) the continent gave rise to major taxa of primates that included the dryopithecine apes of the Miocene–Pliocene age (21,000,000 BP) and the earliest known hominid, *Ramapithecus punjabicus* (see HOMINIDAE). With the onset of the Pleistocene (about 2,000,000 BP), Asia was one of the habitats of the australopithecines, who, by middle Pleistocene times (500,000–200,000 BP), were replaced by *Homo erectus* forms. Evidence of *Homo sapiens neanderthalensis* (Neanderthal man) and later *Homo sapiens sapiens* (modern man) appeared during the upper Pleistocene, which began about 150,000 years ago. Thus, the major events of human evolution are represented in the paleontological and archaeological record of Asia.

This article is divided into the following sections:

THE FOSSIL RECORD OF PREHISTORIC MAN IN ASIA

Areas of human occupation. Human occupation in Asia from 100,000 years ago until about 35,000 years ago, a period that includes the geological-climatic events of the third interglacial and the initial glaciation of the Würm (Last) Glacial Period, was restricted to a considerable degree by the extension of ice sheets that covered portions of eastern Europe, the Tibetan plateau, and the diagonal mountain chains of Central Asia during periods of peak glaciation. These conditions blocked passage between Europe and eastern Asia save for narrow corridors not covered by ice. For this reason, high-altitude glaciated regions in western Asia and in the Himalayas are poor in prehistoric sites. The Bosporus remained dry land during much of the Pleistocene and formed the main avenue of communication between the Near East and the Black Sea. During periods of maximum glaciation, the Caspian Sea rose 250 to 300 feet, and in this condition of flooding by waters fed by glacial melt it formed with the Volga River a spillway into the Black Sea. The Aral Sea enlarged in rhythm with the Caspian, and to the south and the east of the Ural Mountains a vast swamp marked the limits of glacial ice. With the onset of interglacials, of which the third is the one relevant to the period of time under consideration, these landlocked bodies of water became lowered while the Black Sea was elevated, since it was fed by oceans expanding in size from water liberated by melting marine glaciers.

During these peak glaciation periods, portions of Asia were isolated from Europe.

Thus, with the onset of the Würm glaciation some 70,000 years ago, climatic conditions effectively separated the Neanderthal populations of western Europe from those Neanderthals of western Asia whose occupation sites are recognized today in the Zagros Mountains of Iran and just north of the Elburz Mountains and Hindu Kush in Iran, Soviet Central Asia, and Afghanistan. With the onset of the second phase of glaciation (Würm II Stadial) 40,000 years ago and during a short period of milder climates in Europe and western Asia, the Neanderthal occupations were replaced by the sites of early modern hominids.

The Bering Strait formed an effective land bridge between northeastern Asia and the New World during the glacial epochs but ceased to serve as such with the elevation of sea levels during the Third Interglacial and again after the Würm glaciation. The former continental landmasses of the Sunda Shelf and Sahul Shelf in Southeast Asia were separated at the close of the Pleistocene as sea levels rose. These areas were dry during the Riss and Würm glaciations and provided a passageway for populations moving from Southeast Asia to Australia. The geographical boundary of Wallace's Line, running between Bali and Lombok, Borneo and the Celebes, Mindanao and Sangi, isolated the Australian fauna, including man, from Southeast Asia during the upper Pleistocene. South Asia was affected by glacial activity in the Himalayan region but in the south that area retained a tropical ecological setting throughout most of the Pleistocene. The upper Pleistocene of China is characterized by deposits of yellow earth, or loess, upon which man settled. The climate remained cold and dry for much of this period in China.

Neanderthaloids from western Asia

Remains of Neanderthal man. More than a dozen sites with fossils of *Homo sapiens neanderthalensis* have been located in the Near East. Prehistoric research began there in 1864, when Louis Lartet (who later discovered Cro-Magnon man) rediscovered in Syria an ancient settlement observed some 30 years earlier. In 1878 an inventory of Stone Age artifact discoveries was compiled, but the first fossil find of early man in western Asia was made in 1900 at Grotte d'Antelias, in Lebanon. The remains of a seven-year-old child were recovered in 1938 in Lebanon at Ksar 'Akil, a rock-shelter near Beirut dated to 43,750 years BP. Discovery of an adult Neanderthal skull was made in 1925 at el-Zuttiyeh (Robbers' Cave) at Lake Tiberias in Israel—the "Galilee Skull" now datable to 70,000 years BP. In its vicinity is the cave of Har Qedumim (Jebel Qafzeh), where Neanderthal bones of comparable antiquity were recovered in 1933–35. The cave at Amud, also in this region, yielded in 1961 bones dated to the period of the Würm I Stadial of the last Ice Age (70,000–50,000 BP).

Near Jerusalem the Shuqbā (Shukbah) Cave contained human remains that had been deposited at the end of Neanderthal occupation of this part of Asia—*i.e.*, at about 35,000 years BP. The most critical discoveries in Israel are from two caves adjacent to one another in the Mt. Carmel range—Maghārat at-Tabūn, excavated in 1929–34, and Maghārat as-Skhūl, excavated in 1931–32. The age of occupation deposits at at-Tabūn ranges from 70,000 to 37,750 years BP. The occupation of as-Skhūl may have been slightly later, but both caves have yielded Neanderthal fossils with many physical features characteristic of later *Homo sapiens* hominids.

The original designation *Palaeoanthropus palestinus* assigned to the Mt. Carmel hominids was later dropped from use. The Turkish sites of Karain near Adala, excavated in 1949, and Musa Dağı have yielded teeth that may belong to the Würm I hominids, but the dating of these sites remains uncertain. Shanidar Cave in Iraq was excavated from 1953 to 1960. Its deposits range in age from 60,000 to 44,950 years BP and include the bones of a child and several adults. The two sites of Würm I date in Iran are the Kermanshah Cave, near Bisitun, and the Tamtama Cave, near Rezā'īyeh. Excavation of these fossil-bearing deposits began in 1949.

Fossils of Neanderthals were found in the Soviet Union in 1924 at the cave of Kiik-Koba, in Crimea. Two skeletons, both missing skulls, appear to have been purposeful burials. The deposit dated to the early part of Würm I, while at another Crimean site, called Staroselye, excavated in 1952, the fossil remains date to 35,000 years BP. Teshik-Tash cave, in Uzbekistan, yielded in 1938–39 a child burial of the Würm I–II Interstadial, but the skeletal remains unquestionably belonged to a Neanderthal population. Less certain is the dating of an alluvial deposit containing some prehistoric human remains found in 1925 along the lower Volga River at Undory. Aman-Kutan Cave, in Samarkand, has the earliest dated fossil Neanderthal in Central Asia.

Neanderthaloids from Southeast Asia and eastern Asia

In eastern and Southeast Asia, hominid fossils resembling the western Asiatic *neanderthalensis* hominids have been recovered from sites that date from the early part of the upper Pleistocene and even into the beginning of post-Pleistocene, or Recent, times (10,000 BP). The taxonomic status of these hominids is uncertain, but they have been given the colloquial appellation of Neanderthaloids, even though some populations of this hominid group were contemporaries of *Homo sapiens sapiens*, who emerged in western Asia, Europe, and Africa by the beginning of the Würm II Stadial of the last Ice Age, about 40,000 years BP.

Since the excavation in 1922 at Sjara-osso-gol River in Ordos, China has provided numerous loci with human remains. This site may have been inhabited contemporaneously with the occupation of the other Ordos site, Ti-shao-kou-wan, which was investigated in 1957. Both appear to be of upper Pleistocene date (*c.* 150,000–10,000 BP).

Earlier than these is the Ting-ts'un site, in Shansi, excavated in 1954 and dated to the Third Interglacial (100,000–70,000 BP). Still more ancient is the human skull from the cave at Ma-pa, in Kwangtung, which may be late middle Pleistocene; *i.e.*, *c.* 125,000 years BP. Other series of Neanderthaloids appear in the fossil record of Java at the upper Pleistocene site of Ngandong, on the Solo River.

At the time of the excavation of 11 skulls from Ngandong in 1931–32, the specimens were named *Homo (Javanthropus) soloensis*, but modern systematists regard these fossils as similar to the Chinese Neanderthaloids and to the Neanderthals of western Asia. Two skulls from a limestone terrace overhanging an ancient lake near the village of Wadjak, in Java, were discovered in 1890, and these constitute the earliest discovered fossil hominids from Asia, although they were not reported until 1921. They have been dated to the very end of the Pleistocene or possibly to the beginning of post-Pleistocene times (*c.* 10,000 BP), but they resemble the Ngandong Neanderthaloid specimens in a number of striking ways. Fossil evidence of *Homo sapiens neanderthalensis* has not been reported from southern Asia, although this region contains artifactual materials made by hominids of the period of time under consideration.

A few bone fragments from a late middle Pleistocene deposit (*c.* 125,000 BP) at Ushikawa, on the Japanese island of Honshū, were reported in 1957, but the bones are too incomplete to make possible a reliable identification of their taxonomic status.

Homo sapiens sapiens remains. In western Asia the first appearance of *Homo sapiens sapiens* coincides with the onset of the Würm II Stadial of the last Ice Age, about 40,000 years BP, approximately the same period of time that *sapiens* hominids replace Neanderthals in Europe and Africa. As noted above, Neanderthaloid hominids persisted in eastern and southeastern Asia until the close of the Pleistocene, but they appear to have constituted isolated populations in this part of the world, where modern-type *sapiens* had also appeared by late upper Pleistocene times (*c.* 30,000 BP).

The earliest date for *Homo sapiens sapiens* in Southeast Asia is 37,650 years BP, assigned to a skull specimen discovered in 1959 at Niah Cave, in Borneo. Late upper Pleistocene is also the date for the Chinese fossils

found in 1930 at the Upper Cave of Chou-k'ou-tien, near Peking, in 1951 at Tzuyang (formerly Tzeyang), in Szechwan, in 1956 at Kai-t'o-tung in Laipin, Kwangsi, and at Ch'i-lin Shan, in the same province. Fossils were also found in 1958 at Chaisha (formerly Liukiang), also in Kwangsi; this site may have lower deposits dating to a period contemporary with the Würm I Stadial (70,000–50,000 BP), as is certainly the case at the site of Ch'ang-yang (Lungtung), in Hupeh Province, investigated in 1957.

Japan has yielded a *sapiens* specimen in the fossil record taken from Aichiken, in Honshū, in 1958, but the date can only be specified as upper Pleistocene. In 1921 a skull with Negrito or Pygmy features was reported from an alluvial deposit of the Río Pasig near Manila, but the dating of this specimen from the Philippines is uncertain.

Southeast Asia's record of *sapiens* fossils does not commence until the beginning of the geological Recent period (*i.e.*, after 10,000 BP), save for a single hominid lower molar found in northern Indochina in a deposit of uncertain antiquity. Similarly, southern Asia does not provide a *sapiens* fossil series for this period; the earliest skeletal remains, coming from Sai-Nahar-Rai in Uttar Pradesh date to about 8000 BC.

Near Eastern *sapiens* fossils

The Late Stone Age (Mesolithic) site of Bellanbandi Palassa in Sri Lanka (Ceylon) has yielded a dozen skeletal specimens of *H. sapiens sapiens* from a deposit dated about 5000 years BC.

In the Near East, Lebanon offers two Pleistocene sites with *sapiens* fossils: a cave at Abri Bergy, near Antilas, which was excavated in 1948, and the previously mentioned site of Ksar 'Akil, which has a middle Würm deposit (*c.* 40,000 BP) superimposing the portion of the shelter from which the Neanderthal specimens had been removed in 1938. Similar hominids came from an upper level of the Har Qedumim cave, in Israel, as well as from the Mugharet el-Kebareh and Wādī Maghārah (Mugharet el-Wad) caves of the Mt. Carmel Range, where excavations in 1931 provided data on late upper Pleistocene occupations. At Malta, in Siberia, a late Würm (*c.* 15,000 BC) *sapiens* specimen was recovered in 1929, but other sites in the Soviet Union have provided few skeletal remains from this period.

MORPHOLOGY OF ASIAN FOSSIL REMAINS

Neanderthal morphology in western Asia. The classification of upper Pleistocene Asian hominids as Neanderthal, Neanderthaloid, and sapient forms becomes meaningful when the physical anthropologist compares the osteological and dental anatomy of the fossils from the sites just discussed. Some Neanderthal specimens of western Asia closely resemble the Würm I Neanderthals of Europe with regard to the possession of a massive supraorbital torus (browridges), a low-lying forehead, large face with large eye sockets (orbits), large nose, dolichocranic or mesocranic cranial form, chinned or chinless mandible, bulging of the occipital bone (at the back of the skull) into a "chignon," taurodont molars, a cranial capacity with a mean of about 1,550 cubic centimetres (95 cubic inches), and a range from 1,270 to 1,700 cubic centimetres, inclusive, of both sexes, a modern-like dentition (apart from taurodonty), and a body conformation that was burly and muscularly well developed. The misconception that Neanderthals walked with slightly flexed knees and a hunched posture was based upon the examination of the Neanderthal skeleton from La Chapelle-aux-Saints, in France, an arthritic and aged male. The retroversion of the head of the tibia (large bone of the lower leg) was also considered to be indicative of a slumped posture and plodding gait.

Features of the skull

Recent reinvestigation of the La Chapelle specimen and other Neanderthal skeletons does not indicate that this hominid's locomotor pattern was significantly different from that of later and modern hominids. Stature ranged from about 154 centimetres for females to 173 centimetres for males.

The Asiatic specimens that show the most striking physical resemblances to European specimens of Neanderthal man (such as those from La Chapelle-aux-Saints and La Ferrassie, in France, Spy, in Belgium, and the Neander Valley specimen, in West Germany) are from Amud and Shuqbā, in Israel, as well as some of the skeletons from the series of the Mt. Carmel caves, from Shanidar, in

Major sites of Upper Pleistocene hominid remains in Asia.

Iraq, and from Kiik-Koba, Aman-Kutan, and Teshik-Tash in the Soviet Union.

Other Neanderthal fossils of western Asia, however, bear closer phenotypic similarity to the Third Interglacial Neanderthals of Europe as represented in the sites of Ehringsdorf, East Germany, and Steinheim, in West Germany, and Fontéchevade, in France, where the specimens exhibit less morphological specialization than do the Würm I inhabitants of Europe. These Third Interglacial Neanderthals are more like modern hominids in their possession of lower mean cranial capacity, with a range of 1,100–1,450 cubic centimetres for both sexes, the absence of an occipital "chignon," less muscular marking of the cranial vault, longer faces, and a tendency toward linearity of body build. The postcranial long bones are not bowed, as is the case with many Neanderthal specimens of Europe and western Asia of Würm I times. With these more modern-looking Neanderthals may be associated the western Asiatic fossils from Ksar 'Akil, in Lebanon, Har Qedumim, el-Zuttiyeh, and the majority of specimens from the Mt. Carmel series in Israel and those from the Soviet site of Staroselye. The specimens from Maghārat at-Tabūn and Maghārat as-Skhūl have been studied in greatest detail and are recognized by most physical anthropologists as representative Neanderthal populations evolving into the sapient type of humanity that has dominated this part of the world for the past 40,000 years. For the other sites of western Asia noted earlier, either the fossil evidence is too fragmentary or the comparative anatomical studies are not sufficiently complete to permit classification beyond the statement that a Neanderthal phenotypic pattern seems to be represented.

Neanderthal morphology in eastern Asia. For the Neanderthaloids of eastern Asia, the fossil record is less complete. Incisor teeth from Sjara-osso-gol and Tingts'un are "shovelled," a feature found in high frequency among living peoples of modern Asia and not unknown among *Homo erectus* specimens at the middle Pleistocene site of Chou-k'ou-tien. Cranial bones from Ti-shao-kou-wan and Ma-pa are thick, the skull from the southern China locality having a capacity of 1,225 cubic centimetres as well as robust features similar to the skull vaults from Ngandong. Yet the Javanese skulls, which are 11 in number and the only case of a population series for this period of time, have a mean cranial capacity well under this value, the means for males and females being 1,158 cubic centimetres and 1,042 cubic centimetres, respectively. The range of cranial capacity for the series is 1,035–1,255 cubic centimetres. In this feature the Chinese and Javanese Neanderthaloids do not resemble the Neanderthaloids of Broken Hill and Saldanha Bay, in Africa, but are more like the middle Pleistocene *Homo erectus* specimens from Asia, from which phylogenetic line they most likely evolved. Similarities with *Homo erectus* are also obvious in the pronounced angularity of the occipital bone (at the back of the skull), platyrrhinic nasal indices (indicating wide nasal openings in the skull), the thickness of the parietal bones (at the sides of the skull), and the location of the maximum width of the skull at points just below the parietal area. Yet the frontal torus (browridge) is of the divided pattern, as it is in Neanderthals, rather than forming a continuous bar. It is with the Wadjak specimens that cranial capacities increase to 1,550 cubic centimetres for the female and 1,650 cubic centimetres for the male. Specific features of large and chinned mandibles, broad and flat faces with broad noses and massive browridges, alveolar prognathism (forward projection of the tooth-bearing portion of the upper and lower jaws), and deep palates have led physical anthropologists to note the close similarity of the Wadjak specimens to modern aboriginal Australian and Melanesian populations rather than to modern Asians. Even less is known of the postcranial anatomy of these Neanderthaloids, but stature estimates based on two modern-looking tibial bones (from the lower leg) directly associated with the Ngandong crania suggest a height of about 178 centimetres for the male. The stature of the Ti-shao-kou-wan specimen is estimated for a thick-walled femoral (thigh bone) fragment as 167 centimetres if the specimen was male and 160 centimetres if female. The humerus (upper arm bone) from Ushikawa is thought to belong to a female less than 140 centimetres in height, and it differs from the humeri of modern Japanese by its narrowing of the proximal (shoulder) end and the pronounced thickening of the cortical area of the bone. The short stature and stocky body build of the greater number of Neanderthals and Neanderthaloids is considered by some anthropologists to have been an adaptive mechanism for surviving cold climatic conditions, where increased body bulk helps conserve body heat. Certain features of the Neanderthal-Neanderthaloid face have been explained as thermal adaptations to cold stress. The taller and more linear body conformation of the Solo specimens is especially interesting in view of the fact that this particular population lived in the tropical belt, where cold adaptation was not a factor of survival.

Skull morphology

Body build of Asian Neanderthals

The Asian sapiens fossils. The *Homo sapiens sapiens* fossil specimens are not unlike contemporary Asiatic populations, with the exception of the skull from Niah Cave, which resembles more closely the skulls of Australians than Borneans in structural features. Three of the seven specimens from the Upper Cave site at Chou-k'ou-tien have been compared to contemporary populations of Ainus, Melanesians, and Eskimos, and a broad range of phenotypic and polymorphic features may have been common in this part of Asia during later Pleistocene times (30,000–10,000 BP). Very similar to the skeletal anatomy of present occupants of eastern Asia are the specimens from Tzu-yang, Kai-t'o-tung, Ch'ang-yang, and Chai-sha, Kwangsi, save that the male postcranial skeleton from the latter site suggests a low height of 150 centimetres, which is just on the upper border of Pygmy stature. The skull fragments from Aichi-ken in Japan are sapient, as are the other fossil remains from upper Pleistocene sites in western Asia noted above.

LIFE STYLES OF PREHISTORIC MAN IN ASIA

Stone-tool cultures. The way of life of the Asiatic hominids of this period can be reconstructed in large part from the study of the archaeological data of preserved stone tools and weapons. There are two technological traditions represented in deposits dated to the middle Pleistocene (*c.* 125,000 BP)—the bifacial-hand-ax and cleaver-tool industries of western and central Asia and the chopper–chopping-tool traditions of eastern and southeastern Asia. The transitional zone of these two traditions occurs in India, where it has been defined as the "Movius Line," after H.L. Movius, an American prehistorian who has conducted research in Asia. The bifacial-hand-ax and cleaver-tool tradition is called Acheulean in Europe, Africa, and western Asia, where it appears stratigraphically earlier than the flake-tool industry called Levalloisian, although both flakes and bifaces occur together in some sites in this tricontinental area.

Acheulean and Levalloisian tool traditions

Acheulean hand axes have been found in deposits in the caves of Mt. Carmel, in Israel, in Jordan and Syria, Turkey, Arabia, Iran, Iraq, Afghanistan, and eastward to Armenia, Crimea, and the Caucasus Mountains. The Narbada Valley of India is particularly rich in hand axes, the first discovery of a paleolithic tool in South Asia having been made in the Madras area of India as early as 1863. Levallois flakes made by a prepared core technique occur in increasing frequency with the dawn of the upper Pleistocene in India, where they are a final phase (dating from *c.* 150,000 years ago) of another flake-tool tradition, called Soan. Apart from a few isolated cases of hand axes in China, the only place in Southeast Asia where these tools appear is in Java, where they are associated with the Patjitanian tool industry, which also has certain Levalloisian features. Chopper–chopping tools also appear in Java during this period, as do tool industries called the Sangiran flake culture and the Ngandongian culture. These are marked by the presence of antler picks, stingray barbs, and bola stones as well as small stone flake tools.

With the advent of colder climatic conditions and the

onset of the Würm I Stadial (70,000 BP) in western Asia, the bifacial-hand-ax industries were replaced by flake-tool traditions; one of these was an evolved Levalloisian and another the Mousterian tool industry, in which stone flakes were retouched to make tools but not specifically manufactured from prepared stone cores. The Mousterian tradition is intimately associated with *Homo sapiens neanderthalensis* in western Asia, as is seen at Ksar 'Akil, the caves of Mt. Carmel, a number of sites in Jordan and Syria, Kiik-Koba in Crimea, Shanidar in Iraq, Teshik-Tash in central Asia, Molodova in the western Ukraine, and far eastward in the Ordos region near the Great Wall of China. In southern Asia, the later phase of the Soan tool tradition resembles the Mousterian. Elsewhere in eastern and southern Asia, the chopper–chopping tool tradition persisted until the close of the Pleistocene (*c.* 10,000 BP). In Burma, in the vicinity of the Irrawaddy River, a silicified wood or tuff was manufactured into choppers and retouched flakes. These tools represent the Anyathian culture. The Tampanian culture of Malaysia is another local variation of the chopper-chopping tool tradition. On the shores of the Sea of Azov in southern U.S.S.R. this tradition merged with the limits of diffusion of the Mousterian tradition. At the upper Pleistocene localities of Chou-k'ou-tien, quartz flakes with working at both ends occurred with choppers, chopping tools, and small scrapers. A tool tradition of flaked stone balls and bifacial choppers but no bipolar flaking is called the Fenho Complex, and its Third Interglacial date marks the transition to the upper Pleistocene traditions that have features of the Asiatic Mousterian in combination with older styles. In eastern and southeastern Asia many elements of this culture persist into terminal Pleistocene times, when Mesolithic cultures, characterized by small-blade microliths, replaced the older traditions.

Mousterian tool industries

Fire, shelter, and cultural data. Human occupation during the upper Pleistocene included the areas inhabited by *Homo erectus* of the middle Pleistocene as well as extensions into areas that earlier hominids had not entered. Biological and cultural adaptation to cold climatic conditions permitted settlement of higher altitude regions of Asia, and with the retreat of the ice sheets man followed game fauna into the newly opened country. Cold climates were made more tolerable by the use of caves and rock-shelters, some of which served as places of burial as well as hearths and industry sites. Open-air encampments continued to be used in some regions, however. Fire, which has been reported in Asia as early as 360,000 years ago from evidence of charcoal and charred bone at the *Homo erectus* deposits of Chou-k'ou-tien, in China, was controlled by the hominids of the upper Pleistocene, thus enabling them to move into wider areas of settlement and survive under a wide range of ecological settings. The control of fire by man, along with cave dwelling and the wearing of skins sewn together with bone awls, enabled prehistoric man to survive the cold conditions of the later upper Pleistocene. Traces of fire are found in most of the open-air, cave, and rock-shelter sites where skeletal and artifactual remains have been preserved, but the traces of charcoal and calcined bones do not appear in disturbed deposits, as at Ngandong. Among the undisturbed sites are the caves at Mt. Carmel, Aman-Kutan, Molodova, and Ch'i-lin Shan. Neanderthal man practiced burial of the dead at the Mt. Carmel caves, Kiik-Koba, Teshik-Tash, in the Upper Cave of Chou-k'ou-tien, Ksar 'Akil and Malta. At Molodova, the remains of a hut can be identified by the oval of mammoth bones and tusks enclosing some 15 separate hearths. This is evidence of open-air housing during a warm phase of the upper Pleistocene, although caves and rock-shelters continued to be the most common form of habitation in areas where they were naturally present. Evidence of cannibalism occurs at Solo, as it does in several Neanderthal sites of Europe. The presence of diseased and aged individuals in the Neanderthal community at Shanidar speaks of a more humane aspect of upper Pleistocene life. Pictorial or plastic art does not appear in the archaeological record for Neanderthal man and emerges only with the presence of *Homo sapiens sapiens*.

Fire and shelter

Throughout a broad geographical range of habitation in the Asiatic landmass, upper Pleistocene hominids were successful hunters of large game animals. For the western and central Asiatic Neanderthals these were Paleoarctic fauna, which can be identified as cold adapted or warm adapted according to their occurrence in periods of high glaciation or interglacial–interstadial recessions of the ice. In Israel, the warm-climate fauna are marked by remains of hippopotamus and rhinoceros, cold-climate fauna by deer and antelope. In central Asia the cold-adapted woolly rhinoceros, mammoth, and reindeer were abundant. South and Southeast Asian fauna were distributed also in southern China and merged with the Paleoarctic fauna of northern China. In India, some of the fauna of the middle Pleistocene survived until well into the late upper Pleistocene, as suggested by the presence of certain species of bovids. The persistence of tropical conditions throughout much of the Pleistocene in southern and Southeast Asia gives a very different faunal picture from that of western and Central Asia.

Game animals

PHYLOGENETIC AFFINITIES OF ASIAN FOSSILS TO MODERN MAN

Physical anthropologists are cautious in assuming phylogenetic affinities of living human populations to specific hominid fossil specimens of the Pleistocene, although some scholars have asserted that the living races of man can be recognized in the ancestral hominid record as far back as the middle Pleistocene. Beyond a few thousand years, however, physical resemblances of particular osteological or dental features between living and extinct populations become fewer in number and more tenuous as reliable data for establishing phylogenetic lines and classifications, and it is no longer a common practice in physical anthropology to attempt a "racial phylogeny" for a population beyond the limits of a few millennia. The traditional racial categories of Veddoid, Caucasoid, Mongoloid, Australoid, and the like are no longer regarded as particularly meaningful in relation to knowledge of prehistoric man.

In western Asia, the Natufian people of the Mesolithic of Israel do not resemble the present populations of the Near East; hence, it is not surprising that still earlier hominids, such as the Neanderthals of western Europe, fail to reflect obvious connections with contemporary Israelis, Lebanese, Syrians, etc. In Southeast Asia, the Neanderthaloid specimens from the sites of Solo and Wadjak in Java and Niah Cave in Borneo do not resemble the present inhabitants of mainland and island Southeast Asia, although some features of Neanderthaloid crania appear in the contemporary native populations of Australia and Melanesia. With the coming of Mesolithic (Middle Stone Age) post-Pleistocene cultures (after 12,000 BP) in Southeast Asia, the populations bearing these new traditions are represented in the osteological record by only a few specimens that are similar in anatomically significant ways to modern Southeast Asians. The earliest known fossil specimen of a Pygmy or Negrito population in Asia has come from Indochina, but it is only as ancient as the Neolithic Period of culture (*c.* 8000 BP). The antiquity of Pygmy populations in Malaysia, the Philippines, Andaman Islands, and New Guinea remains unknown, but it no longer seems reasonable to conceive of a "Pygmy race" binding these dwarfed Asiatic groups to Pygmies of Africa. Pygmy populations of Asia bear many more resemblances of physical characters to the macropopulations surrounding them than to more distant Pygmy populations.

Skeletons that can be reasonably identified as Chinese first appear in the Far East around 3000 BC, although some phenotypic variables, such as shovel-shaped incisors, which appear in high frequency in populations of Asiatic descent, occur as well in *Homo erectus* fossils from Chou-k'ou-tien. The high frequency of Chinese characters in the indigenous populations of Southeast Asia is explained by historic movements of Chinese into regions to the south of their ancient cultural area. In

southern Asia, the hominid skeletal record has been recognized as useful in drawing some phylogenetic affinities between living Indians and their ancestors of a few thousand years ago, but the evidence for Pleistocene man in India was established upon the discovery of stone industries rather than upon a rich fossil record. It is with the food-producing Neolithic (New Stone Age) cultures of Asia that biological similarities between extinct and contemporary human populations become apparent, but this represents an antiquity of only four or five millennia. It was from Asia that man moved last to the uninhabited vastness of Oceania, Australia, and the Western Hemisphere. Movements of Asian people into Europe has continued to the present day in eastern Europe and the Aegean.

BIBLIOGRAPHY. Literary sources on prehistoric Asia are numerous, but the most important ones constitute portions of more general works or appear as technical articles in scientific journals. General writings about prehistoric cultures of the Old World, which include discussions of Asiatic sites, are F. BORDES ,*La Palèolithique dans le monde* (1968; Eng. trans., *The Old Stone Age*, 1968); and J.G. CLARK, *World Prehistory: A New Outline* (1969). Regional studies are best represented by C.S. CHARD, "An Outline of the Prehistory of Siberia," *SWest. J. Anthrop.*, 14:1–33 (1958); H.L. MOVIUS, "Palaeolithic and Mesolithic Sites in Soviet Central Asia," *Proc. Am. Phil. Soc.*, 97:383–421 (1953), and "Palaeolithic Archaeology in Southern and Eastern Asia, Exclusive of India," *J. Wld. Hist.*, 2:257–282, 525–553 (1955); H.D. SANKALIA, *Prehistory and Protohistory in India and Pakistan* (1963). Critical sources on dating, stratigraphy, and cultural chronology include F.C. HOWELL, "Upper Pleistocene Stratigraphy and Early Man in the Levant," *Proc. Am. Phil. Soc.*, 103:1–65 (1959); and K.P. OAKLEY, *Frameworks for Dating Fossil Man* (1964). The physical anthropology of prehistoric Asians is discussed in the classic by M. BOULE and H.V. VALLOIS, *Les Hommes fossiles* (1921; Eng. trans., *Fossil Men*, 1957); and in C.S. COON, *The Origin of Races* (1962). Coon interprets the biological data according to a particular phylogenetic school that is not favoured by all contemporary anthropologists, but his discussion of the fossil record is excellent. Regional physical anthropology of prehistoric Asians is represented by K.A.R. KENNEDY, "The Search for Early Man in India," *S.S. Sarkar Memorial Volume* (1972); and by H.N. MICHAEL (ed.), *Ethnic Origins of the Peoples of Northeastern Asia* (1963). More specialized topics are treated by K.A.R. KENNEDY, "Paleodemography of India and Ceylon Since 3000 B.C.," *Am. J. Phys. Anthrop.*, 31:315–319 (1969); and in a series of articles in English, French, and German that appear in G.H.R. VON KOENIGSWALD (ed.), *Hundert Jahre Neanderthaler, Neanderthal Centenary, 1856–1956* (1958).

Aśoka

Aśoka, one of the most significant early devotees of Buddhism, was the last major emperor in the Mauryan dynasty of India during *c.* 265–238 BC (others give *c.* 273–232 BC), his dominions extending over Afghanistan and the entire subcontinent except some southern territories.

The account below of Aśoka's life is based on his own numerous inscriptions or edicts, some short, some long, found at many places, rather than on Buddhist legends that are mostly fanciful or exaggerated. He conquered the Kaliṅga country (modern Orissa State) on the east coast after a very sanguinary war in the eighth year of his reign, but the terrible sufferings the war inflicted on the defeated people moved him to such great remorse that he renounced armed conquests forever. It was at this time that he came in touch with Buddhism and adopted it. Under its influence and prompted by his own dynamic temperament, he resolved to live according to, and preach, the *dharma* (principles of right life) and to serve his subjects and all humanity. He declared his nonaggressive intentions to his neighbours, assuring them of his good will toward them and sent envoys to distant kings bearing his good will and the message of the *dharma*. These actions he called his new policy of "conquest by *dharma*."

Aśoka's view of the *dharma*

By *dharma*, as he repeatedly declared, he understood the energetic practice of the socio-moral virtues of honesty, truthfulness, compassion, mercifulness, benevolence, nonviolence, considerate behaviour toward all, "little sin and many good deeds," nonextravagance, nonacquisitiveness, and noninjury to animals. He spoke of no particular mode of religious creed or worship, nor of any philosophical doctrines. He spoke of Buddhism only to his coreligionists and not to others.

Toward all religious sects he adopted a policy of respect and guaranteed them full freedom to live according to their own principles but he also urged them to exert themselves for the "increase of their inner worthiness." He, moreover, exhorted them to respect the creeds of others, praise the good points of others, and refrain from vehement adverse criticism of the viewpoints of others.

In order to gain wide publicity for his teachings and his work he made them known by means of oral announcements and also engraved them on rocks and pillars at suitable sites. From these inscriptions—the Rock Edicts and Pillar Edicts (*e.g.*, the lion capital of the pillar found at Sarnath, which has become India's national emblem)—mostly dated in various years of his reign and containing statements regarding his thoughts and actions his life and acts are known. There is such a ring of frankness and sincerity in the utterances of Aśoka that they appear to be true.

To practice the *dharma* actively Aśoka went out on periodical tours preaching the *dharma* to the rural people and relieving their sufferings; he ordered his high officials to do the same, in addition to attending to their normal duties; he exhorted administrative officers to be constantly aware of the joys and sorrows of the common folk and to be prompt and impartial in dispensing justice. A special class of high officers, designated "*dharma* ministers," was appointed to foster *dharma* work by the public, relieve sufferings wherever found, and look to the special needs of women, of people inhabiting outlying regions, of neighbouring peoples, and of various religious communities. It was ordered that matters concerning public welfare were to be reported to him at all times. The only glory he sought, he said, was for having led his people along the path of *dharma*. No doubts are left in the minds of readers of his inscriptions regarding his earnest zeal for serving his subjects. More success was attained in his work, he says, by reasoning with people than by issuing commands.

Aśoka's public works and services to Buddhism

Among his works of public utility were the founding of hospitals for men and animals and the supply of medicines; planting of roadside trees and groves, digging of wells, and construction of watering sheds and resthouses. Orders were also issued for curbing public laxities and preventing cruelty to animals.

With the death of Aśoka the Maurya Empire disintegrated and his work was discontinued. His memory survives for what he attempted to achieve and the high ideals he held before himself.

Most enduring were Aśoka's services to Buddhism. He built a number of *stūpas* (commemorative burial mounds) and monasteries and erected pillars on which he ordered inscribed his understanding of religious doctrines. He took strong measures to suppress schisms within the order (the Buddhist religious community) and prescribed a course of scriptural studies for adherents. Tradition recorded in the Ceylonese chronicle *Mahāvaṃsa* says that when the church decided to send preaching missions abroad, Aśoka helped them enthusiastically and sent his own son and daughter as missionaries to Ceylon. It is as a result of Aśoka's patronage that Buddhism, which until then was a small sect confined only to particular localities, spread throughout India and subsequently beyond the frontiers of the country.

A sample quotation that illustrates the spirit that guided Aśoka is: "All men are my children. As for my own children I desire that they may be provided with all the welfare and happiness of this world and of the next, so do I desire for all men as well."

BIBLIOGRAPHY. AMULYACHANDRA SEN (ed.), *Asoka's Edicts* (1956), deals with all aspects of Aśoka's life and work on the basis of archaeological and literary materials. D.R BHANDARKAR, *Asoka*, 3rd ed. (1955); and R.K. MOOKERJEE, *Asoka*, 3rd ed. (1962), are also good studies based on historical materials.

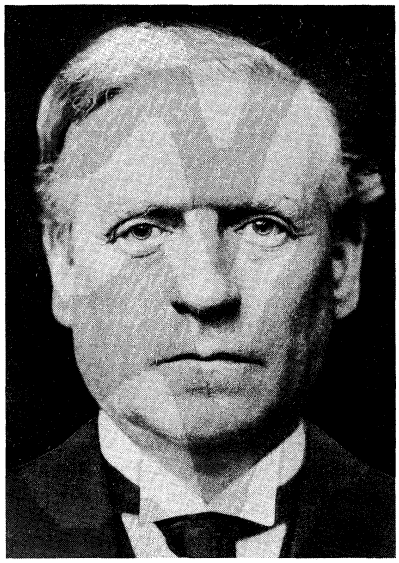
Asquith, H.H.

Liberal British prime minister from 1908 to 1916, Herbert Henry Asquith was responsible for the Parliament Act of 1911 (limiting the power of the House of Lords) and led Britain during the first two years of World War I.

Radio Times Hulton Picture Library



Asquith.

Asquith was born at Morley, Yorkshire, on September 12, 1852, the second son of Joseph Asquith, a small businessman in the wool trade and an ardent Congregationalist, who died in 1860. Asquith was educated at the City of London School from 1863 to 1870 when he won a classical scholarship at Balliol College, Oxford. At Balliol he obtained the highest academic honours, and became a fellow of his college in 1874. Deciding upon a legal career, he entered Lincoln's Inn and was called to the bar in 1876. The following year he married Helen Melland, daughter of a Manchester doctor, by whom he had four sons and one daughter. His early days at the bar were difficult, but from about 1883 onward he became highly successful.

A keen Liberal, Asquith entered the House of Commons for East Fife in 1886 and remained its member for 32 years. He commanded the attention of the House from the first, concentrating particularly upon the Irish question. In 1888 he achieved celebrity as junior counsel for the Irish leader Charles Stewart Parnell, when Parnell was accused, before a parliamentary commission, of condoning political murder. In 1892 Gladstone made Asquith home secretary. Before that, in 1891, his wife had died of typhoid fever, leaving him with a family of young children. Less than three years later he astounded the social and political world by marrying Margot Tennant, who was 12 years younger and the centre of social and intellectual circles far removed from those in which Asquith and his first wife had moved.

His three years as home secretary, though in general an unhappy period for the Liberals, established Asquith's reputation as an administrator and a debater. By 1895 he had become one of the leading figures of his party. Defeated at the polls, the party spent the next 11 years in opposition. Asquith earned during this time a large income at the bar, but the lack of any private means obliged him to refuse the party leadership when it was offered to him in 1898, and Sir Henry Campbell-Bannerman succeeded instead. Asquith did not see eye to eye with the new leader on all questions of foreign and imperial policy. Their divergence became open and public during the South African War (1899–1902), when Asquith, along with Lord Rosebery, Sir Edward Grey, and R.B. Haldane, formed the Liberal League to advocate an imperial policy in support of the government's expansionism. The conflict was temporarily healed after the end of the war and following the Liberals' victory at the polls in 1906, Asquith served as chancellor of the exchequer under Campbell-Bannerman.

Early in April 1908 Campbell-Bannerman resigned and died some days later. Asquith, generally regarded as his inevitable successor, became prime minister and was to hold the office for nearly nine years. He appointed David Lloyd George to the Exchequer and made Winston Churchill president of the Board of Trade. The chief problem confronting him at home was the opposition of the House of Lords to Liberal reforms, and the consequent danger of a rebellion from the frustrated radicals in his own party; abroad there was a growing naval competition with Germany. When Lloyd George endeavoured to raise money for naval increases and social services in his "radical budget" of 1909, the budget was vetoed by the House of Lords.

Parliamentary reform

At this stage Asquith took over the conduct of a constitutional struggle. In 1910 he announced a plan to limit the powers of the upper house, and, after two general elections, persuaded King George V to threaten to create enough new pro-reform peers to swamp the opposition. The resulting Parliament Bill, passed in August 1911, ended the Lords' veto power.

The three years between the end of this episode and the outbreak of World War I were extremely harassing for the prime minister. Abroad, the international situation deteriorated rapidly; at home, controversy was caused by charges of corruption in his government, the disestablishment of the Anglican Church in Wales (1914), and the conflict between Home Rulers and Unionists in Ireland, which nearly led to civil war in 1914. Asquith's policies did little to improve the situation in Ireland.

Though convinced that a German victory over France would be disastrous to the British Empire, Asquith delayed Britain's entry into World War I until public opinion had been aroused by the German attack on Belgium. In war, he trusted his military experts and in general favoured the school that maintained that victory could be won only on the western front.

In May 1915 Asquith had to reconstruct his Cabinet on a coalition basis, admitting Unionists as well as Liberals, and appointing Lloyd George minister of munitions. The coalition was not successful under his leadership. The Dardanelles expedition failed and there was no sign of a breakthrough in the west. At the end of 1915 Asquith substituted Sir Douglas Haig for Sir John French as British commander in chief in France, and appointed Sir William Robertson as the new chief of the imperial general staff. But 1916 was an even unhappier year: the Easter Rising in Dublin caused a grave domestic crisis, and the battle of the Somme led to a complete impasse on the western front. After a protracted struggle, conscription was belatedly introduced. But there was a general aura of dissatisfaction by the autumn, and Asquith was assailed by a strident press campaign. In December he resigned and was replaced by Lloyd George. He never held office again, though he remained leader of the Liberal Party until 1926. In this capacity he often opposed the policies of his successor.

Asquith accepted a peerage as earl of Oxford and Asquith in 1925, and was created a Knight of the Garter shortly afterward. In the last years of his life he was relatively impoverished and wrote a number of books to make money, the best known being *The Genesis of the War* (1923), *Fifty Years of Parliament* (1926), and *Memories and Reflections* (1928). He died at Sutton Courtenay on February 15, 1928, and was buried in the graveyard of the parish church there.

Asquith was a competent statesman, but not a great one. He had no original or innovating genius and lacked the sense of the dramatic needed to convince Britain that it was in good hands in a time of national crisis.

BIBLIOGRAPHY. J.A. SPENDER and CYRIL ASQUITH, *Life of Herbert Henry Asquith, Lord Oxford and Asquith*, 2 vol. (1932), is the official biography, cautious, discreet, and highly favourable. The most up-to-date life is ROY JENKINS, *Asquith* (1964), shorter and more critical than the official biography, though in general pro-Asquith. ROBERT BLAKE, *The Unknown Prime Minister: The Life and Times of Andrew Bonar Law, 1853–1923* (1955), gives the Conservative side of the period;

THOMAS JONES, *Lloyd George* (1951), and FRANK OWEN, *Tempestuous Journey* (1954), give the Lloyd Georgite point of view. Other books worth consulting are A.J.P. TAYLOR, *English History, 1914–1945* (1965); RANDOLPH CHURCHILL, *Winston S. Churchill: The Young Statesman, 1901–14* (1967); and MARTIN GILBERT, *Winston S. Churchill, 1914–16* (1971).

(B.)

Assam

One of the 21 states of the Indian Union, Assam is located in the northeast of India, from which it is almost isolated on the west by Bangladesh. It has an area of 30,452 square miles (78,890 square kilometres) and a population (1971) of about 14,625,000. Until an administrative reorganization in 1972, the Union Territories of Arunachal Pradesh (formerly the Northeast Frontier Agency [NEFA]) and Mizoram and the state of Meghalaya were part of Assam.

Assam is bounded to the north by Bhutan and Arunachal Pradesh; to the east by Arunachal Pradesh, Nagaland and Manipur; to the south by Mizoram and Meghalaya; and to the west by West Bengal, Tripura, and Bangladesh (formerly East Pakistan). To the northwest, a narrow corridor running through the foothills of the Himalayas connects the state with India. Geographically, Assam has no natural boundaries. The capital of the state, formerly located at Shillong (now the capital of Meghalaya), was temporarily shifted to Dispur, a suburb of Gauhāti, in 1972. (For associated physical features, see BRAHMAPUTRA RIVER; HIMALAYAN MOUNTAIN RANGES; for historical background, see INDIAN SUBCONTINENT, HISTORY OF THE.)

History. In the earliest times the territory and its environs were known as Kāmarūpa, a state that had its capital at Prāgjyotiṣapura (modern Gauhāti, in Assam on the southern bank of the Brahmaputra). Ancient Kāmarūpa included roughly the Brahmaputra Valley, Bhutan, the Rangpur district (now in Bangladesh), and Cooch Behār, in West Bengal. King Narakāsura and his son Bhagadatta were famous rulers of Kāmarūpa in the Mahābhārata period, at least 1000 BC. A Chinese traveller, Hsüan-tsang, who visited the country when it was ruled by Bhāskaravarman, about AD 640, left a vivid account of the country and its people. After this, information about ancient Assam is very meagre for a few centuries, but the discovery of several copperplates, clay seals, and stone inscriptions that date from the 7th to the mid-12th centuries has thrown some light on the condition of the country at that time. These archaeological records indicate that the inhabitants of the region attained considerable power and a fair degree of civilization. The copperplates further provide clues to the locations of important ancient settlements and also the routes connecting them.

Rule by the Ahoms

Assam was ruled by various dynasties—the Pālas, Koches, Kachāris, and the Chutiyas—but, because of the constant warfare amongst these princes, there was no stable government in the area until the coming of the Ahoms in the 13th century. The Ahoms crossed the Pātkai Range from Burma and conquered the local chieftains who then ruled the Upper Assam Plain. In the 15th century the Ahoms, who gave their name to the country, were the dominant power in Upper Assam. Two centuries later, after defeating the Koches, the Kachāris, and other local rulers, they also became the rulers of Lower Assam up to Goālpāra. The power and prosperity of the Ahoms reached a zenith during the rule of King Rudra Singh (1696–1714).

Dissension and jealousy among the princes gradually weakened the central administration, with the result that, in 1786, the ruling prince Gaurinath Singh, in despair, sought the aid of the British in Calcutta. Captain T. Welsh, sent by the British governor general in India, restored peace and was recalled in spite of the protests of the Ahom king. Internal strife then caused one crisis after another until, in 1817, the Burmese entered Assam in response to the appeal of the *bar phukan* (governor) Badan Chandra, a rebel against the king. They swept over the country thrice, bringing destruction and misery.

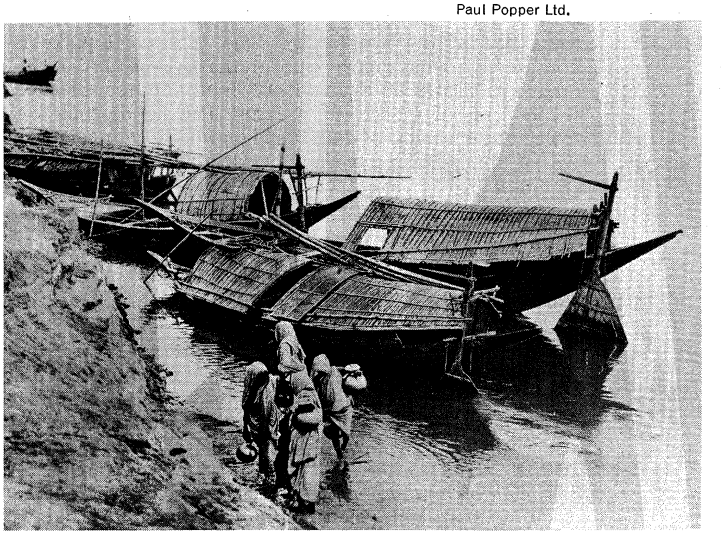
The British, whose interests elsewhere were threatened by these developments, ultimately drove out the Burmese invaders, and, after the Treaty of Yandabo was concluded with Burma in 1826, Assam became a part of British India.

A British agent, representing the governor general, was appointed to administer first the devastated area of Assam. In 1838 Assam was incorporated into British-administered Bengal. By 1842 the whole of Assam Valley had come under British rule. In 1874 a separate province of Assam was created under a chief commissioner, with its capital at Shillong. In 1905, on the initiative of the British viceroy, Lord Curzon, the province was amalgamated with the eastern part of Bengal. The subsequent partition of Bengal was, however, resented, and in 1924 this arrangement was reversed, with Assam once more made a separate province. During World War II, Assam became one of the main supply routes for Allied forces operating in Burma, and within the territory of Assam decisive battles were fought in 1944 in a number of places (including Bishenpur, in Manipur, and Kohīma, in Nāgāland). These battles were instrumental in preventing the Japanese advance into India.

After India achieved independence in 1947 and as a result of the ensuing partition, the district of Sylhet (excluding the Karīmganj subdivision) was ceded to Pakistan. In 1961 and 1962 Chinese armed forces, disputing the McMahon Line as the boundary between India and Tibet, occupied part of the NEFA. In December 1962, however, they voluntarily withdrew to Tibet. In 1963 the Nāga Hills district, formerly a part of Assam, became the 16th state of the Indian Union, under the name of Nāgāland (*q.v.*). A part of Tuensang, a former territory of NEFA, was also added to Nāgāland. In 1970, after the tribal people of the Gāro district and the United Khāsi and Jaintia Hills district, located in the centre of Assam, had also demanded a separate state, an autonomous state named Megalaya (*q.v.*) was created with these two districts. In 1972, the North East Frontier Agency was renamed Arunachal Pradesh and was separated from Assam and the Union Territory of Mizoram was created in the south.

