First, they fell into one of three well-defined categories: they were makers of bicycles, such as Opel in Germany and Morris in Great Britain; builders of horse-drawn vehicles, such as Durant in the United States; or, most frequent of all, they were machinery manufacturers—these included makers of stationary gas engines (Daimler of Germany, Lanchester of Britain, Olds of the United States), makers of marine engines (Vauxhall of Britain), makers of machine tools (Leland of the United States), makers of sheep-shearing machinery (Wolseley of Britain), makers of washing machines (Peerless of the United States), makers of sewing machines (White of the United States), and makers of woodworking and milling machinery (Panhard and Levassor of France). One company (Pierce of the United States) had made birdcages. Two notable exceptions to the general pattern were Rolls-Royce in Britain and Ford in the United States, both of which were founded by partners combining engineering talent and business skill.

In the United States practically all of the producers were assemblers who put together components and parts manufactured by separate firms. The assembly technique was also a method of financing. It was possible to begin building motor vehicles with a minimal investment of capital by buying parts on credit and selling the finished cars for cash; the cash sale from manufacturer to dealer has been integral in the marketing of motor vehicles in the United States ever since. European automotive firms of this period tended to be more self-contained.

The pioneer automobile manufacturer not only had to solve the technical and financial problems of getting into production, but also had to make a basic decision about what to produce. After the first success of the gasoline engine, there was widespread experimenting with steam and electricity; for a brief period the electric automobile actually enjoyed the greatest acceptance because it was quiet and easy to operate, but the limitations imposed by battery capacity proved competitively fatal.

Steam power, a more serious rival, was aided by the general adoption of the so-called flash boiler after 1900, a modification that provided for a rapid raising of steam. The steam car was easy to operate because it did not require an elaborate transmission. On the other hand, high steam pressures were needed to make the engine light enough for use in a road vehicle, requiring expensive construction and difficult maintenance. By 1910 most manufacturers of steam vehicles had turned to gasoline power. The Stanley brothers in the United States, however, continued to manufacture steam automobiles until the early 1920s.

Patent controversies

As often happens with a new technology, the automotive industry experienced patent controversies in its early years. Most notable were two long-drawn-out court cases in Britain and the United States, in each of which a promoter sought to gain control of the new industry by filing comprehensive patents. In Britain the claim was rejected by the courts in 1901, five years after the patent application. In the United States a longer, more complex legal battle ultimately resulted in an agreement among manufacturers for cross-licensing patents (1915).

Mass production. The outstanding contribution of the automotive industry to technological advance was the introduction of full-scale mass production, a process combining precision, standardization, interchangeability, synchronization, and continuity. Mass production was a United States innovation. The United States, with its large population, high standard of living, and long distances, was the natural birthplace of the technique, which had been partly explored in the 19th century. Though Europe had shared in the experimentation, the United States role was underlined in the popular description of standardization and interchangeability as "the American system of manufacture." The fundamental techniques were known, but they had not previously been applied to the manufacture of a mechanism so complex as a motor vehicle (see MASS PRODUCTION).

The kind of interchangeability achieved by the "American system" was dramatically demonstrated at the British Royal Automobile Club in London in 1908, when three Cadillac cars were disassembled, the parts mixed together, 89 parts removed at random and replaced from dealer's stock, the cars assembled, and driven 500 miles without trouble. Henry M. Leland, founder of Cadillac Motors and the man responsible for this feat of showmanship, later enlisted the aid of a noted electrical engineer, Charles F. Kettering, in developing the electric starter, a significant innovation in promoting the acceptability of the gasoline-powered automobile.

Ford and the assembly line. The mass-produced automobile is generally and correctly attributed to Henry Ford, but he was not alone in seeing the possibilities in a mass market. Ransom E. Olds made the first major bid for the mass market with a famous curved-dash Oldsmobile buggy in 1901. While the first Oldsmobile was a popular car, it was too lightly built to withstand rough usage. The same defect applied to Olds's imitators. Ford, more successful in realizing his dream of "a car for the great multitude," designed his car first and then considered the problem of producing it cheaply. The car was the so-called Model T, the best known motor vehicle in history. It was built to be durable for service on the rough American country roads of the period, economical to operate, and easy to maintain and repair. It was first put on the market in 1908, and over 15,000,000 were built before it was discontinued in 1927.

The Model T

When the design of the Model T proved successful, Ford and his associates turned to the problem of producing the car in large volume and at low unit cost. The solution was found in the moving assembly line, a method first tested in the assembly of magnetos. After more experimentation, in 1913 the Ford Motor Company displayed to the world the complete assembly-line mass production of motor vehicles. The technique consisted of two basic elements: a conveyor system and the limitation of each worker to a single repetitive task. Despite its deceptive simplicity, the technique required elaborate planning and synchronization.

The first Ford assembly line permitted only very minor variations in the basic model, a limitation which was compensated for by the low cost. The price of the Model T touring car dropped from $950 in 1909 to $360 in 1916, and an incredible $290 in 1926. By that time Ford was producing half of all the motor vehicles in the world.

Spread of mass production. This success inspired imitation and competition, but Ford's primacy remained unchallenged until he himself lost it in the middle 1920s by refusing to recognize that the Model T had become outmoded. More luxurious and better styled cars appeared at prices not greatly above that of the Model T, and these were increasingly available to low-income purchasers through a growing used-car market. Abroad, William R. Morris (later Lord Nuffield) in Britain undertook to emulate Ford as early as 1912, but found British engineering firms reluctant to commit themselves to large-scale manufacture of automotive parts. Morris in fact turned to the United States for his parts, but these early efforts were cut short by World War I. In the 1920s Morris resumed the production of low-priced cars, along with his British competitor Herbert Austin and André-Gustave Citroën and Louis Renault in France. British manufacturers had to face the problem of a tax on horsepower, calculated on a formula based on bore and the number of cylinders. The effect was to encourage the design of small engines that had cylinders with narrow bore and long stroke, in contrast to the wide-bore, short-stroke engines favoured elsewhere. This handicapped the sale of British cars abroad and kept the level of production from growing. It was not until 1934 that Morris Motors finally felt justified in installing a moving assembly line; the Hillman Company had preceded Morris in this by a year or two.

The effect of the horse-power tax on design

Large-scale organization. Though the appearance of mass production in the automotive industry coincided with the emergence of large-scale business organization, the two had originated independently. They were, nevertheless, related, and reacted on each other as the industry expanded. Only a large firm could make the heavy investment in plant and tooling that the assembly line required, and Ford was already the largest single American producer when it introduced the technique. The mass producer in turn enjoyed a cost advantage that tended to make it increasingly difficult for smaller competitors to survive. Exceptions can be noted along the way, but the trend has been consistent.

General Motors. General Motors, which ultimately became the world's largest automotive firm, and in fact the largest privately owned manufacturing enterprise in the world, was founded in 1908 by William C. Durant, a carriage manufacturer of Flint, Michigan. In 1904 he assumed control of the ailing Buick Motor Company and made it one of the principal American producers. Durant developed the idea for a combination that would produce a variety of models and control its own parts producers. As initially formed, General Motors included four major vehicle manufacturers (Buick, Cadillac, Oldsmobile, Oakland) and an assortment of smaller firms. The combine ran into financial trouble in 1910 and was reorganized by a financial syndicate. A similar combination, the United States Motor Corporation, formed in 1910, collapsed in 1912 and was reorganized as the Maxwell Motor Company. General Motors survived. A new reorganization took place with the return of Durant, with du Pont Company backing, to control in 1916.

Rise of the Big Three. At the end of World War I, Ford was the colossus, dominating the automotive scene with the Model T not only in the United States but through branch plants throughout the world. British Ford was the largest single producer in the United Kingdom. General Motors was emerging as a potential major competitor in the United States. No other automotive firms of comparable size existed.

The next decade brought a striking transformation. The depression of 1921 had far-reaching effects on the American automotive industry; General Motors was plunged into another financial crisis. Alfred P. Sloan became president of the corporation in 1923 and raised it to its unchallenged first place in the industry. Among other steps he gave General Motors a staff-and-line organization, with autonomous manufacturing divisions, which facilitated management of a large corporate structure and became the model for other major automotive combinations. Ford also went through a crisis because the crash caught him involved in the construction of a large new plant (River Rouge) and in the process of buying out his stockholders. Ford weathered the storm (though many of his dealers, unable to sell cars and not permitted to return them, went out of business), but the Ford Motor Company had reached its crest.

Chrysler's entry

The third member of the American "Big Three" was created at this same time. When the Maxwell Motor Company failed in the 1921 depression, Walter P. Chrysler, formerly of General Motors, was called in to reorganize it. It became the Chrysler Corporation in 1925 and grew to major proportions with the acquisition of the Dodge firm in 1928. When Ford went out of production in 1927 to switch from the Model T to the Model A (a process taking 18 months), Chrysler was able to break into the low-priced car market with the Plymouth.

The independents. By 1929 the Big Three had three-quarters of the American market for motor vehicles with most of the remainder divided among the five largest independents (Hudson, Nash, Packard, Studebaker, Willys-Overland). In less than ten years the number of automobile manufacturers in the United States dropped from 108 to 44. Some of the minor firms have technological or personal interest, like Nordyke and Marmon, makers of luxury cars, or E.L. Cord, who marketed a front-wheel-drive car in 1929. The depression years of the 1930s eliminated all but the largest independents and increased still further the domination of the Big Three. Motor vehicle production declined from a peak of over 5,000,000 in 1929 to a low of just over 1,000,000 in 1932. It rose again steadily but had not returned to the 1929 figure when World War II broke out.

Yet, while these years were difficult economically, they saw some significant developments within the industry. Greater emphasis was placed on style in passenger car design, with the general trend in the direction of incorporating body, bumpers, and mudguards into a single pattern of smoothly flowing lines. A number of technical features came into general use: the V-8 engine, introduced by Ford in 1932; three-point engine suspension; free-wheeling (permitting the car to coast freely when the accelerator was released); overdrive (a fourth forward speed); and, on a limited scale, automatic transmission.

Growth in Europe. The period from 1919 to 1939 also witnessed significant growth in automobile manufacturing in Europe, although on a considerably smaller scale than in North America. The European industry was moving in the same directions as the American, toward a mass market for motor vehicles, but it made slower progress for a variety of reasons: lower living standards with less purchasing power, smaller national markets, and more restrictions in tax and tariff policies. Nevertheless, the same trend toward concentration is discernible. British automotive production rose from 73,000 in 1922 (both private and commercial vehicles) to 239,000 in 1929, while the number of producers declined from 90 to 41. Three firms (Austin, Morris, Singer) controlled 75 percent of the British market in 1929.

The apparent analogy to the American experience was temporary. British production was not yet at the level at which the economies of scale gave the larger firms as commanding a lead as in the United States, and there were other factors to create a somewhat different situation. During the 1930s British automotive production continued to increase steadily, in contrast to the American, so that the smaller concerns were not forced to compete for a shrinking market. With output reaching almost half a million in 1937, at the end of the decade there were six major British producers instead of three: Morris, Austin, Standard, Rootes, Ford, and Vauxhall. The last two represented entry by American firms. Vauxhall was bought by General Motors in 1925; Ford had been in Britain since 1911, had lost ground in the 1920s, and had recovered. The Rootes Group, based on Hillman and Humber, was a combine formed by a family that had built a large automobile sales concern and moved from sales to production. The replacement of Singer by Standard was simply the rise of one company and the decline of another, as evidence that open competition could still change the structure of the British automotive industry.

British production gains in the 1930s

In France, three major firms, Peugeot, Renault, and Citroën, emerged in the 1920s. Citroën accounted for 40 percent of French automotive production in 1925, but had reached that dominating position at the cost of financial stability. When André Citroën died before the decade ended, his company came into the hands of Michelin Tire. A new French firm, Simca, rose to prominence in the 1930s. The German automobile industry suffered from the dislocation of World War I and Germany's subsequent economic difficulties. The major developments of the 1920s were the merger of Daimler and Benz in 1926, after the founders of both firms had died (their bitter rivalry for the distinction of being the inventor of the gasoline automobile made any such union during their lifetimes unthinkable), and the entry of General Motors into the German scene through the acquisition of the Opel company in 1929. The Germans were ardent admirers of Henry Ford and his methods, which they termed *Fordismus*, but Ford never succeeded in becoming a power in the German automotive world. During the 1930s the Nazi regime sought to emulate Ford by undertaking mass production of a low-priced car, the Volkswagen, but the onset of war interrupted this project. Italian automobile manufacturers gained a reputation for highly engineered sports and racing cars, but Italy had no mass market and therefore only small-scale production at that time.

The automotive industry at war. During World War I the productive capacity represented by the automotive industry first demonstrated its military value. Motor vehicles were used extensively for transport and supply, and in addition, automotive plants could readily be converted into facilities for the manufacture of military equipment, including tanks and aircraft. For all of the belligerents the conversion of automotive facilities was an afterthought, improvised after the beginning of hostilities, and the United States industry, involved only for a short time, never fully utilized its capacity.

"Shadow factories"

More preparation was made to use the resources of the various automotive industries as World War II approached. The British government built "shadow factories" adjacent to their automotive plants, equipped to go into military production (principally aircraft) when war came, with managerial and technical personnel drawn from the automotive industry. France attempted conversion, but only belatedly and inefficiently. The German automotive industry, which built the military vehicles needed for blitzkrieg warfare, was not fully converted to military production until 1943. In the United States preparation for industrial mobilization was negligible until 1940; in fact, there was no serious effort even to restrict civilian automobile production until after the attack on Pearl Harbor. The American automotive industry, nevertheless, represented such a concentration of productive capacity and skill that once its resources had been harnessed to war production its contribution was stupendous. Between 1940 and 1945 automotive firms made almost $29,000,000,000 worth of military materials, a fifth of the entire United States output. The list included 2,600,000 military trucks and 660,000 jeeps, but production extended well beyond motor vehicles. Automotive firms provided one-half the machine guns and carbines made in the United States during the war, 60 percent of the tanks, all the armoured cars, and 85 percent of the army helmets and aerial bombs.

It had been assumed that automotive facilities could be readily converted to aircraft production, but this proved more difficult than anticipated. Automobile assembly plants did not readily accommodate airframes, nor could an automobile engine factory be converted without substantial modification. In time these problems were resolved and automobile companies contributed significantly to aircraft production.

Britain was better prepared to use the resources of its automotive industry, at that time the world's second largest. The shadow factories became operative, and Austin, Morris, Standard, Daimler, Ford, and Rootes participated in filling the wartime demand for aircraft and aircraft engines. Leyland and Vauxhall built tanks. Lord Nuffield made a notable contribution to the production effort by establishing a system for repairing aircraft, employing the sales and service organization of Morris Motors, and it was subsequently extended to a large number of small contractors.

The automotive industries of the other belligerents were smaller in scale and the facilities for armaments manufacture proportionately greater than in the United States or Great Britain. Consequently, the automotive firms in these countries were concerned chiefly with meeting the insatiable demand for vehicles. The various Ford properties that came under German control and Volkswagen, which turned out the German equivalent of the jeep, were employed in this manner. Renault, a tank manufacturer since World War I, built tanks for France and later for Germany.

The automotive industry since 1945. The years since World War II ended have seen two major developments in the automotive industry. First, there has been a spectacular expansion on a worldwide scale. In 20 years (1950–1970) world output of motor vehicles trebled, from 10,000,000 to 30,000,000 a year; it is significant that the bulk of that increase took place outside the United States, whose share of world automotive production fell from almost 76 percent in 1950 to 28 percent in 1970. The increase in output among the principal producers is shown in Table 1. This phenomenal growth of motor vehicle production was both an index and a cause of the remarkable economic recovery of western Europe and Japan from the devastation of the war.

Table 1: Comparative Totals, Motor Vehicle Production

	1935	1950	1970
U.S.	3,971,241	8,003,056	8,283,949
Japan	...	31,597	5,289,157

The second development has been the continuation and intensification of the trend to concentration in the automotive industry, a trend common to all producing countries. The Soviet Union is a special case, of course, since the state controls all production and distribution of motor vehicles.

Concentration in the United States. At the end of World War II the American automobile industry found itself with its physical plant intact; it had, in fact, been increased because of facilities built by the government for military production. At the same time there was a great pent-up demand for motor vehicles. This situation brought about an ambitious attempt by a newcomer to enter the industry, the first such effort on a substantial scale since the creation of the Chrysler Corporation. The new venture, Kaiser-Frazer, took over the Ford wartime bomber assembly plant at Willow Run, Michigan, as its main assembly centre and produced a range of small and large cars. But it had no technical advance to offer and lacked the resources in capital, management, and sales outlets to compete with the established firms and after several years abandoned the field. The remaining United States independents sought survival in merger. One merged company, Studebaker-Packard, abandoned the American automobile market in 1964 and moved its operations to Hamilton, Ontario. A second, American Motors, managed to remain competitive by introducing the first American "compact," named the Rambler. In competition with the high-powered, ornately decorated cars that dominated the American scene in the 1950s, it succeeded well enough so that the other companies had to

Kaiser-Frazer

meet the competition by producing compacts of their own. The popularity of small foreign cars on the American market also stimulated the trend to compacts.

By the beginning of the 1970s the automotive industry in the United States was concentrated in four major firms (General Motors, Ford, Chrysler, and American Motors, in that order), and one important manufacturer of commercial vehicles, the White Motor Company, which during the 1950s had absorbed most of the separate truck manufacturing firms. A few producers of specialized vehicles remained, along with an assortment of companies making automotive parts and components. Technically, the 1950s and 1960s were marked by improvement and refinement rather than by any important innovation. Diesel engines were increasingly used on trucks and buses. Automatic transmission became virtually standard equipment for passenger cars, and power brakes and power steering found widespread acceptance. In the early 1960s Chrysler experimented with a gas turbine engine for passenger automobiles, but it had too many technical problems for general use.

Styling became increasingly important in automotive design as a marketing device. The general trend in styling became established late in the 1920s when cars began to lose their square, boxlike lines and develop flowing curves. The flow in time encompassed both body and chassis, integrating such formerly separated features as mudguards, running boards, and bumpers. A combination of pressures led American cars in the 1950s to extravagances in the use of chrome and exaggerated tail fins, which ended when the public found the simpler lines of imported cars more attractive.

Growth in Europe. In Europe, motor vehicles were recognized as an export item that could help restore war-shattered economies. Britain, for example, earmarked over one-half its automotive output for export and restricted domestic purchases for several years after the war. In addition, the horsepower tax was abandoned to enable British manufacturers to build profitably for the world market. The most popular British designs (excluding such a specialized luxury vehicle as the Rolls-Royce) continued to be light cars, including a number of models with an ingenious front-wheel drive. The trend to concentration led to the merger of Morris and Austin in 1952, which became the British Motor Corporation, Ltd., a combine that accounted for about two-fifths of Britain's motor vehicle production. Another British combine was formed around Leyland Motors, which had grown to be Britain's largest manufacturer of commercial vehicles and became a power in the passenger car field by acquiring Standard-Triumph and Sunbeam in the 1950s. Leyland and the British Motor Corporation united in 1968 as the British Leyland Motor Corporation, Ltd., a move sanctioned by the government to forestall possible American domination of the British automobile industry. Except for Rolls-Royce, whose automobile production was only a very small part of the company's business, British automobile output was controlled by four firms: British Leyland Motors, Ford, Vauxhall, and Rootes, which came under Chrysler control in 1967.

Introduction of the Volkswagen

The revival of the German automobile industry from almost total destruction was a spectacular feat, with most emphasis centring upon the Volkswagen. At the end of the war the Volkswagen factory and the city of Wolfsburg were in ruins. Restored to production, the plant, in a little more than a decade, was producing one-half of Germany's motor vehicles and had established a strong position in the world market. Breaking away from what had become standard design, the Volkswagen used a four-cylinder air-cooled engine at the rear of the car. The feature proved popular enough to induce other manufacturers to imitate it, but with qualified success. The rear-engine arrangement did not require a long drive shaft but involved problems of weight distribution and consequently of stability. The Volkswagen also dispensed with the annual model change that had become customary with other automobile manufacturers. The company was founded by the German government, but in the 1960s the government divested itself of 60 percent of its interest by selling stock to the public, an unusual case of denationalization in an era when nationalization of industry was far more common.

Fiat (Fabbrica Italiana Automobili Torino), a firm founded in 1899 but without a mass market until the 1950s, dominated Italian automotive production. The French industry was centred on Renault, Peugeot, Citroën, and Simca. Renault was nationalized in 1944 and merged with Peugeot in the 1960s. Simca became a Chrysler property in 1958, and Fiat acquired a 15 percent interest in Citroën. Although Sweden was a relatively small producer, Swedish-built Volvos and Saabs became a factor in the world market during the 1960s.

Japan. The most spectacular rise in automotive production was Japan's. From a negligible position in 1950 Japan climbed in 20 years to become the world's second largest producer of motor vehicles, passing both Britain and Germany. Although the rest of the world knew the Japanese industry through two passenger cars, the Datsun and the Toyota, half of Japan's motor vehicle output consisted of trucks and buses. Japan's post-World War II economic growth created a demand for commercial highway transportation before there was a mass market for private automobiles. Passenger cars now constitute 70 percent of Japanese production.

THE MODERN INDUSTRY

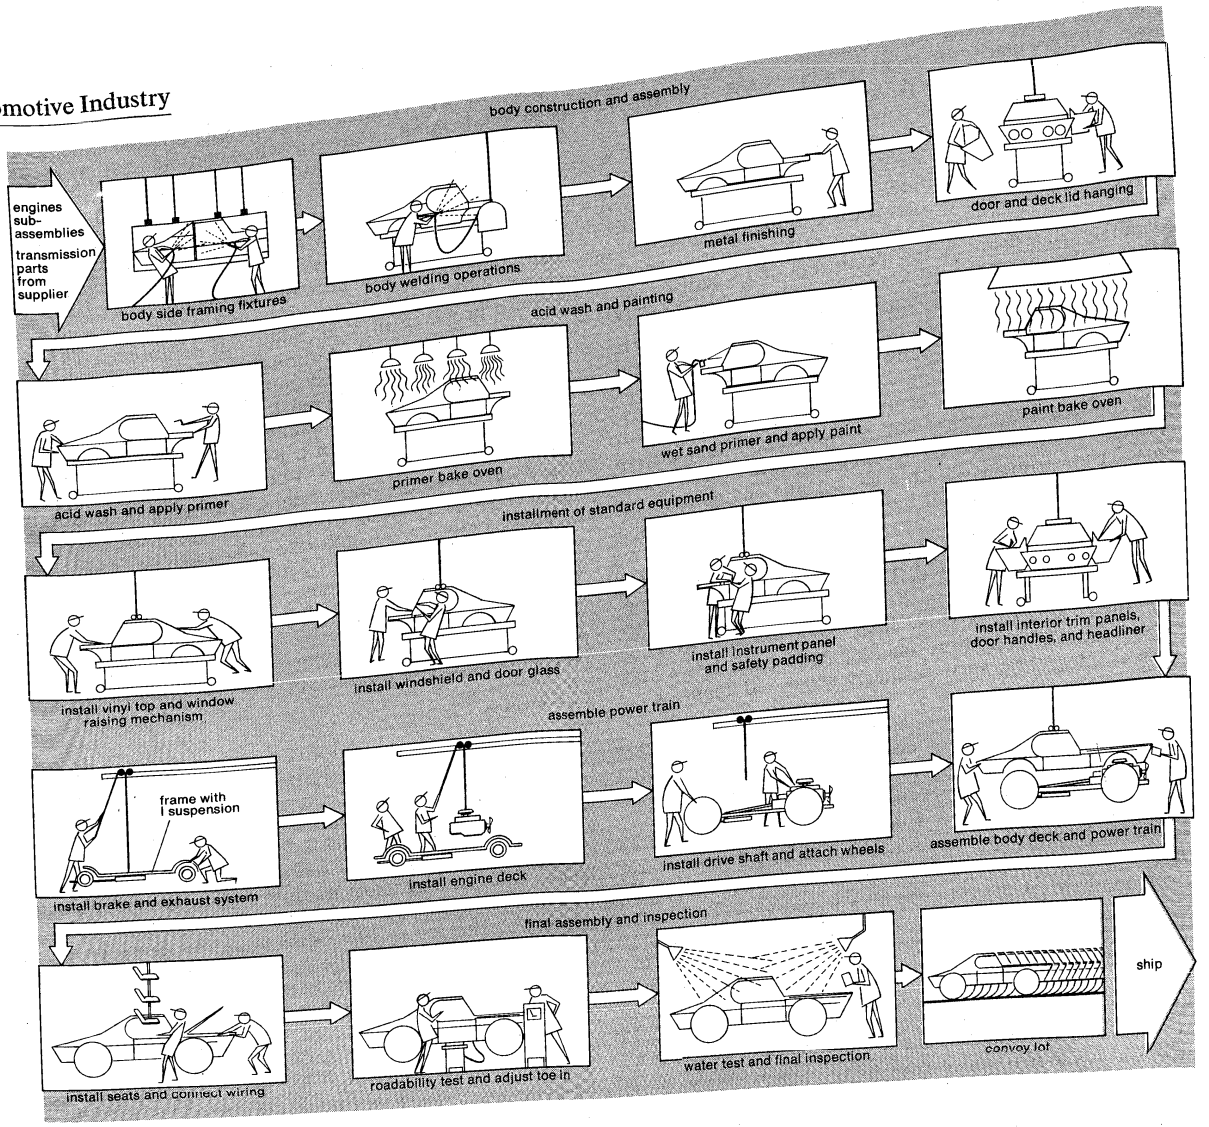
The contemporary automotive industry is a giant and still growing. In the United States, it is the largest single manufacturing enterprise in terms of total value of products, value added by manufacture, and number of wage earners employed. One business in six is dependent on the manufacture, distribution, servicing, or use of motor vehicles; sales and receipts of automotive firms represent 17 percent of the country's wholesale business and 24 percent of the retail. For other countries these proportions are somewhat smaller, but western Europe and Japan are rapidly approaching the United States level.

Concentration. The trend to concentration in the industry has already been traced. In each of the major producing countries the output of motor vehicles is in the hands of a few very large firms, and the small independent producer has virtually disappeared. The fundamental cause of this trend is the technique of mass production, which requires a heavy investment in equipment and tooling and is therefore feasible only for a large organization. Once the technique is instituted, the resulting economies of scale give the large firm a commanding advantage, provided of course that the market can absorb the number of units that must be built to justify the investment. Although the numbers required are difficult to determine exactly, the best calculations, considering both the assembly operation and the stamping of body panels, place the optimum output between 200,000 and 400,000 cars per year for a single plant.

Significance of size of production run

The structural organization of these giant enterprises shows, despite individual variation, a recognizable tendency toward the pattern first adopted by General Motors in the 1920s. There is a central organization with an executive committee responsible for overall policy and planning. The operating divisions are semi-autonomous, each reporting directly to the central authority but responsible for its own internal management. In some situations the operating divisions even compete with each other. The Ford Motor Company was consciously reorganized on the General Motors pattern after World War II; other American automotive firms have similar structures, as do British Leyland Motors and Rootes.

In addition, the largest producers decentralize their manufacturing operations by means of regional assembly plants. These permit the central factory to ship frames and components rather than complete automobiles to the areas served by the assembly plants, effecting substantial savings in transportation costs. This system was worked out for the Ford company as far back as 1911. It was particularly well suited to the extensive market areas of the United States and Canada. The local assembly plant has also been generally employed by United States and European firms to penetrate foreign markets.



Automobile assembly line.
Adapted from *Automotive Industry* (October 1970)

Diversity of product line. The immense resources of the automotive industries in production facilities and technical and managerial skills have been devoted predominantly to the building of motor vehicles, but there has been a consistent strong incentive to extend into related products and occasionally into operations whose relationship to automobiles is remote. The Ford Motor Company has long manufactured tractors.

Ford and General Motors have both been involved in aircraft manufacture. Ford built the famous Ford trimotor, an all-metal transport, from 1924 to 1932. For about 20 years General Motors had an interest in North American Aviation and Bendix Aviation and continues to be an important manufacturer of aircraft engines. It also makes refrigerators, diesel engines, diesel-powered railway locomotives, and earth-moving equipment. All these operations resulted from the acquisition of companies that were actively or experimentally engaged in these fields.

American Motors manufactures electric refrigerators and other household appliances as a result of merging with the Kelvinator Corporation. Ford moved into electronics and astronautics in 1961 by acquiring the Philco Corporation, a manufacturer of radios, televisions, and electronic equipment, and by organizing an Aeronutronic Division. In Europe the same trend is observable. Fiat is an industrial giant that not only makes 90 percent of all Italian cars but also builds aircraft, railway locomotives, marine engines, and electric refrigerators. In addition, it has a division engaged in major civil engineering and construction works. Renault builds tractors and machine tools. British Leyland Motors makes tractors, aircraft engines (through its Alvis division), refrigerators, and household appliances. The major Japanese automobile manufacturers, Toyota and Nissan (Datsun), have affiliates that make railway rolling stock, aircraft and aircraft engines, road rollers, and diesel engines.

Market surveys

New car development. The process of putting a new car on the market has become largely standardized. If a completely new model is contemplated, the first step is a market survey. Since there may be an interval of five years between this survey and the appearance of the new car in the dealers' showrooms, there is a distinct element of risk, as illustrated by the case of the Ford Motor Company's Edsel. (Market research had indicated a demand for a car in a relatively high price range, but by the time the Edsel appeared, both public taste and economic conditions had changed.) Conferences then follow among engineers, stylists, and executives to agree on the basic design. The next stage is a mock-up of the car, on which revisions and refinements can be worked out.

Manufacturing processes. The bulk of the world's new cars come from the moving assembly line introduced by Ford, but much more refined and elaborated (see illustration). The first requisite of this process is an accurately controlled flow of materials into the assembly plants. No company can afford either the money or the space to stockpile the parts and components needed for any extended period of production. Interruption or confusion in the flow of materials quickly stops production. Ford dreamed of an organization in which no item was ever at rest from the extraction of raw material to the vehicle's completion, a dream not yet realized.

The need for careful control over the flow of materials is an incentive for automobile firms to manufacture their own components, sometimes directly but more often through subsidiaries. Yet complete integration does not

exist and is not desired. As a general rule, tires, batteries, and dashboard instruments are procured externally. In addition, and for the same reasons, the largest companies support outside suppliers even for items of inhouse manufacture. First, it may be more economical to buy externally than to provide additional internal facilities for the purpose. Second, the supplier firm may have special equipment and capability. Third, the outside supplier provides a check on the costs of the inhouse operation. United States companies rely more than others on independent suppliers. Only General Motors in the United States produces over half of its own parts.

Production of a new model also calls for elaborate tooling, and the larger the output the more highly specialized the tools. For example, it is expensive to install a stamping press exclusively to make a single body panel for a single year model, but if the model run reaches several hundred thousand, the cost is amply justified.

The assembly process itself has a quite uniform pattern throughout the world. As a rule there are two main lines, body and chassis. On the first, the body panels are welded together, doors and windows installed, and the body painted and trimmed (upholstery, interior hardware, wiring). On the second, the frame has springs, wheels, steering gear, and power train (engine, transmission, drive shaft, and differential) installed, plus brakes and exhaust system. The two lines merge at the point where the car is finished except for minor items and necessary testing and inspection. A variation on this process is "unitized" construction, whereby body and frame are assembled as a unit. In this system the undercarriage still goes down the chassis line for power train, front suspension, and rear axle, to be supported on pedestals until they are joined to the unitized body structure. Engines are constructed in the same way, as a rule, in separate assembly plants.

Automated assembly lines

Assembly lines have been elaborately refined by automatic control systems and transfer machines, which have replaced many manual operations where volume is high. Austin Motors in Britain seems to have pioneered with automatic transfer machines in 1950. The first large-scale automated installation in the United States was a Ford Motor Company engine plant that went into production in 1951. A universally employed form of automatic control has been the use of punch cards and computers to schedule assembly operations so that a variety of styles can be programmed along the same assembly line. Customers can be offered wide choices in body styles, wheel patterns, and colour combinations.

Sales and service organization. Mass production implies mass consumption, which in turn requires an elaborate distributive organization not only to sell the cars but to develop customer confidence that adequate service will be available. In the early days cars were sold direct from the factory or through independent dealers who might handle several different makes. Many of the bicycle manufacturers simply used their existing sales outlets when they added horseless carriages to their line. When sales in large quantities became the objective, however, more elaborate and better organized techniques of distribution became essential.

In the United States the restricted franchise dealership became the uniform and almost exclusive method of selling new cars. In this system the dealer may sell only the particular make of new car specified in his franchise, must accept a quota of cars specified by the manufacturer, and must pay cash on delivery. In return he receives some guarantee of sales territory and may be assisted in various ways by the manufacturer: financing or aid in advertising, for instance. Contracts also specify that the dealer must maintain service facilities on standards approved by the manufacturer.

Seemingly weighted in favour of the manufacturer, the system has been subjected to periodic dealer complaint, producing state legislation and a federal statute in 1956 to protect dealers from arbitrary action on the part of the manufacturers. Yet dealers have never been united in these attitudes, and no effective substitute for the restricted franchise has as yet been found. On the contrary, it is becoming the general practice in other parts of the world where large-scale markets for motor vehicles have been developing.

The United States has about 34,000 franchised passenger-car dealers, all of whom sell both new and used cars, and about 28,000 nonfranchised dealers engaged predominantly in buying and selling used cars. In addition, there are over 100,000 enterprises engaged in general and specialized repairs to motor vehicles and well over 200,000 gasoline stations, most of which do some repair and service work. These are all at least ancillary to the automotive industry.

The market in used cars is an important part of the distribution system for motor vehicles in all countries with a substantial motor vehicle industry because it affects the sale and styling of new cars. The institution of the annual model was adopted in the United States during the 1920s to promote new-car sales in the face of used-car competition. The new model must have enough changes in styling or engineering to persuade prospective buyers that it is indeed an improvement. At the same time it must not be so radically different from its predecessors as to give the buyer doubts about its resale potential.

Like all machinery, motor vehicles wear out. In the United States alone over 7,000,000 are scrapped each year. Some become scrap metal to feed steel furnaces; some go to wrecking yards where usable parts are salvaged. Throughout the world, however, the disposal of discarded motor vehicles has become a problem without a completely satisfactory solution. In too many areas landscapes are disfigured by abandoned wrecks or unsightly automobile graveyards.

International operations. The automotive industry is supranational in its organization and operation and is matched in this respect only by the petroleum industry. Reference has been made to the international expansion of the principal American automobile companies. General Motors owns Vauxhall in Britain, Opel in Germany, and Holden in Australia. Ford has been established for many years in Great Britain, Germany, France, Spain, Denmark, and Holland, and in the early 1960s acquired Willys of Brazil. Chrysler controls Rootes in Britain and Simca in France. The major European producers follow a comparable pattern with worldwide networks of subsidiaries and affiliates, although none operates on as large a scale as General Motors or Ford. Most of the principal motor-vehicle-producing countries export a much higher proportion of their total output than does the United States (Table 2), but this picture is misleading because it does not allow for the very substantial volume of motor vehicle production by American-owned companies in other countries.

Table 2: Motor Vehicle Exports as Percentage of Production
(1969)

	percentage
Canada	83.4
Sweden	60.8
West Germany	57.0
France	47.8

International vehicle registrations

The most promising export markets for motor vehicles were, and fundamentally still are, developed countries with the purchasing power to create a demand for automobiles, essentially North America, Europe, Japan, such Commonwealth states as Australia and New Zealand, and South Africa. Since 1950 there has been a significant shift in market prospects in favour of the developing countries, in that vehicle registrations in those countries have grown almost twice as fast as in the highly developed nations (Table 3). There has been, in consequence,

Table 3: Motor Vehicle Registrations in 20 Leading Countries (1969)

	cars	commercial	total	population per vehicle
U.S.	86,861,334	18,235,269	105,096,603	1.9
Japan	6,933,732	8,192,934	15,126,666	6.8
West Germany	12,198,180	2,099,472	14,297,652	4.1
France	11,670,000	2,100,000	13,770,000	3.7
U.K.	11,504,300	1,901,040	13,405,340	4.0
Italy	9,028,400	834,174	9,862,574	5.4
Canada	6,433,283	1,461,571	7,894,854	2.7
U.S.S.R.	1,560,000	4,075,000	5,635,000	43.0
Australia	3,676,241	949,587	4,625,828	2.7
Brazil	2,041,000	1,161,000	3,202,000	28.0
Spain	1,998,500	688,500	2,687,000	12.0

an intensification of both assembly and distribution in parts of the world not previously important in the automotive industry. In 1965 about 1,000,000 motor vehicles (out of a world total of 25,000,000) were produced outside the major manufacturing nations, about 80 percent in Australia, Spain, Argentina, Brazil, Belgium, and East Germany.

The great bulk of this production is assembly, done in plants affiliated with and usually operated by American, European, or Japanese automotive firms. Because of the small volume of output, the assembly operations are high cost. In a completely free market it would be much cheaper to ship cars from the home plants, but the market is not free. In order to develop their own industries, these nations by and large have tariff policies that make imported cars prohibitively expensive and, in addition, requirements that a substantial portion of the components used in local assembly plants be of domestic origin. A stipulated percentage of local ownership, public or private, is also a normal requirement. The rest of the financing and most of the initial managerial and technical skill come from the parent company. Argentina, Brazil, and Spain have been able to reach 90 to 100 percent of domestic content in car manufacture; India and Mexico between 60 and 80 percent. While these proportions may portend well for the future, they are an additional cost factor at present. An Indian car, for example, with 97 percent domestic content, costs twice as much to produce as the same vehicle in Europe; with 28 percent domestic content, the cost is one and one-half times what it is in Europe.

Economic and social impact. The automotive industry has become a vital element in the economy of the industrialized nations to the extent that motor vehicle production and sales are one of the major indices of the state of the economy in those countries. For the United Kingdom, Japan, France, Italy, Sweden, and West Germany, motor vehicle exports are essential to the maintenance of healthy international trade balances.

The effect of motor vehicle manufacturing on other industries is shown in part in Table 4. Almost one-fourth of United States steel production and well over three-fifths of its rubber output go to the automotive industry, which is also the largest single consumer of machine tools. More than that, the special requirements of automotive mass production have had a profound influence on the design and development of highly specialized machine tools and have stimulated technological advances in petroleum refining, steelmaking, plate glass, paints, and other industrial areas.

The indirect effects are also considerable, through the many businesses such as motor-freight operators and highway construction firms which are automotive related. Finally, truck transportation has grown steadily throughout the world.

Highway development. Before the advent of the motor vehicle, roads in most parts of the world were generally poor. The available methods of road transport were so costly and inefficient that, unless there were special considerations such as military movements, it was not worthwhile to maintain roads for other than local movements. The general use of automobiles created a strong demand for better highways. The first response was to provide for the improvement of existing road networks. Experience subsequently demonstrated that roads for automobile traffic needed to be differentiated functionally, depending on whether they were intended for through or local traffic. Main arteries are best designed as freeways (motorways, *autostrade*, *Autobahnen*); *i.e.*, divided highways with complete control of access and no intersections at grade (see ROADS AND HIGHWAYS).

Highways functionally differentiated

Social effects. A historian said that Henry Ford freed the common man from the limitations of his geography. The statement cogently summarizes the social transformations still proceeding throughout the world as a result of the motor vehicle. It has created mobility on a scale never known before, and the total effect on living habits and social customs is still incalculable. The automobile has radically changed urban life by accelerating the outward expansion of population into the suburbs. As with other automobile-related phenomena, the trend is most conspicuous in the United States but is rapidly appearing elsewhere. The decentralizing trend is accentuated by the fact that highway transportation encourages business and industry to move outward to sites where land is cheaper, access by car and truck is easier than in crowded central cities, and space is available for the one-story structures that permit optimum use of modern materials-handling techniques. Yet the impact on rural life has been, if anything, more pronounced than the effect on the city. In the days of horse-drawn transport the economical limit of wagon transportation was from 10 to 15 miles, so that any community or individual farm farther than 15 miles from a railroad or navigable waterway was effectively isolated from the mainstream of economic and social life.

In urban and rural areas alike the automobile is credited with spawning drastic changes in the sexual mores of the young, who have found in it a privacy not formerly attainable.

Motor vehicles and paved roads have narrowed much of the gap between rural and urban life. Not only can the farmer ship easily and economically by truck and drive to

town when convenient but institutions such as regional schools and hospitals are now accessible by bus and car.

It would be impossible to list all the specific effects of motor vehicle production, but two are especially illustrative. First, the marketing of automobiles has stimulated a great expansion in the use of credit. Installment buying existed before the automobile, but in a limited scope. The technique was introduced into the United States automobile industry in 1916 by manufacturers of medium-priced cars to help meet the competition of the low-priced Model T. It became universal practice in all countries in the purchase of motor vehicles and accustomed people to buying other durable consumer goods in the same way. Second, there has been a striking development of drive-in business, again first in the United States but spreading rapidly everywhere.

Recreational travel. One of the conspicuous impacts of the automobile has been to permit nearly everyone in the automotive countries to travel for recreation. The motor vehicle allows for such auxiliary devices as trailers (caravans in Europe), campers, and boat trailers, to broaden the scope of recreational opportunities.

Adverse effects. The mass use of motor vehicles was bound to have some unforeseen and undesirable consequences, of which three can be singled out: traffic congestion, air pollution, and highway accidents. The approach to each of these problems has illustrated a common propensity to blame the technology, rather than the way in which the technology has been used.

Congestion, pollution, and accidents

City streets were congested long before the automobile existed, but the problem has been compounded enormously by the masses of motor vehicles that attempt to enter or leave cities at peak traffic hours. The constantly growing number of automobiles throughout the world adds to the difficulty of finding remedies for congestion. The heart of the problem is that few city street systems have been designed for automobile traffic. Reliable estimates are that some two-thirds of the vehicles in central business districts are passing through and should have been routed on circumferential highways. Remedying this situation is difficult and expensive. It calls for modern highways to provide ready access both into and around downtown areas. Programs for this purpose encounter vigorous opposition, frequently justified, on the ground that building freeways in cities disrupts neighbourhoods and destroys scenic or historic values.

The widespread use of automobiles for work trips has also led in many cities to a decline in public-transit systems, and there has been much discussion of the need for encouraging the development and use of up-to-date mass-transit media. Given the trend toward dispersal of people and business in urban areas, it seems doubtful that mass transit will appreciably diminish motor vehicle traffic. In any event, for most cities bus systems can provide the needed capacity for public transportation and are the most economical way of doing so.

Atmospheric pollution also antedates the automobile, but the concentration of many thousands of motor vehicles in large cities has given the problem a new dimension. Automobile exhausts contribute from half the atmospheric pollutants in most cities to a high of about 80 percent in Los Angeles, where atmospheric conditions are peculiarly conducive to smog formation. Progress in combatting the problem has been slow because the development of suitable devices has taken time. Studies of alternative power plants are also being made. In the early 1970s only the United States had enacted legislation in this area, but with use of motor vehicles expanding more rapidly elsewhere, action against automobile-caused air pollution seems likely to spread.

The most distressing feature of large-scale use of motor vehicles has been the universally heavy toll of highway accidents. The United States, with the largest number of cars and the heaviest volume of highway travel, has the highest aggregate figures in this category: over 50,000 fatalities and a million disabling injuries annually since 1965. The economic and social costs are virtually beyond measure. Rising concern over this situation led to the passage in 1966 of the National Traffic and Motor Vehicle Safety Act, requiring the incorporation of safety features in cars, and the Highway Safety Act, for developing comprehensive programs of traffic safety. As automobile usage has increased elsewhere, other countries have also had to wrestle with this problem. Studies throughout the world make it clear that traffic safety has three major components—the vehicle, the driver, and the road—and that safety programs must give due weight to all three.

FUTURE TRENDS

Prediction about the future of the automotive industry is necessarily risky, but some trends seem reasonably certain unless drastic and currently unforeseeable change occurs. The production and use of motor vehicles will continue to increase, with the increase proportionately greater in those parts of the world that do not now have large, well-established automotive industries or widespread automobile use, especially the U.S.S.R., India, and Latin America.

Next, given existing public pressures, greater emphasis will be placed on incorporating safety and antipollution features into the design and construction of motor vehicles. Partly because of these pressures, but more because technology changes, the automobile of the future will eventually have a different power plant, although what it will be and when it will come cannot be accurately forecast. Experiments with steam have been much discussed but have not yielded economically practical results. Electric automobiles remain subject to the limitations of the battery. Fuel-cell power plants have acute technical problems to be overcome before they are ready for everyday use in passenger cars. Any or all of these may experience a technological breakthrough, but the most likely replacement for the internal combustion engine is some form of gas turbine.

The automotive industry itself will probably continue to be dominated by a few very large firms. Even where new production develops, current experience is that it occurs in some form of relationship with the existing automotive giants. This scale of operation is inherent in the technology of automotive production. There is likely to be increased diversification as a measure of protection against fluctuation in the market for motor vehicles and possibly against anti-automobile legislation, but this diversification will hardly affect the character of the basic operation.

BIBLIOGRAPHY

General histories: Informed general accounts of the American automotive industry include: R.M. CLEVELAND and S.T. WILLIAMSON, *The Road is Yours* (1951); M. DENISON, *The Power to Go* (1956); and J.B. RAE, *American Automobile Manufacturers: The First Forty Years* (1959), and *The American Automobile* (1965). Comparable accounts for Great Britain are H.G. CASTLE, *Britain's Motor Industry* (1950); and L.T.C. ROLT, *Horseless Carriage: The Motor Car in England* (1950).

Economic and Social Studies: Two comprehensive works on the impact of the automobile are C.D. BUCHANAN, *Mixed Blessing: The Motor in Britain* (1958); and J.B. RAE, *The Road and the Car in American Life* (1971). J.J. FLINK, *America Adopts the Automobile, 1895–1910* (1970), is a unique description of the acceptance of the motor vehicle.

Biographical works: A brief biography of Henry Ford is R. BURLINGAME, *Henry Ford: A Great Life in Brief* (1954). A.P. SLOAN, JR. has a good autobiography, *My Years with General Motors* (1963). The best biography of a leading British automotive figure is P.W.S. ANDREWS and E. BRUNNER, *The Life of Lord Nuffield* (1955). There is an excellent study of the German automotive pioneers in E. DIESEL, G. GOLDBECK, and F. SCHILDBERGER, *Vom Motor zum Auto* (1957; Eng. trans., *From Engines to Autos*, 1960).

Modern industry: An excellent analysis of the American automobile industry in the 1950s and early 1960s is C.E. EDWARDS, *The Dynamics of the United States Automobile Industry* (1965). A comparable study for Great Britain is G. MAXCY and A. SILBERTSON, *The Motor Industry* (1959). The most authoritative work on the expansion of the automotive industry to the developing countries is J. BARANSON, *Automotive Industries in Developing Countries* (1968).

(J.B.Ra.)

Autopsy

Autopsy is the dissection and examination of a dead body and its organs and structures to determine the cause of death, to observe the effects of disease, and to establish the sequences of changes and thus establish evolution and mechanisms of disease processes. The procedure is also variously called necropsy, postmortem, and postmortem examination.

History. Although the Greek physician Galen (AD *c.* 130–*c.* 200) accepted the ancient humoral theory of disease as a faulty mixture of the four body fluids or humours, he was the first to correlate the patient's symptoms (complaints) and his signs (what can be seen and felt) with what was found upon examining the "affected part of the deceased." This was the great leap forward that eventually led to the autopsy and broke an ancient barrier to progress in medicine. The early Egyptians did not study the dead human body for an explanation of disease and death, though some organs were removed for preservation. The first real dissections for the study of disease were carried out by the Alexandrian physicians Herophilus (flourished 300 BC) and Erasistratus (flourished 300 BC). The Greeks and the Indians cremated their dead without examination; the Romans, the Chinese, and Muslims all had taboos about opening the body. Human dissections were not permitted during the Middle Ages; only animals were examined. Medieval prohibition was based on the doctrine that "the Church abhors the shedding of blood." (Opposition to the autopsy still persists among some sects.)

The first dissections

Mondino dei Liucci, of Bologna, did the first public anatomical demonstrations in 1315. It was the rebirth of anatomy during the Renaissance, as exemplified by the work of Andreas Vesalius (*De Humani Corporis Fabrica,* 1543) that made it possible to distinguish the abnormal, as such (*e.g.*, an aneurysm), from normal anatomy. Leonardo da Vinci (1452–1519) dissected 30 corpses and noted "abnormal anatomy"; his records of these and many of his anatomical drawings have come to light only recently. Michelangelo (1475–1564), too, did a number of dissections. Earlier, in the 13th century, Frederick II ordered that the bodies of two executed criminals be delivered every two years to the medical schools, one of which was at Salerno, for an "Anatomica Publica," which every physician was obliged to attend.

In 1348 Pope Clement VI ordered the bodies of plague victims opened; his physician, Guy de Chauliac, described the changes. The first forensic or legal autopsy, wherein the death was investigated to determine presence of "fault," is said to have been one requested by a magistrate in Bologna in 1302; no guilt was found. Antonio Benivieni, a Florentine physician (*c.* 1440–1502), did 15 autopsies explicitly to determine the "cause of death" and significantly correlated some of his findings with prior symptoms in the deceased. Théophile Bonet of Geneva (1620–89) collated from the literature the observations made in 3,000 autopsies. Many specific clinical and pathologic entities were then defined by various observers, thus opening the door to modern practice.

The autopsy came of age with Giovanni Morgagni, the father of modern pathology, who in 1761 described what could be seen in the body with the naked eye. In his voluminous work *On the Seats and Causes of Diseases as Investigated by Anatomy*, he compared the symptoms and observations in some 700 patients with the anatomical findings upon examining their bodies. He proved the dictum of his teacher Antonio Valsalva (1666–1723) that an apoplectic hemorrhage in the brain caused a paralysis on the opposite side of the body. He described syphilitic aneurysms, cirrhosis, and acute yellow atrophy of the liver. In addition, he observed that in pneumonia the lung became solid and took on the substance and appearance of liver, introducing the pathologic term "hepatization." He noted the relationship of the occupation of stone-cutting to tuberculosis of the lung (consumption) and to caseous tuberculous lymph nodes (scrofula). Many other entities, such as brain abscess from a middle ear infection and calcifying hardening of the arteries of the heart, are found among his cases. Most important, in Morgagni's method, study of the patient replaced that of books and commentaries.

With Karl von Rokitansky of Vienna (1804–78), the gross (naked eye) autopsy reached its apogee. Rokitansky utilized the microscope very little and was limited by his own humoral theory. The French anatomist and physiologist Marie F.X. Bichat (1771–1802) stressed the role of the different generalized systems and tissues in the study of disease. It was the German pathologist Rudolf Virchow (1821–1902), however, who introduced the cellular doctrine—that changes in the cells are the basis of the understanding of disease—in pathology and in autopsy. In *Die Cellularpathologie in ihrer Begründung auf physiologische und pathologische Gewebelehre* (*Cellular Pathology Based on Physiological and Pathological Histology*, 1858), he established that the cell is the unit of life, that all cells come from pre-existing cells, that disease is altered cell function or relations or both; proclaimed that the anatomical lesion at the cellular level is the disease; and destroyed utterly the humoral theory. He also warned against the dominance of pathologic anatomy—the study of the structure of diseased tissue—alone as such and stressed that the future of pathology would be physiologic pathology—study of the functioning of the organism in the investigation of disease.

The modern autopsy has been expanded to include the application of all knowledge and all of the instruments of the specialized modern basic sciences. The examination has been extended to structures too small to be seen except with the electron microscope, and to molecular biology to include all that can be seen as well as what still remains unseen.

The procedure. The autopsy procedure itself has changed very little during the 20th century. There has always been a gross examination of the exterior for any abnormality or trauma and a careful description of the interior of the body and its organs. For some time this has been followed by further studies, including microscopic examination, for which purpose portions of tissues and organs (blocks) are embedded in paraffin or other material and thin slivers (sections) are stained by one of the many techniques evolved over the years.

Gross examination

The main incisions in the body remain the same. For the torso, a Y-shaped incision is made. Each upper limb of the "Y" extends from either the armpit or the outer shoulder and is carried beneath the breast to the bottom of the sternum, or breastbone, in the midline. From this point of juncture at the bottom of the sternum the incision is continued down to the lower abdomen where both groins meet in the genital area. The incision extends through all the layers of the abdominal wall, and, with some undermining cuts, the flaps are turned back so that the abdominal cavity is laid open. The chest content is exposed by removal of the sternum, and the intestinal tract is usually removed by stripping the bowel from its attachment.

There are two different schools as to procedure beyond this point. In the Rokitansky method, each organ is removed separately for incision and study. In the en masse method the chest organs are all removed in a single group and all of the abdominal organs in another for examination. The great vessels to the neck, head, and arms are ligated—tied off—and the organs removed as a unit for dissection. The neck organs are explored *in situ* only or removed from below. Dissection then proceeds usually from the back, except where findings dictate a variation in the procedure. Usually groups of organs are removed together so that disturbances in their functional relationships may be determined. In examination of the head, an incision is made across the top or vertex of the scalp and the resulting flaps turned out front and back. The top of the skull is removed. After study of the brain in position, it is freed from its attachments and removed *in toto*. The spinal cord can be removed by sawing through the bodies of the vertebrae from in front or by making another incision from the back and removing the vertebral arches.

The dissector proceeds to examine the external and cut surface of each organ, its vascular structures, including arteries, lymphatics, fascial or fibrous tissue, and nerves. Specimens are taken for culture, chemical analysis, and other studies. Immediately upon completion of the procedure, all of the organs are returned to the body and all incisions carefully sewn. After the body's proper restoration, no unseemly evidence of the autopsy need remain.

After the gross examination of the body the findings are balanced one against another and a list of pathological findings is compiled; this list comprises the tentative or "provisional anatomical diagnoses." Such diagnoses are grouped and arranged in the order of importance and of sequence. On occasion a quick microscopic study is done to confirm a diagnosis so as to assure its proper listing. Finally the examiner lists as the cause of death the one lesion without which death would not have occurred. Though obviously all-important in forensic cases, this aspect of the autopsy analysis is also required in cases not required by law. After all studies—histological, chemical, toxicological, bacteriological, and viral—are completed, any errors of the provisional anatomical diagnoses are corrected and the final anatomical diagnoses and the final cause of death are listed. A statement of analysis of the autopsy that correlates the findings with the clinical picture, the "clinical pathological correlation," concludes the record of the autopsy.

Final diagnosis and final cause of death

The medicolegal autopsy. The forensic autopsy is an imperative function in modern society. The truth must prevail in certified detail if justice is to prevail. The forensic pathologist goes beyond the mere cause of death; he must establish all the facts, both lethal and nonlethal, with any potential bearing whatsoever on the criminal or civil litigation. The cause of death is not automatically revealed when the body is opened; it is not an isolated tangible and delimited entity; it is a *concept*—an opinion—as to mechanism or happening and as such is subject occasionally to differences in interpretation. The legal autopsy requires meticulous detailed descriptions, measurements, and documentation. Experience in the investigation of the scene of a death in medicolegal cases is important, for the evaluation of circumstances of death may be critical in establishing the mode of death—*e.g.*, suicide. The autopsy may not be able, of itself, to determine intent, whereas the scene and the circumstances, such as an empty pill bottle or a note beside the body, may provide unmistakable evidence. Photographic documentation is important in the medicolegal autopsy. The medicolegal postmortem examination must always be complete to rule out any other potential contributory cause of death and therefore must never be limited to a partial study. The identification of the deceased and of all specimens taken from the body is critical; the time of death and the blood grouping must, if possible, be established. The medicolegal autopsy substitutes facts for speculation in the courtroom; it helps convict the guilty and free the innocent. The external examination is important and must include every minute detail of trauma to help determine its nature. The small chemical burn on the lip may indicate poisoning. In the case of wounds, the description must note the depth, direction and extent, bleeding, discoloration, height of the wound above heel, and structures penetrated. All important is the presence or absence of powder burns and their size and configuration as well as whether the wound edges are turned out or in. In all autopsies, but especially in forensic cases, findings must be dictated to a stenographer or recording instrument during the actual performance of the procedure. The record often becomes legal evidence and therefore must be complete and accurate.

External examination

In some jurisdictions administrative codes are specific and provide that the death of any person from criminal violence, or by casualty, or by suicide, or suddenly, while in apparent health, or when unattended by a physician, or in any suspicious or unusual manner, shall be reported forthwith to the office of the chief medical examiner. As many as one-third of the deaths in a community may be reported for investigation to the medicolegal authorities.

Reasons for autopsy. Death represents the final failure of medical care, and so the autopsy is the final evaluation of the care given. The autopsy deals with the particular illness as evidenced in one individual and is more than simply a statistical average. Every autopsy is important to expose mistakes, to delimit new diseases and new patterns of disease, and to guide future studies. With the autopsy one can evaluate the numerous new drugs and modes of therapy; many are toxic and dangerous and can do more harm than good. Bizarre ideas about the nature of human disease are still extant; the autopsy continues to expose such erroneous dogma. Morbidity and mortality statistics acquire accuracy and significance when based on careful autopsies; they also often give the first indication of contagion and epidemics. The autopsy promotes a proper balance between all elements of the health complex—physician, hospital, research and education, and the integration of the multifarious specialties—so that excessive emphasis on any one at the expense of others can be corrected.

The autopsy also provides opportunities for the salvage of human organs for transplantation and for hormone extraction. Growth hormone from cadavers can make a dwarfed child normal; a transplant of a clear cornea can restore sight; a kidney can save a life. Genetic, hereditary, and degenerative diseases are becoming more frequent than those due to infection; the autopsy can point the way to counselling and preventive measures for the family. There is also psychological benefit for the family in the acceptance of the demonstrable disease, the reality of death, and the ultimate decomposition of the body.

Aid to medical education

Probably the most important role of the autopsy today is its contribution to medical education. The autopsy is invaluable in undergraduate, graduate, and continuing education of physicians. It is the focal point at which the profession learns to assess and to apply medical knowledge.

There was a time when virtually all progress in medicine was made at the autopsy table. In the 20th century many refinements in basic science and technology, which are applicable to the living patient, are important for the understanding and treatment of disease. Molecular concepts, however, are no substitute for what can be seen by the naked eye or for the older staples and simple truths of the autopsy. Disease cannot be known only from a battery of reports or from waves on a polygraph or oscilloscope but rather by seeing and understanding its extent and effect as it occurs in the human body.

The autopsy does more than merely determine the cause of death. While the medicolegal autopsy in particular has this important primary objective, most autopsies have a larger purpose: to reveal the sequential changes of disease from start to finish, as altered by intrinsic and extrinsic factors. By piecing together in proper order the static pictures found at each of many different stages of disease in a series of autopsies, an appropriate sequential analysis may be obtained of how the disease proceeds.

Future of the autopsy. Impressed by outstanding advances in biochemistry and molecular biology, some doctors consider the autopsy no longer important. The autopsy must continue to carry out the many routine functions noted above. Like all research, the autopsy is a deficit expenditure for hospitals and will be more costly as it becomes more thorough. The support provided by grants for experimental scientific research in other fields is also needed for the autopsy so that the autopsy can become more productive in research and publication as it becomes more precise and probing. In the future more biochemical, toxicological, and bacteriological studies should be done; viral studies are now more frequently indicated. The use of radioactive isotopes as tracers for test-tube study of the metabolism of tissues still viable after death should be explored. The special autopsy should include withdrawal—at the moment of death to forestall postmortem changes—of tissue and fluids from areas suspected of being foci of disease for study by the electron microscope. Appropriate animal experimentation should follow as indicated.

Only thus can the autopsy match other techniques in

the achievements of modern medicine. There has been a shift of emphasis in all pathology from a concentration on morphology alone to include study of function and molecular biology with sophisticated instrumentation. In the hospital the autopsy will continue to be important for the evaluation of clinical diagnoses and of medical and surgical treatment as well as for continuing education and clinical research. Some researchers believe that it is not unreasonable to look forward to the day when data on every illness, injury, drug, surgical procedure, and other event of significance in disease, including autopsy diagnoses, will be entered, with some form of identification for each individual, in a computer. Then, instead of being simply cancelled out at death the identifying symbol—such as a social security number—could be kept with all the entries; and with the addition of the coded autopsy data, there would be available a permanent storehouse of knowledge for future study of human disease. The life of each person would thus become an invaluable contribution to medical knowledge. In this and many other ways the autopsy can continue and enhance its vital role in medicine.

Averroës

Abū al-Walīd Muḥammad ibn Aḥmad ibn Muḥammad ibn Rushd—called Averroës by the medieval Latin scholars—was one of the most important Islāmic thinkers; he integrated Islāmic traditions and Greek philosophy, especially that of Aristotle, into a system of thought of his own. Averroës' commentaries greatly contributed to the rise of Scholastic philosophy as every page of the Schoolmen shows (*e.g.*, Albertus Magnus and Thomas Aquinas).

Life and works. Averroës was born into a distinguished family of jurists at Córdoba in 1126 and died at Marrakesh, the North African capital of the Almohad (al-Muwaḥḥidūn) dynasty, in 1198. Thoroughly versed in the traditional Muslim sciences (especially exegesis of the Qur'ān—Islāmic scripture—and Ḥadīth, or Traditions, and *fiqh*, or Law), trained in medicine, and accomplished in philosophy, Averroës rose to be chief *qāḍī* (judge) of Córdoba (Qurṭubah), an office also held by his grandfather (of the same name) under the Almoravids (al-Murābiṭūn). After the death of the philosopher Ibn Ṭufayl, Averroës succeeded him as personal physician to the caliphs Abū Ya'qūb Yūsuf in 1182 and his son Abū Yūsuf Ya'qūb in 1184. In 1169 Ibn Ṭufayl introduced Averroës to Abū Ya'qūb, who, himself a keen student of philosophy, frightened Averroës with a question concerning whether the heavens were created or not. The caliph answered the question himself, put Averroës at ease, and sent him away with precious gifts after a long conversation that proved decisive for Averroës' career. Soon afterward Averroës received the ruler's request to provide a badly needed correct interpretation of the Greek philosopher Aristotle's philosophy, a task to which he devoted many years of his busy life as judge, beginning at Seville and continuing at Córdoba. The exact year of his appointment as chief *qāḍī* of Córdoba, one of the key posts in the government (and not confined to the administration of justice), is not known.

Commentaries on Aristotle's works

Between 1169 and 1195 Averroës wrote a series of commentaries on most of Aristotle's works (*e.g.*, the *Organon*, *De anima*, *Physica*, *Metaphysica*, *De partibus animalium*, *Parva naturalia*, *Meteorologica*, *Rhetorica*, *Poetica*, and the *Nicomachean Ethics*). He wrote summaries, and middle and long commentaries—often two or all three kinds on the same work. Aristotle's *Politica* was inaccessible to Averroës; therefore he wrote a commentary on Plato's *Republic* (which is both a paraphrase and a middle commentary in form). All of Averroës' commentaries are incorporated in the Latin version of Aristotle's complete works. They are extant in the Arabic original or Hebrew translations or both, and some of these translations serve in place of the presumably lost Arabic originals; *e.g.*, the important commentaries on Aristotle's *Nicomachean Ethics* and on Plato's *Republic*. Averroës' commentaries exerted considerable influence on Jews and Christians in the following centuries. His clear, penetrating mind enabled him to present competently Aristotle's thought and to add considerably to its understanding. He ably and critically used the classical commentators Themistius and Alexander of Aphrodisias and the *falāsifah* (Muslim philosophers) al-Fārābī, Avicenna (Ibn Sīnā), and his own countryman Avempace (Ibn Bājjah). In commenting on Aristotle's treatises on the natural sciences, Averroës showed considerable power of observation.

His own first work is on *General Medicine* (*Kulliyāt*, Latin *Colliget*), written between 1162 and 1169. Only a few of his legal writings and none of his theological writings are preserved. Undoubtedly his most important writings are three closely connected religious–philosophical polemical treatises, composed in the years 1179 and 1180: the *Decisive Treatise on the Agreement between Religious Law and Philosophy* (*Faṣl*) with its *Appendix: Examination of the Methods of Proof Concerning the Doctrines of Religion* (*Manāhij*); and *The Incoherence of the Incoherence* (*Tahāfut at-tahāfut*) in defense of philosophy. In the two first named Averroës stakes a bold claim: only the metaphysician employing certain proof (syllogism) is capable and competent (as well as obliged) to interpret the doctrines contained in the prophetically revealed law (Shar' or Sharī'ah), and not the Muslim *mutakallimūn* (dialectic theologians), who rely on dialectical arguments. To establish the true, inner meaning of religious beliefs and convictions is the aim of philosophy in its quest for truth. This inner meaning must not be divulged to the masses, who must accept the plain, external meaning of Scripture contained in stories, similes, and metaphors. Averroës applied Aristotle's three arguments (demonstrative, dialectical, and persuasive—*i.e.*, rhetorical and poetical) to the philosophers, the theologians, and the masses. The third work is devoted to a defense of philosophy against his predecessor al-Ghazālī's telling attack directed against Avicenna and al-Fārābī in particular.

Defense of philosophy against theologians

Spirited and successful as Averroës' defense was, it could not restore philosophy to its former position, quite apart from the fact that the atmosphere in Muslim Spain and North Africa was most unfavourable to the unhindered pursuit of speculation. As a result of the reforming activity of Ibn Tūmart (*c.* 1078–1130), aimed at restoring pure monotheism, power was wrested from the ruling Almoravids, and the new Berber dynasty of the Almohads was founded, under whom Averroës served. In jurisprudence the emphasis then shifted from the practical application of Muslim law by appeal to previous authority to an equal stress on the study of its principles and the revival of independent legal decision on the basis of Ibn Tūmart's teaching. Of perhaps even more far-reaching significance was Ibn Tūmart's idea of instructing the heretofore ignorant masses in the plain meaning of the Sharī'ah so that practice would be informed with knowledge. These developments were accompanied by the encouragement of the *falāsifah*—"those who," according to Averroës' *Faṣl*, "follow the way of speculation and are eager for a knowledge of the truth"—to apply demonstrative arguments to the interpretation of the theoretical teaching of the Sharī'ah. But with the hands of both jurists and theologians thus strengthened, Averroës' defense of philosophy continued to be conducted within an unfavourable atmosphere.

Averroës himself acknowledged the support of Abū Ya'qūb, to whom he dedicated his *Commentary on Plato's Republic*. Yet Averroës pursued his philosophical

quest in the face of strong opposition from the *mutakallimūn*, who, together with the jurists, occupied a position of eminence and of great influence over the fanatical masses. This may explain why he suddenly fell from grace when Abū Yūsuf—on the occasion of a "holy war" (*jihād*) against Christian Spain—dismissed him from high office and banished him to Lucena in 1195. To appease the theologians in this way at a time when the caliph needed the undivided loyalty and support of the people seems a more convincing reason than what the Arabic sources tell us (attacks on Averroës by the mob, probably at the instigation of jurists and theologians). But Averroës' disgrace was only short-lived—though long enough to cause him acute suffering—since the caliph recalled Averroës to his presence after his return to Marrakesh. After his death, Averroës was first buried at Marrakesh, and later his body was transferred to the family tomb at Córdoba. It is not rare in the history of Islām that the rulers' private attachment to philosophy and their friendship with philosophers goes hand in hand with official disapproval of philosophy and persecution of its adherents, accompanied by the burning of their philosophical writings and the prohibition of the study of secular sciences other than those required for the observance of the religious law. Without caliphal encouragement Averroës could hardly have persisted all his life in his fight for philosophy against the theologians, as reflected in his *Commentary on Plato's Republic*, in such works as the *Faṣl* and *Tahāfut at-tahāfut*, and in original philosophical treatises (*e.g.*, about the union of the active intellect with the human intellect). It is likely that the gradual estrangement of his two masters and patrons from Ibn Tūmart's theology and their preoccupation with Islāmic law also helped him. That Averroës found it difficult to pursue his philosophical studies alongside the conscientious performance of his official duties he himself reveals in a few remarks scattered over his commentaries; *e.g.*, in that on Aristotle's *De partibus animalium*.

Contents and significance of works. To arrive at a balanced appraisal of Averroës' thought it is essential to view his literary work as a whole. In particular, a comparison of his religious–philosophical treatises with his *Commentary on Plato's Republic* shows the basic unity of his attitude to the Sharīʿah dictated by Islām and therefore determining his attitude to philosophy, more precisely to the *nomos*, the law of Plato's philosopher-king. It will then become apparent that there is only one truth for Averroës, that of the religious law, which is the same truth that the metaphysician is seeking. The theory of the double truth was definitely not formulated by Averroës, but rather by the Latin Averroists. Nor is it justifiable to say that philosophy is for the metaphysician what religion is for the masses. Averroës stated explicitly and unequivocally that religion is for all three classes; that the contents of the Sharīʿah are the whole and only truth for all believers; and that religion's teachings about reward and punishment and the hereafter must be accepted in their plain meaning by the elite no less than by the masses. The philosopher must choose the best religion, which, for a Muslim, is Islām as preached by Muḥammad, the last of the prophets, just as Christianity was the best religion at the time of Jesus, and Judaism at the time of Moses.

Unity of religious and philosophical truth

It is significant that Averroës could say in his *Commentary on Plato's Republic* that religious law and philosophy have the same aim and in the *Faṣl* that "philosophy is the companion and foster-sister of the Sharīʿah." Accepting Aristotle's division of philosophy into theoretical (physics and metaphysics) and practical (ethics and politics), he finds that the Sharīʿah teaches both to perfection: abstract knowledge commanded as the perception of God, and practice—the ethical virtues the law enjoins (*Commentary on Plato's Republic*). In the *Tahāfut* he maintains that "the religious laws conform to the truth and impart a knowledge of those actions by which the happiness of the whole creation is guaranteed." There is no reason to question the sincerity of Averroës. These statements reflect the same attitude to law and the same emphasis on happiness. Happiness as the highest good is the aim of political science. As a Muslim, Averroës insists on the attainment of happiness in this and the next life by all believers. This is, however, qualified by Averroës as the disciple of Plato: the highest intellectual perfection is reserved for the metaphysician, as in Plato's ideal state. But the Muslim's ideal state provides for the happiness of the masses as well because of its prophetically revealed law, which is superior to the Greek *nomos* (law) for this reason. The philosopher Averroës distinguishes between degrees of happiness and assigns every believer the happiness that corresponds to his intellectual capacity. He takes Plato to task for his neglect of the third estate because Averroës believes that everyone is entitled to his share of happiness. Only the Sharīʿah of Islām cares for all believers. It legitimates speculation because it demands that the believer should know God. This knowledge is accessible to the naïve believer in metaphors, the inner meaning of which is intelligible only to the metaphysician with the help of demonstration. On this point all *falāsifah* are agreed, and all recognize the excellence of the Sharīʿah stemming from its divinely revealed character. But only Averroës insists on its superiority over the *nomos*.

The Sharīʿah's concern for the masses

Insisting on the prerogative of the metaphysician—understood as a duty laid upon him by God—to interpret the doctrines of religion in the form of right beliefs and convictions (like Plato's philosopher-king), he admits that the Sharīʿah contains teachings that surpass human understanding but that must be accepted by all believers because they contain divinely revealed truths. The philosopher is definitely bound by the religious law just as much as the masses and the theologians, who occupy a position somewhere in between. In his search for truth the metaphysician is bound by Arabic usage, as is the jurist in his legal interpretations, though the jurist uses subjective reasoning only, in contrast to the metaphysician's certain proof. This means that the philosopher is not bound to accept what is contradicted by demonstration. He can, thus, abandon belief in the creation out of nothing since Aristotle demonstrated the eternity of matter. Hence creation is a continuing process. Averroës sought justification for such an attitude in the fact that a Muslim is bound only by consensus (*ijmāʿ*) of the learned in a strictly legal context where actual laws and regulations are concerned. Yet, since there is no consensus on certain theoretical statements, such as creation, he is not bound to conform. Similarly, anthropomorphism is unacceptable, and metaphorical interpretation of those passages in Scripture that describe God in bodily terms is necessary. And the question whether God knows only the universals, but not the particulars, is neatly parried by Averroës in his statement that God has knowledge of particulars but that his knowledge is different from human knowledge. These few examples suffice to indicate that ambiguities and inconsistencies are not absent in Averroës' statements.

The *Commentary on Plato's Republic* reveals a side of Averroës that is not to be found in his other commentaries. While he carried on a long tradition of attempted synthesis between religious law and Greek philosophy, he went beyond his predecessors in spite of large-scale dependence upon them. He made Plato's political philosophy, modified by Aristotle, his own and considered it valid for the Islāmic state as well. Consequently, he applied Platonic ideas to the contemporary Almoravid and Almohad states in a sustained critique in Platonic terms, convinced that if the philosopher cannot rule, he must try to influence policy in the direction of the ideal state. For Plato's ideal state is the best after the ideal state of Islām based on and centred in the Sharīʿah as the ideal constitution. Thus, he regrets the position of women in Islām compared with their civic equality in Plato's *Republic*. That women are used only for childbearing and the rearing of offspring is detrimental to the economy and responsible for the poverty of the state. This is most unorthodox.

Platonic political philosophy

Of greater importance is his acceptance of Plato's idea of the transformation and deterioration of the ideal, perfect state into the four imperfect states. Muʿāwiyah I, who in Muslim tradition perverted the ideal state of the

first four caliphs into a dynastic power state, is viewed by Averroës in the Platonic sense as having turned the ideal state into a timocracy—a government based on love of honour. Similarly, the Almoravid and Almohad states are shown to have deteriorated from a state that resembled the original perfect Sharīʿah state into timocracy, oligarchy, democracy, and tyranny. Averroës here combines Islāmic notions with Platonic concepts. In the same vein he likens the false philosophers of his time, and especially the *mutakallimūn*, to Plato's sophists. In declaring them a real danger to the purity of Islām and to the security of the state, he appeals to the ruling power to forbid dialectic theologians to explain their beliefs and convictions to the masses, thus confusing them and causing heresy, schism, and unbelief. The study of *The Republic* and the *Nicomachean Ethics* enabled the *falāsifah* to see more clearly the political character and content of the Sharīʿah in the context of the classical Muslim theory of the religious and political unity of Islām.

Use of Plato's works

Leaning heavily on the treatment of Plato's political philosophy by al-Fārābī, a 10th-century philosopher, Averroës looks at *The Republic* with the eyes of Aristotle, whose *Nicomachean Ethics* constitutes for Averroës the first, theoretical part of political science. He is, therefore, only interested in Plato's theoretical statements. Thus he concentrates on a detailed commentary on Books II–IX of *The Republic* and ignores Plato's dialectical statements and especially his tales and myths, principally the myth of Er. He explains Plato, whose *Laws* and *Politikos* he also knows and uses, with the help, and in the light, of Aristotle's *Analytica posteriora*, *De anima*, *Physica*, and *Nicomachean Ethics*. Naturally, Greek pagan ideas and institutions are replaced by Islāmic ones. Thus Plato's criticism of poetry (Homer) is applied to Arab pre-Islāmic poetry, which he condemns. Averroës sees much common ground between the Sharīʿah and Plato's general laws (interpreted with the help of Aristotle), notwithstanding his conviction that the Sharīʿah is superior to the *nomos*. He accepts al-Fārābī's equation of Plato's philosopher-king with the Islāmic *imām*, or leader and lawgiver, but leaves it open whether the ideal ruler must also be a prophet. The reason for this may well be that, as a sincere Muslim, Averroës holds that Muḥammad was "the seal of the prophets" who promulgated the divinely revealed Sharīʿah once and for all. Moreover, Averroës exempts Muḥammad from the general run of prophets, thus clearly rejecting the psychological explanation of prophecy through the theory of emanation adopted by the other *falāsifah*. No trace of this theory can be discovered in Averroës' writings, just as his theory of the intellect is strictly and purely Aristotelian and free from the theory of emanation. In conclusion, it may be reiterated that the unity of outlook in Averroës' religious–philosophical writings and his commentary on *The Republic* gives his political philosophy a distinctly Islāmic character and tone, thereby adding to his significance as a religious philosopher.

Avicenna

Abū ʿAlī al-Ḥusayn ibn ʿAbd Allāh ibn Sīnā, known in the West as Avicenna, the most influential of all Muslim philosopher-scientists, was especially famous for his contributions in the fields of Aristotelian philosophy and medicine. Because of his dominating influence and authority in these fields, he has been given the honorific titles of ash-Shaykh ar-Raʾīs ("the Leading Wise Man") in the East and Prince of the Physicians in the West.

Early years

Avicenna, a Persian who spent his whole life in the eastern and central regions of Persia, was born in Bukhara (now in Uzbek S.S.R.) in 980 and received his earliest education in that city under the direction of his father, who was an Ismāʿīlī (a member of an Islāmic religious and political movement, the theology of which drew on a popularized form of Neoplatonism). Avicenna himself, however, was never attracted to the Ismāʿīlīyah. Since the house of his father was a meeting place for learned men, from his earliest childhood Avicenna was able to profit from the company of the outstanding masters of his day. A precocious child with an exceptional memory that he retained throughout his life, he had memorized the Qur'ān and much Arabic poetry by the age of ten. Thereafter, he studied logic and metaphysics under teachers whom he soon outgrew, and then spent the few years until he reached the age of 18 in his own self-education. He read avidly and mastered Islāmic law, then medicine, and finally metaphysics. Particularly helpful in his intellectual development was his gaining access to the rich royal library of the Sāmānids—the first great native dynasty that arose in Persia after the Arab conquest—as the result of his successful cure of the Sāmānid prince, Nūḥ ibn Manṣūr. By the time he was 21 he was accomplished in all branches of formal learning and had already gained a wide reputation as an outstanding physician. His services were also sought as an administrator, and for a while he even entered government service as a clerk.

But suddenly the whole pattern of his life changed. His father died; the Sāmānid house was defeated by Maḥmūd of Ghazna, the Turkish leader and legendary hero who established Ghaznavid rule in Khorāsān (northeastern Iran and modern western Afghanistan); and Avicenna began a period of wandering and turmoil, which was to last to the end of his life with the exception of a few unusual intervals of tranquillity. Destiny had plunged Avicenna into one of the tumultuous periods of Persian history, when new Turkish elements were replacing Persian domination in Central Asia and local Persian dynasties were trying to gain political independence from the ʿAbbāsid caliphate in Baghdad (in modern Iraq). But the power of concentration and the intellectual prowess of Avicenna was such that he was able to continue his intellectual work with remarkable consistency and continuity and was not at all influenced by the outward disturbances.

Avicenna wandered for a while in different cities of Khorāsān and then left for the court of the Būyid princes, who were ruling over central Persia, first going to Rayy (near modern Tehrān) and then to Qazvīn, where as usual he made his livelihood as a physician. But in these cities also he found neither sufficient social and economic support nor the necessary peace and calm to continue his work. He went, therefore, to Hamadan in west central Persia, where Shams ad-Dawlah, another Būyid prince, was ruling. This journey marked a new phase in Avicenna's life. He became court physician and enjoyed the favour of the ruler to the extent that twice he was appointed vizier. As was the order of the day, he also suffered political reactions and intrigues against him and was forced into hiding for some time; he was even imprisoned.

Life in the court at Hamadan

This was the period when he began his two most famous works. *Kitāb ash-shifāʾ* ("The Book of Healing") is a vast philosophical and scientific encyclopaedia, probably the largest work of its kind ever written by one man. It treats of logic, the natural sciences, including psychology, the *quadrivium* (geometry, astronomy, arithmetic, and music), and metaphysics, but there is no real exposition of ethics or of politics. His thought in this work owes a great deal to Aristotle but also to other Greek influences and to Neoplatonism. His system rests on the conception of God as the necessary existent: in God alone essence,

what he is, and existence, that he is, coincide. There is a gradual multiplication of beings through a timeless emanation from God as a result of his self-knowledge. The *Canon of Medicine* (*Qānūn fī aṭ-ṭibb*) is the most famous single book in the history of medicine in both East and West. It is a systematic encyclopaedia based for the most part on the achievements of Greek physicians of the Roman imperial age and on other Arabic works and, to a lesser extent, on his own experience (his own clinical notes were lost during his journeys). Occupied during the day with his duties at court as both physician and administrator, Avicenna spent almost every night with his students composing these and other works and carrying out general philosophical and scientific discussions related to them. These sessions were often combined with musical performances and gaiety and lasted until late hours of the night. Even in hiding and in prison he continued to write. The great physical strength of Avicenna enabled him to carry out a program that would have been unimaginable for a person of a feebler constitution.

Life in the court at Isfahan

The last phase of Avicenna's life began with his move to Isfahan (about 250 miles south of Tehrān). In 1022 Shams ad-Dawlah died, and Avicenna, after a period of difficulty that included imprisonment, fled to Isfahan with a small entourage. In Isfahan, Avicenna was to spend the last 14 years of his life in relative peace. He was esteemed highly by 'Alā' ad-Dawlah, the ruler, and his court. Here he finished the two major works he began in Hamadan and wrote most of his nearly 200 treatises; he also composed the first work on Aristotelian philosophy in the Persian language and the masterly summary of his "Book of Healing" called *Kitāb an-najāt* ("The Book of Salvation"), written partly during the military campaigns in which he had to accompany 'Alā' ad-Dawlah to the field of battle. During this time he composed his last major philosophical opus and the most "personal" testament of his thought, *Kitāb al-ishārāt wa at-tanbīhāt* ("The Book of Directives and Remarks"). In this work he described the mystic's spiritual journey from the beginnings of faith to the final stage of direct and uninterrupted vision of God. Also in Isfahan, when an authority on Arabic philology criticized him for his lack of mastery in the subject, he spent three years studying it and composed a vast work called *Lisān al-'arab* ("The Arabic Language"), which remained in rough draft until his death. Accompanying 'Alā' ad-Dawlah on a campaign, Avicenna fell ill and, despite his attempts to treat himself, died in Hamadan in 1037 from colic and from exhaustion.

Besides fulfilling the role of the master of the Muslim Aristotelians, Avicenna also sought in later life to found an "oriental philosophy" (*al-ḥikmat al-mashriqīyah*). Most of his works directly concerning this have been lost, but enough remains in some of his other works to give an indication of the direction he was following. He took the first steps upon a path toward mystical theosophy that marked the direction that Islāmic philosophy was to follow in the future, especially in Persia and the other eastern lands of Islām.

Avicenna's influence

In the Western world, Avicenna's influence was felt, though no distinct school of "Latin Avicennism" can be discerned as can with Averroës, the great Spanish-Arabic philosopher. Avicenna's "Book of Healing" was translated partially into Latin in the 12th century, and the complete *Canon* appeared in the same century. These translations and others spread the thought of Avicenna far and wide in the West. His thought, blended with that of St. Augustine, the Christian philosopher and theologian, was a basic ingredient in the thought of many of the medieval Scholastics, especially in the Franciscan schools. In medicine the *Canon* became *the* medical authority for several centuries, and Avicenna enjoyed an undisputed place of honour equalled only by the early Greek physicians Hippocrates and Galen. In the East his dominating influence in medicine, philosophy, and theology has lasted over the ages and is still alive within the circles of Islāmic thought.

(S.H.N.)

Avoidance Behaviour

In one of its major meanings "avoidance" is any behaviour induced by adverse stimuli. The underlying implication that a single neural mechanism is involved (such as a specific part of the brain, which, under electrical stimulation, seems to inflict punishment) remains only a hypothesis. Clearly, the same kinds of avoidance behaviour might result from different underlying physiological mechanisms. Thus, although the various dichotomies, or polarities, of behaviour such as positive and negative, psychoanalytic life and death instincts, and approach and withdrawal concepts may be logical or philosophical conveniences, they seem, nevertheless, to lack clear meaning physiologically.