The landscape. *Physiography.* Except for the districts of Mīkīr Hills and North Cāchār Hills, Assam is generally comprised of plains and river valleys. The state may be divided into three principal physical regions—the Brahmaputra Valley in the north, the Barāk Plain in the south, and the hilly regions that lie between these two valleys.

Paul Popper Ltd.



Sampan skiffs on the Brahmaputra River, Assam, India.

The valley of the Brahmaputra River (*q.v.*) is the dominant physical feature of Assam. The river, which is known as the Ya-lu-tsang-pu Chiang in Tibet, enters Assam near Sadiya, after which it runs directly westward for nearly 450 miles, traversing every district across the

length of Assam before turning due south to enter the plains of Bangladesh. The river valley, rarely more than 50 miles wide, is studded with numerous groups of hills that rise abruptly from the plain. The valley is surrounded on all sides, except on the west, by mountains and is intersected by many streams and rivulets that flow down from the neighbouring hills to empty into the Brahmaputra.

To the southeast of Meghalaya is the small but important Barāk Valley, about 125 miles long and about 60 miles wide. The valley supports a dense population.

Geologically, the Brahmaputra Valley and the Barāk Valley are entirely alluvial in origin and consist of sand, sandstone pebbles, clay, and sometimes a mixture of sand and clay containing decomposed vegetable matter. The Tertiary deposits (from 2,500,000 to 65,000,000 years old) include a similar variety of rocks, among them hard sandstone, soft and loose sand, conglomerates, coal seams, shales, and sandy clays. The lowest Tertiary deposits in some parts of Assam include limestone.

The Mīkīr Hills and part of the North Cāchār Hills form part of the Meghalaya Plateau, which may have been an extended portion of Gondwanaland (an ancient landmass in the Southern Hemisphere that once grouped together South America, Africa, Australia, and part of the Indian subcontinent). This truncated portion of the main plateau displays a rugged topography, with shales of the Barail series exposed in valley bottoms. It has, roughly, a northerly slope, with the outer ranges of the Mīkīr Hills reaching an average elevation of about 1,500 feet (450 metres) above sea level. Higher average elevations of about 3,300 feet (1,000 metres) are reached in the central portion of the hill district east of the Kopili River. (The river has formed plain embayments into the interior of the Mīkīr Hills, largely isolating this section from the main plateau.)

The northern ranges, which extend from Dabaka in the southwest to Bokākhāt in the northeast, attain an average elevation of 2,000 feet (600 metres). Major peaks in the north include Basundhari Parbat (2,540 feet), Raisang (2,420 feet), Mehekongthu (2,095 feet), and Kud Parbat (2,055 feet).

The southern ranges, known as the Rengma Hills, have an average elevation of about 3,000 feet (900 metres). Main peaks in the south are Chenghehishon (4,200 feet) and Khunbaman Parbat (4,300 feet).

Earthquakes

Earthquakes are a common phenomenon in Assam. In modern times the most important Assamese earthquakes have been those that occurred in 1897, with the Shillong Plateau as the epicentre; 1930, with Dhubri as the epicentre; and 1950, with Ch'a-yü (Rima) in Tibet at the NEFA border as the epicentre. The 1950 earthquake is considered to have been one of the five biggest earthquakes in history. It created heavy landslides that blocked the courses of many hill streams. The floods that followed the bursting of these artificial dams caused more loss of life and property than the earthquake itself. (H.D.)

Climate. The average temperature is moderate—about 84° F (29° C) in the hottest month (August). In the cool season, when the northeast monsoon (rain-bearing) wind blows down the Brahmaputra Valley, the average valley temperature in January is 61° F (16° C). At this season the climate in the valley is marked by fogs and a little rain. Assam escapes the normal Indian hot, dry season. Some rain occurs from March onward, but the real force of the monsoon winds is felt from June onward, when they blow at right angles to the Assam hills. By the time the winds have crossed the hills they bring little rain to the valley; Gauhāti receives only about 67 inches. (L.D.S./Ed.)

Vegetation and animal life. The forested area covered 18,500 square miles before the creation of Meghalaya and Mizoram and formerly represented nearly 39 percent of the total area of the state, of which reserved forest, which is efficiently managed by the government, constituted only about 6,400 square miles, or about 12 percent of the total area. The creation of both Meghalaya and Mizoram, however, substantially reduced the state's forest area.

A portion of the reserved forest in Assam is devoted to wildlife sanctuaries. There are several such sanctuaries, of which Kāziranga, the stronghold of the fast-disappearing one-horned rhinoceros, is the most famous. The most important forest products are timber and bamboo, firewood, and lac (shellac). There are about 74 species of timber, of which 49 varieties are commercially exploited. The forests are inhabited by many wild animals.

Population. *Demography.* During the 70 years from 1901 to 1971 the population of what is now Assam increased from 3,290,000 to 14,625,000—an increase of 345 percent, compared with an average increase of 130 percent for India during the same period. The distribution of population is uneven owing to the hilly terrain, the number of rivers, the forests, the small amount of cultivable land, and the lack of industrialization. In the plains the average density is 577 per square mile, whereas in the hills it was only 77.

The unusually rapid growth of population in the state has been due mostly to the immigration into Assam of tea-garden labourers, Nepali graziers, West Bengal Muslims, and Hindu refugees from what is now Bangladesh.

The rural element amounted to some 92 percent of the population of Assam in 1971. Villages with a population of 2,000 or more in 1961 accounted for 50 percent, and 42 percent lived in smaller villages or clusters.

Urbanization

The increase of urban population during the 1960s was significant. The growth of many industries, increased commercial activity, and the desire of the Bangladesh refugees to live near towns were some of the causes of the increase in urban population. Only Gauhāti had a population of more than 100,000. There are 11 towns of more than 20,000 persons. Some areas, such as Badarpur *thānā* (police district), with a 1961 density of 1,388 persons per square mile, have become overpopulated.

Ethnic composition, linguistic patterns, and religious affiliations. The people of the plains districts of the Brahmaputra and Barak valleys are mainly of Indo-Iranian stock, although many are of Mongoloid stock, particularly in the upper Assam region. By the time of their arrival in the Brahmaputra Valley, it would appear that the original Aryan people of Assam had become intermixed with other peoples. Assamese is the principal language and is regarded as the lingua franca of the whole of northeast India. Although scholars trace the history of the Assamese literature from the beginning of the second millennium AD, yet an unbroken record of literary history is traceable only from the 14th century. The majority of the people of the Cāchār district in the Barak Valley speak Bengali.

About two-thirds of the Assamese are Hindus; about a quarter of the population is Muslim. The Muslims are mostly recent settlers from East Bengal, or converts belonging to the lower strata of the peoples of Indo-Iranian origin. A majority of the Hindus accept Vaiṣnavism, which is based on the deity Vishnu.

The tribes in the hills, and also those in the plains, are of Mongoloid stock. They speak dialects of Tibeto-Burman origin, with the exception of the Khasi dialect, which is derived from the Austroasiatic branch of languages. Many of the hill tribes have been converted to Christianity by missionaries, but the majority still observe the customs and festivals of their traditional religion, which is based on animism and has a close affinity to the ancient form of Hindu worship. The Mikirs and Kachāris of the Mīkīr and North Cāchār Hills are mostly Hindus; although they speak dialects of Tibeto-Burman origin, they have adopted Assamese as their first language.

Administration and social conditions. The state government has a unicameral legislature under a governor and a Cabinet. The state of Assam comprises 10 districts —Goālpāra, Kamrup, Nowgong, Darrang, Sibsāgar, Dibrugarh, and Lakhīmpur in the Brahmaputra Valley; Cāchār in the Barak Plain; the Mīkīr Hills; and the North Cāchār Hills. (H.D./Ed.)

Education

In 1968–69 an estimated 2,151,000 children were receiving education, of whom more than 60 percent were boys; 90 percent came from rural areas. Primary educa-

tion was being given to about 75 percent and secondary education to about 25 percent of the children in the respective age groups. Compulsory primary education was in force for children between the ages of six and 12 in 13 towns and about 4,400 villages. The 1971 census recorded that literacy among males was 37 percent and among females only 18 percent. There are universities in Gauhāti, Jorhāt, and Dibrugarh. In 1955 birthrates and death rates were, respectively, about 40 and about 16 per 1,000 persons. Seventeen welfare-extension projects, operating through more than 80 centres and covering 300,000 people, were providing recreational and cultural facilities for women and children. (S.B.L.N.)

The economy. *Agriculture.* Agriculture is of basic importance to Assam. In the early 1970s, about 56 percent of the total working population were directly engaged in agriculture, with another 10 percent employed on the plantations, in forestry, or in other occupations related to agriculture.

Rice accounted for about 70 percent of the sown area. In 1968 to 1969 tea covered an area of almost 520,000 acres and jute about 270,000 acres. These two crops are important foreign-exchange earners. In the early 1960s, Assam grew nearly 50 percent of India's tea and 25 percent of its jute. Cultivation in the Brahmaputra Valley is extensive; other crops grown there include oilseeds, pulses (leguminous plants, such as peas, beans, or lentils), sugarcane, rape (an oil-yielding plant, the leaves of which are used for fodder), mustard, and potatoes.

Fruits that are grown include oranges, pineapples, and bananas. The state produces a surplus of cereals, but there is a shortage of oilseeds and pulses. Double-cropping (growing two crops a year) and other improved methods of cultivation were being introduced in the early 1970s.

The tea gardens

Tea cultivation in Assam was begun as early as 1835. Before Assam's reorganization in 1972, there were almost 750 tea gardens, producing nearly 44,000 pounds of tea annually.

Minerals. In the early 1970s the known minerals of the state were petroleum, coal, limestone, fireclay, china clay, and feldspar. Of these, oil, coal, and limestone were being commercially exploited.

Oil is found at Digboi, Naharkatia, Hugrijan, Moran, Rudrasagar, and Lakowa—all in Upper Assam. Coal is found in the Dibrugarh district of Upper Assam and in the Mīkīr Hills. Railways, plantations, and steamships are the main consumers of Assam coal. Limestone is quarried in the Mīkīr Hills.

Industry. In spite of its raw materials, industrial growth in Assam is in its infancy, for—with the exception of tea and oil—there are few industries of significance. Industrial development is handicapped mainly by Assam's isolation from the rest of India, by a bad transport system, by a small local market, and by the lack of sufficient capital. A number of industrial enterprises have nevertheless been started. These include a fertilizer plant at Namrup, a jute mill at Silghāt, a sugar mill at Dergaon, a paper mill at Jogighopa, a spun-silk mill at Jagiroad, and a cement factory at Bokajān. There are also many sawmills and plywood and match factories that make use of the timber supplies of Assam. A number of food-processing units for rice, oil, and fruit were being established in the early 1970s. The oil refinery at Digboi was built as early as 1899; the Noonmati refinery near Gauhāti started production in 1962. The Bāruni refinery is in Bihār state but is supplied crude oil from Assam through a pipeline. A petrochemical complex is planned for Bongaigaon.

Transport and communications. A poor transport and communication system has been the main hindrance to the economic development of Assam. Though the four recognized forms of transport—road, rail, air, and water—all exist, none satisfactorily serves the needs of the region. The isolated location of Assam, linked as it is with the rest of India by only a narrow corridor between the Himalayas on one side and Bangladesh on the other, has to a great extent prevented the development of quick and efficient road and rail systems in the region. The growth of an inland water-transport system has similarly been checked by the inclusion of the lower part of the Brahmaputra in Bangladesh. Assam had about 1,400 miles of railways, about 12,000 miles of motorable roads, and 6,000 miles of inland waterways in the early 1970s. There was also a considerable amount of airborne traffic between Assam and Calcutta. The important airports are Borjhār (Gauhāti), Mohanbāri (Dibrugarh), Lilābāri (North Lakhīmpur), Rowroyāh (Jorhat), Sāleni (Tezpur), and Kumbhirgrām (Silchar). The airports are used by the Indian Airlines Corporation (IAC) for civil air transport of passengers and freight.

Cultural life and institutions. The cultural life of Assam is interwoven with the activities of a number of cultural institutions and religious centres like *satra* (seat of a religious head, the Satrādhikār) and *namghar* (prayer hall). Several *satras* established at different places in Assam have been looking after the religious and social well-being of the villagers as well as of some urban dwellers for the last 400 years. The Assamese people observe all the pan-Indian religious festivals such as Durgā-pūjā, Dol-jātrā or Holī (*i.e.*, festival when colour is sprinkled with joy and a sentiment of brotherhood), and Janmastami (birthday of Lord Krishna). But the most important social and cultural celebrations are the three Bihu festivals observed with great enthusiasm irrespective of caste, creed, and religious affinity. The Bihus were originally agricultural festivals observed by the villagers at different seasons of the year. The Bohāg Bihu, celebrated in mid-April with the commencement of the new year (first day of the Bohāg or Baiśākh month which falls usually on the 14th of April) during the spring season, is the most important one. It is also known as Rangāli Bihu (*rang* means merry-making and fun). It is observed by dancing and singing in open spaces as well as in the houses of villagers. The mother or other ladies of the family present a hand-woven *gāmochā* (towel) to each and every member of the family on this day.

The second important Bihu, the Māgh Bihu, celebrated in mid-January (in the month of Māgh), is a harvest festival. It is performed with community feasts and bonfires. It is also known as Bhogāli Bihu (*bhog* means enjoyment and feasting). The third Bihu festival, the Kāti Bihu, is observed in mid-October. It is also known as the Kangāli Bihu (*kangāli* means poor) because by this time of a year, the house of a common man is without foodgrains as the stock is usually consumed before the next harvest.

Another important aspect of the cultural life of the people of Assam, particularly of the women, is weaving of fine silk and cotton cloths with various floral and other decorative designs. Every Assamese house, irrespective of caste, creed, and social status, has at least one loom and each grown-up girl is required to know the art of weaving.

Association Football (Soccer)

Association football, popularly known as soccer, is the only form of football played with a round ball, which can be more readily controlled and encourages a more open game than the oval-shaped variety. Because tackling is less violent than in other forms—American football, for example—soccer can be played in school playgrounds and streets. In Rio de Janeiro the beaches are given over each weekend to matches between barefoot teams, and the quality of play explains why Brazil produces such fine players.

The highly skilled professionals and international players are the apex of a vast pyramid embracing millions of schoolboys, youths, amateurs, and minor professionals of all grades and qualities.

The patterns and clarity of purpose of the game make it easy to understand and easy to play. Scoring a goal is a rare and dramatic achievement because the ball has to be propelled into a target 8 yards (7.3 metres) wide and 8 feet (2.4 metres) high, guarded by a goalkeeper and protected by defenders. While soccer has an attraction for the casual onlooker and occasional player, it also has a depth of virtuosity that delights the connoisseur. The game looked very simple when played by the great Hungarian side (team) of the 1950s but, in fact, their easy style was based on supreme skill and common understanding, the result of years of training individually and together.

Soccer orginated in Great Britain, where it was refined into a sophisticated team game. The first competition between England and Scotland was held in 1872. Eleven years later it was enlarged into the British Championship, with Wales and Northern Ireland taking part. Since then a host of international tournaments, at club and national level, has sprung up.

The governing body of association football, the Fédération Internationale de Football Association (FIFA) has more members than the United Nations. Its membership was brought to 135 at the 1970 congress, compared with 126 in the UN. It is estimated that 600,000,000 to 1,000,000,000 people followed the 1970 World Cup in Mexico by television and radio. These facts are striking evidence of the tremendous popularity of the game, both as a participating sport and an entertainment.

This article is intended for the general reader who may have no knowledge of the sport. Therefore, in addition to tracing the history and outlining the present status of association football, the article is designed to help a spectator understand a game he may be watching. For information on the specific rules or how to play, the reader should consult the works listed in the bibliography.

History of the game. Where football began nobody knows for certain. A primitive form is mentioned in a Chinese military text of the 3rd or 4th century BC. Roman soldiers also had a variety of football called *harpastum,* and there are evidences of football-like games in ancient Greece, Mexico, and Japan.

The Romans spread football through Europe, where it developed during the Middle Ages, notably in Italy, into a rough sport often played between towns, involving hundreds of players and with the goals perhaps half a mile apart. These mob games, called *mêlées* or mellays, were boisterous and dangerous. There were many attempts to ban them, including a proclamation by Edward II of England in 1314: "We command and forbid, . . . on pain of imprisonment, such games to be used . . . in future." As indicated by Shakespeare's reference in his *Comedy of Errors,* Act II, however the game persisted:

> Am I so round with you as you with me
> That like a football you do spurn me thus?
> You spurn me hence and he will spurn me hither;
> If I last in this service you must case me in leather.

British public schools and universities, particularly Cambridge, took up football in the first half of the 19th century. It was the period of "muscular Christianity," of cold baths, rigorous discipline, and fair play, and the game was a means of achieving these virtues. Different rules persisted despite an attempt by Cambridge University to unify them in 1846.

Development of organization. The Football Association (FA) was brought into being on Oct. 26, 1863, for the express purpose of establishing a uniform set of rules. Although William Webb Ellis sowed the seeds of Rugby football by carrying the ball at Rugby School as early as 1823, the FA hoped to fuse both codes by permitting a player who caught the ball to run with it. Discussions over three months, however, failed to bridge the gap and Rugby adherents, led by the Blackheath club, broke away.

Separation from Rugby

Soccer became one of Britain's greatest exports, spread by soldiers, sailors, merchants, engineers, priests. The Danes were the first to take to it, forming the Boldspil Union in 1889. Sailors took the game to Brazil, and two Englishmen launched it in Russia through their cotton mill in Orekhovo-Zuyevo. In the United States the universities were the first disciples, and the names of early clubs, such as the Kensington F.C. of Saint Louis and Shamrock F.C. of Cincinnati, indicated their British origin (see also FOOTBALL, AMERICAN AND CANADIAN).

By the turn of the century, the standard had risen dramatically throughout the world; and in 1902 Austria and Hungary played the first of their more than 100 international tournaments, to be followed three years later by Argentina and Uruguay. Europe looked to England to take the lead in establishing a world governing body. The English FA, however, "in a monumental example of British insularity" as the FA's official history admits, coldshouldered the approach.

On May 21, 1904, Belgium, Denmark, France, Holland, Spain, Sweden, and Switzerland founded FIFA in Paris. After years of mind changing, the British countries, led by progressive FA secretary Sir Stanley Rous, joined the fold in 1946. Sir Stanley left the FA to become FIFA President in 1960 and continued his efforts to unify the game's adherents. By this time, alarming differences in interpretation of rules had developed, particularly in South America, where the shoulder charge, harassing the goalkeeper, and tackling from behind were abhorred, while interfering with an opponent not playing the ball was tolerated. The differences explained the unseemly clashes in unofficial world club championship play between representatives of Europe and South America from 1960 on.

FIFA's growth was steady. By its 25th birthday there were 40 members, and by 1963 there were more than 100. FIFA has headquarters in Zurich and is association football's ultimate governing body. The power to alter the rules, however, still lies mainly with the British countries, which have four votes to the rest of the world's two on the International Board. There are six regional confederations under FIFA—Europe, South America, Central and North America, Asia, Africa, and Australasia—and each has wide control over discipline and competitions in their geographical areas.

Rule changing authority

In England the mob football, which had been refined by the upper classes at public schools and universities, was taken back avidly by the people, with a significant effect on the rest of the world. Professionalism was legalized in 1885 by the English FA, and that in turn led to the Football League being formed by some of the strongest clubs three years later in order to stimulate interest and thereby attendances. Teams played each other both at home and away, receiving two points for a win and one for a draw. There were 12 founder clubs, including the still famous Everton, Aston Villa, Derby, and Wolverhampton Wanderers. Today the league has 92 members, divided into four divisions. At the end of a season, the top teams of the lower divisions are promoted into the places of low-ranking teams in the upper divisions.

Practically every country now has a professional league modelled on England's. In Brazil the vast distances have led to separate leagues, one embracing the teams in the Rio de Janeiro area and the other those around São Paulo. The U.S.S.R. and Germany used to have regional leagues, but improved transportation permitted national mergers.

The standard of play rose sharply through the stimulus of competition and full-time training of the players. The game also became increasingly commercialized, and outstanding players were idolized and paid princely wages. Pele, of Brazil, probably the finest footballer the world has known, earned around $250,000 a year at his peak, from the game itself, from advertising, from a television series, from selling his name for use on a brand of coffee, and so on. Ironically, England clung to a maximum wage of $56 a week until 1961, when a strike threat by the Players' Union forced wage hikes.

Large sums of money are paid for the transfer of a player from one club to another. The record fee of over a million dollars was paid by Juventus of Turin to Varese for the Sicilian forward Piero Anastasi. The deals are not confined to teams in the same association, and Italian clubs have been the importers on the grandest scale. They raided Argentina in the 1930s, not merely signing several players but also fielding them in the 1934 World Cup winning team, claiming they had Italian ancestry. Because the wholesale use of foreign stars hindered development of their own youngsters, the national team's performance declined, and import was banned in 1964.

In England there is often a conflict of interests between the big clubs, which look to their parent body, the league, for support, and the association, which is in the main an amateur organization. The association usually selects the international team, but the clubs may claim that they have first call on their players because they produce, groom, and pay them.

Soccer in the United States

The intense interest shown in the televising of the 1966 World Cup competition encouraged sponsors to believe that soccer would flourish in the United States. Foreign players were imported to make up teams. Unfortunately, the formation of rival leagues, the United Soccer Association and the National Professional League, split what audience there was, and clubs lost up to $1,500,000 each in the opening season. Most Americans continued to regard association football as an alien game played only by ethnic groups.

Three years later the U.S. leagues merged and the 17 teams were reduced to six. More important, the drive to foster the game at the grass roots was paying off, and more high schools and colleges organized teams.

Competition. One of the aims of FIFA was to organize a world championship, and the move took substance after soccer was a success in the 1920 and 1924 Olympic Games. Jules Rimet, president of FIFA from 1921 onward, was a driving force in establishing the championship, and the first gold trophy was named after him.

In 1930, because of travelling difficulties and the unwillingness of clubs to release players, only 13 countries took part in the first tournament in Uruguay; in the competitions in 1966 and 1970, by contrast, there were more than 70 entries, necessitating regional tournaments to reduce the final number to 16. Uruguay became the first champion and won again in 1950—a remarkable achievement for a country with fewer than 3,000,000 inhabitants.

World Cup competition was to be staged every four years between Olympic Games, and the second was in Italy, where it was blatantly used—as were the Berlin Olympics of 1936—for Fascist propaganda. Guided by its manager Vittorio Pozzo, Italy won in 1934 and won again in France in 1938.

Brazil dominated post-World War II competitions, which were renewed in 1950. True, they lost to Uruguay in the 1950 final before 200,000 spectators in their own Maracana stadium in Rio. And in Switzerland in 1954, they were knocked out by Hungary in an unsavoury match in which three players were sent off and the fighting continued in the dressing rooms. Then they won three of the next four tournaments, 1958 in Sweden, 1962 in Chile, and 1970 in Mexico, to make the Jules Rimet Trophy their own. The adventurous freedom of Brazil's forwards was a refreshing contrast to the cautious, defensive football of the period.

Yet Brazil did not reach the heights of Hungary, which went from 1949 to 1955 with only one defeat, which came in the 1954 World Cup final against West Germany. Hungary enjoyed four world-class players and was the first foreign side to beat England on their own soil, by a score of 6–3 in 1953.

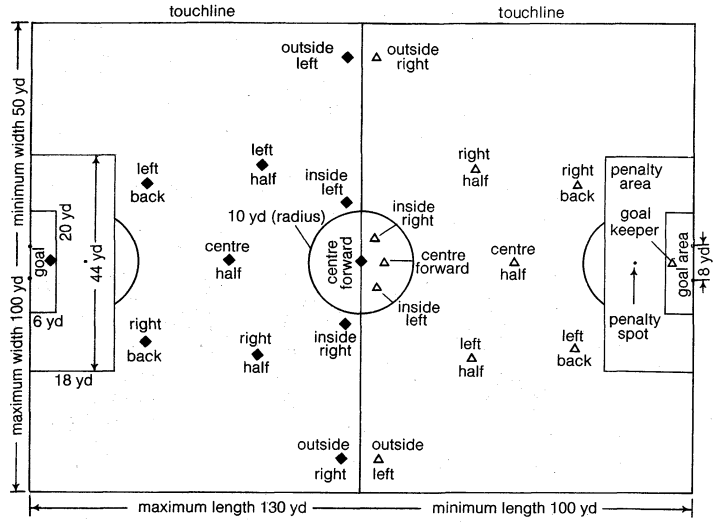

Figure 1: Soccer field and the positions of players at the kickoff.

The severity of the defeat was just punishment for England's stagnating insularity. They had an earlier warning when they entered the World Cup for the first time in 1950 and suffered a humiliating 1–0 defeat by the United States in a sensational giant-killing act. The reverse by Hungary caused a salutary revival, and England won the World Cup as host country in 1966.

The Olympic Games

The Olympic association football tournament was first staged in the 1908 games in London and has been in every Olympics since then, except at Los Angeles in 1932. England won the first two tournaments and then withdrew, mainly because of objections to broken-time payments (compensation for loss of regular salary) to amateurs. FIFA evaded the problem of defining an amateur and left it to the consciences, many of them easy-going, of the individual nations. Uruguay's title-winning sides of 1924 and 1928 were virtually professional.

The cynical attitude toward amateurism made the International Olympic Committee often look dubiously at the inclusion of soccer in the games, but the power of FIFA and the high attendances at matches made it difficult to eliminate. After World War II, the Iron Curtain countries dominated Olympic play because they claim they have no professionals, although realists dub their players "government amateurs." Hungary won in 1952, 1964, and 1968; the Soviet Union in 1956; and Yugoslavia in 1960. FIFA tried to redress the balance by banning players with World Cup experience from the Olympics.

The European Cup originated in 1955 for league champions of the 33 countries in membership with the European FA. The first five tournaments were won by Real Madrid, possibly the finest club side of all time. They were marshalled by Alfredo di Stefano, an Argentinian with phenomenal technique and stamina. The Latin countries dominated the cup until Celtic of Glasgow won in 1967. The success of the European Cup led to the launching of the Cup Winners' Cup for winners of the national cup competitions and the European Fairs Cup for 64 leading clubs. In 1960 South America started the equivalent of the European Cup competition, the Copa de Libertadores, and opened the way for an unofficial world club championship (beginning 1960), determined annually by a match between the winners of the European and the South American cups.

Playing the game. The aim is to propel the ball into the goal, using any part of the body except the hands and arms; the side scoring more goals wins. The ball is a round, leather-covered, inflated rubber bladder 27–28 inches (about 68–71 centimetres) in circumference and 14–16 ounces (435–497) grams) in weight. The players

Rules

move the ball by hitting it with head or foot from one teammate to another or by dribbling—a series of very short kicks, usually with the instep or side of the foot. Only the goalkeeper of the 11 players is allowed to handle it, and he is restricted to the penalty area, a rectangular area in front of the goal, 44 yards (40.2 metres) wide and extending 18 yards (16.5 metres) into the field. The game is of 90 minutes duration and is divided into equal halves. The teams change ends after a 5-minute half-time interval. For international matches, the pitch (playing field) must be 110–120 yards (approximately 100–110 metres) long and 70–80 yards (64–75 metres) wide. Markings on the field and the usual positions of players at the start of the game are shown in Figure 1.

UPI

World-famed soccer star Pelé (Brazil) has characteristically darted past the defender to intercept the ball and take a shot at the goal during the 1970 World Cup final against Italy at Mexico City. Brazil won 4–1 to become world champions for the third time.

Women and schoolboys usually play a shorter game on a smaller pitch. The game is controlled by a referee, who is also the time keeper, and two linesmen who patrol the touchlines, or sidelines, signalling when the ball goes out of play.

While solo runs and dribbles are spectacular, association football is essentially a team game, based on accurate passing of the ball among members of the same side. Passing produces the fluid movements and varied patterns that make the game an attractive spectacle. A distinctive feature is the development of heading, and many thrilling goals are scored by a forward jumping to hit the ball with his forehead.

Free kicks are awarded for fouls or violations of rules; all players of the offending side must be ten yards from the ball. Free kicks may be either direct, from which a goal may be scored, for more serious fouls such as kicking an opponent, tripping, or handling the ball; or indirect, from which goals cannot be scored until after the ball has touched another player, awarded for lesser violations such as obstruction (interfering with an opponent while not playing the ball). A penalty kick, a direct free kick awarded to the attacking side in the penalty area, is taken from a spot 12 yards from the centre of the goal, with all players other than the defending goalkeeper and the kicker outside the penalty area.

Considering the tremendous advances in play in the 20th century, it is remarkable that there have been only two major alterations of the rules in the period—those related to "offside" and to player substitution. A man is offside if he receives a forward pass from a colleague in the opponent's half with fewer than two opponents—three before the rule was changed—between himself and the goal line. The interpretation often causes controversy, even though the linesmen generally guide the referee by positioning themselves alongside the foremost attacker on each team.

The flagrant use of substitutes in many countries forced the FIFA's International Board to alter the rule limiting teams to 11 players. At first it was hoped to restrict changes to injured players, but it is now permissible to replace any two at any time. Substitutes were used for the first time in the World Cup in 1970—two from five on the reserve bench—and it proved an invaluable innovation because of the heat and altitude of Mexico City, site of the contest.

The biggest changes have been in uniforms and equipment. Clothing has become attenuated, and heavy boots have given way to shoes. Many players have discarded shin guards. Conformity of dress is not essential, provided that the sides can be identified and the goalkeeper is distinguishable. The rules also permit players to participate barefoot.

Styles of play

Although professionalism and the league system brought benefits, they are partly responsible for the growing blight of defensive football. Herbert Chapman, shrewd manager of the Arsenal team in the 1930s, pulled back the centre halfback to be a third back and operated with four forwards instead of five. Italy, possibly the most commercialized soccer country, introduced the Catenaccio system (see Figure 2), with an extra man, named the sweeper or libero (free man), behind another four defenders, plugging holes where they developed.

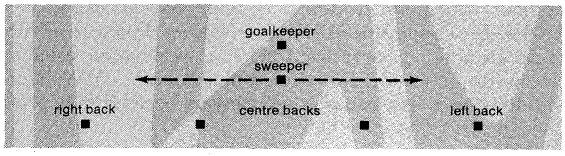

Figure 2: Catenaccio defense, showing the positions of players and the range of the sweeper.

Ideally, with both tactics the solid defenses were the springboard for quick counter attacks and, in Scotland's Alex James, Arsenal had the man to organize them. But with most imitators it was solely a case of stopping the other side from scoring.

A defensive outlook was also encouraged by the European club tournaments, which were played on a home and away basis, the winning side being that with the greater aggregate of goals. As a result, visiting teams did not go for a win but concentrated on keeping down the opponent's score in the hope of obtaining more goals in the return match. A bold attempt to reverse this trend was made by the North American Soccer League in 1969, awarding six points for a win, three for a draw, and a bonus point for each goal up to three. A side losing heavily still had an incentive to go for goals.

One of the few attacking ideas to come forward after World War II was the withdrawn centre forward (see Figure 3) of Hungary's Nandor Hidegkuti in the 1950s.

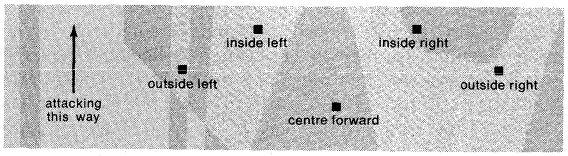

Figure 3: The positions of players for the withdrawn centre forward attack.

He played behind the attack, luring the centre halfback with him, and the inside forwards were the spearhead. The line had an M shape instead of the fashionable W formation.

Teams used to have specialists who stuck to their roles—wingers out on the touchlines, backs deep in defense, and centre forwards lying upfield. They gradually gave way to all-around players who realized their responsibilities in all departments of the game. Work rate became as important as skill, and method football took over. Brazil grouped its outfield players in a 4–2–4 formation when winning the 1958 World Cup and still gave outlet to its brilliant individualists. England won the World Cup in 1966 playing 4–3–3—without a winger—and four years later often operated 4–4–2, fielding only two strikers up front.

Too much can be made of numbers and systems. Basically, the aim is to put a man with time and room to spare in a shooting position near the opponent's goal, and it does not matter whether the man is nominally a forward or a defender. Attitude of mind is as important as technical excellence in achieving the aim.

Asterales

The order Asterales consists of a single very large family of flowering plants, the Asteraceae, also called Compositae. The Asteraceae family is one of the largest families of flowering plants, perhaps the largest. The number of species is not accurately known; but estimates of 15,000 to 20,000 are current. The only other family with a comparable number of species is the orchid family, Orchidaceae. Asterales is the name-bringing order for the subclass Asteridae in the class Magnoliopsida (dicotyledons) of the division Magnoliophyta (angiosperms, or flowering plants). The order includes many familiar garden ornamentals, such as asters, chrysanthemums, dahlias, daisies, marigolds, sunflowers, and zinnias. Some other members of the group, such as dandelions, ragweeds, and thistles, are familiar weeds. Lettuce and safflower are examples of economically important members of the Asterales order.

GENERAL FEATURES

Unique flowers a distinguishing characteristic

The most obvious and outstanding general feature of the Asterales is that the flowers are characteristically grouped into compact inflorescences (heads) that superficially resemble individual flowers. The name Compositae refers to this feature; what appear to be individual flowers are actually composite flowers. Each such head is ordinarily subtended by a usually green involucre of small modified leaves (bracts), which bear the same relation to the flower head that the green sepals do to an individual flower in other families. Furthermore, in more than half the members of the order, the flowers in the outermost row or rows of the head have a modified, mainly flat and elongate corolla (the collection of petals) that more or less resembles an individual petal of an ordinary flower. The "petals" of a daisy or sunflower are actually these outermost flowers of the head. Various members of the order may produce anywhere from one to several hundred or even more of these composite-flowered heads.

Several other families or individual genera of flowering plants have the flowers grouped in heads more or less resembling those of the Asterales, but they lack the syndrome of other features that characterize the order, and most of them especially lack the complex pollen-presentation mechanism (see below *The flower*).

Structural diversity and distribution. Members of the Asterales order are diverse in habit and habitat. They are most characteristically herbs of sunny places in temperate to subtropical regions, but they are not at all so restricted. Not many of them are large trees, and not many of them are adapted to life in undisturbed moist tropical forests, but otherwise they are ubiquitous. They are trees, shrubs, herbs, or woody or herbaceous vines. The herbs are annual, biennial, or perennial, with or without an active cambium (a zone of growth contributing to stem thickness). Some of them are megaphytes (coarse, simple, or sparsely branched shrubs with thick, soft, almost herbaceous stems). Many of the perennial herbs have long, creeping rhizomes (underground root-like stems) from which large colonies (clones) can develop by vegetative multiplication; others are taprooted, or fibrous-rooted from a caudex (stem base) or short rhizome. The leaves are simple or less often compound, and their arrangement along the stem may be opposite, alternate, or less commonly whorled; not infrequently they are opposite toward the base of the stem and alternate above. Species occur from the Arctic to the Antarctic and from above the timberline to the ocean shores. In addition to the more ordinary habitats, some of them are adapted to growth in sand dunes; others to cliff crevices; others to talus slopes; others to seleniferous, gypsiferous, or alkaline soils; and others to fields or disturbed sites around human habitations. A few species are aquatic.

Centres of diversity

The greatest centres of diversity in the order are the dry highlands of Mexico, where the primitive tribe Heliantheae is especially well represented, and the Mediterranean–Near East region. South Africa is an important secondary centre of diversity. In most temperate regions more than 10 percent of the species of angiosperms belong to the Asterales. In tropical regions the percentage is smaller, but the numbers are still significant.

Economic importance. The greatest economic importance of the Asterales order lies in the use of many of its members as garden ornamentals. Species and garden hybrids of *Aster*, *Bellis* (English daisy), *Callistephus* (China aster), *Chrysanthemum*, *Cosmos*, *Dahlia*, *Helianthus* (sunflower), *Rudbeckia* (coneflower, black-eyed Susan), *Tagetes* (marigold), and *Zinnia* are well-known garden favourites. *Achillea* (yarrow), *Ageratum*, *Anaphalis* (pearly everlasting), *Anthemis*, *Artemisia*, *Calendula*, *Centaurea*, *Echinops* (globe thistle), *Erigeron* (daisy), *Eupatorium*, *Gaillardia* (blanketflower), *Helichrysum* (strawflower, everlasting), *Liatris*, *Ratibida* (coneflower), *Santolina*, and *Stokesia* are also familiar in gardens. The florists' cineraria, a popular wintertime pot flower, is *Senecio cruentus*, originally from the Canary Islands.

The most important food plant in the Asterales is lettuce, *Lactuca sativa*, a European cultigen, followed by the common sunflower, *Helianthus annuus*, a native of the United States. Sunflower seeds are excellent poultry food, and a light-golden-yellow oil made from them is used as a salad oil and in cooking and the manufacture of margarine, soap, paint, and varnish. The oil cake is fed to livestock, and the whole plant is used as ensilage. Flowers of safflower, *Carthamus tinctorius*, are the source of a red and a yellow dye, and the seeds produce an edible oil that is also used in soap, paint, and varnish. Several other members of the order, such as the artichoke (*Cynara scolymus*) and the Jerusalem artichoke (*Helianthus tuberosus*), are of minor importance as food plants.

Chemical compounds derived from Asterales

Pyrethrum, an insecticide that does not produce the environmental problems associated with DDT and other synthetic products, is obtained from the flowers of several species of *Chrysanthemum*, notably *C. cinerariaefolium*. Extracts from several species of *Artemisia*, notably *A. cina* from the Middle East, have been much used to expel intestinal worms, whence the common name wormwood applied to this genus. *Artemisia absinthium* is the source of a poisonous oil used to give the liqueur absinthe its distinctive character.

A few other members of the order have minor economic uses, and several of them have excited interest as a possible source of rubber. Guayule (*Parthenium argentatum*) and the Russian dandelion (*Taraxacum koksaghyz*) are two species that have been studied in this regard, but neither is economically profitable when other sources of rubber are available.

The ragweeds (*Ambrosia*), dandelions (*Taraxacum*), and thistles (*Carduus*, *Cirsium*, and *Onopordum*) are the most troublesome weeds in the Asterales order. Among the wind-pollinated weeds, *Ambrosia artemisiifolia* (common ragweed) and *Ambrosia trifida* (giant ragweed) are two of the most important plant species causing the allergic reaction known as hay fever.

NATURAL HISTORY

Pollination. Pollination is effected by diverse agents, most commonly various sorts of insects. The individual flowers of most species are relatively small, and the nectar within the corolla tube is thus readily available to most insect visitors. The pollen itself is freely exposed on the surface of the head, and such heads are likely to be visited by diverse kinds of insects. A considerable minority of members of the order are wind pollinated; these generally have small and inconspicuous flower heads.

Some species are pollinated by both wind and insects. *Solidago speciosa*, one of the common goldenrods of eastern United States, for example, produces a considerable amount of airborne pollen in addition to attracting insect visitors. The goldenrods, like the ragweeds, generally flower in late summer and fall; and because they are common and conspicuous when the ragweeds are pollinating, they have often been blamed for the allergies that are actually caused primarily by the ragweed.

A relatively few species are regularly self-pollinated; the genus *Psilocarphus* provides an example of this method. Bird pollination is also uncommon, but the tropical American genus *Mutisia* is bird pollinated.

Production of fertile seeds asexually

Various genera and individual species of the order are known to be reproduced by apomixis, the setting of seed without fertilization, either completely or in addition to normal sexual means. The genus *Antennaria* (pussytoes), well-known in the Northern Hemisphere, is dioecious (male and female heads on separate plants), and some of the species are represented in large parts of their range only by pistillate (female) plants. In this genus, normal sexual reproduction produces equal numbers of staminate and pistillate plants, but apomictic reproduction yields only pistillate plants. Among the members of the Asterales order, as in other orders, apomixis is often associated with polyploidy (the presence of three or more complete sets of chromosomes in every cell) and a past history of hybridization.

Seed dispersal. The fruit of the Asterales is an achene; *i.e.*, it is dry, contains only one seed, and does not open at maturity. The apparent seeds of the sunflower, for example, are actually achenes. The hull is the achenial wall, and the proper seed coat surrounding the embryo is thin and insignificant. In speaking of seed dispersal of the Asterales, it should be realized that it is actually the achenes, each containing a seed, that are dispersed.

The seeds of many Asterales species are distributed by wind, having fluffy or parachute-like structures that provide buoyancy. In others, such as *Coreopsis* (tickseed), the achene is thin and flat, and the surface area is increased by the presence of an even thinner expanded margin (wing). Some have barbed structures or are provided with hooks or spines, as in cocklebur (*Xanthium strumarium*) or burdock (*Arctium* species), that engage man or animals as means of transport. Other means of seed dispersal are less common. The achenes of species that grow in wet places may be carried in mud on the feet of migrating waterfowl; those of some streamside species have minute air cavities in the wall and are buoyant, achieving dispersal by floating until they become waterlogged. In *Centaurea* and some related genera, the achenes are attractive to ants, which carry them about and feed upon special parts of the wall. The achenes of some field weeds have been widely distributed by becoming mixed with the seeds of cultivated crops. Many other members of the order have no obvious means of seed dispersal.

FORM AND FUNCTION

The flower. The flowers of the Asterales are sympetalous; *i.e.*, the petals are joined together by their margins, forming a tubular or mainly strap-shaped corolla that often has apical teeth representing the petal tips. The flowers are also epigynous; *i.e.*, the other floral parts are attached to the top of the ovary rather than beneath it. These two features occur individually in various other groups of flowering plants, but their occurrence in combination is much more limited.

The calyx (collection of sepals) of the Asterales is so highly modified, in contrast to that of other orders, that it is given a different name, the pappus. The pappus consists of one to usually several or many dry scales, awns (small pointed processes), or capillary (hairlike) bristles; in some, the scales may be joined by their margins to form a crownlike ring at the summit of the ovary. In only a few genera (*e.g.*, *Marshallia*) of the primitive tribe Heliantheae does the calyx consist of five regularly placed scales that are obviously homologous with sepals. Often the pappus is completely wanting. When the pappus consists of numerous capillary bristles, as in the common dandelion (*Taraxacum officinale*), it facilitates wind distribution of the achenes. In some other genera, such as *Bidens* (beggar ticks), the pappus awns are barbed, permitting them to stick in fur or clothing, and some achenes are thus transported by animals. In many other genera, especially those with the pappus of scales or a crown, the function of the pappus is obscure.

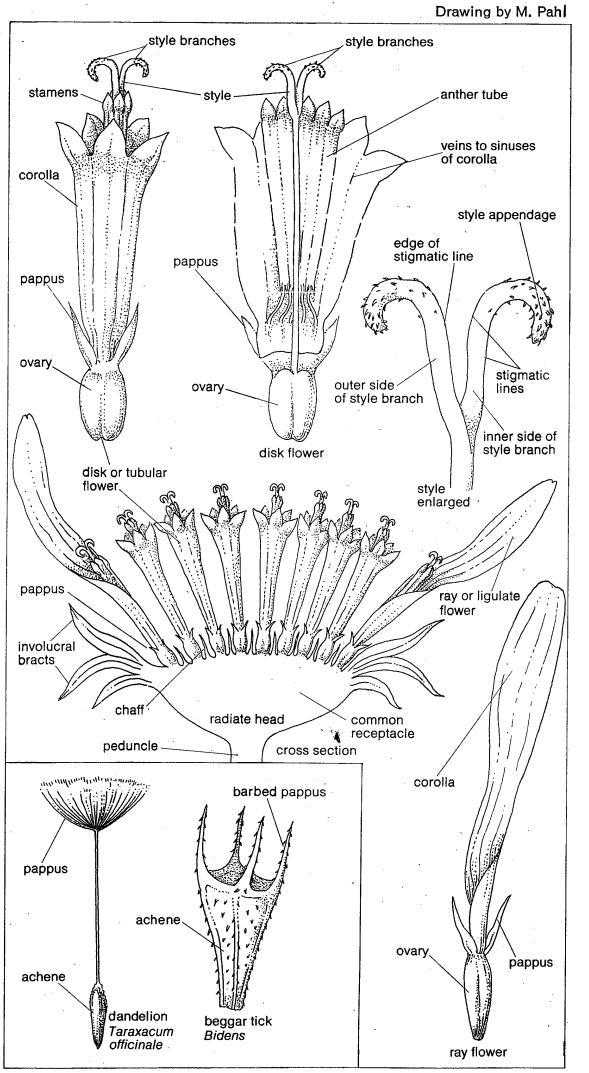

Figure 1: Floral structures of the Asterales.

Pollen-presentation mechanism

The pollen-presentation mechanism of the Asterales is especially characteristic, being shared only by the orders Campanulales and Calycerales and a few genera of the family Rubiaceae, in the order Gentianales. The stamens (male reproductive structures) are generally joined to-

gether by their anthers (pollen producing region of stamen) to form a tube; the stamens open toward the centre by lengthwise slits, releasing the pollen into the tube. The style (part of the female structure) grows up through the tube, pushing the pollen out ahead of it. The style usually has two branches that separate after it has grown up through the anther tube. The stigmatic surfaces (pollen receiving regions) are usually arranged in lines along the inner margins of these branches, well back from the sterile tips (appendages), which are the structures that push out the pollen. The stigmatic lines later become exposed to the air, when the style branches spread apart.

The pistil (female structure) is composed of two carpels, united to form a compound ovary with a terminal style. There is usually a nectar-producing region (nectary) in the form of a minute ring surrounding the style atop the ovary. The ovary has only one locule (seed cavity), with a single ovule arising from the base. The fact that the ovule is basal provides the best single distinction of the Asterales from the related order Calycerales, which also has involucrate heads with a similar pollen-presentation mechanism but which has the ovule pendulous from the top of the ovary.

As in most flowering plants, the ovule is anatropous; *i.e.*, it is curved back on itself so that the micropyle (the apical opening) is alongside the funiculus (the stalk). As in other members of the subclass Asteridae, the ovule has a single, rather thick integument (outer covering layer, the forerunner of the seed coat) rather than the double integument found in so many other orders. The seed has no endosperm; its reserve food is stored largely in the two cotyledons (seed leaves) of the embryo.

The inflorescence. The secondary inflorescence of the Asterales (*i.e.*, the arrangement of the flower heads) is typically cymose (determinate). The terminal head blooms first, followed by the terminal heads of the main branches. After that the sequence is less clear, not infrequently being mixed, with both cymose and racemose (indeterminate) components. Only rarely, and then clearly as a derived condition, is the secondary inflorescence racemose throughout, with the lowest heads blooming first and the terminal ones last.

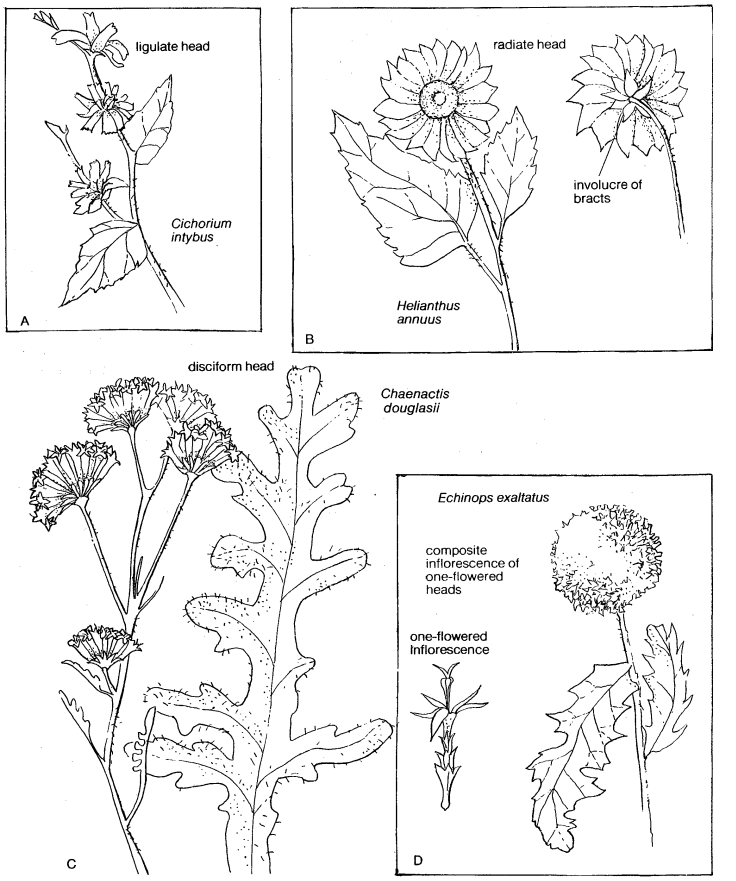

Figure 2: Inflorescence types in the order Asterales.
Drawing by R. Findahl based on (A,B, radiate head, D) G.H.M. Lawrence, *Taxonomy of Flowering Plants* (1951), The Macmillan Company; and (B, involucre of bracts) J. Craighead, F. Craighead Jr., and R. Davis, *A Field Guide to Rocky Mountain Wildflowers*, reprinted by permission of the publisher Houghton Mifflin Company

Sequence of flowering

The sequence of flowering within the individual heads, on the other hand, is always racemose (indeterminate, centripetal). The outer flowers bloom first, and there is a progressive spiral of flowering thence to the centre of the head. The head is in essence a compact shoot, with spiral (alternate-leaved) phyllotaxy. The involucral bracts are more or less modified leaves, and very often they are green and leafy in texture. Sometimes the flowers in the outermost row of the head are borne in the axils (angles) of involucral bracts, sometimes not.

In many members of the order, especially the relatively primitive tribe Heliantheae, the common receptacle (the short stem tip, on which all the flowers of the head are borne) is also provided with bracts, to which the individual flowers are axillary. The receptacle is said to be chaffy when these bracts are present and naked (or sometimes bristly) when they are not. Sometimes the receptacle is chaffy only toward the margin or only toward the centre. In some genera (notably of the tribe Cynareae) the receptacle is bristly; *i.e.*, it is beset with bristles that are difficult to interpret in terms of bracts, although that may be their eventual evolutionary origin.

Flowering head types. Individual heads of most members of the Asterales order are said to be ligulate, radiate, discoid, or disciform, according to the kinds of flowers they contain. The simplest type is the discoid head, with all the flowers having a regular, tubular corolla, the generally four or five apical teeth representing the tips of the petals. This kind of flower is called a disk flower. Ordinarily the flowers in a discoid head are all perfect (with reproductive parts of both sexes) and fertile. In a comparison of the flower head to the individual flowers of other kinds of plants, the discoid head lacks the marginal, petal-like flowers. Thistles and ageratums are examples of Asterales species with discoid heads.

The radiate head has disk flowers in the centre, surrounded by one or more marginal rows of another kind of flower, the ray flower. The corolla of ray flowers is very irregular. It is tubular at the base but prolonged on the outer side into a generally flat projection, the ray, or ligule. These rays are the petallike parts, in a comparison of the flower head to an ordinary flower. The ray in radiate heads represents only three lobes of the corolla; often there are two or three minute apical teeth. The other two corolla teeth (those toward the centre of the head) are much reduced or, often, wanting.

The details of size and structure of ray flowers in a radiate head vary, but the position of the ray flowers with respect to the disk flowers is absolutely constant. The disk flowers are always central and the ray flowers marginal. Ray flowers in radiate heads are never perfect (bisexual). Instead they are pistillate (with female reproductive parts only) or neutral (with a vestigial, nonfunctional ovary and no style). Disk flowers in a radiate head are usually perfect, but sometimes they are functionally staminate, with a normal pollen presentation mechanism but without a viable ovary.

"Double-flowered" plants

Occasional mutant forms of species that normally have radiate heads have most or all of the disk flowers more or less transformed into ray flowers, with only a few (or no) normal disk flowers in the centre. These "double-flowered" forms do not survive long in nature, but they are valued and perpetuated horticulturally because of their more showy flower heads. The "daisy-flowered" chrysanthemums, with only a single marginal row of ray flowers, have the normal type of radiate head, but the more commonly cultivated kinds of mums are double flowered. The garden dahlia is another member of the Asterales order that is cultivated in both normal and double-flowered types, with the double-flowered ones being more frequent. China asters, marigolds, and zinnias are also commonly cultivated in double-flowered forms.

The disciform head is a special derivative of the radiate type. It resembles the discoid head in lacking the mar-

ginal rays, but the outer flowers are pistillate, with a tubular, rayless corolla. The corollas of these marginal pistillate flowers are generally very slender, in comparison to the normal disk corollas, and they do not have the four or five well-defined teeth of the disk corollas. *Artemisia stelleriana*, one of several plants called dusty miller, has disciform heads, as do plants of the genus *Gnaphalium* (cudweed). Some species, such as *Erigeron compositus*, show a complete series of transitions from the radiate to the disciform type of head, the ray part of the marginal corollas varying from elongate to short to very short to lacking.

Radiate, discoid, and disciform heads occur in various tribes of the Asteraceae family. The ligulate head, on the contrary, is almost entirely restricted to one tribe, the Lactuceae (Cichorieae), and is found in all members of that tribe. Ligulate heads consist entirely of one kind of flower, the ligulate flower. Ligulate flowers superficially resemble the ray flowers of radiate heads in having the corolla tubular at the base and prolonged on the outer side into a flat, strap-shaped ligule. They differ from ray flowers in being ordinarily perfect (with functional stamens as well as a pistil) and especially in the structure of the ligule itself, which consists of all five lobes of the corolla and generally shows five terminal teeth. The dandelion is a familiar plant with ligulate heads. The term ligulate flower is often loosely used to cover both ray flowers and the type here described as ligulate. It is helpful, however, to have separate terms for these two kinds of ligule-bearing flowers, and no other terms for them are in general botanical use.

Still another kind of flower is found nearly throughout another tribe, the Mutisieae. This tribe is largely tropical, and only one of its genera, *Gerbera*, is familiar in cultivation in temperate regions. Most members of the Mutisieae have some or all of the corollas bilabiate (two-lipped), with a large, three-lobed (sometimes four-lobed) outer lip and a smaller, two-lobed (or one-lobed) inner lip. These bilabiate flowers may be either pistillate or perfect. When pistillate, they are always external to any perfect flowers that may be present in the head. Often they are much like ordinary ray flowers, except that there are two small teeth at the top of the corolla tube, opposite the ligule. The Mutisieae tribe shows every transition from the typical disk flower to the typical ray flower and the typical ligulate flower.

Disk corollas in the Asterales generally have an unusual sort of vascular system, scarcely found outside the order. There are as many longitudinal veins as corolla lobes, typically five, but the veins are directed to the sinuses of the corolla rather than to the teeth. At the sinus each vein forks, one fork following along the margin of each corolla tooth and meeting the vein from the other side of the tooth at the tip. Ray flowers and ligulate flowers are similar, but some of the larger rays have more numerous veins, and many of the smaller ones have reduced or no veins.

Numbers of flowers. A curious feature about the flower heads of the Asterales is the frequency with which the number of ray flowers (and sometimes also involucral bracts) reflects the Fibonacci series, a mathematical series that proceeds 1, 1, 2, 3, 5, 8, 13, 21, 34, . . ., with each succeeding number being the sum of the two previous ones. Fibonacci numbers also appear in efforts to explain the arrangement of leaves on a stem (phyllotaxy) in angiosperms in general. The appearance of Fibonacci numbers as absolute numbers in heads of the Asterales is thought to reflect the fact that the flower head is a compact shoot. Given the existence of normal phyllotaxy on this shoot, it is easier to produce a symmetrical arrangement with 5, 8, 13, or 21 rays than with other numbers such as 7, 9, 11, 19, etc. Heads with 13 rays, for example, probably have a 5/13 phyllotaxy (5 turns around the stem to pass through 13 leaf bases, before the next leaf is directly above the first one). Given the same phyllotaxy, a head with 14 rays would have the 14th ray on top of the first one, and one with only 12 rays would have a gap in the series.

Fibonacci numbers in composite flower heads

These Fibonacci numbers, when they appear, often represent tendencies rather than fixed numbers, especially when the number is 13 or more. Five-rayed or 8-rayed heads may be very constant, with few or no examples of other numbers; but it is not uncommon to see within one local population (or on one plant) a range of 10 to 16, with 13 as the high point of the curve of distribution. Sometimes there is even a bimodal curve, with high points on adjacent Fibonacci numbers, such as 13 and 21, or 21 and 34.

EVOLUTION

Fossil record. The fossil record of the Asterales is not especially useful in helping to understand the evolutionary history of the group. The floral structures that would permit identification of the order on critical technical features are rarely fossilized, and with few exceptions fossils can be referred to the group only by a close resemblance to modern species or genera. A fossil (*Palaeanthus problematicus*) from the Upper Cretaceous Period (about 75,000,000 years ago) in New Jersey is more or less suggestive of a sunflower head, but it could equally well be any of several other things, and its status as a member of the Asterales order is dubious at best. The oldest generally accepted fossil representatives of the order are some dandelion-like achenes of Oligocene age (about 30,000,000 years ago). There is also a recently discovered fossil from the Oligocene–Miocene boundary region (26,000,000 years ago) in Montana that looks very much like a head of the modern genus *Viguiera* (tribe Heliantheae) and has been so interpreted in the literature. The order is poorly represented in Miocene (about 13,000,000 years ago) and even Pliocene (about 5,000,000 years ago) deposits, not becoming abundant until the Pleistocene (beginning about 2,500,000 years ago), but this situation doubtless reflects the difficulty of identification rather than a real absence of the group.

Oldest fossils of aster order

Phylogeny. Phylogenetic speculations in the absence of a useful fossil record are hazardous, but there is a fair degree of agreement among students of the Asterales (synantherologists) about the evolutionary trends within the order. The interpretation necessarily depends mainly on comparison of living members of the group, in the light of generally accepted principles of angiosperm evolution. Present evidence permits taxonomists to believe that the currently accepted broadscale organization and evolutionary concepts concerning the Asterales order are probably correct, but some major uncertainties remain. In the following discussion, as elsewhere in this article, the terms primitive and advanced refer to phyletically anterior, or primary (*i.e.*, early appearance in a group), as opposed to subsequent, or secondary, status and imply nothing at all about the adaptive significance of the features in question.

It is generally believed that the ancestral prototype of the Asterales was woody, perhaps a small tree. Some of the woody members of the group (*e.g.*, the sagebrush, *Artemisia tridentata*) are clearly only secondarily woody, deriving from herbaceous ancestors within the order, but many more or less woody Mexican species of the Heliantheae tribe are considered to be primitively woody. Many of the temperate zone herbs in the order, such as the common sunflower, develop a considerable amount of wood, but the stem does not persist from one year to the next.

It is believed that opposite leaves are primitive in the Asterales, and alternate or whorled leaves derived. Numerous transitional forms from opposite to alternate leaves occur in the Heliantheae, a tribe considered on a syndrome of features to be relatively primitive within the order. Many of the Heliantheae have the lower leaves opposite and the upper ones alternate. It is thought that a progressive phyletic change from opposite to alternate phyllotaxy began in the flower heads and spread progressively farther down the stem until all the leaves were alternate.

The presence of a well-developed resin system (a system of ducts or intercellular spaces lined with specialized cells that secrete resin, a sticky organic substance insoluble in water) in the vegetative parts is considered to be a primitive feature in the Asterales. Reduction and

Resin and latex systems

loss of the resin system proceed from the top downward. Presence of a latex system, on the other hand, is secondary, and its phyletic development proceeds from the top downward. Elaboration of the latex system is usually associated with reduction of the resin system, but the two systems are anatomically and genetically independent. A few genera and species have both the latex and the resin system.

Since each head represents a complete inflorescence, it is assumed that primitive members of the order had relatively few heads, each with relatively numerous flowers. The cymose secondary inflorescence (the arrangement among the heads) is also primitive.

Synantherologists are agreed that aggregation and reduction in the inflorescence have been pervasive trends within the order. The culmination of these trends is the production of composite composites, such as in *Echinops* (tribe Cynareae) and *Lagascea* (tribe Heliantheae), which have numerous one-flowered, individually involucrate heads aggregated into a secondary head with its own secondary involucre.

Another assumption based on the premise that the flower head is a complete inflorescence is that the involucre primitively consisted of several series of green, more or less leaflike bracts. Involucres with dry, nongreen bracts, or with the bracts in only a single series, are thus considered as derived rather than primitive. The situation is not perfectly simple and straightforward, however. It is not always easy to distinguish the outer involucral bracts from the uppermost leaves of the peduncle (flower stalk), and in diverse species in various tribes the involucre has evidently been augmented by modification of these uppermost peduncular leaves into bractlike structures.

The presence of chaff on the receptacle is uniformly considered to be a primitive character in the order and its absence to reflect a loss. Only one tribe, Heliantheae, has more representatives with the receptacle chaffy than with it naked.

The discoid head, with the flowers all tubular, has traditionally been considered the primitive type within the family, but this concept is now held to be too simplistic. Scattered throughout the several usually radiate headed tribes (Heliantheae, Astereae, Anthemideae, Arctotideae, Inuleae, Senecioneae, and Calenduleae) are special subtribes, genera, species, infraspecific taxa (varieties, races, etc., within a species), and individuals with discoid heads. Among the radiate tribes the absence of rays represents a loss, and the discoid head is phyletically secondary. The consistently discoid tribes Cynareae, Eupatorieae, and Vernonieae are more difficult to explain as secondarily discoid, but neither is there any reason to suppose that they are primitive in other respects.

Evolutionary appearance of the ray flower

There is no doubt that the ray flower is, phyletically, a modification of the disk flower, but its time of appearance during the evolutionary development of the order is not known. If, as is thought by some, it occurred in pre-Asteralean ancestors and was transmitted to the earliest members of the Asterales order as a normal feature of the group, then the discoid tribes have lost their rays, and all discoidy in the order is secondary. On the other hand, if the change took place in the ancestors of the Heliantheae tribe, after this group had already diverged from the ancestors of the present discoid tribes, then discoidy is primary in the discoid tribes and secondary only in the radiate tribes.

The Mustisieae tribe is a special case. It shows all transitional stages in the development of ray flowers from disk flowers, and the changes evidently occurred within the tribe rather than in remote pre-Asteralean ancestors. The Mutisieae are advanced in other features, however, notably the caudate ("tailed") anthers, and the radiate tribes could not have evolved from them. Evolution of rays in the Mutisieae shows how it may have happened elsewhere in the order, but it is not the direct source of the rays in other tribes.

Synantherologists consider fertile disk flowers to be more primitive than functionally staminate ones. Similarly, pistillate, fertile ray flowers are considered to be more primitive than ray flowers that are sterile but that still have a style; the neutral ray, lacking even a style, is still further advanced.

Yellow floral pigments have been considered to be primitive in the Asterales, and anthocyanic pigments, which produce blue to red colourings in flowers and other plant parts, to be derived. This hypothesis has been extended to suggest that the sequence is from carotenoids (yellow to red pigments) to anthoxanthins (yellow to scarlet flavonoid pigments, visually similar to the carotenoids) to anthocyanins (blue to purple or crimson flavonoid pigments). Thus the major chemical change, from carotenoids to flavonoids, occurs without much influence on the actual flower colour, and the major change in flower colour reflects a very minor chemical change.

The restriction of the stigmatic surfaces to parts of the style well back from the tip is part of the pollen presentation mechanism syndrome. The condition of the Heliantheae tribe, in which the stigmatic lines are often not well differentiated from the nonstigmatic part of the style branches, is considered to be primitive in this regard. Both ray flowers and ligulate flowers generally have well-defined stigmatic lines extending all the way to the tip of the style branches, which are without a sterile appendage. This condition is thought by some to argue for the evolution of both of these floral types very early in the evolutionary history of the order, before the style tips were sterilized.

The Asterales, like the angiosperms in general, are so beset with parallel evolution (*i.e.*, the independent appearance of similar structures in related groups) that it is often difficult to distinguish independently evolved similarities from those inherited from a common ancestor. There is, in fact, no sharp line between these two conceptually different types of similarity, and close parallelism among phyletic lines from closely related ancestors is very common indeed. Before all the members of an admittedly natural group can be traced back to a common ancestry, it is likely that the path will lead outside the confines of the group. These considerations apply with especial force to the genera and tribes of the Asterales. A genus that combined all the primitive features found in various genera of the tribe Astereae would probably have to be referred to the tribe Heliantheae. The Astereae, like the other tribes, probably evolved as a set of closely related genera undergoing similar sorts of evolutionary changes, rather than by diversification from a single genus that had all the characteristic features of the tribe.

For the reasons noted above, there may never have been an original member of the Asterales, primitive in all respects within the order but possessing all the essential features of the group. Nevertheless, it is conceptually useful to consider what such a plant might have been like and from what other group it might have originated.

Description of proposed Asterales ancestor

The hypothetical ancestral prototype of the Asterales, subject to the limitations noted in the preceding paragraph, may be considered to have been a small to medium-sized tree, probably in or near the dry highlands of Mexico. It had a well-developed resin system and opposite, simple, exstipulate leaves with anomocytic stomates (lacking specialized supporting cells around the guard cells). It had relatively few heads, terminal to the branches and more or less cymosely arranged. Each head had more or less numerous yellow flowers, collectively subtended by an involucre of several series of herbaceous bracts. The head may have been radiate or less probably discoid. The rays, if it had them, were pistillate and fertile. The receptacle was chaffy, with each bract subtending a flower. The flowers were arranged in a close spiral, blooming from the outside of the spiral toward the centre. The flowers were epigynous (*i.e.*, the floral parts attached to the top of the ovary), and the disk flowers were perfect. The pappus consisted of five scales. The disk-corollas were regular and of five lobes, with the midveins to the teeth and lateral veins to the sinuses well developed. The anthers were joined into a tube, into which the pollen was released; they did not have a sterile tail. The style grew up through the anther tube, pushing out the pollen, and there was no sharp differentiation of the

style branches into stigmatic lines and sterile appendages. The ovary was of two carpels, with a single basal ovule.

No presently existing genus combines all of these features, but more of them are found together in the Heliantheae than in the other tribes, and if such a plant did exist it would probably be referred to that tribe. The Heliantheae tribe is thus generally considered to be the most primitive tribe in the order. The Astereae, Anthemideae, Arctotideae, Inuleae, and Senecioneae tribes are generally considered to be derived directly from the Heliantheae, and the Calenduleae tribe is thought to be a specialized derivative of Senecioneae. These several tribes collectively constitute the radiate tribes.

The phyletic position of the discoid tribes (Cynareae, Eupatorieae, and Vernonieae) is less certain, but the Arctotideae do provide a sort of link to the Cynareae, suggesting that this latter tribe, at least, may also be derived eventually from the Heliantheae tribe. The Mustisieae tribe is thought to be allied to the Cynareae, and it also provides a tenuous link to the Lactuceae, the most isolated and distinctive tribe of the order.

Looking backward for possible ancestors to the Asterales, it is found that the families Rubiaceae (order Gentianales) and Caprifoliaceae (order Dipsacales) come the nearest to providing the required features. Many authorities have thought that these two families are themselves closely related. Some of the other members of the Dipsacales order, such as the family Dipsacaceae, have often been compared to the Asterales; but they are already too advanced to serve as possible ancestors, being herbaceous and having a terminal rather than a basal ovule.

In the past, the Asteraceae family was often included in the order Campanulales, but that order is basically herbaceous and alternate leaved and thus can scarcely be ancestral to the Asterales. The small order Calycerales, which has involucrate heads much like those of the Asterales, is also excluded by being herbaceous and alternate leaved. The Calycerales order, furthermore, has a terminal ovule. The Campanulales and Calycerales do have a pollen-presentation mechanism similar to that of the Asterales, and this is probably the main reason that the Asteraceae family has often been associated with the order Campanulales; but a similar mechanism is also present in some members of the Rubiaceae family.

Functional significance of evolutionary adaptations

A comprehensive interpretation of the evolutionary origin and diversification of the Asterales order in terms of adaptation and survival value is difficult and has never been seriously attempted. The flower head obviously acts as a single large flower, with the ray flowers serving the function of petals to make the flowers conspicuous and attractive to a wide range of insects. The pollen-presentation mechanism, which makes the pollen available to all kinds of pollinators, fits well into such a scheme. The pappus in many genera is clearly adapted to seed dispersal. On the other hand, the repeated reduction and loss of both the ray flowers and the pappus are more difficult to account for, although presumably there could be a series of different explanations for the different examples. The functional significance of both the resin system and the latex system is obscure. There is no obvious value in the change from opposite to alternate leaves, nor in the frequent reduction and aggregation of the flower heads to form clusters of small heads. Indeed, there would seem to be some wastage of energy in composite composites such as *Lagascea* and *Echinops*, which continue to produce apparently useless individual involucres around the one-flowered heads that make up the compound head.

CLASSIFICATION

The most widely accepted arrangement of the species of the Asteraceae family into genera and tribes dates essentially from the work of George Bentham, in 1873. Many new genera and species have been described since that time, and the limits of many genera have had to be reconsidered, but botanists still turn to his treatment for an overall view of the family and for information on the characteristics and limits of genera that have not been recently revised. Bentham recognized 13 tribes. One of these, the Helenieae, is now submerged by many students of the family in the tribe Heliantheae, but the others are still generally accepted, with only minor modifications.

Annotated classification. The annotated classification presented here is based essentially on that of Bentham, with minor modifications that recognize recent work by other authorities.

ORDER ASTERALES

Individual flowers epigynous, perfect or unisexual, sympetalous, regular or irregular, commonly 5-merous, the calyx wanting or more often represented by a set of 1 to many hairs, bristles, or scales collectively called the pappus; stamens alternate with the corolla lobes, the filaments attached in the lower part of the corolla tube, the anthers generally elongate and united into a tube; ovary bicarpellate but unilocular, with a single, erect, basal, unitegmic ovule; style growing up through the anther tube, usually 2-cleft, the branches commonly with ventromarginal stigmatic lines that do not reach the tip; fruit an achene; flowers sessile in a centripetally flowering head on a common receptacle, sometimes individually subtended by a small bract (chaff), and almost always collectively subtended by an involucre of few to many bracts; herbs, shrubs, or trees with the heads arranged in various sorts of basically cymose inflorescences. One family, about 900 genera, and 15,000 to 20,000 species with worldwide distribution.

Family Asteraceae (Compositae)

The only family of the order.

Subfamily Asteroideae

Heads radiate, discoid, or disciform, or (in Mutisieae) with the flowers bilabiate, but never (save in a few Mutisieae) strictly ligulate; plants mostly with well-developed resin ducts and without latex, or less often with latex in isolated cells or pockets, only rarely in a system of anastomosing canals; pollen grains variously spiny or nearly smooth to sometimes lophate with 30 or more lacunae, not appearing angular.

Tribe Heliantheae. Leaves (at least the lower ones) tending to be opposite, but sometimes wholly alternate; heads radiate, less commonly discoid or disciform, predominantly yellow; involucral bracts tending to be herbaceous and in several series, but often variously modified; receptacle chaffy in most genera, less often naked, the genera with naked receptacle often taken as a separate tribe, Helenieae, but actually consisting of several diverse groups separately related to the remainder of the Heliantheae; pappus of scales, or a crown, or a few firm awns, or none; anthers basally obtuse to sagittate, but not tailed; style branches often more or less short-hairy throughout and with the stigmatic lines poorly defined, varying to those as are found in the tribes Astereae or Anthemideae. About 230 genera, predominantly in the New World. Familiar genera include *Ambrosia* (ragweed), *Bidens* (beggar ticks), *Coreopsis* (tickseed), *Cosmos*, *Dahlia*, *Helenium* (sneezeweed), *Helianthus* (sunflower), *Rudbeckia* (coneflower), *Tagetes* (marigold), *Xanthium* (cocklebur), and *Zinnia*.

Tribe Astereae. Leaves alternate, generally entire or toothed, seldom dissected; heads radiate, less often discoid or disciform, variously yellow or anthocyanic, often with yellow disk and anthocyanic or white rays; involucral bracts generally in 2 or more series, herbaceous to papery in texture; receptacle naked; pappus of diverse sorts, often of numerous capillary bristles; anthers basally obtuse to sagittate, but not tailed; style branches with ventromarginal stigmatic lines and a terminal, usually externally short-hairy appendage. About 120 genera, most abundant in the New World. Familiar genera include *Aster*, *Baccharis* (groundsel tree), *Bellis* (English daisy), *Callistephus* (China aster), *Erigeron* (daisy, fleabane), *Haplopappus* (goldenweed), and *Solidago* (goldenrod).

Tribe Anthemideae. Leaves alternate, mostly more or less dissected, varying to entire and then mostly small; heads radiate to often discoid or disciform, generally yellow, or with white rays; involucral bracts mostly rather dry and scarcely herbaceous, with very thin and more or less transparent or translucent margins and tip; receptacle chaffy or naked; pappus none, or of a few small scales or a crown; anthers not tailed; style branches with ventromarginal stigmatic lines, mostly ending abruptly in a tuft of minute hairs; plants mostly with a characteristic odour, unique to this tribe. About 60 genera, mostly of the Old World, especially the Mediterranean region and South Africa. Familiar genera include *Achillea* (yarrow), *Anthemis*, *Artemisia*, and *Chrysanthemum*.

Tribe Arctotideae. Leaves alternate, often more or less spiny, as is also the involucre; heads radiate to discoid, most commonly yellow; receptacle naked or sometimes chaffy; an-

thers not tailed; style branches resembling those of the Cynareae (to which the Arctotideae show some transitional forms) or *Ursinia*, of the Anthemideae. About 15 genera, all of the Old World, mostly in South Africa.

Tribe Inuleae. Leaves mostly alternate and entire, very often white-woolly; heads radiate or discoid to very often disciform, generally yellow or yellowish; involucral bracts herbaceous to often dry and papery, sometimes brightly coloured; receptacle chaffy or naked; pappus mostly of numerous capillary bristles, rarely of scales or none; anthers prolonged at the base into slender, sterile tails; style branches generally smooth or nearly so and without definite appendages, truncate to broadly rounded, the stigmatic lines often confluent around the tip. About 160 genera, most abundant in the Old World. Familiar genera include *Anaphalis* (pearly everlasting), *Gnaphalium* (cudweed), *Helichrysum* (strawflower, everlasting), *Inula* (elecampane), *Leontopodium* (edelweiss).

Tribe Senecioneae. Leaves alternate or sometimes opposite; heads radiate to less often discoid or disciform, most often yellow; involucral bracts mostly equal and uniseriate, often with a calyculus of much reduced outer bracts, occasionally in several series; receptacle generally naked; pappus of numerous capillary bristles; anthers not tailed; style branches with ventromarginal stigmatic lines, most often truncate and with a tuft of minute hairs at the end; achenes mostly all alike. About 60 genera, widely distributed. Familiar genera include *Arnica* and *Senecio* (one of the largest genera of flowering plants, with perhaps 1,500 species).

Tribe Calenduleae. Like the Senecioneae, but the pappus wanting and the achenes mostly of different shapes, those of the outermost flowers of the head distinctly unlike the others, often of unusual form. The smallest tribe, with about 9 genera, almost entirely African, especially South African. *Calendula* is the most familiar genus.

Tribe Eupatorieae. Leaves mostly opposite or whorled; heads strictly discoid, usually anthocyanic or white, never bright yellow; receptacle usually naked; anthers obtuse or rarely sagittate at the base; pollen grains minutely spiny, not lophate (crested or with ridges); style branches with short, inconspicuous stigmatic lines and a more or less elongate, papillate, often club-shaped (thicker distally than below) appendage. About 45 genera, largely confined to the New World, most abundant in tropical and subtropical countries. *Eupatorium*, a large genus of about 600 species; *Ageratum;* and *Liatris* (blazing star) are familiar genera.

Tribe Vernonieae. Leaves alternate; heads strictly discoid, usually anthocyanic or white, not yellow; receptacle naked; anthers more or less strongly sagittate at the base, sometimes almost tailed; pollen generally lophate, with a network of usually spiny ridges enclosing 30 or more lacunae; style branches elongate and gradually attenuate, minutely short-hairy outside, generally with short, inconspicuous, ventromarginal stigmatic lines toward the base. About 50 genera, most abundant in the New World, especially in tropical and subtropical countries. *Vernonia*, with about 600 species, is the only really familiar genus. *Stokesia*, of the southeastern U.S., is occasionally cultivated as a garden flower.

Tribe Cynareae. Leaves generally alternate, often more or less spiny, as also the involucre; heads discoid, most commonly anthocyanic; receptacle bristly to less commonly chaffy or naked; anthers tailed at the base; pollen grains spiny to smooth, not lophate; style with a thickened, often minutely hairy ring and an abrupt change of texture below the branches, papillate thence to the tip, the branches commonly more or less united below. About 50 genera, mostly in the Old World, especially in the Mediterranean region and the Near East, less frequent in North America. *Arctium* (burdock), *Carduus* (thistle), *Carthamus* (safflower), *Centaurea* (knapweed), *Cirsium* (thistle), and *Echinops* (globe thistle) are familiar genera.

Tribe Mutisieae. Leaves alternate; heads generally with some or all of the corollas 2-lipped, less often all regular but very deeply cleft; anthers more or less strongly tailed; other features diverse. About 70 genera, mostly in the Southern Hemisphere or in equatorial regions, especially in the mountains of South America. *Gerbera* is the only genus familiar in cultivation.

Subfamily Cichorioideae

Heads ligulate; plants with latex in a more or less well-developed system of anastomosing canals, but without resin ducts, or occasionally with resin ducts in the roots; pollen most often lophate, appearing angular, with about 6 to 21 lacunae enclosed by a network of usually spiny ridges; leaves mostly alternate; involucral bracts often subequal in 1 or 2 series.

Tribe Lactuceae (Cichorieae). The only tribe of the subfamily. About 65 genera, mainly in the Northern Hemisphere. *Cichorium* (chicory), *Hieracium* (hawkweed), *Lactuca* (lettuce), *Sonchus* (sow thistle), *Taraxacum* (dandelion), and *Tragopogon* are familiar genera.

Critical appraisal. Although the order Asterales is morphologically (structurally) and ecologically very diverse, it is absolutely sharply defined. There is not a single species about which there is any doubt as to its inclusion in or exclusion from the order. Botanists dealing casually with the order have often been so impressed by its diversity that many have suggested it must be an artificial rather than a natural group, but serious students, both past and present, are agreed that it is highly natural.

Unity of the aster order

The great majority of species of Asterales could be included in a single genus if the standards of sharpness of distinction that are useful in some other families were rigorously applied. Only the tribe Lactuceae (Cichorieae) stands somewhat apart from the others, and it is connected to the rest by the tribe Mutisieae. In practice botanists have found it necessary, in order to have any mental organization at all, to recognize genera and tribes in the Asterales that are imperfectly defined and are connected by transitional members. The tribes more nearly represent syndromes of correlated tendencies than morphologically definable groups. Each of three tribes (Eupatorieae, Senecioneae, Vernonieae) is dominated by a single very large genus, with which most of the other genera are associated as satellites. A number of the smaller genera may prove to be misplaced, and there is need for a careful reconsideration of generic and subtribal groupings throughout the family, especially in the Heliantheae.

BIBLIOGRAPHY. ARTHUR CRONQUIST, "Phylogeny and Taxonomy of the Compositae," *Am. Midl. Nat.*, 53:478–511 (1955), the most widely accepted interpretative synthesis for the group; GEORGE BENTHAM, "Notes on the Classification, History, and Geographical Distribution of the Compositae," *J. Linn. Soc.*, 13:355–577 (1873), the running explanation to go with the Bentham and Hooker *Genera Plantarum*, a technical work including an authoritative and still useful treatment of the Asteraceae (Compositae) family; SHERWIN CARLQUIST, "Wood Anatomy of Compositae: A Summary, with Comments on Factors Controlling Wood Evolution," *Aliso*, 6:28-44 (1966), interpretation and conclusions based on the author's previous papers dealing with the individual tribes; JAMES SMALL, "The Origin and Development of the Compositae," *New Phytol.*, 16:157–177, 198–221, 253–276 (1917), 17:13–40, 69–94, 114–142, 200–230 (1918), and 18:1–35, 65–89, 129–176, 201–234 (1919), a scholarly and thorough effort to interpret the Compositae in terms of the now discredited Age and Area Hypothesis.

(A.Cr.)

Astrology

Defined as either a science or a pseudoscience, astrology —the forecasting of earthly and human events by means of observing and interpreting the fixed stars, the Sun, the Moon, and the planets—has exerted a sometimes extensive and a sometimes peripheral influence in many civilizations, both ancient and modern. As a science, astrology has been utilized to predict or affect the destinies of individuals, groups, or nations by means of what is believed to be a correct understanding of the influence of the planets and stars on earthly affairs. As a pseudoscience, astrology is considered to be diametrically opposed to the findings and theories of modern Western science.

Nature and significance. Astrology is a method of predicting mundane events based upon the assumption that the celestial bodies—particularly the planets and the stars considered in their arbitrary combinations or configurations (called constellations)—in some causal or significant way, either determine or indicate changes in the sublunar world. The theoretical basis for this assumption lies historically in Hellenistic (*c.* 300 BC–*c.* AD 300) philosophy and radically distinguishes astrology from the celestial *omina* ("omens") that were first categorized and cataloged in ancient Mesopotamia. Originally, astrologers presupposed a geocentric universe in which the planets (including the Sun and Moon) revolve in orbits

whose centres are at or near the centre of the Earth, and in which the stars are fixed upon a sphere with a finite radius whose centre is also the centre of the Earth. Later, the principles of Aristotelian physics were adopted, according to which there is an absolute division between the eternal, circular motions of the heavenly element and the limited, linear motions of the four sublunar elements: fire, air, water, and earth.

Special relations were believed to exist between particular celestial bodies and their varied motions, configurations with each other, and the processes of generation and decay apparent in the world of fire, air, water, and earth. The complexity of these relations, reflected in the complexity of the phenomenal world, was sometimes regarded as providing a system of variables that no human mind could completely control; thereby, the astrologer might be readily excused for any errors. A similar set of special relations was also assumed by those whose physics was more akin to that of the Greek philosopher Plato. For the Platonic astrologers, the element of fire was believed to extend throughout the celestial spheres, and they were more likely than the Aristotelians to believe in the possibility of divine intervention in the natural processes through celestial influences upon the Earth, since they believed in the deity's creation of the celestial bodies themselves.

The role of the divine will

The role of the divine in astrological theory varies considerably. In its most rigorous aspect, astrology postulates a totally mechanistic universe, denying to the deity the possibility of intervention and to man that of free will; as such it was vigorously attacked by orthodox Christianity and Islām. For some, however, astrology is not an exact science like astronomy but merely indicates trends and directions that can be altered either by divine or by human will. In the interpretation of Bardesanes, a Syrian Christian scholar (154–222)—who has often been identified as a Gnostic (a believer in esoteric salvatory knowledge and the view that matter is evil and spirit good)—the motions of the stars govern only the elemental world, leaving the soul free to choose between the good and the evil. And for Gnostics in general, the perceptible universe was viewed as an elaborate mechanical cage in which a bit of the divine has been entrapped by the malevolent creator of the universe, a deity believed to be in opposition to the good, true, and spiritual God, and subsequently divided into individual souls. Man's ultimate goal, then, is to attain emancipation from this astrologically dominated material world. Some astrologers, such as the Harranians (from the ancient Mesopotamian city of Harran) and the Hindus, regard the planets themselves as potent deities whose decrees can be changed through supplication and liturgy or through theurgy, the science of persuading the gods or other supernatural powers. In still other interpretations—*e.g.*, that of the Christian Priscillianists (followers of Priscillian, a Spanish ascetic of the 4th century who apparently held dualistic views)—the stars merely make manifest the will of God to those trained in astrological symbolism.

Purposes of astral omens and astrology. *Purposes of astral omens.* The view that the stars make manifest the divine will is closest to the concept that lies behind the ancient Mesopotamian collections of celestial omens. Their primary purpose was to inform the royal court of impending disasters or success. These might take the forms of meteorological or epidemic phenomena affecting entire human, animal, or plant populations. Frequently, however, they involved the military affairs of the state or the personal lives of the ruler and his family. Since the celestial *omina* were regarded not as deterministic but rather as indicative—as a kind of symbolic language in which the gods communicated with men about the future and as only a part of a vast array of ominous events—it was believed that their unpleasant forebodings might be mitigated or nullified by ritual means or by contrary omens. The *bāru* (the official prognosticator), who observed and interpreted the celestial *omina*, was thus in a position to advise his royal employer on the means of avoiding misfortunes; the omens provided a basis for intelligent action rather than an indication of an inexorable fate.

Purposes of astrology. The original purpose of astrology, on the other hand, was to inform the individual of the course of his life on the basis of the positions of the planets and of the zodiacal signs (the 12 astrological constellations) at the moment of his birth or conception. From this science, called genethlialogy (casting nativities), were developed the fundamental techniques of astrology, which were later applied to a variety of other problems. The main subdivisions of astrology that developed after genethlialogy are general, catarchic, and interrogatory.

Principal subdivisions of astrology

General astrology studies the relationship of the significant celestial moments (*e.g.*, the times of the occurrences of vernal equinoxes, eclipses, or planetary conjunctions) to social groups, nations, or all humanity. It answers, by astrological means, questions formerly posed in Mesopotamia to the *bāru*.

Catarchic (pertaining to beginnings or sources) astrology determines whether or not a chosen moment is astrologically conducive to the success of a course of action begun in it. Basically in conflict with a rigorous interpretation of genethlialogy, it allows the individual (or corporate body) to act at astrologically favourable times and, thereby, to escape any failures predictable from his (or its) nativity.

Interrogatory astrology provides answers to a client's queries based on the situation of the heavens at the moment of his posing the questions. This astrological consulting service is even more remote from determinism than is catarchic astrology; it is thereby closer to divination by omens and insists upon the ritual purification and preparation of the astrologer.

Other forms of astrology, such as iatromathematics (application of astrology to medicine) and military astrology are variants on one or another of the above.

Astral omens in the ancient Near East. The astral omens employed in Mesopotamian divination were later commingled with what came to be known as astrology in the strict sense of the term and constituted within astrology a branch described as natural astrology. Though lunar eclipses apparently were regarded as ominous at a somewhat earlier period, the period of the 1st dynasty of Babylon (18th to 16th centuries BC) was the time when the cuneiform text *Enūma Anu Enlil*, devoted to celestial *omina*, was initiated. The final collection and codification of this series, however, was not accomplished before the beginning of the 1st millennium BC. But the tablets that have survived—mainly from the Assyrian library of King Ashurbanipal (7th century BC)—indicate that a standard version never existed. Each copy had its own characteristic contents and organization designed to facilitate its owner's consultation of the omens.

The four omen categories

The common categories into which the omens of *Enūma Anu Enlil* were considered to fall were four, named after the chief gods involved in the ominous communication: Sin, Shamash, Adad, and Ishtar. Sin (the Moon) contains omens involving such lunar phenomena as first crescents, eclipses, halos, and conjunctions with various fixed stars; Shamash (the Sun) deals with omens involving such solar phenomena as eclipses, simultaneous observations of two suns, and perihelia (additional suns); Adad (the weather god) is concerned with omens involving meteorological phenomena, such as thunder, lightning, and cloud formations, as well as earthquakes; and Ishtar (Venus) contains omens involving planetary phenomena such as first and last visibilities, stations (the points at which the planets appear to stand still), acronychal risings (rising of the planet in the east when the Sun sets in the west), and conjunctions with the fixed stars.

Though these omens are often cited in the reports of a network of observers established throughout the Assyrian Empire in the 7th century BC, they seem to have lost their popularity late in the period of the Persian domination of Mesopotamia (ending in the 4th century BC). During the later period new efforts were made, in a large number of works called *Diaries*, to find the correct correlations between celestial phenomena and terrestrial

events. Before this development, however, portions of the older omen series were transmitted to Egypt, Greece, and India as a direct result of the Achaemenid domination (a dynasty ruling in Persia 559–330 BC) of these cultural areas or of their border regions.

Astral omens in Egypt, Greece, India, China, and Islām. The evidence for a transmission of lunar omens to Egypt in the Achaemenid period lies primarily in a demotic (simplified form of Egyptian hieratic writing) papyrus based on an original of about 500 BC. A more extensive use of Mesopotamian celestial omens is attested by the fragments of a book written in Greek in the 2nd century BC and claimed as a work addressed to a King Nechepso by the priest Petosiris. From this source, among others (including perhaps a work of Eudoxus of Cnidus, a Greek astronomer of the 4th century BC), the contents of *Enūma Anu Enlil* were included in the second book of the *Apotelesmatika*, or "Work on Astrology" (commonly called the *Tetrabiblos*, or "Four Books"), by Ptolemy, a Greek astronomer of the 2nd century AD, the first book of an astrological compendium, by Hephaestion of Thebes, a Greco-Egyptian astrologer of the 5th century AD, and the *On Signs* of John Lydus, a Byzantine bureaucrat of the 6th century. Yet another channel of transmission to the Greeks was through the Magusaeans of Asia Minor, a group of Iranian settlers influenced by Babylonian ideas. Their teachings are preserved in several classical works on natural history, primarily that of Pliny the Elder (*c.* AD 23–79), a Roman natural historian, and the *Geoponica* (a late collection of agricultural lore).

In various Near Eastern languages there also exist many texts dealing with celestial omens, though their sources and the question as to whether they are directly descended from a Mesopotamian tradition or are derived from Greek or Indian intermediaries is yet to be investigated. Of these texts the most important are those ascribed to Hermes Trismegistus (the Greek name for the Egyptian god Thoth) by the Harranians and presently preserved in Arabic, the *Book of the Zodiac* of the Mandeans (a still existing Gnostic sect in Iraq and Khuzistan), the *Apocalypse*, attributed to the Old Testament prophet Daniel (extant in Greek, Syriac, and Arabic versions), and *The Book of the Bee* in Syriac.

Introduction of Mesopotamian literature to India

The transmission of Mesopotamian omen literature to India, including the material in *Enūma Anu Enlil*, apparently took place in the 5th century BC during the Achaemenid occupation of the Indus Valley. The first traces are found in Buddhist texts of this period, and Buddhist missionaries were instrumental in carrying this material to Central Asia, China, Tibet, Japan, and Southeast Asia. But the most important of the works of this Indian tradition and the oldest extant one in Sanskrit is the earliest version of the as yet unpublished *Gargasaṃhitā* ("Compositions of Garga") of about the 1st century AD. The original Mesopotamian material was modified so as to fit into the Indian conception of society, including the system of the four castes and the duty of the upper castes to perform the *saṃskāra*s (sanctifying ceremonies).

There are numerous later compilations of omens in Sanskrit—of which the most notable are the *Bṛhatsaṃhitā*, or "Great composition," of Varāhamihira (*c.* 550), the Jaina *Bhadrabāhu-saṃhitā*, or "Composition of Bhadrabāhu" (*c.* 10th century), and the *Pariśiṣṭa*s ("Supplements") of the Atharvaveda (perhaps 10th or 11th century)—though these add little that is new to the tradition. But in the works of the 13th century and later, entitled *Tājika*, there is apparent a massive infusion of the Arabic adaptations of the originally Mesopotamian celestial omens as transmitted through Persian (*Tājika*) translations. In *Tājika* the omens are closely connected with general astrology; in the earlier Sanskrit texts their connections with astrology had been primarily in the fields of military and catarchic astrology.

Astrology in the Hellenistic period (3rd century BC to 3rd century AD). In the 3rd century BC and perhaps somewhat earlier, Babylonian diviners began—for the purpose of predicting the course of an individual's life—to utilize some planetary omens: positions relative to the horizon, latitudes, retrogressions, and other positions at the moment of birth or of computed conception. This method was still far from astrology, but its evolution was more or less contemporary and parallel with the development of the science of genethlialogy in Hellenistic Egypt.

Equally obscure are those individuals who, living in Egypt under the Ptolemies (a Greek dynasty ruling 305–30 BC), mathematicized the concept of a correspondence between the macrocosm (larger order, or universe) and the microcosm (smaller order, or man) as interpreted in terms of Platonic or Aristolelian theories concerning the Earth as the centre of the planetary system. They conceived of the ecliptic (the apparent orbital circle of the Sun) as being divided into 12 equal parts, or zodiacal signs, each of which consists of 30°; in this they followed the Babylonians. They further regarded each of these 12 signs as the domicile (or house) of a planet and subdivided each into various parts—decans of 10° each, *fines* ("bounds") of varying lengths, and *dōdecatēmoria* of 2°30′ each—each of which is also dominated by a planet. Scattered at various points throughout the ecliptic are the planets' degrees of exaltation (high influence), opposite to which are their degrees of dejection (low influence). Various arcs of the zodiac, then, are either primarily or secondarily subject to each planet, whose strength and influence in a geniture (nativity) depend partially on its position relative to these arcs and to those of its friends and enemies.

The zodiac

Furthermore, each zodiacal sign has a special relation with a part of the human body (the *melothesia*). The 12 signs are further divided into four triplicities, each of which governs one of the four elements. Numerous pairs of opposites (male–female, diurnal–nocturnal, hot–cold, and others), based on the speculations of the followers of Pythagoras, a Greek mystical philosopher of the 6th century BC, are connected with consecutive pairs of signs. Finally, a wide variety of substances in the elemental world and attributes of human character are more or less arbitrarily associated with the different signs. These lists of interrelationships provide the rationale for many of the astrologer's predictions.

The individual planet's influences are related both to its general indications when regarded as ominous in Mesopotamian texts and to the traits of its presiding deity in Greek mythology. But on them are also superimposed the system of the four elements and their four qualities, the Pythagorean opposites (*e.g.*, masculine and feminine, fixed and moving), and lists of sublunar substances. Furthermore, as in the omens, the modes of the planetary motions are carefully considered, since their strengths are partially determined by their phases with respect to the Sun. Also, they exert a mutual influence on each other both by occupying each other's houses and by means of conjunction and aspects—opposition (to the seventh) and quartile (to the fourth or tenth) being generally considered bad, trine (to the fifth or ninth) and sextile (to the third or eleventh) good.

Moreover, as the planetary orbits revolve from west to east, the zodiac rotates daily about the Earth in the opposite sense. From a given spot on the surface of the earth this latter motion—if the ecliptic were a visible circle—would appear as a succession of signs rising one after the other above the eastern horizon. The astrologers regard the one that is momentarily in the ascendant as the first place, the one to follow it as the second, and so on, with the one that rose immediately prior to the ascendant being the 12th. In genethlialogy each place in this *dōdecatropos* determines an aspect of the native's (a person born under a particular sign) life; in other forms of astrology the place determines some appropriate aspect of the sublunar world.

Horoscopes

The astrologer, then, casts a horoscope by first determining for the given moment and locality the boundaries of the 12 places and the longitudes and latitudes of the seven planets. He reads this horoscope by examining the intricate geometric interrelationships of the signs and their parts and of the planets of varying computed strengths with the places and with each other and by associating with each element in the horoscope its list of

Table 1: The Signs and Relationships of the Zodiac

Pisces	feminine, common	water	Jupiter	Saturn Jupiter Mars	Jupiter Moon Mars	Venus (27°)

correspondences in the sublunar region. Any horoscopic diagram, of course, will yield an enormous number of predictions, including many that are contradictory or extravagant. The astrologer thus must rely on his knowledge of his client's social, ethnic, and economic background and on his own experience and good sense to guide him in avoiding error and attaining credibility.

Since about 100 BC the above method has been the essential procedure of astrology, though various refinements and additional devices occasionally have been introduced. There is space here only to mention briefly some innovations associated with the Hermetic tradition (associated with Hermes Trismegistus) and with Dorotheus of Sidon, an influential astrological poet of the third quarter of the 1st century AD. The first is the system of lots, which are influential points as distant from some specified points in the horoscopic diagram as two planets are from each other. The second is the prorogator, a point on the ecliptic that, travelling at the rate of one degree of oblique ascension a year toward either the descendant or ascendant, determines a person's length of life. Another is the method of continuous horoscopy,

Table 2: Relationship of Positions in the Zodiac to Aspects of Life

under which anniversary diagrams are compared with the base nativity to provide annual readings. And, finally, certain periods of life are apportioned to their governing planets in a fixed sequence; these period governors in turn share their authority with the other planets by granting them subperiods. All of these complications serve, among other purposes, to provide the astrologer with convenient excuses for his inevitable errors.

Astrology after the Hellenistic period. *In India.* Greek astrology was transmitted to India in the 2nd and 3rd centuries AD by means of several Sanskrit translations, of which the one best known is that made in AD 149/150 by Yavaneśvara and versified as the *Yavanajātaka* by Sphujidhvaja in AD 269/270. The techniques of Indian astrology are thus not surprisingly similar to those of its Hellenistic counterpart. But the techniques were transmitted without their philosophical underpinnings (for which the Indians substituted divine revelation), and the Indians modified the predictions, originally intended to be applied to Greek and Roman society, so that they would be meaningful to them. In particular, they took into account the caste system, the doctrine of metempsychosis (transmigration of souls), the Indian theory of five elements (earth, water, air, fire, and space), and the Indian systems of values.