Alternative usage defines avoidance behaviour by describing a number of patterns: active avoidance (fleeing), passive avoidance (freezing stock-still or hiding), and a pattern of protective reflexes, as seen in the startle response. There is good reason to suppose that, in cats, for example, each of these patterns is coordinated separately by the brain. One kind of fleeing, in which the cat moves continuously and shows much upward climbing, is produced by electrical stimulation of specific parts of the brain (hypothalamic sites). Stimulation of other sites (in the thalamus) generates other types of fleeing movements, causing the animal to crouch, look around, move, slink close to the floor, and hide, if possible. In general, among birds and mammals, brain sites for fleeing of the first type occur in hypothalamic and mesencephalic zones.

Brain function in coordination of patterns

Protective reflexes in mammals include ear retraction to a position of safety—pressed against and somewhat behind the skull—as when a horse is seen to lay its ears back. Among the monkey-like bush babies (*Galagos*) the outer ear folds up laterally and longitudinally at the same time, under threat. The eyes are closed, and the muscles around the eye are contracted, adding to the protection. During this so-called startle reflex, breathing is checked, and the mouth corners are pulled back to expose the teeth; this prepares both for biting in defense and also for movements of the tongue and for head shaking to free the mouth of any dangerous or distasteful substance that may have been taken in. In most mammals, the limbs flex as if ready for a leap; in the human startle reflex, the arms are thrust outward as if ready to grasp at a support.

It is helpful to consider avoidance behaviour in terms of factors that elicit it (*e.g.*, specific stimuli) and regulate it (*e.g.*, hormones).

Factors in avoidance behaviour. *Specific stimuli.* Warning calls and visual signals that are unique to different species of birds and mammals effectively and specifically evoke avoidance patterns. In some cases, learning clearly emerges as a factor; thus, members of a colony of birds seem to learn to respond to the alarm calls of all species present in the colony. Among ducklings, a visual model

to evoke fleeing and hiding can be fashioned as a cardboard cutout. When moved overhead in one direction, the model resembles a short-necked, long-tailed hawk, and the ducklings flee from it; when moved in the other direction, the model looks like a harmless, long-necked goose, and the ducklings tend to stay calm. The model is effective, however, in eliciting the two kinds of behaviour only when the ducklings are accustomed to geese flying over but not hawks.

Innate factors also contribute to such responses (see INSTINCT). Domestic chicks, for example, show crouching and freezing in response to the long alarm call of their species. Many of the perching birds (passerines) will gather to mob when stimulated by the sight of an owl. The eyes in the characteristic owl face have been found to be especially important; even birds reared in isolation respond to man-made models with appropriate eyespots painted on. It has been suggested that many human beings are specifically (and perhaps instinctively) disturbed by the sight of snakes—the notion of a legless object perhaps being a key stimulus. Human responses to spiders and centipedes with conspicuous legs also may be intense. In the reaction to snakes at least, notwithstanding Freudian explanations that they symbolize male sex organs, the behaviour of people may be compared with owl mobbing among passerine birds.

Specific chemical signals can induce avoidance behaviour; some are released by minnows and tadpoles when their skin is damaged (usually indicating to fellows that there is danger). These chemicals appear to be specific for each species of fish and are highly effective in producing fleeing (see CHEMORECEPTION). Many ants produce volatile alarm substances (terpenes) that are attractants to other ants at low concentrations and, in high concentrations near their source, produce rapid locomotion, defense postures, and, sometimes, fleeing. Some invertebrate avoidance responses are reflexes evoked by very specific stimuli; rapid swimming by cockles clapping their shells, for example, is elicited by starfish extract. Shell jerking is produced in a freshwater snail (*Physa*) by contact with a leech, another specific response to a major predator.

Pain, startle, and novelty. Painful stimuli are pre-eminent among those that produce avoidance. Among mammals (including man) many such responses are patently inborn, as is the reflex withdrawal of one's finger from a hot griddle.

To classify a stimulus as startling or novel requires some comparison with previous stimulation. Human responses (orientation reflex) to startling or interesting stimuli may be studied by presenting a series of repeated tones; the orientation reflex tends to appear at the moment at which some change in the usual sequence (such as a longer or shorter tone) occurs. There is some evidence that the hippocampus (a brain structure) is involved in the human experience of novelty. Surgical removal of the hippocampus in many animals makes avoidance responses to strange objects far more persistent; a comparable operation in small parrots (lovebirds) greatly increases the persistence of calls that gather others for mobbing. Probable role of the hippocampus

Probably the hippocampus takes part in establishing memory of any new stimulus, and once this has occurred, the stimulus is no longer novel. Removal of other brain structures (the amygdala) reduces avoidance of strange objects (*e.g.*, in lovebirds) and also makes fleeing and defensive attack less likely.

Passive and active avoidance. Passive avoidance is achieved by the inhibition of a previously exhibited response. Thus, after a laboratory animal has learned to approach a food dish, it may then be punished by an electric shock whenever a selected visual or auditory stimulus is present. In passive avoidance, the animal may freeze as soon as the stimulus is given; in active avoidance, the animal is given the opportunity of fleeing.

Freezing proper entails general motor inhibition, which, if sustained, may pass into signs of reduced arousal. States of considerable loss of muscle tonus, of eye closure, and many signs of deep sleep have been variously termed feigning death or animal hypnosis. In very young fowl, such signs can be induced simply by holding the animal firmly if the experience is novel (and thus presumably frightening). Such states tend to occur as an alternative to fleeing when the apparently frightening stimulus is difficult to locate or to escape. Among social mammals (*e.g.*, cats or dogs) the status and confidence of an animal may be inferred from its degree of leg extension, arched back (vertebral tonus), and cocky tail elevation. Threat from which there seems no escape may induce a progressive approach to immobility and to general motor inhibition.

Punishment. Inhibitory interconnections have been postulated between the punishment and reward systems within the brain. One line of evidence suggesting a single punishment system rather than a number of them includes behavioral and neurological resemblances in the responses of animals to fear-inducing and to frustrating circumstances. If either fear or frustration is induced during conditioning, both produce resistance to extinction. Both are specifically opposed by barbiturate drugs.

Whatever its physiological basis, negative reinforcement (punishment) can induce in an animal both the inhibition of the response that produced the punishment and the avoidance of the location at which it occurred. Sometimes the tendency to show avoidance behaviour develops further with time, even without additional training. Thus, when being conditioned to discriminate between stimuli (*e.g.*, two tones), some breeds of dog (*e.g.*, Alsatians), if made to wait for food reward or given an impossible discrimination to perform, will howl and show great excitement. On later days, they may first resist mounting the conditioning stand and finally resist approaching the room to which earlier they ran eagerly, presumably for the rewards of food. Stimuli associated with the training room are sometimes said to act as secondary negative reinforcers (secondary punishments) in such a case.

Avoidance conditioning of the leg of a cockroach

Even a piece of cockroach nervous system (metathoracic ganglion) and the leg it controls have been shown to be capable of avoidance conditioning. If each contact of the leg with a water surface is paired with an electric shock, the leg comes to be retracted on contact with the water; no such change occurs in a control leg receiving the same number of shocks at random. The conditioning is accompanied by a very marked decrease in a chemical (acetylcholinesterase) found in the nervous system; since it greatly facilitates transmission of some nerve impulses, such a chemical may well be basic to this primitive kind of learning.

Hormonal effects. Male hormones (androgens) cause the performance of new mobbing calls in the breeding season by many male passerine birds (*e.g.*, chaffinch) and also some other birds (*e.g.*, farmyard cock); it is not certain whether the effect is specific to the vocalization or whether the hormone produces a general change in responsiveness to frightening stimuli. Female hamsters are initially faster than males to emerge from a box and also move about more in a strange place; perhaps females innately tend to be less nervous. Females behave more like male hamsters if given a small injection of male hormone (testosterone) in the second day of life; the adult difference survives castration, so it probably rests on sexual differentiation of the nervous system rather than on adult hormone levels.

The adrenocorticotropic hormone (ACTH) from the pituitary glands of many animals may facilitate avoidance behaviour. ACTH has other direct effects on the nervous system (*e.g.*, facilitating male sexual behaviour).

Functions of avoidance behaviour. *Fleeing and escape.* Most animals capable of locomotion show a rapid locomotor reflex to painful or startling stimuli. Such a reflex is very ancient in an evolutionary sense; it is present even in such primitive marine animals as the slender, tiny, translucent amphioxus. The rapid propulsion of an octopus or squid by its own jet of water or of a crayfish by a blow of its tail, the sudden leap and flight of a grasshopper, and the retraction of a worm into its hole—all are examples of such avoidance behaviour. Reflex escape movements

Many invertebrates commonly compete in speed against

their vertebrate predators, which tend to have faster conducting individual nerve cells; in order to compete successfully, the invertebrates seem to have evolved giant nerves (bundle of individual cell fibres), for the broader a nerve is, the faster it conducts. Among such lower animals, perhaps one-third or more of the nerve cord running the length of the body is made up of fibres responsible for initiating the escape response of the species. The fibres of a cockroach, for example, activate a mechanism that produces rapid running when the rear end (anal cerci) is disturbed by air movements. Bony fishes also have such structures, the Mauthner cells, that initiate escape swimming when stimulated.

Escape may be facilitated not only by speed of response but also by its explosive onset (*e.g.*, after a period of shamming death), making it difficult for a predator to predict the behaviour of a prospective meal. Escape movements may stop as suddenly as they start. Many animals may even be especially conspicuous in escape (*e.g.*, showing coloured hind wings, as do some grasshoppers and moths), so that their disappearance appears even more sudden. Presumably, the predator, engaged in pursuing and tracking a moving prey, finds its difficult to shift quickly enough to a different kind of search and so is unable to localize the exact point of disappearance.

In many instances, rapid locomotion is enough to frustrate a predator; in others, direction is crucial (*e.g.*, a fish moving upward to the water surface or downward to the bottom or, among birds, a more elaborate celestial orientation). Under threat, insects such as pond skaters (*Vellia*) flee toward the nearest shore; beach fleas (amphipods) flee to the sea; and particular populations of ducks have a preferred compass direction for escape (so-called nonsense orientation).

Freezing. Immobility usually makes detection less likely. For stick insects and other animals resembling twigs or leaves, when immobility itself becomes conspicuous against moving foliage, the animals' compensatory swaying increases the camouflage effect. There seems to be an evolutionary conflict between camouflage and the need for conspicuous signals in communication. Social groups commonly keep in touch by calls or by movements such as tail flicks, which are inhibited during freezing or even under incipient immobility. Movements may be made conspicuous by patches of white or colour on a bird's outer tail feathers, or under a mammal's tail. The well-known white rear patch of hair among antelopes, for example, is hidden when the tail is folded or lowered under conditions of safety.

Protection reflexes, armour, and spines. Facial protective reflexes are usually well developed in flat-faced mammalian predators like cats and tarsiers, whose eyes and ears are especially exposed to injury by prey. The reflexes also are exaggerated in social species for use in communication; thus ear flattening in horse and dog displays has a counterpart in scalp retraction among Old World monkeys. The scalp movements and raised brows are effectively used in communication, despite the greatly reduced mobility of ears among monkeys. Limbs and other appendages (*e.g.*, antennae) are withdrawn or used to protect sensitive areas by both vertebrates and invertebrates. Among mollusks and such groups as sea squirts and barnacles, the whole soft body can be retracted into a protective shell, or carapace; a kind of door (operculum) may be used to stop the entrance (*e.g.*, among snails and barnacles), and trap-door spiders pull the stopper in place behind them. Bone may have evolved in fossil vertebrates as protective armour in jawless ancient fishes (ostracoderms), probably as a result of natural selection in the face of dominant arthropod predators (eurypterids). With the evolution of jaws, the vertebrates themselves gave rise to nearly all later large predators. Evolutionary advantage then apparently came with complex sense organs and behaviour; in most vertebrate lines there is evidence of a progressive reduction in body armour (dermal bone). Thus, although such cartilaginous fishes as sharks and rays do not exhibit such bony skins, they may well have evolved from heavily armoured ancient fishes (placoderms).

Armour nevertheless has evolved repeatedly, particularly among animals incapable of fast locomotion; trunkfish (boxfish), for example, have a body entirely boxed by bony plates; and tortoises and turtles are perhaps the most completely armoured of four-legged animals. The turtles seem to have evolved early from the basal stock of the reptiles; thanks to the shell (carapace) within which they can withdraw head, limbs, and tail, they represent one of the few reptilian orders that have remained consistently successful. The turtle's dorsal carapace appears to consist of newly evolved plates of dermal bones, but the belly plates (ventral plastron) may well be retained in part from fish ancestors. Reptilian land vegetarians usually tended to evolve armour, as in the fossil dinosaurs such as stegosaurs and ankylosaurs.

The completely armoured turtles and tortoises

South American toothless animals (edentates) such as anteaters are probably survivors of a comparable early development in mammals. The armour of armadillos and the presence of bony plates in the skin of the extinct sloths suggest that the whole group may derive from an armoured ancestor. The appearance of hair in the mammal line, partly inferred from the presence of fleas in early evolutionary periods, seems to have led to the evolution of a light, spiny type of armour. Such modern mammals as hedgehogs, echidnas, insect-eating tenrecs, and some rodents and their relatives (lagomorphs) all possess defensive spines that are commonly erectile and are often able to roll into a ball like an armadillo.

Chemical means of defense may be widely distributed in the body, making the animal distasteful to predators. Some of these chemical compounds may be derived from plants eaten or synthesized by the animal itself (*e.g.*, bufotoxin in toads). Although the animal attacked may be killed and thus not benefit, his fellows do since they are likely to be avoided by the predator. Poison or distasteful substances may also be ejected from a bodily reservoir and squirted at the enemy (*e.g.*, the skunk, some ants) or inserted into a puncture made by a spine (*e.g.*, triggerfish) or teeth (*e.g.*, certain snakes). Many poisons act to paralyze muscles by blocking nerve transmission at the neuromuscular junction (*e.g.*, cobra venom).

Warning behaviour. Mobbing behaviour apparently advertises the presence of a predator that is potentially but not immediately dangerous; thus mammalian nest predators can be safely mobbed by flying birds, as can owls in the daytime. From the safety of trees, such mammals as monkeys and squirrels mob predators on the ground. Mobbing calls are typically easy to locate, the calls being short and staccato, and they provide excellent cues of distance and direction (see SPACE PERCEPTION: *Auditory cues;* PERCEPTION OF MOVEMENT: *Auditory*). Conspicuous movements, such as tail flicks among small birds and squirrels, accompany the calls.

More urgently, intense warning behaviour is given in response to sources of immediate danger (*e.g.*, hawks actively hunting). Under these circumstances, warning calls are usually long whistles that make location difficult because of their gradual onset and termination and their narrow ranges of pitch. The evolution of warning behaviour that puts the displaying animal in danger (such as these intense warning calls) seems likely to come about only if the benefit to offspring and other members of the species is great. Indeed, it has been calculated that if an individual loses his life as the result of his warning behaviour, increased transmission of his family's genes will result only if the reproductive rate of relatives (as close as sisters) is doubled as a result of his sacrifice.

BIBLIOGRAPHY. R.A. HINDE, *Animal Behaviour: A Synthesis of Ethology and Comparative Psychology*, 2nd ed. (1970), comprehensive and detailed coverage of the theory of animal behaviour that may be too difficult in parts for the lay reader; S.P. GROSSMAN, *A Textbook of Physiological Psychology* (1967), an unusually clear treatment of this field, although now somewhat outdated.

(R.J.A.)

Azerbaijan Soviet Socialist Republic

One of the 15 union republics of the Soviet Union, the Azerbaijan Soviet Socialist Republic, or Azerbaijan

S.S.R., is the easternmost of the three such entities—the others are Armenia and Georgia—that occupy the area fringing the southern flanks of the Caucasus Mountains. To the south lies Iranian Azerbaijan, to the east the waters of the Caspian Sea. In addition to a variegated and often strikingly beautiful natural environment, the Azerbaijan of the later 20th century offers a blend of traditions and modern development. The proud and ancient people of its remoter areas retain many distinctive folk traditions, but the lives of its 5,600,000 or so inhabitants (the population has more than doubled since the 1920s) have been touched by an accelerating modernism characterized by industrialization, the development of power resources, and the growth of the cities, in which half the people (though only 42 percent of the Azerbaijanis) now live. Industry dominates the economy, and more diversified pursuits have supplemented the exploitation of oil, which made Azerbaijan the world's leading producer at the beginning of the 20th century. Fine horses and caviar continue as some of the more distinctive traditional exports of the republic.

Administratively, the Azerbaijan S.S.R., which was established on April 28, 1920, now includes the geographically separate Nakhichevan Autonomous S.S.R., which, with its capital, Nakhichevan, lies beyond an intervening strip of Armenian territory. The Nagorno-Karabakh Autonomous Oblast, of which Stepanakert is the administrative centre, is also an administrative division. The territory of Azerbaijan covers 33,400 square miles (86,600 square kilometres), larger than Sri Lanka and about the same size as Portugal. Its capital is the ancient and economically important city of Baku, whose harbour is the best on the Caspian Sea. For further details see CAUCASUS MOUNTAINS; CASPIAN SEA; RUSSIA AND THE SOVIET UNION, HISTORY OF.

THE LAND

Landscapes. As a result of its broken relief, its drainage patterns, and its climate, Azerbaijan is characterized by a variety of landscapes. More than 40 percent of its territory is taken up by lowlands, about half lies at 1,300 to 4,900 feet (400 to 1,500 metres), and areas above 4,900 feet (1,500 metres) occupy a little more than 10 percent of the total area.

The mountain regions. The highest peaks are Bazardyuzi, Shakhdag, and Tufan, all part of the Great Caucasus, which forms a natural northern boundary for the republic. Magnificent spurs and ridges, cut into by the deep gorges of mountain streams, make this part of Azerbaijan a region of great natural beauty.

Forests and wildlife

The slopes of the mountains are covered with beech, oak, and pine forests, and the animal life includes Caucasian deer, roe deer, wild boar, brown bear, lynx, European bison (wisent), chamois, and leopard, though the latter is rare. Typical birds include the Caucasian grouse and the stone partridge.

The spurs of the Little Caucasus, in southwest Azerbaijan, form the second important mountain system, which includes the Shakhdag, Murovdag, and Zangezur ranges and also the Karabakh upland. The large and scenic Lake Gyoygyol lies at an altitude of 5,138 feet.

The southeast part of Azerbaijan is bordered by the Talysh Mountains, with Kyumyurkyoy as the highest.

The Kura-Araks Lowland. This vast territory is named after the main river and its tributary. The Shirvan, Milskaya, and Mugan plains are part of this lowland and have similar soils and climate, the difference in names reflecting purely historical considerations. Plant life is that of the steppe and semidesert, and gray soils and saline solonchaks and, in higher regions, gray alkaline solonetz and chestnut soils prevail. A well-developed network of canals between the Kura and Araks rivers makes it possible to irrigate a major part of the lowland. The Upper Karabakh Canal, 109 miles (175 kilometres) long, provides a vital link between the Araks River and the Mingechaur Reservoir on the Kura River. The reservoir, constructed in 1953, contains 565,000,000,000 cubic feet (16,000,000,000 cubic metres) of water and has a surface area of 234 square miles (605 square kilometres) and a maximum depth of 246 feet (75 metres). An associated hydroelectric power plant has a capacity of 360,000 kilowatts. The Upper Karabakh Canal alone irrigates about 250,000 acres (100,000 hectares) of fertile land, and in addition supplies the Araks River with water during dry summer periods.

The Upper Shirvan Canal, the second most important, is 75 miles long and also irrigates about 250,000 acres.

Climate. The dry subtropical climate prevailing in central and eastern Azerbaijan is characterized by a mild winter and a long (four to five months) and very hot summer, with an average temperature of 81° F (27° C) and a maximum temperature of 109° F (43° C).

Southeast Azerbaijan is characterized by a humid subtropical climate and has the highest precipitation in the republic, reaching 47–55 inches (1,200–1,400 millimetres) a year, most of which falls in the cold months.

A dry continental climate, with a cold winter and a dry, hot summer, prevails in the Nakhichevan Autonomous S.S.R. at altitudes of 2,300 to 3,300 feet (700 to 1,000 metres). Moderately warm, dry or humid types of climate are to be found in other parts of Azerbaijan. The mountain forest zone has a moderately cold climate, while an upland tundra climate characterizes the altitude of 9,850 feet (3,000 metres) and above. Frosts and heavy snowfalls make the passes at such altitudes inaccessible for three or four months of the year.

THE PEOPLE

Cosmopolitan ethnic heritage

Ethnic composition. Today's Turkic Azerbaijanis, who comprise about 74 percent (up from 68 percent in 1959) of the republic's population, combine in themselves the predominantly Turkic strain, which flooded Azerbaijan especially during the Oğuz Seljuq migrations of the 11th century, with mixtures of older inhabitants—Iranians and others—who had lived in Transcaucasia since ancient times. In the Nakhichevan A.S.S.R., about 94 percent of the 219,000 (1974) inhabitants are Azerbaijanis, whereas more than 80 percent of the 154,000 people of the Nagorno-Karabakh Autonomous Oblast are Armenian. These subunits of the union republic were established to minimize friction between the two nationalities.

Demographic trends. Russians make up the largest minority in Azerbaijan, in 1970 comprising 10 percent, down from 13.6 percent in 1959, an unusual trend not found in most of the Soviet Union. Population estimates showed the republic's population to have risen from 5,117,081 at the census of 1970 to about 5,606,000 in 1975. The average population density reached 168 per square mile (65 per square kilometre) by the mid-1970s. Urban population constitutes half the republic's total, and 42 percent of the Azerbaijanis themselves live in cities (as do 92 percent of the 510,000 Russians). The 42 percent of Azerbaijanis urbanized is a larger proportion than is common in non-Slavic republics; of the 1,359,000 people (1974 estimate) in the Greater Baku metropolitan area, about 46 percent are Azerbaijanis. Other cities are Kirovabad, formerly Ganja (190,000 in 1970), Sheki (43,000), Lenkoran (36,000), and Nakhichevan (33,000). New cities established during the 1950s and '60s include Sumgait (124,000), Mingechaur (43,000), Ali-Bayramly (34,000), and Stepanakert (30,000).

ECONOMY

Azerbaijan is a developed industrial and agrarian republic, with the balance between the gross output of agriculture and that of industry gradually tilting in favour of the latter; in 1960 gross industrial output accounted for 71 percent and agriculture for 29 percent of the total output; in 1970 the corresponding figures were 83 and 17.

New industrialization

The emphasis on heavy industry has considerably expanded two traditional industries—petroleum and natural gas—but engineering and light and food industries are also of growing importance.

Natural resources. At the turn of the 20th century Azerbaijan was the world's leading petroleum producer, and it was also the birthplace of the oil-refining industry. In 1901, for example, Azerbaijan produced 11,400,000 tons of oil, more than the United States; it accounted

for 95 percent of Russian and 50 percent of the world production. As the 20th century progressed, however, Azerbaijan's role in oil production decreased as the industry developed in other regions of the Soviet Union and the world, though by the mid-1970s the annual output of oil in Azerbaijan amounted to 19,500,000 tons.

Azerbaijan also has other natural resources, including gas, iodo-bromide waters, lead, zinc, iron, and copper ores, nepheline syenites utilized in the production of aluminum, common salt, and a great variety of building materials, including marl, limestone, and marble.

Fuel and power. The development of Azerbaijan's industry created a demand for fuel and power supplies. By the mid-1970s, the yearly electric-power output of the republic had reached 14,200,000,000 kilowatt-hours. Almost 90 percent of the electricity is produced at thermoelectric power stations, which have been built throughout the republic. The largest of these are Ali-Bayramly (capacity 1,120,000 kilowatts); the northern station in Baku (319,000 kilowatts); and Sumgait (470,000 kilowatts). Hydroelectric stations, among which is that at Mingechaur (2,400,000 kilowatts), produce a further 1,500,000,000 kilowatt-hours, and new hydroelectric stations are planned for the 1970s and '80s on the Kura and Araks rivers.

Industry. Azerbaijan has a diversified industrial base, with heavy industry and its leading branches—power, manufacturing, and chemicals—predominating.

Branches of the processing industry, producing mineral fertilizers, gasoline, and kerosine, herbicides, industrial oils, synthetic rubber, plastics, etc., are developing. Sumgait has emerged as the major centre of this industry, as well as of ferrous metallurgy.

The republic's share in the total output of Soviet manufacturing has increased considerably in the third quarter of the 20th century. Azerbaijan manufactures equipment for the oil and gas industry, electrical equipment of all kinds, and many appliances and instruments. Some of these goods are exported to other countries. This type of industry is located mostly in Baku, Kirovabad, and Mingechaur, and there are plans to extend it also to Agdam, Kazakh, and Sumgait.

Light industrial manufactures include cotton and woollen textiles, knitwear, traditional household items and souvenirs, footwear, and other consumer goods. The cities of Sheki, Stepanakert, Kirovabad, Mingechaur, and Baku are the main centres of this industry. Food processing plants are distributed fairly evenly throughout the republic. Azerbaijan fisheries are of particular importance because of the sturgeon of the Caspian Sea; sturgeon roe is made into caviar of world renown.

Agriculture. Azerbaijan's agriculture has also been developing: although arable land in Azerbaijan constitutes only 7 percent of the total, the republic accounts for 10 percent of the gross agricultural output of the Soviet Union. Raw cotton is the leading agricultural product. In 1913 cotton production amounted to 64,000 tons, in 1940 to 154,000 tons; the 1974 figure of 584,000 tons made Azerbaijan one of the leading cotton-producing areas in the Soviet Union. Tobacco is the second most valuable crop, and the republic's annual output, about 42,000 tons (1973), constitutes 8 percent of the total Soviet yield. Favourable conditions for grapes have contributed to the development of this branch of agriculture: Azerbaijan produced 5,500 tons of grapes in 1913 and 100,000 tons in 1960. The ensuing years witnessed a further increase, with the yield reaching 174,000 tons by 1965 and 480,000 tons by 1973. During the 1970s, production of grapes is expected to reach 770,000 tons annually. Most of the grape varieties grown in Azerbaijan are used for wine making. Tea was introduced into the republic fairly recently, and the necessary prerequisites exist that make it possible to enlarge the output. Vegetables, particularly early varieties, fruit, walnuts, and hazelnuts are also promising crops. Special attention is being paid to extending the areas under pomegranates. Some districts, particularly those of Sheki, Zakataly, and Geokchay, are—as they have been traditionally—engaged in silkworm breeding.

Development of viticulture

High commodity output is not characteristic of Azerbaijan's animal husbandry. More than 5,000,000 sheep and goats form its main livestock, while cattle number some 1,600,000. Riding horses, especially the valuable Karabakh breeds, are exported.

Economic regions. *The Apsheron region.* This includes the Apsheron Peninsula and several other areas of eastern Azerbaijan. As a result of its advantageous geographical position, it is crossed by freight routes connecting Azerbaijan and the whole of Transcaucasia with the North Caucasus and Central Asia. Numerous highways also run from the peninsula to every corner of the republic.

On the shores of the Caspian Sea, the Apsheron region nevertheless remains one of the most arid parts of Azerbaijan. Its main natural wealth is mineral, including oil, natural gas, iodo-bromide waters, and limestone, used in building and cement production.

Such cities as Baku, the capital of the republic, Sumgait, and other industrial centres make the Apsheron region one of the most highly industrialized and densely populated areas of Azerbaijan.

Baku

Baku itself owes its modern growth to the development of the oil industry; oil derricks encircle the city, and it acts as a magnet to workers from many areas. In 1886 the population of Baku had already reached 86,000, against 6,000 in 1830, and by 1974 it exceeded 910,000; its metropolitan area in that year had a population of 1,360,000, or a quarter of the total for the entire republic. Contemporary Baku is one of the largest and most attractive cities in the Soviet Union. Situated on natural terraces running down to a gulf of the Caspian Sea, the city has a two-mile-long picturesque boulevard and many historic sites.

Modern Sumgait, 22 miles northwest of Baku, is currently a centre of the iron and steel, nonferrous metallurgical, and chemical industries, although the development of light engineering is envisaged.

The Lenkoran region. This area of southern Azerbaijan is well endowed by nature, with evergreen vegetation and thick beech and oak forests. Warm climate crops, such as tea, feijoa (a fruit-bearing shrub), rice, grapes, tobacco, and citrus trees, flourish there. The region is also becoming one of the largest producers of spring and winter vegetables in the Soviet Union.

Mild winters draw many birds to the Caspian coast, and a reservation provides a resting home for flamingos, swans, pelicans, herons, and buzzards.

The towns of Lenkoran, Astara, and Massaly are small, and the Talysh, or Talīshī—Iranian people who form the bulk of the local population—have preserved their old customs and traditions. Industry is mostly concerned with the processing of agricultural goods, while in the mountains the Talysh make colourful rugs and carpets.

The Kuba-Khachmas region. This lies to the north of Apsheron. Its coastal lowlands specialize in grain and vegetable production, while vast orchards surround the towns of Kuba and Kusary. The mountain slopes are used for grazing. Special kinds of sheep are bred in order that their skins may be utilized in the fur industry.

The Shirvan region. An industrially and agriculturally developed part of Azerbaijan, this area is centred on the Shirvan Plain. The Mingechaur hydroelectric station is located here, and a new thermoelectric station was under construction in the 1970s. The area also has a well-developed network of highways. Industry is generally engaged in the processing of such agricultural products as cotton, grapes, and fruit. The most important vineyards lie in the vicinity of Shemakha, a town famed for its wines, notably Matrasa and Shemakha, respectively dry red and sweet. In Kyurdamir a fragrant dessert wine of the same name is produced. The best varieties of pomegranates are grown near Geokchay.

The Mugano-Salyany region. Lying south of the Kura River and within the boundaries of the Mili and Mugan plains, this area specializes in cotton growing, producing about 70 percent of the gross cotton output of the entire republic. Cotton-ginning plants are located in Barda, Salyany, and Ali-Bayramly, all of which, in addition to

Cotton production

being located on the Kura River, have the advantage of being junctions of railways and motor roads. A thermal power station stands near Ali-Bayramly.

The Southwestern region. This includes the Nagorno-Karabakh Autonomous Oblast, as well as Lachin, Fizuli, and Kubatly administrative districts. As the average altitude is 4,900 feet (1,500 metres), it is one of the areas in the republic where broken relief impedes the development of transport, industry, and agriculture. Agricultural production is concentrated in the mountain valleys. Animal husbandry constitutes 60 percent of the gross agricultural output, the leading branches being sheep and pig raising. Grapes, tobacco, and grain are the main crops.

Armenians form the greater part of the population. The Nagorno-Karabakh Autonomous Oblast is well known in the Soviet Union for the longevity of its people; many have a life-span of more than 100 years.

The Kirovabad-Kazakh region. Occupying a special place in the plans for the future development of the republic, this region is situated in the centre of Transcaucasia at the junction of the Azerbaijan, Armenian, and Georgian republics. The region has conditions favourable both for human life and for intensive agriculture. Trade routes have crossed this part of Azerbaijan from time immemorial, and the ancient town of Ganja (now Kirovabad) was founded here. It is an important industrial centre, with light, food, engineering, chemical, and nonferrous metallurgical industries. Naftalan is a health resort.

The Sheki-Zakataly region. This area includes the towns of Sheki (formerly Nukha), Zakataly, and Belokany. Its territory borders on the Great Caucasus, which shields it from cold northern winds. Numerous mountain rivers provide it with an ample supply of water, and the region is densely populated. Agricultural products include tobacco, aromatic plants (mint, basil, and roses), rice, corn (maize), and various fruits. The area is also the largest Soviet producer of hazelnuts and walnuts.

The Nakhichevan region. This is a typical semidesert, although a system of irrigation makes it possible to cultivate grapes, cotton, and grain. There are several sources of mineral water in the foothill areas of the Nakhichevan A.S.S.R.

TRANSPORTATION

Railways

Most of the rivers of Azerbaijan are not navigable, and most freight—including that sent out of the republic—is carried by rail. Considerable portions of the rail network are electrified, and total track mileage is about 1,150. Annual freight turnover is about 66,000,000 tons, the principal goods carried being oil products, building materials, timber, and grain. The major railway lines go through the Kura Valley and connect Baku with Tbilisi and Batumi in the Georgian S.S.R.

Motor transport is used extensively for both freight and passengers within the republic. The total length of highways has reached 13,400 miles, and the annual freight turnover by truck is some 3,090,000,000 ton-miles (4,520,000,000 ton-kilometres). Highways connect various parts of the republic and are often the only means of land communication between some of the remote mountain districts and the administrative centres and large cities.

Baku, on the Caspian, is one of the busiest seaports in the Soviet Union, handling such important and vital goods as oil, timber, grain, and cotton. A ferry link (1962) between Baku and Krasnovodsk (also on the Caspian, in the Turkmen S.S.R.) has increased considerably the amount of cargo passing through Azerbaijan.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Constitutional and political framework. The Azerbaijan constitution (1937) declares it to be one of the 15 constituent republics forming the Soviet Union. Though sovereignty and equality are claimed for it, both are limited by the fact that the republic lacks independence in foreign affairs, military matters, economic planning, domestic political control, and cultural and ideological questions, in all of which it must defer to the central Soviet authorities in Moscow. At the top of the governmental structure within Azerbaijan today are the republic's Supreme Soviet, selected from a single slate of candidates for a four-year term, and its Presidium, selected by the Supreme Soviet. The duties of both are largely ceremonial rather than legislative. The highest executive and administrative body of the republic's government is the Council of Ministers. Local branches of government are the *oblast* and city soviets. The judicial system includes a Supreme Court and lower courts.

Communist Party

The Communist Party of Azerbaijan, a subordinate branch of the Communist Party of the Soviet Union (CPSU), is the only authorized political organization. Among the 249,670 members (1970) in the republic, Azerbaijanis comprised 66 percent, noticeably less than their proportion (almost three-quarters) of the whole population of the republic. Armenians made up almost 14 percent of the Azerbaijan party membership, and Russians 12.4 percent, though they constituted only 9.4 and 10 percent of the population, respectively. Small minorities made up the remainder. The closely connected Azerbaijan Komsomol (Young Communist League) has a membership of 432,000. Labour union membership totals about 1,242,000; the unions are not concerned with relations between workers and management except in connection with such matters as incentives to increase production.

Social services. The republic has a well-established health service with large specialized clinics and medical research institutes. More than 1,000 hospitals and polyclinics are active. Medical service, provided without direct charge to patients, is supported by general taxation on individual employees and workers and by taxes from income of factories and other firms.

The network of medical and prevention establishments is growing: by the mid-1970s there were 27 doctors, 44 paramedical personnel, and 95 hospital beds for every 10,000 people.

Science and culture. In the course of its long history, Azerbaijan has given the world a number of outstanding thinkers, poets, and scientists. Among the medieval scientists and philosophers, Abul Hasan Bakhmanyar (11th century), the author of numerous works on mathematics and philosophy, and Abul Hasan Shirvani (11th–12th centuries), the author of *Astronomy*, may be noted. The poet and philosopher Nẹzāmī, called Ganjavī after his place of birth, Ganja (now Kirovabad), was the author of *Khamseh* ("The Quintuplet"), composed of five romantic poems, including "The Treasure of Mysteries," "Khosrow and Shīrīn," and "Leyli and Mejnūn."

The people of Azerbaijan have kept their ancient musical tradition. The art of *ashug*s, who improvise songs to their own accompaniment on a stringed instrument called a *kobuz*, remains extremely popular. *Mugam*s, vocal and instrumental compositions, are widely known, the town of Shusha being particularly famous for this art.

In the Soviet period, illiteracy has been virtually eradicated, and a network of institutes of higher education, research centres, theatres, and similar bodies has been established. By 1971 there were 13 institutes for higher education in Azerbaijan with more than 100,000 students. The largest is the Azerbaijan Institute of Petroleum and Chemistry, in whose seven departments more than 17,000 students attend classes.

Education at all levels is supported by taxes levied upon working people and firms and is available without direct tuition charge.

The Azerbaijan Academy of Sciences was established in 1945 and in 1975 had 51 full members and 44 corresponding members. The academy coordinates the activity of 30 research centres, including institutes of cybernetics, physics, theoretical problems of chemical technology, petrochemical processes, and genetics.

Since World War II a number of new cultural institutions have been established. By the mid-1970s the republic had 13 state theatres, half of them in Baku, about 2,500 clubs, 38 museums, and 3,200 libraries with about 25,300,000 volumes. The opera and ballet are widely at-

tended. Some of Azerbaijan's composers, notably Uzeir Hajjibekov (the operas *Ker-Ogly* and *Leyli and Mejnūn* and the operetta *Arshin Mal'Alan*) and Kara Karayev (the ballets *Seven Beauties* and *The Path of Thunder*), have international reputations. The latter's symphonic music is also well known abroad.

Publishing

Azerbaijan has no private publishing; several government firms publish scientific books and magazines as well as books and magazines about art and literature in Azerbaijani, Russian, and other languages. Of the 1,283 book titles issued in 1973, 70.5 percent appeared in Azerbaijani and most of the rest in Russian. Copies of books in Azerbaijani per person fell from 2.8 annually around 1959 to 2 about 1970; the reason for this probably was the striking increase (51.4 percent) in the republic's Azerbaijani population and a failure to provide more copies to meet the increase.

Magazines

The magazines *Literaturny Azerbaidzhan* (in Russian), *Azerbaijan Gadïnï* ("Azerbaijan Woman," in Azerbaijani), and *Azerbaidzhanskoye neftyanoye khozyaistvo* ("Azerbaijan Petroleum Economy," in Russian) have the highest circulation.

Newspapers of the republic appearing in the Azerbaijani language numbered 92 in 1973 out of a total 116 in all languages.

Baku has several radio stations, a television studio, and a film studio.

PROSPECTS

Important changes have taken place in the structure of the economy of the republic over the past decades, with the industrial rate of growth surpassing that of agriculture. According to the 1971–75 plan of economic development, adopted by the 24th Congress of the Communist Party of the Soviet Union, a more rapid development of engineering and chemical industries was envisaged, and the latter's output was to rise steeply with the completion of a new chemical plant in Sumgait. A new microbiological industry was also to come into existence, making artificial fodder out of by-products of oil processing. In agriculture, new irrigation and drainage schemes were planned.

New residential quarters were to be built in Baku and to be connected with the city centre by new subway lines already partially in operation. The water supply of the capital was to be improved and increased with the building of a new water-supply system bringing water from the Kura River and the Samur-Apsheron Canal.

Among the problems facing the republic is the difficulty found by Azerbaijani intellectuals and executives in placing their educated, talented students in employment, commensurate with their abilities, in the urban areas, especially Baku. Despite the fact that the percentage of non-Azerbaijanis living in the republic dropped between 1959 and 1970, Russians and Armenians, the two largest minorities, grew in absolute numbers in the period. In Azerbaijan, Russians, Armenians, Jews, and Tatars live and work largely in the cities. Their presence in the urban work force creates a dilemma for Azerbaijani authorities seeking to advance their own graduates and at the same time to avoid ethnic tension and discrimination.

Azov, Sea of

An inland sea of the Atlantic Basin, the Sea of Azov (Azovskoye More in Russian, spelled Azovskoje More in the transliteration system of the Akademiya Nauk) is situated on the southern shores of the European portion of the Soviet Union. Separated on the south from the Black Sea by the Kerch and Taman peninsulas, it meets the Black Sea at the Kerch Strait.

Physical characteristics. Its area is 15,000 square miles (38,000 square kilometres), its mean depth 26 feet (eight metres), and its maximum depth 46 feet. It is thus the world's shallowest sea. Mean water volume is 77 cubic miles (320 cubic kilometres). The west, north, and east shores are low-lying, with sandstone deposits containing mussel fossils; the south shores are mainly high and jagged and composed of limestone. Characteristic features of the shores are alluvial mussel-fossilized spits, which separate many shallow bays and the estuaries from the sea. Some of the estuaries are connected directly with the sea; others are separated from it by sandy overspills. Into the Sea of Azov flow the great rivers Don and Kuban and many lesser ones such as the Mius, the Berda, the Obitochnaya, and the Yeya.

The topography of the bottom is even but has a minute incline toward the centre. Bottom deposits are composed of sand, mussel fossils, and silt. Certain parts of the southern shore are marked by rocky soil. The geological history of the Sea of Azov is inseparably connected with that of the Black Sea. The Sea of Azov formed in the Middle Miocene Epoch (16,000,000 years ago) as part of a wide basin. In the Early Pliocene (beginning 7,000,000 years ago), the basin of the Black Sea and the Sea of Azov was isolated from the ocean. In the subsequent period, connections with the Caspian Sea, through the Manych Trench, and with the Mediterranean Sea were formed and broken several times. In the Middle and Late Pliocene the Cimmerian and Kuyalnits basins formed and evolved into the Chaudin Basin on the sites of the Sea of Azov and the Black Sea; they had a connection with the Caspian Sea at the time but evidently were isolated from the Mediterranean. At the beginning of the Quaternary Period (2,500,000 years ago) the Sea of Azov acquired roughly the outline it has today. Toward the end of this period a connection between the Black Sea and the Mediterranean Sea was established (a stage known as the Karangats Basin).

Former connection with the Caspian Sea

Climate. The climate of the Sea of Azov is continental and temperate. In the winter, northeast and east winds predominate, bringing cold air from the mainland. The mean January–February air temperature ranges from 30° F (−1° C) in the south to 21° F (−6° C) in the north, the minima being around −27° F (−33° C). Under the influence of cyclones, heavy frosts often alternate with thaws, and there are frequent fogs. July is the warmest month, with a mean temperature of 75° F (24° C). The maximum temperature is around 104° F (40° C).

Hydrology. The hydrological regime is determined by the continental situation of the sea, the climate, the influx from the rivers, and the water exchange with the Black Sea, as well as by the water-related activity of man in the basin. The yearly water balance of the Sea of Azov in the centre consists of 9.5 cubic miles from river inflow and 3.2 cubic miles of precipitation, minus evaporation of 8.1 cubic miles; 4.2 cubic miles of surplus freshwater flows out through the Kerch Strait. As a result of the freshwater surplus the mean salinity is only 11 parts per thousand in the south, 9–10 in the rest of the sea, and 2–4 in the inlet areas. In certain years, because of changes in the water turnover through the Kerch Strait and changes in the river influx, salinity may rise to 12–13 parts per thousand in the south, and to 11–11.5 in the north, or may sink to 10.5 in the south and 8–9.5 in the north. Sivash Lake is particularly noted for salinity. Here, as a result of heavy evaporation and a weak link with the sea (through the Tonky Strait), the salinity reaches 124–166 parts per thousand.

Extensive water freshening and low air and water temperatures cause an annual freezing. The ice forms in November–December in Taganrog Bay and spreads southwest, reaching its fullest extent in February. Thawing occurs in March and April.

Currents and tides

Currents flow in a counterclockwise rotation, but under the influence of winds they may reverse. They may reach a speed of 10 to 12 inches per second. The mean water

level of the sea varies as much as 13 inches from year to year, according to the river influx. Tidal oscillations of the water level may reach 18 feet. The oxygen content of the water is ten to 11 millilitres per litre in winter and five to six millilitres per litre or more in summer. In summer, during extended calms, the oxygen on the bottom may dissipate entirely through oxidation, causing the fish to die. The Sea of Azov is rich in nutrient salts; but throughout the year the nutrient-salt content varies radically with river influx and consumption of salts by living organisms.

Animal life and vegetation. There is an extraordinarily high level of biological productivity, resulting from the sea's shallowness, the excellent mixing and even warming of the water, and the input of great quantities of nutrient material by the rivers. Its varieties of phytoplankton total 188, and 25–30 varieties of macrophytes are found. Among flowering plants zostera is common. The fauna includes 324 invertebrate species and 79 species of fish, including sturgeon, perch, bream, herring, sea-roach, gray mullet, minnow, shemaja, and bullheads. Sardines and anchovies are particularly abundant. Local fisheries catch an average of 1,500,000 tons per year.

Navigation. The Sea of Azov handles much freight and passenger traffic. The progress of heavy oceangoing craft is hampered by shallowness at some points. Icebreakers assist in winter navigation. Principal ports are Taganrog, Zhdanov, Yeysk, and Berdyansk. (A.M.Mu.)

Aztec Religion

Aztec religion consists of the mythology, beliefs, and practices of the people of the Aztec Empire in pre-Spanish Mexico. According to their own traditional history, the Aztecs, a Nahuatl-speaking tribe, departed in AD 1168 from Aztlán, somewhere in northwestern Mexico or the southwestern United States, where they had dwelt for more than a thousand years. When they tried to settle in the central valley of Mexico, among civilized states such as Colhuacán, Azcapotzalco, Texcoco, in the 13th century, they were treated as semibarbarous intruders. Poor and landless, they managed to build Mexico-Tenochtitlán, a village of reed huts, on some islands and sandflats in the lakes. It was not until the reign of Itzcóatl (1428–40) that they began their ascent to the leadership of the League of the Three Cities (Mexico, Texcoco, Tlacopan), which eventually became what is now called the Aztec Empire.

In the process of building that empire through war, diplomacy, and trade, the Aztecs became involved with various aboriginal ethnic groups, whose godheads, myths, rites, and beliefs they readily borrowed. Their religion appeared as a synthesis that combined many features from different cultures.

SOURCES

Aztec religion is known through a large number of documents, which may be divided into five categories:

Early accounts written by the conquistadors. Important among these are the *Cartas de Relación* ("Letters of Information"), sent by Hernán Cortés to his emperor, Charles V, and the *Historia verdadera de la conquista de la Nueva España* ("True History of the Conquest of New Spain") by Bernal Díaz del Castillo. Rites, ceremonies, temples, paraphernalia of the cults, are often described in these accounts. Their value, however, is lessened by the writers' ignorance of the Aztec language, their lack of understanding of the Indian way of thinking, and their deep hostility to the native religion, which they considered to be inspired by the devil. These documents, therefore, should be interpreted with utmost caution.

Early accounts by Roman Catholic missionaries. Paradoxically enough, the priests generally showed more understanding and tolerance than did the laymen. Thanks to their training and theological knowledge, they were able to analyze the Indian mind and to gain insight into the meaning of the myths and ritual. They believed that the native gods were devils and that the whole religion was a trap set by Satan to destroy the souls of the Indians. Yet most of them (for example, Toribio de Motolinía) were moved by a sincere compassion toward the aboriginal population and did their best to observe and describe its way of life. The missionaries, as a rule, learned the native languages, especially Aztec.

The most illustrious of these priests was Father Bernardino de Sahagún. He arrived in Mexico very early (1529), learned the Nahuatl tongue, and spent his life building a wonderful monument, a real encyclopaedia called *Historia general de las cosas de Nueva España* ("General History of the Things of New Spain"). Sahagún deeply loved "his sons the Indians." Most of his work was devoted to an incredibly detailed account of the beliefs and rites, dictated to him in Nahuatl by Aztec noblemen and priests. Although as a Catholic monk he severely condemned their religion, he admired the Aztecs' high standards of morality, the virtues of the priests, the ideals of the rulers, the knowledge of the native thinkers. Thus the Nahuatl text of Sahagún's "History" may be said to provide a truly boundless treasury of mythological lore, descriptions of the rites, theological concepts, and religious poetry.

The Aztec encyclopaedia

Aztec sacred books. These works, known as codices, which were kept in the temples, were written (or rather, painted) on deerskin or agave-fibre paper, by scribes *(tlacuiloanime)*, who used a combination of pictography, ideograms, and phonetic symbols, and dealt with the ritual calendar, divination, ceremonies, and speculations on the gods and the universe. Most of the texts were destroyed after the Conquest, but some outstanding specimens have survived, such as the Codex Borbonicus, the Codex Borgia, the Codex Fejérváry-Mayer, and the Codex Cospiano.

The interpretation of these manuscripts is far from easy. Only a few of them, such as the Borbonicus, are truly Aztec, while others, of the utmost importance, such as the Borgia, seem to emanate from the priestly colleges of the "Mexica-Puebla" area, between the central highlands and the Oaxaca Mountains.

Another kind of book, either pre-Cortesian or post-Cortesian, affords valuable material. Examples are such historical manuscripts as the Codex Telleriano-Remensis, the Azcatitlán, the Codex of 1576, and the Codex Mendoza; they describe the history of the Aztec tribe and state, and occasionally depict religious scenes and events.

Books written by Aztec chroniclers. These works were written in the Latin alphabet, either in Nahuatl or in Spanish, by learned natives, such as Tezozómoc, Ixtlilxóchitl, and Chimalpahin, who used ancient pictographic manuscripts as their basis. Some of these books, such as the *Anales de Cuauhtitlán* (in Nahuatl; "Annals of Cuauhtitlán"), or the *Historia de los Mexicanos por sus pinturas* (in Spanish; "History of the Mexicans through their Paintings"), are anonymous compilations.

Archaeological materials. These include statues of deities, religious bas-reliefs and mural paintings, clay statuettes and vases, and stone or wooden masks. Since most Aztec art is of a highly symbolic nature, such objects can convey important information. Their interpretation, of course, often raises delicate problems, which may be solved only through careful checking against written sources.

HISTORY

Early religious life in central Mexico. Early religious phenomena can only be deduced from archaeological remains. Numerous clay figurines found in tombs afford little evidence of religious beliefs during the agricultural Pre-Classic periods of Zacatenco and Ticomán (roughly 1500 to the 1st century BC). It is possible, however, that terra-cotta statuettes of women were meant to represent an agricultural deity, a goddess of the crops. Two-headed figurines found at Tlatilco, a site of the late Pre-Classic, may portray a supernatural being. Clay idols of a fire god in the form of an old man with an incense burner on his back date from the same period.

The first stone monument on the Mexican plateau is the pyramid of Cuicuilco, near Mexico City. In fact, it is rather a truncated cone, with a stone core; the rest is made of sun-dried brick with a stone facing. It shows the main features of the Mexican pyramids as they were developed in later times. It was doubtless a religious monument, crowned by a temple built on the terminal platform and surrounded with tombs. The building of such a structure obviously required a protracted and organized effort under the command of the priests.

The final phase of the Pre-Classic cultures of the central highland forms a transition from the village to the city, from rural to urban life. This was a far-reaching social and intellectual revolution, bringing about new religious ideas together with new art forms and theocratic regimes. It is significant that Olmec statuettes have been found at Tlatilco with late Pre-Classic material.

Olmec civilization

The Olmec civilization, whose heartland is generally held to have been in the Gulf of Mexico area in the states of Tabasco and Veracruz (La Venta, Tres Zapotes), may be considered, in the present condition of scholarly knowledge, as the first of the higher native cultures in Middle America. Its beginnings were contemporary with the late Pre-Classic, as early as the 3rd century BC or even the 9th century BC; its late phase extended down to the 5th century AD, contemporaneous with the Classic "golden age." Traces of the characteristic Olmec style are to be found throughout the Mexican territory from the Gulf Coast to the Oaxaca Valley and the Morelos and Guerrero areas.

The Olmecs, a native people whose origin and language remain unknown, developed the arts of architecture and sculpture. They built ceremonial centres, erected carved monoliths and altars, and devised a system of hieroglyphic writing. Their bas-reliefs and carved jadeites (sodium aluminum silicates, a form of jade) clearly show gods, priests and mythical scenes. A jaguar cult seems to have held a central place in the religious beliefs and practices, coupled with that of a peculiar "baby," an infant whose features (especially the mouth) suggest a tiger.

Classic religious life: Teotihuacán. Although jaguars occasionally appear in religious frescoes at Teotihuacán, the main Classic site of the central plateau, Olmec religion does not seem to have taken root in the highlands. Archaeological discoveries show that the influence of the large ceremonial centre of Teotihuacán was felt as far as the Mayan area of Guatemala. The Toltecs worshipped earth and water deities: the rain god, known in later times as Tlaloc in Nahuatl, the water goddess (Chalchiuhtlicue in Nahuatl); and the Feathered Snake (Quetzalcóatl in Nahuatl), a symbol of the fertility of the soil.

The Classic civilizations of the 1st millennium AD—Teotihuacán on the central mesa, El Tajín near the Gulf Coast, the Zapotec city of Monte Albán in Oaxaca, the Mayan cities of Chiapas, Yucatán, Guatemala, and Honduras—had many religious features in common, such as the rain god called Cocijo by the Zapotecs and Chac by the Maya.

Other Classic centres

At Palenque and other Mayan centres, a maize god was worshipped under the form of the Foliated Cross, a stylized cornstalk; there was also a sun cult, as evidenced by the carved reliefs of the Temple of the Sun at Palenque. Classic religion revolved mainly around deities linked with agriculture.

The Teotihuacán frescoes show that the benevolent rain god was believed to provide men, after death, with an eternal paradise, depicted as a tropical garden where they sang, danced, and played among flowers and fruit trees. There is no evidence there of human sacrifice. The priests are shown offering incense, rubber balls, and jade plates. Some features of ornamental art (*e.g.*, the scroll motif) also strongly suggest that the Teotihuacán theocracy was led by a priestly caste that may have come from the "hot lands," the rain-forest lowlands between the central plateau and the Gulf Coast. The bulk of the population, who worked on the land and provided the manpower for building monuments, may have belonged to agricultural tribes such as the Otomi, who in later times worshipped both an earth and moon goddess of fertility and a rain god.

Teotihuacán declined in the 8th century. External influences mark the so-called Mazapan transitional phase. A god, Xipe Totec, whose cult seems to have originated in the Yopi area of the Pacific slopes of Mexico, appears for the first time on the highland. Human victims were sacrificed to him.

Toltec religion. In the 9th century, a Nahuatl-speaking people from northern Mexico invaded the central area and founded a city called Tollan or Tula. Those warlike Toltecs worshipped astral deities such as Tezcatlipoca, the god of the night sky. The whole history of Tula until the 10th century is made up of the struggle between the old Teotihuacán religion symbolized by Quetzalcóatl (Feathered Snake) and the new one brought by the invaders. Vanquished by Tezcatlipoca's sorcery, the benevolent Feathered Snake fled from Tula. Thus central Mexico submitted to the cruel rites of the sky and war gods, who demanded the blood of human victims.

Rise of the Aztecs. The disintegration of the Toltec civilization after the fall of Tula in 1168 opened the central highland to the wandering Chichimec (barbarous) tribes of northern Mexico. Some cities such as Xochimilco, Colhuacán, Cholula remained as strongholds of the Toltec religious tradition. Others were founded by the newcomers like Azcapotzalco, Texcoco, Tlaxcala, and eventually Tenochtitlán (Mexico). After the 14th century, in spite of chronic warfare among 28 city-states, a community of culture developed through trading relations, a common language (Nahuatl), and intermarriage between the ruling families. Each city-state worshipped its particular tribal god: Quetzalcóatl (Cholula), Camaxtli (Tlaxcala), Huitzilopochtli (Mexico), but there was a general interchange of myths and rites.

Aztec synthesis of tribal cults

The Aztec religion, therefore, combined the astral cults of the northern tribes with those of the earth and rain gods of the sedentary peasants. Thus the pyramid of the main *teocalli* (temple) supported two sanctuaries of equal size, one devoted to Huitzilopochtli, god of the sun and of war, the other consecrated to Tlaloc, the ancient rain god. The priestly hierarchy, likewise, was headed by two high priests of equal rank, the Feathered Snakes: one of them bore the title of "priest of Tlaloc," the other that of "priest of Our Lord" (Huitzilopochtli).

The tendency of the Aztec mind to syncretism is illustrated by their pantheon, which at the time of the Spanish conquest included the Otomi fire god Otontecuhtli, the Huaxtec love goddess Tlazoltéotl, the Yopi god "Our Lord the Flayed One" (Xipe Totec), the earth goddess of the northern steppes Itzpapalotl, and the deity of anointments and medicine Tzapotlatenan from the Zapotec area. Some religious hymns were sung in foreign ("Chichimec") languages; rites connected with the Venus worship had been borrowed from the Mazatecs of Oaxaca.

Survivals after the Spanish Conquest. This traditional tendency to religious syncretism did not disappear altogether as a result of the Spanish Conquest and the mass conversion of the Indians to Christianity. Although virtually all the native people (with a few exceptions, such as the unevangelized Maya Lacandones of Chiapas) became devout Catholics, their conversion did not prevent them from retaining both magical and religious rites and beliefs down to this day. Most Indian groups still make offerings to the rain gods on mountaintops, "feed" the earth by sacrificing and burying animals, and cure sickness by magical means. The belief in the *nahual*, an individual totemic animal, is widespread. The *peyote* cult is still of the utmost importance among the Huichol of northwestern Mexico.

In many cases the ancient religion has combined with Christianity. Thus the pre-Spanish pilgrimage to the earth and moon goddess Tonantzin at Tepeyac has now taken the form of the cult devoted to Our Lady of Guadalupe, whom the Nahuatl-speaking Indians still call Tonantzin and whom the Otomi call by the name of the ancient moon deity. In most villages purely Indian brotherhoods

combine the cult of the Roman Catholic saints with pre-Cortesian ceremonies. In rural areas Mexican Catholicism is permeated by such survivals.

MYTHS

Cosmogony and eschatology. The Aztecs believed, as did other Middle American Indians, such as the Maya-Quiché, that four worlds had existed before the present universe. Those worlds or "Suns" had been destroyed by catastrophes. Mankind had been entirely wiped out at the end of each Sun. The present world was the fifth Sun.

The myth of the 'Suns'

The first Sun was called *nahui-ocelotl*, "Four-Jaguar," a date of the ritual calendar. Mankind was destroyed by jaguars. The animal was considered by the Aztecs as the *nahualli* (animal disguise) of Tezcatlipoca.

At the end of the Second Sun, *nahui-ehécatl*, "Four-Wind," a magical hurricane had transformed all men into monkeys. That disaster was caused by Quetzalcóatl in the form of Ehécatl, the wind god.

A rain of fire had put an end to the third Sun, *nahui-quiahuitl*, "Four-Rain." Tlaloc as the god of thunder and lightning presided over that period.

The fourth Sun, *nahui-atl*, "Four-Water," ended in a gigantic flood that lasted for 52 years. Only one man and one woman survived, sheltered in a huge cypress. But they were changed into dogs by Tezcatlipoca, whose orders they had disobeyed.

Present mankind has been created by Quetzalcóatl. The Feathered Snake with the help of his twin Xolotl, the dog-headed god, succeeded in reviving the dried bones of the old dead by sprinkling them with his own blood. The present Sun is called *nahui-ollin*, "Four-Earthquake," and is doomed to disappear in a tremendous earthquake. The skeleton-like monsters of the west, the *tzitzimime*, will then appear and kill all mankind.

Two deeply rooted concepts are revealed by these myths. One is the belief that the universe is unstable, that death and destruction continually threaten it. The other emphasizes the necessity of the sacrifice of the gods. Thanks to Quetzalcóatl's self-sacrifice, the ancient bones of Mictlan, "the Place of Death," have given birth to men. In the same way the sun and moon have been created: the gods, assembled in the darkness at Teotihuacán, built a huge fire; two of them, Nanahuatzin, a small deity covered with ulcers, and Tecciztécatl, a richly bejewelled god, threw themselves into the flames, from which the former emerged as the sun and the latter as the moon. Then the sun refused to move unless the other gods gave him their blood; they were compelled to sacrifice themselves to feed the sun.

Cosmology. According to the Aztec cosmological ideas, the universe has the general shape of a cross. To each of the four world directions are attached five of the 20 day-signs, one of them being a Year-Bearer (east, *acatl*, reed; west, *calli*, house; north, *tecpatl*, flint knife; south, *tochtli*, rabbit), a colour (east, red or green; west, white; north, black; south, blue), and certain gods. The fifth cardinal point, the centre, is attributed to the fire god Huehueteotl, because the hearth stands at the centre of the house.

Above the earth, which is surrounded by the "heavenly water" (*ilhuicátl*) of the ocean, are 13 heavens, the uppermost of which, "where the air is delicate and frozen," is the abode of the Supreme Couple. Under the "divine earth," *teotlalli*, are the 9 Hells of Mictlan, with 9 rivers that the souls of the dead must cross. Thirteen was considered a favourable number, 9 extremely unlucky.

All the heavenly bodies and constellations were divinized, such as the Great Bear (Tezcatlipoca), Venus (Quetzalcóatl), the stars of the north (Centzon Mimixcoa, "the 400 Cloud-Serpents"), the stars of the south (Centzon Huitznáua, "the 400 Southerners"). The solar disk, Tonatiuh, was supposed to be borne on a litter from the east to the zenith, surrounded by the souls of dead warriors, and from the zenith to the west among a retinue of divinized women, the Cihuateteo. When the night began on the earth, day dawned in Mictlan, the abode of the dead.

Deities. The ancient tribes of central Mexico had worshipped fertility gods for many centuries when the Aztecs invaded the valley. The cult of these gods remained extremely important in Aztec religion. Tlaloc, the giver of rain but also the wrathful deity of lightning, was the leader of a group of rain gods, the Tlaloques, who dwelt on mountaintops. Chalchiuhtlicue (the One Who Wears a Jade Skirt) presided over fresh waters, Huixtocihuatl over salt waters and the sea. Numerous earth goddesses were associated with the fertility of the soil and with the fecundity of women, as Teteoinnan (Mother of the Gods), Coatlicue (the One Who Wears a Snake Skirt), Cihuacóatl (Snake-Woman), Itzpapalotl (Obsidian-Butterfly). Their significance is twofold: as fertility deities, they give birth to the young gods of maize, Centéotl, and of flowers, Xochipilli; as symbols of the earth that devour the bodies and drink the blood, they appear as warlike godheads. Tlazoltéotl, a Huaxtec goddess, presided over carnal love and over the confession of sins.

Vegetation and fertility gods

Xipe Totec, borrowed from the faraway Yopi tribe, was a god of the spring, of the renewal of vegetation, and at the same time the god of the corporation of goldsmiths. Human victims were killed and flayed to honour him.

The concept of a Supreme Couple played an important role in the religion of the old sedentary peoples such as the Otomi. Among the Aztecs it took the form of *intonan intota*, "Our Mother, our Father," the Earth and the Sun. But the Fire-god Huehueteotl was also associated with the Earth. In addition, Ometecuhtli (the Lord of the Duality) and Omecihuatl (the Lady of the Duality) were held to abide in the 13th heaven: they decided on which date a human being would be born, thus determining his or her destiny.

Among the fertility gods are to be counted the "400 Rabbits" (Centzon Totochtin), little gods of the crops, of *octli* (a fermented drink) and drunkenness, such as Ometochtli and Tepoztécatl.

The Aztecs brought with them the cult of their tribal sun and war god, Huitzilopochtli, "the Hummingbird of the Left," who was considered "the reincarnated Warrior of the South," the conquering sun of midday. According to a legend probably borrowed from the Toltecs, he was said to have been born near Tula. His mother, the earth goddess Coatlicue, had already given birth to the 400 Southerners and to the night goddess Coyolxauhqui, whom the newborn god exterminated with his *xiuhcoatl* (turquoise-snake).

Tezcatlipoca, god of the night sky, was the protector of the young warriors. Quetzalcóatl, the ancient Teotihuacán deity of vegetation and fertility, had been "astralized" and transformed into a god of the morning star. He was also revered as a wind god and as the ancient priest-king of the Toltec golden age: the discoveries of writing, the calendar, and the arts were attributed to him.

People of the Sun. The Aztecs thought of themselves as "the People of the Sun." Their duty was to wage cosmic war in order to provide the sun with his *tlaxcaltiliztli* (nourishment). Without it the sun would disappear from the heavens. Thus the welfare and the very survival of the universe depended upon the offerings of blood and hearts to the sun, a notion that the Aztecs extended to all the deities of their pantheon. Human sacrifice, as a result, became the most important feature of ritual.

Mythology of death and afterlife. The beliefs of the Aztecs concerning the other world and life after death show the same syncretism already observed. The old paradise of the rain god Tlaloc, depicted in the Teotihuacán frescoes, opened its gardens to those who died by drowning, lightning, or as a result of leprosy, dropsy, gout, or lung diseases. He was supposed to have caused their death and to have sent their souls to paradise.

Two categories of dead persons went up to the heavens as companions of the Sun: the Quauhteca (Eagle People), who comprised the warriors who died on the battlefield or on the sacrificial stone, and the merchants who were killed while travelling in faraway countries; and the women who died while giving birth to their first child and thus became Cihuateteo, "Divine Women."

Quauhteca and Cihuateteo

All the other dead went down to Mictlan, under the northern deserts, the abode of Mictlantecuhtli, the skeleton-masked god of death. There they travelled for four years until they arrived at the ninth Hell, where they disappeared altogether.

Offerings were made to the dead 80 days after the funeral, then one year, two, three and four years later. Then all link between the dead and the living had been severed. But the warriors who crossed the heavens in the retinue of the Sun came back to earth after four years as hummingbirds. The Cihuateteo, "Divine Women," used to appear at night at the crossroads and strike the passers-by with palsy.

World view. The world vision, or *Weltanschauung*, of the Aztecs conceded only a small part to man in the scheme of things. His destiny was submitted to the all-powerful *tonalpohualli* (the calendrical round); his life in the other world did not result from any moral judgment. His duty was to fight and die for the gods and for the preservation of the world order. Moreover, witchcraft, omens, portents dominated everyday life. That such a pessimistic outlook should have coexisted with the wonderful dynamism of Aztec civilization is in itself a remarkable achievement.

PRACTICES AND INSTITUTIONS

Aztec ritual calendar. *Tonalpohualli*, an Aztec term meaning "the count of days," is the name of the ritual calendar of 260 days. It runs parallel to the solar calendar of 365 days, which was divided into 18 months of 20 days and 5 supplementary unlucky days. The word *tonalli* means "day" and "destiny": the 260-day calendar was mainly used for purposes of divination. The days were named by the combination of 20 signs (natural phenomena such as *ehecatl*, wind, *ollin*, earthquake; animals like *tochtli*, rabbit, *ocelotl*, jaguar; plants as *acatl*, reed; objects like *tecpatl*, flint knife, *calli*, house) with the numbers 1 to 13. Thus the calendrical round included 20 series of 13 days.

Astrology and divination

Specialized priests called *tonalpouhque* interpreted the signs and numbers on such occasions as birth, marriage, departure of traders to faraway countries, and election of rulers. Each day and each 13-day series was deemed lucky, unlucky, or indifferent according to the deities presiding over it. Thus *ce-coatl* (one-snake) was held as favourable to the traders, *chicome-xochitl* (seven-flower) to the scribes and the weavers, *nahui-ehecatl* (four-wind) to the magicians. The men who were born during the *ce-ocelotl* (one-jaguar) series would die on the sacrificial stone, those whose birth took place on the day *ome-tochtli* (two-rabbit) would be drunkards, etc. The *tonalpohualli* dominated every aspect of public and private life. The same system can be found among all the Indian cultures of Middle America; its origin is at least as ancient as the Olmec civilization.

Temples and ceremonial centres. The ceremonial centres, such as the holy city built at the heart of Mexico, Tenochtitlán, consisted mainly of temples (*teocalli*), pyramids whose terminal platform supported the sanctuary proper. Some temples dedicated to the wind god were round. Other buildings, the *calmecac*, were used as the residence of the priests and as colleges of higher education. To the temple were annexed courts for the ceremonial ball game (*tlachtli*), sacrificial stones (*techcatl*), skull racks (*tzompantli*), and ritual bathhouses (*temazcalli*). All the districts (*calpulli*) of the city had their own temples, as well as the corporations of traders and craftsmen.

Human sacrifice. The outstanding feature of Mexican ritual from Toltec times was human sacrifice. The victims were either war prisoners or slaves bought for that purpose. In some cases the victim was chosen from among a certain category (women, young men). Death by sacrifice was considered a certain way of gaining a happy eternal life. It was therefore stoically accepted or even voluntarily sought. The victim wore the dress and ornaments of the god and was called *ixiptla*, the god's "image." The priests forced the victim backward on the sacrificial stone; one of them opened the victim's breast with a stroke of his flint knife and tore out the heart, which was burned in a stone urn (*cuauhxicalli*). In some ceremonies victims were decapitated, drowned, or burned. Part of their flesh was also ritually eaten.

At the end of each 52-year cycle, the ceremony called tying up the years was performed on the Huixachtécatl mountaintop. The priests lit the New Fire on the breast of a victim. The last renewal of the Fire took place in 1507.

Priesthood and rites. The clergy were extremely numerous. Most priests came from noble families, but sons and daughters of "plebeians" could accede to priesthood. Under the two high priests, the *Mexicatl teohuatzin* was at the head of all religious activities in the city and the provinces, with two assistants, one in charge of ritual, the other of education. The huge estates of the temples were administered by a general treasurer. Each deity had his own college of priests. Both male and female priests remained celibate.

A special category of priests, the *tonalpouhque*, interpreted the sacred books to predict the future. Those who consulted them used to pay them with clothes and food.

Feasts and festivals

As each month of 20 days was marked by a feast, sacrifices, pageants, flower offerings, and dances and songs dedicated to a particular god or group of gods, the activities of the clergy were manifold and unceasing. There were, in addition, ceremonies on certain days of the ritual calendar, and ceremonies performed by various corporations: traders, goldsmiths, feather workers, salt-makers, water bearers, healers, and midwives.

The clergy did not directly intervene in affairs of state but its influence was doubtless extremely strong. Priests of high rank were members of the electoral body that designated the rulers.

Sorcerers. The Aztecs believed in and greatly feared sorcery. The sorcerers (*nahualli*, a word meaning "disguise") were supposed to be endowed with the power of transforming themselves into animals, such as dogs and owls. They could cause sickness and death by burning a wooden figurine representing the intended victim of their witchcraft. Some sorcerers secretly opened the tomb of a recently buried woman who had died in childbirth (*i.e.*, of a "divinized woman") and severed her left forearm. Using the arm as a magical wand, they would put the members of a household to sleep and make off with their belongings.

Sorcerers, also called owl-men, prepared herb love potions as well as poisonous drinks.

Although witchcraft was punished by death, there is evidence that its practice was widespread and that sorcerers exacted gifts of considerable value from those who had them cast spells on their enemies.

Other practices. The physicians and midwives—both influential and esteemed professions—made wide use of religious rites and formulas. Several deities, it was believed, could cause illnesses or cure them. Skin diseases, ulcers, leprosy, dropsy, were attributed to Tlaloc, eye afflictions to Xipe Totec, and venereal diseases to Xochipilli. The healers addressed their prayers to these gods. Specialized deities were invoked, such as Ixtlilton for the sicknesses of children, the goddesses Quato and Caxoch, who cured headaches, the earth goddess who protected pregnant women and presided over the steam bath (*temazcalli*).

Rites like incense burning, rubbing with tobacco—considered a living being to which prayers were addressed—and ceremonial drinking of hallucinatory potions were performed by the physicians both in diagnosis and in treatment.

PLACE OF AZTEC RELIGION IN ANCIENT AMERICA

While the Aztec Empire brought to Mexico a new principle of political unity, religion remained a mixture of local beliefs and practices. The priesthood tried to introduce some order into the theological chaos of a religion that included many different traditions and cults.

The great sky god Tezcatlipoca, for instance, was said to assume several personalities and names. As the "black Tezcatlipoca," he remained the traditional northern deity of the night stars. As red, he was identified with Xipe Totec. As blue, he became Huitzilopochtli himself. Among the other gods, only Quetzalcóatl was considered Tezcatlipoca's brother and equal; all the other deities had been created by those two brother gods.

Nezahualcóyotl, the king of Texcoco (1431–72), had erected a temple in the form of a high tower without any statue or idol to the "unknown god, creator of all things," a faceless, mythless deity called Ipalnemohuani, "the One By Whom We Live." But it is unlikely that such a metaphysical concept could have spread among the population, which remained attached to local and traditional ideas and rites.

Aztec religion is only one form of Middle American native religion, or rather the form it assumed in later times. Even outside the Aztec area, among the Yucatec Maya for instance, many myths and practices, such as human sacrifice, closely parallel those of central Mexico.

Andean religion, on the contrary, as observed in the Inca Empire, shows many important differences. Even though some features may have been common to both the Andean and Mexican areas in a distant past (*e.g.*, the feline cult), separate developments had taken place for many centuries. It is significant that the ritual calendar so prevalent in Middle America, with its highly peculiar combination of 13 numbers and 20 day-signs, is not found anywhere in the Andes.

Baʿal Shem Ṭov

Israel ben Eliezer, called the Baʿal Shem Tov (Master of the Good Name) and also known by the acronym Besht, was the charismatic founder of Ḥasidism, a Jewish spiritual movement originated in the 18th century that demands the total hallowing of human existence. He was also responsible for divesting Kabbala (esoteric Jewish mysticism) of the rigid asceticism imposed on it by Isaac ben Solomon Luria in the 16th century. The Besht's life has been so adorned with fables and legends that a biography in the ordinary historical sense is not possible.

Early life

The Besht was born about 1700, probably at Tluste (Polish Tłuste, now Tolstoye), in southern Ukraine. Contemporary Jews called the village Okop or Akuf, depending on the Hebrew vocalization. As a young orphan he held various semi-menial posts connected with synagogues and Hebrew elementary religious schools. After marrying the daughter of the wealthy and learned Ephraim of Kuty, he retired to the Carpathian Mountains to engage in mystical speculation, meanwhile eking out his living as a lime digger. During this period his reputation as a healer, or *baʿal shem*, who worked wonders by means of herbs, talismans, and amulets inscribed with the divine name, began to spread. He later became an innkeeper and a ritual slaughterer and, about 1736, settled in the village of Medzhibozh, in Podolia. From this time until his death, he devoted himself almost entirely to spiritual pursuits.

Though the Besht gained no special renown as a scholar or preacher during his lifetime, he made a deep impression on his fellow Jews by going to the marketplace to converse with simple people and by dressing like them. Such conduct by a holy man was fiercely condemned in some quarters but enthusiastically applauded in others. The Besht defended his actions as a necessary "descent for the sake of ascent," a concept that eventually evolved into a socio-theological theory that placed great value on this type of spiritual ministration.

While still a young man, the Besht had become acquainted with such figures as Rabbi Naḥman of Gorodënka and Rabbi Naḥman of Kosov, already spoken of as creators of a new life, and with them he regularly celebrated the ritual of the three sabbath meals. In time it became customary for them to deliver pious homilies and discourses after the third meal, and the Besht took his turn along with the others. Many of these discourses were later recorded and have been preserved as the core of Ḥasidic literature. When the Besht's spiritual powers were put to a test by other members of the group—an indication that he probably was not yet recognized as the "first among equals"—he reportedly recognized a *mezuza* (ritual object affixed to a doorpost) as ritually "unfit" by means of his clairvoyant powers.

Renunciation of asceticism

The Besht gradually reached the point where he was prepared to renounce the strict asceticism of his companions. In words recorded by his grandson Rabbi Baruch of Medzhibozh, he announced:

> I came into this world to point a new way, to prevail upon men to live by the light of these three things: love of God, love of Israel, and love of Torah. And there is no need to perform mortifications of the flesh.

By renouncing mortification in favour of new rituals, the Besht in effect had taken the first step toward initiating a new religious movement within Judaism. The teaching of

the Besht centred on three main points: communion with God, the highest of all values; service in ordinary bodily existence, proclaiming that every human deed done "for the sake of heaven" (even stitching shoes and eating) was equal in value to observing formal commandments; and rescue of the "sparks" of divinity that, according to the Kabbala, were trapped in the material world. He believed that such sparks are related to the soul of every individual. It was the Besht's sensitivity to the spiritual needs of the unsophisticated and his assurance that redemption could be attained without retreat from the world that found a ready response among his listeners, the common Jewish folk. He declared that they were, one and all, "limbs of the divine presence."

The Besht and his followers were fiercely attacked by rabbinical leaders for "dancing, drinking, and making merry all their lives." They were called licentious, indifferent, and contemptuous of tradition—epithets and accusations that were wild exaggerations, to say the least.

Assessment

An understanding of the Besht's view of the coming of the Messiah depends to a great extent on the interpretation of a letter attributed to, but not signed by, the Besht. It affirms that the author made "the ascent of the soul," met the Messiah in heaven, and asked him when he would come. The answer he received was: "when your well-springs shall overflow far and wide"—meaning that the Besht had first to disseminate the teaching of Ḥasidism. According to one view, the story indicates that the messianic advent was central in the Besht's belief; according to another, it effectively removes messianic redemption from central spiritual concern in the life that must be lived here and now.

Among the Besht's most outstanding pupils was Rabbi Jacob Joseph of Polonnoye, whose books preserve many of the master's teachings. He speaks with holy awe of his religious teacher in tones that were echoed by other disciples, such as Dov Baer of Mezrechye, Rabbi Nahum of Chernobyl, Aryeh Leib of Polonnoye, and a second grandson, Rabbi Ephraim of Sydoluvka, who was but one of many to embellish the image of his grandfather with numerous legends.

During his lifetime, the Besht brought about a great social and religious upheaval and permanently altered many traditional values. In an atmosphere marked by joy, new rituals, and ecstasy, he created a new religious climate in small houses of prayer outside the synagogues. The changes that had occurred were further emphasized by the wearing of distinctive garb and the telling of stories. Though the Besht never did visit Israel and left no writings, by the time he died, in 1760, he had given to Judaism a new religious dimension in Ḥasidism that continues to flourish to this day. (R.S-U.)

BIBLIOGRAPHY. DOV BAER, *Shivḥé ha-Besht* (1814), is the earliest collection of legends (in Hebrew) about the Ba'al Shem Ṭov. SAMUEL A. HORODEZKY, *Shivḥé ha-Besht* (1947), arranges systematically Dov Baer's desultory legends, with preface and commentary. DAN BEN-AMOS and JEROME R. MINTZ (eds. and trans.), *In Praise of Baal Shem Tov* (1970), offers an English translation of Dov Baer's legends, based upon the 1814 edition. MEYER LEVIN, *The Golden Mountain* (1932); and MARTIN BUBER, *Die Legende des Baalschem* (1932; Eng. trans., *The Legend of the Baal-Shem*, 1955), retell with literary flair the legends of the Ba'al Shem Ṭov. SALOMO BIRNBAUM, *Leben und Worte des Baalschem* (1920; Eng. trans., *The Life and Sayings of the Baal Shem*, 1933), contains excerpts from the writings and teachings of the Ba'al Shem Ṭov. See also the selected bibliography in DAN BEN-AMOS and JEROME R. MINTZ (*op. cit.*), pp. 273–279.

(S.Z.L.)

Bābur

Bābur (Ẓahīr-ud-Dīn Muḥammad), the first Mughal (or Mongol) emperor of India and founder of the Mughal dynasty there, was a many-sided man, a poet and diarist of genius, a soldier of distinction, a statesman, and an adventurer. He came from the Barlas tribe of Mongol origin to which the conqueror Timur belonged, but isolated members of the tribe had become Turks in language and manners through long residence in Turkish regions. Hence Bābur, though called a Mughal, drew most of his support from Turks, and the empire he founded was Turkish in character. His family had become members of the Chagatai clan, by which name they are known.

Bābur, inspecting a garden, portrait miniature from the *Bābur-nameh*, 16th century. In the British Museum (MS. Or 3714).

Early years

Bābur (authorities disagree over whether the name means "lion," "tiger," or "panther") was born on February 15, 1483. He was fifth in direct male descent from Timur and 13th, through the female line, from Genghis Khan, the first of the great Mongol conquerors. Bābur's father, 'Umar Shaykh Mīrzā, ruled the small principality of Fergana to the north of the Hindu Kush (mountains). Because there was no fixed law of succession among the Turks, every prince of the Timurids—the dynasty founded by Timur—considered it his right to rule the whole of Timur's dominions. These territories were vast, and, hence, the princes' claims led to unending wars. The Timurid princes, moreover, considered themselves kings by profession, their business being to rule others without observing too precisely whether any particular region had actually formed a part of Timur's empire. Bābur's father, true to this tradition, spent his life trying to recover Timur's old capital of Samarkand, and Bābur followed in his footsteps. The qualities needed in this jungle of dynastic warfare were the ability to inspire loyalty and devotion, to manage the turbulent factions often rent by family feuds, and to draw revenue from the trading and agricultural classes. Bābur eventually mastered them all, but he was also a commander of genius.

For ten years (1494–1504) Bābur sought to recover Samarkand and twice occupied it briefly (1497 and 1501). But, in Muḥammad Shaybānī Khān, a descendant of Genghis Khan and ruler of the Uzbeks beyond the Syrdarya (Jaxartes) river, he had an opponent more powerful than even his close relatives. In 1501 Bābur was decisively defeated at Sar-e Pol and within three years had lost both Samarkand and his principality of Fergana. There was always hope at that time, however, for a prince of ability with engaging qualities and powers of leadership. In 1504 Bābur seized Kābul with his personal followers, maintaining himself there against all rebellions and intrigues. His last unsuccessful attempt on Samarkand (1511–12) induced him to give up a hopeless quest and to concentrate on expansion elsewhere. In 1522, when he was already turning his attention to Sind and India, he finally secured Qandahār, a strategic site on the road to Sind.

When Bābur made his first raid into India in 1519, the

Punjab was part of the dominions of Sultan Ibrāhīm Lodī of Delhi, but the governor, Dawlat Khān Lodī, resented Ibrāhīm's attempts to diminish his authority. By 1524 Bābur had invaded the Punjab three more times but was unable to master the tangled course of Punjab and Delhi politics sufficiently to achieve a firm foothold. Yet it was clear that the Delhi sultanate was rent with dissension and ripe for overthrow. After mounting a full-scale attack there, Bābur was recalled by an Uzbek attack on his Kābul kingdom, but a joint request for help from ʿĀlam Khān, Ibrāhīm's uncle, and Dawlat Khān encouraged Bābur to attempt his fifth, and first successful, raid.

Setting out in November 1525, Bābur met Ibrāhīm at Pānīpat, 50 miles (80 kilometres) north of Delhi, on April 21, 1526. Bābur's army was estimated at no more than 12,000, but they were seasoned followers, adept at cavalry tactics, and were aided by new artillery acquired from the Ottoman Turks. Ibrāhīm's army was said to number 100,000 with 100 elephants, but its tactics were antiquated, and it was rent with dissension. Bābur won the battle by coolness under fire, his use of artillery, and effective Turkish wheeling tactics on a divided, dispirited enemy. Ibrāhīm was killed. With his usual speed Bābur occupied Delhi three days later and reached Āgra on May 4. His first action there was to lay out a garden by the river Yamuna, now known as the Ram Bagh.

First victory in India

This brilliant success must have seemed at the time to be little more than one of his former forays on Samarkand. His small force, with the unaccustomed Indian hot weather upon them and 800 miles from their base at Kābul, was surrounded by powerful foes. All down the Ganges Valley were militant Afghan chiefs, in disarray at the moment but with a formidable military potential. To the south were the kingdoms of Mālwa and Gujarāt, both with large resources, while in Rājasthān, Rānā Sāngā of Mewār (Udaipur) was head of a powerful confederacy threatening the whole Muslim position in north India. Bābur's first problem was that his own followers, who, suffering from the heat and disheartened by the hostile surroundings, wished to return home as Timur had done. By employing threats, reproaches, promises, and appeals, vividly described in his memoirs, Bābur diverted them. He then dealt with Rānā Sāngā, who, when he found that Bābur was not retiring as his Turkish ancestor had done, advanced to the attack with an estimated 100,000 horses and 500 elephants. With most of the neighbouring strongholds still held by his foes, Bābur was virtually surrounded. He sought divine favour by abjuring liquor, breaking the wine vessels, and pouring the wine down a well. His followers responded both to this act and his stirring exhortations and stood their ground at Khānua, 37 miles west of Āgra, on March 16, 1527. Bābur used his customary tactics—a barrier of wagons for his centre, with gaps for the artillery and for cavalry sallies, and wheeling cavalry charges on the wings. The artillery stampeded the elephants, and the flank charges bewildered the Rājputs, who, after ten hours, broke, never to rally under a single leader again.

Bābur had now to deal with the defiant Afghans to the east, who had captured Lucknow while he was facing Rānā Sāngā. Other Afghans had rallied to Sultan Ibrāhīm's brother Maḥmūd Lodī, who had occupied Bihār. There were also Rājput chiefs still defying him, principally the ruler of Chanderi. After capturing that fortress in January 1528, Bābur turned to the east. Crossing the Ganges, he drove the Afghan captor of Lucknow into Bengal. He then turned on Maḥmūd Lodī, whose army was scattered in Bābur's third great victory of the Ghāghara, where that river joins the Ganges, on May 6, 1529. Artillery was again decisive, helped by the skillful handling of boats. Bābur's dominions were now secure from Qandahār to the borders of Bengal, with a southern limit marked by the Rājput desert and the forts of Ranthambhor, Gwalior, and Chanderi. Within this great area, however, there was no settled administration, only a congeries of quarrelling chiefs. An empire had been gained but had still to be pacified and organized. It was thus a precarious heritage that Bābur passed on to his son Humāyūn.

Consolidation of his conquests

In 1530, when Humāyūn became so ill that his life was despaired of, Bābur is said to have offered his life to God in exchange for Humāyūn's, walking seven times round the bed to complete the vow. Humāyūn recovered, and, from that time, Bābur declined, to die in Āgra on December 26, 1530.

Bābur is rightly considered the founder of the Indian Mughal Empire, even though the work of consolidating the empire was performed by his grandson Akbar. Bābur, moreover, provided the glamour of magnetic leadership that inspired the next two generations.

Assessment

Bābur was a military adventurer of genius, an empire builder of good fortune, and an engaging personality. He was also a Turki poet of considerable gifts that would have won him distinction apart from his political career. He was a lover of nature who constructed gardens wherever he went and complemented beautiful spots by holding convivial parties. Finally, his prose memoirs, the *Bābur-nāmeh*, have become a world classic of autobiography. They were translated from Turki into Persian in Akbar's reign (1589) and into English (1921–22). They portray a ruler unusually magnanimous for his age, cultured, witty, convivial, and full of good fellowship and adventurous spirit, with a sensitive eye for natural beauty.

BIBLIOGRAPHY. Bābur's own autobiography, the *Bābur-nāmeh* in the original Turki, is available in English as the *Memoirs of Bābur*, 2 vol. (1921–22). L.F. RUSHBROOK WILLIAMS, *An Empire-Builder of the Sixteenth Century* (1918), provides a good introduction both to Bābur and to the contemporary Indian situation. J.F. GRENARD, *Baber, fondateur de l'empire des Indes* (1930; Eng. trans., *Baber, First of the Moguls*, 1931), is a good interpretative study. The standard work in English is WILLIAM ERSKINE, *A History of India Under The Two First Sovereigns of the House of Taimur, Báber and Humáyun*, 2 vol. (1854). A condensed but valuable study is by E. DENISON ROSS in *The Cambridge History of India*, vol. 4, ch. 1 (1963). For further information, see *The Encyclopaedia of Islam*, new ed., vol. 1 (1960).

Babylon

Babylon (Bab-ilu) was one of the most famous cities of antiquity, the capital of southern Mesopotamia (Babylonia) from the early 2nd until the late 1st millennium BC, and of the Neo-Babylonian Empire in the 7th and 6th centuries BC. Situated on the Euphrates River about 55 miles (88 kilometres) south of Baghdad, the city exists only as extensive ruins near the modern town of al-Ḥillah, Iraq.

History. Though traces of prehistoric settlement exist, Babylon's development as a major city was late by Mesopotamian standards, no mention of it occurring before the 23rd century BC. After the fall of the 3rd dynasty of Ur, under which Babylon had been a provincial centre, it became the nucleus of a small kingdom established in 1894 BC by the Amorite king Sumuabum, whose successors consolidated its status. The sixth and best known of the Amorite dynasts, Hammurabi (1792–1750 BC), conquered the surrounding city-states and raised Babylon to the capital of a kingdom comprising all southern Mesopotamia and part of Assyria (northern Iraq). Its political importance, together with its favourable geographical position, made it henceforth the main commercial and administrative centre of Babylonia, while its wealth and prestige made it a target for foreign conquerors.

Old Babylonian kingdom

After a Hittite raid in 1595 BC, the city passed to the control of the Kassites (*c.* 1570), who established a dynasty lasting over four centuries. Later in this period, Babylon became a literary and religious centre, the prestige of which was reflected in the elevation of Marduk, its chief god, to supremacy in Mesopotamia. In 1234 Tukulti-Ninurta I of Assyria took Babylon, though subsequently the Kassite dynasty reasserted itself until 1158, when the city was sacked by the Elamites. Babylon's acknowledged political supremacy is shown by the fact that the dynasty of Nebuchadrezzar I (1124–1103) made it their capital, although they did not originate there. This dynasty endured for over a century.

Just before 1000, pressure from Aramaean immigrants

from northern Syria brought administrative dislocation inside Babylon. From this period to the fall of Assyria in the late 7th century BC, there was a continual struggle between Aramaean or associated Chaldean tribesmen and the Assyrians for political control of the city. Its citizens claimed privileges, such as exemption from forced labour, certain taxes, and imprisonment, which the Assyrians, with a similar background, were usually readier to recognize than were immigrant tribesmen. Furthermore, the citizens, grown wealthy by commerce, benefitted by an imperial power able to protect international trade, but suffered economically from disruptive tribesmen. Such circumstances made Babylon usually prefer Assyrian to Aramaean or Chaldean rule.

From the 9th to the late 7th centuries Babylon was almost continuously under Assyrian suzerainty, usually wielded through native kings, though sometimes Assyrian kings ruled in person. Close Assyrian involvement in Babylon began with Tiglath-pileser III (744–727 BC) as a result of Chaldean tribesmen pressing into city territories, several times usurping the kingship. Disorders accompanying increasing tribal occupation finally persuaded Sennacherib (704–681 BC) that peaceful control of Babylon was impossible, and in 689 he ordered destruction of the city. Esarhaddon (680–669 BC) rescinded Sennacherib's policy, and, after expelling the tribesmen and returning the property of the Babylonians to them, undertook the rebuilding of the city; but the image of Marduk, removed by Sennacherib, was retained in Assyria throughout his reign, probably to prevent any potential usurper from using it to claim the kingship. In the mid-7th century, civil war broke out between the Assyrian king Ashurbanipal and his brother who ruled in Babylonia as subking. Ashurbanipal laid siege to the city, which fell to him in 648 after famine had driven the defenders to cannibalism.

Neo-Babylonian Empire

After Ashurbanipal's death, a Chaldean leader, Nabopolassar, in 626 made Babylon the capital of a kingdom that under his son Nebuchadrezzar II became a major imperial power. Nebuchadrezzar undertook a vast program of rebuilding and fortification in Babylon, labour gangs from many lands increasing the mixture of the population. Nebuchadrezzar's most important successor, Nabonidus, campaigned in Arabia for a decade, leaving his son Belshazzar as regent in Babylon. Nabonidus failed to protect property rights or religious traditions of the capital, and attempted building operations elsewhere to rival Marduk's great temple of Esagila. When the Persians under Cyrus attacked in 539 BC, the capital fell almost without resistance; a legend (accepted by some as historical) that Cyrus achieved entry by diverting the Euphrates is unconfirmed in contemporary sources.

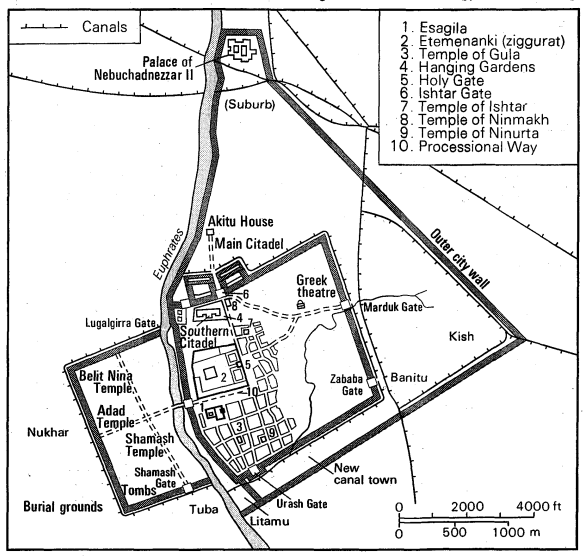
Under the Persians, Babylon retained most of its institutions, became capital of the richest satrapy in the empire, and, according to Herodotus, the world's most splendid city. A revolt against Xerxes I (482) led to destruction of its fortifications and temples, and the melting down of the golden image of Marduk.

Conquest by Alexander the Great

In 331 Babylon surrendered to Alexander the Great, who confirmed its privileges and ordered the restoration of the temples. Alexander, recognizing the commercial importance of the city, allowed its satrap to issue coinage and began construction of a harbour to foster trade. In 323 Alexander died in the palace of Nebuchadrezzar; he had planned to make Babylon his imperial capital. Alexander's conquest brought Babylon into the orbit of Greek culture, and Hellenistic science was greatly enriched by the contributions of Babylonian astronomy. After a power struggle among Alexander's generals, Babylon passed to the Seleucid dynasty in 312. The city's importance was much reduced by the building of a new capital, Seleucia, on the Tigris, to which part of Babylon's population was transferred in 275.

The ancient city. Evidence of the topography of ancient Babylon is provided by excavations, cuneiform texts, and descriptions by the 5th-century Greek historian Herodotus and other classical authors. The extensive rebuilding by Nebuchadrezzar has left relatively little archaeological data in the central area earlier than his time, while elsewhere the water table has limited excavation in early strata. The reports of Herodotus largely relate to the Babylon built by Nebuchadrezzar.

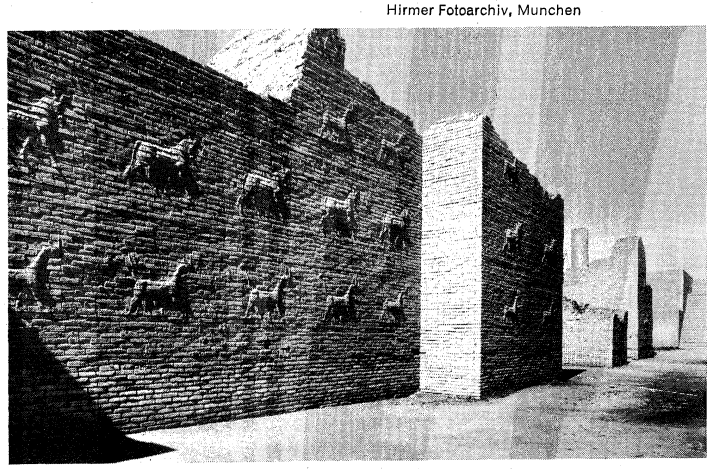
Adapted from *Westermann Grosser Atlas zur Weltgeschichte*, Georg Westermann Verlag, Braunschweig



Babylon during the reign of Nebuchadrezzar II.

Nebuchadrezzar's Babylon was the largest city in the world, covering 2,500 acres (10,000 hectares). The Euphrates, which has since shifted its course, flowed through it, the older part of the city being on the east bank. There the central feature was Esagila, the great temple of Marduk, with its associated ziggurat (a tower built in several stages) Etemenanki. The latter, popularly known as the Tower of Babel, had a base 100 yards on a side, and its seven stages, the uppermost a temple in blue glaze, reached to a height of 300 feet (91 metres). Four other temples in the eastern half of the city are known from excavations and a larger number from texts. Along the Euphrates, particularly in the neighbourhood of Esagila, were quays for trading vessels, and textual evidence that Babylon was an entrepôt for trade with south Babylonia points to the existence of warehouses. The river was spanned by a bridge on brick piles, with stone capping, to the western half of the city. The streets were laid out on a grid, with the main axis parallel to the river. From Esagila northward passed the paved Processional Way, its walls decorated with enamelled lions. Passing through the Ishtar Gate, adorned with enamelled bulls and dragons, it led to the Akitu House, a small temple outside the city, visited by Marduk at the New Year festival. West of the Ishtar Gate, one of eight fortified gates, were two palace complexes that covered about 40 acres with their fortifications.

Hirmer Fotoarchiv, Munchen



The Ishtar Gate, Babylon, 6th century BC.

East of the Processional Way lay an area that since the time of Hammurabi had contained private dwellings built around central courtyards. A powerful double wall, reinforced by a fosse (ditch), enclosed the city on both sides of the Euphrates. Beyond the city walls to the east an outer rampart of triple construction, 11 miles long, met the Euphrates south and north of the city, at its northern junction enclosing another palace. Between the inner and outer defenses was irrigated land with a network of canals, some going back to the time of Hammurabi. Greek tradition refers to the Hanging Gardens, a simulated hill of vegetation-clad terracing over a vaulted substructure that in Hellenistic times was deemed one of the Seven Wonders of the World. The German archaeologist R. Koldewey identified the base of this early in the 20th century AD with a part of the palace complex, though the tradition could have arisen from the existence of trees on the ziggurat.

Hanging Gardens

The present site. The present site, an extensive field of ruins, contains several prominent mounds. The main mounds are (1) Babil, the remains of Nebuchadrezzar's palace in the northern corner of the outer rampart; (2) Qasr, comprising the palace complex (with a building added in Persian times), the Ishtar Gate, and the Emakh temple; (3) Amran ibn Ali, the ruins of Esagila; (4) Merkez, marking the ancient residential area east of Esagila; (5) Humra, containing rubble removed by Alexander from the ziggurat in preparation for rebuilding, and a theatre he built with material from the ziggurat; and (6) Ishin Aswad, where there are two further temples. A depression called Sahn marks the former site of the ziggurat Etemenanki. An over-life-size basalt lion, probably of Hittite origin and brought to Babylon in antiquity, stands north of the Ishtar Gate.

Archaeology. After minor surveys and excavations by the British scholar C.J. Rich (1811 and 1817), and the English diplomat A.H. Layard (1850), the French orientalist F. Fresnel, the German assyriologist J. Oppert (1852–54), and others, a major archaeological operation began under R. Koldewey of the Deutsche Orient-Gesellschaft in 1899, continuing unbroken until 1917. In the course of his excavation of the structures mentioned, Koldewey also discovered cuneiform inscriptions, statues, steles (pillars), terra-cotta reliefs, cylinder seals, pottery, glassware, and jewellery. Further brief investigations were made by the Deutsches Archäologisches Institut in 1956 under H.J. Lenzen at the Greek theatre, and in 1966 under H.J. Schmidt at the site of Etemenanki. Restoration of the Emakh temple, and of part of the Ishtar Gate, the Processional Way, and the palace complex was begun in 1958 by the Iraq Department of Antiquities, which has also built a half-size model of the complete Ishtar Gate at the entrance to the site.

BIBLIOGRAPHY. The principal excavator's own account of his results is given in a good popular form by R. KOLDEWEY, *Das wieder erstehende Babylon*, 4th ed. (1925; Eng. trans., *The Excavations at Babylon*, 1914). H.W.F. SAGGS, "Babylon," in D. WINTON THOMAS (ed.), *Archaeology and Old Testament Study*, pp. 39–56 (1967), gives a summary of medieval and early modern investigations of the site of Babylon, together with an account of the results of the excavations there, and related evidence, oriented to its biblical interest. H.W.F. SAGGS, *Everyday Life in Babylonia and Assyria* (1965), popular account of particular aspects of Babylonian life, pp. 156–180 dealing with the Babylon of Nebuchadrezzar.

Bach, Johann Sebastian

Although he was admired by his contemporaries primarily as an outstanding harpsichordist, organist, and expert on organ building, Johann Sebastian Bach is now generally regarded as one of the greatest composers of all time and is celebrated as the creator of the *Brandenburg Concertos*, *The Well-Tempered Clavier*, the *Mass in B Minor*, and numerous other masterpieces of church and instrumental music. Appearing at a propitious moment in the history of music, Bach was able to survey and bring together the principal styles, forms, and national traditions that had developed during preceding generations and, by virtue of his synthesis, enrich them all.

He was a member of a remarkable family of musicians who were proud of their achievements, and about 1735 he drafted a genealogy, *Ursprung der musicalisch-Bachischen Familie* ("Origin of the Musical Bach Family"), in which he traced his ancestry back to his great-great-grandfather Veit Bach, a Lutheran baker (or miller), who was driven from Hungary to Wechmar in Thuringia, a historic region of Germany, by religious persecution late in the 16th century and died in 1619. There were Bachs in the area before that, and it may be that, when Veit moved to Wechmar, he was returning to his birthplace. He used to take his cittern to the mill and play it while grinding was going on. Johann Sebastian remarked, "A pretty noise they must have made together! However, he learnt to keep time, and this apparently was the beginning of music in our family."

Until the birth of Johann Sebastian, his was the least distinguished branch of the family; its members had been competent practical musicians, but not composers such as Johann Christoph, Johann Michael, and Johann Ludwig. In later days the most important musicians in the family were Johann Sebastian's sons, Wilhelm Friedemann, Carl Philipp Emanuel, and Johann Christian (the "English Bach").

Early years. J.S. Bach was born at Eisenach, Thuringia (now in East Germany), on March 21, 1685, the youngest child of Johann Ambrosius Bach and Elisabeth Lämmerhirt. Ambrosius was a string player, employed by the town council and the ducal court of Eisenach. Johann Sebastian started school in 1692 or 1693 and did well in spite of frequent absences. Of his musical education at this time, nothing definite is known; but he may have picked up the rudiments of string playing from his father, and no doubt he attended the Georgenkirche, where Johann Christoph Bach was organist until 1703.

By 1695 both his parents were dead, and he was looked after by his eldest brother, also named Johann Christoph (1671–1721), organist at Ohrdruf. This Christoph had been a pupil of the influential keyboard composer Johann Pachelbel, and he apparently gave Johann Sebastian his first formal keyboard lessons. The young Bach again did well at school, until in 1700 his voice secured him a place in a select choir of poor boys at the school at the Michaelskirche, Lüneburg (now in West Germany).

First keyboard lessons

His voice must have broken soon after this, but he remained at Lüneburg for a time, making himself generally useful. No doubt he studied in the school library, which had a large and up-to-date collection of church music; he probably heard Georg Böhm, organist of the Johanneskirche; and he visited Hamburg to hear the renowned organist and composer Johann Adam Reinken at the Katharinenkirche, contriving also to hear the French orchestra maintained by the Duke of Celle.

He seems to have returned to Thuringia in the late summer of 1702, for, at some time between July and No-

vember, he applied for the post of organist at Sangerhausen (in modern East Germany). But for ducal interference, he would have obtained it; and, when every allowance is made for the low technical standards of that area, this means that he must already have been a reasonably proficient organist. His experience at Lüneburg, if not at Ohrdruf, had turned him away from the secular string-playing tradition of his immediate ancestors; thenceforth, he was, chiefly, though not exclusively, a composer and performer of keyboard and sacred music. The next few months are wrapped in mystery, but, by March 4, 1703, he was a member of the orchestra employed by Johann Ernst, Herzog von Weimar (brother of Wilhelm Ernst, whose service Bach entered in 1708). This post was a mere stopgap; he probably already had his eye on the organ then being built at the Neukirche in Arnstadt; for, when it was finished, he helped to test it, and in August 1703 he was appointed organist—all this at the age of 18. Arnstadt documents imply that he had been court organist at Weimar; this is incredible, though it is likely enough that he had occasionally played there.

The Arnstadt period. At Arnstadt, on the northern edge of the Thuringian forest, where he remained until 1707, Bach devoted himself to keyboard music, the organ in particular. While at Lüneburg, he had apparently had no opportunity of becoming directly acquainted with the spectacular, flamboyant playing and compositions of Dietrich Buxtehude, the most significant exponent of the north German school of organ music. In October 1705 he repaired this gap in his knowledge by obtaining a month's leave and walking to Lübeck (over 200 miles [300 kilometres]). His visit must have been profitable, for he did not return until about the middle of January 1706. In February his employers complained about his absence and about other things as well: he had harmonized the hymn tunes so freely that the congregation could not sing to his accompaniment, and, above all, he had produced no cantatas. Perhaps the real reasons for his neglect were that he was temporarily obsessed with the organ and was on bad terms with the local singers and instrumentalists, who were not under his control and did not come up to his standards. In the summer of 1705 he had made some offensive remark about a bassoon player, which led to an unseemly scuffle in the street. His replies to these complaints were neither satisfactory nor even accommodating; and the fact that he was not dismissed out of hand suggests that his employers were as well aware of his exceptional ability as he was himself and were reluctant to lose him.

Acquaintance with Buxtehude's music

During these early years, Bach inherited the musical culture of the Thuringian area, a thorough familiarity with the traditional forms and hymns (chorales) of the orthodox Lutheran service, and, in keyboard music, perhaps (through his brother, Johann Christoph) a bias toward the formalistic styles of the south. But he also learned eagerly from the northern rhapsodists, Buxtehude above all. By 1708 he had probably learned all that his German predecessors could teach him and arrived at a first synthesis of northern and southern German styles. He had also studied, on his own and during his presumed excursions to Celle, some French organ and instrumental music.

Among the few works that can be ascribed to these early years with anything more than a show of plausibility are the *Capriccio sopra la lontananza del suo fratello dilettissimo* (*Capriccio on the Departure of His Most Beloved Brother*, 1704, BWV 992); the chorale prelude on *Wie schön leuchtet* (*How Brightly Shines*, *c.* 1705, BWV 739); the fragmentary early version of the organ *Prelude and Fugue in G Minor* (before 1707, BWV 535a). (The "BWV" numbers provided are the standard catalog numbers of Bach's works as established in the *Bach-Werke-Verzeichnis*, prepared by the German musicologist Wolfgang Schmieder.)

The Mühlhausen period. In June 1707 Bach obtained a post at the Blasiuskirche in Mühlhausen in Thuringia. He moved there soon after and married his cousin Maria Barbara Bach at Dornheim on October 17. At Mühlhausen things seem, for a time, to have gone more smoothly. He produced several church cantatas at this time; all of these works are cast in a conservative mold, based on biblical and chorale texts and displaying no influence of the "modern" Italian operatic forms that were to appear in Bach's later cantatas. The famous organ *Toccata and Fugue in D Minor* (BWV 565), written in the rhapsodic northern style, and the *Prelude and Fugue in D Major* (BWV 532) may also have been composed during the Mühlhausen period, as well as the organ *Passacaglia in C Minor* (BWV 582), an early example of Bach's instinct for large-scale organization. Cantata No. 71, *Gott ist mein König* (*God is my King*), of February 4, 1708, was printed at the expense of the city council and was the first of Bach's compositions to be published. While at Mühlhausen, Bach copied music to enlarge the choir library, tried to encourage music in the surrounding villages, and was in sufficient favour to be able to interest his employers in a scheme for rebuilding the organ (February 1708). His real reason for resigning on June 25, 1708, is not known. He himself said that his plans for a "well-regulated [concerted] church music" had been hindered by conditions in Mühlhausen and that his salary was inadequate. It is generally supposed that he had become involved in a theological controversy between his own pastor Frohne and Archdeacon Eilmar of the Marienkirche. Certainly, he was friendly with Eilmar, who provided him with librettos and became godfather to Bach's first child; and it is likely enough that he was not in sympathy with Frohne, who, as a Pietist, would have frowned on elaborate church music. It is just as possible, however, that it was the dismal state of musical life in Mühlhausen that prompted Bach to seek employment elsewhere. At all events, his resignation was accepted, and shortly afterward he moved to Weimar, some miles west of Jena on the Ilm River. He continued, nevertheless, to be on good terms with Mühlhausen personalities, for he supervised the rebuilding of the organ, is supposed to have inaugurated it on October 31, 1709, and composed a cantata for February 4, 1709, which was printed but has disappeared.

Cantatas of the Mülhausen period

The Weimar period. Bach was, from the outset, court organist at Weimar and a member of the orchestra. Encouraged by Wilhelm Ernst, he concentrated on the organ during the first few years of his tenure. From Weimar, Bach occasionally visited Weissenfels; in February 1713 he took part in a court celebration there that included a performance of his first secular cantata, *Was mir behagt*, or the *Hunt Cantata* (BWV 208).

Late in 1713 Bach had the opportunity of succeeding Friedrich Wilhelm Zachow at the Liebfrauenkirche, Halle; but the Herzog raised his salary, and he stayed on at Weimar, becoming concertmaster on March 2, 1714, with the duty of composing a cantata every month. He became friendly with a relative, Johann Gottfried Walther, a music lexicographer and composer who was organist of the town church, and, like Walther, Bach took part in the musical activities at the Gelbes Schloss (Yellow Castle), then occupied by Herzog Wilhelm's two nephews, Ernst August and Johann Ernst, both of whom he taught. The latter was a talented composer who wrote concertos in the Italian manner, some of which Bach arranged for keyboard instruments; the boy died in 1715, in his 19th year.

Unfortunately, Bach's development cannot be traced in detail during the vital years 1708–14, when his style underwent a profound change. There are too few datable works. From the series of cantatas written in 1714–16, however, it is obvious that he had been decisively influenced by the new styles and forms of the contemporary Italian opera and by the innovations of such Italian concerto composers as Antonio Vivaldi. The results of this encounter can be seen in such cantatas as numbers 182, 199, and 61 in 1714; 31 and 161 in 1715; and 70 and 147 in 1716. His favourite forms appropriated from the Italians were those based on refrain (ritornello) or da capo schemes in which wholesale repetition—literal or with modifications—of entire sections of a piece permitted him to create coherent musical forms with much larger dimensions than had hitherto been possible. These newly acquired techniques henceforth gov-

Italian influence on Bach

erned a host of Bach's arias and concerto movements, as well as many of his larger fugues (especially the mature ones for organ) and profoundly affected his treatment of chorales.

Among other works almost certainly composed at Weimar are most of the *Orgelbüchlein* (*Little Organ Book*); all but the last of the so-called 18 "Great" chorale preludes; the earliest organ trios; and most of the organ preludes and fugues. The "Great" *Prelude and Fugue in G Major* for organ (BWV 541) was finally revised about 1715, and the *Toccata and Fugue in F Major* (BWV 540) may have been played at Weissenfels.

On December 1, 1716, Johann Samuel Drese, musical director at Weimar, died. He was then succeeded by his son, who was rather a nonentity. Bach presumably resented being thus passed over; and in due course he accepted an appointment as musical director to Prince Leopold of Köthen, which was confirmed in August 1717. Herzog Wilhelm, however, refused to accept his resignation—partly, perhaps, because of Bach's friendship with the Herzog's nephews, with whom the Herzog was on the worst of terms. About September a contest between Bach and the famous French organist Louis Marchand was arranged at Dresden. The exact circumstances are not known; but Marchand avoided the contest by leaving Dresden a few hours before it should have taken place. By implication, Bach won. Perhaps this emboldened him to renew his request for permission to leave Weimar; at all events he did so but in such terms that the duke imprisoned him for a month (November 6–December 2). A few days after his release, Bach moved to Köthen (in modern East Germany), some 30 miles (50 kilometres) north of Halle.

The Köthen period. There, as musical director, he was concerned chiefly with chamber and orchestral music. Even though some of the works may have been composed earlier and revised later, it was at Köthen that the sonatas for violin and clavier, viola da gamba and clavier, and the works for unaccompanied violin and cello were put into something like their present form. The *Brandenburg Concertos* were finished by March 24, 1721; in the sixth concerto—so it has been suggested—Bach bore in mind the technical limitations of the Prince, who played the gamba. Bach played the viola by choice; he liked to be "in the middle of the harmony." He also wrote a few cantatas for the Prince's birthday and other such occasions; most of these seem to have survived only in later versions, adapted to more generally useful words. And he found time to compile pedagogical keyboard works: the *Clavierbüchlein* for W.F. Bach (begun January 22, 1720); some of the *French Suites;* the *Inventions* (1720); and the first book (1722) of *Das Wohltemperierte Klavier* (*The Well-Tempered Clavier*, eventually consisting of two books, each of 24 preludes and fugues in all keys and known as the Forty-eight). This remarkable collection systematically explores both the potentials of a newly established tuning procedure, which, for the first time in the history of keyboard music, made all the keys equally usable, and the possibilities for musical organization afforded by the system of "functional tonality," a kind of musical syntax consolidated in the music of the Italian concerto composers of the preceding generation and a system that was to prevail for the next 200 years. At the same time *The Well-Tempered Clavier* is a compendium of the most popular forms and styles of the era: dance types, arias, motets, concertos, etc., presented within the unified aspect of a single compositional technique: the rigorously logical and venerable fugue.

Influence of The *Well-Tempered Clavier* on keyboard music

Maria Barbara Bach died unexpectedly and was buried on July 7, 1720. About November, Bach visited Hamburg; his wife's death may have unsettled him and led him to inquire after a vacant post at the Jacobikirche. Nothing came of this, but he played at the Katharinenkirche in the presence of Reinken. After hearing Bach improvise variations on a chorale tune, the old man said, "I thought this art was dead; but I see it still lives in you."

On December 3, 1721, Bach married Anna Magdalena Wilcken, daughter of a trumpeter at Weissenfels. Apart from his first wife's death, these first four years at Köthen were probably the happiest of Bach's life. He was on the best terms with the Prince, who was genuinely musical; and in 1730 Bach said that he had expected to end his days there. But the Prince married on December 11, 1721, and conditions deteriorated. The Princess—described by Bach as "an *amusa*" (that is to say, opposed to the muses)—required so much of her husband's attention that Bach began to feel neglected. He also had to think of the education of his elder sons, born in 1710 and 1714, and he probably began to think of moving to Leipzig as soon as the cantorate fell vacant with the death of Johann Kuhnau on June 5, 1722. Bach applied in December, but the post—already turned down by Bach's friend, Georg Philipp Telemann—was offered to another prominent composer of the day, Christoph Graupner, the musical director at Darmstadt. As the latter was not sure that he would be able to accept, Bach gave a trial performance (Cantata No. 22, *Jesu nahm zu sich die Zwölfe* [*Jesus called unto Him the Twelve*]) on February 7, 1723; and, when Graupner withdrew (April 9), Bach was so deeply committed to Leipzig that, although the Princess had died on April 4, he applied for permission to leave Köthen. This he obtained on April 13, and on May 13 he was sworn in at Leipzig.

He was appointed honorary musical director to Köthen, and both he and Anna were employed there from time to time until the Prince died, on November 19, 1728.

Years at Leipzig. As Director of Church Music for the city of Leipzig, Bach had to supply performers for four churches. At the Peterskirche the choir merely led the hymns. At the Neukirche, Nikolaikirche, and Thomaskirche, part singing was required; but Bach himself conducted, and his own church music was performed, only at the last two. His first official performance was on May 30, 1723, the first Sunday after Trinity Sunday, with Cantata No. 75, *Die Elenden sollen essen.* New works produced during this year include many cantatas and the *Magnificat* in its first version. The first half of 1724 saw the production of the *St. John Passion*, which was subsequently revised. The total number of cantatas produced during this ecclesiastical year was about 62, of which about 39 were new works.

Production of the *St. John Passion*

On June 11, 1724, the first Sunday after Trinity, Bach began a fresh annual cycle of cantatas, and within the year he wrote 52 of the so-called chorale cantatas, formerly supposed to have been composed over the nine-year period 1735–44. The Sanctus of the *Mass in B Minor* was produced at Christmas.

During his first two or three years at Leipzig, Bach had produced a large number of new cantatas, sometimes, as recent research has revealed, at the rate of one a week. This phenomenal pace raises the question of Bach's approach to composition. Bach and his contemporaries, subject to the hectic pace of production, had to invent or discover their ideas quickly and could not rely on the unpredictable arrival of "inspiration." Nor did the musical conventions and techniques or the generally rationalistic outlook of the time necessitate this reliance, as long as the composer was willing to accept them. The Baroque composer who submitted to the regimen inevitably had to be a traditionalist who willingly embraced the conventions.

Symbolism. A repertory of melody types existed, for example, that was generated by an explicit "doctrine of figures" that created musical equivalents for the figures of speech in the art of rhetoric. Closely related to these "figures" are such examples of pictorial symbolism in which the composer writes, say, a rising scale to match words that speak of rising from the dead or a descending chromatic scale (depicting a howl of pain) to sorrowful words. Pictorial symbolism of this kind occurs only in connection with words—in vocal music and in chorale preludes, where the words of the chorale are in the listener's mind. There is no point in looking for resurrection motifs in *The Well-Tempered Clavier.* Pictorialism, even when not codified into a doctrine, seems to be a fundamental musical instinct and essentially an expressive device. It can, however, become more abstract, as in the case of number symbolism, a phenomenon observed

Use of pictorial symbolism

too often in the works of Bach to be dismissed out of hand. Number symbolism is sometimes pictorial; in the *St. Matthew Passion* it is reasonable that the question "Lord, is it I?" should be asked 11 times, once by each of the faithful disciples. But the deliberate search for such symbolism in Bach's music can be taken too far. Almost any number may be called "symbolic" (3, 6, 7, 10, 11, 12, 14, and 41 are only a few examples); any multiple of such a number is itself symbolic; and the number of sharps in a key signature, notes in a melody, measures in a piece, and so on may all be considered significant. As a result, it is easy to find symbolic numbers anywhere, but ridiculous to suppose that such discoveries invariably have a meaning.

Besides the melody types, the Baroque composer also had at his disposal similar stereotypes regarding the further elaboration of these themes into complete compositions, so that the arias and choruses of a cantata almost seem to have been spun out "automatically." One is reminded of Bach's delightfully innocent remark "I have had to work hard; anyone who works just as hard will get just as far," with its implication that everything in the "craft" of music is teachable and learnable. The fact that no other composer of the period, with the arguable exception of Handel, even remotely approached Bach's achievement indicates clearly enough that the application of the "mechanical" procedures was not literally "automatic" but was controlled throughout by something else —artistic discrimination, or taste. "Taste," a most respected attribute in the culture of the 18th century, is an utterly individual compound of raw talent, imagination, psychological disposition, judgment, skill, and experience. It is unteachable and unlearnable.

As a result of his intense activity in cantata production during his first three years in Leipzig, Bach had created a supply of church music to meet his future needs for the regular Sunday and feast-day services. After 1726, therefore, he turned his attention to other projects. He did, however, produce the *St. Matthew Passion* in 1729, a work that inaugurated a renewed interest in the mid-1730s for vocal works on a larger scale than the cantata: the now-lost *St. Mark Passion* (1731), the *Christmas Oratorio*, BWV 248 (1734), and the *Ascension Oratorio* (Cantata No. 11, *Lobet Gott in seinen Reichen;* 1735).

St. Matthew Passion and *Christmas Oratorio*

Nonmusical duties. In addition to his responsibilities as musical director, Bach also had various nonmusical duties in his capacity as the cantor of the school at the Thomaskirche. Since he resented these latter obligations, Bach frequently absented himself without leave, playing or examining organs, taking his son Friedemann to hear the "pretty tunes," as he called them, at the Dresden opera and fulfilling the duties of the honorary court posts that he contrived to hold all his life. To some extent, no doubt, he accepted engagements because he needed money; he complained in 1730 that his income was less than he had been led to expect (he remarked that there were not enough funerals); but, obviously, his routine work must have suffered. Friction between Bach and his employers thus developed almost at once. On the one hand, Bach's initial understanding of the fees and prerogatives accruing to his position—particularly regarding his responsibility for musical activities in the University of Leipzig's Paulinerkirche—differed from that of the town council and the university organist, Johann Gottlieb Görner. On the other hand, Bach remained, in the eyes of his employers, their third (and unenthusiastic) choice for the post, behind Telemann and Graupner. Furthermore, the authorities insisted on admitting unmusical boys to the school, thus making it difficult for Bach to keep his churches supplied with competent singers; they also refused to spend enough money to keep a decent orchestra together. The resulting ill feeling had become serious by 1730. It was temporarily dispelled by the tact of the new rector, Johann Matthias Gesner, who admired Bach and had known him at Weimar; but Gesner stayed only until 1734 and was succeeded by Johann August Ernesti, a young man with up-to-date ideas on education, one of which was that music was not one of the humanities but a time-wasting sideline. Trouble flared up again in July 1736; it then took the form of a dispute over Bach's right to appoint prefects and became a public scandal. Fortunately for Bach, he became court composer to the Elector of Saxony in November 1736. As such, after some delay, he was able to induce his friends at court to hold an official inquiry, and his dispute with Ernesti was settled in 1738. The exact terms of the settlement are not known; but, thereafter, Bach did as he liked.

Instrumental works. In 1726, after he had completed the bulk of his cantata production, Bach began to publish the clavier *Partitas* singly, with a collected edition in 1731, perhaps with the intention of attracting recognition beyond Leipzig and thus securing a more amenable appointment elsewhere. The second part of the *Clavierübung*, containing the *Concerto in the Italian Style* and the *French Overture* (*Partita*) *in B Minor* appeared in 1735. The third part, consisting of the *Organ Mass* with the *Prelude and Fugue* ["St. Anne"] *in E Flat Major* (BWV 552), appeared in 1739. From *c.* 1729–36 Bach was honorary musical director to Weissenfels; and, from 1729 to 1737 and again from 1739 for a year or two, he directed the Leipzig Collegium Musicum. For these concerts he adapted some of his earlier concertos as harpsichord concertos, thus becoming one of the first composers in history—if not the very first—of concertos for keyboard instrument and orchestra, just as he was one of the first to use the harpsichordist's right hand as a true melodic part in chamber music. These are just two of several respects in which the basically conservative and traditional Bach, as is becoming increasingly recognized, was a significant innovator as well.

Innovations as a keyboard composer

About 1733 Bach began to produce cantatas in honour of the Elector of Saxony and his family, evidently with a view to the court appointment he secured in 1736; many of these secular movements were adapted to sacred words and re-used in the *Christmas Oratorio*. The Kyrie and Gloria of the *Mass in B Minor*, written in 1733, were also dedicated to the Elector, but the rest of the *Mass* was not put together until Bach's last years. On his visits to Dresden, Bach had won the regard of Graf Hermann Karl von Keyserlingk, the Russian envoy, who commissioned the so-called *Goldberg Variations;* these were published as part four of the *Clavierübung* about 1742, and Book Two of the "Forty-eight" seems to have been compiled about the same time. In addition, he wrote a few cantatas, revised some of his Weimar organ works, and published the so-called *Schübler Chorale Preludes* in or after 1746.

Last years. In May 1747 he visited his son Emanuel at Potsdam and played before Frederick II the Great of Prussia; in July his improvisations, on a theme proposed by the King, took shape as *The Musical Offering*. In June 1747 he joined a Sozietät der Musikalischen Wissenschaften (Society of the Musical Sciences) that had been founded by his former pupil Lorenz Christoph Mizler; he presented the canonic variations on the chorale *Vom Himmel hoch da komm' ich her* (*From Heaven Above to Earth I Come*) to the society, in manuscript, and afterward published them.

Of Bach's last illness little is known, except that it lasted several months and prevented him from finishing *The Art of the Fugue*. His constitution was undermined by two unsuccessful eye operations performed by John Taylor, the itinerant English quack who numbered Handel among his other failures; and he died on July 28, 1750, at Leipzig. His employers proceeded with relief to appoint a successor; Burgomaster Stieglitz remarked, "The school needs a cantor, not a musical director—though certainly he ought to understand music." Anna Magdalena was left badly off. For some reason, her stepsons did nothing to help her, and her own sons were too young to do so. She died on February 27, 1760, and was given a pauper's funeral.

Unfinished as it was, *The Art of the Fugue* was published in 1751. It attracted little attention and was reissued in 1752 with a laudatory preface by Friedrich Wilhelm Marpurg, a well-known Berlin musician, who later became director of the royal lottery. In spite of

Publication of *The Art of the Fugue*

Marpurg and of some appreciative remarks by Johann Mattheson, the influential Hamburg critic and composer, only about 30 copies had been sold by 1756, when Emanuel Bach offered the plates for sale. As far as is known, they were sold for scrap.

Emanuel Bach and the organist-composer Johann Friedrich Agricola (a pupil of Sebastian's) wrote an obituary; Mizler added a few closing words and published the result in the journal of his society (1754). There is an English translation of it in *The Bach Reader*. Though incomplete and inaccurate, the obituary is of very great importance as a firsthand source of information.

Bach appears to have been a good husband and father. Indeed, he was the father of 20 children, only ten of whom survived to maturity. There is amusing evidence of a certain thriftiness, a necessary virtue; for he was never more than moderately well off, and he delighted in hospitality. Living as he did at a time when music was beginning to be regarded as no occupation for a gentleman, he occasionally had to stand up for his rights both as a man and as a musician; he was then obstinate in the extreme. But no sympathetic employer had any trouble with Bach, and with his professional brethren he was modest and friendly. He was also a good teacher and from his Mühlhausen days onward was never without pupils.

REPUTATION AND INFLUENCE

For about 50 years after Bach's death, his music was neglected. This was only natural; in the days of Haydn and Mozart, no one could be expected to take much interest in a composer who had been considered old-fashioned even in his lifetime—especially since his music was not readily available, and half of it (the church cantatas) was fast becoming useless as a result of changes in religious thought.

At the same time, musicians of the late 18th century were neither so ignorant of Bach's music nor so insensitive to its influence as some modern authors have suggested. Emanuel Bach's debt to his father was considerable and Bach exercised a profound and acknowledged influence directly on Haydn, Mozart, and Beethoven.

After 1800 the revival of Bach's music gained momentum. The German writer Johann Nikolaus Forkel published a *Life, Genius and Works* in 1802 and acted as adviser to the publishers Hoffmeister and Kühnel, whose collected edition, begun in 1801, was cut short by the activities of Napoleon. By 1829 a representative selection of keyboard music was nonetheless available, although very few of the vocal works were published. But in that year the German musician Eduard Devrient and the German composer Felix Mendelssohn took the next step with the centenary performance of the *St. Matthew Passion*. It and the *St. John Passion* were both published in 1830; the *Mass in B Minor* followed (1832–45). The Leipzig publisher Peters began a collected edition of "piano" and instrumental works in 1837; the organ works followed in 1844–52.

Publication of the *Mass in B Minor*

Encouraged by Robert Schumann, the Bach-Gesellschaft (BG) was founded in the centenary year 1850, with the purpose of publishing the complete works. By 1900 all the known works had been printed, and the BG was succeeded by the Neue Bach-Gesellschaft (NBG), which exists still, organizing festivals and publishing popular editions. Its chief publication is its research journal, the *Bach-Jahrbuch* (from 1904). By 1950 the deficiencies of the BG edition had become painfully obvious, and the Bach-Institut was founded with headquarters at Göttingen (West Germany) and Leipzig, to produce a new standard edition (the *Neue Bach-Ausgabe* or NBA) expected to comprise 84 volumes.

In retrospect, the Bach revival, reaching back to 1800, can be recognized as the first conspicuous example of the deliberate exhumation of old music, accompanied by biographical and critical studies; and it served as an inspiration and a model for subsequent work of that kind.

Among the biographical and critical works on Bach, the most important was the monumental study *Johann Sebastian Bach* (2 vols., Leipzig, 1873–80), by the German musicologist Philipp Spitta, covering not only Bach's life and works but also a good deal of the historical background. Although wrong in many details, the book is still indispensable to the Bach student.

Editions of Bach's works. The word *Urtext* (original text) may lead the uninitiated to suppose that they are being offered an exact reproduction of what Bach wrote. It must be understood that the autographs of many important works no longer exist. Therefore, Bach's intentions often have to be pieced together from anything up to 20 sources, all different. Even first editions and facsimiles of autograph manuscripts are not infallible guides to Bach's intentions. In fact, they are often dangerously misleading, and practical musicians should take expert advice before consulting them. Editions published between 1752 and *c.* 1840 are little more than curiosities, chiefly interesting for the light they throw on the progress of the revival.

No comprehensive edition is trustworthy throughout: neither Peters nor the BG nor even the NBA. Nevertheless, it is advisable to begin by finding out whether the music desired has been published by the NBA.

MAJOR WORKS

Vocal music (sacred)

MASSES: *Mass in B Minor*, BWV 232 (1724–46); 4 Lutheran masses (*i.e.*, containing only settings of the Kyrie and the Gloria).

ORATORIOS: *Christmas Oratorio*, BWV 248 (1734); *Easter Oratorio* (*Kommt, eilet und laufet*, BWV 249; 1725); *Ascension Oratorio* (1735).

PASSIONS: *Passion According to St. John*, BWV 245 (1724); *Passion According to St. Matthew*, BWV 244 (1729).

CANTATAS: About 200 for different Sundays in the church year (1707–after 1735; mainly 1714–16, 1723–27), mostly for soloist(s), chorus, and orchestra.

OTHER WORKS: *Magnificat in D Major*, BWV 243; 7 motets; 2 Sanctus settings (3 others based on works by other composers); 186 independent chorale harmonizations.

Vocal music (secular)

CANTATAS: 24, mostly for soloists, chorus, and orchestra—all on German texts, except two Italian. They include the *Coffee Cantata* (*Schweigt stille, plaudert nicht*, BWV 211; *c.* 1732) and the *Peasant Cantata* (*Mer hahn en neue Oberkeet*, BWV 212; 1742).

OTHER WORKS: 5 songs for voice and continuo and 1 quodlibet for four voices and continuo.

Orchestral music

CONCERTOS: 6 *Brandenburg Concertos* (pre-1721); 2 concertos for violin and orchestra and one for two violins (1717–23); 7 for one harpsichord, 3 for two harpsichords, 2 for three and 1 for four harpsichords; 1 concerto for harpsichord, flute, and violin.

OTHER ORCHESTRAL WORKS: 4 overtures (suites); *Sinfonia in D Major* (incomplete).

Chamber music

SONATAS: 2 for violin and continuo; 2 for flute and continuo; 1 for two flutes and harpsichord; 2 for flute, violin and continuo; 3 for harpsichord and flute; 3 for harpsichord and viola da gamba; 6 for harpsichord and violin.

OTHER CHAMBER MUSIC: *Das musikalisches Opfer* (1747) for strings, flute, and continuo; 6 unaccompanied sonatas (partitas) for violin (*c.* 1720); 6 unaccompanied suites (sonatas) for cello (*c.* 1720).

Organ music

CHORALE PRELUDES: 140 chorale preludes including the *Orgelbüchlein* (mainly 1714–16); *Clavierübung*, vol. 3 (1739), and *Schübler Chorale Preludes* (1746 or later).

FUGUES: 18 preludes and fugues (1708–17, 1729–39), including the "St. Anne" in E flat major and the "Wedge" in E minor; 5 toccatas and fugues (1700–17), including the "Dorian" in D minor; 3 fantasies and fugues; 4 other fugues.

OTHER ORGAN COMPOSITIONS: Variations on the chorale *Vom Himmel hoch* (1747); *Passacaglia in C Minor*, BWV 582 (1708–17); 4 concertos; 7 fantasies; 4 preludes; 6 sonatas (trios); 3 trios.

Harpsichord music

COLLECTIONS: *Clavierübung*: vol. 1 (1726–31), 6 partitas; vol. 2 (1735), *French Overture in B Minor* and *Concerto in the Italian Style;* vol. 3 (1739) is organ music with 4 "duets" for harpsichord; and vol. 4 (1742), *Goldberg Variations; The Well-Tempered Clavier*, 2 vol. (1722 and 1742), containing 48 preludes and fugues, one in each key in each book; *Clavierbüchlein* (1720), for Wilhelm Friedemann Bach, con-

taining 15 two-part and 15 three-part inventions, 20 preludes, 2 chorale preludes, 2 allemandes, 4 minuets, a fugue, and an "applicatio"; *Clavierbüchlein* (1722) and *Notenbuch* (1725), both for Anna Magdalena Bach, containing marches, minuets, a musette, polonaises, etc.; 6 *French Suites* and 6 *English Suites.*

OTHER HARPSICHORD WORKS: *Aria variata* in A minor; 2 capriccios; *Chromatic Fantasy and Fugue;* 5 fantasies, 2 with fugues; 12 *Little Preludes;* 4 preludes and 6 for beginners; 4 preludes and fughettas, 3 preludes and fugues; 2 sonatas; 4 miscellaneous suites; 7 toccatas and arrangements.

For unspecified instrument(s)

Die Kunst der Fuge (1749); 16 fugues and 4 canons.

BIBLIOGRAPHY

Catalogs: WOLFGANG SCHMIEDER, *Thematisch-systematisches Verzeichnis der musikalischen Werke von Johann Sebastian Bach. Bach-Werke-Verzeichnis* (BWV; 1950), the standard catalog of Bach's music, including a comprehensive bibliography (up to 1950) for each work; PAUL KAST, *Die Bach-Handschriften der Berliner Staatsbibliothek* (1958), a descriptive catalog of the Bach manuscripts in the possession of the Deutsche Staatsbibliothek, Berlin, the largest single repository with over 75 percent of the surviving Bach sources.

Collections of correspondence, sketchbooks, and reminiscences: Bach-Dokumente I: Schriftstücke von der Hand Johann Sebastian Bachs (1963), a critical edition of all surviving nonmusical documents, such as letters and receipts, in Bach's hand; and *Bach-Dokumente II: Fremdschriftliche und gedruckte Dokumente zur Lebensgeschichte Johann Sebastian Bachs 1685–1750* (1969), a critical edition of all known printed and handwritten discussions of and references to Bach dating from his lifetime—both volumes of the *Dokumente* are edited by WERNER NEUMANN and HANS-JOACHIM SCHULZE and are published as supplements to the *Neue Bach-Ausgabe;* HANS DAVID and ARTHUR MENDEL (eds.), *The Bach Reader: A Life of Johann Sebastian Bach in Letters and Documents,* rev. ed. (1966); ROBERT L. MARSHALL, *The Compositional Process of J.S. Bach,* 2 vol. (1972), with transcriptions of all surviving musical sketches and drafts included in vol. 2.

Biography and criticism: PHILIPP SPITTA, *Johann Sebastian Bach,* 2 vol. (1873–80; Eng. trans., *Johann Sebastian Bach: His Work and Influence on the Music of Germany, 1685–1750,* 1883–85, reprinted 1951)—Spitta's monumental study is still the standard biography, although no longer valid in many particulars. Further important full-length studies are: ALBERT SCHWEITZER, *J.S. Bach,* 2 vol. (1905; Eng. trans., 1911, reprinted 1966), an influential, if highly subjective and personal interpretation; CHARLES SANFORD TERRY, *Bach: A Biography* (1928), a useful supplement (based on new archival researches) to the biographical portions of Spitta's work; KARL GEIRINGER, *Johann Sebastian Bach: The Culmination of an Era* (1966), the only full-length account of the life and works to make use of the far-reaching results of research in the 1950s by Alfred Dürr and Georg von Dadelsen bearing on the chronology of Bach's works.

On the vocal music: ALFRED DURR, *Die Kantaten von Johann Sebastian Bach,* 2 vol. (1971), a general survey plus individual essays on each cantata by one of the principal editors of the *Neue Bach-Ausgabe;* WERNER NEUMANN, *Handbuch der Kantaten Joh. Seb. Bachs,* 3rd ed. (1966), a handbook of useful factual data and schematic analyses of all the cantatas; *Johann Sebastian Bach. Sämtliche Kantatentexte* (1956), a complete critical edition of the cantata texts; W.G. WHITTAKER, *The Cantatas of Johann Sebastian Bach, Sacred and Secular,* 2 vol. (1959), a stimulating appreciation, but needs to be used with caution.

On the instrumental music: HERMANN KELLER, *Die Orgelwerke Bachs* (1948; Eng. trans., *The Organ Works of Bach,* 1967) and *Die Klavierwerke Bachs* (1950), the historical context of Bach's organ and keyboard works, and individual analyses of the compositions; D.F. TOVEY, *A Companion to "The Art of Fugue"* (1931), an analysis; HANS T. DAVID, *J.S. Bach's Musical Offering: History, Interpretation, and Analysis* (1945).

On performance: ERWIN BODKY, *The Interpretation of Bach's Keyboard Works* (1960), a controversial but stimulating approach; WALTER EMERY, *Bach's Ornaments* (1953), a discussion of the problems and suggested solutions; ARTHUR MENDEL, the preface of his edition of the vocal score of *The Passion According to St. John* (1951).

(W.Em/Ro.Ma.)

Bacon, Francis

Francis Bacon, lawyer, courtier, statesman, philosopher, and master of the English tongue, is remembered popularly for the sharp worldly wisdom of a few dozen essays; by historians for his power as a speaker in Parliament and in some famous trials and as James I's lord chancellor; and more critically, as a man who claimed all knowledge as his province and, after a magisterial survey, proceeded urgently to advocate new ways by which men might establish a legitimate command over nature to the glory of God and the relief of man's estate.

By courtesy of the National Portrait Gallery, London

Francis Bacon, oil painting by an unknown artist. In the National Portrait Gallery, London.

LIFE

Youth and early maturity. Bacon was born January 22, 1561, at York House off the Strand, London, the younger of the two sons of the lord keeper, Sir Nicholas Bacon, by his second marriage. Through his mother, Ann Cooke, a woman famed for her erudition and Protestant zeal, he was related to William Cecil, Lord Burghley, Elizabeth I's principal minister, and was closely connected later with his cousin Robert Cecil, earl of Salisbury, who succeeded William as chief minister of the crown and retained that post under James I. Francis and his brother Anthony were sent to study under John Whitgift—the vice chancellor of Cambridge and later archbishop of Canterbury—at Trinity College in 1573. Their two years in Cambridge, however, were broken by ill health; neither had a strong constitution. Bacon's distaste for what he termed "unfruitful" Aristotelian philosophy began at this time. In 1576 Francis went to Paris with Sir Amias Paulet, the English ambassador to France, and in his household acquired some knowledge of the French court. He was recalled abruptly after the sudden death of his father in 1579 and found himself with a poorer patrimony than he might have expected. From this time until well into the next reign, Bacon was haunted by financial stress; in 1598 he was arrested for debt, although mainly he kept afloat by borrowing on security, a practice that became habitual and dangerous.

Bacon's family

Early legal career and political ambitions. Bacon turned first toward a legal career. In 1576, shortly before he left for Paris, Francis and his brother had been admitted as "ancients" (senior governors) of Gray's Inn, one of the four inns of court that served as institutions for legal education, in London. In 1579 he took up residence at the Inn and in 1582 became a barrister and progressed in time through the stages of reader (lecturer at the Inn), bencher (senior member of the Inn), queen's, and then king's counsel extraordinary to the solicitor general and the attorney general. These positions left their mark in a number of professional publications. The staple of his career was legal, but the law did not satisfy his political and philosophical ambitions.

He occupied himself with the tract "Temporis Partus Maximus" ("The Greatest Part of Time") in 1582; it has not survived. In 1584 he sat as member of Parliament for Melcombe Regis in Dorset and subsequently represented Taunton, Liverpool, the County of Middlesex, Southampton, Ipswich, and the University of Cambridge. In 1589 a "Letter of Advice" to the Queen and *An Advertisement touching the Controversies of the Church of England* indicated his political interests and showed a fair promise of political potential by reason of his level-headedness and disposition to reconcile. Already in 1585 the sequence of Bacon's fine letters applying for support and preferment had begun, with an approach to Sir Francis Walsingham, the secretary of state, followed by a direct, manly letter to his kinsman Burghley. A grant of the reversion (*i.e.*, the right of succession to the office) of the clerkship to the Star Chamber—a law court that handled certain cases reserved from the ordinary courts to the judgment of the king or queen—was cold comfort and brought no advantage until 1608. In 1593 came a bad setback to his political hopes: he took a stand objecting to the government's intensified demand for subsidies to help meet the expenses of the war against Spain. Elizabeth took offense, and Bacon was in disgrace over several critical years when there were chances for legal advancement. He had refused to apologize, and the penalty was heavy.

Letters in search of support and preferment

Relationship with Essex. Meanwhile, sometime before July 1591, both Francis and his brother, Anthony, had become acquainted with Robert Devereux, the young earl of Essex, Burghley's ward, and a prime favourite of the Queen. Anthony's devotion to Essex was simple and disinterested; Francis saw in the Earl the "fittest instrument to do good to the State" and acted accordingly. He offered Essex the friendly advice of an older, wiser, and more subtle man and provided him with speeches for masques—*i.e.*, short dramatic presentations performed by masked actors at social gatherings. Essex did his best to mollify the Queen, and when the office of attorney general fell vacant he enthusiastically supported the claim of Bacon. His advocacy failed, however, and in 1594 the attorney's position went to Sir Edward Coke, a great English lawyer and Bacon's constant rival, who had been supported by Burghley. In the following year Essex and Burghley joined in recommending Bacon for the post of solicitor general; but Elizabeth refused to appoint him, although she did make him one of her learned counsels. Essex sought to make up for these disappointments by pressing upon Bacon a gift of land at Twickenham. Francis, in his letter of acceptance, employing a metaphor from land tenure, made a significant proviso, explaining that his lordship might have only as much as might lawfully be enclosed from ground that he reckoned to be for common use. Essex recommended him again—and again without success—for the post of master of the rolls, the vice chancellor of the chancery court. It seems that this all too insistent advocacy was more of a hindrance than a help.

The dubious and traitorous actions of Essex

Bacon had begun also to feel doubts about his patron's courses of action. By 1598 Essex's failure in the islands voyage, in which he attempted to intercept Spanish treasure ships returning from the New World at the Azores, made him harder to control; and Bacon's efforts to divert his energies to Ireland—where the Irish Catholics were rebelling against the English troops stationed there to help enforce the establishment of the Elizabethan church—were only too successful. In a later account Bacon averred that what he gave Essex was a warning about the desperate Irish situation; from a private letter, however, it appears that he had also argued encouragingly for this venture. When it went wrong and Essex lost his head and returned against orders, Bacon certainly did what he could to sort things out and steady tempers down. He merely managed to offend both sides, and in June 1600 he found himself as the Queen's learned counsel taking part in the informal trial of his patron. He made his position clear in a letter of July 20: his priority was to be *bonus civis* ("good citizen") and next *bonus vir* ("good man"). Essex bore him no ill will and shortly after his release was again on friendly terms with him. In Essex's desperate project of seizing the Queen, forcing her to dismiss his rivals, and rousing the city of London in his support, Bacon had neither share nor knowledge. After Essex's abortive rebellion of February 8, 1601, Bacon viewed Essex as a traitor and drew up the official report that was heavily corrected on submission to royal authority and published as *A Declaration of the Practices and Treasons attempted and committed by Robert, late Earle of Essex.*

There is no means of knowing what these moves may have cost Bacon in terms of ill feeling. Nevertheless, in 1604 he published the *Apologie in certaine imputations concerning the late Earle of Essex* in defense of his action; it is a coherent piece of self-justification over the changed relationship between the two men, but to the imaginations of posterity it does not carry complete conviction. The assessment made by James Spedding, the 19th-century editor of Bacon's works, however, finds no fault in any part of Bacon's conduct toward Essex. It is perhaps the lack of evidence of personal distress that has left so sour a taste in many mouths.

Career in the service of James I. When Elizabeth died in 1603, Bacon's letter-writing ability was directed to finding a place for himself and a use for his talents in James I's services. He pointed to his concern for Irish affairs, the union of the kingdoms, and the pacification of the church as proof that he had much to offer the new king.

Through his cousin Robert Cecil, Bacon was one of the 300 new knights dubbed in 1603. The following year he was confirmed as learned counsel and sat in the first Parliament of the new reign in the debates of its first session. He was also active as one of the commissioners for discussing a union with Scotland. In the autumn of 1605 he published his *Advancement of Learning*, dedicated to the King, and in the following summer he married Alice Barnham, the daughter of a London alderman. Preferment in the royal service, however, still eluded him, and it was not until June 1607 that his petitions and his vigorous though vain efforts to persuade the Commons to accept the King's proposals for union with Scotland were at length rewarded with the post of solicitor general. Even then, his political influence remained negligible, a fact that he came to attribute to the power and jealousy of Cecil, then earl of Salisbury and the King's chief minister.

Political advancement

After Salisbury's death in 1612, Bacon renewed his efforts to gain influence with the King, writing a number of remarkable papers of advice upon affairs of state and, in particular, upon the relations between Crown and Parliament. The King adopted his proposal for removing Coke from his post as chief justice of the common pleas and appointing him to the King's Bench, while appointing Bacon attorney general in 1613. During the next few years Bacon's views about the royal prerogative brought him, as attorney general, increasingly into conflict with Coke, the champion of the common law and of the independence of the judges. It was Bacon who examined Coke when the King ordered the judges to be consulted individually and separately in the case of Edmond Peacham, a clergyman charged with treason as the author of an unpublished treatise justifying rebellion against oppression. It was he who instructed Coke and the other judges not to proceed in the case of commendams (*i.e.*, holding of benefices in the absence of the regular incumbent) until they had spoken to the King. Coke's dismissal in November 1616 for defying this order was quickly followed by Bacon's appointment as lord keeper in March 1617. The following year he was appointed lord chancellor and baron Verulam, and in 1620/21 he was created viscount St. Albans.

The main reason for this progress was his unsparing service in Parliament and the court, together with persistent letters of self-recommendation; according to the traditional account, however, he was also aided by his association with George Villiers, first earl and, later, duke of Buckingham, the King's new favourite. Bacon accepted the status of favourites—he had cultivated Robert

Carr (later earl of Somerset) a little before, during his period of favour—and regarded it as a calling according to the detailed and sound advice offered in a formal letter (published posthumously) to Villiers. It would appear that he became honestly fond of Villiers; many of his letters betray a feeling that seems warmer than timeserving flattery. Villiers, for his part, stood by Bacon to the best of his ability, even during Bacon's troubled later years.

Among Bacon's papers a notebook has survived, the *Commentarius Solutus* ("Loose Commentary"), which is revealing. It is a jotting pad "like a Marchant's wast booke where to enter all maner of remembrance of matter, fourme, business, study, towching my self, service, others, eyther sparsim or in schedules, without any maner of restraint." This book reveals Bacon reminding himself to flatter a possible patron, to study the weaknesses of a rival, to set intelligent noblemen in the Tower of London to work on serviceable experiments. It displays the multiplicity of his concerns: his income and debts, the King's business, his own garden and plans for building, philosophical speculations, his health, including his symptoms and medications, and an admonition to learn to control his breathing and not to interrupt in conversation. Plainly this was a busy man with no time, one would think, to write three dozen plays. Between 1608 and 1620 he prepared at least 12 draftings of his most celebrated work, the *Novum Organum*, and wrote several minor philosophical works; in 1609 he published the remarkable set of interpreted myths *De Sapientia Veterum* ("The Wisdom of the Ancients").

The major occupation of these years must have been the management of James, always with reference, remote or direct, to the royal finances. The King relied on his lord chancellor but did not always follow his advice. Bacon was longer sighted than his contemporaries and seems to have been aware of the imminent crisis of civil war; he dreaded innovation and did all he could, and perhaps more than he should, to safeguard the royal prerogative.

Whether his policies were sound or not, it is evident that he was, as he later said, "no mountebank in the King's services." James Spedding, one of Bacon's biographers, has drawn up a handsome testimonial: James I knew "that for the last 15 years he had been the most laborious, affectionate, zealous, attentive, faithful, and modest of servants, and the most moderately rewarded."

Fall from power. By 1621 Bacon must have seemed impregnable, a favourite not by charm (though he was witty and had a dry sense of humour) but by sheer usefulness and loyalty to his sovereign; lavish in public expenditure (he was once the sole provider of a court masque); dignified in his affluence and liberal in his household; winning the attention of scholars abroad as the author of the *Novum Organum*, published in 1620, and the developer of the *Instauratio Magna* ("Great Instauration"), a comprehensive plan to reorganize the sciences and to restore man to that mastery over nature that he was conceived to have lost by the fall of Adam.

Charges of bribery

But Bacon had his enemies. Two charges of bribery were raised against him before a committee of grievances over which he himself presided. The shock appears to have been twofold, because Bacon, who was casual about the incoming and outgoing of his wealth, was unaware of any vulnerability and was not mindful of the resentment of two men whose cases had gone against them in spite of gifts they had made with intent of bribing the judge. The blow caught him when he was ill, and he pleaded for extra time to meet the charges, explaining that genuine illness, not cowardice, was the reason for his request. Meanwhile, the House of Lords collected another score of complaints. Bacon admitted the receipt of gifts but denied that they had ever affected his judgment; he made notes on cases and sought an audience with the King that was refused. Unable to defend himself by discriminating between the various charges or cross-examining witnesses, he settled for a penitent submission and resigned the seal of his office, hoping that this would suffice. The sentence was harsh, however, and included a fine of £40,000, imprisonment in the Tower of London during the King's pleasure, disablement from holding any state office, and exclusion from Parliament and the verge of court (*i.e.*, the jurisdiction of the Marshalsea Court, which settled disputes in which members of the royal household were party). Bacon commented to Buckingham: "I acknowledge the sentence just, and for reformation's sake fit, *the justest Chancellor that hath been in the five changes since Sir Nicolas Bacon's time.*" The magnanimity and wit of the epigram sets his case against the prevailing standards. To the lord keeper he confessed: "My affliction hath made me understand myself better and not worse; yet loving advice, I know, helps well."

Bacon did not have to stay long in the Tower, but he found the ban that cut him off from access to the library of Charles Cotton, an English man of letters, and from consultation with his physician more galling. He came up against an inimical lord treasurer, and his pension payments were delayed. He lost Buckingham's goodwill for a time and was put to the humiliating practice of roundabout approaches to other nobles and to Count Gondomar, the Spanish ambassador; what remissions came were hard earned by vexations and disappointments. Despite all this his courage held, and the last years of his life were spent in work far more valuable to the world than anything he had accomplished in his high office. Cut off from other services, he offered his literary powers to provide the King with a digest of the laws, a history of Great Britain, and biographies of Tudor monarchs. He prepared memoranda on usury and on the prospects of a war with Spain; he expressed views on educational reforms; he even returned, as if by habit, to draft papers of advice to the King or to Buckingham and composed speeches he was never to deliver. Some of these projects were completed, and they did not exhaust his fertility. He wrote: "If I be left to myself I will graze and bear natural philosophy." Two out of a plan of six separate natural histories were composed—*Historia Ventorum* ("History of the Winds") appeared in 1622 and *Historia Vitae et Mortis* ("History of Life and Death") in the following year. Also in 1623 he published the *De Augmentis Scientiarum*, a Latin translation, with many additions, of the *Advancement of Learning*. He also corresponded with Italian thinkers and urged his works upon them. In 1625 a third and enlarged edition of his *Essayes*, which had first appeared in 1597, was published.

Profuse literary production of his last years

Certainly, adversity discovered in Bacon the virtues of patience, unimpaired intellectual vigour, and a good sense of acceptance. Physical deprivation distressed him for himself and his wife, but what hurt most was the loss of favour; it was not until January 20, 1622/3, that he was admitted to kiss the King's hand; the full pardon that would have cleared his name never came. Finally, in March 1626, driving one day near Highgate (a district to the north of greater London) and deciding on impulse to discover whether snow would delay the process of putrefaction, he stopped his carriage, purchased a hen, and stuffed it with snow. He was seized with a sudden chill, which brought on bronchitis, and died on April 9, 1626.

THOUGHT

Internal conflict in Bacon's works

Even the simplest recitation of relevant facts reveals that a determining principle in Bacon's composition was the constant competition between two strains: he could argue plausibly now for the active and now for the contemplative way of life; what he could not do was commit himself solely to either. Although each avocation is complicated enough to call for separate consideration, it is essential to recognize their ultimate interdependence. In periods of optimism he argued that one could be made to support the other, with money and position ensuring leisure for philosophical speculation; in more realistic periods of gloom, he came to know that the rivalry had been dangerous and damaging. Change of focus from short-term to long-term calculations was embarrassing for him and for his critics. It was one thing to begin in 1610 the *New Atlantis*—a utopian fiction that describes an ideal state in which the principles of Bacon's philosophy are carried out by political machinery and

under state guidance—and another thing to cope with James I's dilemmas. In the *De Sapientia Veterum*, interpreting the riddles of the Sphinx, he observed:

> for so long as the object of meditation and inquiry is merely to know, the understanding . . . finds in the very uncertainty of conclusions and variety of choice a certain pleasure and delight; but when they pass from the Muses to Sphinx, . . . whereby there is a necessity to present action, choice and decision, then they begin to be powerful and cruel; and unless they be cowed, they strangely torment and worry the mind.

Plan for the restoration of philosophy. Whatever may be thought of Bacon's purposes in attending to his political fortunes and patriotic aims, his sincerity as a philosopher cannot be disputed. If to leave works unfinished and huge plans only sketched in is to fail, then he failed in his philosophical endeavours as in his political ones. Such an estimate, however, takes no account of his true vision—the command of nature by way of obeying her.

His philosophical writings and sources of his thought. The most convenient mapping of Bacon's philosophical writings is to be found in the list of contents in the first three volumes of the edition of his works by R.L. Ellis and J. Spedding. Firstly, there are the completed parts of his *Instauratio Magna:* the magnificent prefatory matter, the *Novum Organum* (a presentation of a new method of logic), the "Parasceve ad Historiam Naturalem et Experimentalem" (a short sketch of the requirements of a fundamental natural history), and the *De Augmentis Scientiarum* (a classification of the sciences based on an analysis of the faculties and objects of human knowledge). Secondly, there are writings that were evidently intended at one time or another to be parts of the *Instauratio:* three short treatises, a few fragments, and a collection of observations of phenomena entitled *Sylva Sylvarum*. Lastly, there is a group of scientific and philosophical speculations not, it is assumed, to be included but interesting as exhibiting something of the emergence of the author's ideas and the variety of his styles.

Modern scholars have studied the development of the distinctive elements in his system beginning with the germinal statements in a masque speech praising knowledge; in a short presentation such as this article, however, the outlines must be drawn from his more mature expressions. In general, two things should be borne in mind. Bacon's chaplain-secretary has asserted that he wasted none of his time or mental reserves on what he could learn from other men's books. Modern critics have shown that he derived a great deal from Bernardino Telesio (a 16th-century philosopher who revolted against medieval Aristotelianism and advocated the empirical method), from Juan Huarte, a 16th-century Spanish philosopher and physician, and from medieval and Renaissance encyclopaedic compilations. What he read he used; it became his substance and was often the better for passing through the sieve of his good sense. Secondly, it was his deliberate intention to stake claims. This habit makes his frequent repetitions and modifications easier to understand.

Advancement of Learning

His theory of knowledge. The value that Bacon attached to knowledge is seen in the first book of the *Advancement of Learning*, which is often neglected because of ignorance of the attacks on knowledge at this time that made a defense pertinent. Bacon was not merely beating the air, however; there was religious, social, and skeptical opposition. First, knowledge was defended from the suspicions and perversions that it suffered from the zeal of divines, from the criticisms of politicians who contended that knowledge weakened action, and from the discredits brought upon it by learned men themselves. Bacon had no use for the manners of pedants, but he did believe that the learned can claim magnanimity in that they are aware of the frailty of their persons, the casualty of their fortunes, and the dignity of their souls and vocations. He deplored fantastic, contentious, and "delicate" learning; men should strive for substantive matter before words, and the matter itself must not decay into the tortuous questions of the medieval Scholastics. More serious is the deceit that destroys the essential form of knowledge, for truth of being and truth of knowing are one. He classed as "peccant humours" the affectations of extremes of novelty or antiquity, distrusted the premature reduction of knowledge into "arts," suspected the admiration of human nature to the neglect of nature proper; he foresaw the bias of the specialist and the dangers of a hasty dismissal of doubts. The greatest error of all is the mistake of misplacing the end of man's knowledge, which is to give a true account of the gift of reason.

Bacon had a love of order, and the second book of the *Advancement of Learning* makes this clear. Bacon's "province"—embraced by the phrase "all knowledge"—is divided according to the faculties of memory, imagination, and reason with elaborate but serviceable subdividing. Bacon paid slight attention to divinity and poetry in this survey because they were flourishing; he preferred to concentrate upon areas of defect or deficiency. He addressed the work to the King in the unpropitious year of the Gunpowder Plot—a conspiracy for blowing up James I and the Parliament on November 5, 1605—and produced the enlarged version in 1623.

Although he was sincerely convinced of the wholeness of knowledge, Bacon made no secret of the bias of his interest: the "domain of philosophy and the sciences" is the realm "without which I care not to live." In the proemium, preface, and plan for the *Magna Instauratio* he proposed as a severe and solitary task the radical recasting of the commerce between the mind of man and the nature of things; he looked for the release of inventive powers as a result of the improved ways of exploring nature's subtlety; he searched for principles that will direct action. In his restoration, syllogistic reasoning is to be demoted in favour of a critical induction based on experimental testing. His aim was to subdue and overcome the necessities and miseries of humanity. In this introduction to his great work, the plan for a natural history was outlined; samples of his scientific method at work were promised, together with a garnering of miscellaneous observations; and, finally, the beginning of the philosophy to which these preparations lead was indicated. A sincere dedication to the glory of God graces the undertaking. The substance of his great undertaking could be pieced together from other passages in public and private writings; the doctrine is also delivered chiefly through the mythological stories in the *De Sapientia Veterum*.

Novum Organum

In *Novum Organum* the teaching was cast into aphorisms in which a group of three ideas work like leaven. They are: the need for a new logic (thus the title of the collection); the attempt to discover the "forms" of what he believed to be a limited number—an "alphabet"—of simple natures (*i.e.*, qualities such as heat or whiteness); and the collection of a comprehensive natural history. Taken separately the three are not difficult to grasp; it is their relatedness that has been found puzzling and unsatisfactory. Bacon envisaged knowledge as a pyramid with natural history as its base, physics as the middle, and metaphysics as the vertical point. Intermittently, he attended to the base, contributing what he could. His valuation of this part of the work seems to have increased, and toward the end of his life he gave it prime importance.

Philosophy of science. His standing as a scientist, in the modern sense of the term, is low. He is found to have been out of date and overcautious in astronomical theory; he failed to recognize the Scottish mathematician John Napier's invention of logarithms and, in general, underestimated mathematics; he was ill informed about leverage, the acceleration of bodies, and the circulation of the blood. Spedding sought to find a cause for these deficiencies and viewed Bacon's failure to recognize the work of some of the foremost men of his day as symptomatic of an intellectual imbalance; his mind, so quick to note likenesses, was not equally ready to distinguish differences. He stood in a dangerous isolation, unwilling to handle what he was not fully equipped to understand. Some critics have referred to his habitual inaccuracy.

Bacon, characteristically enough, was ahead of his critics when (gracing the weakness by a metaphor) he admitted, "I can not thridd needles so well."

His so-called inductive method and its defects. Bacon's loudly announced views concerning the need for a new logic have led to a closer association of his name with induction than is credible. Inductive reasoning did not originate with Bacon, nor does the process as developed by the natural sciences since his day derive directly from his formulation; what he urged, however, is not merely derivative or valueless. Setting aside both deduction and simple enumerative induction as means of interpreting nature's ways, he elaborated his own method by which ascent was to be made from particulars to axioms of a middle class of generality, and then by means of the control of negative and graded instances arranged in tables by presentation, exclusion, and rejection to axioms of the broadest degree of generality. The method, which is demonstrated with some elaboration in *Novum Organum* by means of a search for the essential nature of heat, has been criticized as open to two radical objections. In the first place, the laboriousness of his method requires the aid of hypotheses, and Bacon gave no help toward the formulation of such concepts, although, ironically enough, he supplied just such an aid, or *bona notio*, in the investigation of heat. He was so intent on advertising his new instrument as foolproof that he refused to allow enough for the inventive genius of other men or even to recognize the limits of his own share of genius. Secondly, the method breaks down when it is related to the end proposed, that is, the discovery of "forms." Bacon himself had great difficulty in giving an adequate and exact definition of what he meant by a form. A study of the various passages in the *Novum Organum* in which the definition of forms is attempted seems to show that Bacon's forms were not ideas or abstractions but highly general physical properties that are limitations or specific manifestations of some higher genus. Further, it is hinted that these general qualities may be looked upon as the modes of action of simple bodies. Part of the difficulty in understanding Bacon's method is the result of his choice of terms. He knowingly took over the terms metaphysic and form from medieval Scholasticism and modified their connotations; he was also likely to use the terms motion, law, and nature somewhat loosely.

Forms, laws, motion

Contributions to a philosophy of nature. Spedding was of the opinion that the doctrine of the forms is extraneous to Bacon's method, but it has not been so regarded by recent critics. A scrutiny of what Bacon meant by "law" when the term was used as a synonym for form was made by Adolfo Levi, a 20th-century Italian philosopher, by way of the unusual route of working backward from the test case of the inquiry into the form of heat. His interpretation was adopted by A.E. Taylor, an English historian of philosophy, and it carries important implications when the nature (or form) of Bacon's own genius is considered. According to Levi:

> In modern physics the laws are the expression of functional relationships which exist between phenomena, universal and necessary relationships of quantitative nature, while the Baconian forms consist in geometric-mechanic conditions, that is, they are essences contributed by structures and movements not determined by phenomenal relations.

Levi's interpretation hinges on the understanding of *motus* ("movement") in the phrase *lex actus sive motus* as nominative, and not, as formerly taken, as genitive; thus, the form of heat is movement, not the law of movement.

> Bacon, however, did not wish to determine quantitative relations—but to discover the inmost essence of the physical world, that is, to construct what are now called explanatory hypotheses for phenomena such as the mechanical concept of heat and the wave theory of light.

Such an ambition marks him out among scientists as a philosophical genius. When science seeks with such hypotheses to reach the intimate structure of reality, it becomes almost imperceptibly a philosophical intuition. According to Taylor:

> He has received high praise on the ground that, as has been alleged, his method enables us to answer a question which he was not raising, and had been depreciated on the ground that the true method for dealing with this question is not that which he recommends.

Bacon's reputation is thus somewhat tarnished; nevertheless, his contributions to science and philosophy are real. A remark in *Sylva Sylvarum* ("Forest of Forests") averring that "all bodies whatsoever, though they have no sense, yet they have perception" struck Alfred North Whitehead, an influential 20th-century British philosopher, as a genuine intuition. Furthermore, Bacon demonstrated great prudence in attaching so much importance to the discipline leading to the dynamic theory of motion; his promotion of the study of the natural sciences was greatly influential, even if his method was not followed. Thirdly, he is important for the grandeur of his vision and his heartening conviction of the unity of knowledge. Lastly, in the eyes of Taylor, Bacon has "the *temper* of a philosopher"; whatever may have been the failings of his character, it does not seem that excessive self-conceit was among them.

Enduring features of his search for truth

Bacon was humble in the search for truth; he was willing to admit uncertainty and incompleteness and referred his work to the continuing search of other men and ages. Instead of offering exaggerated acclamation or shrill rejection—and he has suffered from both extremes—it is now possible without insult to accord him a more tempered admiration. In moments of exaltation he foolishly claimed "to see an end of the matter," to have the "key" to things; but in more sober hours he knew better. The precious instrument of scientific method, he realized, would be useless without the natural history; the alphabet of simple natures might need revision; and the logic would need aids to reduce the dangers of confusion in its laboured procedure.

The idols. Perhaps the most valuable of these aids is the warning about the idols or false appearances of the mind. The topic arose five times as he worked out the form it should take. These deep fallacies of the mind, or general classes of errors into which the human mind is prone to fall, are arranged in the *Novum Organum* as the four *idola:* (1) The *idola tribus*, "idols of the tribe," are fallacies incident to humanity or the race in general. Of these, the most prominent are the proneness to suppose in nature greater order and regularity than there actually is; the tendency to support a preconceived opinion by affirmative instances, neglecting all negative or opposed cases; and the tendency to generalize from few observations or to give reality to mere abstractions, figments of the mind. Manifold errors also result from the weakness of the senses, which affords scope for mere conjecture; from the influence exercised over the understanding by the will and passions; from the restless desire of the mind to penetrate to the ultimate principles of things. (2) The *idola specus*, "idols of the cave," are errors incident to the peculiar mental or bodily constitution of each individual, because an individual's view of things is based on the state of his mind. Errors of this class are innumerable because there are numberless varieties of disposition; but some very prominent specimens can be indicated. These include the tendency to make all things subservient to or take the colour of some favourite subject; the extreme fondness and reverence for either what is ancient or what is modern; and excess in noting either differences or resemblances among things. (3) The *idola fori*, "idols of the market place," are errors arising from the influence exercised over the mind by mere words. This, according to Bacon, is the most troublesome kind of error and has been especially fatal in philosophy. Words introduce a fallacious mode of looking at things in two ways: first, there are some words that are really merely names for nonexistent things; secondly, there are names hastily and unskillfully abstracted from a few objects and applied recklessly to all that have the faintest analogy with these objects. (4) The *idola theatri*, "idols of the theatre," are fallacious modes of thinking resulting from received systems of philosophy and from erroneous methods of demonstration.

The Essayes. Bacon sought to help mankind not only with "the secrets of science" but also with "the difficulties of living," and he envisaged his new logic as extensible to human affairs. In the *Essayes* he attempted to study the "simple natures" of such things as ambition, dissimulation, revenge, and love. He recorded experiences derived from history and his own observations. He could not precisely set up experiments, but he did examine instances of behaviour and motivation, and upon these he generalized brilliantly. He subtitled the *Essayes* the "inwards of things" or "dispersed meditations" and associated this literary form not with the writings of the French author Michel de Montaigne but with the letters of Seneca. He found that this form of expression gave him scope for disinterested comment; it did not demand that he argue a case or urge a cause or manipulate anyone to make the best of things; it gave him the freedom to show both what men do and what men ought to do. This mixture of realism and the ideal of expediency and morality makes these succinct and lucid pieces not simple reading but full of worldly wisdom for the reader who has learned the author's technique.

PERSONAL CHARACTERISTICS

Bacon provided a formal self-portrait in the proemium to the *Magna Instauratio:*

> For myself, I found that I was fitted for nothing so well as for the study of truth; as having a mind nimble and versatile enough to catch the resemblances of things (which is the chief point) and at the same time steady enough to fix and distinguish their subtler differences; as being gifted by nature with desire to seek, patience to doubt, fondness to meditate, slowness to assert, readiness to reconsider, carefulness to dispose and set in order; and as being a man that neither affects what is new nor admires what is old, and that hates any kind of imposture.

John Aubrey, a 17th-century English antiquary, wrote a vivid portrayal of Bacon in which he noted that Bacon had a "delicate, lively hazel eie. Dr. Harvey told me it was like the eie of a viper." He noted Bacon's sensuousness: he had "musique in the next room where he meditated"; sweet herbs and flowers were always before him as he dined; his men's boots were of Spanish, not neat's, leather, because of the smell. From the few extant familiar letters of Bacon there is some evidence that he had an appreciation of simple friendships, but he did not invite intimacy; he frequently applied to himself the psalm likening himself to a stranger in life's pilgrimage.

Bacon was proud of his father; he had been affected by his mother, who fussed over his diet and late hours; he was attached to his brother. It seems that his marriage with Alice Barnham, though childless, was not unhappy, although toward the end of his life she gave him reason to alter his will. To judge by two essays, "On Love" and "On Marriage," Bacon had no use for romance. In general, everything points to him as having been reserved, wary, self-sufficient, and yet sensitive. The testimony of two men who had the most chance to study his habits and humours—his chaplain and secretary William Rawley and his friend Tobie Matthew, the son of an English prelate—offer tributes of discerning affection. "I never saw in him any trace of a vindictive mind," wrote Tobie Matthew. "It is not his greatness that I admire, but his virtue; it is not the favours I have received from him, . . . but his whole life and character." Rawley knew him as a good master and host, generous in conversation, eager to hear each man's observations, dictatorial at his table, courteous in the courts, a good servant himself and in return good to those who served him.