The Indians also found it useful to make more elaborate the already complex methodology of Hellenistic astrology. They added as significant elements: the *nakṣatras* (or lunar mansions); an elaborate system of three categories of *yogas* (or planetary combinations); dozens of different varieties of *daśās* (periods of the planets) and *antardaśās* (subperiods); and a complex theory of *aṣṭakavarga* based on continuous horoscopy. The number of subdivisions of the zodiacal signs was increased by the addition of the *horās* (15° each), the *saptāṃśas* (4⅔° each), and the *navāṃśas* (3°20′ each); the number of planets was increased by the addition of the nodes of the Moon (the points of intersection of the lunar orbit with the ecliptic), and of a series of *upagrahas*, or imaginary planets. Several elements of Hellenistic astrology and its Sāsānian offshoot (see below *In Sāsānian Iran*), however —including the lots, the prorogator, the Lord of the Year, the triplicities, and astrological history—were introduced into India only in the 13th century through the *Tājika* texts. Besides genethlialogy, the Indians particularly cultivated military astrology and a form of catarchic astrology termed *muhūrta-śāstra* and, to a lesser extent, iatromathematics and interrogatory astrology.

In Sāsānian Iran. Shortly after Ardashīr I founded the Sāsānian Empire in AD 226, a substantial transmission of both Greek and Indian astrology to Iran took place. There were Pahlavi (Iranian language) translations of Dorotheus of Sidon, Vettius Valens, Hermes, and an Indian called (in the Arabic sources) Farmasp. Since the Pahlavi originals are all lost, these translations provided the only knowledge of the Sāsānian science. Genethlialogy in Iran was essentially an imitation of the Hellenistic (though without any philosophy), onto which were grafted some Indian features, such as the *navāṃśas* and a Śaivite interpretation of illustrations of the Greco-Egyptian deities of the decans. The most influential and characteristic innovation of the Sāsānian astrologers was the development of the theory of astrological history—that is, the writing of history, both past and future, on the basis of extensions of the techniques of the prorogator, the Lord of the Year, the planetary periods, and the continuous horoscopy employed in Hellenistic genethlialogy. This was done in conjunction with Zoroastrian millennarianism (the division of the finite duration of the material creation into 12 millennia).

In Islām. Astrology entered Islāmic civilization in the 8th and 9th centuries in three simultaneous streams—Hellenistic, Indian, and Sāsānian. Arabic translations from the Greek and Syriac represented the Hellenistic science, from Sanskrit the Indian version, and from Pahlavi the Sāsānian combination of the two. But to these influences Islāmic astrology, through the work of Abū Maʿshar, an astrologer of the 9th century, added the Harranian adaptation of the Neoplatonic definition of

Significance of Arabic astrology

the mode of astral influences in terms of Aristotelian physics. Abū Ma'shar further elaborated Sāsānian astrological history and greatly expanded the number of lots that an astrologer had to take into consideration. Much attention was paid by the Muslims to catarchic and interrogatory astrology, but, after the 9th century, Arabic astrological writings ceased to be original, degenerating into introductory handbooks or vast compendia. Under attack by the theologians for denying divine intervention in the world and man's free will, astrology rapidly declined in its appeal to Muslim intellectuals after the Mongol invasions of the 13th century, though not before its influence had been experienced in India, the Latin West, and Byzantium.

In Byzantium. During the last upsurge of paganism in the 5th and 6th centuries AD, Byzantium (the Eastern Roman Empire) boasted a host of astrologers: Hephaestion, Julian of Laodiceia, "Proclus," Rhetorius, and John Lydus. Though their works are singularly unoriginal compilations, they remain extremely valuable as the main sources for an understanding of earlier Hellenistic astrology. By the end of the 6th century, however, the general decline of the Byzantine Empire's intellectual life and the strong opposition of the church had combined to virtually obliterate astrology, though some practice of reading celestial omens survived in Byzantium as it also did in western Europe. The science was revived only in the late 8th century and the 9th century under the impact of translations from Syriac and Arabic. The period from about 800 to 1200 was the most propitious for Byzantine astrology; numerous texts were translated and many compilations assembled, but nothing was essentially added to astrological theories or techniques. This period was rivalled only by a last flowering of astrology in the late 14th century, when John Abramius and his students revised the older astrological treatises in Greek to provide the Renaissance with vulgate texts.

In western Europe. The astrological texts of the Roman Empire were written almost universally in Greek rather than in Latin; the only surviving exceptions are the poem *Astronomica* of Manilius (*c.* AD 15–20), the *Matheseos libri* ("Books on Astrology") of Firmicus Maternus (c. 335), and the anonymous *Liber Hermetis* ("Book of Hermes") from the 6th century. In the absence of astronomical tables in Latin, however, none of these was of any use, and astrology for all practical purposes disappeared with the knowledge of Greek in western Europe. It was revived only with the numerous translations of Arabic astrological and astronomical treatises executed in Spain and Sicily in the 12th and 13th centuries, supplemented by a few translations directly from the Greek. But the new astrology in the Latin-reading world remained essentially an offshoot of Islāmic astrology, gaining an adequate representation of its Hellenistic originals only in the 15th and 16th centuries. These two centuries also witnessed the fullest flowering of astrology in western Europe, frequently in conjunction with Neoplatonism and Hermeticism. By the 17th century, however—with the displacement of the Earth from the centre of the universe in the new astronomy of Copernicus (1473–1543), Galileo (1564–1642), and Johannes Kepler (1571–1630), and with the rise of the new mechanistic physics of Descartes (1596–1650) and Newton (1642–1727)—astrology lost its intellectual viability and became scientifically untenable. Though Kepler attempted to devise a new method of computing astrological influences in the heliocentric (Sun-centred) universe, he did not succeed, since no astral influences are possible in a Newtonian universe.

Effect of modern science on astrology

Astrology today. Newtonian physics eradicated a belief in astrology among the educated. The practice of the now pseudoscience continued among nonintellectuals in the West, gradually losing contact with its rich tradition and becoming more and more fraudulent, though in countries such as India, where only a small intellectual elite has been trained in Western physics, it manages to retain here and there its position among the sciences. Regardless of its validity, some Indian universities offer advanced degrees in astrology.

Recently in the West, however, astrology has regained a large popular following, though there does not seem to have been any effort made to re-establish a firm theoretical basis for it. The divisions of the year governed by the 12 zodiacal signs (which are derived from Hellenistic astrology) as depicted in newspapers, manuals, and almanacs are as follows:

Aries, the Ram, March 21–April 19
Taurus, the Bull, April 20–May 20
Gemini, the Twins, May 21–June 21
Cancer, the Crab, June 22–July 22
Leo, the Lion, July 23–August 22
Virgo, the Virgin, August 23–September 22
Libra, the Balance, September 23–October 23
Scorpio, the Scorpion, October 24–November 21
Sagittarius, the Archer, November 22–December 21
Capricorn, the Goat, December 22–January 19
Aquarius, the Water Carrier, January 20–February 18
Pisces, the Fish, February 19–March 20

Attempts have been made to incorporate into the general astrological scheme the planets discovered since the Renaissance and to find some sort of statistical relation between planetary positions and human lives. None of these attempts appear to be at all convincing, however, and no serious explanation seems to exist regarding the alleged spheres of influence of the planets, the alleged nature of their influences, or the manner in which they are received. Nor has any modern astrologer proved that arbitrary arcs (houses or zodiacal signs) on a nonexistent circle (the ecliptic) are endowed with existence and with attributes, much less with the power to affect human lives. Moreover, since the phenomena of this world are now largely explainable by the hypotheses of modern science, it is difficult to understand how astrological influences can also be responsible for them. In short, modern Western astrology, though of great interest sociologically and popularly, generally is regarded as devoid of intellectual value.

BIBLIOGRAPHY. The fundamental work on Greek astrology is A. BOUCHE-LECLERCQ, *L'astrologie grecque* (1899). Material concerning ancient astrological literature is assembled in W. and H.G. GUNDEL, *Astrologumena* (1966), though this work must be used with caution. For the older astral omens of Mesopotamia, the most convenient survey is P. HILAIRE DE WYNGHENE, *Les Présages astrologiques* (1932). Aspects of Sāsānian astrology, and in particular its application to history, are covered by D. PINGREE, *The Thousands of Abû Ma'shar* (1968); and E.S. KENNEDY and D. PINGREE, *The Astrological History of Mâshâ'allâh* (1971). The best account of astrology in Islām is by C.A. NALLINO, "Astrologia e astronomia presso i Musalmani. 1. Astrologia," in his *Raccolta di scritti editi e inediti*, vol. 5, pp. 1–41 (1944). The Indian astrologers are dealt with in detail by D. PINGREE in *Census of the Exact Sciences in Sanskrit*, vol. 1 (1970).

The philosophical criticisms of astrology developed in antiquity are discussed by D. AMAND, *Fatalisme et liberté dans l'antiquité grecque* (1945). The position of astrology in the pagan religions is reviewed by F. CUMONT, *Astrology and Religion Among the Greeks and Romans* (1912); and its role in Hermeticism and in theurgy, two of the principle esoteric philosophies of late antiquity, is expounded respectively by A.M.J. FESTUGIERE, *La Révélation d'Hermès Trismégiste*, 4 vol. (1944–54); and by H. LEWY, *Chaldaean Oracles and Theurgy* (1956).

A useful compendium of knowledge about modern astrology is N. DEVORE, *Encyclopedia of Astrology* (1947); an interesting sociological study of the rise of modern astrology in France is J. MAITRE, "La Consommation d'astrologie dans la France contemporaine," in *La Divination*, vol. 2, pp. 429–447 (1968).

(D.E.P.)

Astronomical Maps

The brighter stars and planets are easily recognized by a practiced observer. The much more numerous fainter celestial bodies can be located and identified only with the help of astronomical maps, catalogs, and in some cases almanacs.

The first astronomical charts, globes, and drawings, often decorated with fantastic figures, depicted the constellations, recognizable groupings of bright stars known by imaginatively chosen names that have been for many

centuries both a delight to man and a dependable aid to navigation. Several royal Egyptian tombs of the second millennium BC include paintings of constellation figures, but these cannot be considered accurate maps. Classical Greek astronomers used maps and globes; unfortunately, no examples survive. Numerous small metal celestial globes from Islāmic makers of the 11th century onward remain. The first printed planispheres (representations of the celestial sphere on a flat surface) appeared in 1515, and printed celestial globes made their debut at about the same time.

Telescopic astronomy began in 1609, and by the end of the 17th century the telescope was applied in mapping the stars. The invention of the telescope also made possible maps of the surface details both of the Moon and of the planets. (Maps of individual bodies are discussed in their respective articles.)

In the latter part of the 19th century, photography gave a powerful impetus to precise chart making, culminating in the 1950s in the *National Geographic Society–Palomar Observatory Sky Survey*, a portrayal of the part of the sky visible from Palomar Observatory in California, now part of the Hale Observatories.

Many modern maps used by amateur and professional observers of the sky show stars; dark nebulae of obscuring dust; and bright nebulae, masses of tenuous, glowing matter. Specialized maps show sources of radio radiation, sources of infrared radiation, and quasi-stellar objects having very large red shifts and very small images. Astronomers of the 20th century have divided the entire sky into 88 areas, or constellations; this international system codifies the naming of stars and star patterns that began in prehistoric times. Originally only the brightest stars and most conspicuous patterns were given names, probably based on the actual appearance of the configurations. Beginning in the 16th century, navigators and astronomers have progressively filled in all the areas left undesignated by the ancients.

THE CELESTIAL SPHERE

To any observer, ancient or modern, the night sky appears as a hemisphere resting on the horizon. Consequently, the simplest descriptions of the star patterns and of the motions of heavenly bodies are those presented on a sphere.

The daily eastward rotation of the Earth on its axis produces an apparent diurnal westward rotation of the starry sphere. Thus the stars seem to rotate about a north or south celestial pole, the projection into space of the Earth's own poles. Equidistant from the two poles is the celestial equator; this great circle is the projection into space of the Earth's Equator.

Figure 1 illustrates the celestial sphere as viewed from some middle northern latitude. Part of the sky adjacent to a celestial pole is always visible (the shaded area in the diagram) and an equal area about the opposite pole is always invisible below the horizon; the rest of the celestial sphere appears to rise and set each day. For any other latitude the particular part of sky visible or invisible will be different and the diagram must be redrawn. An observer situated at the Earth's North Pole could observe only the stars of the northern celestial hemisphere. An observer at the Equator, however, would be able to see the entire celestial sphere as the daily motion of the Earth carried him around.

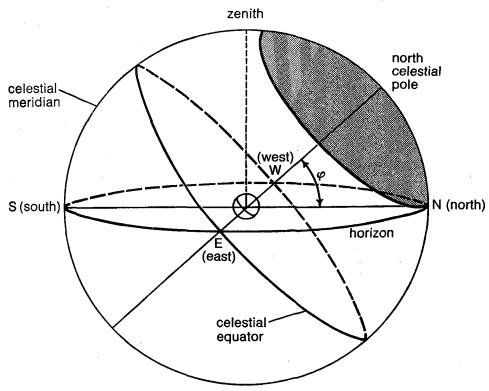

Figure 1: Celestial coordinates seen by an observer in mid-northern latitudes. His celestial meridian is a great circle passing through his zenith and the poles. His astronomical horizon meets the celestial sphere at infinity.

In addition to their apparent daily motion around the Earth, the Sun, Moon, and planets have their own motions with respect to the starry sphere. Since the Sun's brilliance obscures the background stars from view, it took many centuries before men discovered the precise path of the Sun through the constellations that are now called the signs of the zodiac. The great circle of the zodiac traced out by the Sun on its annual circuit is the ecliptic (so called because eclipses can occur when the Moon crosses it.)

The zodiac and the ecliptic

As viewed from space the Earth slowly revolves about the Sun in a fixed plane, the ecliptic plane. A line perpendicular to this plane defines the ecliptic pole, and it makes no difference whether this line is projected into space from the Earth or from the Sun. All that is important is the direction, because the sky is so far away that the ecliptic pole must fall on a unique point on the celestial sphere (Figure 2).

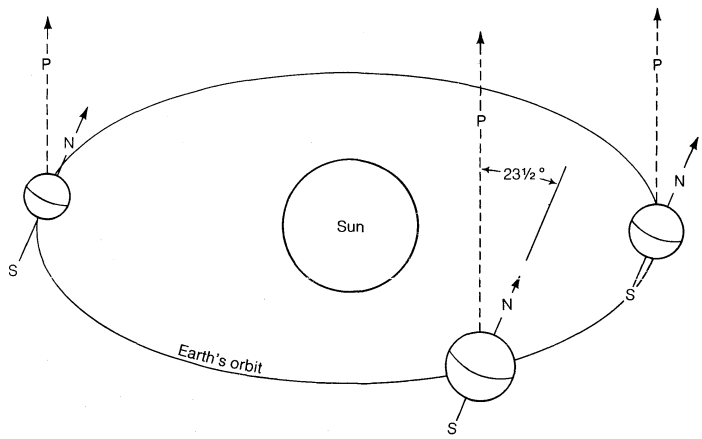

Figure 2: The north celestial (N) and the north ecliptic (P) poles at various positions of the Earth in its annual path around the Sun. Dotted lines are all perpendicular to the plane of Earth's orbit, and all intersect the celestial sphere at the north ecliptic pole. Solid lines drawn through Earth's poles, perpendicular to Earth's Equator, all point to celestial north. The angle of 23½° remains constant.

The principal planets in the solar system revolve about the Sun in nearly the same plane as the Earth's orbit, and their movements will therefore be projected onto the celestial sphere nearly, but seldom exactly, on the ecliptic. The Moon's orbit is tilted by about five degrees from this plane, and hence its position in the sky deviates from the ecliptic more than those of the other planets with the exception of Pluto.

Because the blinding sunlight blocks some stars from view, the particular constellations that can be seen depend on the position of the Earth in its orbit; that is, on the apparent place of the Sun. The stars visible at midnight will shift westward by about one degree each successive midnight as the Sun progresses in its apparent eastward motion. Stars visible at midnight in September will be concealed by the dazzling noontime Sun 180 days later in March.

Why the ecliptic and celestial equator meet at an angle of 23° 26.6′ is an unexplained mystery originating in the past history of Earth. The angle gradually varies by small amounts owing to Moon- and planet-caused gravitational perturbations on the Earth. The ecliptic plane is comparatively stable, but the equatorial plane continually shifts as the Earth's axis of rotation changes its direction in space. The successive positions of the celestial poles

Precession of the equinoxes

trace out large circles on the sky with a period of about 26,000 years. This phenomenon, known as precession of the equinoxes, causes a series of different stars to become pole stars in turn. Polaris, the present pole star, will come nearest to the north celestial pole around the year AD 2100. At the time the pyramids were built, Thuban in the constellation Draco served as the pole star, and in about 12,000 years the first-magnitude star Vega will be near the north celestial pole. Precession also makes the coordinate systems on precise star maps applicable only for a specific epoch.

CELESTIAL COORDINATE SYSTEMS

The horizon system. The simple altazimuth system, which depends on a particular place, specifies positions by altitude (the angular elevation from the horizon plane) and azimuth (the angle clockwise around the horizon, usually starting from the north). Lines of equal altitude around the sky are called almucantars. The horizon system is fundamental in navigation, as well as in terrestrial surveying. For mapping the stars, however, coordinates fixed with respect to the celestial sphere itself (such as the ecliptic or equatorial systems) are far more suitable.

The ecliptic system. Celestial longitude and latitude are defined with respect to the ecliptic and ecliptic poles. Celestial longitude is measured eastward from the ascending intersection of the ecliptic with the equator, a position known as the "first point of Aries," and the place of the Sun at the time of the vernal equinox around March 21. The first point of Aries is symbolized by the ram's horns (♈).

Unlike the celestial equator, the ecliptic is fixed among the stars; however, the ecliptic longitude of a given star increases by 1.396° per century owing to the precessional movement of the equator—similar to the precessional movement of a child's top—which shifts the first point of Aries. The first 30 degrees along the ecliptic is nominally designated as the sign Aries, although this part of the ecliptic has now moved forward into the constellation Pisces. Ecliptic coordinates predominated in Western astronomy until the Renaissance. (In contrast, Chinese astronomers always used an equatorial system.) With the advent of national nautical almanacs, the equatorial system, more suited to observation and navigation, gained ascendancy.

The equatorial system. Based on the celestial equator and poles, the equatorial coordinates, right ascension and declination, are directly analogous to terrestrial longitude and latitude (see Figure 3). Right ascension, measured eastward from the first point of Aries (see above), is customarily divided into 24 hours rather than 360°, thus emphasizing the clocklike behaviour of the sphere. Precise equatorial positions must be specified for a particular year, since the precessional motion continually changes the measured coordinates.

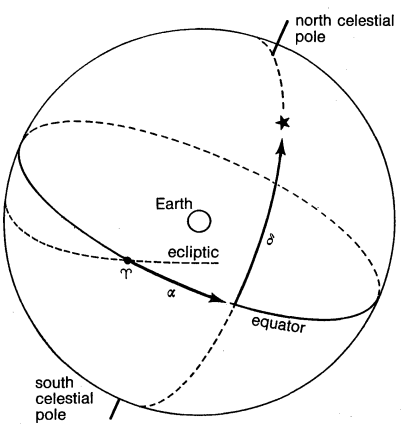

Figure 3: *Equatorial system of coordinates: right ascension (α) and declination (δ) of a star.*
Both are angular measurements, though right ascension is usually given in hours rather than degrees of arc and is measured eastward from the "first point of Aries" (♈), where the Sun crosses the celestial equator in March. Declination is considered positive (+) north of the celestial equator and negative (−) south of it.

Galactic coordinates. For problems relating to the structure of the Galaxy, astronomers have introduced the galactic equator, a great circle girdling the sky and centred in the Milky Way. Galactic longitude is measured from a specified location in Sagittarius in the direction of the nucleus of the Galaxy and is taken as positive in a direction obliquely northward in the sky (increasing declination). Galactic latitude is measured from the galactic equator and is positive toward the north galactic pole in Coma Berenices.

THE CONSTELLATIONS AND OTHER SKY DIVISIONS

The constellations carry man back to the dawn of astronomy. Their erratic star patterns, often whimsically depicted by early man, are in part the fossil remains of a primitive mythology; but as such they have extraordinary interest.

Ancient references to the constellations

The oldest astronomical cuneiform texts, from the second half of the 2nd millennium BC, record the Sumerian names of the constellations still known as the lion, the bull, and the scorpion. Drawings of these astronomical animals appear on Babylonian boundary stones of the same period, and the earlier occurrence of these motifs on prehistoric seals, Sumerian vases, and gaming boards suggests that they may have originated as early as 4000 BC. In China a handful of configurations show similarity to those of the West, including the scorpion, lion, hunter (Orion), and northern dipper, suggesting the possibility of a very old common tradition for a few groups, but, otherwise, almost complete independence.

Greek literature reflects the impact of the stars on the life of an agricultural and seafaring people. Homer (*c.* 9th century BC) records several constellations by the names used today, and the first mention of circumpolar stars is in the *Odyssey*. Odysseus is

> Gazing with fixed eye on the Pleiades,
> Boötes setting late and the Great Bear,
> By others called the Wain, which wheeling round,
> Looks ever toward Orion and alone
> Dips not into the waters of the deep.
>
> *Odyssey*, V

In England the Great Bear (Ursa Major), or Big Dipper, was still called Charles's Wain (or Wagon) in Shakespeare's day:

> An't be not four by
> The day I'll be hanged; Charles' Wain is over
> The new chimney and yet our horse not pack'd.
>
> *King Henry IV*, Part I, Act ii, Scene 1

This form derives from Charlemagne, and according to *The Oxford English Dictionary*, apparently from a verbal association of the name of the bright nearby Arcturus with Arturus, or Arthur, and the legendary association of Arthur and Charlemagne.

The earliest systematic account of the constellations is contained in the *Phaenomena* of Aratus, a poet of the 3rd century BC, who described 43 constellations and named five individual stars. Cicero recorded that

> The first Hellenic globe of the sky was made by Thales of Miletus, having fallen into a ditch or well while star-gazing. Afterwards Eudoxos of Cnidus traced on its surface the stars that appear in the sky; and . . . many years after, borrowing from Eudoxos this beautiful design and representation, Aratos had illustrated it in his verses, not by any science of astronomy, but by the ornament of poetical description.
>
> *De republica*, I, 14

The *Almagest*

By far the most important list of stars and constellations still extant from antiquity appears in the *Almagest* of the great Alexandrian astronomer Ptolemy (Claudius Ptolemaeus; flourished 2nd century AD). It contains ecliptic coordinates and magnitudes (measures of brightness) for 1,022 stars, grouped into 48 constellations. Numerous writers have stated that Ptolemy simply borrowed his material from a now-lost catalog of Hipparchus compiled in 129 BC. A critical analysis of the Hipparchian fragments still extant, including his commentary on the *Phaenomena* of Aratus, indicates that (1) the catalog of Hippar-

Constellations described by Ptolemy: the zodiac				
Aries	*Arietis*	Ari ♈	Ram	
Taurus	*Tauri*	Tau ♉	Bull	*Aldebaran:* Pleiades; M1 (Crab Nebula)
Gemini	*Geminorum*	Gem ♊	Twins	*Castor: Pollux*
Cancer	*Cancri*	Can ♋	Crab	Praesepe (star cluster)
Leo	*Leonis*	Leo ♌	Lion	*Regulus*
Virgo	*Virginis*	Vir ♍	Virgin	*Spica:* Virgo cluster of galaxies
Libra	*Librae*	Lib ♎	Balance	
Scorpius	*Scorpii*	Sco ♏	Scorpion	*Antares:* many star clusters
Sagittarius	*Sagittarii*	Sgr ♐	Archer	Galactic centre; many star clusters
Capricornus	*Capricorni*	Cap ♑	Sea-goat	
Aquarius	*Aquarii*	Aqr ♒	Water-bearer	
Pisces	*Piscium*	Psc ♓	Fishes	
Other Ptolemaic constellations				
Andromeda	*Andromedae*	And	Andromeda (Princess)	M31 (Great Spiral Galaxy)
Aquila	*Aquilae*	Aql	Eagle	*Altair*
Ara	*Arae*	Ara	Altar	
Argo Navis	*Argus Navis*	Arg	Ship Argo	now divided into Carina, Puppis, Pyxis, and Vela
Auriga	*Aurigae*	Aur	Charioteer	*Capella:* M36, M37, M38 (open star clusters)
Boötes	*Boötis*	Boo	Herdsman	*Arcturus*
Canis Major	*Canis Majoris*	CMi	Greater Dog	*Sirius* (brightest star)
Canis Minor	*Canis Minoris*	CMi	Smaller Dog	*Procyon*
Cassiopeia	*Cassiopeiae*	Cas	Cassiopeia (Queen)	Tycho's nova, 1572 (visible in daytime)
Centaurus	*Centauri*	Cen	Centaur	*Alpha* (nearest star to Sun); *Beta*
Cepheus	*Cephei*	Cep	Cepheus (King)	Delta Cephei (prototype for cepheid variables)
Cetus	*Ceti*	Cet	Whale	Mira Ceti (first recognized variable star)
Corona Austrina	*Coronae Austrinae*	CrA	Southern Crown	
Corona Borealis	*Coronae Borealis*	CrB	Northern Crown	
Corvus	*Corvi*	Crv	Raven	
Crater	*Crateris*	Crt	Cup	
Cygnus	*Cygni*	Cyg	Swan	"Northern Cross"; *Deneb*
Delphinus	*Delphini*	Del	Dolphin	"Job's Coffin"
Draco	*Draconis*	Dra	Dragon	Thuban (polestar in 3000 BC)
Equuleus	*Equulei*	Equ	Little Horse	
Eridanus	*Eridani*	Eri	River Eridanus or river god	*Achernar*
Hercules	*Herculis*	Her	Hercules (Greek hero)	M15 (great globular star cluster)
Hydra	*Hydrae*	Hya	Water Snake	
Lepus	*Leporis*	Lep	Hare	
Lupus	*Lupi*	Lup	Wolf	
Lyra	*Lyrae*	Lyr	Lyre	*Vega:* M57 (Ring Nebula)
Ophiuchus	*Ophiuchi*	Oph	Serpent-bearer	
Orion	*Orionis*	Ori	Hunter	*Rigel: Betelgeuse;* M41 (Great Nebula)
Pegasus	*Pegasi*	Peg	Pegasus (Winged horse)	Great Square (of Pegasus)
Perseus	*Persei*	Per	Perseus (Greek hero)	Algol (eclipsing star); h and χ Persei (double cluster)
Piscis Austrinus	*Piscis Austrini*	PsA	Southern Fish	*Fomalhaut*
Sagitta	*Sagittae*	Sge	Arrow	
Serpens	*Serpentis*	Ser	Serpent	
Triangulum	*Trianguli*	Tri	Triangle	M33 (nearby spiral galaxy)
Ursa Major	*Ursae Majoris*	UMa	Great Bear	seven brightest stars are Big Dipper or Plough
Ursa Minor	*Ursae Minoris*	UMi	Lesser Bear	Polaris (the north pole-star)
Southern constellations, added c. 1600				
Apus	*Apodis*	Aps	Bird of Paradise	
Chamaeleon	*Chamaeleontis*	Cha	Chamaeleon	
Dorado	*Doradus*	Dor	Swordfish	Large Magellanic Cloud
Grus	*Gruis*	Gru	Crane	
Hydrus	*Hydri*	Hyi	Water Snake	
Indus	*Indi*	Ind	Indian	
Musca	*Muscae*	Mus	Fly	
Pavo	*Pavonis*	Pav	Peacock	
Phoenix	*Phoenicis*	Phe	Phoenix (Mythical bird)	
Triangulum Australe	*Trianguli Australis*	TrA	Southern Triangle	
Tucana	*Tucanae*	Tuc	Toucan	Small Magellanic Cloud
Volans	*Volantis*	Vol	Flying Fish	
Constellations of Bartsch, 1624				
Camelopardalis	*Camelopardalis*	Cam	Giraffe	
Columba	*Columbae*	Col	Dove	constellation formed by Plancius, 1605
Monoceros	*Monocerotis*	Mon	Unicorn	
Constellations of Hevelius, 1687				
Canes Venatici	*Canum Venaticorum*	CVn	Hunting Dogs	M51 (Whirlpool Galaxy)
Lacerta	*Lacertae*	Lac	Lizard	
Leo Minor	*Leonis Minoris*	LMi	Lesser Lion	
Lynx	*Lyncis*	Lyn	Lynx	
Scutum	*Scuti*	Sct	Shield	star cloud in Milky Way
Sextans	*Sextantis*	Sex	Sextant	
Vulpecula	*Vulpeculae*	Vul	Fox	M27 (Dumbbell Nebula)
Ancient asterisms now separate constellations				
Carina	*Carinae*	Car	Keel [of Argo]	*Canopus*
Coma Berenices	*Comae Berenices*	Com	Bernice's Hair	Coma (star cluster); north galactic pole
Crux	*Crucis*	Cru	[Southern] Cross	*Alpha; Beta*
Puppis	*Puppis*	Pup	Stern [of Argo]	
Pyxis	*Pyxidis*	Pyx	Compass [of Argo]	
Vela	*Velorum*	Vel	Sails [of Argo]	
Southern Constellations of La Caille, c. 1750				
Antlia	*Antliae*	Ant	Pump	
Caelum	*Caeli*	Cae	[Sculptor's] Chisel	
Circinus	*Circini*	Cir	Drawing Compasses	
Fornax	*Fornacis*	For	[Chemical] Furnace	
Horologium	*Horologii*	Hor	Clock	
Mensa	*Mensae*	Men	Table [Mountain]	
Microscopium	*Microscopii*	Mic	Microscope	
Norma	*Normae*	Nor	Square	
Octans	*Octantis*	Oct	Octant	
Pictor	*Pictoris*	Pic	Painter's [Easel]	
Pyxis	*Pyxidis*	Pyx	Mariner's Compass of Argo	
Reticulum	*Reticuli*	Ret	Reticle	
Sculptor	*Sculptoris*	Scl	Sculptor's [Workshop]	south galactic pole
Telescopium	*Telescopii*	Tel	Telescope	

*The 12 constellations of the Zodiac are accompanied by their symbols. †First magnitude stars are given in italics.

chus did not include more than 850 stars and (2) Ptolemy most likely obtained new coordinates for even those 850 stars. The evidence suggests that Ptolemy, who for over a century has been considered a mere compilator, should be placed among the first-rank observers of all ages.

Nevertheless, Ptolemy's star list presents a curious puzzle. The southernmost heavens, invisible at the latitude of Alexandria, naturally went unobserved. On one side of the sky near this southern horizon, he tabulated the bright stars of the Southern Cross (although not as a separate constellation) and of Centaurus, but on the opposite side a large area including the first magnitude star Achernar has been left unrecorded. Because of precession, before 2000 BC this region would have been invisible from Mesopotamia. Perhaps neither Hipparchus nor Ptolemy considered that part of the heavens unnamed by their ancient predecessors. Ptolemy's catalog of 1,022 stars remained authoritative until the Renaissance.

Ptolemy divided his stars into six brightness, or magnitude, classes. He listed 15 bright stars of the first magnitude but comparatively few of the faint, much more numerous but barely visible sixth magnitude at the other limit of his list. Al-Ṣūfī, a 10th century Islāmic astronomer carried out the principal revision made to these magnitudes during the Middle Ages. Ulugh Beg, grandson of the Mongol conqueror Tamerlane, is the only known Oriental astronomer to reobserve the positions of Ptolemy's stars. His catalog, formed in 1420–37, was not printed until 1665, by which time it had already been surpassed by European observations.

Constellations of the zodiac. The Mesopotamian arrangement of constellations has survived to the present day because it became the basis of a numerical reference scheme—the ecliptic, or zodiacal, system. This happened around 450 BC, when the ecliptic was clearly recognized and divided into twelve equal signs of the zodiac. Most modern scholars take the zodiac as a Babylonian invention; the oldest record of the zodiacal signs as such is a cuneiform horoscope from 419 BC. But since Greek sources attribute the discovery of the ecliptic to Oenopides in the latter part of the fifth century BC, a parallel development in both Greece and Babylon should not be excluded.

At the time the zodiac was established, it was probably necessary to invent at least one new constellation, Libra. Centuries later Ptolemy's *Almagest* still described the stars of Libra with respect to the ancient figure of the scorpion.

The decans. Two other astronomical reference systems developed independently in early antiquity, the lunar mansions and the Egyptian decans. The decans are 36 star configurations circling the sky somewhat to the south of the ecliptic. They make their appearance in drawings and texts inside coffin lids of the 10th dynasty (around 2100 BC) and are shown on the tomb ceilings of Seti I (1318–1304 BC) and of some of the Rameses in Thebes. The decans appear to have provided the basis for the division of the day into 24 hours.

Besides representing star configurations as decans, the Egyptians marked out about 25 constellations, such as crocodile, hippopotamus, lion, and a falcon-headed god. Their constellations can be divided into northern and southern groups, but the various representations are so discordant that only three constellations have been identified with certainty: Orion (depicted as Osiris), Sirius (a recumbent cow), and Ursa Major (foreleg or front part of a bull). The most famous Egyptian star map is a 1st century BC stone chart found in the temple at Dandarah and now in the Louvre. The Zodiac of Dandarah illustrates the Egyptian decans and constellations, but since it incorporates the Babylonian zodiac as well, many stars must be doubly represented, and the stone can hardly be considered an accurate mapping of the heavens.

Hsiu and *nakṣhatra*

Lunar mansions. Called *hsiu* in China and *nakṣhatra* in India, the lunar mansions are 28 divisions of the sky presumably selected as approximate "Moon stations" on successive nights. At least four quadrantal *hsiu* that divided the sky into quarters or quadrants were known in China in the 14th century BC, and 23 are mentioned in the *Yüeh Ling*, which may go back to 850 BC. In India a complete list of *nakṣhatra* are found in the Atharvaveda, giving evidence that the system was organized before 800 BC. The system, however, of lunar mansions may have a common origin even earlier in Mesopotamia.

Relationship of the bright stars and their constellations. Ancient peoples sometimes named individual bright stars rather than groups; sometimes the name of the group and its brightest star were synonymous—as in the case of the constellation Aquila and the star Altair (Alpha Aquilae), both names meaning "flying eagles"—or were used interchangeably as in the case of both the star Arcturus (Alpha Böotis, "bear watcher") and the constellation Boötes ("plowman"). In the star list of the *Almagest,* Ptolemy cites only about a dozen stars by name, describing the others by their positions within the constellation figures. Most star names in current use have Arabic forms, but these are usually simply translations of Ptolemy's descriptions; for example, Deneb, the name of the brightest star in the constellation Cygnus (Swan), means literally "tail" of the bird.

The earliest astronomical globes and ancient maps

Ptolemy's placement of the stars within apparently well-known figures indicates the earlier existence of star maps, probably globes. An example survives in the so-called Farnese Globe at Naples, the most famous astronomical artifact of antiquity. This huge marble globe, supported by a statue of Atlas, is generally considered to be a Roman copy of an earlier Greek original. It shows constellation figures but not individual stars, although the stars may have been painted on the stone.

A unique hemispherical celestial map, which furnishes a remarkable connecting link between the classical representation of the constellations and the later Islāmic forms, is painted in the dome of a bath house at Quṣayr 'Amra, an Arab palace built in Jordan around AD 715. The surviving fragments of the fresco show parts of 37 constellations and about 400 stars.

Circumstantial evidence suggests that a flat representation of the sky, in the form of a planisphere using a stereographic projection, had come into use by the beginning of the present era. This provided the basis for the astrolabe, the earliest remaining examples of which date from the 9th century AD. The open metalwork of the top moving plate (called a spider or rete) of an astrolabe is essentially a star map, and these instruments together with associated manuscript lists provide the basic documentation for Arabic star names.

If astrolabes are excluded, the oldest existing portable star map from any civilization is the Chinese Tunhuang manuscript in the British Museum, dating from about AD 940 (see Figure 4). A Latin document of about the same age, also in the British Museum, shows a planisphere to illustrate the *Phainomena* of Aratus, without, however, indicating individual stars. The oldest illuminated Islāmic astronomical manuscript, an AD 1010 copy of al-Ṣūfī's book on the fixed stars, shows individual constellations, including stars (see Figure 5).

The earliest known western maps of the Northern and Southern Hemispheres with both stars and constellation figures date from 1440; preserved in Vienna, they may have been based on two now-lost charts from 1425 once owned by Regiomontanus. In 1515 Albrecht Dürer drew the first printed star maps, a pair of beautiful planispheres closely patterned on the Vienna manuscripts. Dürer and his collaborators numbered the stars on the charts according to the order in Ptolemy's list, a nomenclature that gained limited currency in the 16th century. The first book of printed star charts, Alessandro Piccolomini's *De le Stelle Fisse* (1540), introduced a lettering system for the stars; although frequently reprinted, application of its nomenclature did not spread.

New constellations: 16th–20th centuries. Star charts contained only the 48 constellations tabulated by Ptolemy until the end of the 16th century. Then Pieter Dircksz Keyser, a navigator who joined the first Dutch expedition to the East Indies in 1595, added twelve new constellations in the southern skies, named in part after exotic birds such as the toucan, peacock, and phoenix.

The southern constellations were introduced in 1601 on

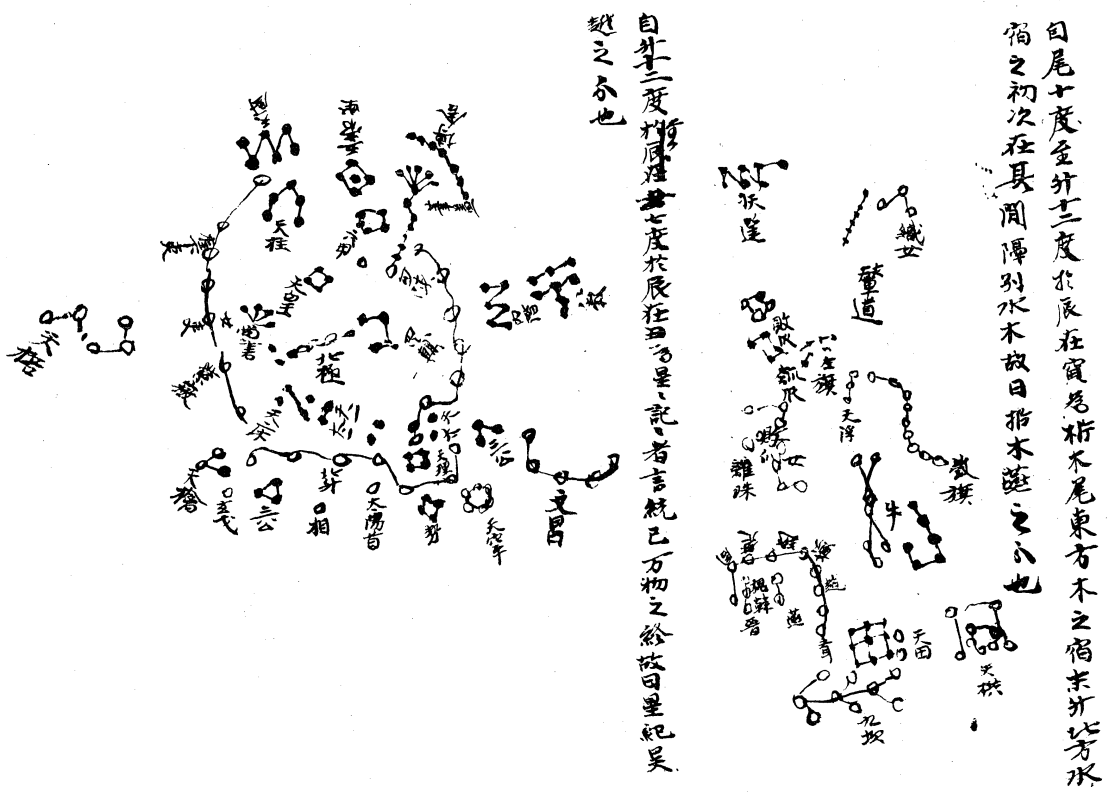

Figure 4: Chinese Tunhuang manuscript, the oldest existing portable star map, excluding astrolabes (*c.* AD 940). In the British Museum (MS. Stein 3326). Actual width of portion shown, about 12¾ inches (32 centimetres).

a celestial globe by J. Hondius and again in 1603 on the celestial globe of Willem Blaeu and on a single plate in the *Uranometria* of Johann Bayer. The *Uranometria*, a handsome work that must be considered the first serious star atlas, devotes a large plate to each of the 48 traditional figures. (The constellation Perseus is shown in Figure 5.) Its scientific integrity rests on Tycho Brahe's newly determined stellar positions and magnitudes.

In his *Uranographia* of 1687, the German astronomer Johannes Hevelius devised seven new constellations visible from midnorthern latitudes that are still accepted, including sextans (the sextant), named for one of his own elaborate astronomical instruments. Fourteen additional southern constellations were formed by Nicolas Louis de Lacaille after his visit to the Cape of Good Hope in 1750. They appeared in the *Memoires* of the Académie Royale des Sciences for 1752 (published in 1756). All other attempts to invent constellations have failed to win acceptance.

The classic atlases of Bayer and Hevelius as well as Flamsteed's *Atlas Coelestis* (1729) showed only the brighter naked-eye stars. J.E. Bode's *Uranographia* of 1801 was the first reasonably complete depiction of the stars visible to the unaided eye. It included an early use of constellation boundaries, a concept accepted and refined by 19th-century cartographers (see Figure 6). F.W.A. Argelander's *Uranometria Nova* (1843) and B.A. Gould's *Uranometria Argentina* (1877) served to standardize the list of constellations as they are known today. They divided Ptolemy's largest constellation, Argo Navis (the ship), into three parts: Vela (the sail), Puppis (the stern), and Carina (the keel).

The list of constellations

The definitive list of 88 constellations was established in 1930 under the authority of the International Astronomical Union. Its rectilinear constellation boundaries preserve the traditional arrangements of the naked-eye stars. The smallest of the constellations, Equuleus (the little horse) and Crux (the southern cross), nestle against those over ten times larger, Pegasus and Centaurus respectively. The standard boundaries define an unambiguous constellation for each star.

STAR NAMES AND DESIGNATIONS

Star names. Of approximately 5,000 stars visible to the unaided eye, only a few hundred have proper names, and less than 60 are commonly used by navigators or astronomers. A few names come almost directly from the Greek, such as Procyon, Canopus, and Antares—the latter derived from "anti-Ares" or "rival of Mars" because of its conspicuous red color. The stars Sirius ("scorcher") and Arcturus ("bear watcher") are mentioned both by Homer and Hesiod (8th century BC?). Aratus names those two as well as Procyon ("forerunner of the dog"), Stachys ("ear of corn"?, now Spica), and Protrugater ("herald of the vintage," now Latinized to Vindemiatrix). Protrugater, a relatively faint star in a dull region of the sky, is a rare example from antiquity of a star named for obvious calendarial reasons.

Arabic names

The *Al* that begins numerous star names betrays their Arabic origin, *al* being the Arabic definite article "the": Aldebaran ("the follower"), Algenib ("the side"), Alhague ("the serpent bearer"), Algol ("the demon"). A conspicuous exception is Albireo in Cygnus, possibly a corruption of the words *ab ireo* in the first Latin edition of the *Almagest* in 1515.

Most star names are in fact Arabic and are frequently derived from translations of the Greek descriptions. The stars of Orion illustrate the various derivations: Rigel, from *rijl al-Jawzah*, "leg of Orion," Mintaka, the "belt," and Saiph, the "sword," all follow the Ptolemaic figure; Betelgeuse, from *yad al-Jawzah*, is an alternative non-Ptolemaic description meaning "hand of Orion"; Bellatrix, meaning "female warrior," is either a free Latin translation of an independent Arabic title, *an-najid*, "the conqueror," or is a modification of an alternative name for Orion himself. Only a handful of names have recent origins—for example, Cor Caroli, the brightest star in Canes Venatici, named in 1725 by Edmond Halley.

Other designations. Bayer's *Uranometria* of 1603 introduced a system of Greek letters for designating the principal naked-eye stars. In this scheme, the Greek letter is followed by the genitive form of the constellation name, so that alpha (α) of Canes Venatici is Alpha Ca-

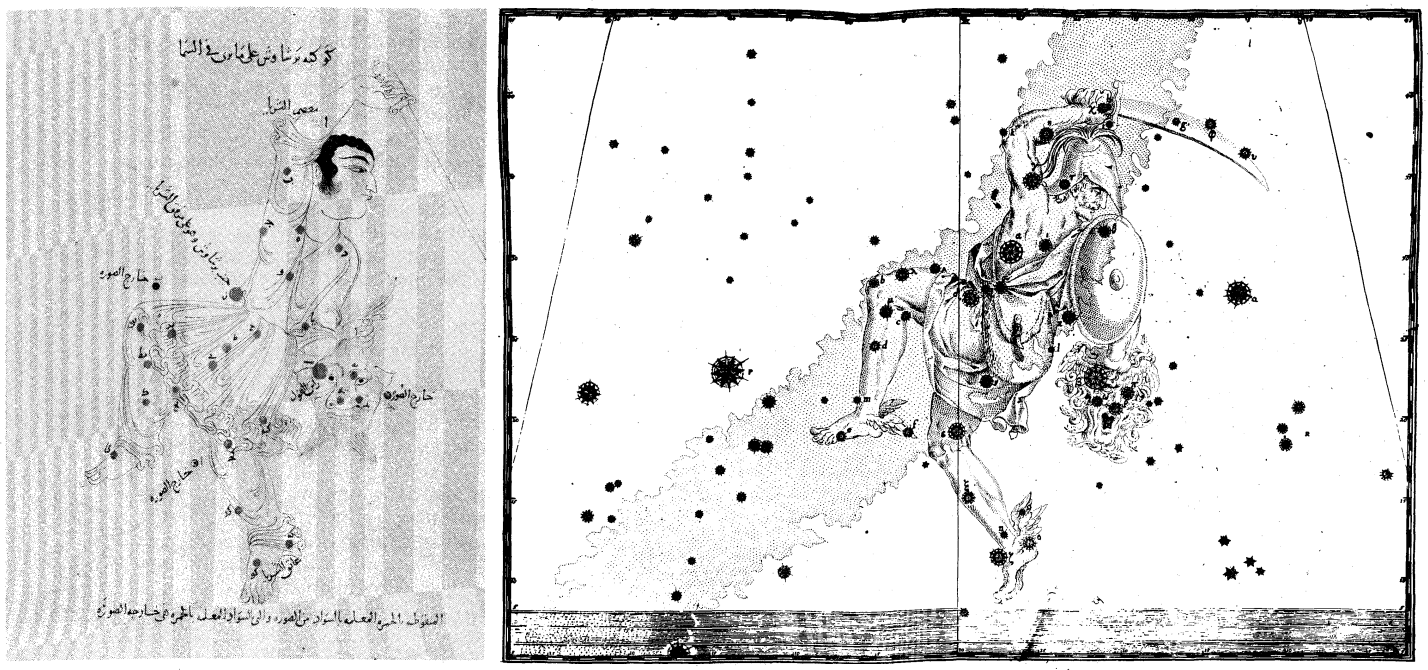

Figure 5: *The constellation of Perseus.*
(Left) From *Suwar al-Kawākil al-thābitah* ("Book of the Fixed Stars"), executed by 'Abd ar-Rahmān Ibn 'Umar as-Sūfī, AH 400 (AD 1009-10). In the Bodleian Library, Oxford (MS Marsh 144, p. 111). (Right) From Johann Bayer's *Uranometria*, 1603, a set of maps in which the use of Greek letter notation for bright stars was first introduced. The Milky Way appears as a dotted band through the figure, and the horizontal stripes at bottom indicate the ecliptic band.

num Venaticorum. Bayer's letters and their extension to newer constellations apply to about 1,300 stars. John Flamsteed, in his *Historia Coelestis* (1712), numbered the stars within each of 54 constellations consecutively according to right ascension, and the Flamsteed numbers are customarily used for the fainter naked-eye stars such as 61 Cygni.

Designations of faint and variable stars

An astronomer wishing to specify an even fainter star will usually take recourse to a more extensive or more specialized catalog. Such catalogs generally ignore constellations and list all stars by right ascension. Thus, astronomers learn to recognize that BD +38°3238 refers to a star in the *Bonner Durchmusterung* and that HD 172167 designates one in the *Henry Draper Catalogue* of spectral classifications; in this case, both numbers refer to the same bright star, Vega (Alpha Lyrae). Vega can also be specified as GC 25466, from Benjamin Boss' *General Catalogue of 33,342 Stars* (1937), or as ADS 11510, from Robert Grant Aitken's *New General Catalogue of Double Stars* (1932). These are the most widely used numbering systems. For more obscure names, such as Ross 614 or Lalande 21185, most astronomers would have to consult a bibliographical aid to discover the original listing.