It has been observed that Bacon's concern was with things before men—*i.e.*, things of the mind—or, at best, with man rather than men. This attitude has given rise to many critical descriptions; the poet Alexander Pope, for example, added the damning "meanest" after the epithets "wisest, brightest." Few have sprung to Bacon's defense.

Intellectual and imaginative life

Although it is difficult to penetrate the private life of Bacon, his intellectual and imaginative life lies wonderfully open. Nicholas Hilliard, the miniaturist, is recorded as saying, "Oh, that I had a canvas to paint his *mind*." Bacon wrote of himself that he was "naturally fitted rather for literature than for anything else." He practiced a functional rhetoric and sought "masculine, plain sense"; nevertheless, his prose was enriched by the unobtrusive use of a variety of images. It is by style that he attracts, holds, and haunts; the reader is enabled to share the movement of his mind and is infected with the emotion that energized his thinking. He was interested in the theory of the arts of communication and expert in their practice, both as a speaker and as a writer. Equally evident is his sense of control; his sentences are elaborately balanced; his presentations are firmly structured.

His writings are pointers to the development of science and philosophy; they are preservers of a range of human experience, promoters of a belief that there was intended a marriage between nature and man's mind. Sir Henry Wotton, as provost of Eton College, recommended that his contemporary Bacon be "read in my domestic college as an ancient author." This heralded the tributes of the Royal Society in the next generation and the continued praise of his literary genius.

MAJOR WORKS

PHILOSOPHICAL WORKS: *The Twoo Bookes of Francis Bacon of the Proficience and Advancement of Learning Divine and Humane* (1605); *Novum Organum* (1620); *Historia Ventorum* (1622); *Historia Vitae et Mortis* (1623); *De Augmentis Scientiarum* (1623); an enlarged edition in Latin of the *Advancement of Learning.*

LITERARY AND HISTORICAL WORKS: *Essayes* (first published as 10 essays in 1597; enlarged to 38 in 1612; and to 58 in 1625); *De Sapientia Veterum* (1609); *The Historie of the Raigne of King Henry the Seventh* (1622); *The Translation of Certaine Psalmes into English Verse* (1625); *Apophthagmes new and old* (1625).

POLITICAL WORKS: *A Declaration of the Practices and Treasons attempted and committed by Robert, late Earle of Essex* (1601); "Certain Considerations touching the better Pacification and Edification of the Church of England" (1604); *Apologie in certaine imputations concerning the late Earle of Essex* (1604).

POLITICAL WORKS: "The Felicity of Queen Elizabeth" (1651; translation of "In Felicem Memoriam Elizabethae," written in 1608).

LEGAL WORKS: "The Elements of the Common Lawes of England" (2 parts, 1630; the second tract is probably not by Bacon); *Cases of Treason* (1641); "The Learned Reading of Sir Francis Bacon upon the Statute of Uses" (1642).

POSTHUMOUSLY PUBLISHED WORKS: (PHILOSOPHICAL): *Sylva Sylvarum* (1627, with the unfinished *New Atlantis*). (LITERARY): *Promus of Formularies and Elegancies* (1883); *The Poems of Francis Bacon,* collected and edited by the Rev. A.B. Grosart (1870).

(K.M.L.)

Bacon, Roger

Roger Bacon was an English Franciscan friar of the 13th century who was active as a philosopher, scientist, and educational reformer. Having become familiar with virtually all of the science known in his time, Bacon (as he himself complacently remarked) displayed a prodigious energy and zeal in the pursuit of experimental science; indeed, his studies were talked about everywhere and eventually won him a place in popular literature as a wonder worker. Bacon thus represents a historically precocious expression of the empirical spirit of experimental science, though his actual practice of it seems to have been exaggerated.

Early life

Bacon was born of a wealthy family about 1220. The place of his birth is uncertain; in one tradition it is assigned to Ilchester in Somerset, in another to the parish of Bisley in Gloucester. He was well versed in the classics and enjoyed the advantages of an early training in the quadrivium (geometry, arithmetic, music, and astronomy); and he boasted that he had frequently "heard" and "read" the works of Aristotle. Inasmuch as he later lectured at Paris, it is probable that his master of arts degree was conferred there, presumably not before 1241—a date in keeping with his claim that he saw the Franciscan professor Alexander of Hales (who died in 1245) with his own eyes and that he heard the master scholar William of Auvergne (died 1249) dispute twice in the presence of the whole university.

University and scientific career. In the earlier part of his career, Bacon lectured in the faculty of arts on Aristotelian and pseudo-Aristotelian treatises, displaying no indication, however, of his later preoccupation with science. His Paris lectures, important in enabling scholars to form some idea of the work done by one who was a pioneer in introducing the works of Aristotle into Western Europe, reveal an Aristotelianism strongly marked by Neoplatonist elements stemming from many different sources. The influence of Avicenna on Bacon has been exaggerated.

About 1247 a considerable change took place in Bacon's intellectual development. From that date forward he expended much time and energy and huge sums of money in experimental research, in acquiring "secret" books, in the construction of instruments and of tables, in the training of assistants, and in seeking the friendship of savants —activities that marked a definite departure from the usual routine of the faculty of arts. The change was probably caused by his return to Oxford and the influence there of the great scholar Robert Grosseteste, a leader in introducing Greek learning to the West, and his student Adam de Marisco, as well as that of Thomas Wallensis, the bishop of St. David's. From 1247 to 1257 Bacon devoted himself wholeheartedly to the cultivation of those new branches of learning to which he was introduced at Oxford—languages, optics, and alchemy—and to further studies in astronomy and mathematics. It is true that Bacon was more skeptical of hearsay claims than were his contemporaries, that he suspected rational deductions (holding to the superior dependability of confirming experiences), and that he extolled experimentation so ardently that he has often been viewed as a harbinger of modern science more than 300 years before it came to bloom. Yet research on Bacon suggests that his characterization as an experimenter may be overwrought. His originality lay not so much in any positive contribution to the sum of knowledge as in his insistence on fruitful lines of research and methods of experimental study. As for actual experiments performed, he deferred to a certain Master Peter de Maricourt (Maharn-Curia), a Picard, who alone, he wrote, understood the method of experiment and whom he called *dominus experimentorum.*

Stress on experiment

Bacon, to be sure, did have a sort of laboratory for alchemical experiments and carried out some systematic observations with lenses and mirrors. His studies on the nature of light and on the rainbow are especially noteworthy, and he seems to have planned and interpreted these experiments carefully. But his most notable "experiments" seem never to have been actually performed; they were merely described. He suggested, for example, that a balloon of thin copper sheet be made and filled with "liquid fire"; he felt that it would float in the air as many light objects do in water. He seriously studied the problem of flying in a machine with flapping wings. He was the first person in the West to give exact directions for making gunpowder (1242); and, though he knew that, if confined, it would have great power and might be useful in war, he failed to speculate further. (Its use in guns arose early in the following century.) Bacon described spectacles (which also came soon into use); elucidated the principles of reflection, refraction, and spherical aberration; and proposed mechanically propelled ships and carriages. He used a camera obscura (which projects an image through a pinhole) to observe eclipses of the sun.

Career as a friar. In 1257 another marked change took place in Bacon's life. Because of ill health and his entry into the Order of Friars Minor, Bacon felt (as he wrote) forgotten by everyone and all but buried. His university and literary careers seemed finished. His feverish activity, his amazing credulity, his superstition, and his vocal contempt for those not sharing his interests displeased his superiors in the order and brought him under severe discipline. He decided to appeal to Pope Clement IV, whom he may have known when the latter was in the service of the Capetian kings of France. In a letter (1266) the Pope referred to letters received from Bacon, who had come forward with certain proposals covering the natural world, mathematics, languages, perspective, and astrology. Bacon had argued that a more accurate experimental knowledge of nature would be of great value in confirming the Christian faith, and he felt that his proposals would be of great importance for the welfare of the church and of the universities. The Pope desired to become more fully informed of these projects and commanded Bacon to send him the work. But Bacon had had in mind a vast encyclopaedia of all the known sciences, requiring many collaborators, the organization and administration of which would be coordinated by a papal institute. The work, then, was merely projected when the Pope thought that it already existed. In obedience to the Pope's command, however, Bacon set to work and in a remarkably short time had dispatched the *Opus majus* ("Greater Work"), the *Opus minus* ("Lesser Work"), and the *Opus tertium* ("Third Work"). He had to do this secretly and notwithstanding any command of his superiors to the contrary; and even when the irregularity of his conduct attracted their attention and the terrible weapons of spiritual coercion were brought to bear upon him, he was deterred from explaining his position by the papal command of secrecy. Under the circumstances, his achievement was truly astounding. He reminded the Pope that, like the leaders of the schools with their commentaries and scholarly summaries, he could have covered quires of vellum with "puerilities" and vain speculations. Instead, he aspired to penetrate realms undreamed of in the schools at Paris and to lay bare the secrets of nature by positive study. The *Opus majus* was an effort to persuade the Pope of the urgent necessity and manifold utility of the reforms that he proposed. But the death of Clement in 1268 extinguished Bacon's dreams of gaining for the sciences their rightful place in the curriculum of university studies.

Appeal to the Pope and *Opus majus*

Bacon projected yet another encyclopaedia, of which only fragments were ever published, viz., the *Communia naturalium* ("General Principles of Natural Philosophy") and the *Communia mathematica* ("General Principles of Mathematical Science"), written about 1268. In 1272 there appeared the *Compendium philosophiae* ("Compendium of Philosophy"). In philosophy—and even Bacon's so-called scientific works contain lengthy philosophical digressions—he was the disciple of Aristotle and

not of St. Augustine or the Persian philosopher Avicenna; even though he did incorporate Neoplatonist elements into his philosophy, his thought remains, nevertheless, Aristotelian in its main lines.

Sometime between 1277 and 1279, Bacon was condemned to prison by his fellow Franciscans because of certain "suspected novelties" in his teaching. The condemnation was probably issued because of his bitter attacks on the theologians and scholars of his day, his excessive credulity in alchemy and astrology, and his penchant for millenarianism under the influence of the prophecies of Abbot Joachim of Fiora, a mystical philosopher of history. How long he was imprisoned is unknown. His last work (1292), incomplete as so many others, shows him as aggressive as ever. A traditional source relates that he died in 1292 and was buried in the Franciscan church at Oxford. Exaggerated accounts of his admirable experiments doubtless suggested the title *doctor mirabilis* ("wonderful teacher") by which he became known to posterity.

BIBLIOGRAPHY. ANDREW G. LITTLE (ed.), *Roger Bacon* (1914), comprehensive and critical essays contributed by various eminent scholars on the occasion of the commemoration of the seventh centenary of Bacon's birth, is a collection that still retains its value. Two works that are complementary and contain fresh biographical insights and extensive bibliographies are THEODORE CROWLEY, *Roger Bacon: The Problem of the Soul in His Philosophical Commentaries* (1950), presenting his philosophical positions; and STEWART C. EASTON, *Roger Bacon and His Search for a Universal Science: A Reconsideration of the Life and Work of Roger Bacon in the Light of His Own Stated Purposes* (1952). ERICH HECK, *Roger Bacon: Ein mittelalterlicher Versuch einer historischen und systematischen Religionswissenschaft* (1957), contains a critical survey of previous work and detailed studies of Bacon's approach to the scientific study of religion. A.C. CROMBIE, *Robert Grosseteste and the Origins of Experimental Science, 1100–1700*, pp. 139–162 (1953), is a balanced account of Bacon's contributions to science.

(T.Cr.)

Bacteria

Bacteria are microscopic organisms present in almost all natural environments, often in extremely large numbers: billions in a gram of rich garden soil and millions in one drop of saliva. They constitute the class Schizomycetes, of the division Schizomycophyta. The influence of bacteria in the biosphere is incalculable. Without them, the soil would not be fertile and thus could not sustain plants, on which animals ultimately depend for food. Although some bacteria cause disease, most species are benign, and many are involved in processes of direct benefit to man. For bacterial diseases, see the articles INFECTIOUS DISEASES; DISEASES OF ANIMALS; DISEASES OF PLANTS.

GENERAL FEATURES

Appearance. Bacteria are unicellular micro-organisms, among the smallest living creatures known (only the related rickettsias and the viruses are smaller). One of the periods on this page would cover about 250,000 average-sized bacteria, which are measured in micrometres, or microns (one micron, μ, equals $\frac{1}{1,000}$ millimetre, or $\frac{1}{25,000}$ inch). There are three bacterial cell types on the basis of shape (see Figure 1): spherical (coccus), rodlike (bacillus), and spiral (spirillum). Each type retains its character under standard conditions of laboratory cultivation but may show changes in appearance under different environments. When conditions are favourable, bacteria grow rapidly (some can reproduce every 15 minutes), forming visible colonies on culture plates in the laboratory. The colonies are distinctive in colour, shape, and texture for certain species and in some cases for the different varieties, or strains, within a single species.

Cell shapes

Distribution. Bacteria are ubiquitous, occurring in virtually every conceivable environment: from polar ice to hot springs; from mountain tops to the ocean deeps; from plant and animal bodies to forest soils. Most bacteria are active in environments in which the temperature is above 5° C (about 40° F); some marine and soil types

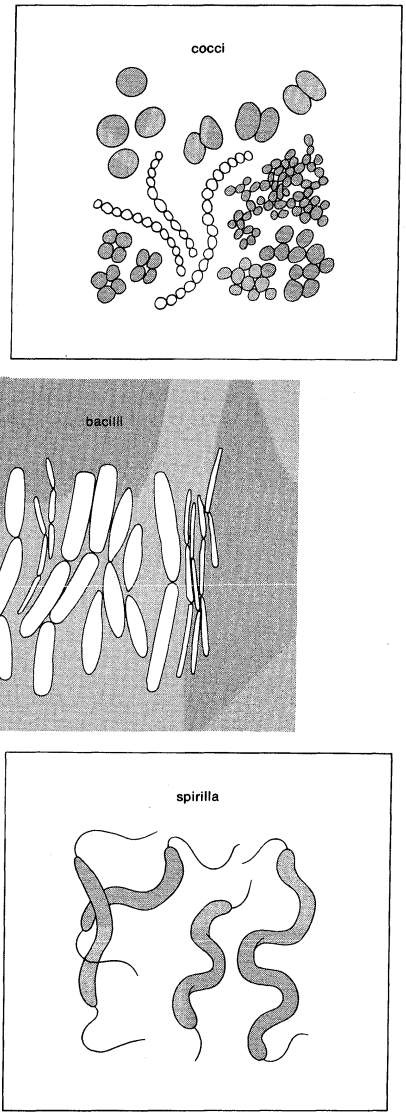

Figure 1: The three major bacterial cell types.
Reprinted from *The Spectrum of Life* by Harold A. Moore and John R. Carlock. Copyright ©1970, Harper & Row, Publishers, Inc.

are exceptional in being active at temperatures near or slightly below 0° C (32° F). The upper limit is around 30° C (86° F) for soil bacteria and 37° C (99° F) for animal parasites; the maximum temperature, above which growth does not occur, is around 70° C (160° F). Beyond these limits bacteria become inactive. Some survive in a dormant (or spore) state, reviving when conditions become more favourable. This capability has allowed bacteria to become perhaps the most widespread organisms on Earth.

Ecological significance

Importance. Bacteria are instrumental in performing numerous critical biochemical transformations of substances in nature, changing them from complex to simple compounds that can be used by plants, man, and other animals. Bacteria in the rumen (largest compartment of the stomach) of the cow digest the cellulose in grasses and animal feed, thus making this matter available as a nutrient for the animal. The organic waste substances in sewage are degraded by bacteria and transformed into compounds that are suitable nutrients for plant growth. In fact, all of the remains of animals and plants are eventually converted to soil through the activities of bacteria and other micro-organisms and thus made available again to growing plants.

It can be assumed—until evidence disproves it—that any naturally occurring substance can be degraded (metabolized) by some species of bacteria. In some instances, these biochemical transformations are judged by man to be beneficial: as when *Streptomyces griseus*

produces the antibiotic streptomycin as a by-product of its metabolism; or when certain strains of bacteria produce cheese and other dairy products by metabolizing constituents of milk; or when certain nitrogen-accumulating bacteria add needed nitrogen to the soil. Other transformations, however, may be detrimental to man's interests, as when *Clostridium botulinum* excretes a toxin responsible for botulism (a type of food poisoning), or when certain strains of bacteria excrete substances that cause disease. Less detrimental are the effects of bacterial deterioration: spoilage of food, corrosion of metals, decay of wood, and other undesirable alterations of substances.

Higher animals, including man, live in constant intimacy with large numbers and a great variety of bacteria. The oral cavities, intestinal tracts, and skin are inhabited by bacteria that, under normal circumstances, create no problems (Figure 2). There are occasions, however, when bacteria break through the normal body barriers and cause an infection. Certain bacteria are more prone to this behaviour than others and are called pathogens, or disease producers (Figure 2). Some pathogens have an affinity for specific parts of the body: meningococcal bacteria infect the meninges, or brain membranes; tubercle bacteria invade the lungs; and diphtheria-causing bacteria establish themselves in the throat. Other bacterial pathogens exhibit less specificity: staphylococcal bacteria, for example, may infect the skin, causing boils or furuncles; the bloodstream, causing septicemia (blood poisoning); or the bones, establishing a condition known as osteomyelitis.

In some cases the biochemical transformations of bacteria are actually exploited industrially to convert raw materials into products that are economically valuable. When the substance is abundant and cheap and the product is valuable and in demand, a bacterial industrial process is likely to be established. Selected examples of products manufactured on an industrial scale through the utilization of bacteria are shown in Table 1. Other industrial processes are developed by man to combat the deterioration of materials by micro-organisms (see FOOD PRESERVATION).

Bacteria as experimental subjects

Bacteria represent a form of life that can be conveniently studied under laboratory conditions. Furthermore, and more importantly, many of the biological processes that take place in the bacterial cell are closely related, if not identical, to processes that take place in higher organisms, including man. Thus, the bacterial cell provides an extremely useful model for the study of intricate biological, physiological, and biochemical processes. Indeed, much of the knowledge that has been acquired since the end of World War II in biochemical genetics, enzymes, and the synthesis of vitamins and their functions has resulted from investigations of bacteria.

NATURAL HISTORY

In view of the widespread occurrence of bacteria, it is not surprising that measures are taken by man to reduce or control their numbers in habitats that are exploited for human welfare. In the following sections, therefore, emphasis is on those particular environments of bacteria that impinge on man's needs.

Growth and reproduction. The life cycle of bacteria involves growth and reproduction, as in other organisms; certain features, however, are unique to micro-organisms.

The term growth, in the microbiological sense, refers to increase in a given population rather than to increase in

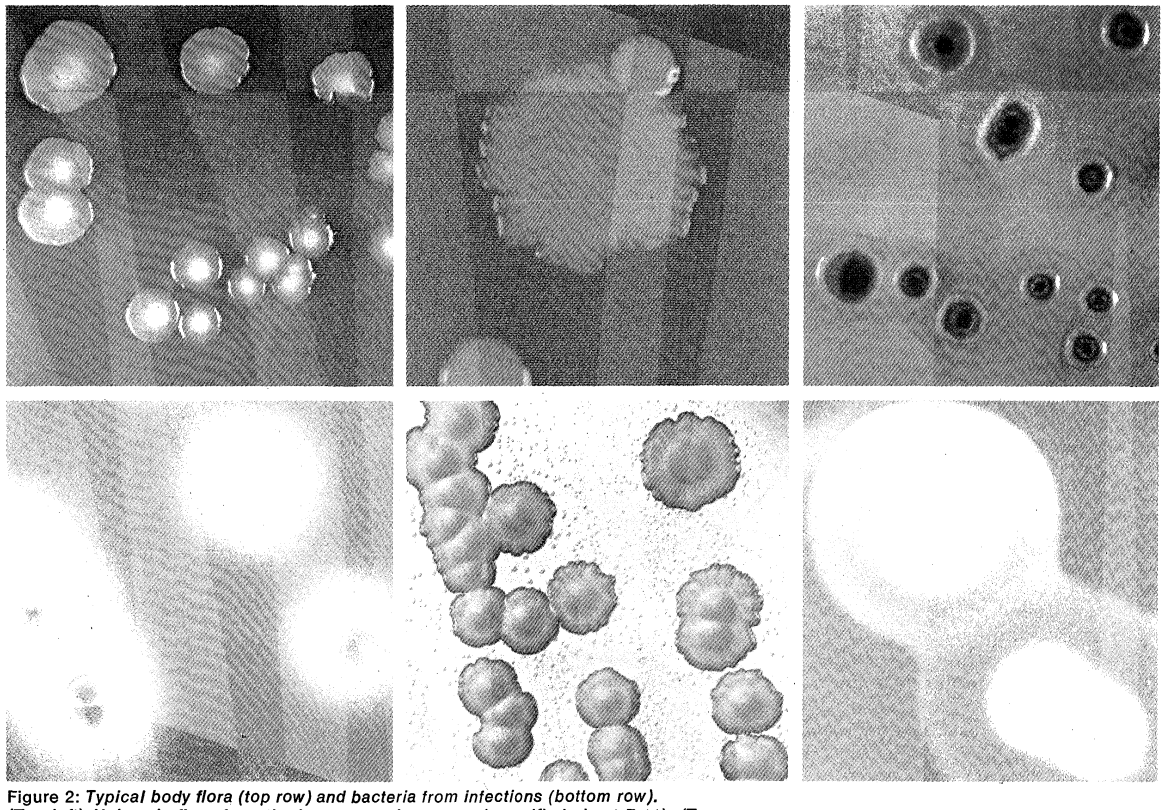

Figure 2: *Typical body flora (top row) and bacteria from infections (bottom row).* (Top left) *Neisseria flava* from the human nasal passage (magnified about 7 ×). (Top centre) Aerobic *Lactobacillus* (large colony) and *Staphylococcus albus* (small colony) from the human vagina (magnified 11 ×). (Top right) *Escherichia coli*, grown on eosin methylene blue dye, from a normal stool (magnified about 7 ×). (Bottom left) Colonies of beta-hemolytic streptococci on blood agar show zones cleared of blood cells surrounding each colony; these bacteria were isolated from the sore throat of a child who later developed rheumatic fever (magnified about 19 ×). (Bottom centre) *Hemophilus influenzae* (small colonies) isolated from a child suffering from spinal meningitis. Position of the *H. influenzae* colonies around larger *Staphylococcus* colonies, which provide a factor necessary for their growth, illustrates the "satellite phenomenon" (magnified about 14 ×). (Bottom right) *Clostridium perfringens*, isolated from infected human gallbladder, as grown under strict anaerobic conditions on blood agar. Zones of complete and partial clearing are characteristic of this species of *Clostridium* (magnified 8.5 ×).

Table 1: Examples of Compounds Produced by Bacteria on an Industrial Scale

product	bacterium	substrate
Lactic acid	*Lactobacillus delbrueckii*	acid-hydrolyzed cornstarch, or whey, plus nutrient and $CaCO_3$
Bacterial amylase	*Bacillus subtilis*	vegetable protein plus sugar for surface cultivation; starch, cereal, grain, and protein for subsurface cultivation
Bacterial protease	*B. subtilis*	protein, carbohydrate, salts
Dextran	*Leuconostoc mesenteroides*	sucrose plus nutrients
Cobalamin (vitamin B_{12})	*Streptomyces olivaceus*	distiller's solubles, dextrose, $CaCO_3$
	Propionibacterium freudenreichii	$CoCl_2$
Vinegar	*Acetobacter* species	alcohol
Streptomycin	*Streptomyces griseus*	hydrolyzed protein and sugar
Monosodium glutamate	*Micrococcus* species	sugar

the size of an individual micro-organism, or bacterium in this context. There are, to be sure, changes in the size of an individual bacterial cell at certain stages of the multiplication process, as is shown below.

Reproduction. Bacteria characteristically reproduce by an asexual process called binary fission, in which one cell divides into two new cells (Figure 3). A single bacterial cell, under optimum physical conditions for growth, performs metabolic functions including synthesis of intracellular substances. The cell elongates, and the cell wall becomes pinched in at the midpoint: finally, a transverse cell wall separates the parent cell into two new cells (daughter cells) that separate, and the process commences again. The reproduction and multiplication process is by geometric progression: one cell forms two, two cells form four, four form eight, eight form 16, 16 form 32, and so forth. The time required for the populations to double—*i.e.*, for one cell to divide in two—is the generation time (*G*); it can be calculated from the following formula:

Generation time

$$G = \frac{t}{n} = \frac{t}{3.3 \log b/B}.$$

In the formula, *B* is the number of bacteria at the start of the investigation; *b* is the number of bacteria at the end of the time period; *t* is the time period; and *n* is the number of generations. The experimental data—that is, the values for *B*, *b*, and *t*—must be obtained during the period of the total growth cycle known as the log phase of growth (described below). The generation times of bacterial species vary over a wide range. *Escherichia coli*, one of the most rapidly growing bacteria, has a generation time of approximately 15 minutes; *Mycobacterium tuberculosis*, a slow-growing bacterium, can have a generation time as long as 16 hours.

Although binary fission is the characteristic and typical mode of reproduction for the true bacteria (order Eubacteriales), among some bacterial species, particularly those of the higher orders of bacteria, other processes of reproduction occur. *Rhodomicrobium vannielii* (order Hyphomicrobiales), for example, exhibits a budding type of reproduction; *Streptomyces* (order Actinomycetales) species produce chains of spores; *Mycoplasma* (order Mycoplasmatales) reproduce by the segmentation of elementary units within a body surrounded by a membrane.

There are also instances of sexual reproduction (conjugation) among bacterial species. It occurs at low frequency among bacteria found in the intestine (enteric, or coliform, bacteria—*Escherichia*, *Shigella*, and *Salmonella*). In this process, conjugal pairs, or mating types, of bacteria make transient physical contact. Conjugal pairs consist of a donor (male) and a recipient (female) cell. In conjugation, a piece of chromosome from the donor cell is transferred into the recipient cell, in which it becomes a part of the recipient's chromosome. This is one way by which genetic material is exchanged in bacteria.

The bacterial growth curve. When bacterial cells are placed in a medium providing all of the nutrients necessary for growth (growth medium), the population increases according to a pattern identified as the bacterial growth curve (Figure 4). The four stages are the lag phase, log phase, stationary phase, and decline phase.

After their introduction into a medium, bacterial cells do not immediately reproduce according to their characteristic generation time; instead, the population remains constant for a period longer than the generation time. During this period individual cells actively metabolize (synthesize new cytoplasmic material) and increase in size. After the cells have undergone a rigorous physiological adjustment to the new medium, they divide.

The first cell division initiates the log phase, during which repeated division occurs at a rate consistent with the generation time. Theoretically, this stage describes a logarithmic progression, the population doubling with each new generation of cells. In theory, also, all cells grow at the same rate and reproduce at the same time. This synchronous growth period eventually terminates as cells phase out of the regular reproduction pattern, and some actually die.

Under optimum conditions, in terms of the nutrients available and the physical environment, the maximum viable population is attained at the end of the log phase, with some vigorous bacterial species achieving a density of 10,000,000,000 cells per millilitre.

For a period of time, the length of which depends on the species, the population is stationary. Among the factors responsible for this levelling off of the population are the following, which generally occur in some combination: production of inhibitory substances, depletion of nutrients, and death of cells.

The stationary phase terminates as the death rate of the population exceeds that of formation of new cells. The population steadily decreases until, eventually, all of the cells die.

Ecology. *Bacteria in water.* Good quality drinking water contains very few bacteria per millilitre and no coliform bacteria. The coliform bacteria, including *Escherichia coli* and *Aerobacter aerogenes*, are found in the intestinal tract of man and other animals. Their presence in water indicates that the water has been polluted with fecal material and hence may contain

The coliform bacteria

pathogens. The usual procedures employed in municipal water-purification plants—settling, filtration, and chlorination—are designed to remove or destroy these and other micro-organisms.

Sewage, defined as the used water supply of a community, contains wastes from domestic and industrial sources. Bacteria in sewage are of importance for two reasons. First, as pollutants: human excrement in sewage may contain pathogenic bacteria, which, if not removed or killed, may enter domestic water sources or supplies (Figure 5). Second, as cleansers: the treatment of sewage, particularly the breakdown (dissimilation) of organic material (*e.g.*, proteins, carbohydrates, and fats) requires the activity of bacteria. Sewage treatment facilities, including residential septic tanks, municipal sludge digesters, activated sludge digesters, and trickling filter and sand filter processes, are all designed to utilize bacteria to break down organic matter in sewage.

The breakdown of organic matter, however, imposes a biochemical oxygen demand (BOD) on the environment into which sewage is dumped (*e.g.*, a body of water). The greater the amount of organic matter, the greater is the amount of oxygen required for its oxidation and, hence, the greater the BOD. This process can be very disruptive to aquatic life in natural streams and lakes. One of the objectives in sewage treatment is to oxidize organic matter as completely as possible and thereby reduce the BOD prior to the discharge of the sewage (effluent) into natural bodies of water. Sewage digestion tanks and aeration devices are designed to exploit the metabolic capacity of bacteria to accomplish this objective (see SEWAGE SYSTEMS).

The microbial population of the sea consists of bacteria, algae, protozoans, and fungi. Bacteria of all physiological and metabolic types inhabit the various regions, extending from the surface layer of the sea to the bottom mud. They are responsible for transformations of both organic and inorganic compounds that serve as nutrients for marine life. The dissimilation of organic compounds, under aerobic (oxygenated) conditions, yields ammonia, carbon dioxide, and sulfate and phosphate salts. These products serve as the nutrients for algae and other planktonic life, which, in turn, synthesize organic compounds that may eventually serve as food for mollusks and fishes.

Bacteria in air. Air contains bacteria and other microorganisms that are suspended and circulated for varying periods of time, depending upon atmospheric conditions and the size of the particles that carry the micro-organisms.

Extremes of bacterial concentration

Generalizations about the microbial component of air can be made only with reference to a particular environment and the circumstances that prevail at a given time: for example, a hospital ward during bed-making time (agitation of bed linens and movements of personnel stir dust that may bear large numbers of bacteria into the air); a city street following a heavy rain (the air is washed and relatively free from bacteria). Air at an altitude of 10,000 feet (3,000 metres) usually has relatively few dust particles and, therefore, considerably fewer bacteria than are common in air at lower altitudes.

Tremendous numbers of bacteria are ejected into the atmosphere by a sneeze or cough. They remain suspended in air on particles referred to as droplet nuclei, which may consist of a single bacterium—in which case the particle remains airborne for a long period of time. When the particles consist of aggregates of bacteria coated with mucus or affixed to other cells, they settle out on surfaces in a short time. Airborne bacteria from the respiratory tract of man are potentially hazardous; they include *Mycobacterium tuberculosis*, which causes tuberculosis; *Neisseria meningitidis*, which causes meningitis; *Streptococcus pyogenes*, which causes strep infections; and *Diplococcus pneumoniae*, which causes pneumonia.

A.W. Rakosy—EB Inc.

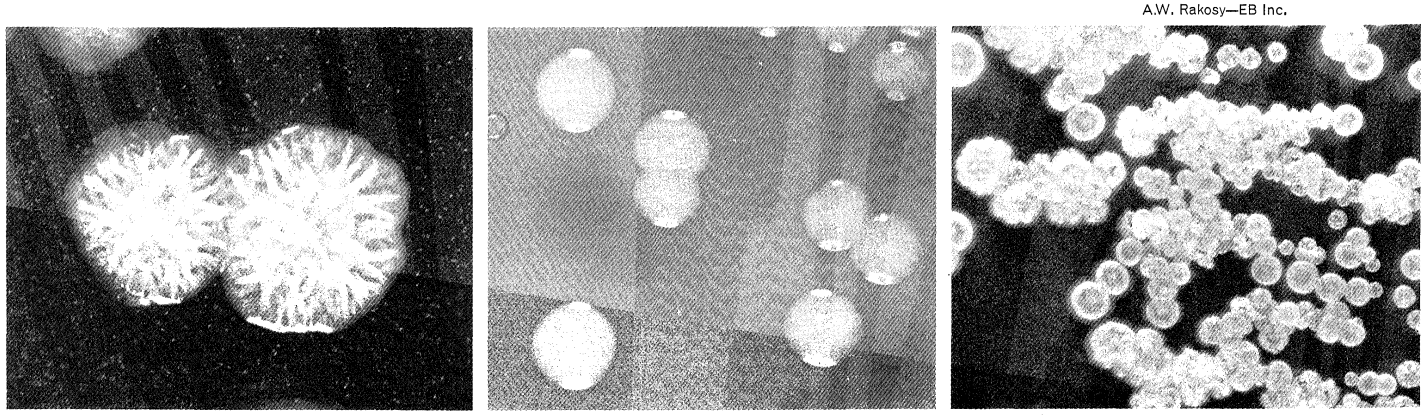

Figure 5: *Colonies of bacteria from water, dust, and soil.*
(Left) Rough colonies of *Pseudomonas pseudomallei* isolated from surface waters in Southeast Asia. These bacteria cause systemic meliodosis, a lethal infection in man. (Centre) Smooth colonies of *Micrococcus luteus*, on blood agar, isolated from dust particles from a clean room. (Right) Rough colonies of *Streptomyces griseus* isolated from soil (magnified 13 ×).

Bacteria occur on plant surfaces and will grow if conditions are favourable. They also invade and infect plant tissues, from which they are dispersed periodically into the atmosphere. Soil, particularly rich garden soil, contains countless bacteria per gram; soil dust dispersed into the air contributes a multitude of bacteria and resistant bodies formed by them (spores).

Airborne bacteria, as already mentioned, are important in the dissemination of diseases of man, of other animals, and of plants. They are also important as the source of contamination of many materials—*e.g.*, pharmaceutical preparations, surgical devices, and foods—thus necessitating precautionary procedures when "bacteria-free" conditions are desired (see below *Control*).

Bacteria in soil. Soil bacteria are extremely active in effecting biochemical changes in soil, which is the repository of the remains of plant and animal life; through microbial attack, materials are eventually transformed into the very substances that characterize soil—humus and minerals.

It is customary to view the chemical changes performed by bacteria in the soil as cyclic processes of the various elements; *e.g.*, the nitrogen cycle, the carbon cycle, and the sulfur cycle. At some stage of each cycle the element exists in its elemental form; *i.e.*, uncombined with any other elements. Certain species of bacteria are capable of converting the element into an inorganic compound that can be utilized as a plant nutrient and thereby transformed into an organic compound. The plant is consumed by animals, and the organic compound is incorporated into animal tissue. Eventually, animal and plant tissues return to the soil, where bacteria decompose them and thereby again release the elements as well as various other products (see BIOSPHERE).

Nitrogen fixers

The nitrogen cycle serves to illustrate the role of bacteria in performing various chemical changes. Nitrogen fixation, one of the key transformations in the nitrogen cycle, is performed by bacteria of several physiological types. Nitrogen-fixing bacteria are capable of transforming raw nitrogen into a form suitable for use by plants. They live in intimate association with a leguminous plant, in which case they are designated symbiotic nitrogen fixers; this type lives within lumps (nodules) on the plant's root system. Species of bacteria that can fix nitrogen in soil that is free from the plant-root system are referred to as nonsymbiotic nitrogen fixers. The best known genera are *Azotobacter* and *Clostridium*, although many others are now known to be capable of nonsymbiotic nitrogen fixation.

Bacteria in food. Milk drawn from a healthy cow contains relatively few bacteria per millilitre, but it is not sterile (free of living bacteria). Furthermore, procedures for handling the milk may add additional bacteria through contamination. Because milk is an excellent medium for the growth of bacteria, an initial small population (inoculum) can increase rapidly if the milk is not properly processed. Bacteria may merely cause spoilage or may present a serious health hazard if they are pathogenic. Bacterial pathogens transmitted through milk may originate in the cow or in man. A cow infected with the tubercle bacillus may transmit this organism, through milk, to man. Brucellosis, or undulant fever, also can be transmitted from cows to man via milk. Alternatively, an infected milk handler can contaminate the milk; outbreaks of typhoid fever, scarlet fever, and diphtheria have been known to occur in this fashion. Proper treatment of milk by the process of pasteurization —either the low-temperature, holding method (145° F [63° C] for 30 minutes) or the high-temperature, short-time method (161° F [72° C] for 15 seconds)—destroys all pathogens.

Bacterial conversion of milk

On the credit side, however, selected species and strains of bacteria convert milk and casein (milk protein) into such desirable products as buttermilk, yogurt, and cheese. Commercial cultured buttermilk is prepared from skim milk that has been inoculated with a starter culture and allowed to incubate until the desired changes occur. The starter culture consists of *Streptococcus lactis* or *Streptococcus cremoris*, together with *Leuconostoc citrovorum* or *Leuconostoc dextranicum*. Yogurt and other fermented milk products are produced in a similar manner but through the activities of different selected cultures of bacteria.

The formation of cheeses is likewise dependent upon the activity of micro-organisms. The curd from which cheese is made is precipitated (made to settle out) from milk by an acid-producing bacterium, such as *Streptococcus lactis*. Following removal of moisture and the addition of salt, the curd is allowed to ripen by the action of selected bacteria. Lactobacilli, streptococci, and propionibacteria are important for the ripening of Swiss cheese; *Brevibacterium linens* is responsible for the flavour of Limburger cheese; and molds (*Penicillium* species) are used in the manufacture of Roquefort and Camembert cheeses.

Bacteria in nondairy foods are as significant as those in milk and dairy products. The variety of bacteria that contaminate foods and the diversity of foods can result in a wide array of types of food spoilage. When allowed to grow in food, certain bacteria can cause food poisoning; they secrete a toxin that, when ingested by humans, can cause either a severe gastrointestinal upset—as in *Staphylococcus aureus* food poisoning—or death—as in botulism (caused by the toxin of *Clostridium botulinum*). It follows that one of the major concerns of food microbiology is the development and assessment of techniques to preserve foods from spoilage and contamination.

Food may be the carrier of pathogenic bacteria and thus be responsible for food-borne infections, among which the more frequently occurring are typhoid fever (*Salmonella typhosa*); salmonellosis (*Salmonella* species other than *S. typhosa*); and shigellosis, or dysentery (*Shigella dysenteriae*).

Notwithstanding the detrimental effects of food contamination, other bacterial populations are responsible for a variety of special foods, produced through bacterial fermentation; these include pickles and other pickled products, sauerkraut, and olives.

Control. Many materials and products, as well as certain environmental areas, require either the reduction or destruction of microbial populations. In a hospital operating room, for example, procedures are observed that reduce the microbial contents of the air to a very low level; on the other hand, the glucose solution used for intravenous injection is processed to be sterile—absolutely free of any form of life.

Degrees of control

Physical and chemical means are available to accomplish sterilization. The method of choice depends upon several considerations, not the least of which is the effect of the sterilizing procedure on the object being sterilized. If the material being sterilized is to be discarded following sterilization, such as used bacteriological media from a laboratory, then there is no problem except effectiveness of the sterilization procedure; however, if the material to be sterilized is a vitamin solution, for example, the procedure must be effective enough to sterilize without affecting the quality of the vitamin product.

Heat. High temperature, applied in a variety of ways, is one of the most effective sterilizing agents. Heat may be applied in the form of incineration, steam under pressure (autoclave), or dry heat (hot-air oven).

Incineration procedures range from the passing of an object through a bunsen burner flame in the laboratory to the burning of infected animal carcasses or contaminated bedding in large furnaces.

Steam under pressure, which is the principle of operation of the autoclave (an elaborate pressure cooker), is perhaps the most widely used sterilization procedure. The autoclave is a standard item of equipment in laboratories, hospitals, industries involved in food processing, and enterprises concerned with sterilization procedures and the manufacture of sterile products.

Dry heat, as in hot-air ovens, also accomplishes sterilization, but, in contrast to steam heat, higher temperatures and longer exposure times are required. Equipment that can be sterilized in an autoclave at 121° C (250° F) within ten to 15 minutes requires 160° C (320° F) for a period of two hours in a hot-air oven. Hot-air steriliza-

tion is used for materials that might be adversely affected by moist heat or that should not be directly exposed to moist heat because of necessary packaging.

The heat afforded by boiling water and pasteurization processes markedly reduces the bacterial flora but does not truly sterilize. Pasteurization, as previously mentioned, is designed to kill only the serious pathogens that might occur in milk; some bacteria and, in particular, bacterial spores are not killed. Similarly, boiling water kills the vegetative (active) bacterial cells but not necessarily the spores.

Radiation. Ultraviolet radiation (in the 2650-angstrom region [one angstrom = 10^{-8} centimetre]) is extremely bactericidal; that is, capable of killing bacteria. When properly used—namely, under conditions that allow direct exposure of organisms to the radiation—the microbial population can be effectively reduced. Ultraviolet rays, however, have a very low order of penetration; a thin film of glass filters out most of the rays.

Antibacterial action of gamma rays

Gamma radiations, which are emitted from radioactive isotopes, have great penetrating power as well as a high lethal effect. This combination of characteristics—high penetration and high bactericidal activity—makes them extremely effective as sterilizing agents. But several technical problems are associated with practical applications of gamma radiations: the development of an adequate supply of radiation sources and the availability of equipment designed to guarantee safety to its operators.

Certain materials cannot be exposed to physical agents without being adversely altered in some manner. Many medicines, including antibiotics, and other biological solutions may be destroyed or inactivated by any of the methods described so far. In such cases filtration is the appropriate method for sterilization. A wide variety of filters are available that are porous enough to allow fluids to pass through but not micro-organisms.

Chemicals. Sterilization can also be accomplished with such chemicals as the gas ethylene oxide. With the appropriate concentration, humidity, and temperature, ethylene oxide is a powerful sterilizing agent. In addition, it has the ability to penetrate considerably through materials. Ethylene oxide is widely used for the sterilization of many materials, including plastic devices, that could not undergo the other procedures.

Many chemicals for the control of micro-organisms are available for application to environmental surfaces or materials; they are not intended to effect sterilization, but they do reduce the microbial population or eliminate certain types of micro-organisms. These chemical agents are variously termed antiseptics, germicides, disinfectants, and sanitizers on the basis of their action (see ANTISEPTIC AND GERMICIDE).

FORM AND FUNCTION

In normal environments bacteria exist not only in large numbers but also in great diversity. In order to understand the characteristics of the individual species comprising these mixed populations, it is necessary to study each species as a pure culture, by isolating bacterial cells from colonies on a specific nutrient referred to as the medium. This isolation (pure culture) from the colony can be maintained as a pure culture by periodic transfer to fresh medium. Alternatively, a pure culture can be lyophilized (dried while frozen and sealed under vacuum) and kept viable (capable of dividing) in this condition for many years. Characterization of a pure culture requires a study of cell morphology, cultural and physiological characteristics, biochemical (or metabolic) processes, antigenic characteristics, and pathogenicity.

Morphological features. *The bacterial cell.* The typical cell of a species of Eubacteriales, or "true" bacteria, is a bacillus approximately one micron in diameter and a few microns in length. Coccoid cells may occur in characteristic arrangements: *e.g., Diplococcus pneumoniae* occurs in pairs; *Staphylococcus aureus* occurs in grapelike clusters; *Streptococcus pyogenes* occurs in chains; *Sarcina lutea* occurs as a cuboidal arrangement of cells; and *Micrococcus tetragenus*, as the name suggests, occurs in tetrads, or groups of four cells.

In contrast to the true bacteria are the "higher" bacteria, whose appearance suggests some primitive or abortive attempt toward cellular differentiation. They are usually much larger than the true bacteria and often bear some resemblance to yeasts, molds, algae, or protozoans.

A typical bacterial cell is shown in Figure 6; not all bacterial species possess all of the structures shown. All bacterial cells contain nuclear substance, but it is not organized into a discrete nuclear structure as in higher organisms; there is no nuclear membrane, and mitotic division, the mechanism by which the cells of plants and animals divide, does not occur. The blue-green algae are akin to bacteria in this respect; together they are characterized as procaryotes, in contrast to eucaryotes, the cells of which possess a discrete nuclear structure.

The typical bacterium

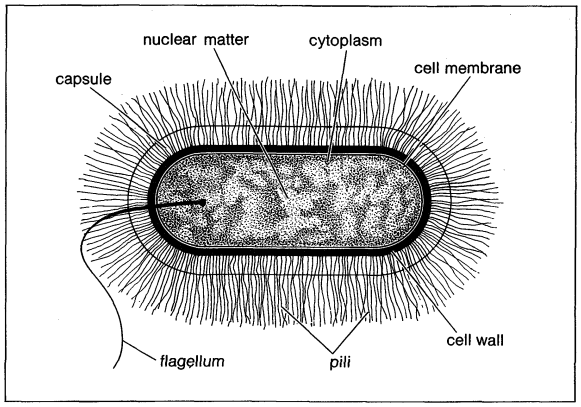

Figure 6: Schematic drawing of structure of a typical bacterial cell of the bacillus type.

All bacterial cells possess a membrane and a cell wall. There are distinct differences among species in terms of the chemical composition of these structures, however. The cells of some bacterial species possess whiplike structures called flagella, the number and arrangement of which are typical for a species. Shorter, rigid appearing, spikelike projections known as pili, or fimbriae, appear on some cells. Certain cells are surrounded with a gelatinous or slimy material, the capsule (Figure 7). Many bacteria can assume a dormant state as a spore; in fact, during sporulation the entire vegetative cell, in essence, is transformed into the spore body.

From W.H. Taylor and E. Juni, "Pathways for Biosynthesis of a Bacterial Capsular Polysaccharide," *Journal of Bacteriology* (May 1961)

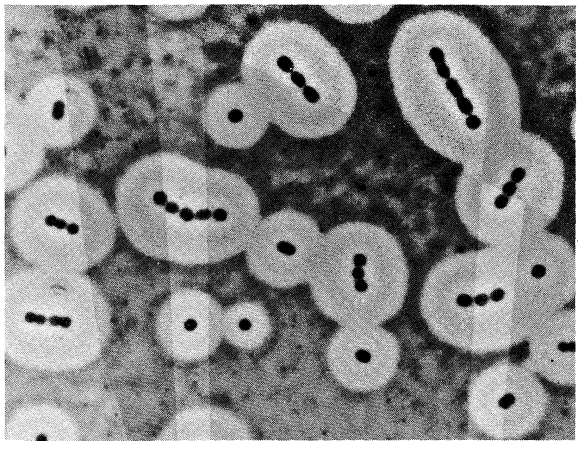

Figure 7: Capsular material surrounding these bacteria (*Acinetobacter calcoaceticus*) is revealed in a suspension of India ink and viewed through the light microscope (magnified about 2500 ×).

Staining techniques are used to demonstrate the various bacterial cell structures. One of the most important staining procedures involves the gram stain (named after its inventor, H.C.J. Gram, a Danish physician). This is a differential stain; *i.e.*, bacteria are said to be gram positive or gram negative depending upon whether they retain the

purple colour of the original stain (crystal violet) at the end of the procedure, or whether it is washed out and the red colour of the counterstain (safranin) shows (Figure 8).

More refined characterization of the anatomy of a bacterial cell can be accomplished by electron microscopy, in which bacterial cells are sliced into very thin sections and then viewed under very high magnification; electron micrographs reveal a great deal of complex detail: layers in the cell surface, internal structures, as well as connections or continuity between certain structures.

The bacterial colony. The gross appearance of bacterial growth in or on media defines the cultural characteristics of a species. When a specimen containing bacteria is inoculated onto an agar medium (a standard preparation of nutrients with a gel-like consistency), colonies develop, each from an isolated bacterial cell. Such colonies (Figure 9) vary in characteristics depending upon the species. They may be pinpoint in size or several millimetres across; flat or raised and convex; smooth or broken edged; stringy, brittle, or buttery in consistency; coloured internally or excreting substances that colour the surrounding medium; and opaque, transparent, or translucent.

Bacteria cultivated as agar slant cultures (slanted medium in test tubes) exhibit differences in characteristics much like those described for colonial appearance (Figure 10). In liquid media (broth), growth may be confined to the surface as a film (pellicle); uniformly distributed throughout the liquid; or particulate, with a tendency to form a sediment.

Physiological features. *Physical requirements.* On the basis of temperature requirements for growth, bacteria are grouped into three categories: psychrophiles, 0° to 30° C (32° to 86° F); mesophiles, 15° to 45° C (59° to 113° F), with best growth in the range 25° to 40° C (77° to 104° F); and thermophiles, 45° to 60° C (113° to 140° F) and above. Bacteria within each group exhibit specific minimum, maximum, and optimum temperatures for growth; for example, *Pseudomonas delphinii* grows at 1° C and 30° C (34° F and 86° F), with optimum growth occurring at 25° C (77° F), and *Bacillus thermoliquefaciens* grows at 37° C and 70° C (99° F and 158° F), with optimum growth occurring at 60° C (140° F).

Temperature categories of bacteria

Atmospheric oxygen is required by some, but not all, bacteria; others are inhibited by its presence. Bacteria are classified as aerobes when they require oxygen to grow and as anaerobes when they cannot grow in the presence of oxygen; facultative anaerobes do not require oxygen and can grow in its presence.

Some bacteria grow in a wide range of salt concentrations; others, such as marine bacteria, require salt levels of 10 to 15 percent for optimal growth. Most bacteria grow best in an environment near neutrality (neither acidic nor alkaline); some, however, grow under strongly acid conditions (*Thiobacillus thiooxidans*) and others under strongly alkaline conditions (*Nitrobacter* species). Most bacteria, and especially those intimately associated

with man, grow best without light. Photosynthetic bacteria, however, require light.

Nutritional requirements. The establishment of the specific nutritional requirements for various bacterial species required the development of media consisting of known chemical compounds in prescribed amounts, on which the bacteria could be cultivated in the laboratory. In a broad sense, bacteria, on the basis of nutritional requirements, can be divided into two groups: autotrophs and heterotrophs. Autotrophs are capable of growing entirely on inorganic ingredients, with atmospheric carbon dioxide as the exclusive source of carbon. Heterotrophs require an organic form of carbon and, in addition, may require other organic substances, such as amino acids and vitamins.

The autotrophic sulfur-oxidizing bacteria can grow on powdered sulfur, ammonium sulfate, potassium phosphate, calcium chloride, magnesium sulfate, ferric sulfate, water, and carbon dioxide. From these relatively simple chemical substances the autotrophic bacterium can synthesize and organize the vast array of complex organic substances of which it is made.

Heterotrophs exhibit great diversity in their nutritional requirements. *Escherichia coli*, the most frequently studied heterotrophic species, can grow on the ingredients listed above for autotrophic sulfur-oxidizing bacteria, except that carbon from an organic source (such as the sugar glucose) is also essential. *Salmonella typhosa* has a requirement slightly different from that of *E. coli* in that not only glucose but also an amino acid (tryptophan) is required. *Staphylococcus aureus*, another typical heterotroph, requires several amino acids and at least one vitamin, thiamin. *Lactobacillus* species are considerably more fastidious; they require many amino acids, several vitamins, and purine and pyrimidine compounds.

Some bacteria, especially certain pathogens, such as the syphilis bacterium (*Treponema pallidum*), require a complex medium that is provided only by living animal tissue. Such bacteria have so far not been cultivated even in a complex bacteriological medium of peptone (a digest of animal protein) and meat extract (or meat broth), with supplemental substances such as blood, serum, and other animal fluids.

Biochemical activities. Bacteria are capable of carrying out many chemical changes, both in the breakdown of complex substances and in the synthesis of new products. A compound may be degraded to different end products by different bacterial species, just as the same nutrients may be synthesized into different substances by different species.

Decomposition of carbohydrates

Dissimilation. Complex organic carbon compounds, such as pectin, cellulose, and starch, are readily degraded by many bacteria. Pectins are complex carbohydrates that occur in plants. Enzymes produced by species of *Erwinia*, *Bacillus*, and *Clostridium* are capable of converting pectin to galacturonic acid and further to sugar and other products. Cellulose, the major constituent of plant tissue, is transformed to dextrins and then to glucose by species of *Cellulomonas*, *Cytophaga*, *Streptomyces*, and *Clostridium*. Several *Bacillus* and *Clostridium* species produce enzymes that convert starch to sugar.

After the complex carbohydrates have been broken down into their constituent units (*e.g.*, glucose), these units are utilized in a variety of ways—*e.g.*, to produce a variety of other compounds. Bacterial species are characterized in part on the basis of the characteristic products they form from glucose. Table 2 lists several genera of bacteria, together with representative products of their glucose dissimilation.

The process of protein dissimilation (proteolysis) is accomplished by enzymes known as proteinases, which are produced by species of such genera as *Clostridium*, *Bacillus*, *Proteus*, and *Pseudomonas*. The proteinases decompose the protein molecules, hydrolyzing (breakdown involving water) the linkages (peptide bonds) between the amino acids that constitute the molecule. The result is the formation of peptides, chains of amino acids. Enzymes called peptidases then break down the peptides into individual amino acids. In turn, the amino acids may be degraded through several processes; deamination, the removal of the amino group ($-NH_2$) by enzymes called deaminases, the end products being ammonia (NH_3) and a fatty acid; decarboxylation, the removal of the carboxyl group ($-COOH$) by enzymes called decarboxylases, the end products being carbon dioxide and an amine; or amino acid fermentation, a breakdown more extensive than either deamination or decarboxylation, and resulting in more complex and varied end products, depending on the amino acid being degraded.

Table 2: Bacteria Grouped According to Major Products of Glucose Dissimilation

groups (with examples of some genera)	representative products
Lactic acid bacteria	
Streptococcus *Lactobacillus* *Leuconostoc*	lactic acid only or lactic acid plus acetic acid, formic acid, and ethyl alcohol; those species producing only lactic acid are *homofermentative;* those producing lactic acid plus other compounds are *heterofermentative*
Propionic acid bacteria	
Propionibacterium *Veillonella*	propionic acid plus acetic acid and carbon dioxide
Coli–aerogenes–typhoid bacteria	
Escherichia *Aerobacter* *Salmonella*	formic acid, acetic acid, lactic acid, succinic acid, ethyl alcohol, carbon dioxide, hydrogen, 2,3-butylene glycol (produced in various combinations and amounts depending on genus and species)
Acetone, butyl-alcohol bacteria	
Clostridium *Butyribacterium* *Bacillus*	butyric acid, butyl alcohol, acetone, isopropyl alcohol, acetic acid, formic acid, ethyl alcohol, hydrogen, and carbon dioxide (produced in various combinations and amounts depending on species)
Acetic acid bacteria	
Acetobacter	acetic acid, gluconic acid, kojic acid

Synthesis. The extensive capacity of a bacterium to synthesize complex molecules is shown when the simple chemical substances upon which an autotroph grows are compared to the complex chemical composition of the bacterial cells that are produced. In addition to the large, complex molecules that constitute cell structure, other substances of significance are elaborated by bacterial cells, including antibiotics, pigments, toxins, and polysaccharides (complex carbohydrates).

Fats, or lipids, composed of fatty acids and glycerol (*i.e.*, triglycerides), can be degraded by such bacteria as *Pseudomonas*, *Proteus*, *Achromobacter*, *Alcaligenes*, *Bacillus*, *Micrococcus*, and *Clostridium*. The end products of the dissimilation of fats are glycerol and fatty acids, which can be broken down further.

Pathogenicity. It was implied above that a pathogen has the potential to produce a disease in a given host species—a plant, an animal, or even another bacterium species. The power of a bacterium to cause a disease, termed virulence, varies within a species. Some strains are highly virulent; *i.e.*, a small number of cells can establish the infection. Other strains have a low degree of virulence and produce infection only when transmitted in massive numbers. Furthermore, some strains of a pathogen may lose their virulence. A quantitative expression of virulence can be determined by performing laboratory experiments to establish the number of bacterial cells required to infect or kill a standard experimental animal. The expression lethal dose$_{50}$ (LD_{50}) refers to the number of bacteria necessary to kill 50 percent of the organisms inoculated.

Virulence

Factors that contribute to the virulence of a bacterial pathogen are not yet completely understood, except in those instances in which the pathogen causes damage by secreting a potent toxin (an exotoxin). Diphtheria bacteria (*Corynebacterium diphtheriae*), for example, establish themselves in the mucous membrane of the upper respiratory tract of man; as they grow, they produce an exotoxin that is absorbed by the mucous membranes and causes the death of cells in the host. It is the exotoxin that does the damage to the host; a strain of *C. diph-*

theriae that does not produce the exotoxin cannot cause diphtheria.

Not all virulent pathogens produce an exotoxin; most, in fact, do not. *Salmonella typhosa*, the typhoid fever bacterium, produces an endotoxin, a complex substance associated with, or bound to, the surface structures of the bacterial cell. Endotoxins damage host tissues and host metabolism in ways not yet clearly understood. Other substances that contribute to the virulence of various pathogens are described in Table 3.

Table 3: Substances Contributing to the Virulence of Pathogenic Bacteria

substance	action
Hyaluronidase	increases permeability of tissue spaces to bacterial cells
Coagulase	increases resistance of bacteria to phagocytosis (engulfment by defense cells, or phagocytes)
Hemolysins	destroy red blood cells
Collagenase	dissolves collagen, a connective tissue protein
Leucocidin	kills white blood cells (specifically leucocytes) and hence decreases phagocytic action
Exotoxins and endotoxins	interfere with normal metabolic processes

Antigenic features. When bacterial cells enter the tissues of an animal, it is likely that they will act as antigens, agents that evoke the production of substances called antibodies. Antibodies are produced by an animal as part of its immunological defense against any foreign substance that can threaten its welfare.

Micro-organisms can be characterized in detail by performing antigenic analyses on them as well as on products (*e.g.*, toxins) of their metabolism.

Antigen–antibody reactions are highly specific and highly sensitive. A bacterial cell consists of many different antigens (*e.g.*, flagellar, capsular, and cell wall antigens). The antigen pattern in one bacterial species differs from that in another. Although it is not uncommon for related species (*e.g.*, *Salmonella typhosa* and *Salmonella paratyphi*) to share certain antigens, each also contains other antigens that are unique.

Variability. The characteristics of one bacterial species are sufficiently definitive and constant to delineate it from other species. This distinctiveness does not mean, however, that each characteristic is evident and manifest by all strains of all species under all conditions.

Environmentally induced variation

Reversible changes. Bacteria, under uniform conditions, will manifest a constancy of characteristics. If the same species of bacteria is placed in different environments—different physical conditions or different chemical composition of medium—the resultant growth may differ. In fact, the morphological and physiological characteristics are not identical at all stages of the growth curve of a bacterium. The morphology of cells from an "old" culture differs from that of "young" cells. In addition, the formation of a capsule is significantly influenced by the composition of the medium; bacteria that, in a nutrient broth, exhibit no capsules may produce large capsules when grown in milk. Some of the enzymes produced by bacteria are produced only when the compound on which the enzyme acts (substrate) is present; they are called adaptive enzymes, in contrast to constitutive enzymes, which are produced irrespective of the substrate.

Changes of the types just described are transient; they reflect what occurs during a stage of growth or in response to a change in the environment. The genetic endowment (genotype) of the organism remains the same, regardless of the different expressions (phenotype) that are seen under different environmental circumstances.

Permanent changes. Daughter cells that contain genetic information different from that of the parent cell constitute a new genotype. Such permanent-type genotypic changes may occur through four different processes: mutation, conjugation, transformation, and transduction.

Mutation involves a sudden alteration of a gene that is inherited by subsequent generations. Some bacterial cells in the process of normal growth undergo mutation; however, the ratio of mutant cells to unchanged cells is very small. The number of mutants in a population can be greatly increased by exposing the bacteria to certain physical agents (*e.g.*, ultraviolet rays, X-rays) or to chemicals (*e.g.*, mustard gas and organic peroxides).

Many different kinds of bacterial mutants have been isolated and characterized; they exhibit alterations in nutrition, drug resistance, pigmentation, and colonial form, among other characteristics.

Conjugation (sexual reproduction), a rarity in bacteria, results in recombinations of genes in the cells that pair (see above *Reproduction*).

Transformation also involves the transfer of genetic information from one cell to another, but pairing does not occur. Deoxyribonucleic acid (DNA) that is released from one cell (the donor) is taken up by another cell (the recipient) and incorporated into the genetic apparatus of the latter.

Changes caused by viruses

Transduction involves the transfer of genetic substance from one cell to another via a bacteriophage, a virus that infects bacteria. The bacteriophages produced in a host cell are released when the cell is destroyed by the infection. Some of the virus particles may be contaminated—*i.e.*, carry fragments of DNA from the host bacterium. When such a contaminated virus particle penetrates another bacterial cell, the bit of DNA from the original host is carried with it and, under certain circumstances, may become incorporated into the DNA of the recipient cell, thus changing the genetic constitution of the latter.

EVOLUTION AND CLASSIFICATION

Origin and relationships. Bacteria have existed from very early periods in the history of life on Earth. They have been detected as fossils in rocks dating from at least Devonian times (as early as 395,000,000 years ago). On the basis of their indistinct nuclear matter, bacteria are assumed to be closely related to the blue-green algae. It has been speculated that a photosynthetic ancestor may have given rise to both the bacteria and the blue-green algae.

Several groups of bacteria show features that suggest relationships to other classes of organisms: these features do not necessarily indicate a close relationship, however. Actinomycetes form branching units and reproductive stages similar to the fungi. Mycoplasmas (formerly called PPLO and L forms) are variable organisms that seem to lack in organization. Myxobacteria resemble, in some ways, the slime molds.

Rickettsias, rodlike or oval unicellular animal parasites, are smaller than bacteria but have a similar internal structure. Speculation is that they may represent highly modified small bacteria that became parasitic in the past and now can live no other way.

Classification. *Distinguishing taxonomic features.* Shape and size of the bacterial cell are aids in classifying bacteria, as is the appearance of the colonies that are formed. Other characteristics, however, assume even greater significance because they are more consistent under different environmental conditions. These include the kinds of foods utilized, the products of metabolism, reactions to specific chemicals, antigenic composition, and degree of tolerance to environmental change.

The ten orders of the class are distinguished primarily on the shape and rigidity of the bacterial cell and on locomotor ability; on the capacity of individual bacteria to aggregate in chains or clusters of special shape; and on special physiological characteristics.

Annotated classification. The following classification, featured in the edition of *Bergey's Manual of Determinative Bacteriology*, is generally accepted.

CLASS SCHIZOMYCETES

Unicellular micro-organisms generally ranging from 1 to 5 microns in size; variable in shape and in nutritional needs; lacking a distinct nucleus; most species without chlorophyll; occur singly or in chains or clusters and form distinctive colonies; about 1,500 species; worldwide distribution.

Order Pseudomonadales

Rigid-walled cells of variable shape, in some species forming chains; photosynthetic pigment present in certain species; cells usually motile by means of a single flagellum. Species in soil and in freshwater and saltwater. Examples of genera: *Vibrio*

comma (cholera bacteria), *Pseudomonas*, *Nitrosomonas*, *Thiobacillus*.

Order Chlamydobacteriales
Rigid-walled cells in many-celled filaments (trichomes), frequently ensheathed; occasionally produce motile spores; trichomes often attached to a surface; species in freshwater and marine habitats. *Sphaerotilus natans* common in polluted water.

Order Hyphomicrobiales
Rigid-walled cells often attached to surface by a stalk; reproduction by budding (as in yeasts) rather than by ordinary division. Genera include *Rhodomicrobium* and *Hyphomicrobium*.

Order Eubacteriales
Rigid-walled cells, coccoid or bacilloid, sometimes in chains; motile forms move by means of laterally emergent flagella; not acid-fast (*i.e.*, retaining a bacterial dye when treated with an acidic solution); includes the largest number of genera of concern to man—*e.g.*, *Escherichia, Diplococcus, Staphylococcus, Streptococcus, Bacillus, Lactobacillus*.

Order Caryophanales
Rigid-walled cells in trichomes; motile by means of lateral flagella; very large cells (up to 30μ long and 3μ across); occur in water and decomposing matter as well as in the intestines of arthropods and vertebrates. *Caryophanon latum*, common in cow dung, and *Simonsiella muelleri*, found in the mouths of humans and domestic animals.

Order Actinomycetales
Rigid-walled cells that may grow out in a branching system, resembling mold colonies; includes *Mycobacterium tuberculosis* (tuberculosis bacterium), *Streptomyces*.

Order Beggiatoales
Rigid-walled cells, usually large and often in trichomes that move by gliding motion as do some blue-green algae; genera include *Beggiatoa, Thiothrix*.

Order Myxobacteriales
Flexible-walled cells that creep on surfaces. Stalked fruiting bodies usually develop from a spreading colony, like slime molds. Found in soil, compost, manure, and rotting wood; genera include *Myxococcus, Chondrococcus, Sorangium*.

Order Spirochaetales
Spiral cells that swim by flexion; found in water and in the bodies of vertebrates; genera include *Borrelia, Treponema*, and *Leptospira*, all parasites of man and other animals.

Order Mycoplasmatales
Flexible-walled cells, nonmotile, highly variable in shape at different life stages; includes *Mycoplasma* and forms once known as pleuropneumonia-like organisms (PPLO) and L forms, which are apparently intermediate between true bacteria and rickettsias.

The stability of bacterial taxonomy

Critical appraisal. The classification of bacteria, relatively stable and generally accepted as given above, encompasses ten well-established orders. The question of higher categories, however, has not yet been resolved: are the bacteria very primitive plants or another kind of organism altogether? Some biologists favour a taxonomic system in which the bacteria (class Schizomycetes) are grouped with the rickettsias and viruses (class Microtatobiotes) as the division Schizomycophyta, which, in turn, is grouped with the Phylum Cyanophyta (blue-green algae) as a subkingdom, Monera, of the kingdom Protista (of equal rank with the kingdoms of Plantae and of Animalia). Such a scheme obviates the need for assigning these procaryotic organisms (*i.e.*, without distinct nuclei) to the kingdom Plantae, which is not quite suitable.

For many years the actinomycetes, myxobacteria, and mycoplasmas were listed as bacteria even though they have unusual life cycles and variable structure. It is now fairly well established, however, that they do belong in the class Schizomycetes. The rickettsias, which were occasionally grouped with the bacteria, are now considered an order, Rickettsiales, of the class Microtatobiotes.

(1967), a textbook on the activities of micro-organisms important in foods, as well as methods for their detection and control; T.R.G. GRAY and DONALD PARKINSON (eds.), *The Ecology of Soil Bacteria* (1968), reports given at the International Symposium on Soil Bacteriology, University of Toronto; A.E. KRISS *et al.*, *Microbial Population of Oceans and Seas* (1967; orig. pub. in Russian, 1964), a synoptic picture of the distribution and range of marine micro-organisms; C.A. LAWRENCE and S.S. BLOCK (eds.), *Disinfection, Sterilization, and Preservation* (1968), a handbook on the principles and practical aspects of the control of micro-organisms by chemical and physical methods; JOEL MANDELSTAM and K. MCQUILLEN (eds.), *Biochemistry of Bacterial Growth* (1968), a description of the way in which the simple organic and inorganic constituents of the medium are transformed into bacterial cell material; M.J. PELCZAR, JR. and R.D. REID, *Microbiology*, 3rd ed. (1972), a textbook presenting the major areas of study in the field of microbiology; ALAN RHODES and D.L. FLETCHER, *Principles of Industrial Microbiology* (1966), a general survey of industrial microbiological processes; A.J. SALLE, *Fundamental Principles of Bacteriology*, 6th ed. (1967), a textbook concerned with the fundamental concepts of basic and applied microbiology; R.Y. STANIER, M. DOUDOROFF, and E.A. ADELBERG, *The Microbial World*, 3rd ed. (1970), an advanced textbook covering the major characteristics of micro-organisms—*i.e.*, morphology, physiology, and biochemistry; F.S. THATCHER and D.S. CLARK (eds.), *Microorganisms in Foods: Their Significance and Methods of Enumeration* (1968), reports of the meeting of the International Committee on Microbiological Specifications for Foods, including information on occurrence, methods of detection, and technical procedures; A.H. WALTERS and J.J. ELPHICK (eds.), *Biodeterioration of Materials* (1968), a collection of scientific papers given at the First International Biodeterioration Symposium.

(M.J.P.)

Baden-Württemberg

Theodor Heuss, the first president of the Federal Republic of Germany, called his native Baden-Württemberg "the model of German possibilities," and by the early 1970s there were several indications that the possibilities were becoming realized in this very young German state (*Land*). By that time, Baden-Württemberg ranked third in both area and population among the West German states, having grown more than any other in the period following World War II. Its total area, 13,803 square miles (35,750 square kilometres), was larger than that of Belgium or Israel; and its population, in passing the 8,800,000 mark, approximated to that of Cuba or Greece. Included in the figure were over 500,000 foreign workers from the Mediterranean region, a higher number than that for any other German *Land* and, because it reflects the need for workers, a good indication of the high rate of industrialization in the region. Other favourable economic indicators demonstrated that Baden-Württemberg had high export totals, a high proportion of population engaged in industry and trade, few strikes, and a high percentage of homeowners' and building loans. Strategically located in the southwest of the nation, the *Land* is bordered by France in the west and by Switzerland in the south—a factor that has facilitated the influx of foreign workers. Formed under post-World War II occupational rule, and confirmed by a December 1951 referendum, the *Land* consists of three former *Länder:* Württemberg-Baden (in the American zone), Südwürttemberg-Hohenzollern and Südbaden (both in the French zone). The merger took effect in 1952. The capital is at Stuttgart.

The Land. Within the 1,026-mile- (1,651-kilometre-) long border of Baden-Württemberg lies one of the most geographically varied territories of the German Federal Republic, with the forests of the upland regions alternating with fertile highlands, green meadows, lakes, and marshes, giving the landscape a unique character. The geographical boundaries of the *Land* are the waters of the Bodensee (Lake Constance) and the upper Rhine in the south, the widening Rhine Valley in the west, the

River Main in the north, and the River Iller in the east. In addition, the source of the River Danube is at Donaueschingen, a popular excursion point, and the river cuts through the eastern part of the state on the first part of its journey across the European continent. The Danube is the main drainage basin south of the European water divide, which bisects the *Land*.

Source of the Danube

Using criteria from both physical and human geography, it is possible to divide Baden-Württemberg into the following eight natural regions.

The valley of the upper Rhine. Before the Roman conquest of western Europe, the upper Rhine River was one of the main trading arteries on the Continent, and this region also included immense hardwood forests, most of which have fallen prey to floods and the timber industry over the ensuing centuries. The fertile southern part of the upper Rhine Valley now has many vegetable orchards, and the sun-drenched vineyards around Mount Kaiserstuhl produce wine that ranks among the finest of all wines produced in the German Federal Republic.

The Black Forest. Germany's largest continuous forest area, the Black Forest spreads westward to the banks of the Rhine River. Idyllic valleys break its uniformity, and over the years, low-lying portions have filled with water, with many small lakes now contributing to the forest's enchanting, if somewhat foreboding, scenery. The highest point is the Feldberg, 4,898 feet (1,493 metres). The Black Forest edges into the Hotzenwald (Hotzen Forest) in the south, where many lakes and reservoirs feed the numerous power stations. Typical of this area is the so-called *Schwarzwaldhaus*, or Black Forest house, with its roof jutting far beyond its sides and its driveway leading straight up into the hayloft under the roof of the barn. The owners of these small holdings live predominantly from cattle breeding, the timber industry, and tourism.

The Alpenvorland ("alpine foreland"). This deep trough at the edge of the Alps stretches from the formerly volcanic area of the Hegau Mountains in the west to the meadows of the Allgäu in the east. Within its area lies the famous Bodensee and numerous, apparently irregular, rolling hills, with many lakes and marshes, which give the region a distinct appearance. The marshy ground is used for therapeutic baths, hence the number of health spas in this area. Here, too, small holdings predominate, with a solitary main building containing living quarters in the front, barn and hayloft in the back, threshing floor in the middle, and stables lining both sides. The farmers' main income is derived from cattle breeding and dairy products. The Allgäuer cheese is internationally famous.

The Schwäbische Alb (Swabian Alb). Emerging from the flats of the Alpenvorland but sectioned off from it by the Danube Valley, the Schwäbische Alb covers the area between the Black Forest and the Fränkische Alb (Franconian Alb). In the north its mountains fall abruptly into the valley of the Neckar River. Chalk formations and depleted forests make the Schwäbische Alb a barren terrain and Baden-Württemberg's poorest district. The weaving of linen textiles and sheep raising were the main sources of income for the population before the onset of synthetic textiles curtailed the breeding of sheep and forced many farmers to seek additional income in the cities of Heidenheim, Ulm, Reutlingen, or Balingen.

The Neckarland. The fertile Neckarland region belongs among the most densely populated areas in the entire Federal Republic. There is a profusion of vineyards along the Neckar and its many tributaries; other produce grown in the region includes potatoes, sugar beets, and a variety of fruit and vegetables, together with some grain. The many medieval castle ruins have left a distinctive mark on the partly forested landscape, which is also broken by occasional cornfields. Small villages used to line the local highways, but since the end of World War II new high buildings have pushed city and town limits further and further into these surrounding rural districts.

Hohenlohe. The granary of Baden-Württemberg, the Hohenlohic district, lies around the old free city of Schwäbisch Hall and extends all the way to the borders of Bavaria at Rothenburg ob der Tauber. Unlike the custom of the Alb region, where holdings were divided among heirs, the laws of primogeniture (inheritance by the first-born) in this area resulted in a preservation of large estates. A bad effect of this has been that the many young people who do not inherit any land at all have had to find work somewhere else. The numerous, often well preserved, castles in this area are nevertheless ample evidence of the wealth of Hohenlohe in past centuries.

Large estates preserved

The Odenwald (Oden Forest). Often called *Badisch-Sibirien* (the "Siberia of Baden"), the hilly Odenwald region unites Baden-Württemberg with the *Land* of Hessen, in the north. Its location outside the main traffic arteries as well as its raw climate prevented any cultural or economic growth for centuries, and only in the years since 1950 has a developing small industry created extra income possibilities for the local small farmer.

The Kraichgau. Located between the Rhine and Neckar rivers, the fertile Kraichgau district is the site of wheat, corn, tobacco, and fruit culture. The Schwetzinger asparagus of this area is famous far beyond its borders. The castles of Schwetzingen and Bruchsal, reconstructed since World War II, complement the many castles around the cities of Karlsruhe and Mannheim.

The climate of Baden-Württemberg varies greatly among the regions of the *Land*. The upper Rhine Valley is the warmest area, with a yearly mean average of 48°–50° F (9°–10° C) whereas the Alb—the "raw Alb"—is the most inhospitable, with a mean average of about 40°–44° F (4.5°–7° C). Here, and in parts of the Black Forest, there is a yearly average of two months of frost. As a rule, spring comes to the southern part of the upper Rhine Valley before the 20th of April but does not reach the highest regions of the Alb until after the 25th of May. The latter region also has the highest amount of precipitation in the *Land*, because of the westerly winds that drive ocean cloud formations across France to discharge over the slopes of the Black Forest and the Alb. The annual rainfall in the upper Rhine Valley is 26 inches (650 millimetres), compared with 79 inches (2,000 millimetres) on the Feldberg, a favourite ski resort. The average precipitation in the Alb district is 40 inches (a little over 1,000 millimetres), but in the valley of the Neckar River and in the valley of the Tauber River, lying further east, the amount is often less than 24 inches (600 millimetres), and most of this is summer rain.

Climatic variation

A characteristic feature of Baden-Württemberg is the great number of urban settlements; the urban density is two to three times that of northern Germany. By the 1970s, more than 60 of these settlements, many of which had been founded by the Staufers (one of the numerous lesser rulers who governed this area at one point or another in its long history), had populations less than 2,000. Such towns as Ludwigsburg, Rastatt, and Öhringen still retain their typical residential character. The garrison towns, such as Ulm and Münsingen, are of more recent date. Heidelberg, Tübingen, and Freiburg im Breisgau, university centres dating back to the Middle Ages, have been joined in recent years by new universities in Konstanz and Ulm.

The people. The north German regards the people of Baden-Württemberg with some contempt. The nickname *Schwaben*, or even *Spätzle-Schwaben*, is often used. *Spätzle*, a local variety of homemade dumplings, is the favourite staple dish of south Germans. The term *Schwaben* is a misnomer, since most of the native Swabians, descendants of the Suabi, an ancient Germanic tribe, live only in the southeast of the state. The people in the west and southwest of Baden-Württemberg are Alemanni, blood relatives of the French Alsacians and the neighbouring Swiss Alemanni. The influence of the Palatinate population is very strong in the northwest of Baden-Württemberg, whereas the Franconians pushed their way into the centre of the state from the northeast. The linguistic boundary between Franconians and Swabians runs approximately from Baden-Baden in the west, through the Stuttgart area, to Crailsheim in the east.

The geographical boundary between religions has no connection with the origin of the people. Catholics outnumber other denominations in the predominantly Ale-

Religious distribution

mannic Südbaden and Südwürttemberg; Protestants and Evangelists constitute the majority in the more Franconian Nordwürttemberg, and both faiths are more or less equally represented in Nordbaden. Historical developments within the state account for these differences: some ruling houses were Catholic, others, Lutheran Protestant, and each left its mark on the local subjects. In addition to these two main religions, there is a great variety of sects and free churches, especially in Württemberg, most of them a part of the Pietistic movement or of other Protestant origin.

Baden-Württemberg's great post-World War II expansion owed much to the fact that almost a quarter of its population is composed of people who moved to the *Land* as fugitives or displaced persons from the east. Their influx is partially explained by ancestral links between them and the states of Baden and Württemberg in previous centuries. In addition, many simply saw opportunities for a new start in this part of Germany, which had been spared the brunt of wartime destruction. From 1945 to 1950, the rural areas of the state provided the best prospects for housing and employment, but the following years saw a return of the working force to the industrial centres—so much so that many a local farmer's son or daughter got caught up in the ensuing migration from rural areas to the cities. The capital, Stuttgart, witnessed a spectacular growth, gaining as many as 10,000 people a year, and there was severe depopulation of many rural districts. By the early 1970s, only the high rents in the cities apparently kept even more people from moving to the locality in which they worked. Many preferred to build their own home on cheaper ground in small dormitory villages, and to commute instead. Stuttgart alone has more than 100,000 commuters daily, almost one-quarter of the total working force, and a quarter of the entire working force of the *Land* are daily commuters.

The economy. Baden-Württemberg may be regarded as the one West German *Land* in which economic life is dominated by middle class businessmen and small farmers. Although such world famous firms as Daimler–Benz started as small workshops in Stuttgart and Mannheim, there is no heavy industry in the region. On the other hand, Baden-Württemberg is the centre for highly specialized mechanical and textile industries. The lack of valuable mineral and other deposits in Baden-Württemberg forces the population to earn its livelihood by the manufacture, improvement, and finishing of goods. Baden-Württemberg now produces 90 percent of all clocks and watches produced in West Germany, 83 percent of all custom jewelry, 50 percent of all leather goods, 45 percent of all musical instruments, 40 percent of all instruments used in medicine, 39 percent of all food and produce, 37 percent of all cigars, and 30 percent of all hardware.

Lack of resources

The industrial centres are concentrated in the Neckar Valley between Esslingen, Stuttgart, and Heilbronn, and this area accounts for more than half the total production of the *Land*. Other industrial areas are found on the banks of the Rhine near Mannheim—the *Land's* second largest city after Stuttgart—and near Karlsruhe and Ulm. More recently, the border district of the upper Rhine has gained in economic importance; close to the French and Swiss borders and in the centre of the European Economic Community, it is the preferred site for new branch offices, of German, as well as French and Swiss, companies.

At the 1970 census, 56 percent of all those gainfully employed in Baden-Württemberg worked in the production industry, with a shrinking 7 percent in agriculture and forestry, 14 percent in trade and commerce, and 23 percent in other fields of the economy.

Agricultural decline

Agriculture continues to pose problems: at the start of the 1970s there were 157,000 farmers with total holdings of less than 12 acres (about five hectares) of arable land apiece. Their economic survival was seen to depend on their ability to buy or lease additional land. Similarly, the 51,000 farmers with slightly larger holdings had to specialize—in animal breeding, produce, or wine production—if they, too, were not to become bankrupt. Of the state's total of 264,000 farms, only 3,250 were larger than 72 acres (30 hectares) of land. Most of the small farmers were therefore forced to earn their livelihood in industry, returning to their farms in the afternoon, and taking their factory vacations during harvest time.

Many of the farmers of the early 1970s added to their income by converting either their own homes, or other nearby property, to tourist use. The well-known spas of Baden-Baden, Wildbad, and Badenweiler provided additional tourist facilities, while 30 other smaller spas had been enlarged and improved considerably with financial help from the *Land* authorities.

Transportation. Lacking natural resources, and forced to depend mainly on commerce and trade, Baden-Württemberg pays particular attention to its transportation system. As early as 1955 the government prepared a general plan that, by the early 1970s, had been twice improved and adapted to more recent technological developments. The plan called for three express highways (*Autobahn*), traversing the state from north to south, and four more running from west to east. These were to be supported by an extensive system of improved four-lane smaller highways, together with appropriate railway developments. The Rhine and Neckar have been improved as waterways, augmenting this intricate network. By 1971, the Neckar had been canalized as far as Plochingen, and the Rhine could be used for shipping as far as Rheinfelden. In the early 1970s, negotiations were under way with Switzerland with a view to dredging the Rhine up to Waldshut, and possibly to the Bodensee, making the river navigable up to these points. Finally, Baden-Württemberg, near Stuttgart, has one international airport (accounting for over 1,650,000 air passengers in 1970) and some 22 smaller airfields.

Administration and social conditions. Since 1952 the state assembly (Landtag) of Baden-Württemberg has had 120 members, distributed in proportion to the population of the four administrative districts of Nordwürttemberg (capital Stuttgart), Südwürttemberg-Hohenzollern (capital Tübingen), Südbaden (capital Freiburg), and Nordbaden (capital Karlsruhe). Seventy members are elected by direct popular vote, the remainder by proportional representation. The *Land* entered the 1970s as the only one in the Federal Republic still governed by the "grand coalition" of the Union of Christian Democrats (CDU) and the Social Democrats (SPD). The smaller Free Democrats (FDP/DVP) also retained representation, but the Union of Refugees and Disowned (Bund der Heimatvertriebenen und Entrechteten; BHE) and the Communists lost their minor representation of the 1950s in the ensuing decade, which, from 1968 onwards, saw the rise of the right-wing National Democrats. As a rule, the strongest faction in the state assembly chooses the president after the elections; after majority confirmation, he in turn appoints his ministers, choosing within and without the assembly. In the early 1970s, the left-centre Social Democrats, the strongest party in Baden-Württemberg in terms of organization, had over 50,000 members; the Union of Christian Democrats had slightly more than 45,000 members; and the Free Democrats had a little more than 10,000 members.

Political parties

The *Land* is divided into two judicial districts: those of the supreme assize courts of Baden and Württemberg, each including several provincial courts and many local courts. The local courts were extensively reorganized into larger districts in the early 1970s. A peculiarity of Baden-Württemberg is its community courts, in which lay officials may settle civil rights disputes within the village or community. The local notary office is also a unique feature among the German *Länder*.

The Centre for the Clearing of National Socialist Crimes (Zentrale Stelle zur Aufklärung nationalsozialistischer Verbrechen) in Ludwigsburg has gained an international reputation, sifting thousands of documents from foreign archives concerning atrocities committed by Germans under the Third Reich. It has also started court proceedings against former Nazis.