Variable stars have their own nomenclature, which takes precedence over designations from more specialized catalogs. Variable stars are named in order of discovery within each constellation by the letter R to Z (providing they do not already have a Greek letter). After Z the double form RR to RZ, SS to SZ, . . . is used; after ZZ come the letters AA to AZ, BB to BZ, and so on, the letter J being omitted. After the letters QX, QY and QZ, the names V335, V336, etc., are assigned. Hence the first lettered variable in Cygnus is R Cygni, and the most recently named one is V1252 Cygni. The names were assigned by the Soviet authors of the *General Catalogue of Variable Stars* (3rd edition, 1969), with the approval of the Commission on Variable Stars of the International Astronomical Union.

Two catalogs are frequently used for designating clusters, nebulae, or galaxies. The shorter list of these, which includes about 100 of the brighter objects, was compiled in three installments by a French astronomer, Charles Messier, in the latter part of the 18th century; M1 and M31 are examples of this system, being respectively the Crab Nebula and the great galaxy in Andromeda. A much more extensive tabulation in order of right ascension is the *New General Catalogue* (NGC; 1890), followed by the *Index Catalogue* (IC; 1895, 1908); examples are NGC 7009 or IC 1613.

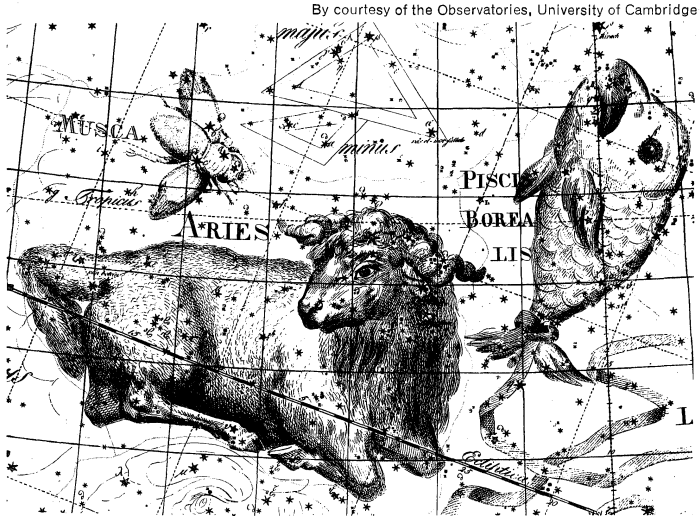

Figure 6: The constellation Aries (the Ram) and others, from J.E. Bode's *Uranographia*, 1801. The constellation Musca (the Fly) shown here is obsolete; the modern constellation Musca is in the southern skies.

MODERN STAR MAPS AND CATALOGS

Near the end of the 16th century, Tycho Brahe, a Danish nobleman, resolved to provide an observational basis for the renovation of astronomy. With his large and sturdy (but pretelescopic) quadrants and sextants, he carefully measured the positions of 777 stars, to which he later added enough hastily observed stars to bring the catalog up to exactly 1,000. A comparable catalog of southern stars was not available until 1678, when the young Edmond Halley published positions of 350 stars measured during a British expedition to St. Helena.

The first Astronomer Royal, John Flamsteed, pioneered the use of telescopic sights for measuring stars' positions. His *Historia Coelestis Britannica*, published posthumously in 1725, listed 3,000 stars, greatly exceeding all former catalogs in number and accuracy. These observations provided the basis for his great *Atlas Coelestis* (1729). The measurements of the third Astronomer Royal, James Bradley, achieved a precision within a few seconds of arc; as reduced by the German astronomer F.W. Bessel in 1818, his positions are the oldest still considered useful in modern astronomy.

Survey and zone maps and catalogs. The German word *Durchmusterung*, literally a "scanning through," was introduced by F.W.A. Argelander, an astronomer who undertook to list all the stars visible in the three-inch Bonn refractor. Keeping the telescope fixed, he recorded the stars, zone by zone, as the Earth's rotation carried the stars past the field of view. The resulting *Bonner Durchmusterung* (1859–62), or *BD* catalog, contains 324,189 stars to about the 9th magnitude between declinations +90° and −2°. The accompanying charts, published in 1863, far surpassed all former maps in completeness and reliability. In spite of the lapse of more than a century, these maps are of continual great value today. The Bonn survey was extended to −23° in 1886, and at Córdoba, Argentina, it was carried to the parallel of −62° by 1908, and to the south pole by 1930; because observing conditions changed over the many years required, the resulting *Córdoba Durchmusterung*, or *CD*, lacks the homogeneity of its northern counterpart.

The *Bonner Durchmusterung*

In 1867 Argelander proposed to the German Astronomical Society (Astronomische Gesellschaft) a massive project to document stellar positions with far greater precision. Although the observing of selected star positions with meridian circle telescopes had become well established by observers in the 18th and early 19th centuries, the new plan called for meridian observations of all stars down to the ninth magnitude. A score of observatories on four continents, each responsible for a specific zone of declination, cooperated to complete the catalog and its southern supplements. The northern sections, known as the *AGK1*, were published by zones; not until 1912 was it complete to −18°.

Meanwhile, in quite another way, the Dutch astronomer J.C. Kapteyn completed an inventory of the southern sky by the measurement of the positions and magnitudes of about 454,000 stars from a set of photographic plates, taken in Cape Town. Known as the *Cape Photographic Durchmusterung* (1896–1900), or *CPD*, the result covers the sky from declination −19° to the South Pole, down to the 11th magnitude.

Beginning in 1924, the Astronomische Gesellschaft catalog was repeated photographically by the Bonn and Hamburg-Bergedorf observatories; published in 1951–58, the new catalog is called the *AGK2*. Neither the *AGK1* nor the *AGK2* provided information on proper motions—that is, the small but perceptible individual movements of the stars in the plane of the sky. Therefore, another set of photographic plates were obtained in Hamburg during the 1950s in order to obtain the motions; the resulting *AGK3* was distributed on magnetic tape in 1969.

In 1966 the Smithsonian Astrophysical Observatory in Cambridge, Massachusetts, issued a reference star catalog to be used as an aid in finding artificial-satellite positions from photographs. Although the *SAO Star Catalog* of 258,997 stars contains no new basic data, it does present the information in a particularly useful form. An accompanying computer-plotted atlas (1968), which includes over 260,000 stars plus galaxies and nebulae, achieves an unprecedented accuracy for celestial cartography.

Fundamental catalogs. The measurements of accurate places for vast numbers of stars rests on painstakingly and independently determined positions of a few selected stars. A list of positions and proper motions for such selected stars well distributed over the sky is called a fundamental catalog, and its coordinate system is a close approximation to a fixed frame of reference. When the German astronomers began the *AGK2* in the 1920's, they first required a fundamental reference system that by the following decade was defined in the *Dritter Fundamental-Katalog des Berliner Astronomischen Jahrbuchs*, or *FK3*. The *Fourth Fundamental Catalogue* (1963), or *FK4*, published by the Astronomisches Rechen-Institut in Heidelberg, contains data for 1,535 stars and has now superseded the *FK3*.

Photometric catalogs. A complete mapping of the sky includes magnitudes (and colours) as well as positions and motions. The great survey catalogs included magnitude estimates, but since photometric procedures are quite different from astrometric ones, a separate family of photometric catalogs has developed. Visual observations provided the basis for major tabulations published at Oxford, Harvard, and Potsdam around the turn of the century, but these were soon superseded by photographic work. Studies of galactic structure, which required accurate magnitudes for at least some very faint stars as well as the bright ones, led to the establishment of the plan of 206 selected areas. These were well-defined areas of sky containing stars of many representative kinds that could be used as standards of comparison, and the *Mount Wilson Catalogue of Photographic Magnitudes in Selected Areas* (1930), which was made about 20 years later, was for many years a leading reference for celestial photometry. Today, several catalogs of photoelectric measurements in three or more colours set the standards for precision magnitudes.

The *Mount Wilson Catalogue*

Another important physical quantity that can be measured is a star's spectral type (that is, a class assigned according to the details seen in the star's spectrum; it turns out to be an indicator of both temperature and size of the star). One of the greatest collections of astronomical data is the *Henry Draper Catalogue* (1918–24), formed at Harvard by Miss A.J. Cannon and E.C. Pickering. The *HD* lists spectra of 225,300 stars distributed over the entire sky, and the *Henry Draper Extension* (1925–36, 1949) records 133,782 additional spectra.

Photographic star atlases. Astronomical photography was scarcely past its infancy when an international conference in Paris in 1887 all too hastily resolved to construct a photographic atlas of the entire sky down to the 14th magnitude, the so-called *Carte du Ciel*, and an associated *Astrographic Catalogue*, with measured star places down to the 12th magnitude. The original stimulus had come in 1882 with the successful construction of a 13-inch astrographic objective lens at Paris. For decades the immense *Carte du Ciel* enterprise sapped the energies of observatories around the world, especially in France, and even now is incomplete in the form originally planned. Within a few years of its inception, E.C. Pickering at Harvard showed that highly corrected and efficient multiple-component lenses could considerably reduce the effort involved in mapping the sky photographically. Nowadays such a program could be speedily completed with the aid of the automatic measuring machines.

The first photographic atlas of the entire sky (if a set of 55 glass plates offered by Harvard in 1903 be excepted) was initiated by an energetic British amateur. Issued in 1914, the (John) *Franklin-Adams Charts* comprise 206 prints with a limiting magnitude of 15.

The monumental *National Geographic Society-Palomar Observatory Sky Survey*, released in 1954–58, reaches a limiting photographic magnitude of 21, far fainter than any other atlas. (The southernmost band has a slightly brighter limiting magnitude of 20.) Each field was photographed twice with a 48-inch Schmidt telescope at Mount Palomar to produce an atlas consisting of 935 pairs of prints made from the original blue sensitive and red-sensitive plates, each about 6° square. The atlas proper extends to a declination of −33°, but 100 additional prints from red-sensitive plates now carry the coverage to −45° (see Figure 7).

Atlases for stargazing. Three modern atlases have gained special popularity among amateur as well as professional observers. *Norton's Star Atlas*, perfected through numerous editions, plots all naked-eye stars on 8 convenient charts measuring 10 × 17 inches and in-

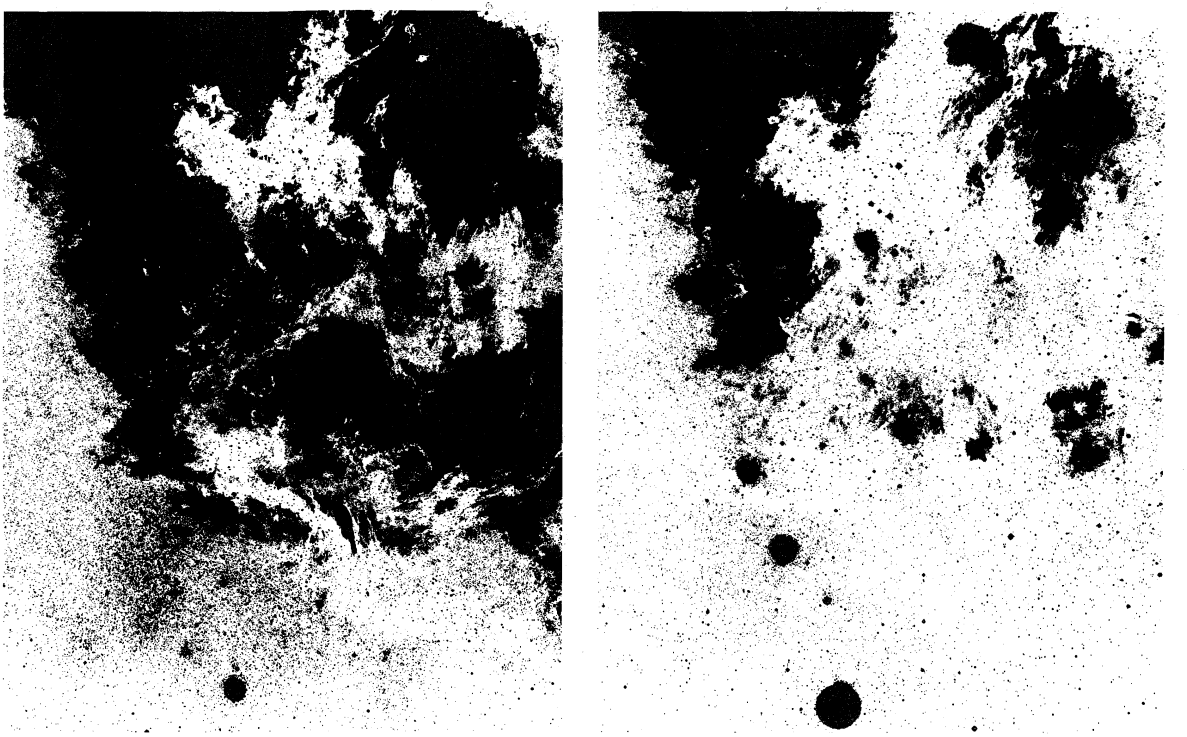

Figure 7: Negative plates showing part of the North America Nebula in (left) red light and (right) blue light. Note the much greater extent of the nebulosity in the dark areas (left).

cludes an excellent lunar map. The *Atlas Coeli 1950.0* (4th ed., 1962), commonly called the *Skalnate Pleso Atlas of the Heavens 1950.0*, shows stars to magnitude 7.75, nebulae, clusters, galaxies, and radio sources. Its 16 charts, measuring 16 by 22 inches, are famed for their cartographic clarity. An associated reference catalog gives additional information on the celestial objects plotted in the atlas. The German astronomer Hans Vehrenberg's *Photographischer Stern-Atlas* (1962–64), covering the entire sky in 464 sheets, each 12° square, has probably reached wider use than any other photographic atlas because of its quality and comparatively modest cost.

CATALOGS AND MAPS OF THE GALAXIES

Photograhic studies. The *Reference Catalogue of Bright Galaxies* (1964) gives positions, classifications, magnitudes, and other data for 2,599 galaxies brighter than about magnitude 13; it replaces the list of 1,249 galaxies tabulated in 1932 in the Shapley–Ames survey at Harvard. The *Catalogue of Galaxies and of Clusters of Galaxies* (1961–68) by the California astronomer Fritz Zwicky and his collaborators records 31,350 galaxies and 9,700 clusters found on the Palomar Sky Survey and is intended to be complete to photographic magnitude 15.5; the *Morphological Catalogue of Galaxies* (1962–68) by a group of Soviet astronomers contains data for about 29,000 galaxies on the basis of the Palomar Sky Survey, as well as data for about 5,000 additional fainter galaxies. *The Hubble Atlas of Galaxies* (1961) illustrates 176 galaxies in 50 plates and serves as a guide to a revised version of Hubble's classification scheme. The *Atlas of Peculiar Galaxies* (1966) shows 338 objects mainly on photographs taken with the 200-inch telescope on Palomar.

The sky in nonvisual wavelengths. Space-age explorations of the heavens in radio, infrared, ultraviolet, and X-ray radiations open the possibility of mapping the sky as it is seen in other wavelengths. Such maps are at best rudimentary, although the basic data are becoming increasingly available. Of particular note are the Cambridge catalogs for discrete radio sources; the successive surveys have been designated 1C, 2C, 3C, 4C, and 5C. A catalog of 2,270 radio sources at Sydney (1958–61) has been repeated at shorter wavelengths and extended at Parkes, Australia (1965–66). In radio wavelengths it is also possible to map the general level of radiation, which increases toward the Milky Way and especially toward the galactic centre. Maps of this sort have enabled astronomers to define much more precisely the system of galactic coordinates.

LUNAR MAPS

Early maps. The study of lunar topography became possible with the beginning of telescope astronomy in 1609. Galileo's *Sidereus Nuncius* (1610) contained five drawings of the Moon, all so rough that the features can be only approximately identified today. At about the same time the pioneering English scientist Thomas Harriot and his pupils examined the Moon with a telescope; but these observations were not described in print until 1788, and his map of the Moon remained unpublished until 1965.

The first lunar map to give names to features was prepared by Michel Florent van Langren, and appeared as a small broadsheet at Brussels in 1645. His map for the first time assigned proper names to 322 markings, mostly craters, but virtually none of his nomenclature has survived. The *Selenographia* (1647) of Johannes Hevelius, containing three maps and 40 drawings of the Moon, became a fundamental work in this field; nevertheless, of all the names he proposed only a few of those for lunar mountains remain in current use.

Continuing use of Riccioli's names

Much of today's basic nomenclature for the visible face of the Moon derives from a map in the *Almagestum Novum* (1651) of the Italian lunar observer G.B. Riccioli, though the actual work was done primarily by Riccioli's collaborator, F.M. Grimaldi. In this scheme, craters along the central line were named after famous philosophers and astronomers in historical order, with Plato, Archimedes, and Eratosthenes in the north and a chain leading from Ptolemy to Tycho in the south. The Jesuit authors relegated Copernicus, Kepler, and Galileo to the western quadrant, outside the mainstream of astronomy. Riccioli and Grimaldi commemorated themselves by large lunar craters even farther to the west, near the edge of the visible surface.

The finest achievement in 17th-century lunar cartography was a great, and now very rare, lunar map by the director of the Paris Observatory, Giovanni Domenico

Cassini; 53 centimetres across, this superbly engraved work prepared between 1671 and 1679 shows each feature in relief as if illuminated from the same angle. Considering that Cassini obtained his observations with a small but very long and clumsy refractor, his accomplishment is indeed noteworthy.

A new stage in selenography was inaugurated in mid-18th century when improved telescopes equipped for micrometer measurements came into use. The German astronomer Johann Tobias Mayer pioneered the new technique at Göttingen, but except for the coordinates of 23 reference points, his measurements remained unpublished for more than a century. In 1822, W.G. Lohrmann, a professional surveyor, began measuring the positions of several score craters; though completed in 1836, his topographic map was not fully published until 1878. Meanwhile, in 1836 a Berlin banker, Wilhelm Beer, and the astronomer J.H. Mädler published the *Mappa Selenographia*, as observed with a 4-inch refractor and based on 105 fundamental points related with those of Lohrmann. This landmark of lunar cartography, nearly a metre in diameter, remained unsurpassed in its wealth of information for several decades, until the appearance in 1878 of the vast lunar atlas compiled in Athens by the then director of the Athens Observatory, J.F. Julius Schmidt. Schmidt's map, divided into 25 sections, records the positions of 32,856 features.

Photographic maps. Rapid advances in photography were beginning to reduce visual selenography to secondary importance by the end of the 19th century. By 1909 three major photographic lunar atlases had appeared. The *Lick Observatory Atlas of the Moon* (1896–97) reproduced photographs taken with their 36-inch telescope, then the largest refractor in the world. The *Photographischer Mond-Atlas* (1899), prepared by Ladislaus Weinek of Prague, was based on 200 plates taken at Lick and at Paris. The *Atlas Photographique de la Lune* (1896–1909) by M. Loewy and P. Puiseux, containing enlargements of 80 plates made at the Paris Observatory, became the standard work for five decades.

The *Photographic Lunar Atlas* (1960), edited by G.P. Kuiper and his collaborators, includes 281 enlargements of plates obtained at the Lick, Mt. Wilson, Yerkes, McDonald and Pic du Midi observatories. Forty-four lunar regions are shown under four or five different angles of solar illumination. In an associated Rectified Lunar Atlas (1963), pictures of the Moon were projected onto a sphere and rephotographed in order to diminish the foreshortening caused by the curvature of the Moon's surface. The *Consolidated Lunar Atlas* (1967) consists of a better selection of photographs published in the form of positive prints. Although these will probably remain the ultimate photographic atlases resting on Earth-based observation, they have already been superseded by results from space missions. Even the far side of the Moon, unknown until the Soviet Luna-3 in 1959 and the Zond-3 in 1965, has now been recorded in more detail than the front side was in the *Photographic Lunar Atlas*.

Modern maps. A major lunar mapping project, far larger and more detailed than any previous effort, was initiated in 1960 by the Aeronautical Chart and Information Center (ACIC) of the United States Air Force. Their principal cartographic series, the 1:1,000,000 lunar charts, are based on more than 90,000 photographs secured at the Pic du Midi Observatory and supplemented by visual observations with the 24-inch refractor of the Lowell Observatory in Flagstaff, Arizona. Unlike previous lunar charts, these have been rectified to remove the perspective effects of the Moon's curvature. This ACIC series has become conveniently available in *The Times Atlas of the Moon* (London, 1969).

Mosaics of photographs from the Lunar Orbiter program provide the basis for ACIC charts of a still larger scale, 1:100,000, for possible landing sites (see MOON).

BIBLIOGRAPHY. R.H. ALLEN, *Star Names and Their Meanings* (1899; reprinted as *Star Names: Their Lore and Meaning*, 1963), a classic compendium; for a more trustworthy treatment of Arabic names, see PAUL KUNITZSCH, *Arabische Sternnamen in Europa* (1959). See also E.J. WEBB, *The Names of the Stars* (1952). JOSEPH NEEDHAM, *Science and Civilisation in China*, vol. 3, *Mathematics and the Sciences of the Heavens and the Earth* (1959); and K. LUNDMARK, "Luminosities, Colours, Diameters, Densities, Masses of the Stars," in *Handbuch der Astrophysik*, vol. 5, ch. 4 (1932–33), are both far more germane to astronomical maps than their titles imply. Current information may be found in H. EICHHORN, "Star Catalogues," in I.I. MUELLER, *Spherical and Practical Astronomy*, ch. 6 (1969); and ZDENEK KOPAL, *The Moon*, esp. ch. 15 (1969).

(O.G.)

Astronomical Spectroscopy, Principles of

Almost the only means of learning about celestial objects is through the analysis of electromagnetic radiation emitted by or reflected from them. Spectroscopy—*i.e.*, the analysis of such radiation into individual frequencies—can give a remarkable amount of information. Individual atoms and molecules absorb or emit light at characteristic frequencies, and can, therefore, be selectively observed.

The spectrum of a star is a series of overlapping images in its constituent colours, arranged in order of frequency (or wavelength). An example is the display of colours produced by sunlight when it is refracted and dispersed by a prism. Since the spectrum covers a much larger area than a single image it is much fainter than if the star would appear in integrated light.

Information on the physical state of an object can be obtained through the spectrographic comparison of different frequencies of its radiation (emission) or lack of it (absorption). Line-of-sight velocities of stars, planets, regions of the Sun, and so on, can be obtained from the Doppler-frequency shift (*i.e.*, an alteration in the frequency of the radiation from a moving source in proportion to the change in line-of-sight velocity). The spectral region that has been studied most is that of visible light with small extensions into the infrared and ultraviolet: the range of frequencies is about two to one. A much wider range of frequencies may be included, from microwave radio to X-rays, a ratio of 200,000,000 to 1. Although frequency is the more fundamental property of a wave, it is conventional to speak of wavelength, which is easier to visualize and which is related to frequency in that the frequency times the wavelength equals the speed of light. The spectroscopist is concerned with wavelengths from 20 centimetres to ten angstroms (100,000,000 Å = one centimetre). The wavelength limits of visible light are roughly 4,000 Å (blue) and 7,000 Å (red).

THE NATURE OF ASTRONOMICAL SPECTRA

Spectral lines and the continuum. The methods of spectrum analysis vary according to the wavelength region being studied. A familiar example of a spectroscope is a radio receiver, which can be adjusted to any wavelength between 550 and 1,870 metres, or to 30 metres for a shortwave set. Each broadcast station may be said to produce a "line" in the spectrum; the use of the word

Spectral image of star group Hyades, viewed through a prism placed before the telescope lens, revealing their temperature and basic composition.
By courtesy of the Department of Astronomy, University of Michigan

"line" arises from the appearance of a single visible frequency when the light is passed through a narrow slit; in a spectroscope, the series of coloured images of the slit are focussed in orderly array. The best known natural line that is produced in interstellar space by hydrogen atoms is in the radio region at 21 centimetres. Radio spectroscopists usually work at a single wavelength region. They must use not only a very sensitive receiver as their spectroscope but also a large antenna or radio telescope, which like other telescopes, selects a small area of the sky and collects from it as much energy as possible. Optical spectroscopy is done with the aid of prisms or, more commonly now, diffraction gratings, which disperse light into its component wavelengths. With suitable optical arrangements, the spectrum can be recorded on a photographic plate or measured by a photoelectric detector.

Continuous radiation: the so-called continuum

A common spectral feature is the so-called continuum, in which energy is radiated over a broad band of wavelengths, or colours. A familiar example of continuous radiation is the radiation from the glowing filament in a light bulb, or from hot coals in a fire. Because of the lack of discrete features comparable to the spectral lines, continua tend to contain less information than line spectra, but they are still important. In particular, the change of colour from red through white to blue indicates increasing temperature for a solid body and for most stars. Most astronomical continua contain absorption lines, which are closely related to the emission lines mentioned above. Whether a line from a given element will appear as an absorption or an emission line depends on physical conditions in the vicinity of the source and in the background.

Molecular lines and bands. Dust, gas, and solid bodies near a star will reflect or scatter its light, imposing in the process additional spectral features. The spectra of the planets are quite similar to the solar spectrum because they shine by reflected light from the Sun. Most contain additional absorption lines and molecular bands, however, because of gases in the planetary atmospheres. If solid surfaces can be seen, they modify the reflected continuous spectrum, the colour of which is changed by absorptions in the rock or other material. The Earth's own atmosphere adds its absorption to all astronomical spectra viewed from below it. No X-rays or ultraviolet light beyond 3,000 Å can reach the surface; oxygen and ozone absorb everything at the longer wavelengths between 1,000 Å and 3,000 Å, all gases absorb them below 1,000 Å. Discrete bands (groups of closely spaced lines) of molecular oxygen, O_2, are found at red and near-infrared wavelengths, particularly near 7,600 and 12,700 Å. Starting in the yellow wavelengths and becoming stronger and stronger in the infrared, water vapour produces many complicated bands and is opaque over large regions. Other important infrared absorbers are carbon dioxide and ozone; absorptions by extremely small (trace)

amounts of other gases can also be observed. Out to 14 microns (140,000 Å), only about half the spectrum can be observed through the Earth's atmosphere; from 14 to 1,000 microns the atmosphere absorbs everything and the opacity is complete. Because much of the infrared absorption is due to water vapour, a very large improvement can be obtained by observing from a jet aircraft; a balloon, though it can go higher, is little better because it generally floats in a cloud of its own vapour. For the ultraviolet and X-ray regions a rocket or satellite is necessary, and even for the infrared these vehicles give a clearer view.

Formation of spectra. The spectrum of a star is influenced by a number of competing effects, which may be seen most clearly in simple situations. It is useful to consider what happens to light from a strong source with a continuous spectrum as it passes through a cool gas: the case approximated by sunlight passing through the Earth's atmosphere, or by the light from a distant star passing through the interstellar medium. Radiation at certain frequencies (written as f) is absorbed by molecules in the atmosphere as they make a transition from their normal "ground state," or state of lowest energy, to some "excited state" at a higher energy (E) according to the relation $E = hf$ (in which h is a fundamental physical constant called Planck's constant). Dark lines (gaps) in the spectrum correspond to the absorbed frequencies. The excited state may be one of increased rotation or vibration of the atoms within the molecules, and the absorbed wavelengths are then in the infrared spectral region. A change in electronic motion influences frequencies in and near the visible region. Removal of an electron (ionization) or separation of the component atoms (dissociation) of a molecule requires still more energy, and results in the strong continuous absorptions of the ultraviolet spectral region. The frequencies absorbed by a given atom or molecule are unique to it, and give an absolute identification. Analysis of the closely spaced lines in a molecular band gives an excellent measurement of the temperature of a gas; this method can be applied to the atmospheres of several of the planets and the coolest stars. The width of individual lines depends mainly on the gas pressure or on the temperature if the pressure is very low.

The second simple case of influences on spectra is that of a low-pressure gas in which some of the atoms or molecules are continually receiving energy; that is, being excited by the impact of fast electrons, as in a neon sign. Relaxation of the excited particles to lower energy states, and eventually to the ground state (lowest of all), is accompanied by the emission of radiation at characteristic frequencies. Transitions that end at the ground state give bright lines at the wavelengths that are absorbed under other conditions. Perhaps the purest natural example of such radiance at discrete wavelengths (bright lines) is the aurora borealis, the northern lights produced in the upper atmosphere by fast electrons associated with the interaction of the solar wind and the Earth's magnetic field. The spectra of many gaseous nebulae in the Galaxy beyond the solar system show similar effects.

The concept of optical depth in gases. In the above examples it has been implicitly assumed that the gas is "optically thin"; *i.e.*, it is at least somewhat transparent even at the wavelengths it absorbs most strongly. The opposite extreme is a gas that is "optically thick" at all wavelengths, or at least over a wide range; a prominent example is a stellar atmosphere such as that of the Sun (though it is not equally opaque at all wavelengths). In describing depths within any gas such as an atmosphere of a star or planet, it is convenient to speak in terms of unit optical depth—the depth from which radiation has a probability of about 37 percent of escaping freely. (This percentage is used because it is numerically equal to 1/e, e being the symbol for the number 2.71818 . . ., the base of natural logarithms; with this definition, calculations are greatly simplified.) As a practical example, unit optical depth (or distance) in a fog—the point at which about one-third of the details can be seen—is quite close; on a clearer day it could be almost at the horizon.

Unit optical depth

The corresponding level in the medium depends strongly on wavelength, especially near an absorption line. It is deepest for wavelengths between lines, but even here the gas is remarkably tenuous. For the Sun, unit optical depth in the continuum occurs at pressure and density one-tenth and a few ten-thousandths respectively of the values at the Earth's surface. It was long a mystery how such a thin gas, consisting mostly of atomic hydrogen and helium, could be so opaque, even at a temperature greater than 6,000° K (about 10,300° F). The identity of the most important absorber was recognized only in 1938: it is the negative hydrogen ion, a rather loosely bound combination of a hydrogen atom with an extra electron, which can be dissociated (with corresponding absorption of energy) by any photon (the smallest radiation unit, sometimes called a "quantum" of light) of wavelength shorter than 16,500 Å.

Stellar spectra. Even when the opacity is known at each wavelength, it is a complicated problem to predict the spectrum of a star. A feeling for the processes at work may be obtained by regarding the radiation at each wavelength as arising from the level of the corresponding unit optical depth. The continuum is produced at the lowest visible level, and the centre of a strong line at a higher level. If the lines are to appear dark, this higher level must be cooler, and indeed the temperature is expected to decrease outward from any star. For the Sun, the temperature at heights somewhat above unit optical depth begins to climb again in the chromosphere, the extremely tenuous layers of the outer solar atmosphere; any lines formed there should therefore appear bright instead of dark, as is indeed observed, particularly in the far ultraviolet. A similar explanation applies to the bright lines at visible wavelengths for certain stars.

The "shape" of the continuum is a graph or plot of the amount of its intensity at different wavelengths (or spectrum). Over a considerable wavelength range, this resembles the spectrum of a "black body" (the physicist's name for a perfect radiator), which has a definite shape for each appropriate temperature. In general, the apparent temperature deduced from one region may differ from that measured from another. The reason for this is that the continuous absorption coefficient; that is, the ratio of absorption to emission at a given temperature is changing. The radiation, consequently, comes from different depths and, therefore, from different temperature regions. Temperature found by measuring the shape of the continuum (apparent temperature) is only approximately equal to the actual temperature at the "surface" (unit optical depth).

Planetary spectra. For planets and satellites, problems arise from the presence and amount of atmosphere. Such bodies can have a spectrum that combines contributions from two, almost independent, sources—reflected solar radiation and their own thermal emission at much longer wavelengths. The thermal component is similar to black-body radiation for airless bodies such as Mercury and the Moon; the reflected light, however, does show coloration and some broad absorptions because of surface constituents. For planets with appreciable atmosphere, the physics of the thermal emission resembles that for a star, discussed above. For Mars, the reflected solar radiation can be regarded as coming entirely from the surface, modified by two passages through the thin atmosphere. This approximation breaks down in the ultraviolet and is similarly poor for the Earth, especially in hazy or cloudy regions. Deep, cloudy atmospheres are present on Venus, Jupiter, Saturn, Uranus, and Neptune; the returned solar radiation must be regarded as having been scattered by the same medium that does the absorbing. Again the situation resembles that of a stellar atmosphere, except that the radiation is imposed from outside instead of flowing up from the interior.

Two sources of details in planetary spectra

THE DEVELOPMENT OF ASTRONOMICAL SPECTROSCOPY

Early work on the solar spectrum. In 1666, the English physicist Isaac Newton discovered how to produce a spectrum of the Sun, by means of a glass prism and a

hole in a window blind. Much later, 1800–02, several important discoveries were made with similar equipment. The English astronomer William Herschel probed the solar spectrum with a thermometer and found the measurable heat produced to continue beyond the red end of the spectrum; he had discovered the infrared. In 1802, the ultraviolet was observed by its ability to darken silver chloride. And at this time, an English scientist noted a few dark lines in the solar spectrum, which was studied in much more detail by the German physicist Joseph von Fraunhofer in 1814. Fraunhofer was able to map 754 lines in the solar spectrum, the most prominent of which are still called "Fraunhofer lines." He also observed several bright stars and found that their lines differed from those of the Sun. Fraunhofer made the first crude diffraction grating (an instrument that uses different deviations at different wavelengths to separate light of different colours) by stretching wires between the threads of two screws; with it he was able to measure actual wavelengths in centimetres.

The work of Fraunhofer

Interpretation of the Fraunhofer lines awaited further developments in physics, which in turn depended on further laboratory work. Similar delays in understanding of discoveries recurred until well into the 20th century; only since then has immediate physical interpretation been available for the majority of astronomical discoveries. Earlier, however, astronomers often found many uses for empirical classifications (particularly of stellar spectra) long before a detailed understanding was reached.

Another point to be noted is the importance of advances in technology, as illustrated by Fraunhofer's work and that of his successors; in his day, it was difficult to obtain glass in large, homogeneous pieces. Telescope lenses were small, and reflecting telescopes did not become practical until methods were developed, initially in 1856, for the deposition of a reflecting film of silver on the front surface of a glass mirror. Without large reflecting telescopes, spectroscopy would still be limited to the study of the Sun and a few bright stars.

In 1859, the German physicist Gustav Robert Kirchhoff formulated his laws connecting the absorption and emission of light and explained that the Fraunhofer lines were due to absorption by familiar elements present on the Sun. He pointed out that a perfect absorber (described by physicists as a black body) should also be an ideal emitter of light, and suggested its realization in the form of a small hole leading into a large cavity. Two years later, the Swedish physicist Anders Jonas Ångström found the lines of hydrogen on the Sun and initiated a program of wavelength measurements in the unit that now bears his name.

In 1868, the relatively faint solar prominences at the edge of the Sun's disk, the limb, were observed in full daylight. Subsequently, in Sweden the rotation of the Sun was determined from the Doppler effect at its limbs and found to be different in different latitudes of the Sun. A United States physicist, Henry A. Rowland, devised methods of ruling diffraction gratings of very high quality; some Rowland gratings are still in use. In the years 1887–96 he produced a solar spectrum of very high resolution and a catalog of wavelengths and intensities. The spectroheliograph, which enabled observation of the whole Sun or large areas of it simultaneously at a particular wavelength, was invented independently in the United States and France. In 1908 the large magnetic fields in sunspots were discovered from observation of the Zeeman effect; that is, the shift in the positions, shapes, and structure of the sunspots' spectral lines that results from the interaction of the atoms with the magnetic field. In recent years the solar magnetograph has been used to extend this work to the production of detailed maps of the solar magnetic field.

Early work on the spectra of stars and nebulae. In 1855, an English astronomer, William Huggins, began the study of the spectra of the Sun, stars, nebulae, comets, and planets. He reaped a harvest of astronomical discoveries, mainly by visual observation of spectra, though he succeeded in applying photography in 1875. He found many different types of stellar spectra. He showed from the nature of its emission spectrum that the Orion Nebula is gaseous, but found the Andromeda Nebula (now known to be a galaxy) to have a stellar-type spectrum and therefore concluded that it was composed of stars. He measured some of the first stellar Doppler shifts and obtained the corresponding line-of-sight, or radial, velocities.

Line-of-sight velocities. The German astronomer Hermann Karl Vogel was the first to introduce the photographic method into spectroscopy, in 1873, and succeeded in determining accurate radial velocities of many stars by measuring the positions of the lines on the photographic spectra. Vogel's work, especially his measurements of radial velocities, stimulated astronomers elsewhere near the turn of the century to undertake systematic studies in this field. At Victoria, British Columbia, for example, many spectroscopic double stars were discovered and many of their orbits have since been determined from measurements of the spectral lines. At Mount Wilson Observatory (now part of Hale Observatories), California, the velocities of hundreds of faint stars were determined with an increase of precision; in the case of the bright star Arcturus, the velocity was measured to about ± 0.01 kilometre per second or 0.006 miles per second. Soviet scientists working at Pulkovo, near Leningrad, and, more recently, at Simeiz, in the Crimea, also made contributions in this field. Numerous measures of stellar motions in the southern sky have been published.

The first measurements from photographs

Chemical composition. A striking result of astronomical spectroscopy is the discovery of the uniformity of chemical composition throughout the universe. Belief in the universal occurrence of the same chemical elements was greatly strengthened when the lines of helium, originally found in the spectrum of the chromosphere of the Sun in 1868, were first produced in terrestrial laboratories about 25 years later. In 1941 the last great enigma of line identification was solved when previously unidentified lines of the solar corona were found to originate in the atoms of the common elements iron, calcium, nickel, and argon excited to a degree of ionization not even dreamed of previously. Earlier, when the so-called nebulium lines in certain nebulae were disposed of in a similar manner, it was remarked that the mysterious substances of the astrophysicists one after another disappeared into "thin air"; the nebulae had, in fact, been found to consist of oxygen, nitrogen, hydrogen, and a few other gases—not very different in composition from air.

The principle of the uniformity of chemical elements has now been extended to include even the distant galaxies, whose light travels for hundreds of millions of years at the rate of 186,000 miles per second before it reaches the eye of the observer. This uniformity means that the atomic building blocks of the universe are the same throughout space. It does not mean that the proportions of these elements are the same in all astronomical objects. Certain stars differ strikingly from others in their composition, and among the most interesting spectroscopic problems of today is the measurement of these differences in the abundance of the elements. Such measurements permit the nuclear processes responsible for the formation of the elements to be inferred. The occasional observation of the unstable element technetium shows that it must have been produced within the last few million years, indicating that element building is still proceeding in stars.

PRINCIPLES OF DESIGN FOR SPECTROSCOPIC INSTRUMENTS

The formation of spectra. Astronomical spectroscopes operate on the same principles as their laboratory counterparts, though they have special features of their own. Spectroscope is used here as a general term for any kind of spectroscopic instrument, such as a spectrograph, which uses photographic detection, or a spectrometer (also called a scanner by astronomers), which uses photoelectric detection.

Spectrographs are used with ground-based (reflecting or refracting) telescopes. They operate at wavelengths from

3,000 Å in the ultraviolet (limited by atmospheric ozone absorption) to about 10,000 Å in the infrared (limited by the sensitivity of available photographic emulsions); most work is done at wavelengths in the range 3,500–7,000 Å.

Optical limitations

Further limitations are encountered if refractors are used because glass refracts different colours by different amounts (the refractive index across the spectrum varies) and only a short wavelength region can be brought to a good focus. The same effect in cheap or defective field or opera glasses can cause coloured halos around objects in view.

High photographic speed, which is necessary when faint objects are to be recorded, requires a camera lens, or mirror system, of short focal (*f*) length and large diameter; that is, a small *f*-number just as in an ordinary camera. Schmidt cameras (named after their inventor, Bernard Schmidt, the German optical worker) can be made at *f*/1 or slightly less, in sizes large enough to accept the light beam from any available grating. In small sizes, semisolid cameras, in which the photographic film is pressed against the glass of the mirror system, can be as fast as *f*/0.35. The limits of faintness that can be recorded have been greatly extended as a result of such increases in speed.

The collimator, a lens introduced to make the light beam parallel, and grating must be matched to the telescope, as illustrated in Figure 1. The telescope admits

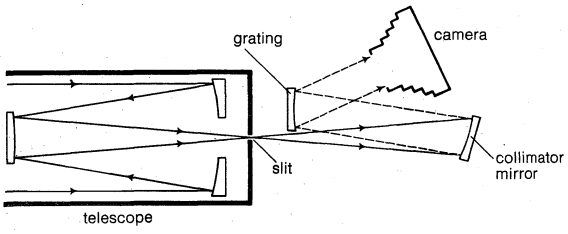

Figure 1: Astronomical spectrograph mounted at the focus of a Cassegrain reflecting telescope. The cones of light converging from the telescope and diverging to the collimating mirror must be matched (see text).

parallel light that is refracted or reflected into a cone that should just fill the grating. A small grating is used with a short-focus collimator; and the longest useful focal length is limited by the size of available gratings. The advantage of a long focal length is that a wider slit can be used for a given resolution (*i.e.*, the degree of spectral purity). The choice of resolution depends on the nature of the investigation and on the brightness of the source; higher resolution always requires longer exposure. For extremely faint stars, or galaxies, the spectrum must be kept short—that is, the dispersion must be kept low, if there is to be any blackening at all in the image; a small grating and a wide slit can be used to prevent any cutoff of light at the slit jaws. Overlapping images of nebulae of galaxies are produced by instruments, called nebular spectrographs, which have such arrangements. On large telescopes, such instruments are placed at the focus of the primary mirror (the prime focus) to minimize the loss of light by extra reflections. Medium-dispersion spectra can be obtained with instruments of moderate size that can conveniently be used as shown in Figure 1. High dispersion spectra are produced by instruments of large size that must be fixed and are therefore mounted at the *coudé* ("elbowed") focus, to which the light is brought by means of two or three additional plane mirrors. In the *coudé* spectrograph many combinations of grating size and camera focal length (but the same camera diameter) are possible. The longest cameras are rather slow photographically; moreover, it is not unusual to lose 90 percent of the light from the telescope behind the slit edges (called jaws), because even a star has a finite size and when its diameter is increased, or blown up, by atmospheric turbulence ("poor seeing"), it can be wider than the slit and only part of the light can pass through. Under such conditions, much of the light gathered by a large telescope is wasted. Only the development of much larger gratings, or a different approach to spectroscopy, can change this situation.

Comparison spectrum

For accurate wavelength identification and measurement, it is essential to include a comparison spectrum from a laboratory source on the same plate. The usual practice is to illuminate both ends of the slit with a spectrum produced by an electric arc, so that the astronomical spectrum is flanked by two comparison spectra. Neon and iron arcs are most commonly used. Use may also be made of natural lines from the Earth's airglow, frequently accompanied by mercury lines from the lights of nearby or distant cities.

Since about 1965, there has been increasing use of image-tube spectrographs for recording very faint objects. In this method, the spectrum is focussed on a photoelectric screen, the cathode, which emits a pattern of electrons. These electrons are focussed by electric and magnetic fields on a fluorescent screen, or sometimes directly on a photographic plate in the vacuum of the tube. If a fluorescent screen is used, the light from it is then transferred to a photographic plate.

Spectral dispersion. *Low-dispersion spectra.* Because the light from a star reaches the Earth in a parallel beam, it is possible in some arrangements to dispense entirely with the preliminary telescope, optical system, slit, and collimator. The essential parts of a spectrograph then remain: the grating (or prism) and the camera (usually a wide-field telescope). When photographed, the star field becomes a field of spectra; these spectra are usually widened for more convenient viewing by a slow motion of the camera at right angles to the dispersion. The ability to take many spectra at once is the chief virtue of the method of "slitless," or "objective prism," spectroscopy. The enormous *Henry Draper Catalogue*, published 1918–24, in which 225,300 bright stars were classified, was produced from objective-prism photographs with small telescopes; more recently, very good quality spectra, over a large angular area of sky, have been obtained with prisms or gratings with angles of a few degrees placed in front of Schmidt-type (wide-field) objectives (see below, spectroscopy at short wavelengths). The slitless method is also used in space spectroscopy, in which compactness and a small number of reflections are advantages. Objective-grating spectrometers and spectrographs have been used in rockets in several experiments and also on the first "Orbiting Astronomical Observatory" in 1970.

Radial velocities (velocities in the line of sight from object to observer) can be measured by the Fehrenbach method developed in the 1940s and named after the French astronomer Charles Fehrenbach. A special prism is used, containing two elements of different glasses, somewhat as in an achromatic lens. The angles are chosen so that a central known wavelength is not deviated; red goes one way and blue the other. Two exposures are made on one plate, with the prism rotated 180 degrees between them. The stellar spectrum can thus be made to serve as its own reference. With suitable precautions, a precision of three to five kilometres per second is achieved.

High-resolution spectra. Spectroscopy of solar, planetary, and interplanetary lines usually requires high spectral resolution. Modern solar work is concentrated on obtaining accurate line profiles; that is, measures of the distribution of absorption or emission with wavelength, which can be obtained only at high resolution. Planetary and interstellar lines are very narrow, because temperatures and pressures are low; such lines may not even be detectable at low and medium resolution because the overlap from neighbouring wavelengths may completely mask them. A further difficulty with planetary atmospheres is that nearly all their absorption lines are in the infrared, for which sensitive detectors do not exist.

The diffraction grating, described above, though valued for its versatility, is only one of several means for selecting wavelengths.

The Fabry-Perót interferometer consists of a pair of closely and accurately spaced plane-parallel glass plates, with special reflecting coatings on the inner surfaces. Used with photoelectric detection, it has become popular

since the introduction of efficient evaporated coatings for the two reflecting surfaces. The plates are located in a chamber in which the pressure can be changed, which makes it possible to measure radiation over a very narrow range of the spectrum. Its greatest virtue is the large angular acceptance; high resolution can be obtained, with no loss of light at a slit, when it is used with the largest telescopes. It is inconvenient when used to scan more than a small range of wavelengths; the Fabry-Perót interferometer is most useful for detailed exploration of a single line for profiles or Doppler shifts.

High resolution spectra in the infrared region

For the infrared above 10,000-angstroms wavelength, an old device, the Michelson interferometer has been perfected into a valuable spectroscopic tool. The principle of Fourier spectroscopy, in its modern form, was suggested by the English astrophysicist Peter Fellgett in 1950, and was subsequently applied successfully to astronomical spectroscopy. The angular acceptance of this instrument is large, like that of the Fabry-Perót interferometer, and, in addition, there is the multiplex advantage, or Fellgett advantage: all wavelengths of the spectrum are measured simultaneously and recorded in a coded form, called an interferogram. The spectrum is obtained from the interferogram by the mathematical process of Fourier transformation (see also OPTICS) in an electronic computer. This method has been used to produce spectral atlases of the one to three micron region for the Sun, the four brightest planets, and several bright stars. The spectral atlases of the inner planets are of better quality than solar atlases of the early 1950s in spite of the enormous differences in light level. The improvement in resolution, by a factor of ten to 100 over the best previous work, has resulted in the identification of several new gases in the atmospheres of Mars and Venus. At shorter wavelengths, for which photomultipliers are available, the Fellgett advantage is cancelled by the corresponding increase of the noise in the detector, and the method is little better than older conventional methods.

Still further in the infrared, medium-resolution spectroscopy is possible with a small Fourier spectrometer, or with a filter disk. An interference filter (a version of the Fabry-Perót interferometer: see above) is deposited around the rim of a transparent disk so that the transmitted wavelength varies smoothly with angle. The spectrum is scanned by the slow rotation of the disk past an aperture, through which the radiation passes to a detector.

At radio wavelengths, an enormous increase of sensitivity is possible because the electromagnetic waves can be treated as electrical signals rather than crude energy fluxes. The difference may be compared to that of using a radio receiver rather than a sensitive thermometer in trying to detect the presence of broadcast radio signals. As mentioned in the introduction, a standard radio receiver is a spectrometer, and the methods used for radio astronomy differ only in technical detail from those of astronomical spectroscopy. Nevertheless, some of the details are important. It is common to obtain a multiplex advantage by the use of multiple channels—essentially, many receivers tuned to adjacent frequencies. Or, a correlation technique may be used; in principle it resembles an electrical form of the Fourier spectrometer, and like it uses an electronic computer.

Radio spectroscopy

Spectrometry. In a spectrometer, a selected wavelength or band of wavelengths from the spectrum passes through an exit slit to a detector. At wavelengths in the ultraviolet, visible, and near infrared ranges, the most sensitive detector is a photomultiplier. At longer wavelengths the preferred detectors are photoconductive cells of lead sulfide, or bolometers (heat detectors) of germanium. From the visible onward, the detectors must be refrigerated at lower and lower temperatures by means of ordinary refrigeration systems, solidified carbon dioxide, liquid nitrogen, and finally liquid helium.

A spectrum can be produced by rotation of the grating, which progressively changes the wavelength that falls on the slit; the successive readings of the detector are recorded. The advantages over photography are the possibility of more accurate measurement, a strictly linear intensity scale, and greater sensitivity at longer wavelengths. The spectrum must, however, be recorded one wavelength at a time while the light of all the rest of the spectrum is wasted. Even so, photoelectric recording may be superior, especially if only a short region of the spectrum is required and if the external conditions do not change during the exposure. Also, various schemes of multiplex spectroscopy are possible, by which many wavelengths can be observed simultaneously. Most of them show their advantage best in the infrared; with photomultipliers, the most practical scheme is through the use of many detectors, each with its own amplifying system.

Spectroscopy at short wavelengths. Spectroscopes designed for the shortwave end of the spectrum, the ultraviolet, do not differ in principle from those used for visible wavelengths. An important change of detail occurs at 1,200 Å: shorter wavelengths are absorbed by all known materials, and, therefore, prisms, lenses, and windows cannot be used. In addition, unnecessary reflections must be avoided because efficient reflecting surfaces do not exist. Concave gratings and windowless photomultipliers are, therefore, used. All instruments must be carried above the atmosphere by rockets or satellites; consequently, sizes are limited and photoelectric detection is favoured, so that the data can be transmitted to the ground by radio. Below 100 Å, X-ray techniques become applicable, and windows can again be used. To improve their efficiency, concave gratings may be used at very small angles of incidence ("grazing" incidence), at which the reflection is almost total, or they may be replaced by Bragg crystals, which operate on the same principles as gratings, but use layers of atoms instead of ruled lines. At the shortest wavelengths, below 10 Å, low-resolution spectroscopy can be done by measurement of the photon energy; one suitable device for this measurement is the proportional counter.

X-ray spectroscopy

Developments in instrumentation have continued to be important in extending the range of spectroscopy. In 1931 reflecting surfaces with evaporated coatings of aluminum were found to be superior to those of silver for resisting tarnish and for achieving higher reflectivity in the ultraviolet. At about the same time, Schmidt developed his wide-field, short-focus camera, which after a few years came to be widely applied in astronomical spectrographs. In 1936, improvements in ruled gratings made possible the concentration of light to an efficiency of 60 percent or better (such a concentration is called a "blaze"). The use of large plane gratings and Schmidt cameras (instead of one or more prisms with lens cameras, which absorbed a significant proportion of the incoming light) totally altered the appearance and the efficiency of astronomical spectrographs. Although photoelectric cells had been used for stellar photometry for several decades, their application to spectroscopy was not practical until the development of the photomultiplier between 1935 and 1939. Later, a great interest developed in image tubes and television techniques.

PROGRAMS IN SPECTROSCOPY

Solar spectroscopy. The Sun is a typical star, near the middle of the known range in both temperature and luminosity. It offers a unique opportunity for detailed study because of the enormous amount of available light and because light from different regions of it can be studied separately. More distant stars are probably at least as complicated as the Sun, and present models of them may omit essential features.

The solar spectrum can be observed in great detail; the available light can be spread out into a spectrum many metres, or yards, long. The dispersion can be made so great that many centimetres may be needed to record the lines in a single angstrom. It is clear, therefore, that with high resolution, a spectrum of very great purity can be recorded and many details of solar behaviour can be accurately studied.

Length of solar spectrum at high dispersion

By using a very long focus telescope, a large image of the Sun can be produced, even when the light-gathering power (determined by the mirror or lens diameter) of the telescope is quite small. Quite small areas such as sunspots, the chromosphere, a flare, or granules (see SUN)

can be studied in detail. A major difficulty in most solar observations is the heating of the instrument and its environment by the Sun, although many sophisticated methods have been tried to overcome it.

Because of the problem of heating, solar telescopes are usually of small to moderate aperture but of long focal length, so that a relatively small amount of light is collected even when a large image is produced. A solar telescope usually has a fixed combination of mirrors, and the light is reflected into it by an arrangement of one (heliostat) or two (coelostat) auxiliary moving plane mirrors. To minimize the effect of the heating of the ground, these mirrors may be mounted on a high tower; or the telescope may be placed in the middle of a small lake. The associated spectroscopes usually feature very high dispersion and spectral resolution, and, therefore, also normally have a long focal length.

A special feature of solar spectroscopy is the study of limited areas that may be much fainter than the disk, or photosphere, such as sunspots on the disk, and the chromosphere and corona near and above the limb. Detailed study of such features requires extreme precautions to avoid inclusion of stray light from the photosphere; telescopes designed for observation of the chromosphere and corona are often called coronagraphs. The chromosphere and corona are optically thin, and the temperature increases with height—that is, distance outward from the Sun; for both reasons, their line spectra appear in emission, not absorption. The classical way of studying them is during a total eclipse, when the Moon just hides the photosphere; the great disadvantage of this method is the infrequency of solar eclipses that occur in convenient locations. The name "flash spectrum" refers to the spectrum of the chromosphere at eclipse (see also ECLIPSE, OCCULTATION AND TRANSIT). It can also be observed, with care, outside eclipse by setting a solar image tangent to a spectroscope slit. Chromospheric features on the disk are best studied in the far ultraviolet because relatively little such light is produced from the underlying photosphere. As the Earth's atmosphere absorbs ultraviolet light, it is necessary to make such observations from outside it. The series of space probes called Orbiting Solar Observatories has been particularly successful, and good results have also come from many rocket flights. Another method is that of surveying the Sun at a single wavelength by a spectroheliograph in which a spectrograph functions as a very narrow-band filter. An image either of the whole disk or of part of the Sun can be built up by a scanning process. Some of the same results can be obtained by a Lyot filter, which is built up of elements of quartz crystals and polarizers. The two commonest wavelengths studied belong to hydrogen (6,563 Å) and ionized calcium (3,933 Å); here, the light from the photosphere is reduced by the presence of deep Fraunhofer lines, and the chromospheric emission can be observed.

Solar characteristics

Spectroscopy can be expected to give information of several kinds on the chemical and physical state of the solar atmosphere: the composition, the temperature, the density, and the state of motion. The best results are obtained from detailed descriptions of the atmosphere (called models) that include all these factors at once. In such a model there is no single temperature for the atmosphere, but a profile relating the temperature to some quantity such as height, density, or optical depth. The only unique "temperature of the Sun" that can be assigned is the effective temperature, about 5,800° Kelvin (10,000° F). This is the temperature at which a black body, or perfect radiator, would emit the same total radiant energy. The temperature of the deepest "visible" region (unit optical depth) is a few hundred degrees greater; about 300 kilometres (200 miles) higher, the temperature of the Sun's disk has its smallest value, about 4,600° K (7,800° F). (This cool region is still occasionally called the "reversing layer," from the obsolete picture of a "photosphere" in which the continuum is produced and a cooler layer above it in which dark—or reversed—lines are formed. The hotter and cooler regions are realities, but the separation of the roles is not.) At still greater heights the temperature rises rapidly. First, in the chromosphere, the temperature rises to 30,000° K (about 54,000° F); farther out, the very extended corona is at about 2,000,000° K (3,600,000° F). The effective temperature of a large sunspot is only about 4,400° K (7,500° F).

The main results of the chemical analysis are as follows: molecules are rare, because of the high temperature; atoms and some positive ions are dominant; nearly all the atoms are hydrogen and helium, in a ratio 14:1; and the remaining 1 percent of the atoms have relative abundances much like those of the Earth and meteorites, except that the three lightest elements after helium (lithium, beryllium, and boron) are much rarer. Some elements are easier to detect and measure in sunspots (low temperature) or in the chromosphere (high temperature). In addition, simple molecules are rather prominent in sunspots.

The rotation of the Sun is most readily determined by following spots at the latitudes at which they occur. The Doppler method works at latitudes far enough from the poles: at the solar equator, one limb (or edge) of the Sun's disk is found to be receding and one approaching, at nearly two kilometres (more than one mile) per second, giving a period of 26.9 days for a complete rotation as seen from the Earth; the period with respect to the stars is shorter by about a day, because the Earth has moved in its orbit around the Sun by 26 degrees in 27 days. At higher solar latitudes the period increases steadily, and at 45° a complete rotation takes 29.5 days.

Close inspection of an image of the Sun reveals that it is covered by bright "granules", separated by a network of slightly darker material. The supposition that the granules represent rising convection cells is supported by the observed radial velocity, about 900 metres per second upward.

The bright lines of the corona were a mystery for many years and were at one time suspected to be caused by an unknown element "coronium." In 1941, a nearly complete explanation was found in terms of iron lacking 9 to 14 electrons, nickel lacking 11 to 15 electrons, and similar ions of calcium and argon. Several other elements have since been included, to account for weaker lines. The energy required to remove as many as 15 electrons from an atom corresponds to a temperature of over 1,000,000° K. The breadth of the lines also implies a high temperature, which produces large line-of-sight random velocities. Many details concerning the properties and behaviour of the outer layers of the Sun that can be obtained from a study of the spectrum at high or low dispersion are described in the article SUN.

Telluric and interstellar absorption lines. Absorptions in the Earth's atmosphere, called telluric absorption lines and bands, are prevalent at nearly all wavelengths except in the blue and near-ultraviolet parts of the spectrum. The features in the solar spectrum called A and B by Fraunhofer are due to atmospheric molecular oxygen, O_2. As described above the atmosphere is opaque below 3,000 Å and through much of the infrared. In the photographic spectral range the principal absorbers, which produce dark bands in the spectrum, are molecular oxygen, O_2, and water, H_2O. In addition there are a number of diffuse bands due to the double molecule, $(O_2)_2$; some are near the O_2 bands, but others are also found at other wavelengths.

It is not always easy to distinguish a telluric line from one coming from the light source, particularly since water has a very complicated spectrum, which is not fully tabulated, and since it is variable in amount. There are two principal tests: telluric lines, unless they are very strong, are narrower than solar and stellar lines; and they vary in strength according to the zenith angle of the source, being much stronger when the source is near the horizon. A third test can be applied if the radial velocity of the source varies with time; the telluric lines are of course "stationary"; that is, they do not share the velocity of the source.

So-called stationary lines

There is another class of stationary line, formed in the interstellar medium. In the spectra of bright distant stars such lines are particularly prominent because their

strength depends on the number of the interstellar particles that produce them between the observer and the source, especially those that are reddened by intervening clouds of interstellar dust: these clouds contain gas as well. Sometimes several lines are seen that correspond to different radial velocities, implying that two or more clouds are moving with distinct speeds along the path. Such patterns are found in the two sodium D lines (5,890, 5,896 Å) and the H and K lines of the calcium ion (3,933, 3,968 Å) as would be expected in clouds containing both sodium and calcium. (Here D, H, and K are the Fraunhofer designations, still in use.) Any other explanation of the correspondence is difficult to imagine. Lines are also known that are produced by simple molecules—CH, CH^+, and CN. The molecular bands are much simpler than those produced at normal temperatures, showing only two or three lines instead of the normal 20 or 30. The temperature of the molecules seems to be in equilibrium with the universal 3° K (−454° F) background radiation that has recently been discovered; and the line intensities for the interstellar compound cyanogen have been used to verify this temperature.

Other absorptions in the ultraviolet that are attributed to interstellar gas have been detected by rocket-borne spectrographs and by the spectrometers aboard the first "Orbiting Astronomical Observatory." Hydrogen, the most abundant atom in nature, is prominent and produces an enormously strong line (called Lyman alpha) at 1,216 Å. Molecular hydrogen has been detected in the difficult-to-observe region 1,000–1,120 Å.

Spectroscopy at radio wavelengths has been used with regard to a number of molecules, in addition to the famous 21-centimetre emission line of atomic hydrogen. This subject is discussed below in a separate section. (See also INTERSTELLAR MEDIUM.)

Stellar spectroscopy. Spectroscopy of faint objects, such as even the brightest stars, poses problems of a quite different nature from those associated with the Sun.

Stellar spectroscopy necessarily must be concerned with the problem of the concentration of radiation, particularly of light. The light from the brightest stars falls on the Earth with an intensity 10^{10} times less than that of sunlight. Since any possible increase in light-gathering power is limited to a few powers of ten, improvements in stellar spectroscopy can be obtained mainly by an increase in exposure time, by a decrease in the dispersion, and by efficiency of design in the spectrograph. The exposure time must be increased to minutes or hours, the length of the spectrum cut down to a few centimetres (at high dispersion) or less (at medium or low), and the sensitivity of the receiver, usually a photocell or photographic plate, made as great as possible. The three examples of classes of spectral dispersion—high, about 2 angstroms per millimetre; medium, about 40–100 angstroms per millimetre; low, from about 200 angstroms per millimetre—can be compared with the dispersion possible in solar spectroscopy, in which, because of the enormous amount of light available, as has been noted above, several centimetres may be used to record the lines in a single angstrom.

Classification of stellar spectra. Spectral classification of stars was initiated in the middle of the 19th century by the astronomer Angelo Secchi in Italy.

At the beginning of the 20th century, a group at Harvard undertook the classification of several hundred thousand stars over the entire sky, an effort that culminated in the *Henry Draper Catalogue* published 1918–24. It provides the basis for all modern astrophysical work.

The system used in the catalog has been refined many times, by means of physical theory and empirical methods. Some terminology has survived from the days of pure empiricism, in particular, "early" and "late" spectral class for "hot" and "cool" stars. Most stars can be placed in the sequence O-B-A-F-G-K-M which is controlled by the temperature of the surface. The sequence is further subdivided by adding the figures 0 to 9 to the letters; *e.g.*, the type B9 precedes type A0. The range is from about 40,000° K (O type, 71,500° F) to 2,000° K (3,100° F) or even 1,500° K (M type); the Sun is intermediate—type G1 at 5,800° K (10,000° F). Parallel sequences exist at the low-temperature, or late, end; stars of class C (formerly class R–N) are rich in carbon, and class S stars are rich in metals like zirconium. The effect on the spectrum of differences in composition is less marked for hotter stars, but such differences are readily resolvable on medium- and high-dispersion spectrograms. Much effort has also been expended in luminosity (or brightness) classification, because the distance of a star can immediately be found if its absolute brightness is known (see STAR). For two stars of equal temperature, the luminosity is proportional to the surface area, or to the square of the radius. Thus, luminous stars are called giants and less-luminous ones are called dwarfs. The pressure at the visible surface of a giant is relatively small, and spectral information about pressure, therefore, indicates the size of the star. Surface pressure may be indicated by the width of hydrogen lines (broad for dwarfs, narrow for giants), or by a comparison between the line strengths or intensities from neutral atoms and those from ions (neutrals favoured for dwarfs, ions for giants). Such work was at first done with high-dispersion spectra and extended to medium dispersion in the 1940s.

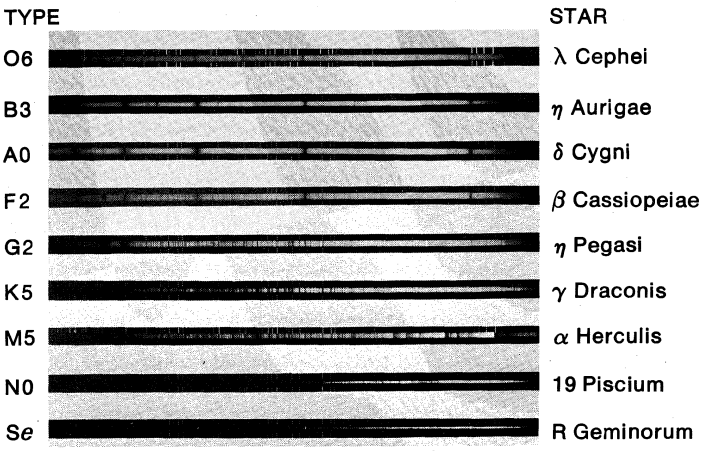

Figure 2: Principal types of stellar spectra, flanked by comparison lines from a laboratory source. Hot stars, at the top, are brightest in the blue; and cool ones, at the bottom, are red. The spectrum at the bottom contains emission lines, denoted by the *e* attached to the spectral class.

The effect of temperature on a stellar spectrum was first quantitatively explained by the Indian physicist M.N. Saha in 1920. At the low temperatures of M-stars, many simple molecules are present, and their bands dominate the spectrum. Increasing thermal agitation at higher and higher temperatures has several effects: molecules dissociate into atoms; many atoms are maintained in excited states in which they can absorb new lines; and atoms are ionized by the loss of an electron. The solar spectrum (class G) illustrates an intermediate temperature stage in which neutral atoms and ions (such as those of calcium and iron) both are seen. Hydrogen lines are moderately strong: they originate from the first excited state of the atom. At Class A, these hydrogen lines are very strong, but most other atoms are ionized and show only a few weak lines. In Class B, even hydrogen begins to be ionized, and helium lines are found; the hotter O-stars show ionized helium.

Many stars of Class F and hotter have broad, dish-shaped lines, though the areas (that is, the total amounts of absorption) are normal. The spread of the line across the spectrum has been shown to be due to rapid rotation of the star; the resulting line shape is characteristic of the rotation speed and from the shape it is found that speeds of rotation at the equator may be as much as 400 kilometres per second (250 miles per second) or more. Such speed is almost enough to throw material out from the equator. Rapid rotation is much less common in cooler stars. It is surmised that most stars are created with high angular momentum from the motions of the collapsing nebula that forms them. For the cooler stars, some brak-

ing mechanism must operate to slow them to velocities as modest as that of the Sun.

Measurement of radial velocities

Velocities in the line of sight have been determined for many stars from the Doppler effect, which shifts all lines by an amount proportional to wavelength. To make such a determination, a spectrum of medium to high dispersion is taken, with a comparison spectrum from a laboratory source on each side. Many precautions are necessary for accurate results; with high dispersion and sharp lines the probable error can be as small as 0.1 km/sec (0.06 mi/sec), but more often, it is 1–2 km/sec (0.6–1.2 mi/sec). A photoelectric method has been developed in which a mask resembling a negative of the stellar spectrum is placed over it. Wherever the transparent lines of the mask are in register with the dark lines of the star, the transmitted light is weakest. This minimum light can be detected by a photomultiplier; the corresponding position of the mask gives the radial velocity in terms of the measured shift from its expected position. This method is much faster than photography, but a given mask can be used only for a narrow range of spectral class. All radial velocities must be corrected for the motion of the observer that results from the rotation and orbital motion of the Earth.

Among the results obtained with the aid of radial velocities are the following: (1) the determination of the velocity (about 20 km/sec or 12 mi/sec) and the direction in space of the motion of the solar system with respect to the nearer stars; (2) the estimation of the random motions of the stars, which for the massive B-stars averages as little as 15 km/sec (9 mi/sec), increasing to nearly 60 km/sec (37 mi/sec) for typical M-dwarfs; (3) the recognition that the entire Galaxy rotates around a distant centre located in the direction of the constellation Sagittarius, with a velocity of between 200 and 300 km/sec (125 and 200 mi/sec) in the region of the Sun; (4) the comparison of radial velocities and proper motions (the rate of movement across the sky is called proper motion) to determine mean distances of groups of stars of any one kind; (5) the discovery of a group of high-velocity stars which are moving with respect to the Sun with speeds of the order of 100 km/sec (62 mi/sec) and in a direction opposite to the normal direction of galactic rotation; (6) the measurement of red shifts in very dense stars (white dwarfs), which are probably the gravitational red shifts predicted by Einstein (see GRAVITATION); (7) the law of linear increase with distance in the velocity of recession of external galaxies; (8) the discovery of numerous stars showing periodic variations in radial velocity—resulting from orbital motions of close double stars or from pulsations in the radii of individual stars (such as Cepheid variables); (9) the study of eruptions in novae and in other expanding shells of gas which surround such stars as P Cygni; (10) the discovery of stationary lines, which do not show the Doppler shifts characteristic of the stars but are interpreted as absorption by clouds of interstellar gas.

Stellar temperatures. The temperature of a stellar "surface," like that of the Sun, is not a well-defined quantity, because the atmosphere is not isothermal (at the same temperature everywhere) and different wavelengths originate at different levels. In a spectral region for which the continuous opacity changes slowly with wavelength, however, the spectrum resembles that of a perfect radiator (black body) at the temperature of the layer at unit optical depth. This condition obtains both for stars that are cooler and for those that are hotter than the Sun, in which the negative hydrogen ion is the dominant cause of the opacity. Measurement of the continuous spectrum, the continuum, of such stars thus yields realistic temperatures, and the colours of the stars obey the usual rule of going from red to yellow, white, and blue as the temperature increases. In the coolest stars (Class M, also C and S), however, so many lines and molecular bands are present that they dominate the spectrum. As a result, the colours, though very red, do not give a good measure of the temperature. Similar reservations apply in the ultraviolet range for almost all stars.

Colour-temperature relationships

Another measure, called "excitation temperature," can be obtained from the relative intensities of suitable lines of an atom, of an atom and its ion, or even of lines of different atoms such as hydrogen and helium. In essence, such intensities form the basis of spectral classification.

Line broadening. The lines of spectra are not perfectly sharp; indeed, a perfectly sharp absorption line would be nearly unobservable. Several broadening mechanisms exist, and observations of the actual shapes of lines (density plotted against wavelength—the line profiles) can be used to infer something about physical conditions in the star. (1) Natural broadening is intrinsic to the atom (or molecule); it is intimately related to the Heisenberg uncertainty principle of quantum mechanics and is usually a very small quantity. (2) Pressure, collisional, or Lorentz broadening is caused by collisions or near-misses with other atoms while the atom in question is radiating or absorbing and becomes more important at high pressures. The shape or profile is similar in the two cases: the opacity falls off as the square of the wavelength difference from the line centre, but at a rate that depends on pressure. (3) Doppler broadening is due to random motions in the line of sight; such motions can be produced in any of several ways. First is thermal agitation; the characteristic speeds are proportional to the square root of the ratio of absolute temperature to atomic or molecular weight and are, therefore, largest for light atoms at high temperature. Mass motions (turbulence) can also be important and are classified according to the optical thickness of the individual moving elements, measured at the centre of the line. Turbulence on a small scale, called microturbulence, for which the elements are thin, affects the spectral lines in the same way as thermal agitation: generally speaking, the lines become strong as well as broad. Turbulent motion on a large scale, called macroturbulence, like stellar rotation, spreads the lines out but does not strengthen them: they become shallow and broad.

Electric and magnetic fields

The shapes and intensities of spectral lines are also affected by the presence of electric and magnetic fields (Stark and Zeeman effects). If a line is produced in the presence of a magnetic field and if the magnetic field is uniform, the line is split into several components; this phenomenon is observed in the spectra of so-called magnetic stars and in sunspots (Zeeman effect). The Zeeman effect produces a broadened line if the spectral purity is not good enough to show the separate components. Strong, uniform electric fields are not present in most astronomical objects, for they are short-circuited by the flow of electrons and ions. Stark broadening, caused by local electric fields around abundant ions, is important, however, especially for hydrogen; collisions with ions are particularly effective in perturbing this atom.

Unusual stellar spectra. A variety of stellar objects show emission lines along with, or instead of, the usual absorptions. According to the general principles discussed above, the regions of the star's atmosphere where these lines are formed are optically thin or, if opaque, must be hottest near the surface. In the most commonly observed case, a star is surrounded by an extended envelope or shell of gas. If this envelope can be observed directly, it is called a nebula.

Not all the processes operating in the formation of stellar spectra, especially the unusual or peculiar ones, are understood, but several can be mentioned here. (1) Rapidly rotating stars, most of which are hot, can throw off gas from their equatorial regions. (2) Processes resembling the emission of the solar wind seem to operate in cool stars, especially giants; here the driving force is probably energy from the violent convection in the outer part of the star. (3) Extremely hot stars may be able to evaporate gas at a substantial rate. (4) Finally, a rather common configuration is that of a close pair of stars. Particularly if one of them has evolved into a giant, a star with an extremely large radius, gas can spill out towards the other star or go into orbit about both of them. Novae, or exploding stars, seem to be of this sort: the gas accumulates on the small, hot star, and is periodically blown off to form an expanding shell. This ex-

Spectra of novae

pansion may be measured by the Doppler effect. At first the shell is optically thick, and its spectrum resembles that of a star but it is abnormally bright because of its large area. In time bright lines appear, as the gas becomes optically thin; finally, "forbidden lines" characteristic of very low densities are seen (the term "forbidden" should be interpreted as meaning "highly improbable"). All these details are noted by careful observations and measurement of details of the spectrum and, in some cases, of their charges.

The rather small class of stars with unusual spectral characteristics called Wolf-Rayet stars are extremely hot; they show emission lines of several-times ionized elements and clear evidence of expanding shells. Many are known to be close binaries. Even normal O- and B-stars, when observed in the far ultraviolet from space, are seen to have expanding shells; the behaviour of the spectral lines resembles that of the P Cygni stars, another class of peculiar stars with expanding shells of gas. Another interesting class contains the cooler T Tauri stars, which are probably accreting material from an associated nebula, and may be in the last stages of formation. (The P Cygni and T Tauri classes are named after the prototype stars).

White dwarfs are stars that are believed to have used up all their nuclear fuel. They concentrate a mass comparable to that of the Sun into a volume comparable to that of the Earth; hence the name dwarf. The colour of their radiation is white. As would be expected, the surface pressure is high and the few spectral lines observed are greatly smeared. White dwarfs cannot have a much greater mass than the Sun; more massive stars must presumably shed the excess. It is thought that planetary nebulae, discussed below, represent the mass ejected in this way. Other stars, perhaps more massive originally, are believed to eject their outer layers more violently, while the core implodes into a neutron star, releasing a vast amount of gravitational energy. This train of events is identified with the rare and unpredictable phenomenon of a supernova. The spectrum of the early stages of a supernova is almost impossible to record. Spectroscopic study of supernovae in nearby galaxies does suggest that very violent events take place but the spectra are difficult to decipher. There is little doubt that the Crab Nebula, discussed below, is the product of a supernova explosion observed by Chinese and Japanese astronomers in 1054.

Planetary spectroscopy. The solar radiation reflected from a planet contains information of two kinds about the planet. (1) In addition to the normal solar spectrum, this radiation produces atomic lines (which are rare) and molecular bands characteristic of the constituents of the atmosphere during the passage of the light through it. (2) Colorations and broad absorptions are characteristic of solid surfaces or cloud material from which the light is reflected; the interpretation of such data is seldom unique, but with care, useful conclusions can be obtained.

Spectral features added by planetary material

Atmospheric absorption lines are usually narrow and can be observed best with high spectral resolution. With the development of *coudé* spectrographs of long focus, with which high-dispersion spectra could be obtained, and infrared-sensitive emulsions in 1933, astronomers succeeded in observing carbon dioxide on Venus and complex absorptions on Jupiter that were later shown to be due to ammonia and methane. Methane is also found on Saturn, Uranus, and Neptune. The lack of ammonia absorption (though there are some reports of it for Saturn) is reasonable at the low temperatures of the outer planets; and the clouds of Jupiter and Saturn are probably ammonia ice.

Observations in the infrared and ultraviolet wavelength regions. Other substances were sought in planetary atmospheres without success, and progress had to await extension of the observable wavelength band further into the infrared region. In 1947 use of a lead-sulfide detector extended the observable infrared out to 2.5 microns, enough to detect carbon dioxide on Mars. The spectral resolution was not high, but the carbon dioxide bands in this region are extremely strong. By 1963, improvements in infrared photography and in *coudé* spectrographs produced a single plate showing a weak band of carbon dioxide at 8,689 Å. The actual purpose of the exposure was to search for evidence of water vapour on Mars at a time of large planetary motion in the line of sight and, therefore, large Doppler shift, which would separate the contributions to the water vapour bands from the Earth's atmosphere and that of the planet; weak absorptions were indeed found. It soon became clear, however, that the atmosphere of Mars is nearly pure carbon dioxide; the only other gases likely to be present in substantial amounts are nitrogen and argon, which are invisible to this type of spectroscopy.

Still another advance, the perfection of high-resolution Fourier spectroscopy, permitted the detection of a trace of carbon monoxide in spectra of Mars obtained by Pierre and Janine Connes, two French astronomers. The resolution and consequent purity of this method is such that many new identifications of features, hitherto hopelessly blended with neighbouring ones, are now possible. Oxygen absorption has been suggested, but may not be real.

Space observations suggest a trace of ozone absorption around 2,500 Å. The emission spectrum of the upper atmosphere of Mars (the daytime airglow) was observed by spectrometers aboard United States flyby spacecraft in 1969. The presence of carbon monoxide and carbon dioxide were confirmed, and traces of hydrogen, oxygen, and carbon atoms, presumably the result of dissociation by solar ultraviolet, were found. No emissions of nitrogen were seen, in striking contrast to the dayglow of the Earth.

Observations of small planetary areas. In 1969, the carbon dioxide (CO_2) absorption and, since it must be proportional, the pressure of the atmosphere of Mars at the surface, above a large number of small areas of Mars were measured. On the assumption that higher ground levels had less atmosphere above them, these data were then converted to a topographic map showing large-scale relief of more than 10 kilometres (6 miles). A similiar method was applied to data from spacecraft flying past Mars in 1969. Both sets of data agree, in most respects, with topography deduced from Earth-based radar.

Venus

Quantitative analysis of the Venus atmosphere is hampered by the ubiquitous haze. The path taken by the radiation as it is scattered from point to point in the atmosphere is unknown, but is presumably similar at nearby wavelengths; thus, the relative abundances of various gases can be obtained. The most abundant gas is known to be carbon dioxide again, from direct chemical analysis by three Soviet Union entry probes. With this knowledge, the amounts of the remaining gases can be obtained. One hundred and ninety bands of carbon dioxide have been identified in the Connes spectra. Rare isotopes of carbon and oxygen also have been identified from peaks in the spectra that are shifted from the positions of the main carbon dioxide lines because of the mass differences between the isotopes. This technique has been possible for the first time because of the very large improvement in the resolution provided by the Connes spectra. The isotopic abundances are found to be the same as on Earth. Carbon monoxide is also present, in three isotopic forms. A most unexpected result was the detection of trace amounts of hydrogen chloride (two isotopic forms) and hydrogen fluoride. Oxygen absorption has not been detected. Water vapour is definitely present, but the amount is variable and probably too small to permit the cloud particles to be ice. Much of the work on water vapour has been done from high-altitude platforms to avoid the telluric absorption. One United States scientist has worked with unmanned balloons, and another has used a jet aircraft. Ground-based observations are limited to dry periods at times of large Doppler shift. Far-ultraviolet emission by hydrogen and oxygen atoms has been observed by means of a rocket-borne telescope and spectrometer; the hydrogen has been observed in detail from Soviet Union and United States spacecraft.

The outer planets

It has long been realized that the low density of Jupiter (and also of the other three giant planets, Saturn, Uranus, and Neptune) implies the presence of large amounts of

hydrogen, and the detection of methane (CH_4) and ammonia (NH_3) offered support for this reasoning. But direct detection of H_2 became possible only in 1949, when laboratory work showed the existence of two classes of infrared absorption that could be sought by direct observation. Broad pressure-induced lines were soon found in the spectra of Uranus and Neptune. A decade later, the narrow quadruple lines of hydrogen produced in relatively rare transitions were observed on Jupiter, and they have been studied in detail since; the expected dominance of hydrogen is confirmed. In 1963, use of a large balloon-borne telescope made possible the observation of very strong pressure-induced absorption on Jupiter in the 2.4-micron region, with similar results. Spectroscopy from rockets has also demonstrated the presence of hydrogen atoms in the upper atmosphere of Jupiter.

Spectroscopy of comets. Special difficulties in comet observation include the sporadic nature of cometary appearances; also, as all cometary radiations are either reflected or induced by the effect of sunlight, changes occur constantly in the spectrum as the comet approaches and recedes from the Sun. In the past, most comet spectra have been made at low dispersion, partly because a short exposure or the use of a slow or small telescope was necessary. Such spectra show the gross features well, but fine details can best be studied only on the rare occasions when a really bright comet can be observed at high dispersion.

The nature of comets has been revealed in some detail by spectroscopy. A nucleus, heated by the Sun, gives off a cloud of gases, many of which are unstable free radicals. Ions are also produced and are blown radially away from the Sun by the solar wind. Spectra of the head, the brightest and densest part of the comet, show the presence of C_2, C_3, CH, CN, NH, NH_2, OH, H, and O; sometimes, near the Sun, sodium and iron lines also appear. The tail ions are CO_2^+, CO^+, and N_2^+; the presence of dust is revealed by the solar spectrum it scatters. The nucleus is composed of compounds like H_2O, NH_3, and CH_4 along with heavier hydrocarbons and dust. These molecules are released by the heat of the Sun and dissociated and ionized mainly by solar ultraviolet radiation. The detection of hydrogen atoms was accomplished only in 1970 by two spacecraft, the first "Orbiting Astronomical Observatory" and an "Orbiting Geophysical Observatory." The hydrogen cloud is enormous, even on the scale of the visible comet, the tail of which can be millions of kilometres long.

Detailed study of high-dispersion spectra reveals additional information. Motions are found from Doppler shifts, and intensities of molecular bands give "temperatures," which relate to the equilibrium of the molecules of the tenuous gas with solar radiation. (See also COMETS.)

Spectroscopy of meteors. Though meteorites can be recovered and analyzed in the laboratory, there is no assurance of a similar composition for the much smaller objects, the meteors, that vaporize high in the atmosphere. Meteor spectroscopy is worthwhile not only for chemical analysis, but also for clues to the physical conditions in the meteor trail. Meteors form short-lived bright tails, lasting for a few seconds; they appear unpredictably in any part of the sky, but more frequently during meteor showers. The only practical method is to use an objective prism or, more often, a grating with a wide-field camera. Long exposures at random or during meteor showers have yielded a total of some 1,500 spectra, most at very low dispersion, enough for a detailed study. The chemical elements found do indeed suggest a composition similar to the larger meteorites; they include iron, magnesium, sodium, calcium, manganese, chromium, aluminium, nickel, hydrogen, and silicon, some of them ionized. A curious fact is the appearance of the auroral green line of atomic oxygen in some meteor spectra. Its presence is not fully understood, but presumably it is due to the excitation of atmospheric oxygen. Bands and lines of nitrogen are also seen. One existing spectrum shows, in addition to the usual metallic lines, many molecular bands suggesting cometary material. Apparently present are the oxides of iron, magnesium, calcium, and carbon, as well as CN and C_2. For the other lines, the degree of excitation depends on the velocity and consequent heating of the meteoric particle: slow ones show temperatures around 1,700° Kelvin (2,600° F), and faster ones may reach 3,200° Kelvin (5,300° F). (See also METEORS.)

Analyzing meteor spectra

Spectroscopy of nebulae. The word nebula in Latin means a cloud, and has been applied in the past to many kinds of cloudy objects. Current usage favours restriction of the term to literal clouds of gas, dust, or both; aggregations of stars are called clusters or galaxies, depending on their size and structure. Usually a distinction can readily be made with the spectroscope: clusters and galaxies show a stellar spectrum, whereas gaseous nebulae show a bright-line spectrum. Borderline cases exist; some galaxies have emission lines, and dust clouds near a suitable star (effective temperature 20,000° Kelvin or cooler) can behave as reflection nebulae showing essentially the same spectrum as the exciting star. A well-known example is found in the Pleiades star cluster.

Spectra of gaseous irregular nebulae. Gaseous nebulae are usually excited by intense ultraviolet light from one or more hot stars in the neighbourhood. A very hot star emits huge amounts of far-ultraviolet radiation—the maximum of the black-body spectrum is at 1,000 Å for a temperature of 29,000° K (about 52,000° F). All the gas near it is, therefore, ionized and constitutes an "HII region." The term HII, or H^+, refers to ionized hydrogen. The outer boundary of an HII region is rather sharp; here the ionizing radiation is quickly used up, and the hydrogen in the surrounding HI region is mostly neutral. If the gas is uniform around the star, the HII region is called a Strömgren sphere after the Danish astronomer Bengt Strömgren, who first studied their structure in detail. The observed nebula may appear irregular because of patchy absorption by dust clouds, or because the density of hydrogen varies in different directions.

Emission processes

The emission lines of an HII region, or emission nebula, are produced by two main processes. Electrons and positive ions are continually recombining; in particular, electrons and protons recombine into hydrogen atoms. The result is a continual production of excited atoms and of ions in lower stages of ionization; a rich recombination spectrum results. Because hydrogen is very abundant, its lines are particularly prominent. In addition to the familiar lines in the visible and near ultraviolet ranges, there are many more in the radio region. Recombination also produces continuous spectra extending over several hundred angstroms in various spectral regions, and through much of the radio region. These spectra are produced by electrons approaching ions with considerable energy and combining with them into a specific bound energy level. Thus, the width of each continuum gives, in principle, a direct measure of the energy distribution of the electrons. In practice this information is difficult to obtain because of uncertainties in photometry over the required wavelength range.

Subsequently, the electrons are ejected again, having absorbed energy from the radiation of the central star, and most of them have considerable kinetic energy. This energy is quickly shared with the other electrons and ions, which typically attain a temperature of 10,000° K (17,500° F). The more energetic electrons can collisionally bring the atoms and ions of the medium to their lowest excited states. Many of the lines in such an electron-impact spectrum are unobservable in the laboratory; they were for many years half-seriously ascribed to an unknown element "nebulium." But in 1927 the U.S. physicist and astronomer Ira S. Bowen found that they were due to forbidden transitions in the ions of common elements, especially oxygen and nitrogen. In the laboratory the excited states are unable to radiate before they are quenched by a collision with another atom or the wall of the vessel. But in the tenuous environment of a nebula such collisions are so rare as to be unimportant. The excited states in question are of low energy and are very efficiently populated by the electrons in the nebula; indeed, the production of forbidden lines is the process that limits the temperature of the electrons. In 1925 the green

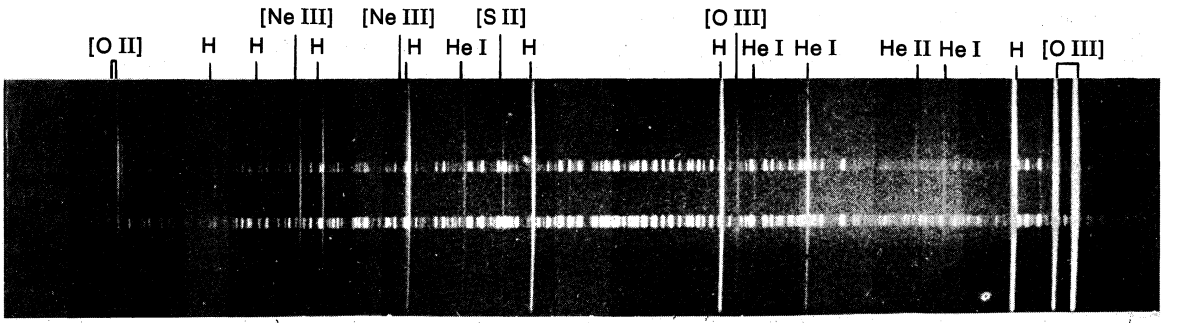

Figure 3: The emission spectrum of the Orion Nebula from 3700 to 5100 Å. showing the Balmer lines of Hydrogen, due to recombination, and the forbidden lines of ionized oxygen, sulfur and neon, due to electron impact.

By courtesy of Hale Observatories; from C. Payne-Gapocshkin and K. L. Haramundanis, *Introduction to Astronomy* (© 1970); Prentice-Hall

auroral line had been similarly identified as a forbidden transition in neutral oxygen, and several other forbidden transitions are now known in the spectrum of the Earth's upper atmosphere.

Bowen fluorescence

A third excitation process was worked out by Bowen in 1934: it is known as Bowen fluorescence. The strongest line of the helium ion, at 304 Å, is emitted by the nebula, and this wavelength happens to coincide with a line of doubly ionized oxygen (OIII). Ions raised to this state may cascade down, through several intermediate energy levels, emitting the observed lines. The last photon radiated can initiate a similar process in nitrogen ions (NIII).

The best-known nebula, visible to the naked eye as the middle "star" in the sword, is the Orion Nebula. Well over 200 lines are identified in its spectrum, representing a dozen of the common elements in several stages of ionization. Several lines are known in the radio region. The composition is similar to that of the Sun. A complicated field of radial velocities is found. The general expansion is about 12 km/sec (7 mi/sec) relative to the central stars. Expanding bubbles are shown in many places by doubled lines—both the front and the back are seen, one approaching and the other receding. It seems that the whole region is in rapid turbulent motion, with discontinuities suggesting shock fronts. Similar data are available for one or two other diffuse nebulae, but in most cases only a general velocity of approach or recession can be obtained.

HII regions can readily be observed in nearby galaxies; in more distant ones, the brightest lines sometimes show above the stellar continuum. The forbidden doublet (a spectral line with two close components) of O^+ at 3,727 Å is found this way in about half the galaxies observed, and even more frequently in spiral and irregular galaxies that tend to be rich in gas. (See also NEBULA.)

Spectra of planetary nebulae. Somewhat over a thousand planetary nebulae are known. The term planetary has nothing to do with the nature of the objects: it refers to the telescopic appearance of the brighter ones—a greenish disk resembling Uranus or Neptune. Photographs usually reveal considerable structure in addition to the basic circular shape. Usually a central star can be seen. Spectral lines near the centre are double and indicate expansion velocities of 10–30 km/sec (6–18 mi/sec). Comparison of this velocity with a typical diameter suggests a lifetime of only 30,000 years. It is generally believed that such nebulae represent the outer envelope of a very old star, whose inner parts are in the process of collapsing into a star of very small diameter called a white dwarf. It is not surprising that this stellar core has an exceedingly high temperature, typically 50,000° K (90,000° F) and sometimes as much as 100,000° K (180,000° F). Though such an object would be expected to be deficient in hydrogen (which is consumed by the processes that cause a star to shine), the abundances of it and of the other chemical elements in both nebulae and central stars seem to be normal. Perhaps the hydrogen is not used up in the outer parts of the star; or perhaps the picture of the central star as a white dwarf is in error.

It is uncertain whether the outer boundary of a planetary nebulae represents the boundary of the ejected gas or a Strömgren sphere embedded in this gas. It is difficult to tell directly from the spectra, because any surrounding HI region would be very faint. Indirect evidence suggests that the smaller nebulae, which are also the youngest and densest, may have HI regions around them. Stratification may be seen directly for ions like He^+ and Ne^{++} which tend to be found closer to the centre than the less-ionized species.

Supernova remnants. The third principal species of nebula is the supernova remnant. The most famous and best-understood example is the Crab Nebula; the supernova associated with it was observed by Chinese and Japanese astronomers in 1054. This remarkable nebula still presents major new insights; in 1968 the supernova remnant was found to be a pulsar (see PULSAR).

Explanation of supernova

It is thought that a supernova represents the explosion of a massive star, during which a core, about the mass of the Sun, is imploded into a neutron star about 12 kilometres (7 miles) in radius. Such a collapse releases an enormous amount of gravitational energy, comparable to the nuclear energy radiated during the lifetime of the normal star; and a large fraction is stored in the rapid rotation of the neutron star. At the same time, the stellar magnetic field is enormously compressed and strengthened. As the star rotates, its magnetic field acts as a powerful dynamo, accelerating ions, and especially electrons, to high velocities: 900 years after the explosion, the rotation rate of the whole star is still 30 revolutions per second, very close to that of a standard electric motor.

Spectroscopically, the star appears blue but shows no absorptions. Photometry and time-resolved photography show that the light is emitted in flashes, twice per revolution, as in a rotating beacon. The source of the light is not understood; no other pulsar is detectable optically, but they are all older than the one in the Crab. The surrounding nebula consists of two parts: an amorphous mass with a continuous spectrum and a high degree of polarization; and a complicated network of ropy filaments with a normal nebular spectrum. In 1953 it was suggested that the continuum is due to synchrotron emission: light given off by electrons moving at almost the speed of light when deflected by a magnetic field. The subsequent observation of polarization confirmed this idea, but the energy source for the electrons was a mystery until the discovery of the pulsar. The synchrotron continuum extends all the way from the radio, through the optical, into the X-ray region. The ultraviolet part of this spectrum seems adequate to explain the excitation of the gas in the filaments. The gas is distinctly deficient in hydrogen and rich in helium.

Expansion velocities

The radial velocities of the filaments have been explored in some detail. There are large irregularities, but the general speed of expansion is about 1,150 km/sec (710 mi/sec). The corresponding transverse expansion can be measured by comparing photographs taken many years apart; the results strongly suggest that the motion has accelerated somewhat since the explosion, presum-

ably under the influence of the energy emitted by the pulsar.

The Crab, though it has received most study, is not a typical supernova remnant. Several others are known; they show much greater expansion velocities, up to 20,000 km/sec (12,000 mi/sec); naturally, they dissipate much faster and are usually observed as rings or hollow spheres. Much of the optical excitation may be from interaction with the interstellar gas at the advancing front.

Spectroscopy of galaxies. One of the most striking of all spectroscopic results was the discovery of the apparent expansion of the universe, by the U.S. astronomer Edwin P. Hubble. He found the remarkably regular rule that distant galaxies appear to recede faster than those that are near our own system: their spectral lines are shifted towards the red. Hubble's Law states that the velocity of recession is proportional to the distance; it has continued to be confirmed by later work. On such faint objects as galaxies, for most of which only low- or medium-dispersion spectra can be obtained even with very long exposure and large telescopes, Doppler shifts can be measured only because they are so large; a typical spectrum on a blue-sensitive plate is only three millimetres long. The nebular spectrograph is used at the prime focus of the telescope to conserve light.

For the brighter galaxies, it is possible to classify the spectra in much the same way as the spectra of individual, relatively close stars and also to obtain some idea of which kinds of star contribute most to the light. Galactic spectra resemble the spectra of the median type of their component stars and can be simulated by combining the spectra of a number of stellar types. The results depend on the wavelength region used: hot stars have a more important effect on the combined spectrum in the blue, and cool ones in the red. A correlation of the spectrum with the appearance of the galaxy exists. For blue wavelengths, elliptical galaxies tend to have predominantly G- or K-type spectra, indicating that most stars in them are somewhat cooler than the Sun. Irregular galaxies have A-type spectra, considerably hotter than the Sun. Spirals are intermediate, the tightly wound ones having cooler spectra than the loosely wound ones.

The presence of gas in galaxies

The presence of gas is indicated by emission lines, especially the nebular doublet (explained above) of ionized oxygen at 3,727 Å, and lines of hydrogen and ionized nitrogen in the red. The correlation with the type of galaxy resembles that for spectral class: prominent in irregulars and improbable in ellipticals. Gas is associated with young, hot stars because copious amounts of gas are necessary for star formation, and because hot stars make the gas more visible. The situation in the nuclei of galaxies appears to be more complicated, but gas is quite common there.

About two dozen of the type called Seyfert galaxies are known, named for the U.S. astronomer, Carl Seyfert, who first studied them in detail; they exhibit starlike, very bright nuclei, with a high-excitation spectrum of broad emission lines. Turbulent motions of several thousand kilometres per second are implied. Somewhat similar are the N galaxies (nuclear galaxies), some of which have considerable redshifts, and that are usually strong radio sources. The relationship of the two groups to each other is obscure, as is the relation of N galaxies to quasars.

Spectroscopy of quasars. Quasi-stellar objects (QSO's), or quasars, are objects that appear to be point sources of light, like stars, but have large redshifts appropriate to distant galaxies. (See QUASI-STELLAR SOURCES.) In their spectra, emission lines are prominent, as is a continuum with absorption lines. Spectra of these objects can only be obtained with very large telescopes because of their extreme faintness.

The nature of the line spectrum was a mystery for several years, in 1963 when a redshift of 0.158 (the increase of wavelength divided by the original wavelength) was found. Within two years a redshift of 2 had been found, and by 1970 one as large as 2.877. In this last case, the far-ultraviolet Lyman-alpha line of hydrogen is shifted from 1,216 Å to 4,714 Å, in the blue. If interpreted as Doppler shifts, redshifts of 2 and 2.877 correspond to velocities of 80 percent and 87.5 percent of the speed of light. Altogether, lines of ten common elements have been identified, and as far as can be determined the composition is like that of the Sun. Relative intensities differ from quasar to quasar, but these differences could be due to different conditions of excitation. Also, since forbidden lines are seen, densities must sometimes be very low in the regions where the spectrum, or part of it, is formed.

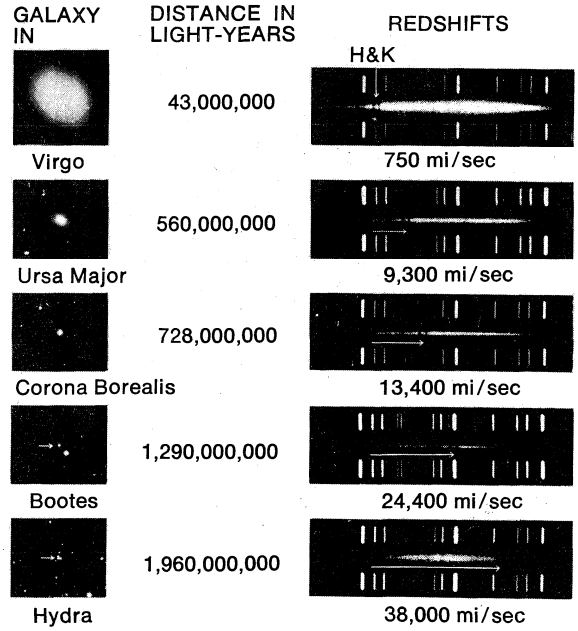

Figure 4: The relation between redshift and distance for five distant galaxies. Redshifts are expressed as velocities, $cd\lambda/\lambda$. Arrows on right indicate shift for calcium lines H and K. One light-year equals about 6 trillion miles, or 6×10^{12} miles.

courtesy of Hale Observatories

Absorption lines are common only in those objects with redshifts approaching or exceeding 2. Most often, the absorption redshift is less than that for the emissions, and in some cases there are two or more redshifts. Unidentified absorptions short of the Lyman-alpha emission are common and may be due to hydrogen at still other shifts, which cannot be verified by correlation with other lines.