The West German supreme courts are located in Karls-

ruhe: the federal constitutional court (Bundesverfassungsgericht) settles constitutional questions, and the federal court (Bundesgerichtshof) is the highest court of appeal for criminal and civil law in the Federal Republic.

At the end of World War II, the greater part of Baden-Württemberg was occupied by American troops, and United States military headquarters have continued to be located in Heidelberg, with many American garrisons in the cities and towns of north Württemberg and north Baden. The headquarters of the limited French forces are in Baden-Baden, while the commander of the Federal German forces for Baden-Württemberg has his headquarters in Stuttgart.

Baden-Württemberg has more universities than any of the other *Länder* of the Federal Republic. In addition to the old classical universities of Heidelberg, Freiburg, and Tübingen, there are technical universities at Stuttgart and Karlsruhe, an agricultural university in Stuttgart-Hohenheim, and a university in Mannheim specializing in economics. The Ulm University for medicine and natural sciences and the reform University of Konstanz were both founded in the 1960s. There are also many other institutions of higher education. Approximately two-thirds of the three- to six-year-olds in the *Land* are enrolled in *Kindergarten*, which get most of their support from churches and similar organizations, and there is a substantial enrollment in other branches of primary and secondary education, in which structure follows the national pattern.

From the 1950s onward, the *Land* government has been greatly concerned with the social welfare of its citizens. It has produced a hospital plan, a plan for the aged, a plan for youth, and an extensive social report. As a result, medical services were extensively improved during the 1960s, with no less than 45 specialized hospitals having been constructed, with further enlargement and modernization of some 70 existing hospitals.

It is not surprising that living costs, wages, and rents differ greatly in the various parts of the state because of its diverse economic structure, with the rural areas being low in living costs and wages and the cities offering high wages, often with excessively high rents. Generally, the level of earning power in Baden-Württemberg exceeds that of other *Länder* in the German Federal Republic. The overall cost of living index rose from 100 to 158 points between 1950 and 1970.

Cultural life and institutions. Baden-Württemberg is strong in architectural monuments. Gothic churches abound in Ulm and Freiburg, and baroque churches in Weingarten (Kreis Ravensburg), Birnau, Steinhausen, Zwiefalten, and Mannheim, together with the former Kaiserpfalz (Kaiser Palace) in Wimpfen and the castle of Rastatt, are popular sightseeing attractions. The state theatres in Karlsruhe and Stuttgart have an international reputation, particularly marked in the case of the Stuttgart ballet. Of the three provincial and eight city theatres, the Mannheimer Nationaltheater merits special mention: Friedrich Schiller's *Die Räuber* (*The Robbers*) had its world premiere on this stage. The chamber orchestra of Stuttgart (Stuttgarter Kammerorchester) has a growing reputation. Such poets and writers as Friedrich Schiller, Friedrich Hölderlin, and Hermann Hesse, together with the great philosophers Georg Friedrich Wilhelm Hegel and Martin Heidegger, are among the *Land*'s most famous sons. The sculptor Otto Dix made an important contribution to the German expressionist movement.

Literary heritage

The two radio broadcast stations in the *Land*, the Süddeutsche Rundfunk in Stuttgart and the Südwestfunk in Baden-Baden, have well-known popular orchestras, and each broadcasts three different program services. In addition to five or more important regional newspapers, the *Stuttgarter Zeitung* is of national significance.

The Baden-Württembergian is particularly likely to be a member of a club or society, and membership in such bódies is far above the average of the other *Länder* in the Federal Republic of Germany. Singing, sports, and gardening clubs abound throughout the *Land*, which is also a leader in the number of local historical and archaeological societies. The Schwäbische Albverein (Swabian Alb Walking Club) is the largest in the whole Federal Republic. Like the Schwarzwaldverein (Black Forest Walking Club), it concerns itself mainly with wildlife preservation.

The numerous adult education clubs and the many university extension courses in the *Land* testify to the continuing importance of education tradition in the region. Since 1970 all branches of public adult education have been brought together and are now a separate unit, the Fortbildungswerk. The annual class attendance of over 1,000,000 persons, many of them under 25, is an indication of the degree of public interest.

From 1952 to 1970, the total economic output of the *Land* increased by 500 percent. During the same time jobs in industry increased by 60 percent and, at the start of the 1970s, were confidently expected to continue to increase at a rate exceeding that of any other German *Land*. As a direct result, Baden-Württemberg is able to set aside more than a quarter of its annual total tax budget for the extension of its educational system, while paying more than 500,000,000 (US $137,000,000; $1 = DM 3.66) marks annually to the poorer states of the Federal Republic, under a national plan for the equalization of finances. Next to the city states of Berlin, Hamburg, and Bremen, Baden-Württemberg is the state with the highest proportion of students in all age groups. In the early 1970s, this was combined with a high number of car owners, and the second lowest rate of unemployment per 1,000 inhabitants. A government report of this period was not necessarily unjustified in concluding with a quotation from Theodor Heuss, "I believe that the daring prophecy that a self-reliant state could evolve there has been fulfilled."

BIBLIOGRAPHY. EBERHARD KONSTANZER, *Die Entstehung des Landes Baden-Württemberg* (1969), is a history of southwest Germany, with emphasis on the period from 1945 to the present; earlier history is treated in ERNST MULLER, *Kleine Geschichte Württembergs* (1949). See also H. GARDINER BARNUM, *Market Centers and Hinterlands in Baden-Württemberg* (1966), for commerce; and W.M. SCHEDE, *Baden-Württemberg: A Panorama in Color* (1965), for a description of the area.

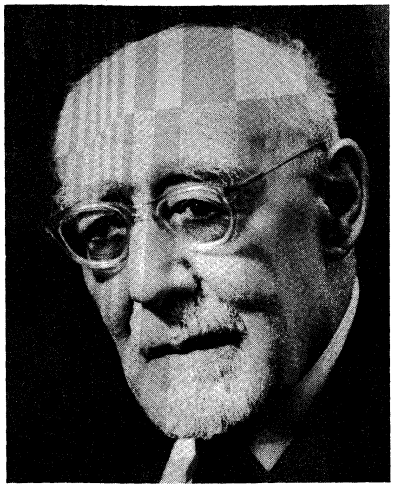
(Er.R.)

Baeck, Leo

Leo Baeck, German Jewish Reform rabbi and theologian, was the spiritual leader and symbol of German Jewry during the period when the Nazis virtually exterminated the European Jews. Baeck was born in Lissa, Posen (then in Prussia), on May 23, 1873. He studied for the rabbinate in Breslau and Berlin, received his Ph.D. in philosophy at the University of Berlin in 1895, and was ordained in 1897 by the progressive Hochschule in Berlin. He immediately displayed his courage and personal independence of thought by being one of the two rabbis within the German Rabbinical Association who refused to condemn the Zionist leader Theodor Herzl (1860–1904) and the First Zionist Congress then meeting in Basel.

Baeck first served as rabbi in Oppeln Silesia (1897–1907), then Düsseldorf (1907–12), and finally Berlin (1912–42). In 1901, Baeck challenged the Protestant theologian and church historian Adolf von Harnack (1851–1930), whose lectures on *The Essence of Christianity* then presented essential original Christianity as a liberal faith that appeared at a unique moment of history and was unrelated to the Jewish tradition. Striving to show the originality of Jesus' teachings, Harnack denigrated the Pharisees and the Judaism they represented and committed lapses of scholarship singled out by the young Baeck. Baeck's own masterpiece, *The Essence of Judaism* (1905), established him as the leading liberal Jewish theologian. In contrast to Harnack, Baeck stressed the dynamic nature of religion, the ongoing development that is man's response to the categorical "Ought," the Divine Imperative. The influence of the German-Jewish philosopher Hermann Cohen (1842–1918) and Neo-Kantianism (German philosophical movement, 1870–1920) is visible, but behind it stands the ethical rigorism of traditional rabbinic thought. The next edition of this

Jewish theologian



Baeck, c. 1948
Picture in the archives of the Leo Baeck Institute, New York

work (1922), greatly expanded, moved on toward Baeck's "religion of polarity" with its dialectical movement between the "mystery" of the Divine presence in life and the "commandment" of the ethical imperative that comes to man in his encounter with God. Baeck expressed the twofoldness of religious experience in the concept of *toladot* "generations," the chain of generations that is Jewish history and that made the Jewish people the vehicle of a continuous revelation that became that people's mission. "A light to the nations," it had to teach the revelation by living these teachings. Judaism was seen as the supreme expression of morality, a universal message expressed through the particular existence of Israel.

The dialogue between Christianity and Judaism was brought to greater clarity and intensity by Baeck's refusal to use evasions in his criticism. Traditional Jews disliked Baeck's early (1901) claim that Jesus was a profoundly Jewish figure and his view in *The Gospel as a Document of Jewish Religious History* (1938) that the Gospels belonged with the contemporary works of rabbinical literature. Christians, on the other hand, felt challenged by his definition of Judaism as the "classic" rational faith confronting a "romantic" Christianity of emotion, in his essay "Romantic Religion" (1922). The American philosopher Walter Kaufmann views this work as Baeck's greatest achievement next to the *Essence of Judaism*. Yet one cannot ignore Baeck's final work, written in the concentration camp, *This People Israel: The Meaning of Jewish Existence* (1955), which moves from the essence of an "ism" to the concrete existence of a people and creates an approach to Jewish life that must be set alongside the thought of the great 20th-century Jewish religious philosophers Martin Buber (1878–1965) and Franz Rosenzweig (1886–1929). Its full implications emerge only when the work is placed into the life of the author.

Baeck's life was his work, revealing his concept of polarity: an army chaplain in World War I, he became a pacifist; a non-Zionist, he became head of the German Keren Hayesod ("Foundation Fund" for Palestine land purchases). Baeck was the president of the German B'nai B'rith ("Sons of the Convenant," the main Jewish fraternal and service organization); the chairman of the Rabbinical Association he had once defied; and taught Midrash (interpretative rabbinical literature) and homiletics at the Berlin Lehranstalt. He was called away from this to preside over the end of the 1,000-year-old German Jewish community.

Leader of German Jewry

In 1933, German Jewry's organizations united in the Reichsvertretung der Juden in Deutschland (National Agency of Jews in Germany) under Leo Baeck and Otto Hirsch (1885–1941), the jurist and community leader who was killed in the Mauthausen concentration camp. Under constant attack, this group took charge of Jewish life in Germany. Millions of dollars were spent annually in clearly defined fields; emigration, economic help, charity, education, and culture. Meanwhile, at the conference table with the Nazis, Baeck and the others battled for time so that lives could be saved. Later critics have felt that all resources should have been focussed on emigration; but the extermination camps were inconceivable to the German Jewish community of the 1930s. It planned to survive Hitler behind ghetto and prison walls—a tragic error of judgment, but scarcely avoidable. Negotiating with Nazis always carried dangers of corruption but Baeck was untouched by this. As late as 1939, he brought a trainload of children to England—and returned to Germany. In public and private, his life was a pattern of moral resistance that, after five arrests, brought Baeck to the Theresienstadt (Terezín) concentration camp.

Theresienstadt was a "model" camp, sometimes shown to outsiders. Its inmates were killed by neglect or illness or sent on to the extermination camps. Out of the 140,000 Jews sent to Theresienstadt less than 9,000 survived. The Nazis confused the death of a Rabbi Beck of Moravia with Leo Baeck; the latter became Number 187,894 and, incredibly, survived. Baeck set up classes inside the camp: over 700 persons would press into a small barracks to listen to lectures on Plato and Kant. This, too, was a way of resistance. There were also Christian inmates whom Baeck served as pastor. Once more, the miasma of evil surrounded him but could not touch him. Critics have said that he was too aloof, or too liberal, but the only criticism to be taken seriously deals with Baeck's decision not to pass on rumours that the "resettlement" trains led to the death camps. The eminent Protestant theologian Paul Tillich (1886–1965), who admired Baeck, asserted that "Baeck should have spoken out . . . the full existential truth must always be made available." Baeck, however, thought the helpless victims should not be deprived of the hope keeping many alive.

On May 8, 1945, the day before Baeck was to be executed, the Russians liberated Theresienstadt, and Baeck stopped the inmates from killing the guards. He survived for a number of years, settling in England, and becoming a British subject; he taught and lectured in Britain and the United States, including a term at Hebrew Union College in Cincinnati. His final writings, notably *Individuum Ineffabile* (1948) and *This People Israel*, continued to express hope in man and the human situation as the area of the revelation. He died in London, on November 2, 1956. In his life, Baeck summarized the greatness and perhaps also some of the flaws of German Jewry, which placed all of its hopes and commitments in western European civilization. In his teachings Baeck gave perhaps the clearest systematic exposition of liberal Jewish religious thought in the 20th century.

BIBLIOGRAPHY. Important works of Leo Baeck include: *Das Wesen des Judentums* (1905, 6th ed. 1932; Eng. trans., *The Essence of Judaism*, 1948), a classic text of modern Judaism; *The Pharisees and Other Essays*, with an introduction by KRISTER STENDAHL (Eng. trans. 1966), a text covering basic historical questions concerning Jewish life at the time of the emergence of Christianity; *Judaism and Christianity*, with an introduction by WALTER KAUFMANN (Eng. trans. 1961), a collection of the more polemical writings of Baeck clearly defining Judaism's disagreements with Christianity; and *Dieses Volk; Jüdische Existenz* (1955; Eng. trans. by A.H. FRIEDLANDER, *This People Israel*, 1966), Baeck's final work, partly written in a concentration camp, covering 3,000 years of Jewish history. The only full-length biographical study published to date is A.H. FRIEDLANDER, *Leo Baeck: Teacher of Theresienstadt* (1968), containing an exposition of Baeck's teachings and an extensive bibliography.

(A.H.F.)

Baer, Karl Ernst von

The 19th-century scientist Karl Ernst von Baer led an extraordinarily varied life; he had a universal mind that ranged both wide and deep. By his comparative and descriptive studies of animal development, he established in modern biology the idea that the life of an animal is a historical event, proceeding from simple to complex, from general to special. He showed that mammals develop from eggs, and that the same organs in different animals develop from the same basic tissue

layers. He gave meaning, by his observations and generalizations, to the concept of epigenesis. This systematization of embryology was responsible for the fact that this new science supplemented comparative anatomy as the dominant biological discipline. He was also a pioneer in geography, ethnology, and physical anthropology.

Baer, lithograph by Rudolph Hoffmann, 1859, after a photograph.

Born on his family's estate in Piep, Estonia, on February 29, 1792, Baer, one of ten children, spent his childhood with an uncle and aunt before he returned at the age of seven to his own family. His parents, of Prussian descent, were first cousins. After private tutoring Baer spent three years at a school for members of the nobility. In 1810 he entered a provincial Estonian university at Dorpat to study medicine, receiving his medical degree in 1814. Dissatisfied with his medical training, he studied in Germany and Austria from 1814 to 1817. The crucial year of his education was the academic year 1815–16, when his studies in comparative anatomy at the University of Würzburg with Ignaz Döllinger introduced him to a new world that included embryology.

In 1817 Baer began his teaching in Königsberg, where he remained until 1834. In 1820 he married Auguste von Medem of Königsberg, by whom he had six children. Although Döllinger had suggested that Baer begin a study of chick development, he was unable to meet the expense of purchasing the eggs and paying an attendant to watch the incubators. This work was done instead by Baer's more affluent friend Christian Pander, who in 1817 described the early development of the chick in terms of what are now known as the primary germ layers—that is, ectoderm, mesoderm, and endoderm.

Major works

From 1819 to 1834 Baer devoted most of his time to embryology, extending Pander's concept of germ-layer formation to all vertebrates. In so doing Baer laid the foundation for comparative embryology. He made many important technical discoveries. In 1827 he described his discovery of the mammalian ovum (egg) in his *De Ovi Mammalium et Hominis Genesi* ("On the Mammalian Egg and the Origin of Man"), thereby establishing that mammals including man develop from eggs. He opposed the popular idea that embryos of one species pass through stages comparable to adults of other species. Instead, he emphasized that embryos of one species could resemble embryos, but not adults of another, and that the younger the embryo the greater the resemblance. This was in line with his epigenetic idea—basic to embryology ever since—that development proceeds from simple to complex, from homogeneous to heterogeneous. One of the most important books in embryology is his *Über Entwickelungsgeschichte der Thiere* (vol. 1, 1828; vol. 2, 1837; "On the Development of Animals"), in which he surveyed all existing knowledge on vertebrate development and from which he derived his far-reaching conclusions. He identified the neural folds as precursors of the nervous system, discovered the notochord, described the five primary brain vesicles, and studied the functions of the extra-embryonic membranes. This pioneering work established embryology as a distinct subject of research, at least in its descriptive aspects. He marked out the main lines of descriptive and comparative study that had to be accomplished before the modern approach—the causal analysis of development—could emerge.

In 1834 Baer moved to St. Petersburg, Russia, where he became a full member of the Academy of Sciences; he had been a corresponding member since 1826. His first duties were as librarian of the foreign division, but he eventually served the Academy in a variety of administrative positions. He retired from active membership in 1862 but continued to work as an honorary member until 1867. After moving to Russia, Baer abandoned embryology. Particularly interested in the Russian north, he became a courageous explorer there; he was the first naturalist to collect specimens from Novaya Zemlya, then uninhabited. During his extensive travels throughout Russia, he developed a great scientific and practical interest in its fisheries. He made significant discoveries in geography, including one concerning the nature of the forces responsible for the configuration of riverbanks in Russia.

Baer's travels also increased his long-standing interest in ethnography. He contributed to the Academy at St. Petersburg by establishing an extensive skull collection. As a result of his interest in skull measurements, he called a meeting of craniologists in Germany in 1861, which led to the establishment of the German Anthropological Society and the journal *Archiv für Anthropologie*. He was responsible also for the founding of the Russian Geographical Society and the Russian Entomological Society, of which he was the first president.

Assessment

In his early days as an embryologist Baer had begun to consider possible relationships, in terms of kinship, between animals. In 1859, the year that Darwin's *Origin of Species* appeared, Baer published a work on human skulls suggesting that stocks now distinct might have originated from one form; the ideas of the two men were formulated completely independently. Baer, however, was no strong adherent to the doctrine of transformation (the pre-Darwinian term for evolution). Although he believed that some very similar animals, such as goats and antelopes, might be related, he was vehemently against the concept expressed in the *Origin of Species* that all living creatures might have evolved from one or a few common ancestors.

In his philosophical writings—and all his embryological writings were philosophical to some degree—Baer saw nature as a whole, even though not in terms of modern evolutionary theory. He viewed the development of organisms and of the cosmos in the same light, and his all-encompassing view of the universe brought together what might otherwise have seemed diverging threads in his thought.

Following his retirement in 1867, Baer went to Estonia; he died in Dorpat (now Tartu) on November 28, 1876.

BIBLIOGRAPHY. BAER'S autobiography is *Nachrichten über Leben und Schriften*, 2nd ed. (1886). Two biographies in German (there are none in English), both entitled *Karl Ernst von Baer*, are by L. STIEDA, 2nd ed. (1886); and by B.E. RAIKOV (1968), both with extensive bibliographies. BAER'S *Entwickelungsgeschichte der Thiere, Beobachtung und Reflexion*, 2 vol. (1828–37), embodies his major discoveries and concepts in embryology; three volumes containing 700 letters by Baer are in course of publication; one has appeared by T.A. LUKINA (1970)—the letters are in Russian and German, the notes in Russian only; see also JANE OPPENHEIMER, "Baer, Karl Ernst von," in the *Dictionary of Scientific Biography*, vol. 1 (1970), for an analysis of his scientific contributions.

(J.M.O.)

Baffin Bay

A thumb-shaped extension of the North Atlantic Ocean, Baffin Bay is really a sea lying between the west coast of Greenland and the islands of the north Canadian Arctic

Archipelago. It extends northwest from the Davis Strait, which covers the Baffin-Greenland shelf (a submarine feature) at the latitude of the Arctic Circle, to latitude 80° north, where the narrow Nares Strait leads directly into the Arctic Basin. Jones and Lancaster sounds provide alternative links to the Arctic Basin through the Canadian Arctic Archipelago. Baffin Bay covers an area of 266,000 square miles (689,000 square kilometres)—slightly larger than Burma—and is about 900 miles (1,450 kilometres) long. A pit at its centre, the Baffin Hollow, plunges to a depth of 7,000 feet (2,100 metres), and the bay, although little exploited by man because of its hostile environment, is of considerable interest to geologists studying the evolution of the North American continent.

Exploration and scientific investigation

Baffin Bay also played an important role in the exploration of North America by Europeans. It was discovered in May 1615 by Robert Bylot, an English sea captain, but his supposedly mutinous tendencies prevented his name from being given to the entity, and the honour went instead to his lieutenant, William Baffin. Even the latter's discoveries came to be doubted until the later explorations of Captain (later Sir) John Ross, in 1818. The first scientific investigations since Bylot's map of the shores were conducted in 1928 by a Danish and also by an American expedition, followed by another, more extensive, survey in the 1930s. Patrol vessels, now aided by aircraft, have long investigated ice distribution in the region, and after World War II a Canadian expedition undertook complex investigations. (For related information see ARCTIC ISLANDS; GREENLAND; NORTHWEST TERRITORIES; and NORTHWEST PASSAGE. See also NORTH AMERICA; WESTERN ARCTIC CULTURES.)

The physical environment. Baffin Bay's oval floor is fringed by the submarine shelves of Greenland and Canada and by ledges at the mouths of sounds. Apart from the central pit, depths range from 800 feet in the north to 2,300 feet in the south. The sediments are mostly terrigenous (composed from earth materials, rather than from animal shell deposits) and include gray-brown homogeneous silts, pebbles, and boulders. Gravel lies everywhere.

The climate is severe, especially in winter, when northeast winds blow off Baffin Island (in the south) and in the bay's northern sector. Northwesterly and southwesterly winds predominate in summer. Easterlies blow off the Greenland coast, and storms are frequent, notably in the winter. January temperatures average −4° F (−20° C) in the south and −18° F (−28° C) farther north. The absolute minimum recorded is an icy −46° F (−43° C) at Jakobshavn, on the Greenland coast, but, paradoxically, there are occasional winter thaws occasioned by the warm, dry, foehn winds that sweep down from the valleys containing Greenland's glaciers. In July the temperature on the shores averages 45° F (7° C), with some snow. Overall, the annual precipitation off Greenland amounts to four to ten inches (100 to 250 millimetres), reaching twice this amount off Baffin Island.

The currents in Baffin Bay flow in a counterclockwise direction, as the West Greenland Current brings in about 35,000,000 cubic feet (990,000 cubic metres) of warm water across the threshold of Davis Strait. At the same time, about twice as much cooled water empties out into the Atlantic along the Baffin Island coast, as Arctic waters push in through the northern sounds. North of 72° N a zone of intensive counterclockwise currents forms an impediment to the West Greenland Current, which consequently hugs the Greenland coast (herding numerous icebergs northward in the process) from Disko Island to Thule (Greenland), at the Bay's northeast tip, where the current turns left into the cold flow.

Icebergs are dense even in August: the ice cover is formed from Arctic pack ice entering through the northern sounds, from local sea ice, and from icebergs that have broken off adjacent glaciers. By late October icefields reach Hudson Strait (between Baffin Island and the Quebec mainland), a region where coastal ice has already been thickening, mostly near Greenland, where prevailing easterly winds make for sheltered conditions. The centre of Baffin Bay is covered with compounded ice in winter, but in the north there is actually a permanent ice-free area (the "northern water") that may be related to the warming effect of the West Greenland Current. Iceberg concentration in the bay is similarly affected. By origin, about 70 percent of the icebergs that drift down to the Newfoundland area have been found to come from glaciers pushing into Baffin Bay between 69° N and 71°40′ N, whereas some 20 percent are formed still further north, in the Melville Bay area, just south of Thule. The largest icebergs are thrust out into the unimpeded waters of the "northern water" area and can be 230 feet long above the surface, reaching down to 1,300 feet below.

The "northern water" icebergs

Sea-water temperature and salinity follow naturally from the ice distribution, currents, and the submarine and other topographic influences already described. The salinity of Arctic waters flowing into Baffin Bay ranges from 30.0 to 32.7 parts per thousand (‰) and their temperature warms up to 41° F (5° C) on the surface in summer, cooling in winter to 29° F (−2° C). The layers 1,300 to 2,000 feet deep reach 34° F (1° C) and a salinity of 34.5 ‰. Below 3,300 feet in the central regions, the water—probably Atlantic in origin—reaches 31° F (−0.5° C), and has a salinity of 34.4 ‰.

Tides are an important and interesting feature: near Baffin Island and the shores of Greenland, the tidal range is about 13 feet, reaching as much as 30 feet where the water is forced through narrow passages. The tidal rate varies between 0.6 and 2.3 miles per hour and the direction of the tides varies by as much as 180°. This phenomenon produces unequal pressure on the fields of floating ice and results in the churning together and crushing of fresh, old, and pack ice. The tidal currents also mix the water layers, enriching the upper strata with nutrient salts and the lower ones with dissolved oxygen.

The biological environment. The dissolution of salts in the water and the warming effect of the currents moving in from the south encourage the development of lifeforms from the smallest creatures of the sea to whales. The numerous single-cell algae nourish small invertebrates, notably euphausiids (an order of small, shrimplike crustaceans), and these in turn are food for larger invertebrates, fish, birds, and mammals. Baffin Bay contains Arctic flounder, four-horned sculpin (a spiny, large-headed, broad-mouthed fish), polar cod, and capelin (a small fish of the smelt family). Migrant fish from Atlantic waters include cod, haddock, herring, halibut, and grenadier (a tapering-bodied, soft-finned fish). Wildlife also includes ringed seals, bearded seals, harp seals, and —in the north—walrus, dolphins, and whales (including killer whales). The coasts are homes of gulls, ducks, geese, eiders, snowy owls, snow buntings (a type of finch), ravens, gerfalcons, linnets, and sea eagles.

Plant cover, too, is remarkably varied, with about 400 types represented. Shrubs include birch, willow, and alder, and also halophytic plants (*e.g.*, those adapted to salty soils), as well as lyme (or tussock) grass, mosses, and lichens. These provide food for rodents and the splendid caribou of the area. Polar bears and Arctic foxes also abound. Large-scale fishing remains undeveloped because of the perils of the heavy ice cover, but local residents—who are mainly Eskimos—carry on some fishing and hunting, often with traditional methods.

BIBLIOGRAPHY. FARLEY MOWAT (ed.), *Ordeal by Ice* (1960), is a collection of original sketches of British expeditions carried out through the 16th–19th centuries, including a history of the discovery of Baffin Bay. See also W.B. BAILEY, "Oceanographic Features of the Canadian Archipelago," *J. Fish. Res. Bd. Can.*, 14:731–769 (1957).

Bagehot, Walter

Walter Bagehot has been described as Victorian England's most versatile genius; essentially he was one of the most influential British journalists of the mid-Victorian years as editor of *The Economist* from 1860 until his early death in 1877. But in addition, he wrote a series of literary essays that have been continually republished

throughout the past century, a book on British politics that remains a widely read classic, and one of the earliest sociological studies to apply the concept of evolution to societies themselves; in addition, he made an important contribution to the theory of central banking. "Had I command of the culture of men," wrote U.S. president Woodrow Wilson, "I should wish to raise up for the instruction and stimulation of my nation more than one sane, sagacious, critic of men and affairs like Walter Bagehot." "Those who have the good fortune to know him still remember him as perhaps the most original mind of his generation," wrote Lord Bryce, British ambassador in Washington and the author of *The American Commonwealth*.

Bagehot, mezzotint by Norman Hirst (born 1862), after a photograph.

Bagehot was born at Langport, Somerset, on February 3, 1826. His father's family had been general merchants there for several generations, whereas his mother—who was a great beauty but was ten years older than his father and had had a tragic first marriage—was a sister of Vincent Stuckey, the head of the largest bank in the west of England. It was the opinion of his relations that his acute political sense derived from his father, whereas the sparkle and originality of his mind came from his mother, even though she became partly insane as she grew older.

Education

Bagehot had the severe schooling of an early Victorian. As a child he went to Langport Grammar School, which had a famous headmaster who had been a friend of the poet Wordsworth; at 13 he was sent to Bristol College, one of the best schools in Great Britain. There he received a grounding in philosophy, mathematics, literature, the classics, and the new natural sciences, of an intensity that no English child today would be thought capable of assimilating.

The obvious university to choose was University College, London, because his father was a Unitarian, and Oxford and Cambridge in those days were dogmatically Anglican. He was a "lanky youth, rather thin and long in the legs with a countenance of remarkable vivacity and characterised by the large eyes that were always noticeable," wrote Sir Edward Fry, one of his friends at Bristol. He had a rather sardonic manner that did not endear him to all of his contemporaries, but he did make a number of lasting friends at University College, notably Richard Holt Hutton, who was for the latter part of the century the distinguished editor of *The Spectator;* William Roscoe, the grandson of the famous historian of the Medicis; Arthur Hugh Clough, the poet; and, of an older generation, Henry Crabb Robinson, who had been the friend of Goethe, Schiller, and Coleridge, and *The Times* correspondent in the Napoleonic Wars. In 1846 Bagehot took his bachelor's degree with first-class honours, despite bad health, and in 1848 his master's degree with the university's gold medal in moral and intellectual philosophy.

For three years after graduation, he studied at the bar but he never liked it, and it was chance that took him into literature. He happened to be in Paris at the end of 1851, when Louis Napoleon's coup d'état took place, and he wrote a series of articles in the leading Unitarian weekly journal of the day describing the coup at first-hand and defending Napoleon. These articles caused much controversy because the coup was widely disapproved of in England. But they convinced Bagehot that he could write, and he settled down to work in his uncle Stuckey's bank, writing in the next six or seven years a series of literary essays on Milton, Shakespeare, Gibbon, Sir Walter Scott, Pierre-Jean de Béranger, together with studies of leading political figures of the past century—Henry St. John Bolingbroke, William Pitt, Sir Robert Peel, and others—that are still widely quoted.

His entry into professional journalism was also accidental. In his role as a banker, he had written various economic articles that had attracted the attention of James Wilson, the man who had founded *The Economist* in 1843 and who was then an influential member of Parliament and financial secretary to the treasury in Lord Palmerston's government. Wilson asked Bagehot to stay, and he immediately fell in love with Eliza, the eldest of Wilson's six daughters. They were married in April 1858, but they had no children, and it is doubtful if Eliza's rather cold personality really suited the warmth and vigour of her husband's.

Work on *The Economist*

He went back to manage the Bristol branch of Stuckey's bank. But a year later Wilson was asked to go to India to reorganize the finances of the Indian government, and he died in Calcutta in 1860, leaving Bagehot in charge of *The Economist*. For 17 years he wrote the main article and improved and expanded the statistical and financial sections that have made it the leading business journal and one of the leading political journals of the world for more than 100 years. More than that, he humanized its political approach with a greater emphasis on social problems. As the American political scientist Walt Rostow has commented, "*The Economist* was not simply the hard bitten advocate of the mid Victorian capitalist."

Bagehot described himself as a conservative Liberal or "between size in politics." Unlike many Liberals, he had grown up in the deep countryside, and he had a strong feeling for the social problems that rapid industrialization and urbanization were creating in Britain. He was also an acute observer of international affairs, with an instinctive affection for France and an equal distrust of Otto von Bismarck's Germany. His early years at *The Economist* coincided with the American Civil War, on whose development he wrote nearly 20 articles; instinctively, he was a Confederate like many of his British contemporaries, but his reason made him a supporter of Abraham Lincoln, of whom he wrote on the day the news of his assassination reached England:

> We do not know in history such an example of the growth of a ruler in wisdom as was exhibited by Mr. Lincoln. Power and responsibility visibly widened his mind and elevated his character. Difficulties, instead of irritating him as they do most men, only increased his reliance on patience; opposition, instead of ulcerating, only made him more tolerant and determined.

In 1867 he published *The English Constitution*, which was an attempt to look behind the facade of the British system of government—crown, Lords, and Commons—in order to see how it really operated and where true power lay. He was one of the first to observe the overriding power of the Cabinet in a party that commanded an effective majority in the House of Commons. He cultivated a number of close political friendships, notably with William Ewart Gladstone, who became the first Liberal prime minister in 1868; with Lord Carnarvon among the Conservatives (the author of the British North America Act, the constitution of Canada); and with William Edward Forster (the author of the first public education act in Britain).

Bagehot never succeeded, however, in entering politics himself. He tried at Manchester, at Bridgwater near his Somerset home (a district that had a notorious reputation

for corruption), and in 1867 for London University. But he was a poor speaker and failed each time.

In 1872 Bagehot published *Physics and Politics*, which was an attempt to apply the new discoveries in anthropology to the development of societies and nations themselves. It is largely forgotten by reason of the vigour acquired by sociological investigation in the 20th century, largely under the stimulus of Karl Marx and Max Weber. But one of its central points, the process of unconscious imitation as a molding force in the development of nations—what Bagehot called "the cake of custom"—had a considerable influence on such philosophical sociologists as William James and Graham Wallas.

All this time, Bagehot and his wife were living in London and he was editing a weekly of growing influence. In his 40s, he became increasingly frail, and such energy as he had was concentrated on professional economic studies. In 1873 he published *Lombard Street*, which, though really a tract arguing for a larger central reserve in the hands of the Bank of England, in fact contains the germ of the modern theory of central banking and exchange control. He was working on a major series of economic studies when pneumonia struck him down on March 24, 1877, at the age of 51. The economist John Maynard Keynes, two generations later, paid tribute to his insight into business psychology.

But the greatest tribute to Bagehot's lively style, humanity, and insight is that his books have been read, republished, and subjected to a continuous stream of critical essays ever since his death. He once made fun of Thomas Macaulay for seeking posthumous fame but has, nevertheless, received a good measure of it himself.

Collected works: EMILIE I. BARRINGTON (ed.), *The Works and Life of Walter Bagehot*, 10 vol. (1915), series containing his books, most of his essays, and over 50 of his *Economist* articles; *The Collected Works of Walter Bagehot*, ed. by NORMAN ST. JOHN-STEVAS (1966–), a more comprehensive edition containing considerably more journalistic material. Vol. 1 and 2, *The Literary Essays*, with an introduction by SIR WILLIAM HALEY, and vol. 3 and 4, *The Historical Essays*, with an introduction by JACQUES BARZUN, have already been published.

Critical works: JOHN MAYNARD KEYNES, "The Works of Bagehot," *Economic Journal*, 25:369–375 (1915), an estimate of Bagehot as an economic writer by the greatest economist of his day; SIR HERBERT E. READ, "Bagehot," in *The Sense of Glory: Essays in Criticism* (1929), a sensitive critique of Bagehot as a litterateur; WOODROW WILSON, "A Wit and a Seer," *Atlantic Monthly*, 82:527–540 (1898), one of the earliest works drawing attention to Bagehot's gifts and versatility by one of his greatest American admirers; GEORGE M. YOUNG, "The Greatest Victorian," in *Today and Yesterday: Collected Essays and Addresses* (1948), an excellent brief portrait.

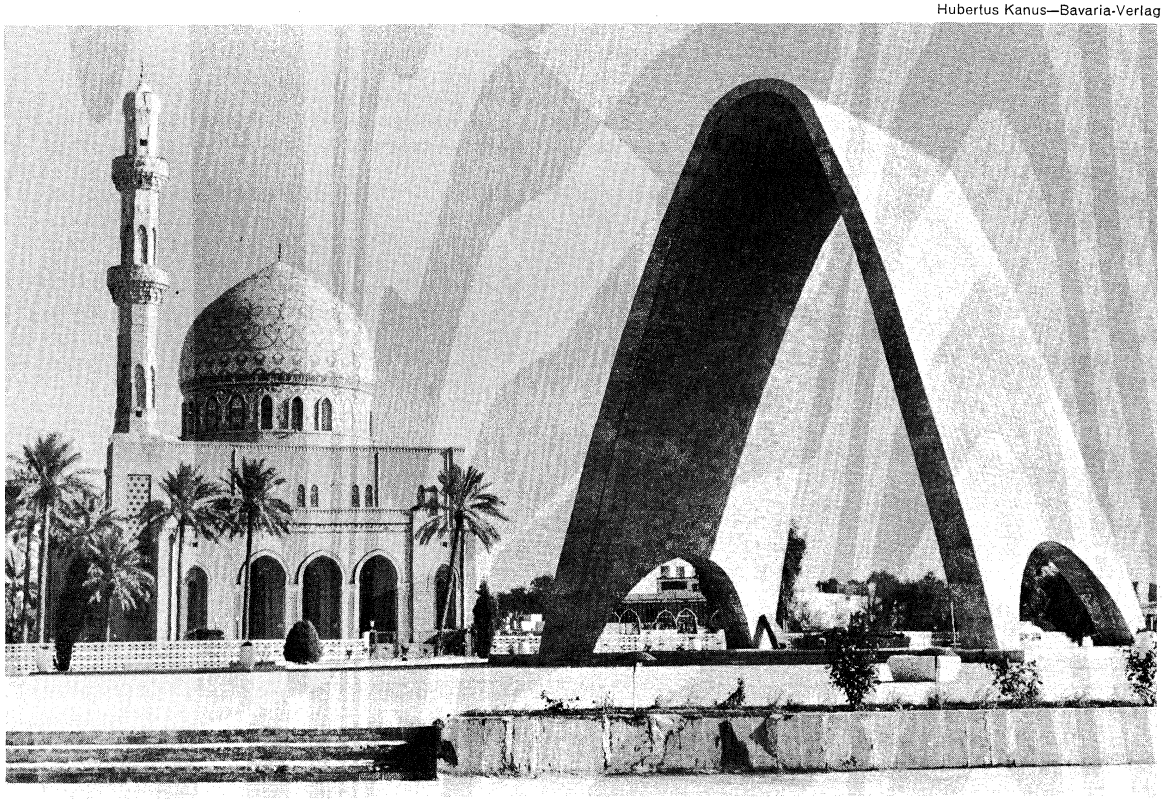
(A.F.B.)

Baghdad

Baghdad, the foremost city of ancient Mesopotamia, is the largest city and the capital of modern Iraq and of the *muḥāfaẓah* (province) of Baghdad. It is situated on the Tigris River in north central Iraq about 350 miles (560 kilometres) northwest of the Persian Gulf. Since the overthrow of the monarchy in 1958, the capital city has been the scene of political turmoil as the country has tried to establish itself as a modern, Socialist, Pan-Arab state. The population of the city early in the 1970s was over 2,100,000.

History. Many capital cities have stood in the vicinity of Baghdad: Agade, Babylon, and Burj ʿAqarqūf, the Kassite capital, lay to the west; Seleucia and Ctesiphon lay about 20 miles to the south. In AD 750 the caliphate was established in Iraq with the foundation of the ʿAbbāsid dynasty by Abū al-ʿAbbās as-Saffāḥ, whose brother and successor, Abū Jaʿfar, known as al-Manṣūr, determined in 762 to build himself a new capital on the site of a Sāsānian village, Baghdad. The Round City of Manṣūr, called Madīnat as-Salām (City of Peace), stood on the west bank of the Tigris, but no traces of its buildings remain, and its exact site is unknown. It was 3,000 yards (2,700 metres) in diameter, with three concentric walls each pierced by four gates, through which passed highways radiating from the caliphal palace at the centre of

Hubertus Kanus—Bavaria-Verlag



Mosque and arch to the Unknown Soldier in Baghdad, Iraq.

the city to the four quarters of the empire. Bazaars were not permitted within the city, and a merchants' quarter, al-Karkh, developed outside the Basra Gate. From the northeast gate the Khorāsān road crossed the Tigris on a pontoon bridge, and beyond this on the east bank lay the palace of al-Manṣūr's heir apparent, al-Mahdī, around which grew up the three suburbs of ar-Ruṣāfah, ash-Shammāsīyah, and al-Mukharrim, the earliest forerunners of the modern city. Baghdad reached the zenith of its prosperity in the 8th and early 9th centuries under Hārūn ar-Rashīd, son of al-Mahdī, who accumulated in his capital the riches and learning of the known world. Many tales reflecting the glory of this period occur in *The Thousand and One Nights*. Hārūn's death was followed by civil war between his two sons, during which the Round City was severely damaged. It was never fully restored; from 836 to 892 the caliphs abandoned Baghdad, where their unruly Turkish bodyguard had become unpopular, for a new capital at Sāmarrā' and after their return at the end of the 9th century they resided in Mukharrim on the east bank. In 1095 a new wall was built around east Baghdad, which survived with many restorations until the 19th century, when it was largely dismantled. One of the two surviving gates, the Talisman Gate, was blown up by the retreating Turks in 1917; the second, Bāb al-Wastanī, or the Middle Gate, still stands and was restored as an arms museum.

Baghdad at its zenith

Despite the declining power of the later caliphs, Baghdad remained a great centre of trade and culture as long as the agricultural prosperity of Iraq continued. Its real downfall came when Hülegü, the Mongol, overran Mesopotamia and sacked Baghdad in 1258, killing the caliph al-Musta'ṣim and, it is said, 800,000 of the inhabitants. The overthrow of the 'Abbāsid government removed the authority that had secured the maintenance of the irrigation system and the protection of the cultivated land against nomadic tribesmen. With its political importance gone, its population decimated, and the economic basis of its life destroyed, Baghdad never again rose above the status of a provincial city until the emergence of Iraq as an independent state after World War I. It remained subject to the Il-Khanid dynasty, successors of Hülegü, until 1340, when it achieved local independence under the Jalāyirids, who made some attempt to restore its fortunes. In 1401 the city was sacked by the last of the Mongol invaders, Timur (Tamerlane), and in 1410 fell under the sway of the Kara Koyunlu (Black Sheep) Turkmens, who gave way in 1469 to the Ak Koyunlu (White Sheep) dynasty. They in turn were expelled by the Persians under Shāh Esmā'īl I in 1508, and in 1534 Baghdad was taken for the first time by the Ottoman Turks under Süleyman I the Magnificent. It was recaptured by the Persian Shāh 'Abbās I in 1623 but was recovered for Turkey by Murad IV in 1638; its frequent changes of allegiance were due in part to its geographical position between the two great empires and in part to the division of its inhabitants between the Shī'ah and the Sunnī sects of Islām, the former favouring the Persian and the latter favouring the Turkish rule. During the 17th century a rapid succession of Turkish governors did little to restore the fortunes of Baghdad. The beginning of the 18th century, however, saw the appointment of two successive governors, father and son, Ḥaṣan and Aḥmad Pasha, who reformed the administration by introducing the slave hierarchy of Circassian civil and military officials known as the Mamlūks and raised the prestige of their capital until it controlled Mesopotamia from Basra to Mardin, owing only a formal allegiance to Istanbul. They were succeeded by a line of Mamlūk governors until the abolition of the Mamlūk system by Sultan Mahmud II in 1831. During the Mamlūk period foreign, notably British, influence became more marked in Baghdad. A British residency was established in the city in 1798, and in 1802 the resident was granted consular rank; under C.J. Rich (1808–21) and H.C. Rawlinson (1843–55) the prestige of the resident was second only to that of the governor. Baghdad was captured by British forces in 1917 and became the capital of the independent kingdom of Iraq in 1921. The city was the scene of an abortive revolt, inspired by anti-British feeling, in 1942 and of a successful army-led coup d'etat in 1958, when the monarchy was overthrown. Another Baghdad coup d'etat in 1963 brought the Ba'th Party to power, which it held briefly and regained in 1968.

Alternate Turkish and Persian control

The contemporary city. *The city site and layout.* The city's situation on the Tigris River is at the river's nearest point to the Euphrates (25 miles) and 20 miles above the Tigris' confluence with its largest tributary, the Diyālā. The site is a level plain at an altitude of 112 feet (34 metres) above sea level. The city was originally built on the west bank of the river, but for more than 1,000 years the greater part has been on the east bank. There is, however, a large and growing suburb on the west side, comprising the quarters of al-Karkh, Karradet Mariam, and al-Manṣūr. The east-bank city is linked with these quarters by bridges, one of which carries a railway. A bridge also leads to Kāẓimayn (Kadjimain), north of al-Karkh, a considerable settlement that has grown up around the tombs of Mūsā al-Kāẓim and Muḥammad al-Jawād, the seventh and ninth of the 12 *imāms* recognized as the true successors of the Prophet by the majority of Shī'ite Muslims. Although the distinction between the city and the metropolitan area appears imprecise, the area of the former is about 14 square miles and that of the latter, 75 square miles.

Climate. Summers (May–October) are dry and intensely hot. Average daily temperatures in July and August are about 80° F (27° C) before sunrise and 105° to 110° F (41° to 43° C) and up to 122° F (50° C) at midday, but they drop below 76° F (24° C) at night. Winters are cooler, with daily average temperatures about 55° F (13° C). The prevailing dry, northwesterly winds, known as *shamāl*s, bring some relief from the heat but also produce dust storms, especially in July. Rainfall averages about five inches (130 millimetres) per year.

Traditional neighbourhoods. The crowded houses and shops of the old city, which were not for the most part of great antiquity or interest, and the labyrinthine lanes and alleys are being replaced by wide streets and new office blocks, stores, and hotels so that the appearance of the old city was gradually changing in the 1970s. Copper, silver, cloth, and other bazaars remain, as do many old buildings, sidewalk cafes, and characteristic minarets and mosques. On the west side of the river is the parliament building, as well as the foreign embassies at the capital. Such principal suburbs as al-Karkh, Karradet Mariam, and al-Manṣūr have their own bazaars and shops, and residential garden suburbs have grown up on both sides of the river. The completion of the Tigris barrage at Sāmarrā' in 1956 relieved Baghdad of the danger of disastrous floods, which caused severe damage on many occasions in history. Flood control made possible an outward expansion of the city, and its new city plan is circular in shape, encompassing both sides of the river.

Changing appearance and expansion

Transportation. Transportation within the city is provided by buses and taxis. Motor traffic has increased sharply since about 1950. The city, which grew up at the intersection of the ancient trade routes from Persia and the Far East down the Diyālā Valley to Baghdad and then up the Euphrates Valley to Syria and on to the Mediterranean or up the Tigris Valley to Armenia and the Black Sea, is still the communications centre of the region. In the 19th century a number of plans were put forward to improve the communications of Baghdad. A survey of the Euphrates and the Lower Tigris was made in 1836, and in 1860 a regular steamer service was established on the Tigris between Baghdad and Basra. By the mid-20th century, river traffic had declined in importance, although in the 1970s there was still some barge traffic on the Tigris between Baghdad and Basra.

The intersection of ancient trade routes

The three major railway lines of the state-owned and operated system all meet at Baghdad. A line runs north to Mosul; not until 1940 was the capital finally linked with Europe by rail when the Baghdad Railway across Syria to Istanbul was completed. One line connects Baghdad with Basra, and another, from Irbīl through Kirkūk, connects it with the northeast provinces.

A regular motor service between Baghdad and Damascus was established in 1923, and in the second half of the 20th century the city was served by highways, most of them following the traditional routes, connecting it to all of Iraq's major cities. Air-conditioned motor coaches transport many of the pilgrims from Iran. The Cairo–Baghdad airmail service was inaugurated in 1921 and was followed by passenger service in 1929. The city has two civilian airports. Its international airport was dedicated in 1970.

Demography. The population of the city in 1970 was over 2,100,000, compared with 1,600,000 in 1965. The rapid growth of the city has resulted in a shortage of housing for recent arrivals, in spite of low-cost public housing projects. The overwhelming majority of the population are Arab. Minor elements include Kurds, Lurs, Afghans, Armenians, Iranians, Sabaeans, and others. The principal language is Arabic, the official language of Iraq. The principal religion is Islām, with the Muslims divided between the two major sects of Sunnī and Shīʿah. The mosques and tombs at Kāẓimayn are Shīʿite shrines, but Baghdad also has a large population of Sunnites. There are a sizable number of Christians. Most of the former Jewish community have migrated to other countries.

Housing and architecture. As in other rapidly growing cities, the influx of population has resulted in housing shortages, and the construction of housing projects has not kept up with housing needs. Such large-scale construction projects as the straightening and widening of streets and the erection of large, modern office and commercial buildings have not only reduced the number of housing units in some areas but have also attracted large numbers of workers seeking jobs. Fortunately, flood control is permitting the city to expand.

The architecture of the city ranges from ancient oriental bazaars and alleys to modern steel, glass, and stone hospitals and hotels. Examples of 13th-century architecture surviving from the ʿAbbāsid period include the ʿAbbāsid palace and the Mustanṣirīyah, a large law college built and endowed by the caliph al-Mustanṣir in 1232; both were restored as museums. Another notable group of buildings surviving from the 14th century includes a mosque and college built in 1358 by Mirjān ibn ʿAbd Allāh, a Jalāyirid governor of Baghdad, together with a fine vaulted *khān* (caravansary, or inn) that is now the Museum of Arab Antiquities. The 100 or more mosques and minarets, including the spectacular gold-domed mosque at Kāẓimayn, completed in the 19th century, add to the architectural interest of the city. Modern structures include the royal mausoleum of King Fayṣal I, founder of the monarchy, the White Palace (government guesthouse), city hall, the ministry of defense building, the Royal Bilat (now the Republican Palace), the buildings of al-Hikma University at Zaʿfarānīyah, and the New Iraq Museum.

Economic life. After World War II Iraq's oil revenues considerably increased, and the new wealth of the country is reflected in the capital, the merchants of which are concerned with the import and distribution and, to a lesser but growing extent, with the manufacture of capital and consumer goods. Most Iraqi industries are in Baghdad and include leather, silks, cotton stuffs, bricks, cement, tobacco products, and the distilling of the alcoholic beverage arrack (from dates and grapes). There are also railway workshops and a steel mill. The country's financial services also are concentrated in the capital, including the Central Bank of Iraq, which has the sole right of issuing currency.

Concentration of industries

Government and services. The city has a military governor and a mayor (*amīn ʿāl-ʿāṣimah*, "guardian of the capital"); the province also has a governor. Baghdad is also the site of the national government and the headquarters of its principal organs and agencies.

Educational facilities were rapidly expanded after the revolution and in Baghdad more nearly achieved the aim of universal compulsory education. Higher education is available free at the University of Baghdad (founded 1958). Also in Baghdad are al-Hikma University of Baghdad (1956), al-Mustansiriya University (1963), four colleges, including the Higher Technical Institute (1960), and the Institute of Fine Arts (1936).

The capital also has been the first to benefit from new housing programs for the poor and from the expansion of health and welfare services and facilities, including new hospitals and clinics. The city's electric-power plants and water-supply facilities are state owned and operated.

Cultural life. As may be inferred from the city's history and its many mosques and minarets, much of its cultural life has centred on its religious sects. The tombs of the two *imams* and the adjacent mosque at Kāẓimayn are among the most important places of Shīʿah pilgrimage.

The Kāẓimayn tombs and mosque

Libraries include al-Awqāf (Library of Waqfs; founded 1929), with collections of Arabic history and literature, and Central Library of the University of Baghdad (1960), which is the depository for Iraqi publications and serves as Iraq's International Exchange Centre. Other cultural institutions include the ʿAbbāsid Palace Museum (1935), the Arms Museum (1940), the Costumes and Ethnographic Museum (1941), The Iraq Museum (1923, reformed 1966), the Iraq Natural History Museum (1946), the Museum of Arab Antiquities (1937), and the National Museum of Modern Art (1963). There are also a number of learned societies in the arts and sciences.

The media. Baghdad had half a dozen or more major daily papers in the 1970s, az-Zaman being generally regarded as the most important. In addition there are political weeklies and periodical technical journals and government publications on education and other subjects. English being the most widely known foreign language, British and U.S. newspapers and periodicals also are read in the capital.

Radio and television have been nationally owned since 1967. Radio Baghdad is Iraq's only station and broadcasts to the entire country over several frequencies and in several languages. Baghdad's television station, the first in any Arabian country, went into operation in 1956.

BIBLIOGRAPHY. Up-to-date literature on Baghdad is sparse, although there are a number of works covering the city's history, such as GUY LE STRANGE, *Baghdad During the Abbasid Caliphate: From Contemporary Arabic and Persian Sources* (1900, reprinted 1924); STEPHEN H. LONGRIGG, *Four Centuries of Modern Iraq* (1925) and *Iraq, 1900 to 1950* (1953); NABIA ABBOTT, *Two Queens of Baghdad, Mother and Wife of Harūn al-Rashīd* (1946); and TAHA BAQIR, *Baghdad* (1959). The early history of modern transportation is covered in MAYBELLE REBECCA CHAPMAN, *Great Britain and the Baghdad Railway, 1888–1914* (1948). ROBERT M. ADAMS, *Land Behind Baghdad* (1965), is a technical study concerning the changing patterns of irrigation, agriculture, and urban settlement. An intimate account of Baghdad itself is given by FREYA STARK in *Baghdad Sketches* (1937).

(E.E.D.M.O.)

Bahā'ī Faith

Bahā'ī faith is a religion founded by Mīrzā Husayn ʿAli (1817–1892; known as Bahā' Allāh, or Bahaullah, Glory of God). The word Bahā'ī derives from *bahā* ("glory, splendour") and signifies a follower of Bahā' Allāh. The religion stemmed from the Bābī faith—founded in 1844 by Mīrzā ʿAlī Moḥammad of Shīrāz, known as the Bāb—which emphasized the forthcoming appearance of "Him Whom God Shall Make Manifest," a new prophet or messenger of God. The Bābī faith in turn had sprung from Shīʿah Islām which believed in the forthcoming return of the 12th *imām* (successor of Muḥammad), who would renew religion and guide the faithful. This messianic view was the basis of the teachings of the Shaykhī sect, so named after Shaykh Aḥmad al-Ahsā'ī. Shaykh Aḥmad and his successor, Sayyid Kāẓim Rashtī, abandoned traditional literalism and gave allegorical interpretations to doctrines such as resurrection, the Last Judgment, and the return of the 12th *imām*. They and their followers (known as Shaykhīs) came to expect the appearance of the Qā'im ("He Who Arises," the 12th *imām*) in the immediate future.

On May 22, 1844, in Shīrāz, Persia, a young descendant of Muḥammad, Sayyid ʿAlī Muḥammad, proclaimed to a learned Shaykhī divine, Mullā Ḥusayn al-Bushrū'ī, that

he was the expected Qā'im, whereupon Mullā Ḥusayn became the first disciple of Sayyid ʿAlī Muḥammad, who assumed the title of the Bāb ("gate," or channel of grace from someone still veiled from the sight of men).

Soon the teachings of the Bāb, the principal of which was the tidings of the coming of "Him Whom God Shall Make Manifest," spread all over Persia, provoking strong opposition on the part of the clergy and the government. The Bāb was arrested and, after several years of incarceration, condemned to death. In 1850 he was brought to Tabriz, where he was suspended by ropes against a wall in a public square. A regiment of several hundred soldiers fired a volley. When the smoke cleared, the large crowd that had gathered at the place of execution saw ropes cut by bullets but the Bāb had disappeared. He was found unhurt in an adjacent building, calmly conversing with a disciple. The execution was repeated, this time effectively. There followed large-scale persecutions of the Bābīs in which ultimately more than 20,000 people lost their lives.

History and extent. Bahā' Allāh, who had been an early disciple of the Bāb, was arrested in connection with an unsuccessful attempt on the life of the *shāh* of Persia, Nāṣer od-Dīn, made in August 1852 by two Bābīs intent upon avenging their master. Though Bahā' Allāh had not known of the plot, he was thrown into the Black Pit, a notorious jail in Teheran, where he became aware of his mission as a messenger of God. He was released in January 1853 and exiled to Baghdad. There Bahā' Allāh's leadership revived the Bābī community, and an alarmed Persian government urged the Ottoman government to move both Bahā' Allāh and the growing number of his followers farther away from Persia's borders. Before being transferred to Constantinople, Bahā' Allāh spent 12 days in a garden on the outskirts of Baghdad, where in April 1863 he declared to a small number of Bābīs that he was the messenger of God whose advent had been prophesied by the Bāb. From Constantinople, where Bahā' Allāh spent some four months, he was transferred to Adrianople. There he made a public proclamation of his mission in letters ("tablets") addressed to the rulers of Persia, Turkey, Russia, Prussia, Austria, and Britain, as well as to the pope and to the Christian and Muslim clergy collectively.

Role of Bahā' Allāh

An overwhelming majority of the Bābīs acknowledged Bahā' Allāh's claim and thenceforth became known as Bahā'īs. A small minority followed Bahā' Allāh's half brother, Mīrzā Yaḥyā Ṣobḥ-e Azal, creating a temporary breach within the ranks of the Bābīs. Embittered by his failure to win more than a handful of adherents, Mīrzā Yaḥyā, assisted by his supporters, provoked the Turkish government into exiling Bahā' Allāh to ʿAkkā (ʿAkko, Acre), Palestine. He became, however, a victim of his own intrigues and was himself exiled to Cyprus.

For almost two years, Bahā' Allāh, his family, and a number of disciples were confined in army barracks converted into a jail. One of his sons and several companions died. When the severity of the incarceration abated, Bahā' Allāh was permitted to reside within the walls of ʿAkkā and later in a mansion near the town. Before his life ended in 1892, Bahā' Allāh saw his religion spread beyond Persia and the Ottoman Empire to the Caucasus, Turkistan, India, Burma, Egypt, and the Sudan.

Bahā' Allāh appointed his eldest son, ʿAbd ol-Bahā' ("Servant of the Glory," 1844–1921), as the leader of the Bahā'ī community and the authorized interpreter of his teachings. ʿAbd ol-Bahā' not only administered the affairs of the movement from Palestine but also actively engaged in spreading the faith, travelling in Africa, Europe, and America from 1910 to 1913. ʿAbd ol-Bahā' appointed his eldest grandson, Shoghi Effendi Rabbānī (1896–1957), as his successor, Guardian of the Cause, and authorized interpreter of the teachings of Bahā' Allāh, thus assuring the continued unity of the believers.

Expansion of the Bahā'ī movement

During ʿAbd ol-Bahā' 's ministry, Bahā'ī groups were established in North Africa, the Far East, Australia, and the United States. Since then the movement has spread to virtually every country in the world, with particularly large and vigorous communities in Africa, Iran, India, the United States, and certain areas of Southeast Asia and the Pacific. No official membership statistics for the entire Bahā'ī community are available. In 1971, however, Bahā'īs resided in more than 50,000 localities throughout the world, with more than 100 national spiritual assemblies (national governing bodies) and no fewer than 6,000 local spiritual assemblies. A current plan of worldwide expansion envisages the formation of 120 national spiritual assemblies and 13,833 local spiritual assemblies by April 1973 (600 of these in the United States). Bahā'ī literature has been translated into more than 400 languages. By 1970 more than 300 African tribes, some 100 American Indian tribes, and nearly 100 tribes and peoples of the Indian subcontinent and the Pacific Ocean were represented in the Bahā'ī community. In the 1960s and early 1970s the Bahā'ī faith was undergoing a period of extremely rapid expansion.

Bahā'ī House of Worship, Wilmette, Illinois.

Sacred literature. Bahā'ī sacred literature consists of the total corpus of the writings of Bahā' Allāh and their interpretation and amplification in the writings of ʿAbd ol-Bahā' and Shoghi Effendi. Bahā' Allāh's literary legacy of more than 100 works includes *al-Kitāb al-Aqdas* ("The Most Holy Book"), the repository of his laws; the *Ketāb-e Īqān* (*The Book of Certitude*), an exposition of essential teachings on the nature of God and religion; *The Hidden Words*, a collection of brief utterances aimed at the edification of men's "souls and the rectification of their conduct"; *The Seven Valleys*, a mystic treatise that "describes the seven stages which the soul of the seeker must needs traverse ere it can attain the object of its existence"; "Epistle to the Son of the Wolf," his last major work; as well as innumerable prayers, meditations, exhortations, and epistles. The Bahā'īs believe that the writings of Bahā' Allāh are inspired and constitute God's revelation for this age.

Religious and social tenets. Bahā' Allāh teaches that God is unknowable and "beyond every human attribute, such as corporeal existence, ascent and descent, egress and regress." "No tie of direct intercourse can possibly bind Him to His creatures . . . . No sign can indicate His presence or His absence . . . ." Human inability to grasp the divine essence does not lead to agnosticism, since God has chosen to reveal himself through his messengers, among them Abraham, Moses, Zoroaster, Buddha, Jesus, Muḥammad, and the Bāb, who "are one and all the Exponents on earth of Him Who is the central Orb of the universe . . . ." The messengers, or, in Bahā'ī terminology, "manifestations," are viewed as occupying two "stations," or occurring in two aspects. The first "is the station of pure abstraction and essential unity," in which one may speak of the oneness of the messengers of God because they are all manifestations of his will and exponents of his word. This does not constitute syncretism,

since "the other station is the station of distinction . . . . In this respect, each manifestation of God hath a distinct individuality, a definitely prescribed mission . . . ." Thus, while the essence of all religions is one, each has specific features that correspond to the needs of a given time and place and to the level of civilization in which a manifestation appears. Since religious truth is considered relative and revelation progressive and continuing, the Bahā'īs maintain that other manifestations will appear in the future, though not, according to Bahā' Allāh, before the expiration of a full thousand years from his own revelation.

In Bahā'ī teachings, God is, and has always been, the Creator. Therefore, there was never a time when the cosmos did not exist. Man was created through God's love: "Veiled in My immemorial being and in the ancient eternity of My essence, I knew my love for thee: therefore I created thee." The purpose of man's existence as taught by Bahā' Allāh is to know and to worship God and "to carry forward an ever-advancing civilization . . . ." Man, whom Bahā' Allāh calls "the noblest and most perfect of all created things," is endowed with an immortal soul, which, after separation from the body, enters a new form of existence. Heaven and hell are symbolic of the soul's relationship to God. Nearness to God results in good deeds and gives infinite joy, while remoteness from him leads to evil and suffering. To fulfill his high purpose, man must recognize the messenger of God within whose dispensation he lives and "observe every ordinance of him who is the desire of the world. These twin duties are inseparable. Neither is acceptable without the other."

Goals of Bahā'ī faith

Civilization, Bahā' Allāh teaches, has evolved to the point where unity of mankind has become the paramount necessity. The Bahā'ī faith, in the words of Shoghi Effendi,

> proclaims the necessity and the inevitability of the unification of mankind, asserts that it is gradually approaching, and claims that nothing short of the transmuting spirit of God, working through His chosen Mouthpiece in this day, can ultimately succeed in bringing it about. It, moreover, enjoins upon its followers the primary duty of an unfettered search after truth, condemns all manner of prejudice and superstition, declares the purpose of religion to be the promotion of amity and concord, proclaims its essential harmony with science, and recognizes it as the foremost agency for the pacification and the orderly progress of human society. It unequivocally maintains the principle of equal rights, opportunities and privileges for men and women, insists on compulsory education, eliminates extremes of poverty and wealth, abolishes the institution of priesthood, prohibits slavery, asceticism, mendicancy, and monasticism, prescribes monogamy, discourages divorces, emphasizes the necessity of strict obedience to one's government, extols any work performed in the spirit of service to the level of worship, urges either the creation or the selection of an auxiliary international language, and delineates the outlines of those institutions that must establish and perpetuate the general peace of mankind.

Practices. Membership in the Bahā'ī community is open to all who profess faith in Bahā' Allāh and accept his teachings. There are no initiation ceremonies, no sacraments, and no clergy. Every Bahā'ī, however, is under the spiritual obligation to pray daily; to fast 19 days a year, going without food or drink from sunrise to sunset; to abstain totally from narcotics, alcohol, or any substances that affect the mind; to practice monogamy; to obtain the consent of parents to marriage; and to attend the Nineteen Day Feast on the first day of each month of the Bahā'ī calendar. The Nineteen Day Feast, originally instituted by the Bāb, brings together the Bahā'īs of a given locality for prayer, the reading of scriptures, the discussion of community activities, and for the enjoyment of one another's company. The feasts are designed to ensure universal participation in the affairs of the community and the cultivation of the spirit of brotherhood and fellowship. Eventually, Bahā'īs in every locality plan to erect a house of worship around which will be grouped such institutions as a home for the aged, an orphanage, a school, and a hospital. In the early 1970s, houses of worship existed in Wilmette, Illinois; Frankfurt am Main, West Germany; Kampala, Uganda; Sydney Australia; and one was being built in Panama. In the temples there is no preaching; services consist of recitation of the scriptures of all religions.

Houses of worship

The Bahā'īs use a calendar established by the Bāb and confirmed by Bahā' Allāh, in which the year is divided into 19 months of 19 days each, with the addition of four intercalary days (5 in leap years). The year begins on the first day of spring, March 21, which is a holy day. Other holy days on which work is suspended are the days commemorating the declaration of Bahā' Allāh's mission (April 21, April 29, and May 2), the declaration of the mission of the Bāb (May 23), the birth of Bahā' Allāh (November 12), the birth of the Bāb (October 20), the passing of Bahā' Allāh (May 29), and the martyrdom of the Bāb (July 9).

Organization and administration. The Bahā'ī community is governed according to general principles proclaimed by Bahā' Allāh and through institutions created by him that were elaborated and expanded by 'Abd ol-Bahā'. These principles and institutions constitute the Bahā'ī administration order, which the followers of the faith believe to be a blueprint of a future world order. The governance of the Bahā'ī community begins on the local level with the election of a local spiritual assembly. The electoral process excludes parties or factions, nominations, and campaigning for office. The local spiritual assembly has jurisdiction over all local affairs of the Bahā'ī community. On the national scale, each year Bahā'īs elect delegates to a national convention that elects a national spiritual assembly with jurisdiction over the entire country. All national spiritual assemblies of the world periodically constitute themselves an international convention and elect the supreme governing body known as the Universal House of Justice. In accordance with Bahā' Allāh's writings, the Universal House of Justice functions as the supreme administrative, legislative, and judicial body of the Bahā'ī commonwealth. It applies the laws promulgated by Bahā' Allāh and legislates on matters not covered in the sacred texts. The seat of the Universal House of Justice is in Haifa, Israel, in the immediate vicinity of the shrines of the Bāb and 'Abd ol-Bahā', and near the shrine of Bahā' Allāh at Bahjī near 'Akkā.

Universal House of Justice

There also exist in the Bahā'ī faith appointive institutions, such as the Hands of the Cause of God and the continental counsellors. The former were created by Bahā' Allāh and later assigned by 'Abd ol-Bahā' the functions of propagating the faith and protecting the community. The Hands of the Cause appointed by Shoghi Effendi in his lifetime now serve under the direction of the Universal House of Justice. The continental counsellors perform the same functions as the Hands of the Cause but are appointed by the Universal House of Justice. Assisting the counsellors in advising, inspiring, and encouraging Bahā'ī institutions and individuals are auxiliary boards appointed by the counsellors and serving under their direction.

BIBLIOGRAPHY. The classic introduction to the Bahā'ī faith, giving a general view of its history and teachings, is J.E. ESSLEMONT, *Bahá'u'lláh and the New Era*, 3rd rev. ed. (1970). GEORGE TOWNSHEND, *The Promise of All Ages*, rev. ed. (1948, reprinted 1957), approaches the Bahā'ī faith from a background of Christianity. The history of the Bahā'ī faith has been studied by many scholars, but the most detailed and poetic account is *The Dawn-Breakers* by MUHAMMAD-I-ZARANDI, surnamed Nabíl, trans. and ed. by SHOGHI EFFENDI (1932, reprinted 1970; 2nd ed., 1953); the latter's *God Passes By* (1944), recounts to the end of the first Bahā'ī century. The most important source for the study of the Bahā'ī faith is the writings of Bahā' Allāh and their interpretation and application by 'Abd ol-Bahā and Shoghi Effendi. Several of Bahā' Allāh's major works are available in excellent English translations. The *Kitáb-i-íqán* (1950) is indispensable for understanding Bahā'ī views of God, progressive revelation, and the nature of religion. *The Hidden Words*, rev. ed. (1954, reprinted 1970), and *The Seven Valleys, and the Four Valleys*, rev. ed. (1952, reprinted 1968), deal with man's spiritual life and the states of the soul. *Gleanings from the Writings of Bahá'u'lláh* (1951) is a representative selection. ABD OL-BAHA's *Some Answered Questions*, rev. ed. (1964), is a record of table talks on various religious themes. *The Secret*

of Divine Civilization (1957) uses the problem of modernization and development to set forth the spiritual prerequisites of true progress and civilization. SHOGHI EFFENDI'S writings include *The World Order of Bahá'u'lláh* (1955), an exposition of principles for the establishment of universal peace and world civilization; and *The Promised Day Is Come* (1961), an examination of the effects of manifestation upon the modern world.

(F.Ka.)

Bahamas

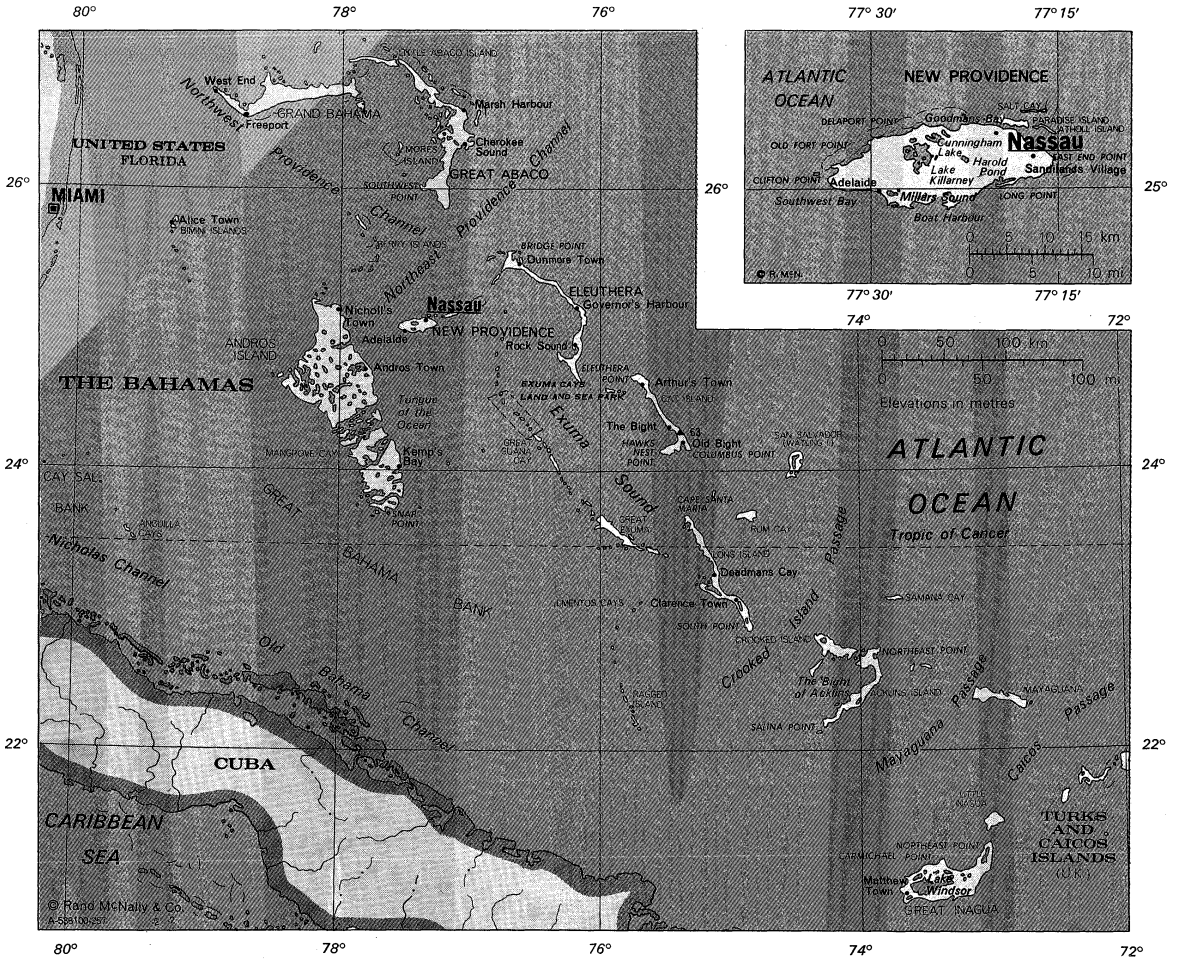
The island group of the Bahamas (Spanish *bajamar*, "shallow water"), a former British colony, since 1973 an independent nation within the Commonwealth of Nations, occupies an irregular submarine tableland that rises out of the Atlantic depths and is separated from nearby lands to the south and west by deepwater channels. Lying to the north of Cuba and Hispaniola, the archipelago comprises nearly 700 islands and cays (small islands), only 22 of which are occupied, and almost 2,400 low, barren rock formations. It stretches for 760 miles (1,220 kilometres) southeasterly from Grand Bahama Island, which lies about 60 miles off the southeastern coast of Florida, to Great Inagua Island, some 50 miles from the eastern tip of Cuba. The total land area is 5,382 square miles (13,939 square kilometres).

Strategic location

The strategic position of the Bahamas, which lie at the geographic centre of the New World landmass, commanding the gateway to the Gulf of Mexico, the Caribbean Sea, and the entire Central American region, has given the history of the islands a unique and often striking character. It was here that Christopher Columbus made his original landfall in the Americas. The subsequent fate of the peaceful original inhabitants remains one of the more tragic episodes in the development of the entire region, while the early attempts at European-dominated settlement were marked by intense national rivalries, interspersed with long periods of lawlessness and piracy. As a result, the society and culture that has evolved in the Bahamas is a distinctive blend of European and African heritages, the latter a legacy of the slave trade. The islands, lacking natural resources other than their magnificent climate and dazzling beaches, have become heavily dependent on the income generated by the extensive tourist facilities that have been developed, often as a result of the injection of foreign capital. The continued popularity of the islands, largely with North American tourists, has maintained a relatively high standard of living among the population, 85 percent of whom are black, but difficulties associated with the transfer of political control to this majority group caused some economic problems from the late 1960s onward.

The capital city, Nassau, is situated on the small (80 square miles [207 square kilometres]) but important New Providence Island. Other islands, known collectively as the Out Islands, include Grand Bahama, which contains the major settlements of Freeport and West End; Andros (2,300 square miles [5,957 square kilometres]), the largest island; and Eleuthera, site of one of the early attempts at colonization. In spite of the concentration of the population in urban centres devoted to tourism, the traditional pattern of small farming and fishing prevails in many villages, notably in the southeastern islands.

The natural environment. *Physical features and climate.* Extensive areas of flat land, generally a few feet in elevation, are the dominant topographic features of the major islands; Andros, for example, has no ground point higher than 71 feet (22 metres). A number of islands fronting the Atlantic have a range or series of ranges of hills on their northeastern side and parallel to the longer axis of the island. These are formed of sand washed ashore and blown inland by the trade winds. The newer hills adjacent to the seashore are normally sand dunes. Solidity increases toward the interior, where the particles become cemented to form Bahama lime-



THE BAHAMAS

stone. Eleuthera and Long Island have the greatest number of hills exceeding 100 feet, and the highest point, 206 feet (63 metres) is on Cat Island. Beneath the soil, the islands are composed of the skeletal remains of coral and other marine organisms.

Temperature and rainfall

The Bahamian climate, mild throughout the year, is one of the great attractions of the area. The average temperature varies from 70° F (21° C) during the winter to 81° F (27° C) during the summer, and extremes very seldom fall below 60° F (16° C) or rise above 90° F (32° C). The average annual rainfall is about 46 inches, occurring mostly during the summer months. Prevailing winds, coming from the northeast in winter and southeast in summer, lend a cooling influence to a generally humid atmosphere. Hurricanes present something of a threat during the period from mid-July to mid-November and have occasionally caused great destruction.

Vegetation and animal life. Extensive and beautiful forests of Caribbean pine are found on Grand Bahama, Great Abaco, Andros, and New Providence. Hardwood forests, known locally as "coppices," also occur on some of the islands. Elsewhere, the woody vegetation consists mostly of shrubs and low trees. Animal life is dominated by frogs, lizards, and snakes, all nonpoisonous, and several species of bats are found in caves along the more rocky coasts. Larger animals include the agouti, a rodent; the raccoon; the iguana; and the elegant flamingo, the national bird. All of these have been much reduced in numbers and in distribution: the barkless dogs reputed to have existed at the time of the original inhabitants may indicate an early link with Africa. In addition, several animals—notably sheep, horses, and other livestock—have been introduced from Europe. The surrounding waters abound with fish and other edible marine animals.

History. It is widely held that on October 12, 1492, Christopher Columbus first stepped ashore in the New World on San Salvador (Watling's Island). He explored this and nearby islands and then sailed to Cuba and Hispaniola. Within 25 years of discovery, the entire indigenous people—Arawak Indians who called themselves Lucayans—had been carried off by the Spaniards to slavery and death in Hispaniola. The islands remained depopulated for more than a century.

In 1648 a band of about 70 English Puritans known as Eleutheran Adventurers, under the governorship of Capt. William Sayle, established a colony on Eleuthera. They had high hopes of establishing a flourishing plantation and an advanced form of government, but unproductive soil, internal discord, and Spanish interference reduced their ambitions to a desperate struggle for survival. Meanwhile, settlers from Bermuda and elsewhere drifted into New Providence. By 1670, when the Bahama Islands were granted to the proprietors of the Carolina colony, New Providence had passed Eleuthera in population and commercial importance, and it became the seat of government. The proprietors took little interest in their colony, however, and it soon became a haven for pirates, whose depredations against Spanish ships provoked frequent and savage retaliatory raids.

Defeat of the pirates

By 1718 it became obvious that proprietary government was a failure, and Capt. Woodes Rogers was sent out as first royal governor to exterminate the pirates and establish conditions attractive to law-abiding settlers. His nearly bloodless conquest of about 1,000 of the brigands set the colony on a course of peaceful progress. During the American Revolution a great many Loyalists fled with their slaves to the islands, doubling the white population and trebling the black. The cotton plantations that they developed yielded well for a few years, but exhausted soil, insect pests, and, finally, abolition of slavery in 1834 led to their ultimate collapse.

Considerable wealth poured into the islands as the result of blockade-running during the American Civil War and the handling of liquor during the Prohibition era of the 1920s in the United States. This kind of activity made no lasting contribution to the islands, however, nor did it establish any firm economic base. Before and after these periods, many attempts were made to grow pineapples, citrus fruits, tobacco, tomatoes, and sisal for export, but despite initial promise, all failed. Through this, however, a majority of Bahamians took to the sea, where searching for wrecks, sponging, and fishing offered excitement and occasional good fortune. After World War II, strenuous efforts to establish tourism as the basis of the economy were strikingly successful, transforming the economic and social structure of the islands.

Politically, Bahamians have had considerable control over their affairs since Captain Rogers gathered the islands' first assembly, in 1729. Constitutional advances in 1964 and 1969 brought the country to the verge of complete self-government. Party politics emerged in 1953, when the Progressive Liberal Party (PLP) was formed by blacks to oppose the group in power, who in 1958 responded with a party of their own, the white-controlled United Bahamian Party (UBP). As the political battle progressed, the PLP raised the cry for majority rule, and many of the acrimonious characteristics of a racial contest were introduced. The climax came after the general elections of 1967, when the PLP was able to form a government with a slight majority. Elections the following year gave that party 29 of the 38 Assembly seats. While there is no doubt that the UBP was defeated mainly on the racial issue, the accusation that that party had introduced criminal-controlled gambling and that some of its members had profited thereby had a telling effect.

In general the PLP advocated stricter government control of the economy, increased Bahamian ownership of business enterprises, and the replacement of foreign workers by Bahamians. Although the move toward self-government received bipartisan support, the UPB advocated that total independence should come later than 1973, the target year of the PLP government. In 1969 the name of Commonwealth of the Bahama Islands was adopted, and on July 10, 1973, on independence, the official form became the Commonwealth of the Bahamas.

The people and the conditions of life. In 1970 there were almost 170,000 permanent inhabitants of the Bahamas, 27,000 of them foreign-born. English is the only language native to Bahamians. In recent years, however, there has been an influx of Haitian labourers who speak French or its creole dialect among themselves. About 15 percent of the population are descendants of English pioneer settlers and Loyalist refugees. The rest are mainly of African descent, many of them with varying amounts of Caucasian blood. The Baptists, with a membership of 49,000, are the largest religious denomination. Episcopalians and Roman Catholics are next in order, with approximately 38,000 each. The Methodist and Evangelical churches claim 12,000 and 10,000, respectively.

Economy. Except for some small, regional pockets of unemployment, Bahamians enjoy full employment and a relatively high standard of living. In 1968 the gross national product was about $227,000,000 and the per capita income $1,260. Economic growth has been stimulated almost entirely by private enterprise, largely by American capital. Traditionally the government has played a passive role, confining its activities to the maintenance of orderly business and social activities. Blacks have every field of opportunity open to them and have made great strides toward economic parity with whites.

Standard of living

Tourism continues to dominate the economy. It is responsible directly and indirectly for more than 70 percent of the gross national product and the employment of almost two-thirds of the manpower. Gambling casinos in several areas add to the attraction of the Bahamas for tourists, 1,300,000 of whom visited the islands in 1970. During the 1960s there was a widespread move away from fishing and farming villages to the centres of tourist activity, with over 17,000 people changing their residence. Of these, 35 percent went to New Providence and 38 percent to Grand Bahama, where Freeport was under development as a deepwater harbour and a tax-exempt tourist, industrial, and commercial area.

Banking and business hold a distant second place in the economy, followed by government and construction. Other industries include a petrochemical refinery and a cement plant at Freeport, which has become second only to Nassau in tourist and commercial activity. Salt is pro-

duced by solar evaporation at Inagua and Long Island and various forms of food production continue at numerous places for domestic consumption.

Since there is no direct taxation, customs duties produce the major share of revenue, in 1970 accounting for about three-fifths of the government's income.

Transportation. There are modern paved roads in Nassau and Freeport and their environs. Elsewhere, roads are constructed of crushed limestone and sometimes surfaced with asphalt, but increasingly they are capable of accommodating motor vehicles. A fleet of small motor vessels carries passengers, freight, and mail weekly between Nassau and the Out Islands. The deep-water harbours of Nassau and Freeport are dredged to depths of 37 feet and 30 feet, respectively. Nassau was visited by about 2,500 foreign ships in 1970, both passenger and freight. The airplane has become of increasing importance to the Bahamian economy. Throughout the islands there are 46 airports, with varying accommodations and facilities. Most of these serve only interinsular aircraft, but international airports are located at Nassau, Freeport, and West End.

Government and services. The government is patterned after that of Great Britain. The governor general since 1973 is appointed by the English monarch, and in turn, he appoints a prime minister who must be a member of the House of Assembly and must be able to command a majority of Assembly votes. The House of Assembly is composed of 38 elected members. The 16-member Senate, which has severely restricted powers, is appointed by the governor, the majority of the members on the advice of the prime minister. The life of the Senate is, like the Assembly's, normally five years, but if the prime minister is unable to control the Assembly effectively or if he considers it expedient, both bodies are dissolved and reconstituted.

Bicameral legislature

Bahamians are relatively free of malnutrition and debilitating diseases, and medical problems are largely those involving common infections. Alcoholism is causing increasing concern as the chief contributor of mental illness, and care for the aged is a mounting social problem. Severe housing congestion and hazardous sanitary conditions exist only in some black areas of New Providence, where housing is substandard and sewage is disposed of in backyard cesspits that tend to overflow. There is little illiteracy, for schooling is compulsory from 5 to 14 years of age. Public secondary and technical schools have been greatly expanded in recent years, but there are no universities.