Alternative interpretations of redshift

The cause of the redshifts is still undetermined (see QUASI-STELLAR SOURCES). Its interpretation remains one of the fundamental problems of spectroscopy. Among other possibilities, it has been suggested that they are caused by gravitational redshifts, but it is difficult to imagine any so large; also, the narrowness of the spectral lines presents a serious problem because it indicates that they must originate in a uniform region of the gravitational field.

Radio spectroscopy. The most famous spectral line of the radio region is the 21-centimetre (1,420-megahertz—a hertz is a cycle per second) emission of the hydrogen atom. There are two reasons for its importance: hydrogen is the most abundant constituent of the interstellar gas; and the Galaxy is transparent in this wavelength region. Moreover, Doppler shifts and the corresponding radial velocities can be found by a procedure as simple as tuning a radio receiver. The existence of the 21-centimetre line was predicted during World War II and was detected almost simultaneously by three different groups a few years later.

The states involved in the 21-centimetre transition are the so-called hyperfine levels of the ground state. In a hydrogen atom, the magnetic moments of the electron and proton can point either parallel or antiparallel; the latter situation has the lower energy, just as it would for

a pair of bar magnets. But the number of electrons with higher energy—that is, at the upper level—is kept up by thermal collisions; even in the extremely tenuous gases of the interstellar medium such collisions occur once every 400 years. On the average, a radio-frequency photon is emitted by an undisturbed, excited atom every 11,000,000 years: the transition is very infrequent; that is, it is highly "forbidden." Nevertheless, in practice, the line is readily detected in any direction, because there is so much hydrogen and because radio techniques with large antennas are so sensitive.

Mapping the Galaxy

In surveying the Galaxy, the different Doppler shifts of various spiral arms are significant. With the aid of a model of galactic rotation, a detailed map was built up by 1958. Because the Doppler shifts are zero in the directions toward and away from the centre, there are two gaps in the map. The spiral arms can be seen rather well and traced for long distances. In the confused region towards the centre, rapid motions can be discerned; it appears that a ring of gas is moving outwards at about 50 km/sec (30 mi/sec). It was found that about 2 percent of the mass of the Galaxy is in the form of gas. The velocity distribution that was once assumed has been shown to be too simple to fit the real Galaxy. Despite progress in refining the map, a truly satisfactory result has yet to be achieved.

Other galaxies can also be observed, and their general Doppler shifts measured. For the nearest objects, fairly detailed maps have been produced.

Atomic hydrogen also has a rich recombination spectrum in the radio region, as first predicted in 1959. These lines are unobservable in the disturbing environment of the laboratory because they are highly susceptible to atomic collisions. The electronic states of hydrogen are described by a quantum number n, which is 1 for the ground state. Lyman alpha, a well-known ultraviolet hydrogen line, is emitted in a transition from $n = 2$ to $n = 1$; Balmer alpha, or hydrogen alpha ($H\alpha$), in the red, is the 3–2 transition. These lines belong to well-known hydrogen series of lines named after prominent physicists. Radio lines have been observed from 8.2 millimetres (56α, 57–56) to 75 centimetres (253α, 254–253). Jumps of two, three, and four are also found, as are lines of helium and (probably) carbon. The best sources are HII regions, as would be expected for a recombination spectrum. The physical information that can be obtained is similar to that found from optical recombination lines. But the radio lines have the important advantage of needing no corrections for interstellar absorption. A radio continuum is also produced, as in the optical region, by the electrons as they are captured into the high orbits.

Molecular lines are known in the range of wavelengths 2.6 millimetres to 36 centimetres, from ten different molecules; they include water vapour, ammonia, formaldehyde, methyl alcohol (CH_3OH), and some sulfur compounds. For three of them, isotopically substituted forms are also observed. A line at 3.36 millimetres has not been identified. It is common to find emission lines, as well as absorptions against strong sources. The emission lines of OH are notable for their high intensity, small size, and unexpected intensity ratios. The only likely explanation is that stimulated emission is amplifying the radio waves; in other words, an interstellar maser (an acronym for the process: microwave amplification by stimulated emission of radiation) is operating.

BIBLIOGRAPHY. Stellar, nebular, and galactic spectroscopy are thoroughly covered in 5 volumes published in the compendium *Stars and Stellar Systems*, ed. by G.P. KUIPER and B.M. MIDDLEHURST; most relevant volumes are 1, *Telescopes;* 2, *Astronomical Techniques;* 5, *Galactic Structure;* 6, *Stellar Atmospheres;* and 7, *Nebulae and Interstellar Matter*. Astronomy and Astrophysics

Astronomy (Greek *astron*, "star"; *nomos*, "law") is the scientific study of all objects outside the Earth and its immediate environment, including the Moon, Sun, planets, stars, the Galaxy and similar external star systems, interplanetary and interstellar matter, and the universe as a whole. It must be distinguished from astrology, which has no scientific basis. Astrophysics, the study of physical and chemical properties of astronomical objects, is a relatively recent development of 19th- and 20th-century astronomy. The term astronomy is often used to include astrophysics.

Until the 17th century, astronomy was concerned largely with the measurement of the positions and motions of the Sun, Moon, planets, and apparently fixed stars visible to the unaided eye. Then the laws of planetary motion were discovered, the telescope was invented and applied to astronomy, and the laws underlying motion and gravitation were formulated. In the 18th century the first ideas based on extensive observations of the structure of the Galaxy that contains the Earth and of the universe were put forward. The 19th century brought the introduction of two basic techniques, spectroscopy and photography, which led to new and quantitative methods for measuring the quantity and quality of light and enabled physical studies to be made of brightnesses, temperatures, and chemical nature of stars and nebulae. Theoretical analysis of their constitution followed. Such studies, enormously advanced in the 20th century through the development of quantum theory and other branches of physics, are called astrophysics. Astronomy now flourishes as never before; unexpected objects such as quasars and pulsars have been discovered, and there are hopes that answers to problems of the origins of the universe, of chemical elements, of the Earth, and of life may be found.

Limitations of astronomy. Compared with other experimental sciences, astronomy has certain limitations. First, apart from meteorites, the Moon, and the nearer planets, the objects of study are inaccessible and cannot be manipulated, although nature sometimes provides special conditions, such as eclipses and other temporary effects. The astronomer must usually content himself with studying radiation emitted or reflected from celestial bodies.

Second, from the Earth's surface these are viewed through a thick atmosphere that completely absorbs most radiation except within certain "windows," wavelength regions in which the radiation can pass through the atmosphere relatively freely in the optical, near-infrared, and radio bands of the electromagnetic spectrum; and even in these windows the atmosphere has considerable effects.

Effects of the atmosphere on observation

For light these atmospheric effects are as follows: (1) some absorption that dims the radiation somewhat, even in a clear sky; (2) refraction, which causes slight shifts in direction so that the object appears in a slightly different place; (3) scintillation (twinkling); *i.e.*, fluctuations in brightness of effectively pointlike sources such as stars, fluctuations that are, however, averaged out for objects with larger images, such as planets (the ionosphere, an ionized layer high in the atmosphere, and interplanetary medium have similar effects on radio sources); (4) image movement because of atmospheric turbulence ("bad seeing") spreads the image of a tiny point over an angle of nearly one arc second or more on the celestial sphere (one arc second equals $\frac{1}{3,600}°$); and (5) background light from the night sky. The obscuring effects of the atmosphere and its clouds are reduced by placing observing stations on mountains, preferably in desert regions (*e.g.*, southern California and Chile), and away from city lights. The effects are largely eliminated by observing from high-altitude aircraft, balloons, rockets, space probes, and artificial satellites. From stations outside all or most of the atmosphere, gamma rays and X-rays—that is, high-energy radiation at extremely short wavelengths—and far-ultraviolet and far-infrared radiation, all completely absorbed by the atmosphere at ground-level observatories, can be measured. At radio wavelengths between about one centimetre and 20 metres,

the atmosphere (even when cloudy) has little effect, and man-made radio signals are the chief interference.

Third, the Earth is a spinning, shifting, and wobbling platform. Spin on its axis causes alternation of day and night and an apparent rotation of the celestial sphere with stars moving from east to west. Ground-based telescopes use a mounting that makes it possible to neutralize the rotation of the Earth relative to the stars; with an equatorial mounting driven at a proper speed, the direction of the telescope tube can be kept constant for hours while the Earth turns under the mounting. Large radio telescopes usually have vertical and horizontal axes (alt-azimuth mounting), with their pointing continuously controlled by a computer.

Precession and nutation

In addition to the daily spin, there are much more gradual effects, called precession and nutation. Gravitational action of the Sun and Moon on the Earth's equatorial bulge causes the Earth's axis to precess like that of a top or gyroscope, gradually tracing out a circle on the celestial sphere in about 26,000 years, and also to nutate or wobble slightly in a period of 18.6 years. The Earth's rotation and orbital motion provide the basic standard of directions of stars, so that uncertainties in the rate of these motions can lead to quite small but important uncertainties in measurements of stellar movements. Precession and nutation are not important in driving the telescope.

The Earth's movements until recently also provided the basis of time measurement from a fixed meridian (Universal Time, or Greenwich Mean Time). In the mid-20th century extremely accurate time measurements using quartz-crystal and atomic clocks have revealed that the length of the day fluctuates by about a millisecond because of tides, winds, and seasonal variations. Furthermore, records of ancient eclipses and modern observations of the Moon and planets (defining, over a long period, Ephemeris Time based on Newton's laws of motion) have revealed that the average length of the day is slowly increasing by about two milliseconds per century because of tidal friction. Thus, Universal Time (based on the Earth's daily rotation) does not flow quite uniformly, and periodical corrections must be made to relate it to Ephemeris Time (needed for positions of the Sun, Moon, and planets) and to atomic time (adopted as the international standard in 1967). Also, the surface of the Earth is not exactly fixed relative to its axis, so that any one place undergoes variations in latitude up to about 0.5″ of arc (equivalent to 15 metres [50 feet] on the surface) in a period of 428 days.

This article is divided into the following sections:

I. Astronomy

Patronage of astronomical investigation

Astronomy has been carried on from the earliest times by amateurs using their spare time and resources and by professionals working in universities and institutions financed by governments or privately (*e.g.*, by charitable foundations). The governmental tradition goes back to antiquity, when priests and other high officials already were engaged in astronomy to fix the seasons and calendar and to study celestial omens. More recently, kings, noblemen, and popes have patronized the subject for its intellectual interest; the Vatican Observatory (founded 1576; refounded 1888) still makes important contributions to astrophysics. From the 17th century, governmental support for astronomy in many countries, justified by the needs of navigation and timekeeping, led to the establishment of national observatories and nautical almanac offices in several countries. In the second half of the 20th century, governmental involvement has greatly increased, partly in line with a general trend toward the promotion of science and partly because of national interest in the exploration of space: government support in some cases takes the form of research contracts to industrial firms. Despite these developments, amateurs using simple equipment still play an important role; *e.g.*, in observations of variable stars, of the Moon and planets, and of occultations (eclipsing) of stars by the Moon and in tracking artificial satellites by optical and radio methods. In some cases, amateurs working together also use ham-radio communications. One of the most famous amateur contributions was the pioneer radio work by Grote Reber in Illinois in detecting radio signals from the Milky Way, work that was fundamental in establishing the science of radio astronomy in the 1940s.

An important part in the development of astronomy has been played since the early 19th century by national and regional astronomical societies, such as the Royal Astronomical Society in London, the American Astronomical Society, and the German Astronomische Gesellschaft, which sponsor meetings and publications and sometimes organize collaboration in research. The British Astronomical Association, the American Association of Variable Star Observers, and other groups all over the world perform a similar function for amateurs. Astronomy also has a strong tradition of international cooperation, motivated partly by the need to combine observations from different parts of the globe and partly by the sheer magnitude of the amount of data to be collected and processed. In the second half of the 20th century also, groups of countries have combined resources to provide such international facilities as the European Southern Observatory and the Inter-American Observatory, both in Chile. Most international cooperation takes place under the auspices of the International Astronomical Union (IAU), founded in 1919. The IAU has members in 45 countries and organizes meetings, publications, and a telegram service for urgent information relating, for example, to appearances of comets, supernovae (violently exploding stars), and other transient phenomena. Other organizations dispense information on the behaviour of the Sun (sunspot numbers, flares), on the fall of meteorites, and on the appearance of meteoric fireballs. Communications may be by telegram, postcard, or any other convenient means.

International co-operation

International cooperation in space exploration is also beginning. Lunar rock samples were distributed to scientists of many countries following the return of Apollo 11 and later lunar landings. Tracking of the earliest Soviet lunar probes was done at Jodrell Bank, England, in cooperation with the Soviets. When Apollo 13 ran into difficulties, prompt offers of tracking help were received from the U.S.S.R.; and many international payloads have gone up with the space laboratories known as Orbiting Astronomical Observatories. In 1971, discussions on docking between Soviet and United States spacecraft were begun.

METHODS OF STUDY

Equipment. Celestial objects are studied through observations (usually involving measurement) or theoretically (mathematically) and occasionally experimentally (*e.g.*, by radar). Apart from special investigations (*e.g.*, of cosmic rays, lunar rocks, and meteorites), astronomical observations involve the study of electromagnetic radiation; *i.e.*, not only light but longer wavelengths in the infrared, microwave, and radio bands of the spectrum and shorter wavelengths in the ultraviolet, X-ray, and gamma-ray bands. Observations usually involve three basic elements: a telescope acting as a camera or as a collector of radiation; a detector such as the eye, a photographic plate, a photomultiplier, radio receiver, ionization chamber; and measuring machines, chart recorders, counters to translate the signal received into numbers. Also there is generally some means of selecting a definite colour of light, or spectral band (*e.g.*, a light filter or tuned amplifier); or radiation may be spread out into a spectrum and recorded or measured at selected places along it.

For some purposes, it is desirable to use telescopes of

Advantages of large telescopes

large diameter or aperture: (1) to collect as much radiation as possible and (2) to improve the fineness of detail that can be distinguished on the sky. The ability of a single telescope to resolve fine detail is limited, especially at radio wavelengths much longer than those of visible light. Better resolution can be provided by interferometers. In an interferometer two or more often widely separated apertures are used together; this arrangement can give the effect of a much larger telescope.

Types of observational information. The main types of information provided by astronomical observation are the following:

Positional information. This allows location and identification of the object and the study of its motions across the line of sight through gradual changes in its position.

Structural information. The Sun, Moon, planets, and nebulae appear as disks, the angular sizes and structural detail of which can be studied through visual observation, photography, or scanning with a telescope and detector. Also, special interferometric techniques enable apparent angular sizes of some stars and radio sources to be measured down to 0.001″ of arc.

Photometric or radiometric information. The amount, or brightness, of radiation in a particular spectral band is measured by comparing it with that received from other objects or from a laboratory standard. In optical astronomy the brightness of the source is usually expressed in magnitudes. Originally (*e.g.*, in Ptolemy's catalog *c.* AD 140), the brightest stars were said to be of the first magnitude, and the faintest visible to the unaided eye of the sixth. Nowadays, magnitudes (including negative and fractional values) are on an exact logarithmic scale such that an increase of 5 in the magnitude represents a decrease in intensity by a factor of 100. There are now many magnitude systems that describe the brightnesses in different colour bands. To relate each magnitude system to the total energy radiated at all wavelengths requires a bolometric (or total-energy) correction, which depends mainly on temperature.

Spectral information. The spectrum of an object shows how its energy is radiated in the form of electromagnetic waves, the different wavelengths being separated for study—*e.g.*, into the different colours of visible light (X-ray, gamma, and other wavelengths of radiation also produce observable spectra). A star radiates over a wide range of wavelengths, so that a stellar spectrum generally has a continuous background, with the wavelength of maximum energy roughly inversely related to temperature, on which narrow, darker absorption features (or sometimes bright emission features) are superposed that correspond to characteristic radiations of gases; gaseous nebulae and radio and X-ray sources have different types of continuous spectra. By studying spectra and comparing them with those of a laboratory source, it is possible to (1) identify elements and compounds; (2) find the velocity of approach or recession in the line of sight (radial velocity); (3) estimate temperatures, densities, and velocity variations over the surface; and (4) find relative amounts of different elements (see ASTRONOMICAL SPECTROSCOPY, PRINCIPLES OF).

Polarimetric information. Electromagnetic radiation can be thought of as waves of varying lengths, all carrying oscillating electric and magnetic fields in a plane at right angles to the direction of travel. After scattering or when magnetic fields are present, the electric field of the radiation may have a preferential direction (plane polarization) or sweep out a circle (circular polarization), in contrast to ordinary radiation, in which its direction varies at random. Polarization measurements, often combined with spectral analysis, thus give information on the scattering (reflecting) properties of planetary surfaces and on magnetic fields in radio sources, the interstellar medium, the Sun, and certain stars.

COMPONENT DISCIPLINES AND THEIR RELATIONSHIP TO OTHER SCIENCES

Planetary sciences. The Earth, accompanied by a relatively large satellite—the Moon—is one of nine known planets, five others of which are also known to have satellites, which along with innumerable minor bodies orbit around the Sun, mostly close to the plane of the Earth's orbit (the ecliptic). Planets and satellites shine by reflecting sunlight, but they also emit infrared and radio waves because their surface temperatures are above absolute zero (0° K; −273° C; −460° F); Jupiter also emits strong radio bursts from a Jovian magnetosphere; *i.e.*, the region of space surrounding the planet and strongly influenced by its magnetic field. Interplanetary space is filled by an extremely tenuous gas of ions (mostly hydrogen nuclei or protons) and electrons, which is called the solar wind, flowing out at high speed from the solar corona; there is also dust near the ecliptic, which scatters sunlight, causing a faint glow in the sky known as the zodiacal light. Other, relatively small bodies orbiting around the Sun are minor planets (asteroids) and comets. The whole collection of the Sun and matter moving under its gravitational control is called the solar system.

Objects in the solar system

Solar-system objects are studied by (1) measurement of changing positions and orbital analysis giving distances and masses (from gravitational action on satellites and other planets); (2) telescopic measurements to find size, polar flattening, surface features, rotation, and optical properties of surface material; (3) spectroscopy revealing molecules in planetary atmospheres (which impose their own absorption lines on reflected sunlight), radial velocities, and rotation; (4) infrared and radio studies for surface temperatures; (5) radar, giving accurate distances and rotational velocities and revealing solid surface features otherwise hidden by clouds; (6) closeup photographs and physical measurements from space probes (*e.g.*, the U.S. Mariner series for Venus and Mars, and the Soviet Luna and U.S. Ranger, Surveyor, and Lunar Orbiter series for the Moon); (7) landings by automatic-instrumented probes, such as the Soviet Venera series for Venus and Luna series and Lunokhod on the Moon and U.S. Ranger and Surveyor landings on the Moon; and (8) manned landings in the U.S. Apollo series of Moon shots (see SOLAR SYSTEM; MOON; and articles on individual planets).

Planetology. Planetology, the study of the solid parts of the planets of the solar system, as geology is that of the Earth, is a relatively new branch of astronomy. Only in the 1960s did sufficient data become available for any planet other than Earth to raise such studies to the level of an independent discipline. Now, information relayed back from space vehicles and obtained by radar is available for Mercury, Venus, Mars, and the Moon. From this information, temperatures and pressures at the base of the atmosphere (Venus) can be found and the relief of the surface plotted; improved values for the radii, periods of revolution, and other characteristics are also available. Many uncertainties remain, and, in this respect, a projected space journey to be called the Grand Tour, possibly during the late 1970s, would provide many more details, particularly about the outer planets, Jupiter, Saturn, Uranus, and Neptune.

Comparisons between Earth sciences and planetary sciences

The planet best known and most studied is, of course, the Earth. Since about 1960 enough information on the nearer planets and the Moon has become available to make possible some detailed comparisons between Earth and these other bodies. Techniques developed and experience gained in the Earth sciences are being brought to bear on studies of the other planets.

The study of planetary atmospheres. The study of planetary atmospheres is concerned with their wind and circulation patterns (governed by the temperature difference from Pole to Equator and the planet's rotation); their temperature and pressure structure (of which something has been learned by observing occasional occultations of stars when a planet such as Venus, Mars, or Jupiter passes in front of them and more by means of space probes to Mars and Venus); and the chemical nature of the atmosphere and its origin; *i.e.*, whether primary (as may be the case with Jupiter) or secondary. Secondary atmospheres are exuded from rocks and afterward modified by solar radiation and, in the case of the Earth, photosynthesis; the atmospheres of the inner or

terrestrial planets seem to be secondary. The smaller, warmer bodies such as Mercury, the Moon, and the minor planets have lost any atmosphere they had, because the average speeds of atmospheric molecules exceed that required to escape from the planet's gravitational attraction. Atmospheres enhance planetary temperatures by the greenhouse effect, whereby the atmosphere like a glass roof lets in sunlight but prevents heat energy created by the sunlight from escaping. This seems to be especially strong on Venus, where carbon dioxide lets in visible sunlight but holds back infrared radiation. Some forms of life could be present on Venus and Mars, but there is no firm evidence for it.

Meteoritics. During its journey around the Sun, the Earth may encounter bodies ranging from tiny specks of dust to minor planets the size of mountains. The smaller bodies, with masses up to about one gram (0.04 ounce), are called meteoroids and are believed to be debris of extinct comets. They are vaporized by friction at about 100 kilometres (60 miles) altitude, leaving behind them shining trails of glowing gas that are seen as meteors (shooting stars or falling stars) and reflect radar waves. About 20 percent of them belong to streams or showers approaching from a definite direction (through perspective effects they appear to diverge from a point of the sky called the radiant) and are encountered annually on orbits that can be identified with those of former comets. Much smaller specks (micrometeorites) are not vaporized and simply fall to the ground. More rarely, larger bodies weighing tens of kilograms come down to about ten kilometres (six miles) height and break up, sometimes with an audible explosion, producing a very bright fireball, or bolide, while still larger bodies crash to the ground as one or more meteorites. These are not associated with meteor streams but come in on orbits suggesting an origin in the belt of minor planets. Round craters up to 40 kilometres (25 miles) across are attributed to falls of meteorites weighing more than 1,000 tons. Special kinds of rounded glassy objects found in certain areas and known as tektites may or may not be of extraterrestrial origin.

The study of meteorites. Meteorites are samples of extraterrestrial material containing vital clues to the chemical composition of the universe and the early history of the solar system. Most are stones or irons. Iron meteorites (alloys of iron with nickel and other elements) may have been formed in the interior of a former planet about 300 kilometres (about 200 miles) in diameter. Stony meteorites are subdivided into two main classes: chondrites (containing droplike inclusions called chondrules) and achondrites (like terrestrial igneous rocks). Chondrites seem to be a fair sample of the raw material of the solar system, in contrast to terrestrial or lunar rocks, which have been more differentiated by melting. Like other pieces of rock or iron, meteorites can be studied using the methods, principles, and techniques of petrology, radioactive dating, and other branches of geophysics and geochemistry. It is of interest to find evidence of shock (shattering), and the texture and composition of a meteorite give clues to its history (see METEORITE).

Petrology and other branches of geosciences as part of meteoritics

The study of meteors. Meteors can be best studied by positional measurements based on both optical and radar observations, by statistics, and, where possible, from their spectra. The last measurements are difficult to obtain because of the sporadic nature of meteors, but a large number of good spectra are now available (see METEOR).

The study of comets and minor planets. Comets are members of the solar system. About 20 per year approach close enough to the Sun to become visible for some months before receding again along highly elongated orbits. Typically, a comet has a small nucleus (not always visible) surrounded by a diffuse coma (Latin: "hair") of dust and gas merging into an immense tail or tails pointing away from the Sun.

Comets, like stars, can be studied for their position and, through their spectra, for their chemistry. Using three position measurements, a preliminary orbit (path in space) can be found; this can then be improved by further observations, if available. Many comets are now known to be periodic; that is, they return and are seen again on roughly the same path a second time or more. The recovery of periodic comets is an important field of cometary study. The origin of comets is rather obscure, but most have such immense periods that they seem to be coming in for the first time. Comets may be occasionally pulled in toward the Sun by gravitational action of passing stars. They could then be frequently captured into the inner part of the solar system by gravitational action of planets, especially Jupiter, whereafter they gradually disintegrate.

The distances of successive planets from the Sun form a fairly regular progression, but until 1800 there was an apparent gap between Mars and Jupiter that is now known to be occupied by a large number of tiny bodies called minor planets, or asteroids, distinguished from comets by their small sharp, starlike images. The study of asteroids occupies astronomers at several large observatories full time. Positions, brightness, and light polarization are all monitored regularly; recovery and identification programs are important, and, because there are now more than 1,700 numbered minor planets, statistical programs are important also (see COMET; PLANET, MINOR).

Lunar sciences. Generally thought of as a satellite of the Earth, the Moon is more like a sister planet because it has a far larger mass (about 1/81 the Earth's mass) in comparison with Earth than other satellites in comparison with their central planet (usually less than 1/1,000). The Moon was observed in the 17th century through one of the first telescopes by Galileo, who named the darker, often circular areas maria ("seas"), although there is no surface water on the Moon.

The name of the Greek moon goddess was Selene. Hence, properly, studies of lunar formations, structure, composition, and so on are called selenography, selenology, and so on. By popular usage, especially in the United States, terms such as astrogeology have become accepted as alternatives.

Lunar photographs and rock samples

Because the Moon is the nearest planetary body in space, it has been the target of many space probes. Many high-quality photographs have been taken from vehicles in orbit around the Moon and by men standing on its surface. Lunar-rock samples have been distributed to hundreds of investigators since 1969, and the laboratory techniques of many disciplines have been brought to bear on them. Many of the traditional beliefs have been swept away in consequence, and lunar science has become a fast-moving field for many scientists other than astronomers. This area can use to real advantage the pooling of many branches of knowledge—chemistry, petrology, geology, and statistics, for example (see MOON).

The amount of new lunar data of the geochemical and geophysical type obtainable from the lunar rocks is immense. Tidally triggered moonquakes have been recorded, and the apparent escapes of gas and dust from within the Moon previously recorded by observers and ignored for years now seem to be real.

Lunar-motion studies

The motion of the Moon is not a simple ellipse around the common Earth–Moon gravity centre, because many factors continuously alter the shape of the orbit slightly; the most important of these are the presence of the Sun and the slight bulges (departures from sphericity) on both the Earth and the Moon. The resulting complexities provided 19th- and early-20th-century astronomer-mathematicians with difficult problems in celestial mechanics. These problems are approached by a method in which a first, very approximate solution is improved upon by taking account successively of as many small differences as seem necessary. Modern work of this kind is done by computer, the work that formerly would have taken a lifetime requiring a few seconds or minutes of computer operation. The results, however, are still approximations; and, though they can now be brought to within seconds and feet of the true (instantaneous) value, they cannot be relied on beyond a certain calculable length of time and, as before, will need continual revision.

The Moon raises tides on the Earth by attracting the nearer parts more strongly than the farther parts (see TIDES). An indirect effect is a very gradual increase in the average lengths of the day and lunar month.

Special types of information may be obtained during times of eclipse. Eclipses of the Moon occur when the Full Moon passes through the Earth's shadow, and eclipses of the Sun when the shadow of the New Moon covers part of the Earth's surface. Eclipses occur only a few times per year, when the Moon (which moves in a plane that is inclined at an angle to that of the Earth's orbit around the Sun) happens to be close enough to the Earth's orbital plane (hence called the ecliptic) at its new or full phase so that all three bodies are in line. By a fortunate coincidence, the Moon has the right size and distance to cover the brilliant photospheric disk of the Sun almost exactly, so that a total solar eclipse, in good weather, may provide many excellent opportunities to obtain data on the outer layers of the Sun, otherwise very difficult to get. These and other eclipse projects are more fully discussed in ECLIPSE, OCCULTATION, AND TRANSIT.

The study of the origin of the solar system. The origin of the solar system is bound up with the origin of stars, galaxies, and the universe itself and thus forms part of cosmogony, the study of the origin and development of the universe, and any theory concerning it must be compatible with all the evidence from the individual members.

Many factors do not fit comfortably into such schemes as are at present under consideration, and there are numerous uncertainties. Many single stars, like the Sun, may have planetary systems, though observational evidence is scanty; sinuous motions of a few nearby stars imply that they have Jupiter-sized companions but with more elliptical orbits.

Evidence from very young, still contracting, variable stars of the T Tauri type (named for their prototype in the constellation Taurus) is thought to be important in understanding the early stages. Theories of the origin of the solar system, however, still contain a large element of speculation.

INVESTIGATION OF THE SCALE OF THE UNIVERSE AND OF THE DISTRIBUTION OF OBJECTS WITHIN IT

The determination of positions. Space stretches indefinitely around the observer in all directions, so that he seems to be in the centre of a sphere—the celestial sphere—on which the stars are seen. Brighter objects have been given names as members of groups called constellations; otherwise they are designated by numbers in catalogs or by coordinates. Three important reference planes are projected as great circles on the celestial sphere; those of the equator (defined by the Earth's Equator), the ecliptic (in which Earth orbits around the Sun), and the Milky Way (or galactic equator), near which most remote stars and clouds of interstellar matter are situated. To each of these planes there corresponds a north and a south pole, along the axis or line perpendicular to that plane. Positional astronomy is concerned with determining the directions of celestial bodies, which can also be looked upon as coordinates on the celestial sphere (similar to latitude and longitude on the Earth's surface).

Reference planes

Most stellar positions are measured on photographs using offsets from "reference" stars observed at the meridian. Radio source positions are found using interferometers or by observing occultations by the Moon. Positions of X-ray sources observed from rockets and satellites raise special problems both of orientation and of achieving fine resolution on the sky because of the problem of relating the rocket position to those of known stars, the X-ray images of which may bear little relation to the familiar optical ones. Space vehicles either roll, bringing different portions of the sky successively within the field of view of instruments on board, or are stabilized by inertial guidance from gyroscopes that provide a platform against which instruments can be moved to sweep around the sky or to slew to a given object through a preset angle; directions are monitored using instruments for measuring magnetic fields, star cameras, and photoelectric star trackers.

One of the oldest applications of positional astronomy is in navigation. The sailor, airman, or astronaut measures the altitude (angle) of a celestial object above the horizon with a sextant, thus establishing (with the aid of tables and chronometers checked by radio time signals) one position line that is a small circle on the Earth's surface. Observation of a second object (or of the same one after travelling at known velocity for a known time) defines a second circle intersecting the first. Large ships now carry automatic star trackers and computers giving a continuous record of position, and star-tracking methods are widely used, even in space travel, despite the increasing development of radio beacons. Manned and unmanned space vehicles are continuously tracked from the ground by optical, radio, and radar methods aided by highly sophisticated dead reckoning, with orbital data continuously updated in a computer.

Applications in navigation

Stars have proper motions—that is, they move across the sky at a slow, individual rate; over years their relative positions gradually change, occasionally by several seconds of arc per year. Stellar motions, studied statistically, are of great value in studying stellar distances and orbits around the centre of the Galaxy. Remote stars have proper motions that are small and hard to measure, but their very smallness can be a useful sign of great distance. Superimposed on the proper motions, which carry the stars uniformly in straight lines, each of the very nearest stars has a small measurable annual oscillation caused by parallax (*i.e.*, by being seen from different points in the Earth's orbit during the year) and sometimes an additional oscillation caused by orbital motion around the centre of gravity of a binary system (two stars in orbit around each other), giving information on stellar masses.

The measurement of distances. Just as distances on the Earth can be related from local measurements (inches and feet or centimetres and metres) through steps of progressively larger dimensions to continental and larger lengths, so have the dimensions of the Earth and planets to be related to the solar system, the nearer stars, the Galaxy, and beyond. At each stage there are yardsticks that can be used to measure distances over a certain range. Among the problems facing astronomers in dealing with the structure of the universe (cosmology) is that of relating the various scales of distance in a way that is reasonably reliable; this is discussed below. A second problem of concern to cosmologists is whether the characteristics of space-time, formerly taken for granted as Euclidean (*i.e.*, conforming to commonsense notions of geometry), are unchanged at the enormous distances of the fainter external galaxies.

Problem of space-time

The measurement of distances within the solar system. The oldest method of measuring distances is that of triangulation—constructing a triangle from a measured base line and two measured angles. The size of the Earth in terms of the current units of distance and the distance of the Moon were thus found with reasonable accuracy already in ancient times. Once the laws of planetary motion were known, it became an easy matter to find relative distances of planets in astronomical units, the astronomical unit being essentially the mean distance between the Earth and the Sun; the problem that then remained was to measure the astronomical unit itself in terms of local units, such as miles or kilometres. This was achieved to an accuracy of about one part in 1,000 by observing suitable planets (*e.g.*, Venus in transit across the Sun and asteroid Eros at its passage within 26,000,000 kilometres [16,000,000 miles] of the Earth in 1931) from widely separated points on the Earth's surface. Similar accuracy was achieved by exploiting two effects of the Earth's orbital motion combined with the finite speed of light—aberration (an annual shift in stellar positions caused by the fact that the Earth's motion tilts the direction from which light is received slightly forward, like raindrops falling on the windshield of a moving car) and an annual variation of up to 60 kilometres per second (134,000

miles per hour) in the radial velocities of suitably placed stars—and by calculating planetary perturbations of the orbits of Eros and certain space probes.

Use of radar for distance measurements

Guidance of planetary space probes demands much higher accuracy, which is provided by radar measurements. Pulses from a powerful transmitter are beamed to a planet, reflected waves are collected by a large radio "dish," and the time delay (light time for the double journey) is very accurately measured. The beaming of continuous waves of well-defined frequency gives an alternative answer (and other information, such as rotation speed) by measuring relative velocities deduced from the change in frequency that is measured. Radar measurements have been carried out on targets including the Moon, the Sun, and the planets out to Saturn. From measurements with Venus since 1961 the astronomical unit has been found to a precision of about 100 kilometres (limited by knowledge of the speed of light) and is close to 149,597,900 kilometres (92,975,699 miles). Time-delay measurements also give a very accurate test of Einstein's general theory of relativity. An analogous experiment with laser beams, an optical analogue of radar, reflected from the Moon is expected to give additional precise information, this time about the Earth also; *e.g.*, on minute shifts of the continents.

The measurement of distances beyond the solar system. Relatively few stars are sufficiently nearby to show a small annual shift in direction relative to more distant stars because of the different positions taken up by the Earth in its orbit around the Sun. Measurements on suitably timed photographs give the annual parallax, defined as the angle subtended at the star by the mean radius of the Earth's orbit. The usual unit of distance is the parsec (pc), the distance corresponding to a parallax of 1″ of arc and equal to 206,265 astronomical units, 3.086×10^{13} kilometres, or 3.26 light-years; one light-year is the distance covered in a year by light travelling at about 300,000 kilometres (186,000 miles) per second. The nearest star (Proxima Centauri) is 1.3 parsecs, or 4.26 light-years, away. Another direct method of finding distances is based on moving clusters of stars, such as the Hyades (40 parsecs away). Methods of determining even greater distances are described in the article PARALLAX, ASTRONOMICAL.

Very large astronomical distances can be found by measuring magnitudes of suitable "beacons" with characteristics that enable them to be identified with nearer objects whose luminosities have been determined from distances found directly. In this way one can fit together overlapping distance scales for progressively more and more distant objects, such as stars, gas in the spiral arms of the Galaxy, distant star systems known as external galaxies, and even the strange objects known as quasars, though there the distances are not universally accepted as reliable. In general, however, considerable confidence can be placed in distance estimates, especially where more than one method is available for comparison of results.

ORBIT THEORY

Mathematical basis of celestial mechanics

The mathematical basis of celestial mechanics is the solution of equations of motion for bodies (planets, stars, galaxies, and so on) moving under the gravitational attraction of others. It was developed in classical form by the English mathematician, physicist, and astronomer Sir Isaac Newton in the 17th century and his successors, starting from the empirical laws of planetary motion that had been discovered by the German astronomer Johannes Kepler. The classical theory is still sufficient for most purposes, but occasionally modifications are required to explain the observations and can be worked out according to Einstein's theory of general relativity.

The two-body problem. The simplest case is that of the two-body problem, in which two effectively point-like masses move in orbits around their mutual centre of mass, or barycentre. Newton showed that the curve traced out is always a conic section: a circle or an ellipse if the relative speed is too small for one body to escape; otherwise a parabola or hyperbola, both of which are smooth, open-ended curves.

Practical considerations. The mutual orbits of two bodies are seldom quite as simple as this because they can be represented as points only if they are symmetrical in all respects, and real planets and other bodies are not. Small corrections must be introduced, and, from the observations of slight differences, planetary characteristics, such as the equatorial bulge of the Earth, can be worked out.

Elements of an orbit

An orbit is defined by six constants, or elements: the period, or major axis, of the ellipse, the eccentricity (degree of departure from a circle), the direction of the major axis in the plane of the orbit, the time of perihelion or periastron passage (when the two bodies are closest together), and two numbers giving the orientation of the orbital plane in space. Elements are constant in the simple two-body case, but they change with time when more masses are present, when one has a slightly nonspherical shape, or when there is a resisting medium. Resistance by the atmosphere and the effect of polar flattening of the Earth change the paths of artificial satellites: polar flattening causes precession of the orbital plane and of the orbit within it, and air resistance causes the satellite to lose energy and height but to gain speed. Such problems cannot be solved, as the two-body case can, in an exact formula; but solutions can be found to a high degree of approximation using modern computers to solve equations of motion by numerical methods. These numerical solutions are valid for only a limited time, say about 1,000,000 years for the planets, because even tiny errors introduced by approximations build up with time; and so it cannot yet be said definitely that the solar system is secularly stable—that is, will remain in much the same form for as long as can be imagined—or, put another way, that planetary-orbital elements will remain the same apart from small oscillations, though it is very likely that this is so.

Another application of orbit theory is to the rotation of galaxies (including the Earth's) in which every star orbits in the collective gravitational field of other stars. Spectral observations of stars and gas clouds in the Earth's and other spiral galaxies show how the speed of rotation varies with distance from the centre and enable the distribution of density and an estimate of the total mass to be deduced. Elliptical galaxies and clusters of galaxies present a more complicated problem, but masses for them can still be found by statistical arguments. Application of present methods to clusters of galaxies gives surprisingly large values of mass compared with the observed luminosity (see GALAXIES, EXTERNAL).

II. Astrophysics

THE STUDY OF THE STARS

Astrophysics, literally the "physics of the stars," is concerned with the processes of physical nature and with evolution in all cosmic objects and is closely related to atomic and nuclear physics, thermodynamics, spectroscopy, plasma physics, solid-state physics, and other fields. Theoretical astrophysics interprets the observations and also uses mathematical methods to solve the equations that describe the physical conditions. It is therefore necessary to study the evidence from stars, interstellar gas, galaxies, and other bodies with the aim of applying laws discovered in the laboratory to the interpretation of the evidence. The most detailed physical evidence from distant bright objects is obtained when the light can be spread out into a spectrum.

The study of stellar structure. Most observable stars are giants (of large radius) or dwarfs, such as the Sun, with average densities of about 0.01 and one gram per cubic centimetre (about that of water), respectively; white dwarfs, such as the companion of Sirius, with about the mass of the Sun, have higher surface temperature but very low luminosity and, correspondingly, a radius like that of the Earth and a density of a ton per cubic inch—about 60 kilograms per cubic centimetre. All these stars are nevertheless gaseous throughout (because atoms in them are stripped of almost all their electrons and are reduced to nuclei taking up very little space) and, indeed, except for white dwarfs, behave like perfect gases. White

dwarfs show a special kind of behaviour (explained by quantum theory) called electron degeneracy, with much higher pressures than in a perfect gas. Neutron stars (probably observed as pulsars) represent a still higher state of compression in which electrons have been crushed onto protons to form a degenerate neutron gas.

The problem of the internal structures of stars

A star is a more or less spherical globe of gas kept in a steady state over long times by the interplay of two opposing forces: gravitational pull of its separate parts on one another and an outward force caused by the increase of pressure inward. Its internal structure is thus a problem in thermodynamics and atomic physics. To maintain the central pressure, the gas must have a high central temperature, about 15,000,000° C (27,000,000° F) for a star with the mass (2×10^{33} grams) and radius (700,000 kilometres [435,000 miles]) of the Sun. Such hot matter necessarily radiates energy, which trickles outward through successive layers of the star and is eventually radiated away as light and heat from the surface. This process leads to a relationship between masses and luminosities of stars (radius having only a minor effect), the luminosity increasing very rapidly with the mass; most stars have masses between 0.1 and ten times that of the Sun, but their luminosities differ over a range of more than 1,000,000.

Radiation causes a steady loss of energy. Degenerate stars can slowly cool down, but ordinary stars cannot, because loss of heat energy leads to contraction and a rise in temperature. Stars must either gradually contract or derive energy from some other source now identified as thermonuclear reactions, causing fusion of light atomic nuclei (mainly hydrogen nuclei or protons) into heavier ones (mainly helium nuclei or α-particles). At the high temperatures in central regions of stars, a few protons move fast enough to circumvent the electrical repulsion exerted on them by other protons or heavier nuclei and stick to them by virtue of short-range nuclear forces. Thus, when hydrogen is gradually transformed into helium, enough energy is made available to enable the Sun to shine at its present rate for about 10,000,000,000 years.

From nuclear physics one may predict how the rate of nuclear reactions depends on physical conditions (chiefly temperature), and atomic theory predicts the rate at which radiation will be absorbed by matter on its way out through the star. Using the appropriate initial chemical composition (typically about 73 percent by mass of hydrogen, 25 percent helium, and 2 percent heavier elements), it is possible to calculate a theoretical model of the internal structure of a stable homogeneous star in which all features are fixed by choosing the total mass.

Stellar evolution

The theory of stellar evolution is concerned with how stars reach this phase by gravitational contraction and what happens afterward as hydrogen begins to be used up in the central regions. The lifetime of a star depends on the rate at which this happens: massive, very luminous stars use up their hydrogen in only about 1,000,000 years, whereas smaller stars, such as the Sun, are more thrifty and can have survived during the age of the Galaxy. Hydrogen is gradually burned to make helium, the core contracts, and the process continues until it becomes so hot and dense that helium itself is ignited to form carbon or oxygen. Contraction of the core is then halted, and the star assumes a complicated structure with two nuclear burning zones. It is probably at this stage that many stars become pulsating variables because of effects occurring in their envelopes while they evolve through a narrow instability strip in the Hertzsprung–Russell diagram, which illustrates the relationship between stellar luminosity and surface temperature. A greater understanding of these problems has been obtained in recent years by detailed numerical calculations using fast computers.

Later stages of stellar evolution have been worked out in rough outline only. The star is expected to become (1) a hot white dwarf (see above), possibly after blowing off its envelope as a planetary nebula; the white dwarf then slowly cools; (2) a neutron star (neither a white dwarf nor a neutron star can have a mass exceeding a certain limit that is not very different from the Sun's mass); (3) a greater mass that will either blow up or simply go on contracting until, in accordance with general relativity theory, it becomes a "black hole" or "collapsar," which can influence its surroundings by gravitational action only. No light or radiation can be received from it at such a stage. Massive stars in any case reach a more advanced state of nuclear evolution, involving successive ignition of heavier nuclei at their centres (see CHEMICAL ELEMENTS, ORIGIN OF). Much of the outer layers may consequently be ejected in an explosion that can be identified with one kind of supernova outburst, leaving a residue at the centre that may become a pulsar. Heavy elements from carbon upward, synthesized in the explosion, may be scattered into the general interstellar medium, gradually enriching the latter in heavy elements that can then be incorporated in later generations of stars; most heavy elements in the universe could have been produced in this way. Supernovae are probably also the main source of cosmic rays.

Outer layers of stars

While the size and total luminosity of a star are governed mainly by its internal constitution, the distribution of radiation over the spectrum depends on the structure of its outer layers, or "atmosphere"—a relatively thin skin from which radiation escapes into space and which contains the only part of the star that is visible. To drive radiation out requires an increase of temperature inward. The region emitting most of the radiation is called the photosphere, and details of the spectrum depend on how the opacity varies with wavelength. The study of stellar atmospheres forms another branch of astrophysics.

The study of stellar atmospheres. Much is learned about stars from their spectra. Measurement of the continuous bright background, or continuum, affords a way of discovering the surface temperatures. It is formed by processes in which radiation is emitted and absorbed in stellar atmospheres: in hotter stars chiefly by the interaction between electrons and protons and in cooler stars by that between electrons and ordinary hydrogen atoms. Superimposed on the continuum are narrow spectral lines (usually dark, caused by absorption by cooler atoms) characteristic of atoms, ions, and molecules that can be identified (and their radial velocities measured) by comparison with lines at similar wavelengths in laboratory sources. Spectral lines also give information on the chemical composition, temperature, and amount of turbulent motion within the star, the star's speed of motion toward the observer or away from him, rotation, progressive changes in novae, and so on. Some stars are spectroscopic binaries showing a periodic shifting or doubling of lines caused by orbital motion; sometimes the components also eclipse each other (*e.g.*, Algol), in which case a great deal of information about mass, radius, and luminosity can be deduced; but very close binaries, such as β Lyrae, are found to be distorted by tidal interaction. Bright lines occur in many stellar spectra, often because an extended gaseous envelope is present.

Finer gradations in the spectrum show differences in pressure caused by differing surface gravity, both being lower in stars of high luminosity; this observation is helpful in estimating absolute magnitudes and, hence, distances. Many of the cooler stars also have two emission lines that are caused by ionized calcium and arise in the outer (chromospheric) layers; their width increases regularly with luminosity, and their intensity in main-sequence stars is inversely related to age, so that deductions regarding age can be made.

Unusual atmospheric compositions in stars

Most nearby stars have about the same atmospheric composition as the Sun, but the spectra of some show composition that may be caused either by the star's own nuclear evolution—a few show the relatively short-lived radioactive element technetium—or by loss of the outer envelope, with consequent exposure of the helium-rich core, or the stars may have been formed long ago before the interstellar medium had been much enriched in heavy elements and hence are very deficient in metals. Some slowly rotating stars, some of which have unusually strong magnetic fields, show extraordinary chemical compositions not easily explained.

The Sun is a quite average star, but it can be studied in great detail and provides an excellent standard to compare with other stars.

An important minority of stars are intrinsically variable, and these are important indicators of distance and stellar population because they are easily identified. The main classes of variable stars are pulsating, irregular, and cataclysmic. They can be readily distinguished by their spectra and light variation.

The study of supernovae. Supernovae are rare and violent, being as bright at maximum as a whole galaxy (say, 10,000,000,000 times the Sun's luminosity) and expending so much energy that the whole star must be disrupted. They are often seen in external galaxies, where they occur perhaps a few times per galaxy per century. Two main types have somewhat different light variations and spectral characteristics. Both expel material at thousands of kilometres per second, and one type may supply heavy elements to the interstellar medium, though there is no direct observational evidence for this. The turbulent Crab Nebula is a radio and X-ray source within the Galaxy, and the nebula and the pulsar discovered in it in 1968 are remnants of a supernova seen in AD 1054. The Crab pulsar is unique in having been detected in light and X-rays as well as in radio waves; a second pulsar, in the constellation Vela, is also located in a recognizable supernova remnant.

THE STUDY OF GALAXIES AND THE UNIVERSE

The study of interstellar material. Rarefied material, such as dust and gas, in interstellar space has important effects because of the vast dimensions of the space in which it is present. Its study depends much on systems of trial and error, because neither the rarefaction nor the extent of space can be reproduced in a laboratory. Studies of complex organic molecules have led to identification of some of these substances in the gas. The exact nature of the dust is uncertain, but it consists of minute grains that may contain ices, graphite, silicates, and more complex organic molecules.

The gas is distributed in the galactic disk, mainly in the form of vast clouds with a few atoms (chiefly hydrogen) per cubic centimetre, which produce sharp interstellar absorption lines in the spectra of remote, hot stars. In the immediate neighbourhood of such stars, the gas glows, especially in light of the red hydrogen line Hα, because stellar ultraviolet radiation ionizes the atoms by stripping off electrons, which are then recaptured with radiation of energy. Such ionized hydrogen clouds are called H II regions, some of which are seen as diffuse nebulae, such as the Orion Nebula. Planetary nebulae emit bright lines by a similar mechanism, but these are smaller, nearly spherical shells expanding from a hot, central contracting old star, whereas diffuse nebulae surround several young stars newly born from them. By studying such useful special regions, a large amount of data about the gas has been gradually built up.