Culture and communications. There is little indigenous culture. Outstanding among traditional group activities is the "Junkanoo" parade on Boxing Day and New Year's Day. The main thoroughfare is given over to hundreds of gaily bedecked celebrants who, with clanging cow bells and beating drums, march and dance to a "Goombay" rhythm of African origin. Island folklore includes stories of a three-toed, human-faced creature called the "Chickcharney" and the workings of Obeah, a local brand of witchcraft. In Nassau about a dozen amateur choral, dramatic, and dancing groups provide fine entertainment with much local flavour. A national trust is concerned with the preservation of wildlife, and a historical society promotes local history.

The oldest extant Bahamian newspaper is the daily *Nassau Guardian*, founded in 1844. The daily *Nassau Tribune* (1903) has the largest circulation in the islands. The only other daily is the *Freeport News*. Political organs are published periodically by various parties. The Bahamas government owns and operates two radio stations with complementary programs. The Out Islands are connected with Nassau through more than 100 radiotelephone and wireless-telegraph stations. Contact is maintained through a 180-voice circuit between Nassau and Miami, Florida, and thence with all parts of the world.

Prospects. Efforts to diversify the Bahamian economy, the country's most pressing need, are presently unpromising, since investors in industry are reluctant to establish plants where shortages of both raw materials and manpower exist. It would seem that the tourist-based economy, which lifted the people out of economic stagnation, must be relied upon for the foreseeable future. But the vulnerability of tourism to world economic conditions was demonstrated by the decrease in visitors and revenue in 1970. This points up also the close tie of the islands to the U.S.

Need to diversify

Bahia

A state of eastern Brazil, Bahia is bounded northwest by Piauí, north by Pernambuco, northeast by Alagoas and Sergipe, east by the Atlantic Ocean, southeast by Espírito Santo, south by Minas Gerais, and west by Goiás. With an area of 216,613 square miles (561,026 square kilometres), it had a population of 7,583,140 at the 1970 census. The capital, Salvador, a port commanding an inlet of the Atlantic Ocean, was once commonly known also as Bahia ("Bay"), whence the state derives its name. (For an associated physical feature, see SAO FRANCISCO RIVER.)

History. On All Saints' Day, November 1, 1501, Portuguese explorers entered the bay on which Salvador now stands: they therefore named it Bahia de Toros os Santos, or All Saints' Bay. The subsequent occupation of the vicinity by the Portuguese led, in 1549, to the merging of four captaincies under the first governor general of Brazil, Tomé de Sousa who in the same year

Early exploration

founded Salvador as the seat of his government. Seized by the Dutch in 1624, the city was recovered by the Portuguese the following year.

When the Empire of Brazil was proclaimed in 1822, Bahia was still controlled by forces loyal to Portugal; but on July 2, 1823, Brazilian troops occupied Salvador, and Bahia became a province of the empire. In 1889, under the republic, Bahia became a state of the Brazilian Federation.

The colonization of the territory had begun in the Recôncavo—that is, in the coastal region—which grew sugarcane and tobacco for export and other crops for the settlers' food. In the semi-arid interior, cattle raising was considerably stimulated in the 18th century, when the discovery of gold and gems in the Diamantina Highland attracted more settlers. The 19th century saw a revival of agriculture: it was the golden age for sugarcane; coffee was also grown on a large scale; cotton production went up; and the forests of the south were turned into profitable plantations of cacao. Rubber plantations were developed at the beginning of the 20th century.

Physical geography. The Diamantina Highland and its northern extension, the Serra do Tombador, run longitudinally across Bahia from the borders of Minas Gerais and constitute the line of greatest elevation, the Diamantina reaching its maximum altitude in Pico das Almas, which is 6,068 feet (1,850 metres) in height. From this dorsal ridge depend the Western Plateau and the Eastern, which vary in altitude between about 650 and 2,600 feet and are characterized by the presence of inselbergs (isolated eminences left by erosion). The Eastern Plateau ends with the heights overlooking the coastal plain.

Major rivers

The major river is the São Francisco, which rises in Minas Gerais and flows north across western Bahia before turning eastward in a great curve to form the frontier between Bahia and Pernambuco and between Bahia and Alagoas, on its long way down to the Atlantic. Its most important waterfall is the Paulo Afonso, on the short Bahia–Alagoas border. The São Francisco's principal tributaries in Bahia are the Rãs, the Santo Onofre, and the Paramirim, on the right bank, and the Carinhanha, the Corrente, and the Grande, on the left.

The second most important river is the Paraguaçu, which has its sources in the Diamantina Highland and flows eastward into All Saint's Bay. Its basin is a cattle-raising zone, with small areas of agriculture, in an otherwise arid region. The river floods periodically.

Other rivers flowing eastward into the Atlantic are the Itapicuru and the Contas, north and south of the Paraguaçu, respectively. The Pardo and the Jequitinhonha both flow across southern Bahia from Minas Gerais.

Climate, vegetation, and animal life. Along Bahia's coastline there are areas with an annual rainfall exceeding 55 inches (1,400 millimetres), as well as sandy stretches on which the Brazilian coconut and the *mangabeira* rubber tree (*Hancornia speciosa*) flourish, while the mud of the estuaries favours mangroves. In the broad-leaved tropical forest, where the annual rainfall exceeds 60 inches (1,500 millimetres) and where the coldest month has an average temperature of 64° F (18° C), the sandy clay soil supports an evergreen vegetation. In the zone of transitional forest, where a dry season interrupts the prevalent humidity, the soils are shallower, and there is a deciduous vegetation of shrubs, smaller plants, and numerous lianas or vines. On some of the tablelands, where sandy soil under a surface crust fails to retain much water, all plant life must be of a kind adaptable to changing conditions. In the extensive *caatinga*, or zone of drought (nearly 60 percent of the state's territory lies within what Brazil's geographers call "the Polygon of Droughts"), the rainy season is irregular, and the annual rainfall never exceeds 24 inches (600 millimetres). Here the landscape is generally wide open and bare, unprotected against erosion, and plants such as cactus predominate. On more sheltered expanses of the higher hinterland, at altitudes between about 2,600 and 2,900 feet, where summers of rain and long seasons of drought alternate, areas of savanna occur on soils of ferrous, clayey, or sandy types.

The *caatinga*

Peccary, tapir, and the two-toed sloth inhabit the forests. In open country the giant armadillo, the scarlet ibis, and the king vulture can be seen.

Population. According to Brazilian estimates, the population is composed as follows: whites, 30 percent; blacks, 19 percent; mulattos, 51 percent.

Population density varies considerably. More than 50 percent of the state's total population is concentrated in the littoral, and especially in the Recôncavo, which represents only 20 percent of the total area. In some *municípios* (departments) of the Recôncavo there are 520 people per square mile; and the towns are even more densely populated. Salvador, the capital, has a metropolitan area covering six *municípios*. Other major cities of the state are Ilhéus, Itabuna, Feira de Santana, and Vitória da Conquista. The arid interior, on the other hand, is sparsely populated and has few towns. Of the total population, 59 percent live in rural areas, and 41 percent are urban.

The language of the people is Portuguese, influenced to some extent by African idiom and slightly by Indian languages. Roman Catholicism is professed by 93 percent of the population, Protestantism by 2 percent, Spiritualism and other beliefs by 5 percent. Many people practice candomblé, a sort of voodoo, but declare themselves Catholics.

Administration and social conditions. The state is ruled by a governor, elected for a four-year term. The 336 *municípios* are administered by *prefeitos* (mayors) and are subdivided into *distritos* (districts).

The standard of living is low. Hygiene is defective, even in urban areas, and illiteracy is widespread, despite efforts to improve medical services and sanitation and to expand primary and secondary schooling. Salvador has two universities, the Federal (5,500 students) and the Católica do Salvador (4,300 students).

Economy. Bahia's mineral resources comprise petroleum (85 percent of Brazil's output), natural gas, lead, copper, chrome, tin, barite, manganese, magnesite, titanium, hematite, quartz, kaolin, marble, asbestos, and amethyst. There is also a hydroelectric potential: the São Francisco River has been harnessed by the Paulo Afonso Dam at its major waterfall (with a capacity of 1,000,000 kilowatts), but the Paraguaçu, the Contas, and the Jequitinhonha remain unexploited.

The most important crops are cacao, tobacco, vegetable oils, piassava, and sisal. Timber is also obtained from the forests. Cattle, which number 8,500,000 head, yield leather and skins.

Heavy industry is represented by the Landulfo Alves petroleum refinery; and by cement works and ironworks. Salvador, Feira de Santana, and Aratu are industrial centres. Energy is mostly hydroelectric, especially from the Paulo Afonso project.

The state has 63,556 miles of road and 1,550 of railway, mostly serving the Recôncavo.

Cultural life. Bahia's colonial past has left a cultural legacy as rich as that of any state of eastern Brazil—and is represented not only by churches, manorial houses, and fortresses but also by numerous works of art. Popular tradition is maintained in many festival customs.

Prominent among cultural institutions are the Academia de Letras da Bahia, the Instituto Geográfico e Histórico da Bahia, and the Instituto de Musica da Bahia.

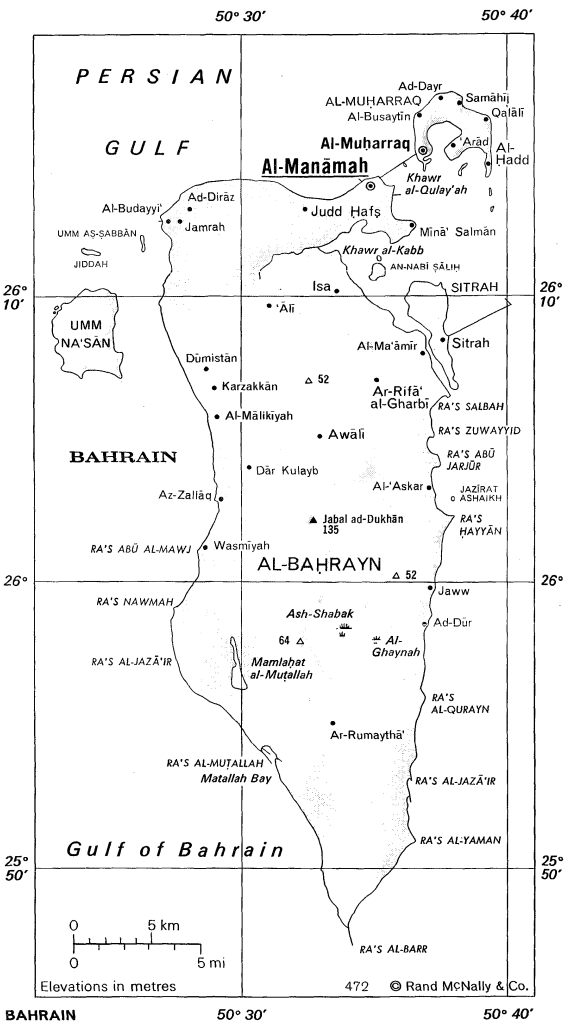
Bahrain

Bahrain, a small Arab emirate in the Persian (Arabian) Gulf, consists of an archipelago of Bahrain Island—extending some 30 miles from north to south and 10 miles from east to west—and some 30 smaller islands. It is situated in a bay on the southern coast of the Persian Gulf between the northeastern Hasa coast of Saudi Arabia to the west and the Qatar peninsula to the east. Its Arabic name, al-Baḥrayn, means "two seas." The total land area is about 256 square miles (662 square kilometres), and its population in the early 1970s was over 200,000.



Bahrain is an independent Arab state which until 1971 had a special treaty relationship with the United Kingdom, which was responsible for the conduct of its foreign affairs and defense. In 1971 Bahrain declared itself independent and became a member of the United Nations. Though oil was discovered in Bahrain in 1932—it was the first discovery on the Arabian side of the Gulf—relatively little oil is now produced, and the emirate's commercial importance is due to its central position in the Gulf. The chief town, port, and seat of administration is al-Manāmah in the northeast of Bahrain Island. The ruler, Shaykh 'Isā ibn Sulmān Āl Khalīfah, resides at ar-Rifa'al-Gharbī, about six miles south of al-Manāmah. (For an associated physical feature see PERSIAN GULF.)

Ancient settlements

History. Bahrain has been inhabited from prehistoric times, and several thousand burial mounds in the north of the main island probably date from the Sumerian period of the 3rd millennium BC. The archipelago was mentioned by Persian, Greek, and Roman geographers and historians. It has been Arab and Muslim since the Muslim conquest of the 7th century AD, though it was occupied and ruled by the Portuguese from 1521 to 1602 and by the Persians from 1602 to 1783. Since 1783 it has been ruled by sheikhs of the Āl Khalīfah family, which originated in the Hasa province of Arabia. Several times during the 19th century the British intervened in the government of the territory to suppress war and piracy and to prevent the establishment of Egyptian, Persian, German, or Russian influence. The first Bahrain–British treaty was signed in 1820; and Bahrain's British-protected status dates from 1861, with the completion of a treaty by the terms of which the sheikh bound himself to refrain from "the prosecution of war, piracy, or slavery." Until 1970 the government of Iran periodically advanced claims to sovereignty over Bahrain, but these were repudiated.

The environment. *Relief.* The state consists of two separate groups of islands. The 217-square-mile island of Bahrain is surrounded by smaller islands. Two of these—al-Muḥarraq and Sitrah—are joined to it by causeway; other islands in the group are an-Nabī Ṣāliḥ Umm aṣ-Ṣabbān, Umm Na'sān, and Jiddah. The second group consists of the Howar Islands, which are situated near the coast of Qatar about 12 miles southeast of Bahrain Island; small and rocky, they are inhabited only by a few fishermen and quarry workers.

The archipelago

While all of the small islands in both groups are rocky and low-lying, rising only a few feet above sea level, the main island is more varied in appearance. Its arched layers of rock consist of limestone, sandstone, and marl (loose clay, sand, or silt containing calcium carbonate); they were formed during the Cretaceous and Tertiary periods (from 7,000,000 to 136,000,000 years ago). The central region rises to 450 feet above sea level at the hill of Jabal ad-Dukhān and is rocky and barren. The southern and western lowlands consist of a sandy plain with some salt marshes. The northern and northwestern areas afford a striking contrast; they form a narrow belt of date and vegetable gardens irrigated from prolific springs and wells that tap artesian water. This water percolates through water-bearing rocks beneath the seabed to rise under pressure in Bahrain. Off the northern coasts of the islands, freshwater also rises in submarine springs on the seabed and has for centuries been captured in skin bags by divers. Since the drilling of artesian wells, however, these submarine springs have been little used.

Climate. Humidity is high throughout the year, and monthly mean temperatures from May until October exceed 85° F (29° C). Winters are cooler and more pleasant, with mean temperatures from December to March below 70° F (21° C). Rainfall, almost entirely confined to the winter months, averages only three inches per year. The predominant wind is the damp, northwesterly *shamal*, but the *gaws*, a hot, dry wind from the south, occasionally brings sand and dust.

Vegetation and animal life. Some 200 different species of desert plants grow in the bare arid portions of the islands, while the irrigated and cultivated areas support fruit trees, fodder crops, and vegetables. The variety of animals is limited by the desert conditions. The gazelle and the hare are not yet extinct, and lizards and jerboas (desert rats) are common, while the mongoose—probably imported from India—is found in the irrigated areas. There is also a surprising variety of birds native to Europe, Asia, and Africa.

Human settlement. In the irrigated areas of northern Bahrain Island, groves of date palms and orchards of banana, citrus, mango, and pomegranate trees create a sense of great fertility. Vegetables and lucerne (alfalfa) are grown under irrigation in the shade of the trees, and cattle graze there also. The Arab villages consist mainly of substantial houses of local stone or of concrete with flat roofs. Some of the temporary settlements of the fishermen and the very poor are constructed of *barasti* (sticks or canes from the date palms). There is little permanent settlement in the southern half of Bahrain Island.

Principal towns

There are two major towns—al-Manāmah and al-Muḥarraq. Al-Muḥarraq still presents the aspect of a traditional Arab town with narrow, winding streets, and dense settlement. Al-Manāmah, with its port of Mīnā' Salmān, blends features of the East and West. It contains several

large hotels, the principal government offices, schools, Western-style shops, and an Arab suq, or bazaar. Another town, Awālī, has tree-lined avenues; most of its houses are single-story bungalows inhabited by expatriate employees of the Bahrain Petroleum Company (Bapco). The town of Isa, a government venture to provide modern housing for 15,000 people and designed by British planners, was inaugurated in 1968.

The people. The population, about 180,000 in 1965, increased to over 200,000 by 1971. Some 82.5 percent of the people are native-born Bahrainis; another 5 percent are Omanis, while the remainder, in lesser proportions, are Indians, Pakistanis, Iranians, and British, in approximately that order. A substantial portion of the foreign community are employed by Bapco, and many Iranians, Indians, and Pakistanis are engaged in commerce. Some of the British work for the Bahrain government. The Muslim population is almost equally divided between the Sunnī and Shīʿah sects; the ruling family and many of the wealthier and more influential people are Sunnī. In the early 1970s the population of al-Manāmah was 89,000 and that of al-Muḥarraq town was 38,000; the two towns between them thus contained more than half of the total population. Arabic is the official language, but English is widely understood.

Total Bahrain	256‡	662‡	182,000§	217,000§

*Provisional. †Geographic divisions are for statistical purposes only; they are not administrative. ‡Total area includes numerous small, uninhabited islands and dependencies of Bahrain. §Figures do not add to total given because of rounding.
Source: Official government figures.

Oil refining

The economy. *Oil.* Although oil has been produced since 1934, annual production is small and amounts to only about 3,800,000 tons from the oil field at Jabal ad-Dukhān. A refinery at Sitrah, however, is a major installation that handles 12,000,000 tons a year. Most of the crude oil is pumped by undersea pipeline from the Arabian American Oil Company (Aramco) fields in Saudi Arabia. Bahrain's role as an exporter of refined petroleum products is, therefore, more important than its role as a producer. An oil concession, which expires in 2024, is held by Bapco, in which two United States companies hold equal shares. Concessions for the marine areas to the north and west of Bahrain are held in equal shares by Aramco and another United States company. About 70 percent of the state's revenue comes from oil royalties and the remainder from customs dues, local taxes, and rent for land and property. Al-Manāmah is a free port for goods in transit.

Industries. The traditional industries of Bahrain were building dhows (Arab sailboats), fishing, pearling, and the manufacture of reed mats. These now exist only on a small scale, partly because of decreased demand and partly because of the availability of more remunerative employment. A modern slipway at Mīnāʾ Salmān handles the repair of ships up to 1,000 tons, and there are manufacturing plants producing building materials, soft drinks, and other consumer goods. The Bahrain Development Bureau, which encourages the development of manufacturing industries, arranged for the establishment of a major aluminum smeltery on the east coast. Production will commence in 1971 and is expected to reach 90,000 tons a year by 1972. Prawns are canned for export by arrangement between a Bahrain company and British fish distributors. Local fishing is also important.

Agriculture. Agriculture contributes significantly to the local food supply, of which dates, other fresh fruits, and vegetables are the main items. Livestock is unimportant, but camels and horses are bred for racing.

Management of the economy. Apart from oil and aluminum smelting, most industry is in private hands. The Bahrain government has a 27.5 percent interest in the international consortium Aluminium Bahrain that controls the aluminum smeltery. Many foreign firms that trade in the Gulf have their head offices in Bahrain.

Transportation. There is an excellent paved road system on Bahrain Island, and buses and taxis serve the principal towns and settlements. The international airport on al-Muḥarraq Island has flights to most countries in the Middle East and is one of the busiest airports in the Gulf. It is used by major airlines and a local aviation service. There are regular steamer services from Bahrain to other Gulf ports, as well as to Karachi and Bombay. Most general cargo is handled at Mīnāʾ Salmān; petroleum products are loaded at the Sitrah jetty.

Air services

Administration and social conditions. Bahrain is to a large extent a welfare state. Medical care and education are free; there are some 40,000 children in primary schools and more than 10,000 students in intermediate and high schools. Housing and transport are partially subsidized by the state.

The four urban and two rural municipalities are administered by councils, half of whose members are elected by male and female rate payers (local government taxpayers) and the remainder appointed by the government.

The ruler is assisted by a Council of Administration, which consists of the heads of various government departments, several of whom are members of the royal family. In the early 1970s the constitution was in a state of transition from that of a traditional Arabian patriarchal system to one of representative democracy.

Cultural life. In spite of its recent rapid economic development, Bahrain remains, in many respects, essentially Arab in its culture and life-style. The state radio station broadcasts only in Arabic, and television transmissions are received from Saudi Arabia. The traditional sports of falconry, gazelle and hare coursing, and horse and camel racing are still practiced by the wealthier Bahrainis.

Several weekly and daily papers are published in Arabic and a small number in English. The British Council in al-Manāmah is the main foreign cultural institution.

Prospects for the future. Bahrain's economy has developed rapidly in recent years, in part because of the fact that the state was able to exploit its early start in the oil industry and in part because of the development of trade in the entire Persian Gulf. Security and stable government have helped to promote this development. If that political stability both in Bahrain and in other Persian Gulf states survives the withdrawal of British forces, there is hope that the economic future of Bahrain will be bright.

BIBLIOGRAPHY. The most detailed general account is J.H.D. BELGRAVE, *Welcome to Bahrain*, 5th ed. (1965), a guidebook with a good account of the geography, history, and customs of Bahrain, together with a bibliography of works in Arabic, English, and French. Another detailed work is A. FAROUGHY, *The Bahrain Islands* (1951). The geog-

raphy of the islands is briefly described in both G. DALYELL, "The Bahrain Islands," *Scot. Geog. Mag.*, 57:58–61 (1941); and GREAT BRITAIN, NAVAL INTELLIGENCE DIVISION, *Iraq and the Persian Gulf* (1944). SIR RUPERT HAY, *The Persian Gulf States* (1959), is a good general account of the sheikhdoms of the Gulf, with an analysis of their political status and of British interests in the Gulf; J.B. KELLEY, "The Persian Claim to Bahrain," *International Affairs*, 33:51–70 (1957), and *Britain and the Persian Gulf* (1968), deal with the long-standing Iranian claim to Bahrain. One of the few articles dealing with social problems arising from economic development, as well as with the long-standing Sunnī–Shīʿah division among the population is F. QUBAIN, "Social Classes and Tensions in Bahrain," *Middle East Journal*, 9:269–280 (1955). A. VILLIER, "The Arab Dhow Trade," *Middle East Journal*, 2:399–416 (1948), and *Sons of Sinbad* (1940), deal with the old maritime trade of Bahrain and the Gulf.

(C.G.S.)

Baikal, Lake

Lake Baikal (Baykalskoye Ozero in Russian, Bajkalskoje Ozero in the transliteration system of the Soviet Akademiya Nauk) is located in the southern part of eastern Siberia within the Buryat Autonomous Soviet Socialist Republic and the Irkutsk (Irkutskaya) *oblast* of the Russian Soviet Federated Socialist Republic. It is the deepest continental body of water on earth, having a maximum depth of 5,314 feet. Its area is 12,200 square miles (31,500 square kilometres), with a length of 395 miles (636 kilometres) and an average width of 30 miles. It contains about one-fifth of the fresh water on the earth's surface and four-fifths of that in the U.S.S.R., or 5,500 cubic miles. Into Lake Baikal flow 336 rivers and streams, of which the largest are the Selenga, Barguzin, Upper (Verkhnyaya) Angara, Turka, and Snezhnaya.

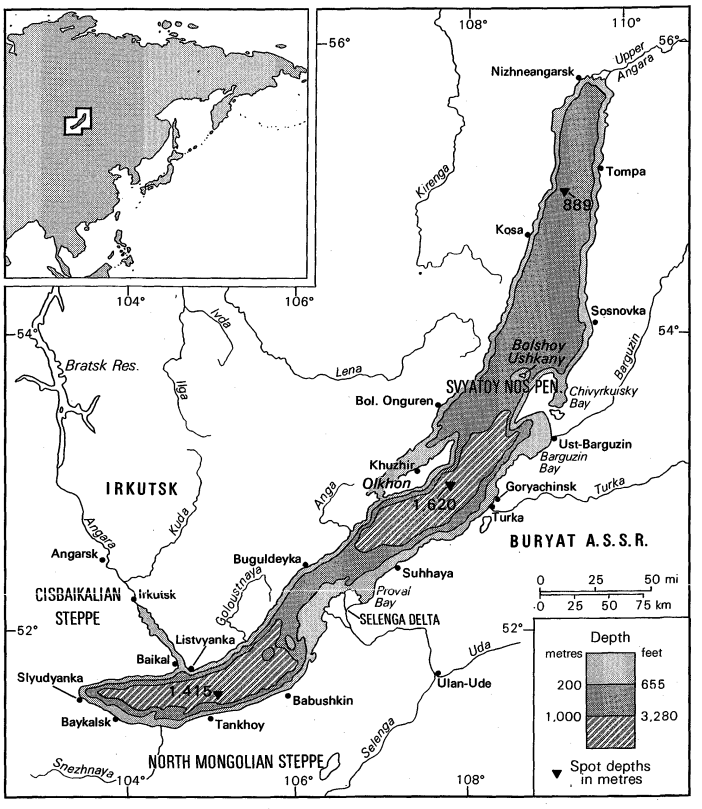
Baikal's geology

Baikal lies in a deep structural hollow surrounded by mountains, some of which tower 6,560 feet above it. The area is formed predominantly of metamorphic, sedimentary, and magmatic rock more than 500,000,000 years old. The sedimentary strata on the floor of the lake may be as much as 20,000 feet thick. Near the shore are remains of extinct volcanoes. Earth movements still continue, and there are occasional severe earthquakes; in 1862 a quake inundated 77 square miles in the northern Selenga River Delta, creating a new bay in Baikal known as Proval Bay. Breaking of the Earth's crust still produces hot mineral springs.

The lake hollow is not symmetrical, having steep slopes on the western shores and gentler slopes on the eastern. About 8 percent of the floor consists of shallows 160 feet deep. The meandering shoreline runs for 1,300 miles, with large indentations at the bays of Barguzin, Chivyrkuysky, and Proval and at Ayaya and Frolikha inlets; the Svyatoy Nos Peninsula juts out into the lake from the southeastern shore. Baikal contains 27 islands, of which five are periodically submerged; the largest are Olkhon (280 square miles) and Bolshoy Ushkany (over three square miles). The influx of water into the lake is primarily from rivers, chiefly the Selenga, while some comes from precipitation and subterranean sources. Most of the outflow is through the Angara River, a tributary of the Yenisey. The water level varies during the year by two or three feet, being highest in August–September and lowest in March–April.

Baikal's climate is much milder than that of the surrounding territory. January–February air temperatures average −2° F (−19° C), and the August temperatures average 52° F (11° C). The lake freezes in January and thaws in May. The water temperature at the surface in August is about 55° F (13° C) and reaches 68° F (20° C) in the offshore shallows. Waves sometimes measure over 15 feet. The water is very clear down to 130 feet, containing few minerals. Its salinity is low.

Plant and animal life in the lake are rich and various. There are over 1,200 animal species at different depths, and around 600 plant species living on or near the surface. About three-quarters of the species are peculiar to Baikal. There are 50 species of fish, belonging to seven families; the most numerous of these are bullheads of the family Cottidae, of which there are 25 species. The omul salmon is heavily fished; also important are the grayling and the lake whitefish. The largest of the fishes is the sturgeon, individuals of which sometimes measure 71 inches and weigh as much as 265 pounds. The one mammal is the Baikal seal. Unique to Baikal is a fish called the golomyanka, of the family Comephoridae, which gives birth to live young. There are 326 bird species in the Baikal area.



Lake Baikal.

Industries on the shores of Baikal include mining (mica and marble), cellulose and paper, shipbuilding, fisheries, and timber. There are many mineral springs, and visitors come to Goryachinsk and Khakusy for the curative properties of the spring waters. The lake is navigated from May to October by wooden rafts.

Anti-pollution measures

The Soviet government has begun to concern itself with the conservation of Baikal and its resources. A government decree concerning measures for the protection and rational use of those resources, and the prevention of polluting emissions from cellulose and other industrial plants, was adopted in June 1971.

In the town of Listvyanka is the Limnological Institute of the Siberian Department of the U.S.S.R. Academy of Sciences and the Baikal Sanatorium. In the town of Bolshiye Koty is the hydrobiological station of Irkutsk A.A. Zhdanov State University. (G.I.G.)

Baking and Bakery Products

Baking, a dry-heat cooking process, is probably man's oldest cooking method. Bakery products are usually prepared from flour or meal derived from some form of grain. Bread, already a common staple in prehistoric times, provides many nutrients in the human diet.

HISTORY

The earliest processing of cereal grains probably involved parching or dry roasting of collected grain seeds. Flavour, texture, and digestibility were later improved by cooking whole or broken grains with water, forming gruel or porridge. It was a short step to the baking of a layer of viscous gruel on a hot stone, producing primitive flat bread. More sophisticated versions of flat bread include the Mexican tortilla, made of processed corn, and the chapatti of India, usually made of wheat.

Improved baking techniques

Baking techniques improved with the development of an enclosed baking utensil and then of ovens, making possible thicker baked cakes or loaves. The phenomenon of fermentation, with the resultant lightening of the loaf structure and development of appealing flavours, was probably first observed when doughs or gruels, held for several hours before baking, exhibited spoilage caused by yeasts. Most doughs exhibit some response to the puffing or leavening action of fermentation, but only wheat yields a flour producing a light, porous structure in baked products. Early baked products were made of mixed seeds with a predominance of barley, but wheat flour, because of its superior response to fermentation, eventually became the preferred cereal among cultural groups sufficiently advanced in culinary techniques to make leavened bread.

Brewing and baking were closely connected in early civilizations. Fermentation of a thick gruel resulted in a dough suitable for baking; a thinner mash produced a kind of beer. Both techniques required knowledge of the "mysteries" of fermentation and a supply of grain. Increasing knowledge and experience taught the artisans in the baking and brewing trades that barley was best suited to brewing, while wheat was best for baking.

By 2600 BC the Egyptians, credited with the first intentional use of leavening, were making bread by methods similar in principle to those of today. They maintained stocks of sour dough, a crude culture of desirable fermentation organisms, and used portions of this material to inoculate fresh doughs. With doughs made by mixing flour, water, salt, and leaven, the Egyptian baking industry eventually developed over 50 varieties of bread, varying in shape and using such flavouring materials as poppyseed, sesame, and camphor. Samples found in tombs are flatter and coarser than modern bread.

The Egyptians developed the first ovens. The earliest known examples are cylindrical vessels made of baked Nile clay, tapered at the top to give a cone shape and divided inside by a horizontal shelflike partition. The lower section is the firebox, the upper section is the baking chamber. The pieces of dough were placed in the baking chamber through a hole provided in the top.

Greek cultures made few improvements in bread and baking; most of their bread was in the form of flat cakes.

In the first two or three centuries after the founding of Rome, baking remained a domestic skill with few changes in equipment or processing methods. According to Pliny the Elder, there were no bakers in Rome until the middle of the 2nd century BC. As well-to-do families increased, women wishing to avoid frequent and tedious bread making began to patronize professional bakers, usually freed slaves. Loaves molded by hand into a spheroidal shape, generally weighing about a pound, were baked in a beehive-shaped oven fired by wood. *Panis artopticius* was a variety cooked on a spit, *panis testuatis* in an earthen vessel.

Although Roman professional bakers introduced technological improvements, many were of minor importance, and some were essentially reintroductions of earlier developments. The first mechanical dough mixer, attributed to Marcus Virgilius Euryasaces, a freed slave of Greek origin, consisted of a large stone basin in which wooden paddles, powered by a horse or donkey walking in circles, kneaded the dough mixture of flour, leaven, and water.

Guilds formed by the miller-bakers of Rome became institutionalized. During the 2nd century AD, under the Flavians, they were organized into a "college" with work rules and regulations prescribed by government officials. The trade eventually became obligatory and hereditary, and the baker became a kind of civil servant with limited freedom of action.

The revival of guilds

During the early Middle Ages baking technology advances of preceding centuries disappeared, and bakers reverted to mechanical devices used by the ancient Egyptians and to more backward practices. But in the later Middle Ages the institution of guilds was revived and expanded. Several years of apprenticeship were necessary before an applicant was admitted to the guild; often an intermediate status as journeyman intervened between apprenticeship and full membership (master). The rise of the bakers guilds reflected significant advances in technique. A 13th-century French writer named 20 varieties of bread varying in shape, flavourings, preparation method, and quality of the meal used. Guild regulations strictly governed size and quality. But outside the cities, bread was usually baked in the home. In medieval England rye was the main ingredient of bread consumed by the poor; it was frequently diluted with meal made from other cereals or leguminous seeds. Not until about 1865 did the cost of white bread in England drop below brown bread.

At that time improvements in baking technology began to accelerate rapidly, owing to the higher level of technology generally. Ingredients of greater purity and improved functional qualities were developed, along with equipment reducing the need for individual skill and eliminating hand manipulation of bread doughs. Automation of mixing, transferring, shaping, fermentation, and baking processes began to replace batch processing with continuous operations. The enrichment of bread and other bakery foods with vitamins and minerals was a major accomplishment of the mid-20th-century baking industry.

FUNCTION OF INGREDIENTS

Flour, water, and leavening agents are the ingredients primarily responsible for the characteristic appearance, texture, and flavour of most bakery products. Eggs, milk, salt, shortening, and sugar are effective in modifying these qualities, and various minor ingredients may also be used.

Flour. Wheat flour is unique among cereal flours in that, when mixed with water in the correct proportions, its protein component forms an elastic network capable of holding gas and developing a firm spongy structure when baked. The proteinaceous substances contributing these properties are known collectively as gluten. The suitability of a flour for a given purpose is determined by the type and amount of its gluten content. These characteristics are controlled by the genetic constitution and growing conditions of the wheat from which the flour was milled, as well as the milling treatment applied.

Low-protein, soft-wheat flour is appropriate for cakes, pie crusts, cookies, and other products not requiring great expansion and elastic structure. High-protein, hard-wheat flour is adapted to bread, hard rolls, soda crackers, and Danish pastry, all requiring elastic dough and often expanded to low densities by the leavening action.

Since most of the nitrogen in foods consists of protein, the protein content of flour is commonly estimated by the Kjeldahl determination, a process measuring the total nitrogen. Protein quality is often evaluated by measuring the elasticity and extensibility of flour-and-water doughs. Specifications for flours to be used in cakes, pies, and pastries may include limitations on the minimum or maximum viscosity developed in aqueous suspensions under standardized conditions. The effectiveness of the starch-digesting enzymes can be estimated by including a time variable.

Flour particle size and the extent of any damage to starch granules during milling are important factors, especially in cookie production, apparently affecting the hydration rate of the flour in low-moisture-content doughs.

Leavening agents. Pie doughs and similar products are usually unleavened, but most bakery products are leavened, or aerated, by gas bubbles developed naturally or folded in from the atmosphere. Leavening may result from yeast or bacterial fermentation, from chemical reactions, or from the distribution in the batter of atmospheric or injected gases.

Use of bakers' yeast

All commercial breads, except salt-rising types and some rye bread, are leavened with bakers' yeast, composed of living cells of the yeast strain *Saccharomyces cerevisiae*. A typical yeast addition level might be 2 per-

cent of the dough weight. Bakeries receive yeast in the form of compressed cakes containing about 70 percent water or as dry granules containing about 8 percent water. On a dry-weight basis, the gas-generating potentials of the two forms of yeast are about the same. Dry yeast, more resistant to storage deterioration, requires rehydration before it is added to the other ingredients.

Bakers' yeast performs its leavening function by fermenting such sugars as glucose, fructose, maltose, and sucrose. It cannot use lactose, the predominant sugar of milk, or certain other carbohydrates. The principal products of fermentation are carbon dioxide, the leavening agent, and ethanol, an important component of the aroma of freshly baked bread. Other yeast activity products also flavour the baked product and change the dough's physical properties.

The rate at which gas is evolved by yeast during the various stages of dough preparation is important to the success of bread manufacture. Gas production is partially governed by the rate at which fermentable carbohydrates become available to the yeast. The sugars naturally present in the flour and the initial stock of added sugar are rapidly exhausted. A relatively quiescent period follows, during which the yeast cells become adapted to the use of maltose, a sugar constantly being produced in the dough by the action of diastatic enzymes on starch. The rate of yeast activity is also governed by temperature and osmotic pressure, the latter primarily a function of the water content and salt concentration.

Leavening with sodium bicarbonate

Layer cakes, cookies (sweet biscuits), biscuits, and many other bakery products are leavened by carbon dioxide from added sodium bicarbonate (baking soda). Added without offsetting amounts of an acidic substance, sodium bicarbonate tends to make dough alkaline, causing flavour deterioration and discoloration and slowing carbon dioxide release. Addition of an acid-reacting substance promotes vigorous gas evolution and maintains dough acidity within a favourable range.

Carbon dioxide produced from sodium bicarbonate is initially in dissolved or combined form. The rate of gas release affects the size of the bubbles produced in the dough, consequently influencing the grain, volume, and texture of the finished product. Much research has been devoted to the development of leavening acids capable of maintaining the rate of gas release within the desired range. Acids such as acetic, from vinegar, or lactic, from sour milk, usually act too quickly; satisfactory compounds include cream of tartar (potassium acid tartrate), sodium aluminum sulfate (alum), sodium acid pyrophosphate, and various forms of calcium phosphate.

The chemical formulas of these compounds do not adequately indicate their functions in doughs. The addition of small quantities of additives during manufacture can greatly affect the reaction rate of the compound. Granule size and form also have modifying functions. Companies specializing in the manufacture of leavening acids usually offer several types of sodium acid pyrophosphate. The chemical formulas are apparently the same, and analysis will only reveal trace element variations, but the slowest reacting member of this series will produce an initial rate of gas evolution several times slower than the rate produced by the fastest acting compound.

Instead of adding soda and leavening acids separately, most commercial bakeries and domestic bakers use baking powder, a mixture of soda and acids in appropriate amounts and with such added diluents as starch, simplifying measuring and improving stability. The end products of baking-powder reaction are carbon dioxide and some blandly flavoured harmless salts. All baking powders meeting basic standards have virtually identical amounts of available carbon dioxide, differing only in reaction time. Most commercial baking powders are of the double-acting type, giving off a small amount of available carbon dioxide during the mixing and makeup stages, then remaining relatively inert until baking raises the batter temperature. This type of action eliminates excessive loss of leavening gas, which may occur in batter left in an unbaked condition for long periods.

Under baking conditions, ammonium bicarbonate, sometimes used to leaven cookies, decomposes entirely to carbon dioxide, water vapour, and ammonia, leaving no residue of solids. Control of its rate of decomposition is difficult, however, and its ammoniacal odour persists unless the finished product is baked almost to dryness.

Leavening by entrapped air

Angel food cakes, sponge cakes, and similar products are customarily prepared without either yeast or chemical leaveners. Instead, they are leavened by air entrapped in the product through vigorous beating. This method requires a readily foaming ingredient, capable of retaining the air bubbles, such as egg whites. To produce a cake of fine and uniform internal structure, the pockets of air folded in during beating are rapidly subdivided into small bubbles with such mixing utensils as wire whips, or whisks.

The small gas bubbles initially present in other doughs and batters also provide focuses for the evolution of gases produced by yeast or chemical reaction.

The vaporization of volatile fluids (*e.g.*, ethanol) under the influence of oven heat can have a leavening effect. Water-vapour pressure, too low to be significant at normal temperatures, exerts substantial pressure on the interior walls of bubbles already formed by other means as the interior of the loaf or cake approaches the boiling point. The expansion of such puff pastry as used for napoleons (rich desserts of puff pastry layers and whipped cream or custard) and *vol-au-vents* (puff pastry shells filled with meat, fowl, fish, or other mixtures) is entirely due to water-vapour pressure.

Shortening. Fats and oils are essential ingredients in nearly all bakery products. Shortenings have a tenderizing effect in the finished product and often aid in the manipulation of doughs. In addition to modifying the mouth feel or texture, they often add flavour of their own and tend to round off harsh notes in some of the spice flavours.

The common fats used in bakery products are lard, beef fats, and hydrogenated vegetable oils. Butter is used in some premium and specialty products as a texturizer and to add flavour, but its high cost precludes extensive use. Cottonseed oil and soybean oil are the most common processed vegetable oils used. Corn, peanut, and coconut oils are used to a limited extent; fats occurring in other ingredients, such as egg yolks, chocolate, and nut butters, can have a shortening effect if the ingredients are present in sufficient quantity.

Breads and rolls often contain only 1 or 2 percent shortening; cakes will have 10 to 20 percent; Danish pastries prepared according to the authentic formula may have about 30 percent; pie crusts may contain even more. High usage levels require those shortenings that melt above room temperature; butter and liquid shortenings, with their lower melting point, tend to leak from the product.

Desirable properties in general-purpose shortenings include bland flavour, white colour (or clarity in liquids), good plasticity (workability), and flavour stability. Shortening manufacturers achieve these characteristics by such physical and chemical treatments as hydrogenation, blending, catalytic rearrangement, fractionation, and controlled crystallization.

In addition to the usual chemical tests applied to fats, commercial bakeries may evaluate shortening by performance tests of such properties as plasticity, icing volume, water absorption, and characteristics produced in the finished cake.

Commercial shortenings may include antioxidants, to retard rancidity, and emulsifiers, to improve the shortening effect. Colours and flavours simulating butter may also be added. Margarines, emulsions of fat, water, milk solids, and salt, are popular bakery ingredients.

Fats of any kind have a destructive effect on meringues and other protein-based foams; small traces of oil left on the mixing utensils can deflate an angel food cake to unacceptably high density.

Liquids. Water is the liquid most commonly added to doughs. Milk is usually added to commercial prepara-

tions in dried form, and any moisture added in the form of eggs and butter is usually minimal. Water is not merely a diluent or inert constituent; it affects every aspect of the finished product, and careful adjustment of the amount of liquid is essential to make the dough or batter adaptable to the processing method. If dough is too wet it will stick to equipment and have poor response to shaping and transfer operations; if too dry, it will not shape or leaven properly.

The use of water in dough

Water hydrates gluten, permitting it to aggregate in the form of a spongy cellular network, the structural basis of most bakery products. It provides a medium in which yeast can metabolize sugars to form carbon dioxide and flavouring components, and allows diffusion of nutrients and metabolites throughout the mass. Water is an indispensable component of the baking-powder reaction, and it allows starch to gelatinize during baking and prevents interior browning of bakery products.

Water impurities affect dough properties. Water preferred for baking is usually of medium hardness (50 to 100 parts per million) with a neutral pH (degree of acidity), or slightly acid (low pH). Water that is too soft can result in sticky doughs, while very hard water may retard dough expansion by toughening the gluten (calcium ions, particularly, promote cross-linking of gluten protein molecules). Water sufficiently alkaline to raise the dough pH may have a deleterious effect on fermentation and on flour enzymes. Although strongly flavoured contaminants may affect the acceptability of the finished product, chlorides and fluorides at concentrations usually found in water supplies have little influence on bread doughs.

Eggs. The differences between yolks and whites must be recognized in considering the effect of eggs on bakery products. Yolks contain about 50 percent solids, of which 60 percent or more is strongly emulsified fat, and are used in bakery foods for their effect on colour, flavour, and texture. Egg whites, containing only about 12 percent solids, primarily protein, and no fat, are important primarily for their texturizing function and give foams of low density and good stability when beaten. When present in substantial amounts, they tend to promote small, uniform cell size and relatively large volume. Meringues and angel food cakes are dependent on egg white foams for their basic structure. Although the presence of fats and oils greatly diminishes its foaming power, the white still contributes to the structure of layer cakes and similar confections containing substantial amounts of both shortening and egg products.

Whole eggs form a relatively low-volume foam of poor stability but are otherwise intermediate in properties between yolks and whites. In mixed whole egg solids, the egg whites represent about two-thirds of the total weight.

Egg products are available to bakers in frozen or dried form. Few commercial bakers break fresh eggs for ingredients because of labour costs, unstable market conditions, and sanitary considerations. Most bakers use dried egg products because of their greater convenience and superior storage stability over frozen eggs. Processed and stored correctly, dried egg products are the functional equivalent of the fresh material, although flavour of the baked goods may be affected adversely at very high usage levels.

The use of dried eggs

Sweetening agents. Normal wheat flour contains about 1 percent sugars. Most are fermentable compounds, such as sucrose, maltose, glucose, and fructose. Additional maltose is formed during fermentation by the action of amylolytic enzymes (from malt and flour) on the starch. Glucose and sucrose are the sugars most frequently added to doughs and batters. The presence of yeast rapidly converts the sucrose to fructose and glucose (*i.e.*, invert sugar). Invert sugar can also be added to mixtures not containing yeast.

Sweetening power is the obvious property of added sugars, but sugars also provide fermentables for yeast activity. Crust colour development is related to the amount of reducing sugars present, and a dough in which the sugars have been thoroughly depleted by yeast will produce a poorly browned crust.

Doughs having high concentrations of dissolved substances retard fermentation because of the high osmotic pressure (low water activity) of the aqueous phase. Sugars constitute the bulk of dissolved materials in most doughs; and for this reason, sweet yeast-leavened goods develop gas and expand more slowly than bread doughs.

Sugar at high concentrations will tenderize the finished baked product by interfering with the hydration of the gluten network and the gelatinization of starch granules.

In addition to cane and beet sugar and corn syrups, honey and molasses often are used as sweeteners in crackers and cookies.

TYPES OF BAKERY PRODUCTS AND PRODUCTION METHODS

Yeast-leavened products. Breads and rolls constitute most of the bakery foods consumed throughout the world, and most bread and rolls are made from yeast-leavened doughs. The yeast-fermentation process leads to the development of desirable flavour and texture, and such products are nutritionally superior to products of the equivalent chemically leavened doughs, since yeast cells themselves add a wide assortment of vitamins and good quality protein.

Satisfactory white bread can be made from flour, water, salt, and yeast. (A "sourdough" addition may be substituted for commercial yeast.) Yeast-raised breads based on this simple mixture include Italian-style bread, and French or Vienna breads. Such breads have a hard crust, are relatively light in colour, with a course and tough crumb, and flavour that is excellent in the fresh bread but deteriorates with age. In the U.S., commercially produced breads of this type are often modified by the addition of dough improvers, yeast foods, mold inhibitors, vitamins, minerals, and small quantities of enriching materials such as milk solids or shortening. Formulas may vary greatly from one bakery to another and between different sections of the country. The standard low-density, soft-crust bread and rolls constituting the major proportion of breads and rolls sold in the U.S. contain greater quantities of enriching ingredients than the lean breads described above.

Breads designed to take advantage of consumer demands for unusual flavours or special nutritional qualities can assume an almost unlimited range of forms and compositions. Whole-wheat bread, using a meal made substantially from the entire wheat kernel instead of flour, is a dense, rather tough, dark product. Breads sold as wheat or part-whole-wheat products contain a mixture of whole grain meal with sufficient flour to produce satisfactory dough expansion. Bread made from crushed or ground whole rye kernels, without any wheat flour, such as pumpernickel, is dark, tough, and coarse textured. Rye flour with the bran removed, when mixed with wheat flour, allows production of a bread with better texture and colour. In darker rye bread, it is customary to add caramel colour to the dough, and most rye bread is flavoured with caraway seeds. Rye bread is sometimes made by the sourdough method, requiring addition of a small portion of a dough previously allowed to develop lactic-acid-producing bacteria. These bacteria are micro-organisms that ferment some of the sugars in the fresh dough batch, producing characteristic tastes and odours. Bakery supply houses offer dehydrated cultures as sourdough substitutes.

Sourdough method for rye bread

Salt-rising bread, a specialty product, derives its pungent aroma from combined yeast and bacterial fermentation. It was formerly made by a natural sourdough method, but commercial cultures are now available to provide the inoculum. The product name refers to the original use of a high-salt concentrate sourdough limiting growth of common yeasts, thus creating a better environment for growth of the desired bacteria species.

Potato bread, another variety that can be leavened with a primary ferment, was formerly made with a sourdough utilizing the action of wild yeasts on a potato mash and producing the typical potato-bread flavour but is now commonly prepared from a mixture of bakers' yeast, potato flour, and water.

The sponge and dough process is usually employed in making white bread and many specialty breads. The other conventional dough-preparation procedure, the straight dough method, in which all of the ingredients are mixed in one step, is rarely used for regular white bread. It is not sufficiently adaptable to allow compensation for the usual fluctuations in ingredient properties.

The sponge and dough mixing method consists of two distinct stages. In the sponge stage, the mixture, or sponge, usually contains one-half to three-fourths of the flour, all of the yeast, yeast foods, and malt, and enough water to make a stiff dough. Shortening may be added at this stage, although it is usually added later, and one-half to three-fourths of the salt may be added to control fermentation. The sponge is fermented until it begins to decline in volume. The time required for this process, called the drop or break, depends upon such variables as temperature, type of flour, amount of yeast, absorption, and amount of malt, which are frequently adjusted to produce a drop in about three to five hours.

At the dough stage, the sponge is returned to the mixer, and the remaining ingredients are added. The dough is developed to an optimum consistency, then returned to the fermentation room.

Judging dough developments

The ability to judge dough development must be acquired by experience. Mixing personnel often learn to estimate the stage of development by the sound of the dough as it slaps the mixer bowl. When objective measuring techniques are employed, optimum development is the stage at which the dough mass exhibits maximum resistance to shearing. Visually, development is optimal when the dough mass, exhibiting a silky sheen, is thrown around the mixer bowl in one piece, stretching elastically from the mixer arm but not breaking into pieces. A piece of this dough, removed from the mixer and stretched with the fingers, can be formed into a thin film having a webbed appearance when viewed by transmitted light.

Advantages of the sponge and dough method include: (1) a saving in the amount of yeast; about 20 percent less is required than for a straight dough; (2) the greater volume and more desirable texture and grain usually produced; and (3) the greater flexibility allowed in operations because, in contrast to straight doughs that must be taken up when ready, sponges can be held for later processing without marked deterioration of the final product.

The sponge method, however, involves extra handling of the dough, additional weighing and measuring, and a second mixing and thus has the disadvantage of increasing labour, equipment, and power costs.

Recommended variations in the straight dough process include the remixed straight dough process, with a small portion of the water added at the second mix, and the no-punch method, involving extremely vigorous mixing. Continuous mixing processes can be considered either straight dough methods or sponge methods, with the "sponge" consisting of the liquid ferment. Based on flour performance, they may be considered straight dough processes (Figure 1).

Yeast-leavened sweet goods, made from mixtures similar in many respects to bread doughs, include "raised" doughnuts, Danish pastries, and coffee cakes. The two main classifications are remix sweet doughs, corresponding to a sponge and dough bread product, and the straight doughs. With these two procedures, an almost infinite number of varieties can be produced by varying flavouring, filling, icing, and shape.

Sweet doughs, richer in shortening, milk, and sugar than bread doughs, often contain whole eggs, egg yolks, egg whites, or corresponding dried products. The enriching ingredients alter the taste, produce flakier texture, and improve nutritional quality. Spices such as nutmeg, mace, cinnamon, coriander, and ginger are frequently used for sweet-dough products; other common adjuncts include vanilla, nuts and nut pastes, peels or oils of lemon or orange, raisins, candied fruit pieces, jams, and jellies.

Although various portion-sized sweet goods are often called "Danish pastry," the name originally referred only to products made by a special roll-in procedure, in which

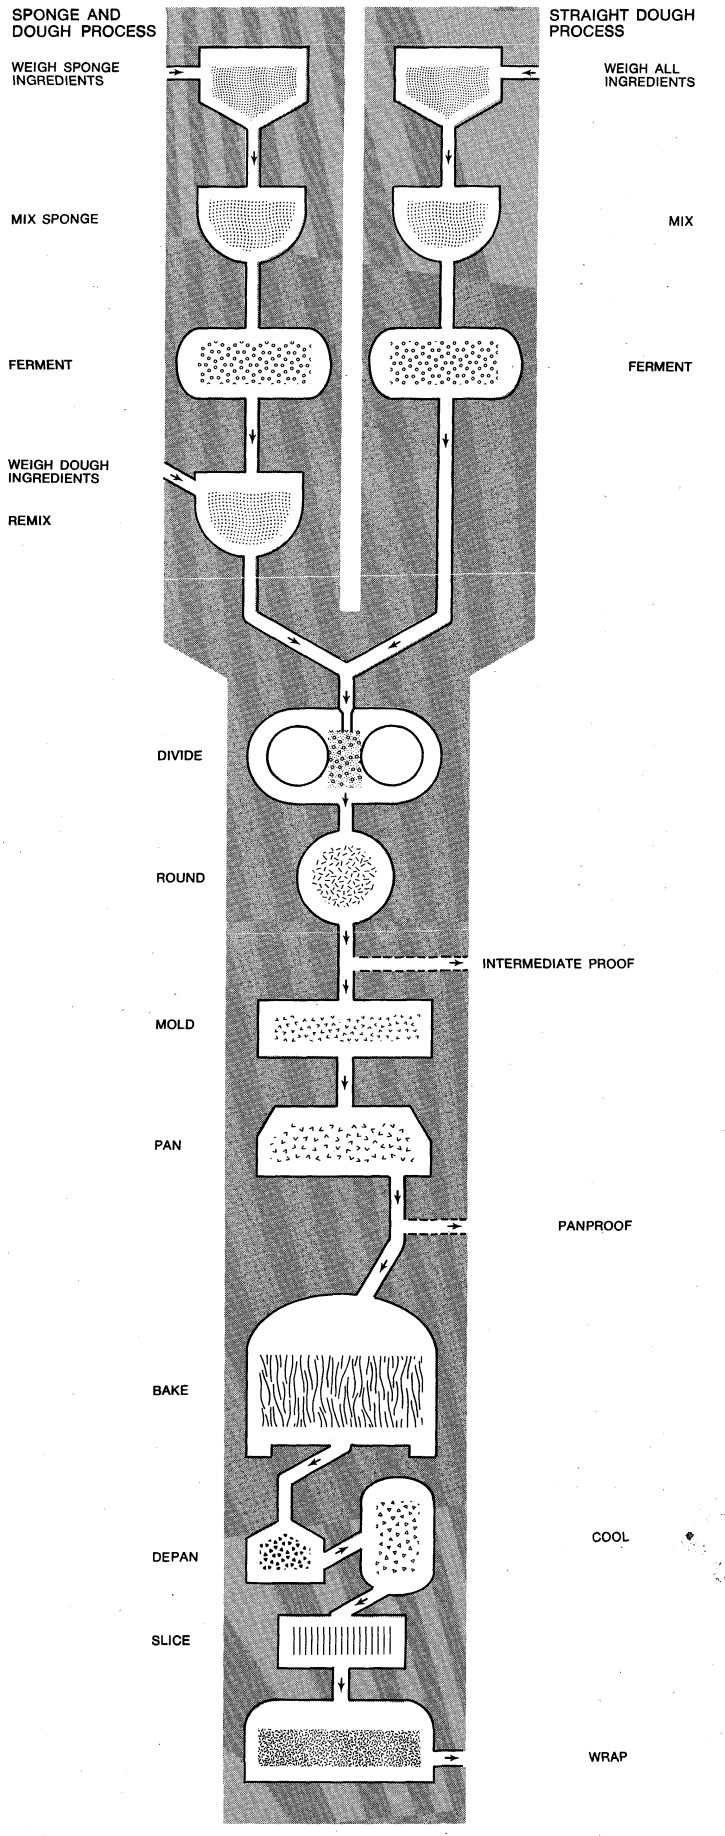


Figure 1: Steps in conventional (batch) production of bread.

Danish pastry production

yeast-leavened dough sheets are interleaved with layers of butter, and the layers are reduced in thickness, then folded to obtain many thin layers of alternating shortening and dough. Danish doughs ordinarily receive little fermentation. Before the fat is rolled in, there is an initial period of 20 to 30 minutes in the refrigerator, allowing some gas and flavour to develop. Proof time, fermentation of the piece in its final shape, is usually only 20 to 30 minutes, at lower temperatures. When properly made, these doughs yield flaky, baked products, rich in shortening, with glossy crusts.

Equipment. In most large, modern bakeries ingredients are mainly received and transferred by bulk-handling methods. Flour is pneumatically conveyed and stored in large tanks; shortening is received and stored in the liquid state; and water is continuously adjusted to the proper temperature and measured by precision pumps. Ingredients used in small quantities, such as milk solids, yeast, and eggs, are sometimes handled in bulk but are more often received and dispensed in small unit packages. In addition to the economic advantages of bulk handling, the mixing effects inherent in transporting and storing by these methods result in high ingredient uniformity.

Bread doughs customarily are mixed in large, horizontal dough mixers, processing about 2,000 pounds per batch, and usually constructed with heat-exchange jackets, allowing temperature control. The objectives of mixing are a nearly homogeneous blend of the ingredients, and "developing" of the dough by formation of the gluten into elongated fibres that will form the basic structure of the loaf. Because intense shearing actions must be avoided, the usual dough mixer has several horizontal bars, oriented parallel to the body of the mixer, rotating slowly at 35 to 75 revolutions per minute (rpm), stretching and kneading the dough by their action. A typical mixing cycle would be about 12 minutes.

The mixed bread dough is dumped into a trough, a shallow rectangular metal tank on wheels, and placed in an area of controlled temperature and humidity (*e.g.*, 80° F and 75 percent relative humidity), where the "sponge" undergoes about four hours of fermentation. The fermented sponge is next dumped into a horizontal dough mixer, often the same mixer that is used for the sponge mix, and the remaining dough ingredients are then incorporated (Figure 2).

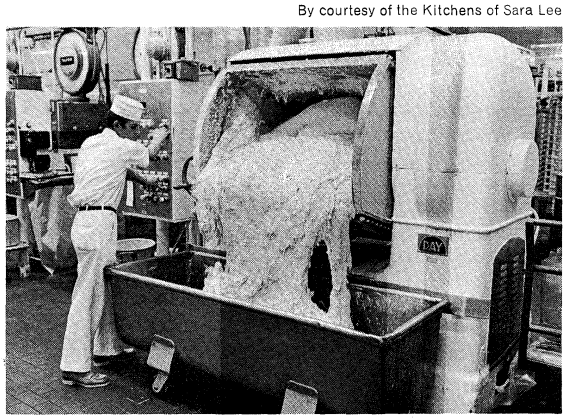

Figure 2: Dough mixer, showing a scientifically mixed batch of Danish dough being dropped into a stainless steel trough. When the mixer is closed, computer-measured liquid and dry ingredients enter at the top of the mixer, assuring uniformity of each batch.

Makeup equipment

The remixed dough is processed by a series of devices loosely classified as makeup equipment. In the manufacture of pan bread, makeup equipment includes the divider, the rounder, the intermediate proofer, and the molder. With the exception of the intermediate proofer, each of these devices changes the shape of the dough piece. Although the dough remains in approximately the same state of chemical and physical development throughout its processing in the makeup equipment, chemical and biological changes do occur in the intermediate proofer.

After the mass of dough has completed fermentation, and has been remixed if the sponge and dough process is employed, the filled trough is moved to the divider area or to the floor above the divider. The dough is dropped into the divider hopper, which cuts it into loaf-sized pieces. Since equipment that subdivides the dough satisfactorily on a weight basis is not yet available, the present apparatus operates on a volumetric basis, forcing the dough into pockets having a known volume. The pocket contents are cut off from the main dough mass, ejecting pieces of constant volume onto a conveyor leading to the rounder. A reciprocating division box is used for measuring. When density is kept constant, weight and volume of the dough pieces is the same, but since continual gas development may cause density variation, fluctuations may occur in the weight of the finished pieces.

Commercial dividers have from two to eight pockets in the cylinder, operate at speeds up to 25 strokes per minute, have a scaling range from 6 to 36 ounces, and use motors having up to 7½ horsepower.

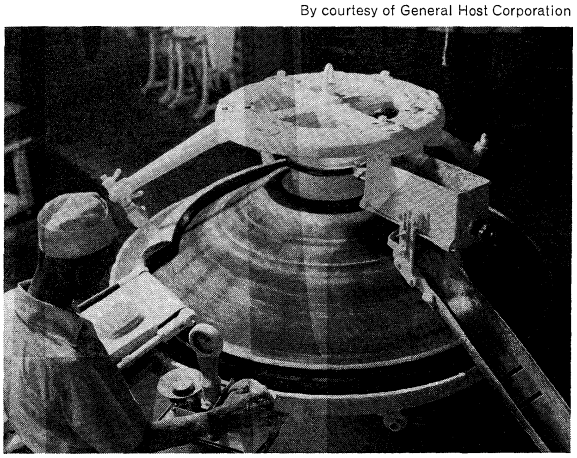

Figure 3: Rounder, which shapes the loaf-size pieces of bread dough into flour-sprinkled balls.

Function of the rounder

Dough pieces leaving the divider are irregular in shape, with sticky cut surfaces from which the gas can readily diffuse. Their gluten structure is somewhat disoriented and unsuitable for molding. The rounder closes these cut surfaces, giving each dough piece a smooth and dry exterior; forms a relatively thick and continuous skin around the dough piece, reorienting the gluten structure; and shapes the dough into a ball for easier handling in subsequent steps. It performs these functions by rolling the well-floured dough piece around the surface of a drum or cone, moving it upward or downward along this surface by means of a spiral track. As a result of this action, the surface is dried both by the even distribution of dusting flour and by dehydration resulting from exposure to air; the gas cells near the surface of the ball are collapsed, forming a thick layer inhibiting the diffusion of gases from the dough; and the dough piece assumes an approximately spherical shape (Figure 3).

Rounding machines vary in such features as configuration of the rounding surface; texture or composition of dough-contacting parts; mechanism for adjusting the relationship of the dough race, or hook, to the fixed drum or cone; and method of applying dusting flour.

Dough leaving the rounder is almost completely degassed. It lacks extensibility, tears easily, has rubbery consistency, and has poor molding properties. To restore a flexible, pliable structure that can be easily shaped by the molder, the dough piece must be allowed to rest while fermentation proceeds. This is accomplished by letting the dough ball travel through an enclosed cabinet, the intermediate proofer, for several minutes. Physical changes, other than gas accumulation, occurring during this period are not yet understood, but there are appar-

ently alterations in the molecular structure of the dough rendering it more responsive to subsequent operations. Upon leaving the intermediate proofer, the dough is more pliable and elastic, its volume is increased by gas accumulation, and its skin is firmer and drier.

Most intermediate proofers are the overhead type, in which the principal part of the cabinet is raised above the floor, allowing space for other makeup machinery beneath it. Intermediate proofers of all types are equipped with variable-speed controls to determine the length of time dough pieces spend within the cabinet. Although interior humidity and temperature control is desirable, most intermediate proofers, having no air-conditioning attachments, depend upon humidity accumulating from the loaves and upon ambient temperatures.

Shaping of dough by molder

The molder receives pieces of dough from the intermediate proofer and shapes them into cylinders ready to be placed in the pans. There are several types of molders, but all have four functions in common: sheeting, curling, rolling, and sealing. The dough as it comes from the intermediate proofer is a flattened spheroid; the first function of the molder is to flatten it into a thick sheet, usually by means of two or more consecutive pairs of rollers, each succeeding pair set more closely together than the preceding pair. The sheeted dough is curled into a loose cylinder by a special set of rolls or by a pair of canvas belts. The spiral of dough in the cylinder is not adherent upon leaving the curling section, and the next operation of the molder is to seal the dough piece, allowing it to expand without separating into layers. The conventional molder rolls the dough cylinder between a large drum, and a smooth-surfaced semicircular compression board. Clearance between the drum and board is gradually reduced, and the dough, constantly in contact with both surfaces, becomes transversely compressed (Figure 4).

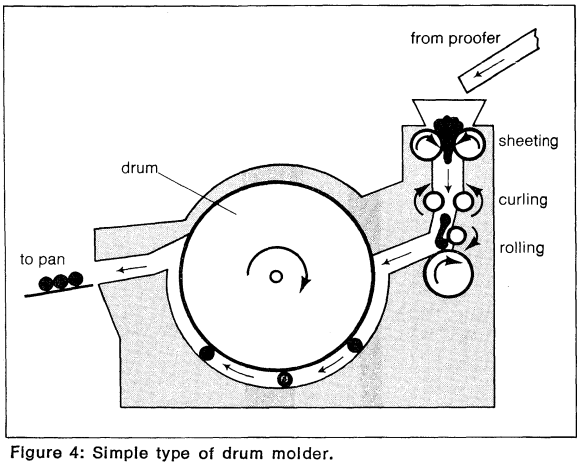

Figure 4: Simple type of drum molder.

The automatic panning device is an integral part of most modern molders. As the empty pans, carried on a conveyor, pass the end of the machine, the loaves are transferred from the molder and positioned in the pans by a compressed air-operated device. Before the filled pans are taken to the oven, the dough undergoes another fermentation, or pan-proofing, for about 20 minutes, at temperatures of 100° to 120° F (38° to 49° C) and relative humidity of about 82 percent.

The output of all other equipment is usually keyed to the oven, probably the most critical equipment in the bakery, operated at full capacity whenever possible. Most modern commercial bakeries use either the tunnel oven, consisting of a metal belt passing through a connected series of baking chambers open only at the ends, or the tray oven, with its rigid baking platform carried on chain belts. Other types include the peel oven, having a fixed hearth of stone or brick on which the loaves are placed with a wooden paddle or peel; the reel oven, with shelves rotating on a central axle in ferris-wheel fashion; the rotating hearth oven; and the draw plate oven. Most ovens are heated by gas burned within the chamber, although oil or electricity may be used. Burners are sometimes isolated from the main chamber, heat transfer then occurring through induced currents of air.

Reactions in the oven are both physical and chemical in nature. Physical reactions include film formation, gas expansion, reduction of gas solubility, and alcohol evaporation. Chemical reactions include yeast fermentation, carbon dioxide formation, starch gelatinization, gluten coagulation, sugar caramelization, and browning.

Automatic loaders and unloaders move the pans in and out of the ovens. Automatic depanners, removing the loaves from the pans, either invert the pans, jarring them to dislodge the bread, or pick the loaves out of the pans by means of suction cups attached to belts.

Continuous bread making. Many steps in the conventional bread-making procedure have been fully automated, but the batch process was the basic approach until about 1955, when two systems relying on truly continuous dough preparation were developed. In both systems the dough is handled continuously from the time the ingredients are mixed until it is deposited in the pan, although the initial fermentation process, still essentially a batch procedure, is conducted in tanks (Figure 5).

Continuous systems, operating without interruption for the addition of ingredients, feed the baker's formula to a device mixing all ingredients into a homogeneous mass. The batter-like material passes through a dough pump regulating the flow and delivering the mixture to a developing apparatus, where kneading work is applied to obtain desirable dough structure and proper gas-retention properties. The dough moves out of the developer into a metering device that constantly extrudes the dough and intermittently severs a loaf-sized piece, which falls into a pan passing beneath (Figure 5).

Although ingredients are generally the same as those used in batch processes, closer control and more rigid specifications are necessary in continuous processing to assure satisfactory operation of each unit. Changes in conditions cannot be readily made to compensate for changes occurring in ingredient properties. Oxidizers, such as bromate and iodate, are added routinely to compensate for the smaller amount of oxygen brought into the dough during mixing. Most of the flavour in continuous-mix breads results from a preferment, called the broth or liquid sponge, a mixture of water, yeast, sugar, and portions of the flour and other ingredients, fermented for a few hours before being mixed into the dough.

Advantages of continuous mixing

In addition to the labour-saving aspects of the continuous-mix process, there are also quality benefits. The grain, or cell structure, of the bread is small and regular, and the loaves are uniform in appearance. The flavour is sometimes considered blander than that of conventionally made loaves, but this characteristic apparently has little effect on consumer acceptance.

The developer, the key equipment in the production line, processing about 100 pounds (45 kilograms) each 90 seconds, changes the batter from a fluid mass having no organized structure, little extensibility, and inadequate gas retention, to a smooth, elastic, film-forming dough. The mechanical effort involved causes a temperature rise of 18° to 24° F (10° to 13° C) in the developer.

Chemically leavened doughs and batters. Many bakery products depend upon the evolution of gas from added chemical reactants as their leavening source. Items produced by this system include layer cakes, cookies, muffins, biscuits, corn bread, and some doughnuts.

The gluten proteins of the flour serve as the basic structural element in chemically leavened foods, just as they do in bread. The relatively smaller amounts of flour, the weaker (less extensible) protein in the soft-wheat flours customarily employed, and the lower protein content of the flour, however, result in a softer, crumblier texture. In most chemically leavened foods, the protein content of the flour, inadequate in quantity and quality to support the amount of expansion required in bread, produces a product of higher density.

Prepared dry mixes, available for home use and for

small- and medium-sized commercial bakeries, vary in complexity from self-rising flour, consisting only of salt, leavening ingredients, and flour, to elaborate cake mixes. Mixes offer the consumer ingredients measured with greater accuracy than possible with kitchen utensils, and special ingredients designed for functional compatibility.

Prepared doughs for such products as biscuits and other quick breads, packaged in cans of fibre and foil laminates, are available in refrigerated form. These products carry the mix concept two steps further; the dough or batter is premixed and shaped. Unlike ordinary canned products, refrigerated doughs are not sterile but contain microbiological organisms from normal ingredient contamination. Spoilage is retarded by low storage temperature, low oxygen tension, and the high osmotic pressure of the aqueous phase.

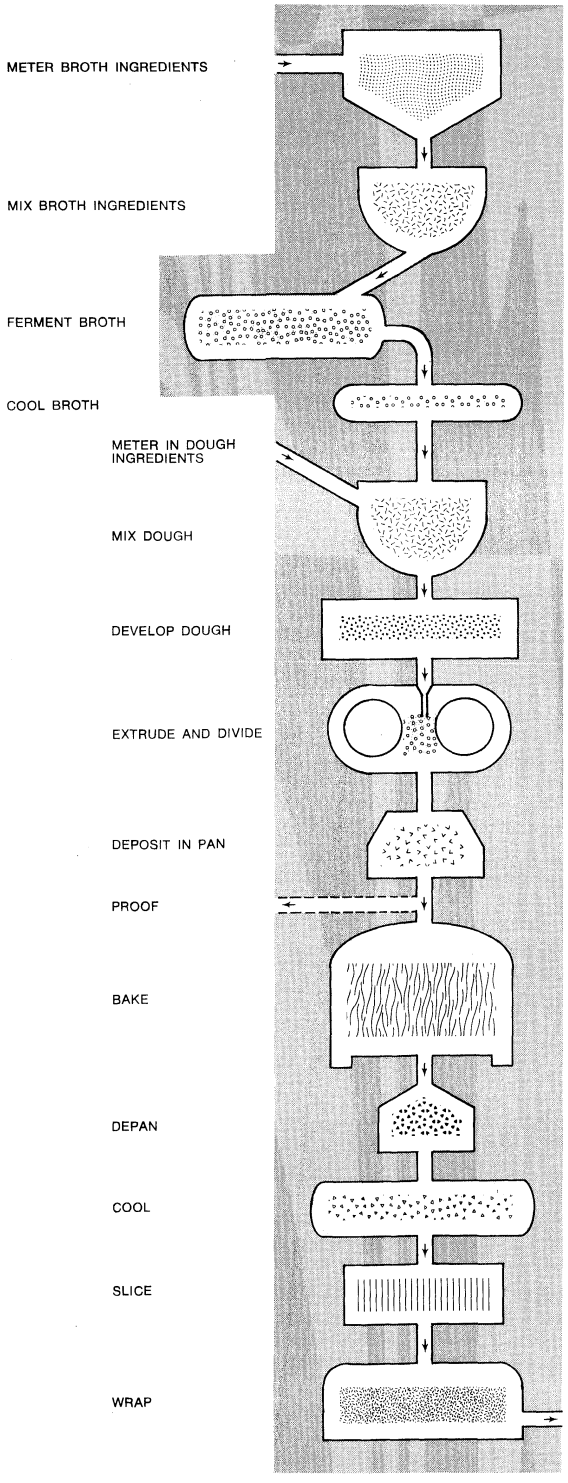

Figure 5: Essential steps in continuous production of bread.

Basic makeup of hot breads

Hot breads, such as biscuits, muffins, pancakes, and scones, constitute a large and important class of chemically leavened bakery foods. They consist of flour, baking powder, salt, and liquid, with varying amounts of eggs, milk, sugar, and shortening. Other variations include the addition of fruits such as raisins, condiments such as peppers, and adjuncts such as cheese. In corn breads a considerable proportion of the flour is replaced by corn meal. Mixing and forming methods, and the baking conditions applied, also affect product appearance, texture, and flavour. For example, a batter suitable for making corn bread might also be used to make muffins or pancakes, and each kind of finished product would vary not only in appearance but also in flavour and texture. Recipes for hot breads usually contain not more than about 15 percent shortening and 5 percent sugar. Eggs, when used, are customarily whole eggs. Milk is often used both for flavour and for its texturizing and crust coloration properties.

Pancake batter formulas are similar to other quick-bread recipes, except for the inclusion of larger amounts of liquid. Some muffins are much like layer cakes in composition, with increased sugar, shortening, and eggs producing more tender texture, sweeter flavour, and lower density. Flavourings, usually constituting only a small portion of the total batter, also differentiate cakes from quick breads. Vanilla is a common flavour in all kinds of cakes, and bitter chocolate (chocolate liquor, baking chocolate) or cocoa, at the 3 or 4 percent level, is used in chocolate or devil's food cakes.

There are traditional rules for assuring "formula balance," or the correct proportioning of ingredients, in layer cakes. For every ten parts of flour, yellow layer cakes should contain 10 to 16 parts sugar by weight, white layer cakes should contain 11 to 16 parts sugar. Shortening should range from three to seven parts for each ten parts of flour. The weight of liquid whole eggs should equal or exceed that of the shortening in the mixture. Total water, including the moisture in eggs and milk, should exceed the amount of sugar by 2½ to 3½ parts. Baking powder weight should equal from 3 to 6 percent of flour weight; salt should equal 3 to 4 percent of flour weight. If the amount of sugar in a formula is increased, the egg content should be increased an equal amount, and more shortening should be added when the percentage of eggs is increased. Additional water is rarely added when the formula contains dry milk, but if the formula water is not sufficient to equal the reconstitution water for the milk, about 1 percent of water for each additional percent of milk solids is added.

Rich formulas (those with large amounts of sugar, shortening, and eggs) are exceptions to the traditional rules, needing less chemical leavening because more air is incorporated during mixing. Their batters display lower specific gravity for the same reason and are baked at a lower temperature; also, batters baked in large-piece sizes require less water and less leavener than those baked in small size pans (*e.g.*, layer cakes as compared with cup cakes).

Common cake varieties include white cake, similar in formula to yellow cake, except that the white cake uses egg whites instead of whole eggs; devil's food cake, differing from chocolate cake chiefly in that the devil's food batter is adjusted to an alkaline level with sodium bicarbonate; chiffon cakes, deriving their unique texture from the effect of liquid shortening on the foam structure; and gingerbread, similar to yellow cake but containing large amounts of molasses and spices.

Variability of cookie recipes

Recipes for cookies (called biscuits or sweet biscuits in some countries) are probably more variable than those for any other type of bakery product. Some layer-cake batters can be used for soft drop cookies, but most cookie formulas contain considerably less water than cake recipes, and cookies are baked to a lower moisture content than any normal cake. With the exception of soft types,

the moisture content of cookies will be below 5 percent after baking, resulting in crisp texture and good storage stability.

Cookies are generally high in shortening and sugar. Milk and eggs are not common ingredients in commercial cookies but may be used in home recipes. Sugar granule size has a pronounced effect on cookie texture, influencing spread and expansion during baking, an effect partly caused by competition for the limited water content between the slowly dissolving sugar and the gluten of the flour.

Equipment. Commercial production methods and equipment for chemically leavened bakery foods are designed to produce specific items, although the horizontal dough mixers used for yeast-leavened products may also be used for mixing chemically leavened doughs and batters. Mixers may be the batch type, similar in configuration to the household mixer, with large steel bowls, open at the top, containing the batter while it is mixed or whipped by beater paddles of various conformations. In continuous mixers, the batter is pumped through an enclosed chamber while a toothed disk rapidly rotates and mixes the ingredients. The chambers may be pressurized to aerate the batter and surrounded with a flowing heat-transfer medium to adjust the temperature.

The shape of layer cakes and other items made from batters results mainly from the form of the container into which the batter is deposited. In production lines shaping or forming equipment is replaced by metering devices extruding the desired volume of batter into each cavity of the baking pan. Metering can be performed by calibrated rotary pumps or by piston-type dispensers. In the production of batter doughnuts, simple extruders form the mixture into ring shape just before it is dropped into the hot fat.

Chemically leavened doughs can be formed by methods similar to those used for yeast-leavened doughs of similar consistency. In the usual sequence, the dough passes between sets of rollers, forming sheets of uniform thickness; the desired outline is cut in the sheet by stamping pressure or embossed rollers; and the scrap dough is removed for reprocessing. Many cookies and crackers are made in this way, and designs may be impressed in the dough pieces by docking pins (used primarily to puncture the sheet, preventing formation of excessively large gas bubbles) or by cutting edges partially penetrating the dough pieces.

Specialized machines designed for the production of fancy sweet goods integrate and automate the operations of sheeting, application of liquid and solid flavouring materials, rolling the sheet into a continuous cylinder, sealing and cutting the roll into sections of the desired size.

Die forming and extrusion of cookies

In addition to the sheeting and cutting methods, cookies may be shaped by die forming and extrusion. In die forming a dough casing may be applied around a centre portion of jam or other material; or portions of dough may be deposited, forming such drop-type cookies as vanilla wafers, chocolate chip, and oatmeal cookies. Extrusion is accomplished by means of a die plate having orifices that may be circular, rectangular, or complex in outline. The mass of dough, contained in a hopper, is pushed through these openings, forming long strands of dough. Individual cookies are formed by separating pieces from the dough strand with a wire passing across the outer surface of the die, or by pulling apart the hopper and oven belt (to which the dough adheres). Fig bars and similar cookies are baked in a continuous strand, then sliced by disk cutters running across the lines of baked, extruded bars as they leave the band oven.

Cookies produced on rotary molders include sandwich-base cakes and pieces made with embossed designs. A steel cylinder, the surface covered with shallow engraved cavities, rotates past the opening in a hopper filled with cookie dough. The pockets are filled with the dough, which is sheared off from the main mass by a blade; and as the cylinder continues its revolution, the dough pieces are ejected onto a conveyor belt leading to the band oven.

Sugar-wafer bases are formed on large griddle-like molds. A thin batter is poured onto the bottom half of a hot mold, and the top section is pressed down, while baking is completed by externally applied heat. The mold is then opened and the wafer ejected.

Most commercial bakery ovens are the band types, although reel ovens are still used, especially in smaller shops or bakeries where short runs are frequent.

Air- and steam-leavened products. The tiny air bubbles mixed into doughs and batters during their preparation, or originating as occluded gases in ingredients such as flour, are highly important as focuses for gas evolution from the dissolved and combined state in both chemically leavened and fermented goods. In addition, the air expands during the baking process, contributing substantially to the leavening action. In foam products, the foams may be the sole source of leavening action, with air entrapped in an agent capable of forming thin vesicle walls (*e.g.*, egg white).

Foams and sponges

The albumen of egg white, a protein solution, foams readily when whipped. The highly extended structure has little strength and must be supported during baking by some other protein substance, usually the gluten of flour. Because the small amount of lipids in flour tend to collapse the albumen foam, flour is gently folded into egg white foams, minimizing contact of fatty substances with the protein. Gluten sponges are denser than the lightest egg-white foams but are less subject to fat collapse. The foam of egg yolks and whole eggs, as in pound cakes, is an air-in-oil emulsion. Proteins and starch, scattered throughout the emulsion in a dispersed condition, gradually coalesce as the batter stands or is heated. Fats and oils, in addition to yolk lipids, can be added to such systems without causing complete collapse but never achieve the low density possible with protein foams and usually have a tender, crumbly texture, unlike the more elastic structure of albumen-based products. Air-leavened bakery products, avoiding the flavours arising from chemical and yeast-leavening systems, are particularly suitable for delicately flavoured cakes. Since the batters can be kept on the acidic side of neutrality, the negative influence of chemical leaveners on fruit flavours and vanilla is avoided.

Rye wafers made of whipped batters are modern versions of an ancient Scandinavian food. High-moisture dough or batter is whipped, extruded onto an oven belt, scored and docked, then baked slowly until almost dry.

Beaten biscuits, an old Southern U.S. specialty, are also made from whipped batter. Air is beaten into a stiff folded dough with many strokes of a rolling pin or similar utensil. Round pieces cut from the dough are pricked with a fork to prevent development of large bubbles, then baked slowly. The baked biscuit is similar to a soft cracker.

All leavened products rely to some extent on water-vapour pressure to expand the vesicles or gas bubbles during the latter stages of baking, but some items also utilize the leavening action produced by the rapid build-up of steam as the interior of the product reaches the boiling point. These foods include puff pastries, used for patty shells and napoleons, and chou pastes, often used for cream-puff cases.

Puff pastry, often used in French pastries, is formed from layered fat and dough. The proportion of fat is usually high, rarely less than 30 percent of the finished raw piece. The dough should be extensible but not particularly elastic; for this reason mixtures of hard and soft wheat flour are often used. The fat should have an almost waxy texture and must remain solid through the sheeting steps. Butter, although frequently used, is not particularly suitable for puff pastry because of its low melting point. Bakers specializing in puff pastry often use special margarines containing high-melting-point fats.

Puff pastry production methods

There are several methods of making puff pastry. In the basic procedure dough is rolled into a rectangular layer of uniform thickness, and the fat is spread over two-thirds of the surface. Although the usual practice is to place lumps of margarine on the dough, a more efficient practice is to place fat slices of equal thickness close to-

gether on the dough surface. The dough is next folded, producing three dough strata enclosing two fat layers. This preparation is next chilled by refrigeration, then rolled, reducing thickness until it reaches approximately the area of the original unfolded dough. The folding, refrigeration, and rolling procedure is repeated several times, and after the final rolling the dough is reduced to the thickness desired in the shaped raw piece.

The goal of this process is reduction of the layers of fat and dough to the minimum thickness consistent with their retention in continuous sheets. Refrigeration helps maintain the fat in solid form throughout the rolling steps; rolling would otherwise tend to mix the fat into the dough. An initial baking period at high temperature causes the puffing and is followed by a lower temperature stage to complete drying.

Correctly prepared puff pastry will expand as much as ten times during baking because of the evolution of large volumes of steam at the interface between shortening and dough. The focuses for production are the microscopic air bubbles rolled into the dough during the layering process. If layering has been properly conducted, the finished pieces will be symmetrical and well shaped, with crisp, flaky outer layers.

Chou paste, used for cream puffs, is made by an entirely different method. Flour, salt, butter, and boiling water are mixed together, forming a fairly stiff dough, and whole eggs are incorporated by beating. Small pieces of the dough are baked on sheets, initially at high temperature. The air bubbles formed during mixing expand rapidly at baking temperatures, filling the interior with large, irregular cells, while the outside browns and congeals, forming a rather firm case. The interior, largely hollow, can be injected with such sweet or savoury fillings as whipped cream or shrimp in sauce.

Unleavened bakery products. The tortillas of Central America and the chapatties of India are later examples of ancient flatbread, which was, for all practical purposes, unleavened. Pie crusts, the major volume item in this category prepared by modern bakeries, usually are unleavened. Small amounts of baking powder or soda are sometimes added to pie-crust doughs, mostly in domestic cookery. This addition, although increasing tenderness, tends to eliminate the desirable flakiness and permits the filling liquid to soak into the crust more rapidly.

Pie crusts are usually simple mixtures of flour, water, shortening, and salt. The shortening proportion is about 30 to 40 percent of the dough. The amount of water is kept low, and the mixing process is kept short to minimize development of elasticity, leading to shrinkage and development of toughness on baking. For flaky crust, the fat should not be completely dispersed through the dough, but should remain in small particles. Commercial producers often employ special mixers using reciprocating, intermeshing arms to gently knead the dough. The doughs are chilled before mixing and forming, to reduce smearing of the shortening.

Flakiness is also related to the type of shortening used. Lard is popular in home cookery for this reason, and also because of its satisfying flavour. Because shortening should be solid at the temperature of mixing, oils are undesirable.

Milk or small amounts of corn sugar may be added to improve crust browning and for their flavour effect. About 1 to 2 percent of the dough will be salt.

MARKETING PREPARATION

Slicing of bread

Bread often is marketed in sliced form. Slicing is performed by parallel arrays of saw blades through which the loaves are carried by gravity or by conveyors. The blades may be endless bands carried on rotating drums, or relatively short strips held in a reciprocating frame. Most bread is sliced while still fairly warm, and the difficulty of cutting the sticky, soft crumb has led to development of coated blades and blade-cleaning devices. Horizontal slicing of hamburger rolls and similar products is accomplished by circular (disk) blades, usually two blades in a slicer, between which four or six rolls are carried by a belt. The cutter blades are separated to avoid cutting completely through the roll, in order to leave a "hinge."

Freezing is an indispensable bakery industry process. Ordinary bread and rolls are rarely distributed and sold in frozen form because of the excessive cost in relation to product value, but a substantial percentage of all specialty products is sold in frozen form. Most bakery products respond well to freezing, although some cream fillings must be especially formulated to avoid syneresis, or gel breakdown. Rapid chilling in blast freezers is preferred, although milder methods may be used. Storage at 0° F (−18° C) or lower is essential for quality maintenance. Thawing and refreezing is harmful to quality. Frozen bakery products can dehydrate under freezer conditions and must be packaged in containers resistant to moisture-vapour transfer.

The use of doughs and batters frozen and stored for later baking facilitates both commercial bakery production and distribution to consumers. Products can be prepared in advance when labour is available, stored frozen, then baked as required to meet customer demand. The unbaked dough can be prepared in central plants, frozen, and transferred to small branch bakeries, reducing the equipment and skilled labour requirements to make freshly baked foods available at branch outlets.

Most U.S. consumers prefer wrapped bread, and the trend toward wrapping is growing in other countries. Sanitary and aesthetic considerations dictate protection of the product from environmental contamination during distribution and display. Waxed paper was originally the only film used to package bread; then cellophane became popular; and polyethylene and combination laminates became common in the late 1960s. Other bakery products are packaged in a variety of containers ranging from open bags of greaseproof material to plastic trays with sealed foil overwraps.

Canning bakery products

In the early 1970s the market for bakery products in tin cans was small. Hunters and campers found canned foods convenient. Canning protects against drying and environmental contamination, but at a cost in texture staling and some degree of flavour staling. In processing, an amount of dough or batter known to fill exactly the available space after baking is placed in a can and the cover is loosely fastened to allow gases to escape. The product is then baked in a conventional oven; the lid is hermetically sealed immediately after baking; and the sealed can is sprayed with water to cool it. Vacuums of 25 inches or more (needed to assure storage stability) can be routinely achieved by this method. Special can linings and sealing compounds are needed to survive oven temperatures, and the exterior must be dark coloured (*e.g.*, olive drab) in order to absorb radiant heat in the oven, avoiding long baking times. Spores of some pathogens are not killed by the conditions reached in the centre of the baked product, but pH and osmotic pressure can be adjusted to prevent growth of spoilage organisms. There is no record of food poisoning attributable to canned bakery food.

QUALITY MAINTENANCE

Bakery products are subject to the microbiological spoilage problems affecting other foods. If moisture content is kept below 12 to 14 percent (depending on the composition), growth of yeast, bacteria, and molds is completely inhibited. Nearly all crackers and cookies fall below this level, although jams, marshmallow, and other adjuncts may be far higher in moisture content. Breads, cakes, sweet rolls, and some other bakery foods may contain as much as 38 to 40 percent water when freshly baked and are subject to attack by many fungi and a few bacteria.

To obtain maximum shelf life free of mold spoilage, high levels of sanitation must be maintained in baking and packing areas. Oven heat destroys all fungal life forms, and any spoilage by these organisms is due to reinoculation after baking. Strict observation of sanitary practices, including the use of fungicides and ultraviolet

lights where possible, reduces contamination to a low level. Mold spores cannot be entirely eliminated, since they are ubiquitous and can be drawn into the package from the outside atmosphere after the package leaves the bakery.

A number of compounds have been proposed for use as fungistats in bread. Some have proven to be innocuous to molds, toxic to man, or both. Soluble salts of propionic acid, principally sodium propionate, have been accepted and extend shelf life appreciably in the absence of a massive inoculum. Acetic acid also has a protective effect.

Bacterial bread spoilage

Bacteria associated with bread spoilage include *Bacillus mesentericus*, responsible for "ropy" bread, and the less common but more spectacular *Micrococcus prodigiosus*, causative agent of "bleeding bread." Enzymes secreted by *B. mesentericus* change the starch inside the loaf into a gummy substance stretching into strands when a piece of the bread is pulled apart. In addition to ropiness, the spoiled bread will have an off-aroma sometimes characterized as fruity or pineapple-like. Formerly, when ropiness occurred, bakers acidified doughs with vinegar as a protective measure, but this type of spoilage is rare in bread from modern bakeries.

Micrococcus prodigiosus causes red spots to appear in bread. At an advanced stage these spots of high bacterial population may liquefy, emphasizing the similarity to blood, which has sometimes led the superstitious to attribute religious significance to this phenomenon. The organism will not survive ordinary baking temperatures, unlike *B. mesentericus*, which forms spores capable of survival in the centre of the loaf, where the temperature rises only to about 212° F (100° C).

Neither ropy nor bleeding bread is particularly toxic to man; the only widespread food poisoning in which bread has been a vector has resulted from ergot, a fungus infection of rye. Ergot contamination of bread made from rye, or from blends of rye and wheat, has caused epidemics leading to numerous deaths.

Baked goods containing such high-moisture adjuncts as pastry creams and pie fillings are susceptible to contamination by food-spoilage organisms, including *Salmonella* and *Streptococcus*. Cream and custard pies are recognized health hazards when stored at room temperature for any length of time, and some communities ban their sale during summer. Storage in frozen form eliminates the hazard.

Undesirable changes in bakery products can occur independently of microbial action. Staling involves changes in texture, flavour, and appearance. Firming of the interior, or "crumb," is a highly noticeable alteration in bread and other low-density, lean products. Elasticity is lost and the structure becomes crumbly. Although loss of moisture produces much the same effect, texture staling can occur without any appreciable drying. Such firming is due to changes in the molecular status of the starch, specifically to a kind of aggregation of sections of the long-chain molecules into micelles, making the molecules more rigid and less soluble than in the newly gelatinized granule. Stale bread can be softened to a state approximating the texture of fresh bread by heating to about 140°–150° F (60°–65° C). Care must be exercised to prevent drying during heating.

Starch retrogradation, the cause of ordinary texture staling of the crumb, can be slowed by the addition of certain compounds to the dough. Most of the effective chemicals are starch-complexing agents. Monoglycerides of fatty acids have been widely used as dough additives to retard staling in the finished loaf.

The crust, dry and crisp in the fresh state, becomes soft and leathery when stale, due to redistribution of moisture between the loaf components. Crust softening is accelerated when the product is enclosed in moisture-proof packaging.

Flavour changes during storage

Changes in flavour occur during the storage of baked products. Some volatile substances evaporate; others oxidize or react with other dough constituents to yield less flavourful compounds. Ethanol contributes to the aroma of freshly baked yeast-leavened products; once it is lost, reheating cannot revive the original flavour. Fortunately, most volatile compounds are adsorbed on other bread constituents and are thus hindered from diffusing away.

QUALITY TESTING

Bakery food testing is mainly oriented toward the determination of sensory attributes. Expert evaluation of the appearance, texture, and flavour of finished products is essential in quality control, but objective measurements are necessary for both finished goods and ingredients.

Bread scoring is a daily bakery routine. Plant production executives and quality-control laboratory personnel assign numerical scores to the volume, shape, crust colour, crumb texture and colour, aroma, taste, and other characteristics of cut loaves representative of the day's production. The numerical scores are usually entered on a form sheet listing the quality factors. The final score is totalled and compared with a minimum representing lowest loaf quality permissible for sale.

Cakes and pies, less uniform and more difficult to evaluate on a rigid scale than other bakery products, are graded less formally, generally on a pass or fail basis.

Objective tests conducted on finished products include chemical analyses for moisture content and the amounts of such important ingredients as shortening, sugar, vitamins and minerals, and physical measurements of density, colour, and texture. In general, the chemical tests are much the same as those conducted on other foods. Moisture content for ordinary white bread is kept just below 38 percent by most producers to meet legal requirements and still obtain the soft, elastic texture preferred by the majority of consumers.

Testing bread texture

Attempts have been made to devise objective tests of bread texture. An instrument designed to measure the yielding of crumb to compression under controlled load, the Baker Compressimeter, applies force from a synchronous motor to a compound lever forcing a plunger of square section into the surface of a slice of bread. A spring and scale arrangement in the lever system measures the deformation of the bread under constant load, or the load required to cause a constant deformation. Other devices simulate chewing to measure the force required to tear the crumb.

Reflectance spectrophotometers provide objective measurement of crust and crumb colour. Standard instruments must be modified to scan areas sufficiently large to average out small-scale nonuniformities.

There are special tests for functional quality applicable to bakery product ingredients. Flour, shortening, leavening, and dried milk are the principal ingredients affecting dough performance during processing. Much experimentation has been applied to development of analytical methods to predetermine accurately the suitability of a flour for a given use. The only conclusive test, however, is use of the flour under conditions encountered during normal processing. Since large-scale tests of this type are expensive, inconvenient, and time-consuming, small-scale evaluations duplicating production conditions as closely as possible usually are substituted. Such empirical procedures are useful, although subject to many theoretical objections.

Instruments have been devised to measure physical properties of standard doughs, including resistance to intense sheer, elasticity of a dough cylinder under elongation, and maximum size of a bubble blown from a film of dough.

Diastatic activity—the rate at which starch is converted to reducing sugars by the enzymes present in the flour or in added malt—governs the gas-production rate, especially in the later stages of dough processing. It therefore affects the inner structure and volume of the loaf or roll and often influences crust colour. Diastatic activity, affected both by amylolytic enzyme activity and the susceptibility to attack of the starch granules, can be expressed as the amount of reducing sugar developed in a given time at controlled temperatures by a standard mixture of flour and water.

Quality standards established by government

Governments may establish quality standards for various bakery products, issuing product definitions and composition requirements, specifying weights, requiring certain hygienic measures, stating labelling requirements, and providing for testing and sampling methods. For example, in the U.S., the Federal Standard of Identity for Bread and Rolls establishes the composition of white, enriched, milk, raisin, and whole-wheat breads, as well as that of the same types of rolls and buns. Virtually all countries with modern baking industries regulate the size and composition of the principal bakery products (*e.g.*, bread).

BAKERY PRODUCTS IN THE HUMAN DIET

Bakery-product consumption varies so greatly among cultures that it is not possible to generalize on a worldwide basis. The United States has shown a steady downward trend in per capita consumption of cereal-based foods for many years, and the consumption of sweet bakery foods, such as cakes and pastry, has been increasingly displacing bread consumption. The worldwide consumption of bakery products is increasing. Many populations that formerly relied solely on rice or coarser grains as their main source of carbohydrates show a preference for compounded bakery products as new industry and increased incomes make them more widely accessible. Japan is an outstanding example of countries following this trend.

Probably 95 percent of the white bread sold in the United States is enriched with thiamine, niacin, riboflavin, and iron, and about 30 states have laws requiring white-bread enrichment. The most common method of vitamin and mineral supplementation is the addition of an enrichment tablet to the dough mixture, but enriched salt and packets formed of water-soluble, edible films are also used. Formerly, calcium and vitamin D were frequently added to enriched bread, but lack of consumer demand and questionable nutritional benefit led to gradual phasing-out of these enrichments.

Lower income families have the highest per capita consumption of bakery foods in the U.S.; a considerable portion of their caloric intake, as well as much of their calcium, iron, thiamine, and protein, comes from this source. Consumption of enriched flour, cornmeal, and bread continues to decrease, however, while unenriched baked-goods consumption is increasing. The contribution of cereals to the diet could be improved by enrichment of consumer mixes and sweet bakery goods. Most bakery products, composed primarily of cereal derivatives, are subject to many of the nutritional generalizations applied to cereals.

Home baking has been in a continual decline for decades, decreasing the sale of enriched flour at the retail level. Cornmeal usage tends to decline as incomes increase and as exposure to convenience foods and to more elaborate cuisines becomes more general. Calories consumed as starchy or bulk foods decrease and "sweet goods," confectionery, or rich bakery items increase as disposable income increases.

Protein concentrates suitable for bakery-product fortification can be made from a wide variety of raw materials. Oilseeds are the largest single protein concentrate source; milk is another excellent source of supplementary protein for bakery foods. India has attempted to encourage consumption of protein-enriched bread, with some success. Except for research projects, little has been done in other countries, however.

Feeding trials show that, with the addition of about 0.5% L-lysine and 0.1% to 0.2% threonine, the nutritional value of the protein in bread would equal that of casein. Addition of nonfat-milk solids to bread is an effective but relatively expensive way of adding the needed lysine, and production of bread of normal appearance and texture is difficult if the dough contains more than 6 percent of skim-milk solids, an insufficient amount to bring the lysine content to the desired level.

In areas where bakery products comprise a large proportion of the diet, they provide an ideal vehicle for nutritional supplementation. The need for additional or better quality protein in the daily diet occurs mostly in the developing countries, where carbohydrate foods—usually cereals—are the diet staples and logical protein carriers. Adding protein supplements to compounded bakery foods, such as bread, is less complicated than adding these enrichments to grains, such as rice, but unfortunately, compounded bakery foods are not much used in many developing countries.

KENT, *Technology of Cereals; with Special Reference to Wheat* (1966); S.A. MATZ (ed.), *Chemistry and Technology of Cereals as Food and Feed* (1959), *Cereal Science* (1969), and *Cereal Technology* (1970). Specialized in-depth discussions of the methods, materials, and products of commercial baking may be found in S.A. MATZ, *Bakery: Technology and Engineering* (1960); and E.J. PYLER, *Baking Science and Technology*, 2 vol. (1952).

(S.A.M.)

Bakunin, Mikhail Aleksandrovich

Mikhail Bakunin, a prominent Russian revolutionary agitator and the chief propagator of 19th-century anarchism, was born on May 30 (new style; May 18, old style), 1814, the eldest son of a small landowner of Premukhino in the province of Tver (now Kalinin). He grew up in idyllic surroundings, romantically devoted to four sisters who were nearer to him in age than his younger brothers. His lifetime of revolt began when he was sent to the Artillery School in St. Petersburg and later was posted to a military unit on the Polish frontier. In 1835 he absented himself without leave, and resigned his commission, narrowly escaping arrest for desertion. For the next five years he divided his time between Premukhino, where he plunged into the study of the German philosophers Johann Fichte and Hegel, and Moscow, where he moved in the literary circles of the critic V.G. Belinsky, the novelist Ivan Turgenev, and the publicist Aleksandr Herzen. In 1840, his opinions still in a state of fluid turbulence, he journeyed to Berlin to complete his education. There he fell under the spell of the Young Hegelians, the radical followers of Hegel, and, having moved to Dresden, in 1842 published in a radical journal his first revolutionary credo, ending with the now-famous aphorism: "The passion for destruction is also a creative passion." This brought him a peremptory order to return to Russia and, on his refusal, the loss of his passport. After brief periods in Switzerland and Belgium, Bakunin settled in Paris, where he consorted with French and German Socialists, including Pierre-Joseph Proudhon and Karl Marx, and with numerous Polish émigrés who inspired him to combine the cause of the national liberation of the Slav peoples with that of social revolution. The February Revolution of 1848 in Paris gave him his first taste of street fighting; and after a few days of eager participation he travelled eastward in the hope of fanning the flames in Germany and Poland. In Prague in June 1848, he attended the Slav congress, which ended when Austrian troops bombarded the city; and later in the year, in the secure retreat of Anhalt-Köthen, in Germany, he wrote his first major manifesto, *An Appeal to the Slavs.* He denounced the bourgeoisie as a spent counter-revolutionary force; he called for the overthrow of the Habsburg Empire and the creation in central Europe of a free federation of Slav peoples; and he counted on the peasant and especially on the Russian peasant, with his tradition of violent revolt, as the agent of the coming revolution.

Early revolutionary activity

Tired of inaction, Bakunin once more plunged into revolutionary intrigues and, engaging in the Dresden insurrection of May 1849, failed this time to escape arrest. The Saxon authorities handed him over to Austria and Austria, after a further period of incarceration, to Russia. In May 1851 he was back on Russian soil in the Peter-Paul Fortress in St. Petersburg. There, at the invitation of the chief of police, he wrote an enigmatic *Confession*, which was not published until 1921. Much of it consists of expressions of repentance for misdeeds and abject ap-

Bakunin.

peals for mercy. But it includes some gestures of defiance and plays heavily on Bakunin's devotion to the Slavs and hatred of the Germans—sentiments that were noted with interest and approval by the Tsar. They did not, however, help the prisoner. He remained for three years in the Peter-Paul Fortress and for three further years in another fortress, the Schlisselburg, in conditions of rapidly deteriorating health. Finally, in 1857 he was released to live in Siberia. There he contracted a marriage, which was not consummated, with the daughter of a Polish merchant. The governor of Eastern Siberia was a cousin of Bakunin's mother, and it was probably through this connection that he obtained permission in 1861 to travel down the Amur, ostensibly on commercial business. Having reached the coast in a Russian ship, he transferred to an American vessel bound for Japan and travelled via the United States to Great Britain.

Bakunin's arrival in London at the end of 1861 reunited him with Herzen, whom he had last seen in Paris in 1847 and who now occupied a pre-eminent position among Russian émigrés as editor of *Kolokol* ("The Bell"). Bakunin's 14-month stay in London led to an irretrievable rift with Herzen, who had shed some of the revolutionary ardour of his youth and had already crossed swords with the critic and novelist Nikolay Chernyshevsky and other extreme radicals of the rising Russian generation. He now found Bakunin's financial, as well as political, irresponsibility hard to bear. When the Polish insurrection broke out early in 1863, Bakunin eagerly embarked with a shipload of Polish volunteers for the Baltic. He got only as far as Sweden, where he spent a fruitless summer. At the beginning of 1864 he established himself in Italy, which became his residence for four years. It was there that he framed the main outlines of the anarchist creed that he preached with unsystematic but unremitting vigour for the rest of his life. It was there, too, that he began to weave that complex network, part real, part fictitious, of interlocking secret revolutionary societies that absorbed his energies and bewildered the followers whom he enrolled in them.

Quarrel with Marx

The most famous episode of Bakunin's later years was his quarrel with Marx. In 1868, then settled in Geneva, he joined the First International, a federation of working-class parties aiming at transforming the capitalist societies into Socialist commonwealths and their eventual unification in a world federation. At the same time, however, he enrolled his followers in a semisecret Social Democratic Alliance, which he conceived as a revolutionary avant-garde within the International. The same organization could not hold two such powerful and incompatible personalities; and at The Hague congress in 1872 Marx, by an intrigue that had little relation to the causes of the quarrel, secured the expulsion of Bakunin and his followers from the International. The breach split the revolutionary movement in Europe for many years to come. Two of Bakunin's major writings, *The Knouto-Germanic Empire* (1871) and *State and Anarchy* (1873), directly reflected his conflict with Marx. Bakunin was as uncompromising a revolutionary as Marx and never ceased to preach the overthrow of the existing order by violent means. But he rejected political control, centralization, and subordination to authority (while making an unconscious exception of his own authority within the movement). He denounced what he regarded as characteristically Germanic ways of thought and organization and opposed to them the untutored spirit of revolt that he found embodied in the Russian peasant. Bakunin's anarchism took final shape as the antithesis of Marx's communism.

During his last years, which he spent in penury in Switzerland, Bakunin reverted to his preoccupation with central and eastern Europe. He was compromised by a short-lived enthusiasm for S.G. Nechayev, a young Russian nihilist who paraded his contempt for conventional morality, achieved notoriety by murdering a fellow conspirator whom he suspected of intending to betray or desert the cause, and for this crime was eventually extradited to Russia by the Swiss authorities. Bakunin consorted with Russian, Polish, Serb, and Romanian émigrés, among whom he found eager disciples; drafted proclamations; and planned revolutionary organizations. His health grew worse; his financial embarrassments became ever more acute, and he depended on the bounties of a few Italian and Swiss friends. But he never wholly lost the resilience of his revolutionary convictions. He died in Bern on July 1 (June 19, O.S.), 1876, aged 62.

Proudhon and Bakunin rank as the founding fathers of 19th-century anarchism. Bakunin formulated no coherent body of doctrine. His voluminous and vigorous writings were often left incomplete. But his fame and personality inspired a large and widely dispersed following. Small anarchist groups existed in Great Britain, Switzerland, and Germany, whereas the powerful anarcho-syndicalist wing of the French trade unions owed more to Proudhon than to Bakunin. Anarchist movements owing allegiance to Bakunin continued to flourish in Italy and especially in Spain, however, where as late as 1936 the anarchists were the strongest revolutionary party.

BIBLIOGRAPHY. The first collection of Bakunin's writings was published in six volumes in French between 1895 and 1913; a complete Russian edition of writings and letters was planned, but only the first four volumes down to 1861 were published (1934–36). A complete edition of the later writings, edited by ARTHUR LEHNING, is in course of publication by the Instituut voor Sociale Geschiedinis, Amsterdam. Bakunin has not been well served by biographers: MAX NETTLAU'S manuscript biography (in German), *Michael Bakunin*, 3 vol. (1896–1900), based on a large mass of documents, was distributed to the main European libraries; Y. STEKLOV'S biography (in Russian), 4 vol. (1926–27), is unfriendly and Marxist; see also E.H. CARR, *Michael Bakunin* (1937).

(E.H.C.)

Balanchine, George

As artistic director and chief choreographer of the New York City Ballet, George Balanchine, in the 20th century, became the most influential name associated with classical ballet choreography in the United States. Working in the classic dance idiom, he created many of his finest ballets, such as *Serenade* (first performed 1935), *Symphony in C* (1948), and *Agon* (1957), with no dramatic themes but with highly original and imaginative dance patterns.

Born on January 9, 1904, in St. Petersburg (Leningrad), of a Georgian family, Georgy Melitonovich Balanchivadze was one of a generation of dancers who spent the World War I years at the Imperial School of Ballet at the Mariinsky Theatre. The theatre closed for some months in 1917, and, until the Imperial School reopened in 1918 as the Soviet State School of Ballet, Balanchine had to support himself with unskilled jobs or by playing

piano in a cinema. After three more years of study, he graduated. The son of a composer, Balanchine had also studied music at the Petrograd (St. Petersburg) Conservatory (1921–24).

As a student Balanchine had already tried choreography. His first work, as early as 1920, was a short piece danced to Anton Rubinstein's *Nuit*. He also choreographed works for evenings of experimental ballet performed by himself and his colleagues at the State School of Ballet. The State's directors discouraged this activity, however. He mounted some new and experimental ballets for the Mikhailovsky Theatre in Petrograd. Among them were *Le Boeuf sur le toit* (1920) by Jean Cocteau and Darius Milhaud and a scene for *Caesar and Cleopatra* by George Bernard Shaw.

Balanchine was one of the first ballet dancers to leave the Soviet Union, initially to tour with a small group, the Soviet State Dancers, which included Aleksandra Danilova, Tamara Gevergeva (later Geva), Nicolas Efimov, and himself. They toured Germany, London, and Paris, where in June 1925 Balanchine joined Sergey Diaghilev's Ballets Russes. (It was Diaghilev who simplified Balanchivadze to Balanchine.)

Period with Diaghilev

It was as a choreographer that Diaghilev envisaged Balanchine—Bronisława Nijinska had recently left Diaghilev and Balanchine assumed her duties—and in 1925 the Ballets Russes danced Balanchine's *Barabau*, the first of ten ballets Balanchine was to mount for Diaghilev. Of the ballets he choreographed for Diaghilev, two survive notably in the world repertoire: *Apollo* (1928), the first example of his individual neoclassical style, and *Le Fils prodigue* (*The Prodigal Son*, 1929).

Martha Swope

Balanchine instructing Allegra Kent, c. 1960.

When Diaghilev died in 1929, Balanchine was sufficiently established to have little difficulty in continuing as a choreographer and ballet master. He worked successively with the Royal Danish Ballet and with the Ballet Russe de Monte Carlo, adding significantly to his reputation by composing *La Concurrence* (1932) and *Cotillon* (1932). In 1933 he was one of the founders of the avant-garde company Les Ballets 1933, whose work so enormously impressed the American dance enthusiast, Lincoln Kirstein, that he invited Balanchine to organize the School of American Ballet and the American Ballet company (of which Kirstein was cofounder and director), thus beginning the association of "Mr. B.," as the ballet world knows him, and the U.S.A.

The American Ballet became the resident ballet company at the Metropolitan Opera in New York, and, during its tenure there, Balanchine produced among other works *Le Baiser de la fée* (1937; *The Fairy's Kiss*). He was also creative in a totally different sphere, as pioneer choreographer for Broadway musicals and Hollywood movies, including the celebrated *Slaughter on Tenth Avenue* ballet in *On Your Toes* (1936).

The end of the largely unsatisfactory association between the American Ballet and the Metropolitan Opera came in 1938. Kirstein founded Ballet Caravan in 1936, with a repertoire of ballets by American choreographers. In 1941 this company and what remained of the American Ballet were united for a Latin American tour, for which Balanchine composed *Concerto barocco* and *Ballet Imperial*. During the World War II period, Balanchine worked in the U.S. for the Original Ballet Russe, Ballet Russe de Monte Carlo, and in Hollywood or on Broadway. In 1947 he was guest ballet master at the Paris Opéra.

Kirstein's determination, however, to establish American ballet under Balanchine's artistic direction never faltered. In 1946 he succeeded in founding the Ballet Society, which developed in 1948 into the New York City Ballet. First centred at the New York City Center and later at the New York State Theatre at Lincoln Center, this company has become particularly identified with Balanchine. A prolific creator in various styles, he has been responsible for most of the New York City Ballet's extensive repertoire. Among the works choreographed for the company were the full-length versions of *The Nutcracker* (1954) and *Don Quixote* (1965).

In 1964 the U.S. dance world was stirred when the Ford Foundation, having granted nearly $8,000,000 to strengthen professional ballet in the United States, presented the entire amount to the New York City Ballet, its affiliated School of American Ballet, and six other ballet companies—all under the direct or indirect influence of Balanchine.

Although he has worked mainly in the U.S., Balanchine is very much an international choreographer, and almost every leading ballet company in the world has mounted at least one of his ballets. Best known abroad are his interpretations of musical compositions, either in a serious vein, such as Brahms' *Liebeslieder Walzer* (1960), or broadly comic, such as Hershy Kay's *Western Symphony* (1954).

Association with Stravinsky

Balanchine had a special artistic relationship with the composer Igor Stravinsky. Stravinsky's connection with the ballet started with Diaghilev, and Balanchine's first association with his music was in choreographing a new version of *Le Chant du rossignol* (*The Song of the Nightingale*) for the Ballet Russe in 1925. A long series of Stravinsky–Balanchine ballets followed; some of them were composed in collaboration.

Other modern composers whose music Balanchine has set to the dance are Arnold Schoenberg (*Opus 34*) and the American composer Charles Ives (*Ivesiana*).

Balanchine studies his scores intensively as a preliminary to composition and begins dance creation only at the first rehearsal. He has said that his ideas come from working with his dancers, but he rarely discusses his ideas with them. He invents rapidly and without indulging in fits of temperament. This approach, together with a predominating impression of cool intellectuality rather than warm emotion in the body of his work, has established Balanchine, to an outside view, as a slightly remote and superhuman personality. The other side of the coin shows a man who has enjoyed working with every kind of musical entertainment in the theatre and in motion pictures.

BIBLIOGRAPHY. An autobiographical chapter is contained in *Balanchine's New Complete Stories of the Great Ballets*, ed. by FRANCIS MASON (1968). See also BERNARD TAPER, *Balanchine* (1962), a full and interesting, if slightly adulatory, account of the man and his work; and ANATOLE CHUJOY, *The New York City Ballet* (1953), an account to date of publication of Balanchine and his company.

(K.S.W.)

Balaton, Lake

Lake Balaton, the largest lake of central Europe, is located in central Hungary, at 46° 50′ N and 17° 45′ E. It has an area 230 square miles (596 square kilometres) wide, and extends for 48 miles (78 kilometres) in a south-

west to northeast direction along the southern foothills of the Bakony Mountains of Hungary. Its average depth is only 10.8 feet (3.3 metres), with a maximum depth of 37 feet (11 metres). The eastern third of the basin is separated to some extent by the Tihany Peninsula, which projects from the northern shore, narrowing the lake at this point to about 1 mile (1.5 kilometres). The Zala River, entering the lake from the eastern Alpine spurs to the west, provides the largest inflow of water, which it transports at the low water-freight rate of six cubic metres per second. Water outflow is through the sluice gates of Siófok, toward the eastern end of the lake, and the entire contents of the lake are replenished about every two years.

Scientific study. The earliest researches on Lake Balaton were carried out by geologists, notably by Lajos Lóczy (1849–1920), who published the first detailed topographical and geological map of the region. The Biological Research Institute at Tihany (established 1927) is the main centre for hydrochemical and biological studies, supplemented by the activities of the Research Institute for Water Resources, which was opened in Balatonszemes in 1952. In 1966 the Hungarian State Geological Institute organized a team for the study of the engineering geology of the Balaton environment.

Geological background. The bed of the Balaton is relatively young; it was formed at the end of the Pleistocene Epoch, less than 1,000,000 years ago, when a structural downwarp of the underlying rocks occurred, caused by the earth movements that dissected the nearby foothills with numerous cross-faults. Originally, there were five small lakes that extended in a north–south chain, but these coalesced when the erosive action of wind, rain, and ice broke down the dividing ridges. Traces of these former lakes can still be seen in the configuration of Lake Balaton today, and the Tihany peninsula is the remnant of one of the dividing ridges.

Origin of the lake

The northern border of the lake is hilly and formed of much older rocks, dating from the Paleozoic and Mesozoic eras, of up to 500,000,000 years ago. The lake itself is bordered by a narrow strip of sedimentary rocks of the Quaternary Period, less than 2,000,000 years old. To the northwest, the Tapocla Bay area is surrounded by hard basalt caps—remnants of volcanic eruptions that took place in the late Pliocene Epoch, 7,000,000 years ago. The area bordering the lake to the south is flat and covered by sand and loess—windblown deposits—of Pleistocene age.

Climate and hydrology. The climate of the region is rather continental, with warm and sunny weather prevailing from May to October. In summer the temperature of the lake ranges from 75° to 82° F (24° to 28° C), but in winter the lake is covered with a sheet of ice about 8 inches (20 centimetres) thick. As the prevailing winds are from the northwest, the southeastern shore of the lake is subject to erosion of its banks by wave action. Oscillations in the levels of the water surface known as seiches, the product of local variations of atmospheric pressure aided by currents in the water, increase the erosive effect. In the Tihany Narrows, the water currents flow with a speed of up to 5 feet (1½ metres) per second. This almost incessant flow scours the lake bed at the tip of the Tihany Peninsula, keeping the two sections of the lake connected with each other.

The chemical composition of the lake differs greatly from that of most central European lakes. The predominant anions, of negatively charged chemical components, are carbonate and sulphate; while the corresponding cations, or positive components, are magnesium, calcium, and sodium: their interaction has given the lake its sulfocarbonate character.

Plant and animal life. The regions around the lake are inhabited by a rich and interesting variety of plant and animal life. There is a wildlife reserve in the Tihany Peninsula, and another one in the extensive reedbeds near Keszthely, where rare water birds nest. The loess region at the southern border of the lake is very fertile, and the volcanic soils to the northwest form the basis of a noted wine-growing region.

Agriculture has nevertheless become less significant as a result of the development of the tourist industry in the decades of the 1960s and 70s. A number of watering places sprang up, notable among which were Siófok, on the southern shore, and Balatonfüred, on the northern shore. The town of Balatonfüred is also famous as a health centre, with medicinal springs for the treatment of heart diseases, and near Keszthely the thermal spring of Hévíz reached temperatures of 97° F (36° C). The oldest and best known settlement is Tihany, noted for its museum and biological station. In all of the resorts, numerous modern hotels have been constructed in recent years, and the annual number of visitors from Hungary and elsewhere in Europe was in excess of 2,000,000 by the start of the 1970s. Watersport and fishing—particularly for the *fogas*, a local delicacy similar to a pike in appearance—were among the main attractions of the lake and its environs.

Development of tourism

BIBLIOGRAPHY. Information on Lake Balaton may be found in J. REISMANN, *Der Balaton* (1962), a travel guide in German; and in two articles in the Hungarian journal, *Földrajzi Közlemények* (1958): B. BULLA, "Geographical Exploration of the Lake Balaton and its Surroundings," and I. KAKAS, "Climatic Problems of Lake Balaton, Hungary" (both with English summaries).

Balboa, Vasco Núñez de

Vasco Núñez de Balboa, Spanish conquistador and explorer and the European discoverer of the Pacific Ocean, ranks with Christopher Columbus, Hernán Cortés, and Francisco Pizarro among the great leaders who founded the Spanish Empire in America. His discovery of the Pacific led to the discovery and conquest of the Inca Empire.

Balboa was born about 1475 in Jerez de los Caballeros, or in Badajoz, according to some sources, in the province of Extremadura. He came from the ranks of that lower nobility whose sons, "men of good family who were not reared behind the plow," in the words of the chronicler Gonzalo Fernández de Oviedo y Valdés, often sought their fortunes in the Indies. In 1500 he sailed with Rodrigo de Bastidas on a voyage of exploration along the coast of present-day Colombia. Later, he settled in Hispaniola (Haiti), but he did not prosper as a pioneer farmer and had to escape his creditors by embarking as a stowaway on an expedition organized by Martín Fernández de Enciso (1510) to bring aid and reinforcements to a colony founded by Alonso de Ojeda on the coast of Urabá, in modern Colombia. The expedition found the survivors of the colony, led by Francisco Pizarro, but Ojeda had departed. On the advice of Balboa the settlers moved across the Gulf of Urabá to Darién, on the less hostile coast of the Isthmus of Panama, where they founded the town of Santa María de la Antigua, the first stable settlement on the continent, and began to acquire gold by barter or war with the local Indians. The colonists soon deposed Enciso, Ojeda's second in command, and elected a town council; one of its two alcaldes, or magistrates, was Balboa. With the subsequent departure of Enciso for Hispaniola, Balboa became the undisputed head of the colony. In December 1511 King Ferdinand sent orders that named Balboa interim governor and captain general of Darién.

Early years in the New World

Balboa meanwhile had organized a series of gold- and slave-hunting expeditions into the Indian chiefdoms of the area. His Indian policy combined the use of barter, every kind of force, including torture, to extract information, and the tactic of divide and conquer by forming alliances with certain tribes against others. The Indians of Darién, less warlike than their neighbours of Urabá and without poisoned arrows, were not formidable foes and often fled at the approach of the Spaniards. The Spanish arsenal included their terrible war dogs, sometimes used by Balboa as executioners to tear Indian victims to pieces.

The Spaniards were told by Indians that to the south lay a sea and a province infinitely rich in gold—a reference to the Pacific and perhaps to the Inca Empire. The

conquest of that land, their informants declared, would require 1,000 men. Balboa hastened to send emissaries to Spain to request reinforcements; the news they brought created much excitement, and a large expedition was promptly organized. But Balboa was not given command. Charges brought against him by his enemies had turned King Ferdinand II against him, and, as commander of the armada and governor of Darién, the King sent out the elderly, powerful nobleman Pedro de Arias de Ávila (usually called Pedrarias). The expedition, numbering 2,000 persons, left Spain in April 1514.

The discovery of the Pacific

Meanwhile, Balboa, without waiting for reinforcements, had sailed on September 1, 1513, from Santa María for Acla, at the narrowest part of the isthmus. Accompanied by 190 Spaniards and hundreds of Indian carriers, he marched south across the isthmus through dense jungles, rivers, and swamps and ascended the cordillera; on September 25 (or 27), 1513, "standing on a peak in Darién," he sighted the Pacific. Some days later he reached the shore of the Gulf of San Miguel and took possession of the Mar del Sur ("South Sea") and the adjacent lands for the king of Castile. He then recrossed the isthmus, arriving at Santa María in January 1514. His letters and those of a royal agent who had been sent to Darién to prepare the ground for the coming of Pedrarias, announcing the discovery of the "South Sea," restored Balboa to royal favour; he was named *adelantado* (governor) of the Mar del Sur and of the provinces of Panamá and Coiba but remained subject to the authority of Pedrarias, who arrived in Darién, now a crown colony and renamed Castilla del Oro, in June 1514.

Troubled relations with Pedrarias

Relations between the two men were, from the first, troubled by the distrust and jealousy of the ailing, ill-natured Pedrarias toward the younger man. The first bishop of Darién, Juan de Quevedo, sought to act as peacemaker and arranged a temporary reconciliation; in a turnabout Pedrarias by proxy betrothed his daughter María in Spain to Balboa. But the underlying causes of friction remained. The suspicious Pedrarias pursued a tortuous policy designed to frustrate Balboa at every turn; but he at last gave Balboa grudging permission to explore the South Sea. By dint of enormous efforts Balboa had a fleet of ships built and transported in pieces across the mountains to the Pacific shore, where he explored the Gulf of San Miguel (1517–18). Meantime, the stream of charges of misconduct and incapacity levelled against Pedrarias by Balboa and others had finally convinced the crown of Pedrarias' unfitness to govern; news arrived in Darién of his imminent replacement by a new governor who would subject Pedrarias to a *residencia* (judicial review of his conduct in office). Pedrarias doubtless feared that Balboa's presence and testimony would contribute to his total ruin and decided to get rid of his rival. Summoned home on the pretext that Pedrarias wished to discuss matters of common concern, Balboa was seized and charged with rebellion, high treason, and mistreatment of Indians, among other misdeeds. After a farcical trial presided over by Gaspar de Espinosa, Pedrarias' chief justice, Balboa was found guilty, condemned to death, and beheaded with four alleged accomplices in January 1519.

BIBLIOGRAPHY. The standard biography in English, well documented and written, is KATHLEEN ROMOLI, *Balboa of Darién: Discoverer of the Pacific* (1953), which also contains an extensive bibliography of sources. There is a judicious survey of Balboa's career in AMANDO MELON Y RUIZ DE GORDEJUELA, *Los primeros tiempos de la colonización. Cuba y las Antillas. Magallanes y la primera vuelta del mundo* (1952). For a discussion of Balboa's route to the Pacific, see ANGEL RUBIO, *La ruta de Balboa y el descubrimiento del Océano Pacífico* (1965). All modern accounts take as their points of departure the great chronicles of PIETRO MARTIRE D'ANGHIERA, *De orbe novo*, trans. by FRANCIS A. MACNUTT, 2 vol. (1912, reprinted 1970); GONZALO FERNANDEZ DE OVIEDO Y VALDES, *Historia general y natural de las Indias*, ed. by JUAN PEREZ DE TUDELA BUESO, 5 vol. (1959); and BARTOLOME DE LAS CASAS, *Historia de las Indias*, ed. by AGUSTIN MILLARES CARLO and preliminary study by LEWIS HANKE, 2nd ed., 3 vol. (1965). See also C.L.G. ANDERSON, *Life and Letters of Vasco Núñez de Balboa* (1941).

(B.K.)

Balkans, History of the

Since the early 19th century, the name Balkan, a Turkish word meaning mountain, has been applied to the easternmost of the three great southern peninsulas of Europe. The peninsula shades gradually into the European mainland, and it is therefore difficult to assign its exact geographical boundaries; but for the purposes of this article the Balkans are taken to mean the territory of the modern states of Greece, Albania, Yugoslavia, Bulgaria, and Romania. The article traces Balkan history from its earliest settlement in the Old Stone Age to the present. The great Bronze Age civilization of the Aegean and the period of classical Greece, however, are treated in separate articles (see AEGEAN CIVILIZATIONS; GREEK CIVILIZATION, ANCIENT). The article also is intended to cover the national histories of the five modern Balkan states, which, despite their deep ethnic, religious, and political differences, share a geographical unity and a common political heritage of nearly five centuries of Turkish rule.

This article is divided into the following sections:

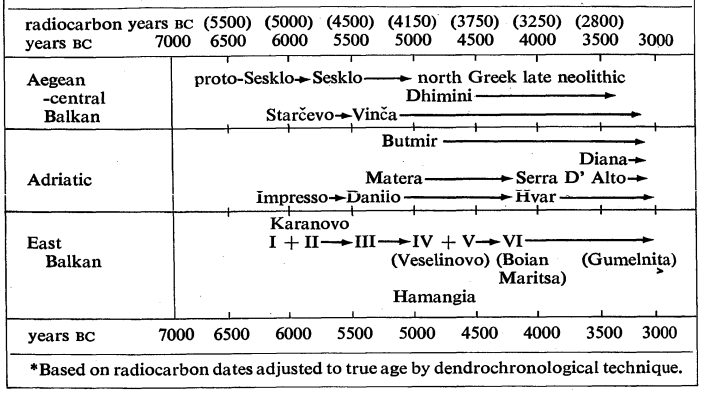
I. The Balkans to 1815

The Balkan Peninsula has been inhabited since Lower Paleolithic (Old Stone Age) times (*c.* 200,000–100,000 BC), but how continuously is not yet known. The Mousterian industries of the Neanderthal man from the early

part of the last glaciation (*c.* 70,000–40,000 BC) are well represented, followed by those of the Upper Paleolithic Aurignacian and Gravettian, *c.* 40,000–*c.* 8000 BC, associated with the physical remains of modern man (*Homo sapiens sapiens*). Evidence of habitation layers of postglacial food-gatherers in caves includes the chipped-stone industry developed from the Gravettian, and it continues into the beginning of the food-producing era.

The development of the Neolithic Period around 7000 BC was characterized by increased sedentariness and reliance upon domesticated plants and animals, permitting the existence of larger demographic units. From this period onward, one can speak of the Balkan culture in more detail.

Chronology of Balkan Neolithic and Chalcolithic Complexes*



*Based on radiocarbon dates adjusted to true age by dendrochronological technique.

OLD EUROPEAN CIVILIZATION

Together with east central Europe, the Balkans formed the core of the earliest European civilization, Old Europe, dated to the period 7000–3500 BC. Old Europe is not merely a provincial reflection of the great civilization of the ancient Near East but rather a distinct culture with roots of its own and a unique identity. The Old Europeans discovered the use of copper in the 6th millennium BC and formed population aggregates that often amounted to small townships, which inevitably involved craft specialization and the creation of religious and governmental institutions. The Old Europeans also evolved a written script.

Regional groupings

Old European civilization may be divided into five regional groups: (1) the Aegean and central Balkan, (2) the Adriatic, (3) the middle Danube, (4) the east Balkan, and (5) the Moldavian–western Ukrainian. The first region embraces the culture of the Neolithic Period in what is presently Greece, Yugoslavia (except the Adriatic seaboard), southeastern Hungary, and western Romania, succeeded by the Chalcolithic Vinča, Butmir, and Tisza cultures. The second area consists of the painted-pottery complex on either side of the Adriatic, including the Matera-Serra d'Alto in southern Italy and the Danilo in Dalmatia. The third variant includes the Lengyel culture of the middle Danube Basin, which displays similarities to the Adriatic complex. To the eastern bloc belong three cultural groups with individual traditions in art: the Hamangia on the Black Sea coast; the Karanovo in Thrace, and its Chalcolithic successors, and the Boian and Gumelnița complexes, which occupied most of modern Macedonia, Bulgaria, and Romania. In the fifth region, Moldavia and the western Ukraine, local Neolithic culture was followed by the formation of the Cucuteni (Tripolye in Russian) civilization. On coastal and inland plains, mounds created by the accumulation of cultural debris attest to the permanence of the farming communities, whereas in the Danubian region a wandering agriculture was practiced. Houses were arranged either around a central structure or in parallel rows. The typical house was a rectangular structure of timber posts completed with wattle-and-daub walls, semi-subterranean dwellings, trapezoidal structures; cultures living in dry Mediterranean conditions built characteristic houses with mud-brick walls, stone foundations, and internal buttresses.

The Neolithic complex left a remarkably uniform artifactual expression, including polished-stone axes, adzes, and small ornaments; clay stamp seals; bone spatulas; bird-shaped vases; and clay models of shrines. Clay and marble votive figurines reflect several types of goddesses, notably the Snake Goddess, the Bird Goddess, and the Great Goddess, and their epiphanies in the form of a bird, toad, bee, butterfly, deer, bear, and dog. A male god is also represented. Loom weights, spindle whorls, and woven-mat impressions on pot bases attest the production of textiles. Typical of the fine pottery is a highly burnished, hemispherical bowl, often on a ring base; the vessel is commonly coated with a red slip, with red-on-white or white-on-red-painted decoration. Cemeteries were unkown and interments are found within the settlement. Infants were buried inside egg-shaped vessels.

Differentiation into regional groups progressed steadily. By the mid-6th millennium BC, there appear the first traces of metallurgy, the Neolithic thus yielding to the Chalcolithic, the age of a mixed copper and stone technology.

Prehistoric Balkan sites.

The central Balkan region. *Proto-Sesklo and Starčevo.* The earliest Neolithic occupation of the Aegean and central Balkans is differently named in each of the modern European countries in which it is distributed—Proto-Sesklo, Starčevo, Körös, Criş—but these are regional variants of a widespread, comparatively uniform cultural complex.

Early Neolithic technology

The subsistence bases relied upon emmer, a primitive variety of wheat, and the domesticated sheep or goat. The identical bone structure of the sheep and goat makes it impossible to distinguish which animal is represented by the remains, but, because neither species was indigenous to Europe in the terminal Pleistocene, or Ice Age, the animals in question must have been introduced from their natural habitat in Anatolia and the Near East. Though their initial introduction was probably a function of ethnic movement across the Aegean, subsequent diffusion may have resulted from acculturation of the Mesolithic population under the stimulus of contact and trade with early farming communities. Radioactive-car-

bon dates and typological study show the Thessalian and Macedonian pre-pottery and early ceramic sites to be Europe's earliest Neolithic settlements.

Excavations conducted between 1965 and 1971 on the Danube above the Iron Gate provide new insight into the process of economic transition to a Neolithic way of life. The early levels comprise permanent settlements without ceramics; their subsistence was based on fishing and on hunting with the dog, the only domesticated animal. The subsequent phases belong to the characteristic central Balkan Neolithic (Starčevo), with the domesticated sheep or goat and wheat. Starčevo farmers increasingly exploited domestic cattle and pigs and hunted and fished in response to the better forested environment. The foremost systematically excavated sites in this region are Lepenski Vir excavated by D. Srejovic in 1965–69 and Padina, excavated by B. Joranovic in 1968–71.

Sesklo. Sites containing Sesklo materials have been discovered throughout Greece; most of these were newly founded settlements, implying an increase in population density. The beginning of the Sesklo phase is defined by the appearance of fine white-slipped pottery, decorated with flame and stair designs, painted in dark red. Shapes included globular-necked jars, footed bowls, straight-walled bowls, and cups and jugs.

The site of Otzaki, in Thessaly, has disclosed a three-phase development of Sesklo ceramic art. Excavation has uncovered two close-standing rows of square houses constructed of rectangular mud bricks. These houses frequently rest upon a stone foundation and are occasionally strengthened by internal buttresses.

Vinča. The Vinča sequence is best documented at the eponymous site, situated 14 kilometres (nine miles) east of Belgrade, which has yielded seven metres of stratified Vinča deposit overlying the Starčevo levels excavated by the Yugoslav archaeologist Miloje Vasić, intermittently from 1908 to 1932. Fine Vinča ceramic wares are burnished in orange or black and decorated with a shallow linear channeling.

The origin of the Vinča black burnished ware need be sought no farther afield than the Maritsa Valley of central Bulgaria. At its greatest extent, the Vinča complex occupied the central Balkans from the Rhodope Mountains north as far as the Banat; west to northeast Bosnia; and eastward to western Bulgaria, southwest Romania, and Transylvania. In architecture and subsistence economy, no marked difference has been discerned between Vinča and the Neolithic Period. Wattle-and-daub architecture continued to be employed, with evidence of the use of split planking in floor and wall construction. Floors were clay plastered. Increasing trade is evidenced by the widespread occurrence of Aegean Spondylus shell, which was used for beads and bracelets. The archaeological data indicate gradual social and economic change and an attendant population increase. Vinča sites occupy as much as 20 acres of river terrace, with houses organized into lined streets.

Concomitant with this expansion was a remarkable artistic development of the Vinča culture, marked by an increase in the quality and number of figurines and other objects that served a ritual function. These symbolic figures testify to an important intensification of spiritual life during the period. Vinča art remained distinct from that of neighbouring groups throughout a millennium or more; and its gradual evolution reflects a remarkably stable and well-organized social structure.

Linear writing

The 1961 discovery at Tărtăria in Transylvania of three clay tablets inscribed with pictographs has encouraged the explanation of import from Mesopotamia at about 3000 BC, but this hypothesis has been invalidated by the mutually reinforcing evidence of stratigraphic typologies and radioactive-carbon dating, which locate the early Vinča period in the latter part of the 6th millennium BC. The Tărtăria tablets were found in a secure Vinča context, and inscribed linear signs on figurines, vases, and spindle whorls of definitively local manufacture appear to confirm that the late 6th and 5th millennia witnessed the development of linear writing. Equivalent inscriptions occur in the east Balkan civilization.

Tisza. Tisza settlements, named after the River Tisza, contemporary to Vinča and distributed in eastern Hungary and the Yugoslav Banat, are smaller than Vinča, consisting of rectangular and semi-subterranean dwellings with pitched roofs apparently resting at ground level. Local domestication of cattle on a scale unprecedented in temperate Europe was proved here.

Butmir. The inland Bosnian Butmir variant was strongly influenced by the Vinča culture and was already producing copper. It is best known from the eponymous site at Butmir (Sarajevo), excavated between 1893 and 1896 by W. Radimsky and F. Fiala, which yielded a significant number of sculptures and fine ceramics, including black-polished ones with incised triangle and spiral decoration encrusted with red and white paint. Typical shapes were biconical bowls; high-pedestal, footed "wine" cups; and hole-mouth pyriform vases. At Obre II, a Butmir site in a forested upland environment near the upper Bosna, excavated in 1967–68 by A. Benac and M. Gimbutas, faunal analysis revealed that over half the domestic animals were cattle and that a considerable amount of hunting was practiced. Einkorn wheat was the chief cereal crop, supplemented by barley and lentils; at the Butmir site itself, pear and apple pips have been found.

At Obre II, wattle-and-daub houses of two rooms, about 15 metres long, containing beehive-shaped bread ovens, wooden platforms, ash pits, storage and ritual vases, spindle whorls, loom weights and tools, were revealed. The calibrated radioactive-carbon dates from this site place the three periods of the Butmir culture at 5000–4000 BC.

The Adriatic. *Impresso.* The Early Neolithic culture of the Adriatic region is known as the Impresso complex; it is characterized by grit-tempered wares impressed with shells or with a stabbing tool. The simple ornamented bowls and the farming economy they served are believed to have developed as a result of rapid diffusion, a corollary to maritime movement and trade along the Adriatic littoral. The Impresso culture of western Yugoslavia represents only a part of a complex widely dispersed throughout the Mediterranean world. The initial stimulus to agriculture probably came through eastern seaborne contact with the indigenous Mesolithic peoples of the Mediterranean coastlands. No considerable ethnic migration need be invoked in explanation.

Impresso sites occupy both caves and open settlements. The Dalmatian open-air settlement of Smilčić near Zadar consisted of wattle-and-daub houses and was enclosed by a deep ditch.

Danilo. The beginning of the Danilo period is marked by the appearance of elaborate red-on-cream-painted wares, with geometric motifs akin to Sesklo designs. This was a flourishing Neolithic culture of the end of the 6th and 5th millennia BC, with contacts with Greece and southern Italy.

The middle Danube. The local indigenous population of Cro-Magnon type prevailed in the middle Danube until the 5th millennium BC, when the periodically migrating farmers were supplanted by the Lengyel complex, named after a site in western Hungary that displays different architectural and artistic traditions. The Lengyel physical type contrasts markedly with the central European Cro-Magnon and is related, rather, to the people of the Adriatic region. Lengyel settlements are fortified with wide ditches and palisades, and the typical painted piriform vases and "fruit stands" have analogies in the Danilo complex. These similarities may reflect an ethnic infiltration from the Adriatic to the Sava basin and the region east of the Alps. The villagers cultivated wheat, barley, and Italian millet; and in addition to tending sheep or goats, they hunted and locally domesticated both cattle and pigs.

The east Balkan area. The east Balkan civilization began around 6000 BC with the first appearance of Neolithic occupation along the Maritsa Valley in Bulgaria. The best known sites are Karanovo, Azmak, and Kazanlŭk. The Karanovo sequence, phases I–VI, has become universally adopted as a chronological yardstick

for the development of east Balkan civilization. (Roman numerals are used by archaeologists to designate the successive layers of occupation found at a particular site, in this case phase I representing the earliest known settlement and higher numerals representing later settlements.)

Karanovo I–III. In the villages of the Karanovo I–II period, rectangular one-roomed houses of six or seven metres to a side, with thick, wattle-and-daub walls, an aligned plank floor, and an internal oven, were arranged in parallel rows. The ceramics show affinities with central Balkan wares, and a rich tool kit includes numerous millstones and sickles of deer antler with flint blades inserted like sawteeth. The plentiful remains of einkorn and emmer wheat, lentils, and bones of domesticated animals confirm the role of mixed farming. Karanovo III pottery typically displays a dark, lustrous black surface, sometimes decorated with plastic bands and knobs or linear incision. The most diagnostic forms are cylindrical and pear-shaped vases with single handles. Karanovo III complex is also known as Veselinovo, after another site in eastern central Bulgaria. Karanovo III corresponds to a considerably increased population; during this phase, elements of the Karanovo III assemblage were carried, probably by a movement of peoples, northwest into the lower Danube region and south beyond the Rhodope Mountains to eastern Macedonia and Thrace. In the north, the intruders came in contact with the Hamangia group on the coast of the Black Sea and with the settlers of the central European Linear Pottery culture. This contact along the lower Danube resulted in the amalgamation of the individual ceramic traditions within the assimilating expansion of the Karanovo III population, bringing about the formation of the "Boian" tradition, a northern variant of east Balkan civilization (the name Boian is derived from an island settlement near the Danube south of Bucharest). The "Vădastra culture" in western Romania represents a sister branch of the same civilization.

Boian. The Boian farmers cultivated einkorn, millet, beans, and flax; they also domesticated and kept cattle, pigs, sheep, and goats, but cattle were by far the most important. Houses arranged in parallel rows in compact villages were fortified by ditches. The Boian pottery was ornamented with excised, white, encrusted spiral and meander designs. There are five subbases of Boian.

During its second phase, Boian material culture spread as far as Moldavia in the northeast, influencing the formation and development of the Cucuteni civilization; it was this vigorous phase that witnessed the first signs of metallurgy. A late Boian temple edifice with trichrome wall decorations and with two exquisitely painted pillars inside has been discovered in the island site of Căscioarele, southeast of Bucharest. Skeletons from a large cemetery at Cernica (near Bucharest) are predominantly of a small-statured Mediterranean type.

Gumelniţa. The advanced stage of east Balkan culture is the Gumelniţa civilization, known from at least 500 tells (mounds of cultural debris) in Romania, Bulgaria, and eastern Macedonia. Gumelniţa itself lies southeast of Bucharest. Other important sites are: Căscioarele; Tangîru and Hîrşova, in the lower Danube region of Romania; and Ruse and Hotnica, in northern Bulgaria. North of the Aegean, the most noteworthy sites are the mounds of Sitagroi and Dikili Taih, excavated in 1968–70 on the plain of Drama. Sedentary Gumelniţa communities occupied compact villages or small towns for a millennium or more. Ceramic models of houses show gabled roofs, round windows, and plastered walls with designs painted in red, yellow, and white. These models all attest to the existence of two-story buildings. A model of a temple edifice discovered on the Danube island of Căscioarele shows four shrines standing on a large substructure.

East Balkan culture

Gumelniţa fine ceramic vessels are distinguished by their technological sophistication. Graphite painting required special kilns to prevent oxidation of the graphite.

Metal production and trade exhibited steady growth during the period: needles, awls, fishhooks, and pins were of copper, and, at the end of the period, axes and daggers were manufactured, a development also found in the Vinča, Tisza, Lengyel, and Cucuteni civilizations. Workshops of flint, copper, gold, Spondylus shell, and pottery imply craft specialization and increasing division of labour. Gold was obtained from Transylvania and copper from the Carpathian sources. Evidence of linear writing is found on ceramics throughout the duration of Boian–Gumelniţa civilization.

Hamangia. The Hamangia settlements and cemeteries are found along the coastal strip between northern Bulgaria and the western Ukraine. Most information comes from the cemetery at Cernavodă, where some 350 graves have been excavated by D. Berciu (1957). Examination of the skeletons has revealed that the population was predominantly Mediterranean; but also found was a distinct local type with a short, broad skull.

The Hamangians practiced mixed farming; they cultivated wheat and vetch and herded sheep and goats, cattle and pigs. Deep-sea fishing appears to have been important to early subsistence.

Figurine art characteristically shows a standing female, breasts and buttocks well-developed, with a columnar head and neck, lacking facial features. Less schematic are the exceptional pair of seated figures from Cernavodă—a male "Thinker" and a comfortably relaxed female, both masked. The earliest ceramics were impressed with cardium shell. Ornaments, found abundantly as grave goods, include huge bracelets and beads of Spondylus shell. The Hamangian complex was superseded by the east Balkan Gumelniţa civilization.

FROM THE BRONZE AGE TO THE COMING OF THE SLAVS

Indo-Europeanization during the Bronze Age. Old Europe was developing into an urban culture, but its power was cut short by a steadily increasing infiltration of the semi-nomadic pastoralists from the Russian steppes in about 3500 BC. Their culture is called Kurgan because of their burial in tumuli (*kurgan* means "barrow" in Turkic and Russian), covering graves in deep shafts. It reveals elements of the hypothetical mother culture of the Indo-European speakers as reconstructed with the help of common words. In the period *c.* 3500–2300 BC, their presence is traced in Danubian Europe, and, after 2300 BC, their arrival is documented in the Aegean and Adriatic regions. Changes in social structure, economy, and religion show that people of different background imposed their ways of life. Centres of the new power are witnessed by strongholds such as Vučedol (at Vukovar in northern Yugoslavia) and Nagyárpád (at Pécs) in southern Hungary). Cultural uniformity is evidenced over the Danubian plain down to Macedonia before 3000 BC. The new culture with persisting elements of Old European substratum is known by the names of Cernavoda in Dobruja, Ezero in Bulgaria, Coţofeni in Transylvania, and Baden in the middle Danube region.

Kurgan culture

By 2000 BC, nuclear groups parent to Indo-European Illyrian-, Armenian-, Venetan-, Phrygian-, Mysian-, Dacian-, Thracian-, and Greek-speaking units were formed; their cultures were typified by military aristocracies, hill forts, small villages, horses, and vehicles. Their archaeological complexes are dubbed Otomani and Wietenberg in Transylvania; Monteoru in Moldavia; Tei in the lower Danube region and Thrace; and Incrusted Pottery in Pannonia and northwestern Yugoslavia.

The centres of military power and of bronze metallurgy in the mid-2nd millennium were in central Europe and Greece: the Unětice-Tumulus in the upper and middle Danube region; the Otomani-Wietenberg in the Carpathian Basin; and the Mycenaean culture in Greece (see AEGEAN CIVILIZATIONS). Trading of transcontinental Baltic amber and Transylvanian and Mycenaean gold and bronze is richly evidenced from the 17th through the 15th century BC.

Around 1400 BC the Tumulus people extended their influence over the whole middle Danube Basin and to the Adriatic coast. As Urnfield peoples, they caused an upheaval in the Balkans in Anatolia and in the east Mediterranean region before and around 1200 BC. Their graves

and pots are found in Macedonia, while their weapons are found in Greece, Crete, Cyprus, Syria, Palestine, and Egypt. The destruction of the Mycenaean culture is attributed to the middle Danubian Urnfield invasion through the Balkan Peninsula and the Adriatic Sea. The Urnfield people were Indo-European speakers, parent to Venetan and perhaps Phrygian, Mysian, and Armenian. In past research they were assumed to be Illyrians, but this name can be used only as a broad cover name and should not be confused with the Illyrians proper, known since the time of Herodotus in Dalmatia, Bosnia, and Hercegovina. This period of raids and migrations, instigated by central European Urnfield peoples (misleadingly called an "Aegean migration"), resulted in a Phrygian, Mysian, and Armenian exodus to Anatolia, the destruction of the Hittite Empire, the Dorian infiltration into Greece, and the introduction of iron technology and a new ethnic configuration in the Balkans.

Illyrians and Thracians during the 1st millennium BC. Illyrians proper occupied western Yugoslavia, Albania, and Epirus, with the Morava-Vardar line as their approximate eastern limit; in the northeast they extended into southwest Romania. Tribes north of the Sava River, Venetans and Pannonians, are usually treated as northern Illyrians. The general name for the period from 750 to 450 BC is "Illyrian Hallstatt." The exploitation of iron ores, particularly in northwestern Bosnia, increased commerce. From the 7th to the 5th century BC, strong tribal centres emerged, together with a powerful aristocracy, as witnessed by extravagantly furnished royal burials. Autochthonous traditions were maintained even after an exchange with Greek merchants and colonizers of the Adriatic coast started around 600 BC. Glasinac, an Illyrian centre near Sarajevo, displayed an uninterrupted development until the period of Celtic influence in the 4th century BC.

The Iron Age in Illyria

From the late 6th and early 5th centuries, the Greek influence is evidenced by masterpieces of Greek workmanship, which arrived through southern Italy. To this period belongs the treasure of Trebeništa at Lake Ohrid, which includes a large bronze krater, or mixing bowl. Greek influence increased markedly in the 4th century BC after the foundation of towns on the islands and coast of the Adriatic, among them Issa (Vis), Pharos (Hvar), Corcyra Melaina (Korčula), Salomae (Solin), Epidaurus (Cavtat), Iader (Zadar), and Tragurion (Trogir).

Written evidence of an Illyrian kingdom on the borders of the Greek world appeared at the end of the 5th century BC; its capital was at Skodra (Skoútari). Before Illyria was annexed to the Roman Empire in 168 BC, it was ruled by 15 monarchs carrying Illyrian names.

The Thracian culture formed of the Bronze Age substratum mixed with that of the semi-nomadic peoples from the Ukraine. The ethnic infiltration is shown by the appearance of an eastern archaeological complex called Noua, dated to the 12th century BC. The cultural melange that produced the Basarabi–Babadag complex of the Hallstatt era is held to be the basic component of the Daco-Thracian culture. Repeated incursion of groups of warriors from the northeast occurred at the end of the 8th century BC, bringing with them Caucasian elements in art and weaponry. This period is called Thraco-Cimmerian; it coincides with the conquest of the Cimmerians north of the Black Sea by the Scythians (*q.v.*), but the actual ethnic infiltration of the Cimmerians into the Balkans is not evidenced. The Scythians proper appeared in the middle of the 6th and the beginning of the 5th century BC; but it was not until the beginning of the second half of the 4th century BC that the Scythians tried a violent and massive penetration into the territory. Contacts with the Scythian world contributed to the wider diffusion of iron metallurgy and the formation of a distinctive Thraco-Scythian style of art.

At the end of the 7th and in the 6th century BC, the Greeks founded several colonies along the western shore of the Black Sea: Apollonia Pontica (Sozopol), Mesembria (Nesebŭr), Odessus, Callatis (Mangalia), Tomis (Constanţa), and Istrus (Hystria). The Greek cultural influx was of fundamental importance. It included the potter's wheel, which was in use by the local inhabitants at the end of the 6th century BC, and the striking of coins, which the Greeks themselves borrowed from the Lydians in Anatolia. The Greeks were interested in timber and wheat from Moldavia and the Ukraine and in silver and gold from the mines of southwestern Thrace. Greek influence steadily increased. At Panagyurishte, in central Bulgaria, a gold service weighing more than six kilograms (13 pounds) included vessels of superb workmanship by Greek artists of the late 4th century BC. Dionysian festivals and worship of Bendis (Artemis) and Ares are ascribed to Greek influence.

Greek colonies on the Black Sea

Dacians, the northern Thracians, are known from Greek sources of the 4th and 3rd centuries BC. A good deal about southern Thracian life and manners is revealed by the Greek authors Homer, Herodotus, Thucydides, and Xenophon. Thracian nobles are shown on Greek vases wearing caps of fur, decorated cloaks, and leather boots. The society was classified into chieftains, warriors, commoners, and slaves. In the mid-5th century BC, the first known Thracian state emerged in the Maritsa Valley, ruled over by the Odrysian king Teres. According to Thucydides this state enjoyed a large revenue and general prosperity. The Odrysian king Sitalces allied himself with Athens and in 429 overran Macedonia. The 4th century marks the final flourishing of the Thracian civilization. Before mid-century Philip II of Macedon brought unity to the area between southern Thrace and Albania and a new power—Macedonia—emerged. Philip's son Alexander III the Great crossed the lower Danube in 335 BC and attacked the Getae.

By about 300 BC, the Getae of Dobruja and the lower Danube, a people akin to the Dacians of Transylvania and Moldavia, combined to form what was virtually a state, an evolved type of military democracy having as its leader the *basileus* Dromichaites, who in 292 conquered Lysimachus. Greek cities on the coast of the Black Sea found protectors and allies in the Getian *basileis*.

About the beginning of the 3rd century BC, bands of Celtic warriors appeared east of the Tisza and advanced toward Oltenia and Transylvania. This movement can be traced by the evidence of their warriors' graves. The military superiority of the Celts, which had at its disposal a developed iron technology, insured their success. The Celtic element, which was present in Romania for several centuries, contributed to the development of iron metallurgy and to the adoption of the iron plowshare, which led to a great expansion in agriculture. Celtic influence left imprints in a novel Getian–Dacian silverwork and coinage. The southern wave of Celtic invasion—toward Thrace, Macedonia, Thessaly, and Greece—was broken at Delphi in the winter of 279–278 BC (see CELTS, ANCIENT).

Arrival of the Celts

The Dacian state extended between the Tisza River and the lower Danube in the period between 200 and 31 BC, reaching its peak during the reign of Burebistas (60–44 BC). For further information see EUROPE, ANCIENT.

Roman conquest and barbarian colonization. After Macedonia crumbled, Thracians, Illyrians, and Dacians were left to their own devices until a major Roman irruption at the end of the 3rd century BC. Thracians and Illyrians combined in self-defense, and there followed a struggle for 150 years. The southern Illyrians were conquered and annexed in 168 BC, but hostilities continued until AD 9, when all Illyrians were entirely subjugated by the Roman general Tiberius (later emperor). The territory along the Adriatic, Dalmatia, Iapodes, and Liburnia, was united as the Roman province of Illyricum. In 29 BC the area between the Danube and the Balkan Mountains was conquered by Crassus and became the Roman province of Moesia, while the area further south was incorporated into the province of Thrace. The emperor Domitian's expedition against the Dacians in AD 85 consolidated his position north of the Danube. In 89 the king of Dacia, Decebalus, was forced into a collaboration with Rome against the Germanic Marcomanni, the Quadi, and the Iranian Sarmatians, the latter coming from the Pontic steppe. The complete conquest of Dacia in 106 followed two vigorous campaigns by the emperor Trajan in 101–

103 and 105–106. The Dacian capital of Sarmizegethusa was captured and the province of Dacia was established.

The process of Romanization was swift. In Romania, Latin completely supplanted the Dacian and Thracian languages. Trade and handicrafts penetrated deep into the provinces. Trade routes connected the growing cities: the northern road led to Sirmium (Sremska Mitrovica on the Sava), Singidunum, Viminacium, and Ratiaria on the Danube; the southern led to Stobi (south of Tiov Veles) and Scupi (now Skopje); and the eastern ran from Sardica (Sofia) via Naissus (Niš) and Margum to Viminacium on the Danube; in the west, the road crossed from Salonae and Narona on the Adriatic through Bosnia to Sirmium. Commercial expansion reached its culmination in the course of the 2nd century. Rome became decentralized and its art cosmopolitan. At the end of the 3rd century, Sirmium became a capital of the empire. Diocletian built his palace near Salonae (Split), and official art was created in Dalmatia, Pannonia, and Moesia. From the time of Marcus Aurelius, the empire lived under the protection of an Illyrian–Thracian army. When Constantine I established Constantinople as a second Rome, in AD 330, the eastern part of the empire split in two: Thrace was included in the prefecture of the Orient, whereas the rest of the peninsula was in the prefecture of Illyrium.

In the 3rd century there began an infiltration of the Goths into the peninsula. About AD 214 the Goths clashed with the Romans at the Dacian frontier and conquered Dacia. The Goths then attacked Thrace continually through the middle and late 3rd century. The Gothic state flourished for nearly 200 years until the Huns invaded and swept across the country.

The coming of the Slavs

The devastation of the empire by the Huns, followed by that of the Bulgars at the end of the 5th century and that of the Avars in late 6th, prepared the ground for a wide Slavic dissemination from their homeland north of the Carpathians in the Ukraine. (M.G.)

THE BALKANS IN THE MIDDLE AGES

The repopulation of the Balkans. With the settlement of the Germanic Ostrogoths in Italy and the disintegration of the Western Roman Empire in the final decades of the 5th century, the Balkans again came under the direct control of the Eastern Empire at Constantinople, at least in theory. But the barbarian invasions of that century had left the Balkan Peninsula a sparsely populated wasteland destined to attract new and more permanent settlers, the Slavs. An Indo-European people, the Slavs had settled in the valley of the upper Vistula in central Poland during the great prehistoric migration that brought most of the ancestors of the modern Europeans from Asia. Basically a sedentary people with a highly developed tradition of agriculture and animal husbandry as well as of hunting and fishing, the Slavs were easy prey to the highly mobile and often strongly united nomadic hordes that swept across eastern Europe. These barbarian tribes easily superimposed their rule over the native Slavic political system of democratically run clans, owing only loose allegiance to a chief, or *župan*. It was as vassals of such nomadic tribes that the Slavs spread into south Russia and Pannonia, a former Roman province that occupied parts of modern Austria, Hungary, and northern Yugoslavia. From these two areas beyond imperial control, the Slavs began their steady movement into the Balkans.

Slav invasion of the Balkans

By AD 517 groups of Slavs were crossing the lower Danube to raid in Thrace, Macedonia, Thessaly, and even Epirus. Almost simultaneously, others were moving into the northwest corner of the Balkans toward the Dalmatian coast. The massive military endeavours of the Byzantine emperor Justinian I elsewhere in the empire left no troops free to man the fortresses protecting the Danube River boundary of his realm. Imperial officials in Constantinople attempted to neutralize the northeastern arm of the Slavic pincers encircling the Balkans by offering the Slavs on the lower Danube the status of *foederati*, paid border guards for the empire. The Slavs, however, became vassals of the Avars, a new Turkic horde of nomads who appeared on the south Russian steppe.

The Avars, akin to the Huns, attempted to follow the route of their predecessors. Driving the remaining Germanic tribes from the Pannonian plain, they established there a new state that loosely controlled the Slavs settled in modern Czechoslovakia, the Balkans, and even north of the lower Danube in south Russia. Both the Avars and their Slavic tributaries undertook plundering expeditions throughout the Balkans. Eventually, the invaders took effective control of many areas as far south as the tip of the Peloponnesus and as far east as the great wall of Thrace, the first line of defense of Constantinople. Usually, the ravaging of territory was followed by permanent Slavic settlements being made in the devastated villages. It was only after 591 that the Byzantine army, finally withdrawn from other theatres of war, attacked the Avar–Slavic armies in the Balkan Peninsula; but by then the situation was hopeless. The Byzantine troops, committed to driving the Avars back beyond the Danube, revolted in 602, and soon the emperor was paying tribute to the Avars while the latter's Slavic vassals moved unimpeded through the Balkan Peninsula, populating it anew. Remnants of the local agricultural population probably remained among the Slavic settlers, but many of the Greek-speaking and Latin-speaking inhabitants took refuge in and around fortified Byzantine cities, particularly along the coasts. The safety of these cities, however, was in no way guaranteed. Thessalonica, the leading city of Macedonia and the second-richest city in the Byzantine Empire, several times came close to falling to the Slavs. In the interior, no imperial islands remained. Singidunum (Belgrade), Naissus (now Niš in Yugoslavia), Sardica (Sofia), Sirmium (now Srem in Yugoslavia)—the mighty fortresses guarding the middle Danube frontier—fell, with the surrounding countryside, to the Avars and Slavs. Contemporary sources often speak of the Balkans simply as Sclavinia (Slavdom). Byzantine control of this region had been so completely disrupted that the emperor Heraclius (*q.v.*) omitted the Balkan provinces from the administrative reorganization of the rest of his realm. Rather, to preserve his capital, Constantinople, Heraclius paid massive tribute to the Avar khan (chief) before he dared move against the equally serious Persian threat on the empire's eastern border.

In 626, however, the strength of the fabled walls of Constantinople and Byzantine naval superiority gave the Byzantines a wholly unexpected but decisive victory against a joint attack by the Avars and Persians. From this point on, both the Persian and Avar states began their rapid decline. Already weakened by a revolt of their Slavic subjects in what is now Czechoslovakia, the Avars were further threatened when Emperor Heraclius invited two strong tribes from beyond the Carpathian Mountains, the Croats and the Serbs, to settle in land held by the Avars in the northwest Balkans. Aided by the Byzantine navy and the few fortified imperial cities left on the Dalmatian coast, these tribes took control first of Dalmatia and then of the territory that, after their occupation, bore their names, the Croatia and Serbia of modern Yugoslavia. Once settled, theoretically as vassals of Byzantium, they mingled with the earlier Slavic settlers.

Return of Byzantine power

Greece from the 7th to the 15th century. The period from the mid-7th century on saw the slow reintegration of the southern Balkans (*i.e.*, Thrace, southern Macedonia, and Greece) not only into the Byzantine administrative and cultural system but also into the Greek-speaking world. The most important factor in reintegrating this territory into the empire was the gradual radiation of Byzantine culture from the Greek coastal enclaves into the surrounding countryside and the subsequent conversion of the new settlers to Greek Christianity. With the institutions of the Byzantine Church came the officials of the Byzantine state. The presence of Greek-speaking natives in the villages taken over by the Slavs served to facilitate the acculturation of the newcomers in many places. Military campaigns against recalcitrant Slavs and occasional resettlement of populations drawn from Asia Minor aided the process in other areas. The progress of Byzantine reabsorption of the southern Balkans is most readily seen in the establishment of "themes"—regular Byzantine administrative units—on the territory of Scla-

vinia. By the end of the 7th century, themes existed in Thrace and in the southeast region of mainland Greece; by the end of the 8th century, themes had been established in the Peloponnesus and Macedonia, and the next century saw the completion of a network of imperial themes covering the southern Balkans (Cephalonia for the Ionian Islands, Dyrrhachium [now Durrës] for Albania and northern Epirus, and Nicopolis for southern Epirus). The history of what is today the territory of Greece becomes a regional history of the Byzantine Empire marked by two peculiarities: occasional uprisings of isolated Slavic tribes in mountainous areas and vulnerability to attack from Bulgaria and Serbia as well as from western Europe.

The northern areas of Greece were often subjected to pillaging and territorial losses at the hands of the Bulgarians and, later, the Serbs; of a more lasting character, however, was the danger to Greece from the West. The Norman rulers of Sicily coveted Greece as a stepping-stone to the Byzantine capital, and, three times in the century and a quarter before the Fourth Crusade, which began in 1202, they launched successful campaigns in Greece. The Norman invasions, however, were but a foretaste of the fate awaiting Greece after the Latin conquest of Constantinople in 1204. The French and Italian leaders of the Fourth Crusade had little difficulty establishing control over most of the territory forming modern Greece. Boniface of Montferrat was crowned king of Thessalonica, and he, in turn, set up his own vassal states, the most important being the duchy of Athens, which included Attica and Boetia, and the principality of Achaea, which encompassed the Peloponnesus. Venice was awarded most of the Greek islands and many of the major ports. Yet the elaborate feudal superstructure erected by the crusaders effected little social change. Generally, Greek landlords were retained in their holdings after swearing fealty to the new Latin suzerain, and the masses continued to pay their taxes and rents as before.

Advent of Western rule

Simultaneously with the advent of Latin rule in eastern Greece and the Peloponnesus, an exile Greek government took control of western Greece from the neighbourhood of Dyrrhachium south to the Gulf of Corinth and established the state of Epirus. Taking advantage of the weakness of the neighbouring Latin states, the Greek government of Epirus quickly spread its power east to Thessaly, northeast to much of Macedonia, and, in 1224, to the city of Thessalonica. The hold of the Epirote government on its new possessions was tenuous, however, and much territory was soon lost both to the Bulgarians and to the exiled Byzantine emperor at Nicaea in Asia Minor, who took Thessalonica. By 1264 the Epirote rulers of Epirus and Thessaly had been forced into an uncomfortable vassal relationship with the restored Byzantine Empire and later were completely incorporated. Eighty years later, there were no longer any independent Greek states in the Balkans, and even the Albanian tribes that had been spreading across Greece for the previous half century recognized the rule of Constantinople. Byzantine territory reached to the borders of the duchy of Athens, which had fallen to a roving band of Catalan mercenaries in 1311. Farther south, the Byzantines, who had retaken Constantinople in 1261, used their foothold on the southern tip of the Peloponnesus to spread their influence outward to the Greek population dissatisfied with the administration of their Latin rulers. By 1340 Byzantium controlled all of the Peloponnesus except for some Venetian-held ports, and the area became the "Despotate of Morea," ruled by viceroys appointed from Constantinople. Within a generation, Morea had also forced the Latin duchy of Athens, together with most of Attica, into submission.

The period of the 1340s saw the beginnings of far-reaching changes in the Balkans. The Byzantine Empire was plunged into civil war and social strife, complicated by a Serbian invasion that occupied most of Macedonia and Greece as far south as the Gulf of Corinth. During the 1340s the Ottoman Turks also established their first permanent settlement in Europe. Yet, although in the next 100 years Greece was absorbed into the Turkish Empire, it was a century of almost frantic cultural activity in Greece. The capital of the Morea at Mistra became a vital centre of Greek studies and Renaissance Humanism, in spite of almost constant Turkish raiding. But eventually, one by one, the Greek cities of Europe fell to the Ottomans (Thessalonica in 1430, Constantinople itself in 1453, Athens in 1456). In 1460, when the Morea fell, all of Greece had become part of the new Turkish Empire.

The Bulgarian Empire under the Asenids about 1241.

Bulgaria. As Avar power was waning in the 7th century, a new threat to the peace of the Balkans appeared —the Bulgars, a Turkish tribe that, after casting off Avar suzerainty, began to cross the Danube. After successfully repulsing a combined land and sea attack by Byzantium in 680, the Bulgars, under their khan Asparukh (Isperich), took control of the area between the Dniester River and the Balkan mountains and quickly subjugated the Slavic inhabitants. This new Balkan state, comprised of an aristocracy of Turkic–Bulgar nobles ruling over a Slavic population, was soon strong enough to demand the payment of tribute by the Byzantine Empire; Bulgaria was to remain thereafter a permanent factor in Balkan history.

After the final defeat of the Avars by Charlemagne in 796, the Bulgarian state spread even farther, taking the Byzantine fortress of Sardica (later Sofia) and besieging the key Byzantine city of Adrianople (modern Edirne, Turkey). The Byzantines retaliated in force, but a Bulgarian ambush took the life of the Byzantine emperor Nicephorus in counter-retaliation. Two years later, the Bulgarian khan Krum was ravaging the suburbs of Constantinople. By 864, however, the Byzantine Empire had recouped enough of its armed strength to force the new ruler, Boris I of Bulgaria (*q.v.*), to accept Baptism from Byzantine missionaries and to establish a branch of the Byzantine church as the state religion of Bulgaria. The gates were opened to a flood of Byzantine culture. When the old Turkic aristocracy rose up against this wave of Byzantinization, the khan Boris, now christened Michael, backed by the Slavic population, crushed the opposition. The entire country quickly became Slavicized, and Bulgaria permanently joined the Byzantine cultural sphere.

Arrival of the Bulgars

The reign of Boris-Michael's son and successor, Symeon (893–927), witnessed the high point of medieval Bulgarian history. The seemingly invincible Bulgarian army conquered most of the Balkans, until the Bulgarian state stretched from the Black Sea almost to the Adriatic and from the middle Danube into northern Greece. The Byzantine Empire in Europe was reduced to Thrace, southern Macedonia, Greece, the islands, and a narrow stretch of territory along the Adriatic coast; and even

these areas were subjected to Bulgarian raids. In the year 913 the Bulgarian army invested Constantinople itself and forced the Byzantine government to crown Symeon as tsar. Symeon dreamed of becoming the unique emperor in Byzantium, but the enthronement of a brilliant general in Constantinople in 920 frustrated his dream.

Tsar Symeon's Byzantine orientation is particularly apparent in the internal reforms he introduced into the structure of Bulgaria. The oligarchic state of Symeon's ancestral Turks became the autocratic centralized state of a neo-Byzantine tsar. The Bulgarian government imitated the Byzantine administrative system down to the very titles of officials and their ceremonial dress and soon even forced the free peasantry into the traditional forms of Byzantine rural servitude on the lands of the magnate boyars. As guide and protector of the church in his realm, Symeon introduced important changes. He encouraged the work of the Slavic-speaking clergy and began to make the Slavic language of his subjects the liturgical language of the church in Bulgaria, which allowed him to replace Greek clergy with his own subjects. Moreover, he made the Bulgarian Church an independent jurisdiction with its own patriarch, as befitted the church of a state ruled by a tsar. The Bulgarian people now had a religious as well as a political symbol of national unity. The new Bulgarian capital at Preslav became a veritable centre of Byzantine culture patronized by the Tsar. Monumental churches and palaces on the Byzantine model made the city a source of wonder to visitors and a young rival to Constantinople itself. The ruler supported translations of Byzantine liturgical, literary, and legal works, as well as the writing of new works in Slavic. From Preslav the Tsar disseminated a syncretic Slavo-Byzantine culture across the Balkans. Large numbers of Bulgarian subjects, however, rejected the state, the church, and the culture that Symeon had fostered and united in a puritanical sect called the Bogomils, which rejected all that was material as evil. This protest movement, which spread into Serbia and particularly Bosnia, significantly weakened the internal cohesion of the Bulgarian state and, coupled with the weakness of Tsar Symeon's successors, left Bulgaria unable to resist a Byzantine attack in 971. Emperor John I (Tzimisces) annexed Bulgaria, abolished the Bulgarian church patriarchate, and carried the Tsar back to Constantinople as a prisoner.