Much has been learned about interstellar gas from radio observations. H II regions emit thermal noise because of the electrical interaction of protons and electrons, but there is general background radio noise from the Milky Way, the continuous spectrum of which indicates a wholly different, nonthermal origin. This noise is synchrotron radiation caused by relativistic (*i.e.*, enormously energetic) electrons spiralling in the magnetic field of the Galaxy at speeds close to that of light. Discrete radio sources within the Galaxy are (1) supernova remnants emitting synchrotron radiation, (2) H II regions and planetary nebulae, or (3) pulsars (discovered in 1967), which emit a short, sharp pulse at very regular but sometimes gradually increasing intervals between 0.03 and two seconds and seem to be rapidly spinning neutron stars with enormous magnetic fields left over after supernova outbursts.

Many spectral lines caused by interstellar gas have been discovered by optical, ultraviolet, and radio observations. Most extensively studied is the 21-centimetre line, produced in ordinary hydrogen atoms. Lines at similar or shorter radio wavelengths are caused by changes in the energy states of various interstellar atoms and molecules, most of which involve some kind of maser action. In a maser the distribution of atoms or molecules among their different possible energy states is maintained at a very different level from that corresponding to thermal equilibrium; this condition makes certain emission sources extraordinarily intense. The unexpected discovery of complex organic molecules in space may shed new light on the question of the origin of life; thus, new discoveries in physics have again been useful in furthering the progress of astrophysics.

Organic molecules in space

Optical spectra of most external galaxies seem to be blends of stellar spectra with a few emission lines from H II regions. Some galaxies, however, have bright star-like nuclei for which the spectrum has a nonstellar continuous background of variable brightness and shows broad emission lines typical of those from a hot, turbulent gas; many of these galaxies have been found to be strong radio, infrared, and X-ray sources, as are certain other extragalactic objects. Many of the radio sources have now been identified optically and fall into two main classes: extended radio galaxies with a peculiar but recognizable optical galaxy at the centre of a double radio source; and quasi-stellar sources or quasars that resemble stars on direct photographs but have emission-line spectra with enormous red shifts (wavelengths up to four times the laboratory wavelength). If these red shifts are of cosmological origin, as for ordinary and radio galaxies, then they indicate enormous distances and hence luminosities. Among other difficulties still unresolved are the following. The total energy stored in relativistic particles and magnetic fields of extended radio galaxies is enormous, a fair fraction of the whole store of nuclear energy in stars of a normal galaxy; quasars are smaller but raise problems of enormous luminosity generated in small volume. Possible sources of gravitational energy on a sufficiently lavish scale might be superstars with perhaps 100,000,000 times the mass of the Sun, disappearance of galactic matter into a central general relativistic singularity or black hole, and a compact cluster of supernovae and neutron stars. A natural scheme of evolution would be for quasars to expand into an extended radio galaxy, perhaps repeatedly.

These problems in high-energy astrophysics have been intensified by infrared, X-ray, and gamma-ray measurements. Many objects in the Galaxy are strong infrared sources at ten to 20 microns' wavelength; these are believed to be newly formed stars surrounded by a "cocoon" of dust, red giants seen through intense obscuration, or compact H II regions containing dust that absorbs ultraviolet and reradiates in the infrared. Some galaxies and certain quasars have a still more dramatic excess of infrared radiation. The Earth's Galaxy and the Andromeda Nebula (Messier 31 [M31]) have compact nuclei that are also quite strong radio and infrared sources, indicating perhaps a quasar-like phenomenon on a much smaller scale.

Enormous energies are also emitted by some objects in the form of X-rays. Galactic X-ray sources are distributed around the Milky Way in the same manner as novae and planetary nebulae, concentrated toward the plane and central bulge. They include objects resembling old novae, the Crab Nebula and its pulsar, and some pulsating sources whose identity is not yet clear. Strong X-rays have also been detected from radio galaxies and others. Finally, there is an X-ray background coming from all directions and caused perhaps by remote quasars and radio galaxies (see X-RAY SOURCES, ASTRONOMICAL).

Cosmic rays

Another phenomenon of astrophysical importance is the presence of the primary cosmic rays; these are relativistic particles (mostly protons) that are believed to contribute about the same amount to the energy stored in the galactic disk (and exert about the same pressure) as do the interstellar magnetic field, turbulent motions of gas, and the cosmic background radiation. They cannot be directly traced to their sources as electromagnetic radiation can, because, being electrically charged, they must spiral around the lines of force of interstellar, interplanetary, and terrestrial magnetic fields. Two astrophysically im-

portant characteristics of cosmic rays are the relative numbers with different energies (energy spectrum) and the chemical composition (or charge and mass distribution). Cosmic rays include some electrons (and a few positrons), and their energy spectrum is of the right kind to explain the spectra of nonthermal radio sources, strengthening the view that the rays originate largely in supernovae. Their chemical composition differs somewhat from that of ordinary material, and the implications of this fact are discussed in the article COSMIC RAYS.

The study of galactic structure and evolution. A galaxy is a large system of stars, dust, and gas; examples are the Earth's Galaxy, of which the Milky Way is part, the two nearby Magellanic Clouds, and the Andromeda Nebula (M31). Most galaxies belong to one of three main structural types: flat spirals with a central bulge, such as the Earth's Galaxy and M31; elliptical galaxies; and irregular systems. In the older literature, external galaxies were often referred to as extragalactic nebulae. The flat disk of spirals, seen projected on the sky as the Milky Way in the case of the Earth's Galaxy, is caused by rotation; the Sun will take about 200,000,000 years to complete one revolution around the galactic centre. Most galaxies are assembled in huge groups or clusters containing tens or hundreds of galaxies.

Knowledge of the Galaxy and of other systems of similar size—the external galaxies—is pieced together from optical data referring to nearby and more distant stars, studies of interstellar dust and gas, radio observations of the gas—at 21 centimetres, the wavelength of a hydrogen atomic transition—and of supernova remnants and other radio sources at other wavelengths. Statistical studies of stellar types and the motions of the stars in painfully limited regions were for many years the only methods of approach to the problem of determining the structure. Now, increasing use of large telescopes has opened up possibilities of direct extension of accurate observations to much greater distances and has also afforded increased possibilities of comparison of the Earth's Galaxy with external systems that can be seen as a whole, yet studied area by area, sometimes star by star, in great detail.

Since 1951, radio studies of the Galaxy have added further evidence; in particular, the radio emission line of atomic hydrogen at 21-centimetre wavelength has been observed in regions of the Milky Way. Because this emission is not absorbed in interstellar space, its measurements provide information of galactic structure out to and beyond the distance of the galactic centre (about 10,000 parsecs). Ideas on spiral structure in these regions can be compared with optical observations of objects in the nearer spiral arms and comparisons traced out from a combination of painstakingly accumulated data.

Evolution of the Galaxy

The evolution of the Galaxy is another aspect of galactic studies, for which the discovery in 1944 of two stellar populations was of great importance, although this idea has since been modified somewhat. Most nearby stars, such as the Sun, have been found to belong to a disk population (Population I) moving in nearly circular orbits close to the galactic plane; the youngest stars are still in spiral arms where they have just been formed by condensation from interstellar clouds. A few nearby stars, however, all about 10,000,000,000 years old, have velocities of more than 150 kilometres per second relative to the Sun because of slower galactic rotation, and these also have a much lower proportion of heavy elements; they move in highly elliptical orbits, often at large angles to the plane of the Milky Way. Because heavy elements presumably result from the cumulative effects of earlier supernova outbursts, these halo, or extreme Population II, stars (resembling stars in globular clusters) are probably among the first stars ever to have been formed. The Galaxy may initially have been a vast gas cloud collapsing in free fall, because the orbits of stars are unmodified by stellar encounters in 10,000,000,000 years and thus are likely to be products of the initial conditions. Gas clouds, on the other hand, undergo collisions, so that their energy of motion would have been changed into heat and radiated away subject to the conservation of angular momentum (the amount of rotational motion); thus, gaseous material would have formed a disk enriched in heavy elements by more massive, short-lived contemporaries of the halo stars. Population I stars were born from the disk and have inherited from it both their orbital motions and their chemical composition. Star formation and presumably heavy-element enrichment are still going on in the disk today, though at a much reduced rate; but the halo population is "fossilized" because there is no interstellar matter present to form new stars. Also, there seems to be no way in which a flattened galaxy can evolve into an elliptical galaxy or vice versa.

Cosmology and cosmogony. Cosmology, the study of the universe as a whole, became a coherent discipline after Einstein's development of the theory of general relativity (1915)—though much can also be understood in Newtonian terms—and the discovery in 1929 that galaxies have spectral red shifts (increased wavelengths of spectral lines indicating velocity of motion away from the observer) proportional to their distances. The distances and times are so great that new problems in their description arise. Three Euclidean dimensions of space and one unidirectional one of uniformly flowing time are no longer necessarily sufficient to frame the phenomena.

Einstein based his theory of gravitation on the principle of equivalence (gravitational accelerations are the same for all test bodies and can therefore be eliminated locally by measuring from an accelerated frame of reference, such as a falling elevator) and expressed the gravitational field mathematically in terms of quantities representing a local curvature of space-time. The theory agrees locally with Newtonian theory (*e.g.*, in applications to the solar system) apart from four effects in which observation favours Einstein's theory (see RELATIVITY; GRAVITATION).

If the universe is assumed to be homogeneous and isotropic (this assumption, called the cosmological postulate, simplifies the situation by supposing the matter to be completely smoothed out), then the theory of general relativity permits the existence of three kinds of space: flat (Euclidean), spherical (closed), and hyperbolic (open). For each curvature there are still several descriptions of a possible universe, called models: expanding, contracting, accelerating, or decelerating (and perhaps oscillating). Different models predict different relationships among red shifts, apparent magnitudes, and angular sizes of very distant galaxies, but the interpretation of these observed quantities involves large and uncertain corrections. Observation does show that the universe is expanding and that if this expansion has been continuous since a point at which it began, the so-called big bang, its age is similar to that of radioactive elements and that of the oldest stars in the Earth's and nearby galaxies, so that the formation of galaxies seems to be connected somehow with the early phases of the universe. The reality of the big bang has been questioned, notably in the steady-state theory, according to which the average density of the universe is kept constant by continuous creation of new matter, and its large-scale appearance always remains the same; but observational results seem rather to favour the big-bang theories (see UNIVERSE, ORIGIN AND EVOLUTION OF).

Models of the universe

III. Trends in modern astronomical investigations

The period since 1950 has produced an enormous widening of the scope of astronomy, thanks to new technologies: electronics, antennas, computers, timekeeping, improvements in the design of radiation and particle detectors, and rocketry. Many observations now involve a combination of sophisticated techniques in different fields, and this situation has led to increasing use of teamwork and interinstitutional collaboration to develop particular experiments or joint national and international facilities. Sophistication has led to escalation in costs, so that most work is done in planned projects funded by specific financial grants; this situation in turn requires increasing effort in costing, justification, and administration.

Another contrast with the past is the increasing role of "invisible" astronomy. Radio astronomy, pioneered in

the 1930s by United States radio engineers Karl Jansky and Grote Reber, was widely ignored until the end of World War II, but since then the use of it has yielded many surprises: nonthermal emission, solar bursts, quasars, pulsars, and complex interstellar molecules. Radio astronomy has also created some of the most impressive astronomical instruments existing today, both dishes and interferometers. To measure angular diameters much less than 1″ of arc—*e.g.*, for hydroxyl (OH) emission sources and quasars—requires interferometry with base lines of thousands of miles stretching across the Earth. Modern standards of timekeeping enable this to be done by recording simultaneously in the Americas and Europe or Australia and combining the recorded signals afterward.

Ultraviolet, X-ray, gamma-ray, and infrared measurements have extended the spectral range of electromagnetic radiation to other invisible wavelengths. Furthermore, astronomers are becoming very interested in different kinds of radiation altogether—*e.g.*, cosmic rays, neutrinos, and gravitational radiation predicted by general relativity theory—and all three are being actively investigated. The result is a much richer universe than man knew in the mid-1940s.

Nevertheless, optical observations have not diminished in importance, partly because a photograph is still the most convenient means of identification, position finding, and study of structure and partly because only a few distances can be found without optical methods. Furthermore, ordinary stars and galaxies, radiating mostly in the near-visible, still present exciting problems. The demand for large optical telescopes is therefore increasing rather than diminishing.

Whether or not ground-based telescopes will be eventually replaced for optical observations by instruments in orbit or on the Moon is not certain. Such a development becomes more probable as space-based instruments and laboratories become more reliable, sophisticated, and flexible. On the other hand, the cost must be considered. Early in the 1970s, a sum of the order of $10,000,000 would buy either a fairly sophisticated instrumented satellite with, say, a 20-inch telescope giving observations for a few years or a fully equipped ground-based 100-inch telescope giving observations for decades; each can do some things that the other cannot. A manned Apollo mission, on the other hand, cost something in the region of $1,000,000,000, and such projects can result only from political decisions by very major powers. For many years to come, therefore, it is plausible that ground-based optical observations will continue to flourish, probably in increasing coordination with radio and space-based observations.

MENZEL, *Astronomy* (1970), are excellent introductions for the general reader. L.H. ALLER, *Atoms, Stars and Nebulae* (1971); L. MOTZ and A. DUVEEN, *Essentials of Astronomy* (1966); C. PAYNE-GAPOSCHKIN, *Introduction to Astronomy* (1954); and A. UNSOLD, *The New Cosmos* (1969), are suitable for students with some background in physics. A. PANNEKOEK, *A History of Astronomy* (1961), is comprehensive and scholarly; interesting aspects of astronomical history are described in H.C. KING, *The History of the Telescope* (1955); and SIR BERNARD LOVELL, *The Story of Jodrell Bank* (1968), while readable extracts from classical papers are reproduced in H. SHAPLEY and H.E. HOWARTH (eds.), *A Source Book in Astronomy* (1929); and H. SHAPLEY (ed.), *Source Book in Astronomy, 1900–1950* (1960). Star charts and lists of objects visible in a small telescope are given in A.P. NORTON and J.G. INGLIS, *A Star Atlas and Reference Handbook (Epoch 1950) for Students and Amateurs*, ed. by R.M.G. INGLIS, 15th ed. (1964); and astronomical pictures are collected in B. ERNST and T.E. DE VRIES, *W.P. atlas van het heelal* (1961; Eng. trans., *Atlas of the Universe*, 1961); and in P. MOORE (ed.), *The Atlas of the Universe* (1970). J.B. SIDGWICK, *The Amateur Astronomer's Handbook* (1955); and the *Journal* (6/year) and annual *Handbooks* of the BRITISH ASTRONOMICAL ASSOCIATION provide information for amateur astronomers, as does the journal *Sky and Telescope* (monthly).

An up-to-date account of solar-system astronomy is F.L. WHIPPLE, *Earth, Moon and Planets*, 3rd ed. (1968); aspects of this are described in J.A. WOOD, *Meteorites and the Origin of Planets* (1968). SIR HARRIE S. MASSEY, *Space Physics* (1964), gives a more technical account of research using rockets and artificial satellites. An excellent introduction to theoretical astrophysics is given by R.J. TAYLER, *The Stars: Their Structure and Evolution* (1970). Astronomical instruments are dealt with in D.S. EVANS, *Observation in Modern Astronomy* (1968); and G.R. MICZAIKA and W.M. SINTON, *Tools of the Astronomer* (1961). B.J. and P.F. BOK, *The Milky Way* (1957), explains galactic structure in simple terms; an introduction to this subject at a more technical level is D. MIHALAS and P.M. ROUTLY, *Galactic Astronomy* (1968). A.D. THACKERAY, *Astronomical Spectroscopy* (1961), is a fine introduction to observational astrophysics. The best introductions to radio astronomy are F.G. SMITH, *Radio Astronomy*, 2nd ed. (1962); and J.S. HEY, *The Radio Universe* (1971). D.W. SCIAMA, *Modern Cosmology* (1971), is a good introduction to cosmology. F.D. KAHN and H.P. PALMER, *Quasars* (1967); and T. and L.W. PAGE (eds.), *Beyond the Milky Way* (1969), explain aspects of extragalactic astronomy in simple terms. C.W. ALLEN, *Astrophysical Quantities*, 2nd ed. (1963), summarizes the subject in numbers and formulas.

(B.E.J.P.)

Atacama Desert

The Atacama Desert (Desierto de Atacama) of Chile is a cool, arid region in northern Chile, 600 to 700 miles (1,000 to 1,100 kilometres) long. Its limits are not exact, but it lies mainly within Antofagasta and Atacama provinces between the south bend of the Río Loa and the mountains separating the Salado-Copiapó drainage basins. To the north, the desert region continues into the Province of Tarapacá.

The desert itself consists mainly of salt pans lying at the foot of the Cordillera de la Costa to the west, and of alluvial fans sloping from the foot of the Precordillera ranges to the east; some of the fans are sandy and covered with dunes, but extensive pebble accumulations are more common.

Topography of the Atacama

Several parts of the Atacama Desert may be distinguished. Its western part includes a coastal chain of mountains 5,000 feet or so in height with peaks reaching to 6,560 feet. There is no coastal plain; through much of their extent the mountains end abruptly in cliffs, some of them higher than 1,600 feet, making communication difficult between the coastal ports and the interior. The railroad from the port of Iquique, for example, must ascend about 2,300 feet before it passes through a valley to the interior.

In the interior a raised depression extends north and south and forms a high plain at an altitude of more than 3,000 feet. Farther to the east is the western range of the Andes, preceded by the Cordillera Domeyko. Here there are numerous volcanic cones, some exceeding 16,000 feet in altitude. Along Chile's northeastern frontier with Argentina and Bolivia, between the western and eastern ranges of the Andes, is a high plateau more than 13,000 feet in altitude, called the Puna de Atacama.

The Desert of Atacama forms part of the arid Pacific shoreline of South America. Moist air masses coming from the tropical Amazon Basin tend to be blocked by the Andes, making the desert one of the driest regions in the world. Some artesian waters exist, but their boron content makes them unsuitable for agriculture. In the Pampa del Tamarugal, to the north of the Río Loa, many salt beds have formed over subterranean waters. In the late 1960s about 37,000 acres were planted with tamarugoes, an acacia-like legume that can be used as fodder for sheep. The sprout sends out a root that descends quickly to the subterranean moisture.

On the coast the aridity is the consequence of the Peru (Humboldt) Current that brings cold water from the Antarctic, causing a thermal inversion—cold air at the surface of the ocean and warmer air higher up. This condition produces fog and stratus clouds, but no rain. Heavy rains fall in Iquique or Antofagasta only two to four times a century.

Temperatures in the desert are relatively low compared with those in similar latitudes elsewhere. The average summer temperature at Iquique is only 66° F (19° C) and at Antofagasta 65° F (18° C).

Area of conflicts over mineral resources

For many years in the 19th century, the desert was the source of conflicts between Chile, Bolivia, and Peru because of its valuable resources, particularly sodium nitrate deposits located northeast of Antofagasta and inland from Iquique. Much of the area belonged to Bolivia and Peru, but the mining industry there was controlled by Chilean interests, which were strongly supported by the Chilean government. From the War of the Pacific (1879 to 1883) between the three countries, Chile emerged victorious. The resulting Treaty of Ancon (1884) gave Chile permanent ownership of sectors previously controlled by Peru and Bolivia, the latter losing its whole Pacific coastline.

The area proved to be one of the chief sources of Chile's wealth until World War I. Nitrate deposits in the central depression and in several basins of the coastal range were systematically mined after the middle of the 19th century. Ports were built at Iquique, Caldera, Antofagasta, Taltal, Tocopilla, Mejillones, and, farther north, Pisagua, and railroads penetrated the mountain barriers to the interior. Prior to World War I, Chile had a world monopoly on nitrate; in some years 3,000,000 tons were extracted, and the taxes on its export amounted to half the government's revenues. The development of synthetic methods of fixing nitrogen have since reduced the market to a regional one, and only 780,000 tons per year were produced in the late 1960s. Once, 120,000 nitrate workers were employed; now there are fewer than 10,000. Whole towns were abandoned, and the port of Pisagua had fewer than 25 inhabitants in 1970.

Some sulfur is still mined in the high Cordillera. The region's chief source of revenue, however, is copper mining at Chuquicamata in the Andes and at Paposo on the coast. The industry developed with the entry of U.S. capital and technical skill in the early part of the 20th century. The deposits are abundant, and the government (1964–70) of Pres. Eduardo Frei (Montalva) had an ambitious development program. The succeeding government of Pres. Salvador Allende (Gossens) nationalized all U.S.-owned copper companies.

Some farming is done in the desert, but this supports only a few thousand people. Lemons are grown at Pica, and a variety of products are cultivated on the shores of the salt marshes at San Pedro de Atacama. At Calama, near Chuquicamata, water from the Río Loa irrigates potato and alfalfa fields.

Atacama had become a region of declining population, despite the presence of the copper industry. The development of fishing and the establishment of canning factories, especially at Iquique, provided employment for relatively few. So far had the decline of population gone that government programs for afforestation and sheep breeding were faced with a lack of manpower.

(J.-L.-F.T.)

Atatürk, Kemal

Kemal Atatürk, a distinguished Turkish soldier, reformer, and statesman, was the founder of the Republic of Turkey and its first president. His successful struggle for the liberation of Turkey against the powers of the Entente (an alliance of Britain, France, and Russia) after Turkey's defeat in World War I has inspired many embryonic states in Asia and Africa to fight for their independence.

Education

Early life and career. Kemal Atatürk, born in 1881 in Salonika, Greece, of a Turkish family of humble origin, was named Mustafa. His mother was Zübeyde Hanım, his father Ali Riza, a minor government employee. When Mustafa was still in the primary school he lost his father, and his mother took the boy to live in the country with her brother. Returning to Salonika later, Mustafa finished primary school and entered the military secondary school in that town in order to become an officer in the Ottoman army. It was at this school that one of his teachers, who admired the boy for his skill in mathematics and who was also called Mustafa, suggested he should call himself Mustafa Kemal (maturity and perfection). After finishing secondary school, Mustafa Kemal went on to the military high school in Manastir, where, observing with hatred the continuous attacks of the Christian Macedonian anarchists on the Turkish population, he became, like most of his fellow cadets, an ardent nationalist.

In 1899 Mustafa Kemal entered the Military Academy in Istanbul. There he came to take a close interest in politics; he and his fellow students read secret pamphlets attacking the despotic rule of Sultan Abdülhamid II. He was especially influenced by the patriotic and liberal thinking of the poet Namık Kemal Bey. He also read books on the French Revolution and developed an admiration for Napoleon.

In 1902 Mustafa Kemal graduated from the Military Academy and entered the General Staff College, where his interest in politics continued. After finishing the college with the rank of captain, he was appointed to the cavalry regiment in Damascus. There, together with some of his friends, he founded a secret society called "Fatherland and Freedom," which, however, failed to make much progress. On his return to Salonika, Mustafa Kemal, like many of his fellow officers, joined the secret "Committee of Union and Progress," which spread its revolutionary activities throughout the armed forces and caused the proclamation of the Constitution of 1908.

Mustafa Kemal devoted all his time and energy to his profession in the following years. In 1911, when the Italians attacked Tripoli, an Ottoman province at that time, he hurried there together with some of his officer friends and, forming troops of the natives, launched successful guerrilla raids on the enemy. In the same year Mustafa Kemal was promoted to major. In the Balkan War of 1912 he was charged with the defense of the Gallipoli Peninsula—a task that gave him an excellent opportunity to study the strategic position of this important area. In 1913 he was sent to Sofia as military attaché, and during his stay there he acquired a good knowledge of the Western standards in taste, the arts, and the relations between men and women in polite society. He made good use of this knowledge later when he set about reforming social life in his country. While still in Sofia, Mustafa Kemal was promoted to lieutenant colonel.

Activities during World War I

When World War I broke out, Mustafa Kemal was appointed to the command of the 19th Division at Çanakkale. He defeated the British at Gallipoli twice and gained for himself in the Turkish press the title of "the Saviour of Istanbul." And he was promoted to colonel. In 1916, serving on the eastern front, he stopped the advance of the Russian forces to the south and was promoted to brigadier general.

In 1917 Mustafa Kemal accompanied the crown prince, Vahideddin, on a state visit to Germany. During a tour of the German Western Front he did not hesitate to express openly his view about the vulnerability of the front and Germany's position in the war. On his return to Istanbul Mustafa Kemal fell ill, and for treatment he went to Vienna and Carlsbad (now Karlovy Vary, Czechoslovakia) where he had a further opportunity to observe European civilization.

In 1918 Mustafa Kemal was appointed to command the 7th Army in Palestine; when he took up his duties, however, the fight with the British had all but ended, and the enemy was advancing northward without meeting any resistance. The Arab guerrillas tóo were launching attacks on the Turkish army. To avoid the capture of the whole 7th Army, Mustafa Kemal withdrew his forces to the north of Aleppo. When, after the Armistice of Mudros (Moúdhros), the German officers and commanders serving in Turkey returned to their country, Mustafa Kemal assumed the command of all the forces of the southeastern front. Disagreeing with the British over the enforcement of the terms of the Armistice, however, he was appointed to a post in the Ministry of War. On his arrival in Istanbul he found the fleet of the Entente anchored in the harbour. The terms of the Armistice were hard enough, but information was now received about a secret agreement reached by the states of the Entente for the partition of the Ottoman territories. Moreover, the minorities in Is-

tanbul and elsewhere had seized the opportunity to organize themselves against the Turks. The Turkish people looked for a means of redress; in some parts of the country they formed organizations called "the Society for the Defence of Rights" to fight against them.

Activities after World War I. In Istanbul there were two main ideas about Turkey's future: the Sultan and his supporters were thinking of placing the country under English protection, while some well-known Turkish journalists and intellectuals were spreading propaganda for placing Turkey under an American mandate. In both cases the aim was to maintain the Ottoman Empire in its cosmopolitan structure. Mustafa Kemal, however, persisted in the idea of an independent Turkish nation living within its national boundaries and believed that this could be achieved if the nation was prepared for a new struggle. Before deciding on a course of action, he had talks with many Turkish and foreign notables, including the Sultan and his ministers. Then he discussed it with his friends, all commanders who were bitterly disillusioned over the abolition of the Ottoman army by the terms of the Armistice, and saw the solution in starting a war of independence in Anatolia.

An excellent opportunity for this presented itself soon: the powers of the Entente were putting pressure on the Turkish government to take measures against riots likely to break out in the eastern provinces. The Sultan appointed Mustafa Kemal as Inspector of the Third Army in Erzurum, endowing him with power over military and civilian authorities. On May 15, 1919, immediately before Mustafa Kemal's departure for Erzurum, the Greeks occupied Izmir.

Mustafa Kemal's secret circular

After a secret interview with the Sultan, Mustafa Kemal left Istanbul with a large suite of staff officers and set foot in Samsun on May 19. In Amasya, with the approval of local corps commanders, he issued a secret circular dated June 22 in which he described the dangers that the country faced: how the government in Istanbul had yielded weakly to the forces of occupation and how the only hope of salvation lay in the nation's own struggle for its liberation. Such a struggle, he added, had already begun, and to make it the decision of the nation itself a national congress would be convoked in Sivas with the participation of three delegates from each province. He ordered all unit commanders to strengthen their forces, disregarding the terms of the Armistice about the demobilization of the Turkish army. Finally, he warned both the military and civilian authorities that henceforth they would take their orders from him alone.

Mustafa Kemal's demands were fervently complied with by the military because his demands meant saving the army from extinction. The army took under its control all postal and telegraphic communications in Anatolia and forced into obedience those civil administrators who tried to resist Mustafa Kemal's orders.

In all the towns and cities he called at on his way to Sivas, Mustafa Kemal met the leading citizens and explained to them his views on a national struggle for independence. He arrived in Sivas amid warm demonstrations of support by the people, and after important talks with the notables of the city, he proceeded to Erzurum, ignoring all orders given by the Sultan's government, under pressure from the states of the Entente for his immediate return to Istanbul. In Erzurum a congress was to be convened on July 23 by the Society for the Defense of Rights in Eastern Anatolia. In the meantime the military and civilian authorities of Erzurum received an order for Mustafa Kemal's arrest and transport to Istanbul. Although this order went unheeded, Mustafa Kemal resigned his commission in the army, deeming it necessary to have more freedom as the leader of the national struggle he had started. Thus he entered the congress as a mere delegate and was elected its president. At his suggestion the congress accepted the National Covenant, which was in the nature of an oath requiring the indivisibility of the fatherland and the successful completion of the national movement. In addition, a Standing Committee of nine members was elected of which Mustafa Kemal was chosen president. On September 4 he opened the National Congress in Sivas, and he was again elected president of the congress. The National Congress adopted all the decisions taken by the Congress of Erzurum and rejected decisively the idea of placing Turkey under American mandate. Resisting a motion for establishing a new state in Anatolia, Mustafa Kemal proposed the joining of all local Societies for the Defense of Rights into one society to be called "the Society for the Defence of Rights in Anatolia and Rumelia." The proposal was accepted, and so the prototype of a political party was formed. The Ottoman cabinet of Ferid Paşa and succeeding Ottoman governments continued to view the national movement as an act of rebellion and Mustafa Kemal's activities as illegitimate.

Participation in nationalist congresses

Role in the founding and reform of modern Turkey. On December 27 Mustafa Kemal transferred the seat of the national struggle to Ankara, thinking it a more convenient location for his purposes. In the meantime, at the general elections of members for the Ottoman Chamber of Deputies in Istanbul, Mustafa Kemal's supporters won an overwhelming majority and succeeded in getting the chamber to proclaim as its own decision the principles of the National Covenant. They also secured the cancellation of the government's former decree about Mustafa Kemal's dismissal from the army. Alarmed at these indications of change in the Ottoman policy, the British occupied Istanbul officially on March 16, 1920, and dissolved the Chamber of Deputies. Mustafa Kemal vehemently protested the British government's action; but, in fact, the occupation of the Ottoman capital and especially the dissolution of the chamber were extremely useful to his aims because they removed the legal obstacle that Istanbul presented to his plan of forming a national government in Anatolia. So, after a new election of deputies, he opened on April 23 in Ankara the first Grand National Assembly of Turkey, and he was elected its president. At Mustafa Kemal's proposal, a constitutional law was passed changing the name of the state to Turkey and stipulating that sovereignty and executive powers would be used on its behalf by the Grand National Assembly. Accordingly, as president of the assembly Mustafa Kemal took upon himself the offices of the prime minister and of the president of the state. Thus ended the Islāmic form of government that had existed in Turkey since the Middle Ages; and, as in the French Revolution, the Turkish people passed suddenly from rule of absolutism and the caliphate to a regime based on national sovereignty. This important change caused serious uprisings in some regions, but they were quickly suppressed by the national forces.

Struggle to consolidate the country

Mustafa Kemal now busied himself with the work of gaining control of such parts of the country as were then under occupation. First, in the east, the Armenians and the Georgians were defeated, and through the mediation of Soviet Russia, a treaty was signed with them that regained for Turkey even the territories she had lost in 1878. After extensive guerrilla warfare, the French in the south evacuated Turkish territories and withdrew to Syria and recognized the legitimacy of the National Government in Ankara. Ignoring Ankara altogether, the British got the Ottoman government to sign the Treaty of Sèvres. The National Government proclaimed that it did not recognize as legitimate a treaty of such terms, whereupon the Greek army extended its area of occupation, advancing within 50 kilometres of Ankara. At this time of great anxiety the National Assembly appointed Mustafa Kemal the commander in chief with extraordinary powers. Indeed, on August 26, 1922, after an all-out offensive planned and directed personally by the Commander in Chief, the Greek army was defeated and forced within two weeks to leave Anatolia completely. Upon this decisive victory and with the mediation of the states of the Entente, an armistice was signed with the Greeks according to which they evacuated all Turkish territories. The British ceded Çanakkale and Istanbul to the National Government. Vahideddin, the last Ottoman sultan, fled abroad, and upon a motion by Mustafa Kemal the National Assembly terminated the 600 years of Ottoman rule in Turkey. The Treaty of Lausanne, signed

on July 24, 1923, established the integrity of Turkey's national frontiers and its complete independence. All privileges granted to the European countries by the Ottomans were cancelled. Thus, Mustafa Kemal realized his dream of founding a completely independent and national Turkish state in place of the Ottoman Empire, that "sick man of Europe" that had been for a long time a subject of strife among the great powers of Europe.

Marriage

In 1922 Mustafa Kemal married Latife Hanım, the well-educated daughter of a wealthy family in Izmir. The marriage was contracted in the modern manner, not in the tradition of Islām. In order to show the Turkish people that the place of women in society was by the side of their men, he took his wife with him on his trips around the country. His marriage did not last long, however. During his long years of single life he had developed an independent habit of living that he found difficult to give up and that his wife could not tolerate.

On one occasion as early as 1917, Mustafa Kemal had remarked that, had he the power and the authority, he would change social life in Turkey at one blow. This opportunity had now presented itself, and he launched on a program of reforms. In place of the Society for the Defense of Rights in Anatolia and Rumelia, he founded the People's Republican Party and became its leader. With the general elections held immediately after the signing of the Treaty of Lausanne, this party, as Turkey's only political party, took complete control of government. On October 29, 1923, Mustafa Kemal proclaimed the Republic and was elected its first president. In 1924 he abolished the caliphate. In the meantime, a group of his friends who were against his drastic methods of reform and who believed in gradual progress over a period of

Reforms

time founded the Progressive Republican Party. Mustafa Kemal went on carrying out his program of reform: he closed down all institutions based on the Muslim canon law, all monasteries, and religious orders. "Science is the most reliable guide in life," he remarked, and abolishing the traditional system of education, which was mainly religious, he established secular schools of the modern type. The whole Ottoman legal system was modernized, and a new civil and penal code was adopted. The Oriental forms of dress that carried a religious significance were discarded in favour of European dress. Dances, balls, and other forms of entertainment involving both men and women were encouraged, and the enlightened classes adopted the European way of life.

Mustafa Kemal's reforms did not go unchallenged. In Eastern Anatolia a man called Şeyh Said stirred up a rebellion to restore the Muslim canon law; in Izmir preparations for a plot to assassinate Mustafa Kemal were reportedly discovered; and there were said also to be some local attempts at rebellion against the use of hats. Mustafa Kemal punished severely all the leaders of these movements, closed down the Progressive Party, and, reverting to the former authoritarian regime, he pursued his program of reform. Setting aside all the old laws and traditions that held women inferior to men, he established complete equality between the sexes, including the right of electing and being elected. In 1928 he substituted Roman characters for the Arabic that had been used in Turkey for centuries. He endeavoured to popularize Western classical music and the theatre in Turkey. In 1930 he made a second attempt at introducing a multiparty regime by allowing the creation of the Free Republican Party; but, as this party soon became a centre for antireformist ideas and activities, it met the same fate as the Progressive Republican Party. Mustafa Kemal also launched a large-scale program of research in the fields of Turkish language and history. By this means he wanted to strengthen in society the ties of national feeling in place of the old ties of religion. In 1933 a law was passed to make the use of family names compulsory, and the National Assembly gave Mustafa Kemal the name Atatürk ("Father of Turks"), which soon became so popular as to supersede his previous name and titles.

Atatürk's foreign policy can be summed up by his motto: "Peace at home, and peace in the world." In economy, he followed a policy of national economy, nationalizing all foreign firms and companies. On the question of Turkey's industrialization, he placed his hope on private domestic capital for a while, but discovering its insufficiency, he decided to encourage etatism (state socialism). In neither case, however, did he achieve any important success. If one or two items of foreign policy are excepted, there was a gradual slowing down in the last five years of Atatürk's life, and his final year passed in serious illness. He died on November 10, 1938, in Istanbul, where he had gone to rest.

Atatürk made major reforms in Turkey in the field of politics, law, and culture that only affected, however, bureaucrats and a minority of well-to-do people in the cities. The poorer part of the population, and especially the peasants who still subsisted in an agricultural order of the medieval type, continued to live much the same as before. Nevertheless, the Western view of life had gained enough power among the educated classes to make a return to the old way of life impossible.

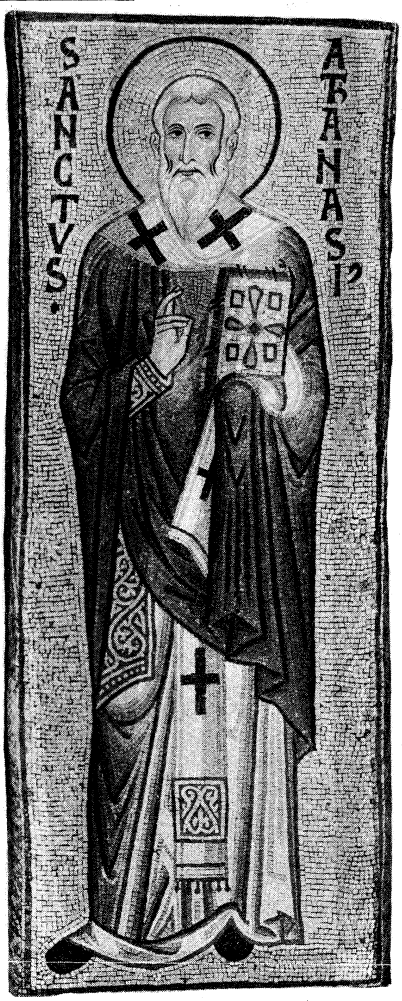
Athanasius, Saint

St. Athanasius, theologian, ecclesiastical statesman, and Egyptian national leader, was the chief defender of Christian orthodoxy in the 4th-century battle against Arianism, the heresy that asserted that the Son of God was a creature of like but not the same substance as God the Father. His two-part work of apologetics, *Against the Heathen* and *The Incarnation of the Word of God*, completed about AD 335, was the first great classic of developed Greek Orthodox theology. In Athanasius' system, the Son of God, the eternal Word through whom God made the world, entered the world in human form to lead men back to the harmony from which they had fallen away. Athanasius reacted vigorously against Arianism, for which the Son was a lesser being, and welcomed the definition of the Son formulated at the Council of Nicaea in AD 325: "consubstantial with the Father."

Life and major works

Athanasius was born at Alexandria, Egypt, about 293 and received his philosophical and theological training there; in 325 he attended Bishop Alexander of Alexandria as deacon at the Council of Nicaea. A recognized theologian and ascetic, Athanasius was the obvious candidate to succeed Alexander when the latter died in 328. The first years of his episcopate were devoted to visitation of his extensive patriarchate, which included all of Egypt and Libya. During this time he established important contacts with the Coptic monks of Upper Egypt and their leader Pachomius. Soon began the struggle with imperialist and Arian churchmen that occupied much of his life. He used political influence against the Meletians, followers of the schismatic bishop Meletius of Lycopolis, who had gone back on the plans made at Nicaea for their reunion with the church; but he refuted specific charges of mistreatment of Arians and Meletians before a hostile gathering of bishops at Tyre (in modern Lebanon) in 335, which he refused to recognize as a general council of the church. When both parties met the emperor Constantine at Constantinople in 336, Athanasius was accused of threatening to interfere with the grain supply from Egypt, and without any formal trial Constantine exiled him to the Rhineland.

The Emperor's death in 337 allowed Athanasius to return to Alexandria, but Constantine's son Constantius, emperor in the East, renewed the order of banishment in 338. Athanasius took refuge at Rome under the protection of Constantius' brother Constans, emperor in the West. An Arian bishop, Gregory, was installed at Alexandria; Athanasius, however, kept in touch with his flock through the annual *Festal Letters* announcing the date of Easter. Pope Julius I wrote in vain on his behalf, and the general council called for AD 343 was no more successful



St. Athanasius, detail of a 12th-century mosaic. In the Palatine Chapel, Palermo, Italy.
Anderson—Alinari

—only Western and Egyptian bishops met at Sardica (modern Sofia, Bulgaria), and their appeal for Athanasius was not accepted in the East. In 346, however, Constans' influence secured his return to Egypt, where he was welcomed as a popular hero. Athanasius' "golden decade" of peace and prosperity followed, during which he assembled documents relating to his exiles and returns in the *Apology Against the Arians*. Nevertheless, after the death of Constans in 350 and the following civil war, Constantius, as sole emperor, resumed his pro-Arian policy. Again political charges were brought against Athanasius, his banishment was repeated, and in 356 an attempt was made to arrest him during a vigil service. This time he withdrew to Upper Egypt, where he was protected in monasteries or friendly houses. In exile he completed his massive theological work *Four Orations Against the Arians* and defended his conduct in the *Apology to Constantius* and *Apology for his Flight*. The Emperor's persistence and reports of persecution at Alexandria under the new Arian bishop George led him, in the more violent *History of the Arians*, to treat Constantius as a precursor of Antichrist.

In 361 the death of Constantius (followed by the murder of the unpopular George) allowed Athanasius to return triumphantly once more to his see. Immediately, he convened a council at Alexandria (362), during which he appealed for unity among those who held the same faith but differed in terminology. The way was thus prepared for the orthodox doctrine of the Trinity—"three Persons in one substance"—which stresses distinctions in the Godhead more than Athanasius usually had done. The new emperor Julian the Apostate rather petulantly ordered Athanasius to leave Alexandria, and he sailed up the Nile again to his exile in Upper Egypt until Julian's death in 363. In 365 the emperor Valens, who favoured Arianism, ordered his exile once more, but this time the popular bishop merely moved to the outskirts of Alexandria for a few months until the local authorities persuaded the Emperor to reconsider. Finally, Athanasius spent a few years in peace until his death on May 2, 373.

Minor works and place in history

Among Athanasius' important works are *The Letters [to Sarapion]* on the divinity of the Holy Spirit and *The Life of St. Antony*, which was soon translated into Latin and did much to spread the ascetic ideal in East and West. Only fragments remain of sermons and biblical commentaries; several briefer theological treatises are preserved, however, and a number of letters, mainly administrative and pastoral. Of special interest are the letter to Epictetus (bishop of Corinth), which anticipates future controversies in defending the humanity of Christ, and the letter to Dracontius, which urges a monk to leave the desert for the active labours of the episcopate. Precision of thought, tireless energy in defense of his convictions and the freedom of the church, and (within certain limits) breadth of understanding have given Athanasius an important place among the teachers and leaders of the church; and as an Egyptian patriot he is also a significant figure in the history of his country.

BIBLIOGRAPHY. The great Benedictine edition of the works of Athanasius (1698), reprinted in J.P. MIGNE, *Patrologia Graeca*, vol. 25–28 (1857), is being replaced by that begun by H.G. OPITZ (*Athanasius Werke*) in 1934; major works are translated in the "Post-Nicene Fathers," Series 2, vol. 4, *Select Writings and Letters of Athanasius* (1892)—the "Prolegomena" to this volume by A. ROBERTSON remains the most complete life. For later discoveries and studies, see H.I. BELL (ed.), *Jews and Christians in Egypt* (1924); and the brilliant summary by F.L. CROSS, *The Study of St. Athanasius* (1945). There are useful sketches in G.L. PRESTIGE, *Fathers and Heretics* (1940, reprinted 1963); and in R.W. THOMSON'S edition of *Contra Gentes and De Incarnatione* (1971). For further references, see E.R. HARDY (ed.), *Christology of the Later Fathers* (1954); and J. QUASTEN, *Patrology*, vol. 3, pp. 20–79 (1960).

(E.R.Ha.)

Atheism

Atheism is the denial of God as the first principle and is thus antitheism, the opposite of theism. The words atheist and atheism can be found as early as in the works of Plato; they recur in the Christian Era in the Letter of Paul to the Ephesians and in the works of the Fathers of the Church, where, for example, St. Ignatius of Antioch attacks the pagans, calling them atheists, and Justin Martyr defends the Christians, claiming that they adore the true God and are thus not atheists. Atheism is opposed to any religion or worship of God; this is indicated by the synonym for atheist: freethinker. To many of its theological critics, atheism is synonymous with impiety, irreligion, disbelief, and even moral corruption, on the ground that every principle and every higher ethical law is rejected.

Divisions and principal forms. Atheism can be divided into theoretical atheism and practical atheism. Theoretical atheism is the denial of God based upon a system of thought that excludes the possibility of the existence of the Absolute. Practical atheism is the denial of God as reflected in the way one conducts his private and public life, leaving the question of God out of consideration and basing conduct solely on finite values.

Theoretical atheism

Theoretical atheism can be either negative or positive. Explicit negative theoretical atheism is attributed to those who unequivocally deny the existence of God and who suppose a concept of the world and of the destiny of man that radically excludes the necessity of the transcendent first principle or of an immortal human soul. Implicit negative theoretical atheism, or cryptoatheism, is attributed to those who, although they affirm the existence of God or of the Absolute, deprive him of some essential attribute. This type of atheism is also known as atheism "by consequence." The encyclopaedia prepared by the 18th-century French philosophers Denis Diderot and Jean d'Alembert equates skepticism (which questions the

ability of the human mind to know), indifferentism (which states that all religions are equally valid), and even agnosticism (which claims that the question of God's existence cannot be answered) with negative atheism because they close off all the paths that lead to God.

Positive theoretical atheism, which predominates in modern thought, replaces the acknowledgment of the transcendent first principle with the autonomy of the subjective thinking element (the *cogito*) within man that leads him to identify knowledge and being (or reality), wisdom and action, freedom and necessity; for the transcendence of God and for personal immortality, it substitutes the emergence of man in the world. Theoretical atheism, insofar as it is a vindication of the total autonomy of man and of his absolute freedom, is also called postulated atheism in the sense that God cannot and must not exist if man is to be guaranteed freedom and responsibility for his duties and his actions. Positive atheism is thus an anthropological atheism in which God is replaced by man.

Practical atheism

Practical atheism consists of ignoring or neglecting any relationship to God in one's actions, or in living as if God did not exist. According to Paul, in the letter to Titus, it is the situation of those who claim to know God but deny him in the things they do. Practical atheism, therefore, involves the orientation of one's life exclusively toward the attainment of earthly goals.

Historical development of atheism. The history of atheism is as complex and obscure as its notion. Atheism seems to have been unknown in the more primitive societies; it appears to be the fruit of civilization and of reflection. Although Plato expressly argues against atheists in the *Laws* and although some lists of men branded as radical atheists have been handed down, explicit atheists were rare in the period of ancient Greece and Rome and in the early Christian Era.

In the Middle Ages, the time of great Christian expansion, explicit atheism was practically unknown. According to some Marxist historians, however, the medieval heresies and the controversies between the schools of thought, especially the arguments concerning the relationships between reason and faith and between freedom and authority, should be interpreted as preparations for modern atheism. The return to a classical pagan conception of life in Humanism and in the Renaissance of the 15th and 16th centuries gave vitality to the atheistic currents that did exist. The Materialism of the ancient Greek philosophers Democritus and Epicurus and the syncretism of the Stoics and the Neoplatonists were fused into a theory that the world is self-contained and self-sufficient (see also STOICISM; PLATONISM AND NEOPLATONISM). The principal inventor and defender of the atheistic conception of the modern state was Niccolò Machiavelli, the Italian statesman and author who died in 1527. In his most famous work, *Il Principe* (written 1513; Eng. trans., *The Prince*, 1954), he defended the principle that the end justifies the means, thus affirming the independence of politics from morals and, in the final analysis, from any form of religion.

Influence of Descartes

Atheism in its modern positive form has been characterized by the thought of the French philosopher and mathematician René Descartes, who, in the first half of the 17th century, attempted to ground his thought on clear and distinct ideas and the proposition *Cogito, ergo sum* ("I think; therefore, I am"). He thus placed the foundation of truth in the evidence and in the freedom of the thinking subject. The Cartesian system is accused of being atheistic because of its mechanistic conception of the world, according to which all natural phenomena can be explained by reference to matter and motion and their laws. The first explicit argumentation defending atheism as moral, as no worse than idolatry, as not leading to corruption or death, was formulated by Pierre Bayle, a late-17th-century Cartesian fideistic skeptic; his defense provided the foundation for modern secularism. At this same time, Deism and British Empiricism were inserted into the intellectual scene by John Locke, who advanced the hypothesis: ". . . whether Omnipotency has not given to some systems of matter fitly disposed a power to perceive and think." This hypothesis became a categorical proposition for the French writer Voltaire and the British freethinker John Toland, who believed in the universal animation of matter and its self-sufficiency. These ideas were the central point of the atheism of the Enlightenment as expressed chiefly by the French Encyclopaedists and the British Deists.

The 18th century witnessed the triumph of the atheism of the French Enlightenment in the intellectual activity of the writers and thinkers referred to as Philosophes, who fused British Deism and Empiricism with Cartesian mechanism. The postulated atheism of these philosophers was expressed systematically and most outspokenly by Baron P.-H.T. d'Holbach, who defined an atheist as "a man who destroys the dreams and chimerical beings that are dangerous to the human race so that men can be brought back to nature, to experience, and to reason."