Barely five years after Tzimisces' victory, however, a revolt broke out in Macedonia that eventually recreated a Bulgaria almost as large as that ruled by Symeon. The revolt was led by the four sons of a provincial governor, the youngest of whom, Samuel, became tsar, locating his capital at Ohrid, where he also established the resurrected patriarchate of the national church. From Ohrid, Tsar Samuel was able to conquer the Serbian principalities, Thessaly, Epirus, and most of Albania, as well as all of Macedonia except the imperial stronghold of Thessalonica. In 1014, however, the long war waged against Bulgaria by the Byzantine emperor Basil II (see BASIL II BULGAROCTONUS), the "Bulgar Slayer," bore fruit. Basil captured and systematically blinded almost 14,000 Bulgarian soldiers. The First Bulgarian Empire quickly disintegrated.

For a brief moment, the Balkans once again belonged to the Byzantine Empire. The core of Samuel's state was divided into themes. The parts of Samuel's domain that lay in modern Yugoslavia were returned to their local princes, who ruled once more as Byzantine vassals. The concessions made by Emperor Basil to local customs in the newly conquered territory, however, were gradually abrogated by subsequent emperors. Finally, the discontent engendered by the growing harshness of Byzantine rule, the chaos of the period of the Crusades, and the disappearance of a powerful centralized administration in Constantinople caused a minor uprising that led to the foundation of the Second Bulgarian Empire.

The leaders of the uprising of 1185, two brothers named Peter and Asen, landed magnates of the Byzantine theme of Bulgaria, were of Vlach origin—that is, descendants of the old inhabitants of Roman Dacia. Their revolt quickly spread across the eastern Balkans, until the Byzantines were forced to recognize the rebels as an independent Bulgarian empire ruled by "Asen, tsar of the Bulgars" and to allow the appointment of an independent archbishop for the new Bulgarian capital at Tŭrnovo as a mark of the state's imperial status. The Bulgarian leaders attempted to re-create the imperial aura of Symeon's days by making Tŭrnovo a new cultural centre for the Balkan's, with magnificent churches and monasteries and flourishing literary groups in close touch with cultural developments in Constantinople. Neither military campaigns nor the fostering of internal opposition to the Asenids could restore Byzantine power in Bulgaria nor even arrest the new state's westward expansion at Byzantine expense. By the time the crusaders captured Constantinople in 1204, Bulgaria was the strongest power in southeast Europe and was still expanding into Thessaly, Macedonia, and Albania.

Second Bulgarian Empire

The death knell for the Second Bulgarian Empire as the decisive element in Balkan politics came most unexpectedly, following the death, in 1241, of one of its most successful rulers, Tsar Ivan Asen II. In the midst of the ensuing succession crisis, a Mongol army slashed its way through the country, wrecking its economy and forcing the payment of massive tribute to the Mongol khans for the next 59 years. Bulgaria was broken as a major power. Serbia and the various Greek states gradually reduced the extent of its territory, while internal dissension produced a chaotic succession of tsars of various political persuasions, including briefly a Turkic Cuman, a reminder of the Bulgarian penchant for calling in nomads from beyond the Danube to strengthen their army. In the end, the combination of external threats and internal disequilibrium opened the way for Turkish conquest. In the years 1393–96 Bulgaria became the first European state to be absorbed into the Ottoman Empire.

The Serbian kingdom of Stefan Dušan, 1340.

Serbs and Croats. After the settlement of the Serbs and Croats in the territory of present-day Yugoslavia in the 7th century, missionaries from the Western Church were called in to restore the lands of Illyricum to Christianity. After the missionaries, at least in Dalmatia and

Croatia, came the margraves of the Frankish Empire. When Charlemagne's knights moved to assert their claim to the western Balkans, the Western cultural orientation that was to distinguish Croatia and Dalmatia from the Byzantine-oriented bulk of the Balkan Peninsula was established. The Frankish domination of Dalmatia and Croatia, however, was by no means uncontested. The Byzantine navy guarded the Adriatic littoral, and the growing Bulgarian Empire's sway extended even west of Belgrade. The Pannonian Croats revolted, albeit unsuccessfully, while the Dalmatian Croats, allied with the Byzantine coastal cities, sought a counterpoise to Frankish domination in the Emperor at Constantinople.

In 879, however, Zdeslav, the last pro-Byzantine ruler of the Croats, was overthrown by the Frankish vassal Branimir. But soon it appeared that the Holy Roman emperors of the Franks were no more able to guarantee the safety of Dalmatia than the distant Byzantine emperors, and in 925 Tomislav, duke of the Dalmatian Croats, turned to Rome for a royal crown, drew the Frankish vassal Croats of Pannonia into his kingdom, and successfully organized local defenses against Symeon's Bulgarian Empire. The resulting kingdom of Croatia prospered through the 11th century.

But, when Zvonimir, the last native Croatian king, was assassinated in 1089, the nobles invited Zvonimir's brother-in-law, King Ladislas I of Hungary, to take the Croatian throne; Ladislas' brother and successor as king of Hungary, Kálmán (Koloman), made this arrangement permanent by the Pacta Coventa of 1102. Henceforth, the king of Hungary was also king of Croatia and was represented there by a ban, or viceroy. The coastal cities in Croatian hands retained their special privileges, however, and local Croatian traditions remained intact. The countryside continued to be ruled by the local *župani*, or chiefs, probably descendants of the original Croats called in during the 7th century. The leading *župani* continued to form a royal council, and national assemblies were called to settle important matters. In some ways, then, the basic traditions of the Croatian people were preserved, even though their political state was henceforth drawn into the affairs of central eastern Europe rather than of the Balkans.

Kingdom of Hungary and Croatia

The history of the Serbs has proved very different from that of the Croats, largely because they settled farther south and east when they came to the Balkans in the 7th century. The Serbs seem to have been absorbed rather completely by the Slavic population of what was to become Serbia. The political organization of the area, however, remained unclear until the mid-9th century, when the grand *župan* Vlastimir united several Serbian tribes against a threatened Bulgarian invasion. Vlastimir also sought Byzantine support, and it was probably in this connection that the Byzantines initiated large-scale missionary work among the Serbs, drawing Serbia into the Byzantine cultural sphere almost simultaneously with the spread of Latin Christianity among the Croats.

In the interior of the Serb lands, Byzantine support seems to have been restricted largely to Christianization, for most of this area was quickly absorbed into the Bulgarian Empire of Symeon early in the 10th century. Once established, however, Bulgarian rule seems not to have been particularly oppressive. Local *župani* continued to rule, though as vassals of the Bulgarian tsar rather than of the Byzantine emperor. Similarly, the fledgling Christian church in Serbia was subordinated to the Bulgarian patriarchate. When, after the death of Tsar Symeon, the Bulgarian Empire disintegrated, an interlude of Serbian unity under Byzantine protection followed; soon, however, it gave way to petty feuding ended only by the conquering forces of Tsar Samuel's new Bulgarian state. The Byzantine defeat of Samuel in 1014 brought the Serbian lands once again under the sway of Byzantium as exercised through local princes. Around the year 1036, however, Stephen Vojislav, the prince of Zeta (modern Montenegro), renounced Byzantine suzerainty and began to absorb neighbouring principalities. By 1077 Zeta had grown important enough to merit a royal crown; under King Constantine Bodin it succeeded in absorbing most of the Serbian principalities. At Bodin's death around 1101, however, the Serbian state fell once more into civil war, and the centre of political gravity shifted northeast to Rascia (Raška). Sometime after 1165, Stephen Nemanja took the throne as grand *župan* of Rascia and founded a dynasty that was to rule more than two centuries.

The signal for the birth of the Serbian Empire of the Nemanjids was the death of the Byzantine emperor Manuel I Comnenus in 1180, after which Byzantium was never again in a position to reassert its rule over Serbia. Before his retirement to a monastery in 1196, Stephen Nemanja had absorbed the kingdom of Zeta as well as considerable territory along the Adriatic and had obtained Byzantine recognition as the ruler of an autonomous state. Nemanja's son and successor, the able Stephen II (1196–1228), did much to solidify the unity of the new Serbian state. He obtained a royal crown from the papacy, and, from the Byzantine emperor in exile at Nicaea, he received an independent archbishop for the Serbian Church in the person of his younger brother, St. Sava, destined to become the patron of the national church of Serbia. The following 100 years of Serbian history were highly complex: the elected *župani* of the clans and tribes became gradually transformed into hereditary castes of lords and nobles, and the drift of free peasants toward serfdom began, a movement that was to accelerate in the following century. In addition, the period saw a tangle of short-term alliances and of wars both with foreign powers and within the ruling Nemanjid family. Through all this, however, the Serbian state continued its steady accumulation of territory, a movement capped by Stefan Dušan.

The Serbian Empire

Magnates bent on acquiring new land for their estates were responsible for placing Dušan on the Serbian throne in 1331, and they were in no way disappointed. A brilliant statesman and military leader, the young king moved quickly to take advantage of civil war in Byzantium. By diplomacy and war he moved his border south, until all of Macedonia except the area around Thessalonica was subject to him, as was most of Albania. In 1346 he was solemnly crowned tsar by the newly created patriarch of the Serbian Church, assisted by the Bulgarian patriarch, for Bulgaria had now become little more than a dependency of the new Serbian Empire. Soon Epirus and Thessaly also fell to the Serbs. Stefan Dušan was also a brilliant administrator of his realm, fostering trade, promulgating a comprehensive legal code, establishing an efficient civil service on the Byzantine model, and, in general, giving his subjects peace and prosperity. Like his Nemanjid predecessors, Dušan endowed the country with monasteries and churches and patronized the arts. The writers of his time continued the tradition of literary productivity inaugurated by St. Sava. At his death Dušan could describe himself as "emperor of the Serbs and Greeks, Bulgars and Albanians," for he had doubled the territory of Serbia and had taken half of the territory remaining to the Byzantine Empire. His rule at Skopje was recognized from the Danube to the Gulf of Corinth and from the Adriatic to the Aegean. There remained for him but one unattained goal, the conquest of Constantinople, which he was preparing at the time of his death.

Stefan Dušan

Within a few years of his death, Serbia, the power and unity of which largely depended on the personality of the monarch, was again an amalgam of petty kingdoms, principalities, and despotates. The enemy was no longer a weakened Byzantine Empire, however, but a unified and growing Ottoman state. The Serbian kingdom of Bosnia was a potential source of hope, but it was compromised as a possible leader of the Balkans by its heretical, radically ascetic Bogomil Church and its proximity to Hungary. Macedonia had fallen into Turkish vassalage by 1371, and, when, on June 15, 1389, the Ottoman sultan Murad I smashed the Christian forces led by the Serbian prince Lazar at the Battle of Kosovo in Serbia, the end of the Balkan Christian states had come. One by one, the Slavic leaders of the Balkans accepted Turkish suzerainty, which, in time, gave way to direct Turkish rule. By 1463 Bosnia, the last major Serbian stronghold, had been taken by the Turks, and there remained free only the tiny

Serbian enclave of Montenegro hidden in the almost impenetrable mountains along the Adriatic coast, a perpetual reminder of Serbia's past independence.

Romania and Albania. The last two ethnic groups to attain statehood in the medieval Balkans represent, curiously enough, two of the oldest ethnic lines inhabiting the peninsula. The Romanians, or Vlachs, as they were usually called in the Middle Ages, represent the descendants of the Latinized Thracian population of the old Roman province of Dacia. Originally inhabitants of the Danubian plain, many of them seem to have migrated into the mountainous region of Transylvania after the withdrawal of the Roman army from Dacia in 271. There they lived the life of nomadic sheepherders, comparatively safe from the barbarian migrations that followed, until the late 12th century, when large numbers of them seem to have moved into the plains of Macedonia, Thrace, and Dobrudja—possibly as a result of tightened Hungarian control over their Transylvanian refuge. There they played a major part in the Second Bulgarian Empire, the leader of which, Ivan Asen I, was often called the tsar of the Bulgars and the Vlachs.

The appearance of the first specifically Romanian state, Walachia (Land of the Vlachs), can be dated to the early 14th century, when large numbers of Vlachs, who had moved from the Carpathian Mountains to the great plain of the lower Danube, united under Prince Besaraba with some of the Vlach population of the Second Bulgarian Empire. In 1349 Moldavia, a second Romanian principality, was founded east of the Carpathians in the Pruth Valley. Its *vojvoda* (military governor) was Bogdan, a former official of the Hungarian government.

Walachia and Moldavia

Like its sister state Walachia, Moldavia was a product of Vlach emigration from Transylvania, where the Hungarian government was encouraging Roman Catholic missionary work among the Eastern Orthodox Romanian population. The Byzantine government eventually recognized the existence of the Romanian principalities by appointing bishops for Walachia and Moldavia. The states adopted forms of government imitative of the Byzantine except for the fact that the *vojvode* were elected from the ruling families by the boyar aristocracy of each state.

It was the misfortune of the Romanians to move toward statehood at a most unpropitious time. Pressed from the rear by their Hungarian former rulers, they also had to meet the growing Turkish power head on. Occasional superb leadership slowed the Turkish advance into the Romanian principalities and ameliorated its results. Finally, in 1393, however, the Walachian *vojvoda* Mircea the Old was forced into vassalage by the Turkish army. Alliances, participation in Hungarian-inspired crusades against the Turks, and cooperation with the sister principality of Moldavia were all vitiated by the military might of the Turks as well as by dynastic civil war. Walachia was rarely more than temporarily free from the burden of tribute to the sultan. With Walachia as a buffer between it and the Turks, Moldavia maintained its independence somewhat longer, although it had to contend not only with Hungary as a neighbour but also with Poland. But in 1455 Moldavia, too, began paying tribute to the Turks. Like his Walachian prototype Mircea, Stephen the Great of Moldavia became a national hero by temporarily breaking with his Ottoman suzerain. In his case, too, the victories were Pyrrhic. Walachia and Moldavia were to remain Turkish dependencies until the age of 19th-century nationalism.

The history of the Albanians in some ways parallels that of the Romanians. As the Romanians were a remnant of the native Thracian people who retreated into the mountains during the earlier barbarian invasions, the Albanians in the western Balkans were remnants of the old Illyrian population who took refuge in the mountain fastnesses along the Adriatic during the great Slavic migration into the Balkans in the 6th century. There, again, like the Romanians, they lived largely as shepherds, having little to do with the larger world of politics for several centuries. Although they were theoretically ruled by the Byzantine governors of Dyrrhachium, Byzantine interference in their mountain territory was minimal. From the 10th to the 14th century, however, almost every state with an interest in the Balkans contended for control of Albania and its strategic coastline. Bulgaria, Serbia, the various rulers of south Italy, Venice, the Greek state of Epirus, and, of course, Byzantium were all involved in the struggle. The contest for domination over Albania had a threefold effect on the population: many Albanians migrated east and south, especially to Thessaly and the Peloponnesus; a distinction developed between the Albanians of the north, who were predominantly Roman Catholic, and those in the south, who were primarily Eastern Orthodox; many of the Greek landowners fled, leaving local government in the hands of minor native chieftains. With the gradual withdrawal of the foreign powers, the country fell into such anarchy and feuding that the land was easily taken by the Turks in 1385. The foremost Albanian leaders were forced to accept Ottoman suzerainty, to pay tribute to the conquerors, and to send their sons as hostages to the sultans.

Contest for Albania

The Albanian national hero, George Castriota, better known under his Turkish name, Skanderbeg, began his career as an Albanian hostage at the Ottoman court. There he was converted to Islām and rose to be an important general, only to desert in 1443, revert to Christianity, and return to his native land to lead a successful revolt against Ottoman rule. His charismatic personality attracted a large following, and his political acumen won him the support of the Kingdom of Naples, the papacy, and even the pragmatic republic of Venice. But, most important, the military ability he had developed in the Ottoman army held back the Turks for 24 years, making him a hero not only in Albania but, indeed, in much of Christendom. His death in 1468 opened the way for Turkish reconquest and large-scale Islāmization of what had previously been a loosely controlled Ottoman dependency, an ironic conclusion to a heroic resistance (see further BYZANTINE EMPIRE). (G.P.M.)

Skanderbeg's revolt

THE BALKANS UNDER OTTOMAN RULE

The Ottoman conquest. The Ottoman Empire had its origins in a small Turkish emirate established in the second half of the 13th century in northwest Anatolia, near the Sea of Marmara and close to the borders of the Byzantine Empire. The name Ottoman was derived from Osman I, a Turkish chieftain who ruled the emirate from 1281 to 1324. An active and aggressive military organization of dedicated frontier warriors, this state first established itself on the European mainland in 1354 on the Gallipoli Peninsula. In 1362 the Ottoman armies took Adrianople, which soon became the Ottoman capital. From this centre the Ottoman armies moved up the Maritsa and Vardar valleys against the Christian states of the Balkans.

The Ottoman successes were made possible by superior military power based on a mobile light cavalry and by excellent leadership and organization. The Christian powers were hampered by their failure either to cooperate among themselves or to secure effective European assistance. Pope Boniface IX's army, sent in an attempt to aid the Hungarians, was crushed by the Ottoman army at Nicopolis in 1396. A second effort in the next century by Pope Eugenius IV collapsed with the defeat of the Christian armies led by János Hunyadi and King Wladyslaw III Warneńezuk of Poland and Hungary at Varna in 1444.

The victorious march of the Ottoman forces into Europe was checked briefly, at the beginning of the 14th century, by internal problems within the empire and by Timur's threat in the east. Under the leadership of Mehmed I (1413–21), who won the struggle for succession, and his successor Murad II (1421–51), the march forward was resumed. The empire at this time also had to develop a navy to deal especially with Venice. Until the end of the 18th century this city-state was a major power in the eastern Mediterranean and waged with the Ottoman Empire a continual duel for control of the islands and the peninsulas of this sea—in particular, Crete, Cyprus, and the Morea.

The greatest single Ottoman military achievement occurred in the reign of Mehmed II (*q.v.*) the Conqueror

(1451–81). Although Ottoman territories now reached far into Europe, the Byzantine Empire, reduced to the city of Constantinople and a small surrounding area, still stood. After long and careful preparation, Mehmed took the city in 1453, a date that compares in Greek history to that of Kosovo in the Serbian national memory. The fall of Constantinople marks also the completion of the process of the subjugation of the Balkan Peninsula to Ottoman rule. The empire now held most of Serbia, Bosnia, Bulgaria, and Greece. Although some isolated areas still resisted, no major centre of opposition remained. With the capture of the imperial city, the Ottoman conquerors made it their capital and developed an administrative system that was to dominate the Balkan region for the next five centuries.

Fall of Constantinople

The Ottoman Empire reached its height in power and prestige during the reign of Süleyman I, known in the West as "the Magnificent" and in Ottoman history as "the Lawgiver" (1520–66). A great military leader and an able administrator, Süleyman extended Ottoman territory far into the centre of Europe. Belgrade fell in 1521; in 1526 Süleyman defeated a Hungarian army at Mohács; and in 1529 the Ottoman army reached Vienna and lay siege to that imperial city. With the failure of this attempt, the limits were set to Ottoman westward expansion, but Süleyman's campaigns had left his country with control over most of Hungary and Transylvania. Transylvania, like the principalities of Walachia and Moldavia, taken in the 15th and 16th centuries, became an autonomous tributary province of the empire. See further OTTOMAN EMPIRE AND TURKEY, HISTORY OF THE.

Although some territorial changes occurred in the Balkans during the next century and a half, the Ottoman Empire lost no significant territory to Christian Europe until after 1683. Moreover, it kept at least titular control of the majority of the Balkan lands until 1878. Thus, for almost five centuries the greater portion of the Balkan people lived under an alien Muslim rule. It is the common experience of the peninsula and one that has profoundly shaped its present condition.

The character of Ottoman rule. When the Balkan people first fell under Ottoman control, they became a part of one of the great empires of world history, a worthy successor to the Roman and Byzantine states, which, too, once had their centres at Constantinople. The negative opinion often held of Ottoman civilization is usually based on judgments made of conditions in the 18th and 19th centuries, when the state was in a period of obvious decline. In the 15th and 16th centuries, however, Ottoman institutions may have offered the Balkan Christian a better life than he had led previously under his native feudal governments.

To understand the political conditions in the Balkans in the Ottoman era, it is first necessary to emphasize that the conquering power was a Muslim and not a Turkish national state. The Ottoman leaders regarded their peoples as divided by religious faith rather than by nationality. Any individual could join the ruling group by converting to Islām. Basing the political structure on this concept, the non-Muslim peoples were divided into five religious communities called millets: Orthodox, Gregorian Armenian, Roman Catholic, Jewish, and Protestant. Each group was under the direction of its religious head. Thus for the Balkan people, the vast majority of whom were Orthodox, the titular leader was the patriarch of Constantinople. But in practice, during the years of Ottoman rule, the Balkan Orthodox church organization became divided into its national components. Constantinople became a Greek centre; the Serbians had their own patriarchate at Peć, and the Bulgarians had a metropolitanate at Ohrid. The Romanians had similar national institutions. Thus national separateness and local tradition were preserved through the ecclesiastical organizations. The Ottoman government expected the church authorities to assume many civil functions, in particular judicial and tax-collecting duties. The Christian churches thus became, in a sense, part of the Ottoman state system.

The Ottoman government had a regularly organized administrative system with its centre in Constantinople and extending over the entire empire. The Balkan lands were part of the region (*beylerbeylik*) of Rumelia; the territories under direct administration were subdivided into provinces and then into lower administrative units. The principal interest of the Ottoman officials was the collection of taxes, which were to pay for the military power and the administration of the empire. Soldiers, policemen, and judges were also present in the administrative centres to maintain conditions beneficial to the proper collection of revenue. Although most of the Balkan lands were administered by Ottoman officials, some areas enjoyed unusual rights of self-government. The Danubian principalities of Walachia and Moldavia, for instance, as well as Transylvania, being autonomous tributary regions, were governed by their own aristocracy. The merchant city of Dubrovnik was an autonomous republic. Certain other cities and regions either had won special rights or were too remote and primitive to arouse Ottoman concern. They enjoyed almost complete self-government. Even among the areas under direct administration, the Ottoman authorities remained chiefly concerned with taxation and the maintenance of public order. They did not attempt to regulate other details of Balkan Christian life. These fell under the jurisdiction of the local village authorities or the church.

Although only Muslims could hold office in the empire or serve in its military forces, converted Balkan Christians came to occupy the highest positions at this time. In fact, these converts came to form the main basis of the military and administrative apparatus of the state. By the time of Süleyman, the highest state offices were held by slave administrators. These were either purchased, were prisoners of war, or were acquired through the *devşirme* system: from the 14th century to about the middle of the 17th, approximately every five years one out of four boys in the Balkans, aged between 10 and 20, was taken from his parents, brought to Constantinople, and converted to Islām. The most able of these were sent to the palace school, where they were trained as administrators, and then assigned posts throughout the empire. Other children recruited in this manner became members of the Janissary Corps—an elite infantry unit armed with muskets—which became the most effective fighting arm of the Ottoman army. Forbidden at first to marry, this body of new converts proved to be fanatic and dedicated soldiers.

The *devşirme* system

In the first period of Ottoman rule, conditions for the Balkan peasant on the land were probably not overly onerous; in fact, he may have enjoyed a better position than his counterpart in western Europe. In theory, the sultan held all of the land taken in war; he was free to dispose of it at will. In practice, the Balkan lands were used to support cavalry units of the army. The members (spahis) were given grants of land (timars) in return for which they had to provide military service. At first, the amount that the peasant had to contribute in dues and services was carefully regulated. Later, however, the system tended to break down. With the introduction of the wide use of firearms the effectiveness of the cavalry was reduced. The government became more interested in increasing the tax load to pay for new weapons.

Despite the fact that the Ottoman government showed a high degree of toleration for non-Muslim faiths, there was no question of equality between religious groups. To rise in Ottoman society the Balkan Christian had to abandon his faith. There were few attempts at forced conversion, but the subordinate position of the Christian was constantly emphasized. He could not wear conspicuous or rich clothes, for instance, or the colour green, sacred to Islām. If when on horseback he passed a Muslim, he was forced to dismount. Old churches could be repaired, but new ones could not be built. They could not have bells or bell towers or be constructed in a place or manner likely to "offend the eyes of the faithful."

Even more important, the Balkan Christian was forced to carry an unequal share of the tax burden of the empire. Although he was not subject to military conscription, he was assessed a special tax as a replacement. He was also liable to other services and payments, particularly in time

of war, which were connected to his secondary status within the state. Despite these and other severe disabilities, it is interesting to note that there were relatively few examples of mass conversions among the Balkan people, with the exception of those that occurred in Bosnia, Albania, and Crete, where local conditions were unusual.

Despite the fact that the Ottoman system of government served to maintain the separation of the national groups, great similarities nevertheless existed in the conditions of life of all of the people who lived under direct Ottoman rule. The vast majority of the Balkan population lived as farmers or herdsmen, either on estates or in the less economically valuable hills and mountains on virtually independent family farms. They inhabited small primitive houses, clustered in villages, where their local and personal affairs were managed by the village elders and the church. Larger towns and cities served principally as trading and administrative centres. Ottoman officials usually resided in the largest cities, as did those Muslims who held large estates. Handicrafts and trades, with their centres in these cities, were organized in a guild system.

The average Balkan peasant in these circumstances lived a primitive existence, cut off from the rest of the world. Since education was controlled by the church and was extremely limited, illiteracy was nearly universal. The life of the individual was limited to his village. Nevertheless, in each region a unique peasant culture was retained. Each area and national group had its own style of houses, decorative patterns, and, most important, its traditional songs and stories that substituted for a written literature.

While the smaller Balkan communities reflected the local peasant culture, the Balkan cities, as the military and administrative centres for the Ottoman authorities, were built according to the architectural preferences of the ruling group. Typical of Ottoman architecture were the massive stone bridges, fortresses, mosques, baths, covered markets, and caravansaries.

Although most of the Balkan peoples tended to prefer to remain on the lands of their ancestors, they could, of course, as citizens of one state, move about within the empire. During the four centuries of Ottoman domination, there was not only much internal migration, due to war and similar causes, but certain nationalities tended to specialize in occupations that drew them out of their national area. For instance, Greek merchants could be found in most major Balkan cities; Vlach (Romanian) shepherds roamed the mountains of the entire peninsula. Some Turks moved from Anatolia to areas such as the Black Sea coast, Macedonia, Bosnia, and Thrace. Albanians served as guards or police in many localities. This intermixture of population caused complications later when it became necessary to draw the boundaries of the national states.

The decline of the Ottoman Empire

Despite the long existence of the empire, signs of weakness appeared in its structure as early as the reign of Süleyman. The Ottoman system could not function well without strong direction from the top. Up through Süleyman the state had been remarkably fortunate in its rulers, but among the 17 sultans who followed, few were men of ability. With the lack of firm direction from above, the administration based on slave officials who rose by merit inevitably changed. Born Muslims and sons of officials naturally sought to enjoy the rewards of public office. The *devşirme* system came to an end by the middle of the 17th century. Parallel with these developments was the increasing corruption of all aspects of Ottoman political life. High offices were regularly sold; the officials who purchased their positions were primarily concerned with recovering their expenses and enriching themselves. The breakdown of the Ottoman administration, which commenced at the centre in Constantinople, spread out to encompass the entire governmental network.

Most dangerous for the future of the empire was the decline of the Janissary Corps. Though its members had gained the right to marry and to enlist their children in its ranks, they were soon forced to earn extra money and many became craftsmen on the side. Thus, this once-powerful military unit degenerated into a weak organization whose chief role in the state was to exert influence on the government. The corps, like the rest of the Ottoman military forces, failed to keep up with Western advances in military technology and organization. The military pre-eminence and the qualities of leadership that had won for the Ottoman Empire its vast domain were now lost.

The Christian, together with his Muslim neighbour, was directly affected by the decline of Ottoman administration. His chief grievances became the willful and arbitrary manner of the local officials and the grave abuses that were now associated with the collection of taxes. The central government relied for this service on tax farmers who competed yearly in bidding for the position. The tax farmer was chiefly interested in making a profit from his investment. Forceful methods and unfair standards of assessment were regularly used to extract high payments. The system was economically ruinous for the peasant and the central government alike.

The Balkan peasant found his standard of life also deeply affected by a change in the landholding system. As mentioned previously, under the timar system, strictly controlled nonhereditary land grants had been made in return for military service. With the relative decline in importance of the cavalry and the reduction in the number of military campaigns, large estates tended to pass into the hands of those who wished to work them at a profit and who now held them as hereditary rights. The peasant who worked the fields of the estates (now called *chifliks*) was reduced to the position of a sharecropper; his dues in kind and in labour were greatly increased.

Among the most severe consequences of the breakdown of the Ottoman government was the rise of lawlessness throughout the peninsula. As the central authority grew weaker, local Muslim leaders throughout the empire established what were in effect small principalities from which they were able to defy Constantinople and war among themselves. The most important of these for Balkan affairs were Ali Pasha of Janina and Pasvanoglu of Vidin. Christian bands of robbers (haiduks or klephts) also existed in large numbers. Their activities, together with the destruction caused by the Ottoman wars of the 18th century, made certain areas uninhabitable for long periods. These conditions were the direct cause of both the Serbian revolt of 1804 and the Greek revolution in the Morea in 1821.

Although all of the inhabitants of the empire suffered from this situation, certain Balkan Christians nevertheless did benefit from the growing weaknesses in the Ottoman system. Of the non-Muslim people, certainly the Greeks associated with either the Ottoman administration or the commercial world were in a privileged position. By the 18th century certain Greeks residing in Constantinople, known as Phanariotes, had come to secure regularly certain high appointments in the Ottoman service. Most important were the offices of grand dragoman (secretary of state) and the governorships (*hospodar*) of Walachia and Moldavia. At the same time, through the patriarchate at Constantinople the Greek hierarchy was able to dominate the other national churches. In the middle of the 18th century, it secured control of the Bulgarian and Serbian ecclesiastical centres at Ohrid and Peć. In addition, Greek merchants were established in the cities of the peninsula, and they controlled a large part of the trade of the Black and the Mediterranean seas. These merchant communities were the most susceptible to the influence of Western political and social ideas.

The position of the Greeks in the empire

After the Greek, the Romanian landowner of the privileged provinces of Walachia and Moldavia held a superior position within the empire. These principalities were never under direct Ottoman administration, although they did pay tribute and they were subject to regulation from Constantinople. In both, a native aristocracy held control over an enserfed peasantry. After the Russian invasions of the early 18th century, during which Romanian leaders cooperated with the enemy, the Ottoman government appointed Greek rather than Romanian governors for the provinces. The Phanariote Greek regime, which lasted until 1821, was extremely corrupt and was strongly disliked by the Romanian aristocracy.

In comparison with these groups, the Serbs and Bulgarians—without a native aristocracy and largely peasants—were at a distinct disadvantage. Both nations suffered severely from the corruption and lawlessness of the time. Their lands were the scene of repeated struggles between local Muslim leaders and of battles with the invading great powers. In the 18th century, both found their national churches taken over by Greeks.

A special word must be said concerning the Albanians and the Montenegrins. As the only Balkan people among whom a majority (70 percent) converted to Islām, the Albanians were not subject to many of the problems of their Christian neighbours. Many rose high in the Ottoman state and in military service. Moreover, the central government made little effort to control closely this distant, backward, mountainous region. Relatively content with their status, the Albanians were the last to establish an independent state. Montenegro, too, although a Christian state under a prince-bishop, because of its poverty and the difficulty of access to its lands, was usually able to govern itself.

The increased role of the European powers. Although the internal problems had become acute long before, in international affairs the empire was able to preserve its territories almost intact until the end of the 17th century. In the second half of that century, a last great offensive was begun and additional lands in the Ukraine were acquired. The symbolic turning point for the Ottoman offensive against Europe was the second siege of Vienna, in 1683. The failure to take the city marked a reversal in Ottoman fortunes. Henceforth, the European states moved against Ottoman possessions. Russia, Venice, Poland, and Austria now joined in a victorious coalition. In 1699 the empire was forced to sign the Treaty of Carlowitz, the first time that the Ottoman government appeared on the diplomatic stage as a clearly defeated power. By this treaty, Austria gained control of most of Hungary, Transylvania, Croatia, and Slavonia; Venice took Dalmatia and the Morea; Poland gained Podolia. Thus large numbers of Balkan people passed from Ottoman to Austrian and Venetian control. The agreement established what was to be until 1878 a relatively stable Austrian–Ottoman frontier along the Danube and Sava rivers. The main territorial gains at the expense of the Ottoman Empire in the next century were to be made by Russia.

Russian invasions

The Russian advances against Ottoman lands began under Peter I the Great at the end of the 17th century. The major acquisitions were made, however, by Catherine II the Great (*q.v.*), who by the end of her reign had won the lands north of the Black Sea to the Dniester River. For the future of the Balkan Peninsula the most important agreement between Russia and the Ottoman Empire was the Treaty of Küçük Kaynarca (1774). By its terms, Russia gained territory in the Black Sea region and certain trade rights, but, most important, because of the ambiguous wording of the treaty, Russia was later to claim that it had won certain rights to speak in behalf of the Orthodox Christians of the empire. In 1781 Catherine joined with Joseph II of Austria (*q.v.*) in what was to be the first of numerous partition agreements among the great powers. According to this agreement, both Austria and Russia were to receive territory, but the majority of the lands of the Ottoman Empire in Europe were to be organized into a Kingdom of Dacia, under Russian influence, and a Greek kingdom with its capital at Constantinople and with Catherine's grandson as its ruler. General European events prevented the success of this venture, but, by the end of the century, it was apparent that Russia was both the chief threat to the empire and the major hope of the Balkan people for outside aid.

The French Revolution and the Napoleonic era. The wars of this period were to have a deep effect on the Balkans, both from the international aspect and because of the response that French Revolutionary ideology evoked within the peninsula. This period also witnessed the entrance of France and Britain actively into the diplomatic and military struggle over the control of the Ottoman Empire. That state, in the midst of another grave internal crisis, now found its lands under attack from France. In 1797 France took the Ionian Islands from Venice. A year later, Napoleon launched an invasion of Egypt and Syria. As a consequence of this action, the empire was in alliance with Britain and Russia from 1798 to 1802. After a period of peace from 1802 to 1806, the Ottoman government shifted sides and joined France against Russia. This alliance proved disastrous, because in the next year, by the Treaty of Tilsit, France came to terms with Russia. It is interesting to note that at this time these two governments discussed a partition of the Ottoman Empire, but they were unable to agree on the fate of Constantinople. In 1812 Russia, faced with an impending French invasion, signed the Treaty of Bucharest with the Ottoman Empire, which ceded the Romanian territory of Bessarabia to Russia.

The Balkan peoples were affected not only by the wars that were waged in the area, but also by the political arrangements made by the several powers. Most influential for the future was the introduction into the Balkans of French Revolutionary institutions and ideology through the Napoleonic conquests. For example, in the Ionian Islands, which France held from 1797 to 1799 and again from 1807 to 1814, a constitutional government on Western patterns was established. The Septinsular Republic was the first Greek national government in modern times. French political experiments also involved South Slav lands. In 1809 Austria was forced to cede to France its Balkan territories. From Dalmatia, Slovenia, Istria, Trieste, and parts of Croatia a new political entity, the Illyrian Provinces, was formed and became a part of the French Empire. As in the Ionian Islands, the government was based on revolutionary principles. The Illyrian Provinces has been described as the first Yugoslav state, as it included within its boundaries Serbs, Croats, and Slovenes.

This period also brought about important changes in Moldavia and Walachia and in Serbia. The Ottoman Empire was forced to agree to an increase of Russian direct influence in the Danubian principalities; henceforth, no governor of either province could be dismissed without Russian consent. Russia thus acquired what was, in effect, a protectorate over the country. This power also played a major role in the events of the first Serbian revolution (see below).

The defeat of Napoleon in 1815 resulted in the restoration of the political and territorial status quo in the Balkans, with only a few exceptions—Russia, of course, retained Bessarabia; the Ionian Islands were placed under British protection; the Illyrian Provinces disappeared as a political entity; and Austria received back its former land and, in addition, acquired Dalmatia. The Ottoman Empire, which did not attend the Congress of Vienna in the aftermath of the Napoleonic Wars, retained most of its territories intact. It was also to be aided by the conservative reaction that followed in a Europe tired of war and revolutionary upheaval.

In Balkan history the French Revolution and the wars of Napoleon mark the shift from the long period of Ottoman domination into the era of the national revolutions of the 19th century. To some extent, the stage had already been set in the 18th century, when both Russia and Austria appealed to the Balkan subject populations for assistance against the Ottoman Empire. These wars, as well as those of Napoleon, had shown how weak the Ottoman military forces really were. Moreover, Balkan nationals had fought in these wars. They had learned modern military methods and they were armed. Equally important, the period of war and internal upset had opened the area to outside influences. The national and liberal ideology of Revolutionary France provided a program that would allow Balkan leaders to combat not only Ottoman political control but also the stifling cultural influence of their Christian church hierarchies.

Although the Balkans were now ready for revolt, the international situation was to change to the detriment of such actions. After the period of war, which had wasted the resources and energy of Europe before 1815, the powers desired, above all, peace with political and social

stability. There occurred in all the European states a conservative reaction directed against revolutionary methods and liberal–national programs. Subject Christian peoples could thus not expect aid or sympathy from abroad. At the same time, it was also apparent to the European powers that the Ottoman Empire was in a dangerous condition of internal decay and military weakness. The question of the fate of the Ottoman territories and of the control of that government became perhaps the most important single diplomatic problem for Europe in the century after the Congress of Vienna. This issue, the so-called Eastern Question, was the direct cause of the two great wars of that period—the Crimean War and World War I—and the occasion of repeated less serious conflicts among the powers. See EUROPEAN DIPLOMACY AND WARS (C. 1500–1914): *Revision of the settlement of Vienna: The Eastern Question again: The Crimean War.*

The basic problem in the disposition of the Ottoman lands was their strategic position across three continents. Because of its past history and its close links with the Balkan people through the Orthodox Church, Russia was in the best position to gain predominant influence in the area. Russia's chief rivals were Austria and Great Britain. The Habsburg monarchy could not afford to allow Russia more political control in lands along its frontiers. The British feared for their communications with their empire, which ran through the eastern Mediterranean, and their control over India. Moreover, despite its favourable relations with the Balkan people, the Russian government, too, because of its abhorrence of revolutionary activity and liberal reform programs, stood after 1815 against national revolt. Thus, although the era of the French wars had prepared the Balkan people for revolution, the international situation was not favourable. Nevertheless, the next 65 years were to witness the establishment of independent, or autonomous, governments for almost all of the Balkan national groups. (C.J./B.Je.)

II. The Balkans from 1815 to 1914

The era of national liberation

The 19th century saw the political and social development of the Balkans and the formation of independent states. During this period the Balkans were drawn, economically and culturally, into the orbit of contemporary Europe. While it is somewhat arbitrary to divide this exceedingly complex and dynamic era into segments, it is possible to delineate four general periods: (1) the beginning of the process of national liberation during the first Balkan revolutions, 1800–30; (2) a period of political and social development, 1830–78; (3) the inclusion of the Balkans in Europe during the age of imperialism, 1878–1903; and (4) the Balkans in European crisis on the eve of World War I, 1903–14.

NATIONAL REVOLUTIONS (1804–30)

At the beginning of the 19th century the Habsburgs ruled the northwestern part of the Balkans, while the Ottomans dominated the main central and southern regions of the peninsula. The development of a national renaissance of the Balkan peoples varied according to the different political and social conditions prevailing in these areas: political development occurred under the Habsburgs, and revolutionary upheavals predominated under the Ottomans.

Three main factors influenced the national revolutions in the areas under the Ottomans: the decline of the Ottoman Empire, provoked by a general crisis of Ottoman feudalism; the gradual shaping of a new Balkan society, as a result of the economic traffic with Europe and the development of local autonomy; and the influence of the "outer" Balkan world on the "inner" (*e.g.*, the influence of the Greek, Bulgarian, and Albanian trading colonies in the Mediterranean and Black Sea areas, of the Serbs in southern Hungary, etc.). The Balkan revolutions had two general aspects: nationalistic and agrarian. The national aspect was expressed in the drive for national liberation, the creation of national economies and cultures, and the political organization of national states. The agrarian aspect was marked by the endeavours of the peasantry to get rid of the Ottoman landlords and take possession of the land.

The Yugoslavs. The Yugoslavs were divided under the Ottomans and the Habsburgs. The Serbs in the south and east were part of the Ottoman Empire and the Slovenes and Croats in the north and west were ruled by the Habsburgs.

The rise of the Serbian principality (1804–30). The creation of the autonomous Serbian state went through three stages: an uprising in 1804–13, the restoration of Ottoman power in 1813–15, and the uprising that led to the achievement of autonomy in 1830. The peripheral position of the Serbs in the Ottoman Empire facilitated the outbreak of the 1804 uprising in the pashalic of Beograd (Belgrade). The movement began as a revolt against the local Ottoman authorities, who themselves had rebelled against the Sultan. After overthrowing the local rulers, the Serbian insurgents, led by the former peasant, Karageorge, went on to fight the imperial army in 1805 and 1806. Through a number of victories in 1806, they liberated all of Serbia. The outbreak of the Russo-Turkish war in 1806 encouraged the insurgents; in the hope that they might win their independence, they asked for help and protection from Russia, Austria, and even Napoleon. But the Napoleonic Wars created an unfavourable international situation and, except for some passing assistance from Russia, the Serbs had to rely on their own forces. The revolution was in motion, however: the Serbian insurgents broadened their political program to include complete independence and planned to join forces with the Montenegrins, Bosnians, and Bulgarians. But the movement collapsed in 1813, after Russia concluded the Treaty of Bucharest with Turkey (1812), enabling the much superior Ottoman army to crush the rebels. Karageorge, accompanied by other leaders and a part of the population, escaped to Austria.

The Serbian struggle for freedom

During the 1804–13 revolution the Ottoman social, economic, and political system in Serbia was completely destroyed and the nucleus of the future Serbia was established. The peasantry carried out an agrarian revolution; a class of small peasant proprietors developed and was destined to become important in the future. The basis of a national economy emerged in the liberated areas. Serbian national culture was shaped through the work of Dositej Obradović, the educational reformer and translator, and Vuk Karadžić, a reformer of the literary language and collector of folk poetry. The effect of the 1804–13 uprising was to make the complete restoration of Ottoman power impossible. This became obvious when another uprising occurred in 1815 under the leadership of Miloš Obrenović. After defeating the Ottoman garrisons in Serbia, Miloš reached a compromise with the Turks that enabled him gradually to widen the bounds of Serbian autonomy. Over the years from 1815 to 1833 he was able to take advantage of growing Serbian strength and declining Ottoman power. Developments elsewhere in the Balkans helped this evolution: rebellions of the Turkish pashas in Bosnia and Albania; an uprising in the Danubian principalities; the Greek revolution; and the Russo-Turkish war of 1828–29. A Russo-Turkish convention, signed at Akkerman in 1826, required Turkey to fulfill its obligations under the Bucharest treaty of 1812 with respect to Serbian autonomy. These stipulations were reiterated in the Russo-Turkish Treaty of Adrianople (1829), together with the requirement that Turkey restore to Serbia the areas in the east that had been liberated in the first rising but later recovered by Turkey. When the Turks were slow to comply, Miloš organized an uprising in those districts and joined them to Serbia in 1833. He was now recognized as the hereditary prince of an autonomous principality under the suzerainty of the sultan.

The Slovenes and Croats. The development of the Slovenes was closely linked with that of central Europe. Placed as they were between the Austrians and the Italians, divided into six political units (Carniola, Styria, Carinthia, Görtz, Trieste, Istria), and exposed to the centralistic policies and Germanizing influence of the Habsburg Empire, the Slovenes encountered many obstacles

The Habsburg domain

on their way to national emancipation. In order to isolate Austria from the Adriatic, Napoleon in 1809 organized the Illyrian Provinces (Slovenia, Dalmatia, a part of Croatia, and the Military Frontier [Vojna Krajina]) with their capital in Ljubljana. His rule introduced French ideas of administration and education, but after 1813 Austria restored the old system. The Slovenian national renaissance found its expression in cultural and literary life, rather than in politics.

The Croatian lands were divided in the 19th century: civil Croatia and Slavonia were ruled by Hungary, while the Military Frontier (a zone of defense against Turkey) and Dalmatia were under Austria. The upper layers of society were either foreign or had been Germanized, the middle class was rudimentary, and the peasantry lived in serfdom. The Croatian national renaissance passed through three phases: the struggle for the use of the popular language in administration and education; the demand for cultural and territorial autonomy; and, finally, the movement for national independence. Croatian politics evolved within the Zagreb-Budapest-Vienna web of Habsburg power. The first Croatian-Hungarian clash occurred in the 1820s when Hungarian nationalism sought to develop a Magyar state from the Carpathians to the Adriatic. This meant Magyarization for all the peoples under Hungarian rule. The Croats responded by stressing their own language and culture.

The Greek revolution. The Greek revolution was even more successful than the Serbian and, from the historian's point of view, represented another large step toward the affirmation of the nationality principle in the Balkans. The Greek achievement was the consequence of Greek social development and of European interference in Greek affairs. The Greeks had created under the Ottomans two societies: one on the mainland and another in the colonies established by their traders all over the Balkans, the Mediterranean, and western Europe. The Greek merchant became the nucleus of the Balkan middle class, the Greek language a lingua franca for the Balkans. To this was added the cultural and political power of the Greek Church in Constantinople and of the Greek Phanariote families who governed Turkey's Danubian principalities from 1711 to 1821. During Napoleon's continental blockade, the Greek merchant fleet dominated trade in the eastern Mediterranean; in 1813 it was composed of 615 ships and 37,500 sailors. The Ionian Islands, occupied by the French in 1797–99 and 1807–14, served as a base for the spread of revolutionary ideas. Various secret organizations cherished the idea of the liberation of Greece. The most effective of them was the Philikí Etairía, formed in Odessa in 1814 to organize a general Balkan uprising for the liberation of Greece. A new impulse was given to its activities when the Phanariote Greek Alexandros Ypsilantis, a Russian army general, accepted the leadership in 1820. Planning to start an uprising in Turkey's Danubian principalities that would spread all over the Balkans to embrace Greece, Ypsilantis invaded Moldavia in March and entered Bucharest. But the attempt ended in failure: the Russian tsar Alexander I denied him the expected support; the general Balkan uprising did not occur; and the Greek movement in the principalities clashed with a similar Romanian movement. Defeated by Ottoman troops at Drăgăşani, Ypsilantis was forced to flee.

Reasons for Greek success

The activities of the Philikí Etairía and the simultaneous rebellion of Ali Pasha in Epirus opened the way for the outbreak of the uprising on the Greek mainland. On March 25 Bishop Germanos raised the banner of revolt at the monastery of Aghia Lavra in the Peloponnesus. The ensuing Greek revolution went through three phases: local successes in 1821–25, the crisis caused by the intervention of Muḥammed ʿAlī of Egypt in 1826–28, and a period of European intervention ending in Turkish recognition of Greek independence in 1832 (see also MUHAMMED ALI PASHA). At the beginning the revolution spread in a flash, embracing the Peloponnesus, central Greece, and the island of Crete. By the summer of 1822 the revolutionaries had captured Missolonghi, Athens, and Thebes. At that point the revolution was checked by the Ottomans and by internal conflicts among the Greeks. The Ottomans hanged the patriarch Gregorios in Constantinople and suppressed the uprising in Thessaly, Macedonia, and Mt. Athos. A stalemate prevailed until the beginning of 1825. There were dissensions among the Greek insurgents, and the aspirations of different classes and regions were too various to be reconciled. In 1822 two Greek governments existed: one on the mainland dominated by Theodóros Kolokotrónis, and the other at Ídhra led by Geórgios Kountouriótis and Aléxandros Mavrokordátos. By 1824 open civil war prevailed in Greece. A turning point came with the intervention of Egyptian forces under Muḥammed ʿAlī's son Ibrāhīm, who landed on the Peloponnesus with a large army in February 1825. By June 1827, burning and plundering, he seemed about to reconquer Greece. Missolonghi, the key fortress of Corinth, fell in April 1826 after a heroic defense, marked by the death of the English poet Lord Byron. The Greek revolution was rescued by the powers of Europe, who, motivated by complex political factors, offered mediation to the belligerents in 1827. An accidental clash between the Ottoman and European fleets at Navarino Bay on October 20, 1827, resulted in the total annihilation of the Turko-Egyptian fleet. In 1828 Britain and France took advantage of the Russo-Turkish war to conclude an agreement with Muḥammed ʿAlī, providing for the evacuation of Egyptian forces from Greece. In March 1829 England, France, and Russia agreed on autonomy for Greece, but a final settlement of Greek affairs was not achieved until February 1830, when the three powers declared Greece an independent monarchy under their protection.

The Greek success furthered the idea of national emancipation throughout the Balkans. The Serbian and Greek revolutions together highlighted and aggravated the European dilemma that was becoming known as the Eastern question: *i.e.*, whether the Ottoman Empire should be preserved for the sake of the European balance of power or should be divided among its successor states. The appearance of the first Balkan states gradually changed the role of the Balkans in European politics: from being objects of European policy, the Balkan peoples were becoming its subjects.

The Romanians at the beginning of the 19th century. Nineteenth-century Romanian development was dominated by the facts of geography and power. The Romanians had as neighbours the Russian, Habsburg, and Ottoman empires. They began the century politically divided: Walachia and Moldavia under the suzerainty of the sultan; Bessarabia under the Russians (from 1812); and Transylvania, the banat of Timisoara, and Bukovina under the Habsburgs. Most Romanians were peasants, and their masters were the Phanariotes, boyars, and the church with its landed estates. Romanian prosperity was based upon exports of grain, stimulating traffic down the Danube and through the Black Sea ports of Galaţi and Brăila. The rising middle class became the agent of the Romanian renaissance. A new national intelligentsia, educated in western Europe, replaced the traditional Old Slavonic, Greek, and Latin with a specific Romanian culture.

The struggle for national unity

A popular national movement in 1821, led by Tudor Vladimirescu, paralleled that of the Greek Etairísts. Although himself an Etairíst and a former lieutenant of the Russian army, Vladimirescu was interested in the Romanian rather than the Greek cause. His program envisaged the election of a national assembly, organization of a national army, and tax reform. But the peasant insurrection was inevitably transforming itself into an agrarian revolution, directed against the boyars. Alienated from the Greek Etairísts by his Romanian goals and from the boyars by the spectre of revolution, Vladimirescu found himself isolated. He tried to negotiate with the advancing Ottoman troops but was captured by the Etairísts and executed in the summer of 1821. His movement was suppressed by the Ottomans. The events of 1821 brought the end of the Phanariote Greek rule in Walachia and Moldavia; the Turks replaced them with Romanian boyars. The Russo-Turkish War of 1828 led to

Russian occupation of the two principalities and the promulgation of the Règlement Organique, which recognized the boyars' landed estates and imposed further restrictions on the peasantry. Exposed to both the old feudal relations and to a developing market economy, the condition of the Romanian peasant worsened during this transitional period.

Obstacles to Bulgarian nationalism

The Bulgarians in the early 19th century. The Bulgarians were at the centre of the Ottoman Empire, exposed to Turkish colonization, economically part of the Ottoman market, and culturally influenced by the Greeks. Nationalist impulses arose from internal economic and social change and from the Bulgarian merchant colonies in the Black Sea area. At the same time the decline of the Ottoman system aggravated the situation of the Bulgarian peasant. In the period from 1792 until 1815 Bulgaria was plagued by armed bands known as Kurdzhali. The most famous rebel was the feudal lord, Osman Pazvanoglu, who in 1794 captured the fortress of Vidin and ruled independently of the Turks. Bulgarian volunteers took an active part in the Serbian and Greek revolutions, as well as in the Russo-Turkish wars. During the war of 1828–29 a Bulgarian committee in Bucharest sought to obtain from the Russian high command the same rights accorded to Serbia, Greece, and the Danubian principalities. Georgi Mamarchev led an unsuccessful uprising in Sliven in 1829. Another attempt by a Tŭrnovo merchant, Velcho Atanasov, in 1835 ended with his arrest and execution.

The Bulgarian cultural renaissance got under way at the beginning of the century. Until the 1830s basic education was developed in schools run by Greek monks. These schools were slowly replaced by Helleno-Bulgarian schools, in which the teaching was modernized and Bulgarian was taught along with Greek. The impulse toward the Bulgarization of education was supplied mainly by emigrants from Russia and the Danubian principalities.

THE DEVELOPMENT OF BALKAN STATES AND SOCIETIES (1830–78)

In the half century after 1830 the principle of national rights made further progress. Three new Balkan states appeared: Romania, Montenegro, and Bulgaria. The peoples living under the Habsburgs took an active part in the 1848 revolution and in the 1867 reorganization of the monarchy. The continuing decline of Ottoman power, and the failure of intended reforms in 1839, 1856, and 1876, gave further impetus to Balkan national revolutionary movements, which reached their zenith in the Eastern crisis of 1875–78.

The Yugoslavs. *Slovenes and Croats under the Habsburgs.* The middle class of Slovenia took advantage of the revolutionary upsurge in 1848 to stress their national program: unification of the Slovenian lands in a federalized Austria, the use of the vernacular language, and a closer cooperation with the other South Slavs. These aims were reinforced by the liberal movement of the 1860s, which took over leadership from the old conservative groups. In 1871 a Yugoslav congress was held in Ljubljana, stressing the need for cooperation among all Yugoslavs living under the Habsburg monarchy.

Slovenian and Croatian nationalism

The Croatian national renaissance was manifest in the Illyrian movement of the 1830s. Its basic idea was to link all Croatian and other Yugoslav lands in a single cultural unit bound by a common literary language and national consciousness. Starting primarily as a cultural movement, the Illyrians gradually became a political party opposing Hungarian domination and the centralistic policy of Vienna. The 1848 revolution that shook the Habsburg monarchy provided the Croats an opportunity to struggle for their national program: unification of all Croatian lands (civil Croatia, Slavonia, Dalmatia, and the Military Frontier); autonomy within a federalized monarchy; and use of the vernacular language in public life and education. In 1848 a similar program was accepted in southern Hungary by the Serbs, who proclaimed an autonomous Serbian Vojvodina. When nationalistic Hungarians rejected their demands, the Croats helped Vienna against the Hungarians. There were also clashes between Serbs and Hungarians in the Vojvodina. After the Revolution of 1848 had been suppressed, the Yugoslavs were subjected to new centralizing policies from Vienna. In the years preceding the reorganization of the Habsburg Empire in 1867, Croatian politics was divided between the three poles. The majority Popular Party called for a unification of Croatian lands in a federalized monarchy based on a Yugoslav program. Another group (called Unionists) desired a compromise with the Hungarians. The young Croatian nationalists espoused a program of Croatian national and political individuality under the Habsburgs. The establishment of the Austro-Hungarian dual monarchy in 1867 was followed by a compromise between Hungary and Croatia in 1868, whereby the kingdom of Croatia was given some kind of autonomy under Hungary. This failed to satisfy the nationalistic impulse in Croatia, which found expression in Ante Starčević's Party of Rights.

Serbia and Montenegro (1830–78). The autonomy achieved by the Serbs in 1830 was followed by internal dissension. Opposition to the autocratic rule of Miloš Obrenović compelled him to abdicate in 1839. Under the rule of Karageorge's son, Alexander, from 1842 to 1858, the government was administered by an oligarchical State Council. The agrarian revolution that had previously occurred was reflected in a law of 1833. Civic rights and efficient government were secured by the civil code of 1844 and by a series of laws concerned with public affairs and education. The aspirations of the Serbs found expression in 1844 in a National Program that called for the unification of all Serbs and access to the Adriatic Sea; efforts were made to achieve this with the help of the western European powers and of other Yugoslavs. The young liberals brought Miloš Obrenović back in 1858. On his death in 1860 he was succeeded by his son, Prince Michael Obrenović, who ruled until 1868. Influenced by the rising tide of nationalism in the Europe of the 1860s, Serbian politics under Michael took a revolutionary course. Michael wanted a general Balkan uprising, a Balkan alliance, and a common war against the Ottomans. In these aims he was seconded by Hungarian and Polish émigrés, Italian national revolutionaries, and Russian Pan-Slavs. Even such statesmen as Cavour and Bismarck encouraged the Serbs in the hope of weakening the Habsburg Empire. After an incident in Beograd, the Ottomans bombarded the city in 1862. War was avoided through the mediation of the European powers, and Ottoman garrisons were withdrawn from the Serbian cities in 1867. The rest of the Turkish population also left Serbia.

Formation of Serbian state

One of the problems encountered by the Ottomans in other territories under their rule was the difficulty of reforming the administration of their empire against the opposition of local beys, or governors. This opposition was especially strong among the conservative landlords and local governors in Albania and Bosnia-Hercegovina; it contributed to the chronic unrest among those populations. The Ottomans sent in their armies several times in the period 1830–50 to put down uprisings.

Montenegro was also involved in conflict with the Ottomans in 1852, 1858, and 1862. The tribal Montenegrins had never been subjugated by the Turks. The formation of a Montenegrin state progressed through these wars, and a central state authority was gradually established. In 1860 Montenegro obtained international recognition.

Greek politics from 1830 to 1878. The development of government administration in the new Greek state was accompanied by conflicts between centralizing and decentralizing tendencies at various levels of Greek society, as well as by foreign intervention. The first president of Greece, Count Ioánnis Kapodístrias, was assassinated in 1831. In 1832 the European powers imposed Prince Otto of Bavaria, who became King Otho. In the first decade of his rule, he introduced a system of centralized, absolute monarchy run mainly by Bavarians. In 1833 a Greek Orthodox Church, independent of the patriarchate in Constantinople, was established. Byzantine law was introduced in 1835, and the University of Athens was created in 1837. But general dissatisfaction with the

rule of foreigners led to a revolt in 1843, forcing the king to dismiss his Bavarians and agree to a new constitution.

Greek irredentism

Greek nationalism was ascendant, both within Greece and throughout the eastern Mediterranean. The consequence was a program of irredentism known as the Megali Idea (Great Idea) that envisaged a Great Greece bounded by the Adriatic, the Black Sea, and the Mediterranean, with its capital in Constantinople. Secret national societies devoted to this goal sprang up in Epirus, Thessaly, Macedonia, and Crete. The revolutionary activities of Greek guerrilla bands in Thessaly and Epirus during the Crimean War (1853–56) strained relations with the Ottomans and also with the French and British. The spread of liberal national ideas throughout the Balkans in the 1860s was reflected in renewed Greek attempts to provoke a Balkan uprising, a rapprochement between Greece and Serbia, the deposition of the Bavarian dynasty in 1862, the unification of the Ionian Islands with the mainland in 1864, and a large, bloody uprising on the island of Crete in 1866. After the ouster of King Otho in 1862, Prince William of the Danish Glücksborg dynasty was elected "George I of the Hellenes." A new, democratic constitution was adopted in 1864, and in the 1870s a two-party system began to emerge. In the years from 1864 to 1880 Greece went through nine elections and had 31 governments.

The union of Moldavia and Walachia

The birth of Romania. For half a century the Danubian principalities had offered hospitality to revolutionary émigrés from the Balkans, and as a result a number of Balkan uprisings in the 1840s were planned in the principalities. In the meantime the idea of Romanian national unity evolved and was especially cherished by the young Romanian intelligentsia. The radical Philharmonic Society, established in 1833, stressed a program of unification and political freedom but failed to realize these goals during the Eastern crisis of 1839–41. The 1848 revolution offered another opportunity to those favouring unification. During the revolutionary days in Paris, Romanian students hoisted the Romanian flag at the Hôtel de Ville. A secret revolutionary organization, the Fratria (Brotherhood), aroused revolutionary fervour at home. An uprising in Moldavia proved a fiasco, but another in Walachia was successful. In Transylvania 40,000 peasants gathered on the "Field of Liberty" and demanded liberal reforms. A civil war broke out between Romanians and Hungarians in Transylvania, joining social to national conflicts. A joint Russo-Turkish military invasion put an end to the liberal nationalist movement, and many of the leaders had to flee the country. During the Crimean War (1853–56) the Danubian principalities were occupied first by the Russians and then by the Austrians. At the Paris peace conference in 1856, France, Prussia, and Sardinia supported the Romanian cause; England, Russia, Austria, and the Ottomans opposed unification. The Treaty of Paris provided for elections in both principalities to ascertain wishes of the population, and these demonstrated an overwhelming wish for unification. After much deliberation, it was decided in 1858 that the principalities would remain separate, with two princes and two assemblies. In 1859 the Moldavian and Walachian parliaments separately elected a single prince in the person of Alexandru Cuza. After further negotiations the union was formally proclaimed on December 23, 1861. The new state took the name of Romania, with Bucharest as its capital.

The young state faced many national, political, and social problems. Many Romanians still lived under foreign rule: in 1867 Transylvania was incorporated in Hungary; Romanians in Bukovina were under Austrian rule; and Bessarabia was part of Russia. Prince Cuza introduced two big reforms: the confiscation of the land of dedicated monasteries (ruled by Greek monks) in 1863, and an agrarian law (1864) that tried unsuccessfully to solve the important peasant problem. During his reign the Code Napoléon was adopted, the judicial system was reorganized, and progress was made in the field of education. Having alienated the boyars and the clergy, Cuza was forced to abdicate in 1866. His successor was Prince Charles of Hohenzollern-Sigmaringen, who took his oath in 1866, became King Carol I in 1881, and ruled until 1914. A new constitution was also adopted in 1866. But the peasant problem remained unsolved.

The Bulgarian national movement

The emergence of Bulgaria. Bulgarian national emancipation required first a social and cultural emancipation. After 1835 the Bulgarian schools gradually introduced teaching in the native tongue, replacing the previous emphasis on Greek. The first Bulgarian-language journals and periodicals, published abroad, appeared in the 1840s. The movement for a Bulgarian church, which began in the 1820s, met opposition from the Greek patriarchate and from the Ottomans. In 1870 the Sultan established a Bulgarian exarchate with 15 dioceses, and the first exarch was elected in 1872. The patriarch immediately excommunicated him and his followers, declaring them schismatics.

Peasant uprisings in the 1830s and 1840s had done much to undermine Ottoman power. In 1850 a peasant revolt in the Vidin district dramatized to Europe the existence of the Bulgarian question. During the Crimean War (1853–56) Bulgarian detachments were formed in the Russian army in the Danubian principalities. An organized revolutionary movement developed, primarily among Bulgarian merchant colonies abroad. A plan for Bulgarian liberation was elaborated by Bulgarians living in Serbia in 1861, and they were allowed to form a Bulgarian military unit in 1862. When the Serbian government hesitated to start a war against the Ottomans, the émigrés moved to Romania, where they obtained the support of Romanian liberals. In 1866 they reached an agreement for a Bulgaro-Romanian coalition. In 1867 the Serbian government and a secret Bulgarian committee in Bucharest signed an agreement for the creation of a common Serbo-Bulgarian state. A number of such secret Bulgarian national revolutionary committees were formed in Romania during the 1860s and 1870s, representing various political views among the émigrés; the movement became more radical and began to put down roots within the country. Among the Bulgarian leaders of the 1860s and 1870s were Georgi Rakovski, who organized national revolution within Bulgaria; Lyuben Karavelov, who fostered the idea of a liberal Balkan federation; Vasil Levsky, who died establishing an internal organization; and Hristo Botev, who linked the national with the social revolution. By the time of the Eastern crisis of 1875, the Bulgarians were prepared for the creation of a state.

Unity against the Ottomans

International politics. *The first Balkan alliance (1866–68).* During the wars of the 1860s that brought the unification of Italy and of Germany, the main goal of European diplomacy was to preserve the status quo in the Balkans. But the leaders of the emerging states and national societies wanted a general Balkan uprising and a final settlement with the Ottomans. To achieve this, they needed to unify their forces. The Greeks took the initiative in 1860 and tried to reach an agreement with Serbia. After long deliberations a treaty (1867) and a military convention (1868) were signed in which Greece and Serbia agreed on the preparation of a Balkan uprising, a common war against the Ottomans, and the application of national self-determination in the Balkans. Serbia and Montenegro had made an agreement in 1866. Romania joined the group by a treaty of friendship and alliance signed with Serbia in 1868. The Balkan alliance was supplemented by an agreement that the Serbian government reached with Bishop Strossmayer in Croatia (1867) for a common Yugoslav state and, by an accord between Serbia and the Bulgarian committee in Bucharest (1867), for a Serbo-Bulgarian union. The alliance disintegrated after the assassination of Prince Michael of Serbia (1868), but the fundamental idea was to be applied later in the Balkan War of 1912: localization of the war without the involvement of the European powers and the concentration of effective military force against the Ottomans.

The Eastern crisis (1875–78). The revolutionary activities of the 1860s exploded in 1875. The uprising in Hercegovina and Bosnia resounded throughout the Balkans, involving the European powers and reopening the Eastern question. In April 1876 an uprising in central

Bulgaria occurred. Serbia and Montenegro declared war on the Ottomans in June 1876, but the Serbian army was defeated. Russia declared war on the Ottomans in April 1877. Overcoming a stubborn Ottoman defense at Petroúsa, the Russians pushed southward until they reached the approaches to Constantinople. Bulgaria was in turmoil, and Serbia reopened hostilities. By the Treaty of San Stefano, imposed on the Ottomans on March 3, 1878, a "great Bulgaria" was created as a Russian satellite, reaching from the shores of the Adriatic to the Aegean and the Black Sea; Serbia, Montenegro, and Romania were to be independent. The Bulgarian arrangement was unacceptable to the European powers, and their reaction led to the Congress of Berlin (June 13–July 13, 1878). Russia was ejected from the Balkans and Austria-Hungary was given a mandate to occupy Bosnia and Hercegovina, thus becoming a Balkan state. Bulgaria was confined to the north of the Balkan range and made an autonomous principality under Turkish suzerainty. Macedonia remained under the Ottomans. Serbia, Montenegro, and Romania obtained recognition of their independence together with territorial changes. None of the Balkan states participated in the Berlin decisions. Greece, through other negotiations, obtained Thessaly and a part of Epirus in 1881. The process of national liberation had been given further impetus, but the Eastern question had not been solved. Instead, the Berlin settlement gave birth to European conflicts that led to World War I.

THE AGE OF IMPERIALISM (1878–1903)

Political and economic influence of the European powers

In the last two decades of the 19th century the Balkans became part of the European political and economic system. Balkan economic, political, and social development was largely a product of European influence. Russian predominance gave way after 1856 to Anglo-Austro-Russian rivalry in the peninsula. European dynasties were introduced in the Balkans: the Bavarian and Danish in Greece, those of Battenberg and Saxe-Coburg in Bulgaria, and the Hohenzollern in Romania. European intervention was a consequence of imperialistic trends in the eastern Mediterranean, the decline of the Ottoman Empire, the opening of the Suez Canal (1869), increased traffic on the Danube, and the extension of railroads. The Balkans gradually became a European crossroads.

A period of economic growth began. Industrialization, initiated by Balkan capitalists, was helped along by European banking and industrial interests through state loans and the opening of railroads and mines. Further social differentiation took place. Though most of the population was still peasant, a middle class was developing along European lines. Modern political parties appeared, and liberals contended with conservatives. The growing strength of the Balkan states found expression in nationalistic policies directed not only against the Ottomans but also against each other.

The Macedonian question. The nature of the area called Macedonia and the ethnic and political character of its inhabitants have been matters of intense dispute in the Balkans. The Greeks have denied the existence of a separate Macedonian nationality, reducing Macedonia to a geographical notion. Bulgarians have claimed the Macedonians as Bulgarians; the Serbs before World War II claimed them as Serbs. After World War II, some Yugoslav historians began to write of a Macedonian nation existing since the Middle Ages and embracing not only the present Yugoslav People's Republic of Macedonia but also parts of Bulgaria and Greece.

Geographically, Macedonia covers the central part of the Balkans. The Vardar valley, with its exit to the Aegean, is the strategic backbone of the peninsula. During the 19th century, as more and more Balkan areas were liberated from the Ottomans, Macedonia was exposed to more intensive Turkish colonization. To the primarily Slavic–Macedonian peasant majority was added a growing urban population in which the Ottoman garrisons and the Greek, Armenian, and Jewish trading middle class prevailed. Economic traffic along the Vardar line and the migration of peasants to the cities led to the gradual formation of a Slav–Macedonian middle class. Educated members of Macedonian society were heavily influenced by Greek culture or, alternatively, by fellow Slavs in Bulgaria and Serbia. There were four large peasant uprisings in the 1880s, influenced by events in Bulgaria, Serbia, and Greece. As Bulgarian activity in Macedonia grew, Greece and Serbia countered with their own national propaganda. During the two last decades of the century Austria encouraged the Serbs in this, while England backed the Greeks. The struggle over Macedonia developed until it was carried on by armed bands.

In the latter part of the 19th century nationalist ideas began to appear. There were demands for the use of the vernacular in schools and for the establishment of a Macedonian church. Revolutionary activities began in the 1880s. The Internal Macedonian Revolutionary Organization (Vatreshna Makedonska Revolutsionna Organizatsia) was created in 1893. Macedonian and Bulgarian wings emerged within it. Its program was "Macedonia for the Macedonians," but as a partner in a future Balkan confederation. Throughout this period Macedonia was torn by conflicts. A bloody uprising in 1903 was repressed by the Turks with heavy reprisals against the noncombatant population.

The Ghegs and Tosks

The Albanian national awakening. The Albanian nation in the Balkans was divided between tribes in the mountainous north (the Ghegs), a feudal society in the southern plains (the Tosks), and a dispersed settlement in the regions of Kosovo, western Macedonia, and Epirus. The north was Roman Catholic, while the south was Muslim and—in Epirus—Greek Orthodox. Albanian emigrants, leaving their poor and overpopulated country, had established national enclaves in other Balkan countries, the eastern Mediterranean, and Italy (in 1901 there were 200,000 Albanians in Italy).

Complex economic, social, and cultural factors governed the Albanian national renaissance. The southern landlords, linked to the Ottomans by common religious and political interests, found in the empire a guarantee of their ruling position and a defense against the growing pressure of the neighbouring Balkan states. The northern tribal society, rejecting the centralistic tendencies of the Ottoman authorities, sought autonomy. Throughout the 19th century the Albanian lands were the scene of local revolts against the Turks. Nationalism, however, flourished mainly among Albanians abroad. Three great Albanian writers promoted Albanian nationalism in Italy: Girolamo De Rada, Demetrio Camarda, and Giuseppe Schiro. The first expression of an organized Albanian national movement in Albania proper was the Albanian League for the Defense of the Rights of the Albanian Nation, established in 1878. Created by Albanians in the Kosovo region as a reaction to the decisions taken by the Congress of Berlin, the League fought against the cession of Albanian territory to Montenegro. It was crushed by the Turks in 1881. The League had nevertheless demonstrated the existence of an Albanian national movement. Further progress was made at the end of the century through the formation of Albanian societies abroad, and the publication by them of Albanian books and periodicals. A national symbol was found in Skanderbeg, the 15th-century fighter against the Turks.

There was no unified Albanian alphabet and writing was in local makeshift Italianate, Hellenic, or Turco-Arabic characters and systems. Political differences prevented the adoption of a single alphabet until 1909, when the Latin was chosen. Turkish schools were established in the 1860s, and subsequently Greek schools in the south; there were no Albanian schools until the 1890s.

After a national uprising in 1912, the European powers accepted the principle of an independent Albania. But no viable national government was formed until after World War I.

Trends among the South Slavs

The Yugoslavs. *Slovenes, Croats, and Serbs under the Habsburgs.* Under the dual Austro-Hungarian monarchy established in 1867, the Yugoslavs had been divided: Slovenia, Istria, and Dalmatia had been assigned to Austria, while Croatia, Slavonia, and the Vojvodina were under the rule of Hungary. The Military Frontier was dissolved and joined to Croatia in 1881.

In Slovenia, where the Austrians imposed a harsh policy of Germanization, the liberals joined with the conservatives in seeking autonomy for the separative Slovenian regions.

Croatia became increasingly linked with the Hungarian economy. A growing nationalism found expression in Ante Starčević's Party of Rights, which demanded the union of all Croatian provinces of the empire, including Dalmatia and Bosnia-Hercegovina. Budapest tried to restrain Croatian opposition by appointing Count Károly Khuen-Héderváry as governor, but his policy of Magyarization only made matters worse. He sought to play off Croats against Serbs in disputes over the future status of Bosnia-Hercegovina. In the 1890s the younger generation began to abandon these futile chauvinistic struggles and to lay the basis for a new course of Yugoslav cooperation.

Bosnia and Hercegovina, under Habsburg rule after 1878, made progress with industrialization and the construction of roads and railways, but the national and agrarian problems remained unsolved. The Habsburg authorities attempted to foster a Bosnian national consciousness. In 1910 it was estimated that 100,000 families still lived under serfdom. A Serb–Muslim uprising in 1882 demonstrated peasant dissatisfaction with the social and political order.

Serbia and Montenegro. The latter part of the century brought economic growth for Serbia, but a decline of its political fortunes at home and abroad. The cattle and grain trade were stimulated by commercial treaties with Austria. A national bank was established in 1883. Government budgets rose from 19,500,000 dinars in 1880 to 76,000,000 in 1900. A Danubian shipping company was started and Serbia was linked with Austria and the Ottoman Empire by rail. European financial capital penetrated the country. Light industry began—breweries, mills, slaughterhouses, sugar refineries, textiles mills.

Serbia was closely tied to Austria-Hungary in 1881 through a secret convention (not made public until 1893) that sanctioned Serbian expansion toward the south. Domestic politics in the 1880s was divided among conservatives, liberals, and a middle class left. The latter succeeded in involving large peasant masses in politics. Serbia was proclaimed a kingdom in 1882. Supported by a conservative minority, King Milan Obrenović IV led an unsuccessful war against Bulgaria's union with Eastern Rumelia in 1885. Defeated by the Bulgarians, King Milan lost his popularity and in 1889 was forced to abdicate in favour of his son Alexander. A liberal Swiss-type constitution was introduced in 1888, but Serbian political life was tumultuous. The behaviour of Alexander and his father Milan, who resumed a personal role in politics, destroyed the prestige of the dynasty.

Montenegro became independent in 1878 through the Congress of Berlin, and its territories were doubled in size. There was an inflow of Italian capital. A modern government was introduced in 1879, with five departments, and the civil law was codified in 1888.

Bulgaria. During the 1877–78 war an important change in social structure occurred in Bulgaria: Ottoman landlords, followed by a large number of Turkish peasants, left the country. The Bulgarian peasantry seized their lands (approximately a quarter of the arable land) and established small and medium-sized farms. This social structure strongly influenced Bulgarian economic and political development.

Bulgaria entered a phase of state-sponsored urbanization and industrialization. At the end of the century there were 1,129 kilometres (700 miles) of railway lines. Foreign capital was imported, mostly through state loans; Bulgaria's foreign indebtedness at the end of the century reached 250,000,000 francs.

Bulgaria's political instability

A liberal constitution was adopted in 1879, and the national assembly elected Alexander of Battenberg as prince of Bulgaria. In Eastern Rumelia, separated from Bulgaria in 1878, the unionist movement, supported by the entire population and all the political parties, organized an army coup and a popular uprising that resulted in the proclamation of the union of Eastern Rumelia with Bulgaria in September 1885. Serbia's attempt forcibly to prevent the unification ended in military defeat.

A number of political parties appeared after 1885, resulting from a split among the Liberals. The role of the army and of the Macedonian émigrés grew. A conflict with Russia deprived Battenberg of Russian support, and a pro-Russian army conspiracy forced him to abdicate in 1886. After a period of crisis, the national assembly elected Prince Ferdinand of Saxe-Coburg-Gotha as his successor in June 1887. The government formed by Stefan Stambolov (1887–94) took a pro-Austrian attitude; in the face of Russian hostility Stambolov had to rule almost as a dictator. The Bulgarian peasantry entered politics at the end of the century, mobilized by the Bulgarian Agrarian Union. But, as in Serbia, political life was unstable at the end of the 19th century: there were plots against the government, political assassinations, a growing underground activity by Macedonian émigrés, and several peasant uprisings.

Greece. The period after 1878 was one of steady economic growth in Greece: the Corinth Canal was completed in 1893; a number of paved highways were begun in the 1880s; and by 1905 Greece had 1,000 kilometres (620 miles) of railroads. Piraeus was becoming the Mediterranean's fourth-largest port. Shipping and light industry flourished, and foreign investment grew. On the other hand there was poverty in the countryside, resulting from overpopulation and from the French tariff on currants; this induced large numbers of Greeks to emigrate in the 1890s.

In foreign affairs the Greeks sought to incorporate Macedonia to the north and the island of Crete to the south. Many Cretans had long nourished the idea of *énosis* (union) of the island with Greece. A Cretan uprising against the Turks in 1866 had been put down. A new uprising in 1896 led to a proclamation of union with Greece in February 1897. Supporting the Cretans, the Greek government sent an armed force to annex the island, but intervention by the European powers followed. In April 1897 Greek troops attacked the Turks in Thessaly and suffered a defeat. The peace settlement required Greece to pay a war indemnity that led to bankruptcy. Crete, however, received its autonomy, and Prince George, the second son of the Greek king, was named commissioner of the island. At the turn of the century Greek politics was characterized by frequent cabinet changes and petty party strife.

Romania. The Romanian economy also made progress after 1878. An oil industry was developed at Ploeşti with financing by German, British, and Dutch capital. By 1906 there were 2,000 kilometres (1,240 miles) of railroads. Romanian trade was closely bound up with Austria-Hungary: 50 percent of Romanian imports were from the Habsburg Empire, and 32 percent of its exports went there in the period 1875–82. The Austro-Romanian tariff war (1886–1893) emancipated Romanian trade. An export surplus enabled the government to borrow abroad to the extent of 1,700,000,000 francs by 1914. Romanian foreign policy turned toward Austria after 1878, and in 1883 the government signed a secret alliance with Austria, Hungary, and Germany (renewed in 1896, 1902, and 1913).

Romania's ties with Austria-Hungary

The central Romanian social and political problem was the peasantry. Although Bucharest was known as "the Paris of the Balkans," the peasantry lived under appalling conditions. About 85 percent of the peasants either had no land or were forced to work part of the time for landlords. Five thousand large estates covered about half of the total arable land.

Romanian politics was divided between the Conservative and Liberal parties. The leader of the Liberals, Ion Brătianu, was until his retirement in 1888 the most influential figure in Romanian politics. His three sons all became leaders of the Liberals. The Romanians had irredentist ambitions in Transylvania, where large numbers of Romanians lived under Hungarian rule. Romania also took part in the Macedonian controversy by claiming the rights of a protector over the Vlachs.

THE BALKANS BEFORE WORLD WAR I (1903–14)

Imperialism, nationalism, and Balkan unity

At the beginning of the century the Balkans were increasingly the scene of international conflict. The European powers had clashing military, political, and economic interests in the peninsula. The Baghdad railway project at the turn of the century symbolized German ambitions to push eastward, challenging French financial dominance in the Ottoman Empire. The growing weakness of Russia upset the Austro-Russian balance in the Balkans, while growing Italian strength in the Adriatic stimulated efforts by Austria-Hungary to reach the port of Thessaloníki and the Aegean.

Among the Balkan countries themselves, developing national strength resulted in a general movement toward political and economic emancipation. In the Yugoslav lands the year 1903 marked a turning point. Croatian political forces began to organize against Hungarian repression, and a similar restlessness was apparent in Bosnia. The assassination of King Alexander Obrenović in Serbia prepared the way for a dynamic, nationalistic foreign policy (under the rule of Peter I Karageorgević). In Macedonia in 1903, the Ilinden uprising displayed to Europe the weakness of Turkey, the "sick man on the Bosphorus." In Croatia and Dalmatia, a coalition of political parties put forward a program calling for Yugoslav unity and social and political reform. The movement received support from Serbia and Montenegro and began to gather impetus. The Balkan states started to arm, buying artillery and ammunition in Europe.

Two tendencies were at work in the Balkans: rivalries among the states for territorial aggrandizement, and a common hostility toward interference from outside powers. A growing inter-Balkan struggle next occurred over Macedonia and was expressed in the activities of armed bands from neighbouring states that brought much suffering to the local populations. The fear of European intervention and the needs of common defense imposed a political rapprochement on Serbia and Bulgaria in 1904, joined later by Montenegro. A peasant revolt in Romania in 1907, put down by the military at the cost of thousands of lives, demonstrated that Romania's agrarian problem was far from solved.

The crisis of 1908–09. A diplomatic struggle among the European powers began in 1908 over railway projects in the Balkans. These projects expressed the political tendencies of the states involved: Austria's push toward the Aegean (the Novi-Pazar railway project), Russia's and Serbia's toward the Adriatic (the Danube–Adriatic project), Italy's penetration of southern Albania (the Vlöre–Munushtir railway), and the effort of Greece and Bulgaria to absorb central Macedonia. In July 1908 the Ottoman garrison in Thessaloníki rebelled, as a result of the revolutionary activity of the Young Turks. The officers (among them Mustafa Kemal, the future leader of the Turkish republic), forced the Sultan to proclaim a constitutional era (see also ATATURK, KEMAL). The Young Turks wanted a regime that would give liberty and equality to all the nationalities within the empire. On October 5 the Bulgarians took advantage of the confusion to proclaim their full independence. On October 6 Austria-Hungary announced its annexation of Bosnia-Hercegovina. Two days later the Cretans proclaimed their union with Greece. The system created by the Congress of Berlin in 1878 had collapsed. The major crisis was over Bosnia-Hercegovina: the Serbs protested vehemently against the annexation; England opposed Austria; Russia backed Serbia and Bulgaria. The Austro-Turkish conflict was settled by an indemnity paid by Austria to the Turks, but the Austro-Serbian conflict brought Europe to the edge of war. Pressure from Berlin in March 1909 forced Russia to yield. Serbia had to follow the Russian example and accept Bosnia's annexation by Austria-Hungary. The crisis of 1908–9 foreshadowed coming events.

Revolt of the Young Turks

The Balkan Wars of 1912–13. The situation in the Balkans remained uneasy. The Albanians, after a short-lived collaboration with the Young Turks, revolted against them in 1909–12. The Cretan *énosis* with Greece failed because of European opposition. This caused general indignation in Greece, opening the way to a military coup and the premiership of the Cretan political leader Eleuthérios Venizélos (*q.v.*). The Venizélos government introduced reforms, reorganized the army, and revised the constitution. Macedonia continued to be a magnet for the nationalist ambitions of the Serbs, Bulgars, and Greeks. The Young Turks banned political parties and national organizations in Macedonia in 1909, and, consequently, the armed bands of various nationalities reopened their guerrilla warfare. An opportunity for an effective cooperation against Turkey presented itself in September 1911, when war broke out between Turkey and Italy in North Africa.

The Balkan alliance against the Ottomans

War against the Ottomans required a Balkan alliance. Serbo-Bulgarian negotiations started in the fall of 1911 but were troubled by differences in regard to the future delimitation of Macedonia. Finally an agreement was reached under Russian auspices in March 1912, providing for the division of Macedonia. A Greek–Bulgarian agreement was reached in May 1912, without touching the delimitation problem. Montenegro then joined the alliance, which disposed of armed forces totalling 750,000 men. The war began in October 1912. The Balkan allies were soon victorious: the Serbs defeated the Ottomans at Kumanovo, joined forces with the Montenegrins to enter Skopje, achieved another victory at Munushtir, and reached the Adriatic at Durrës. The Bulgarians defeated the main Ottoman forces at Kirklareli and Lüleburgaz, advancing to the Çatalca lines in front of Constantinople. The Greeks seized Thessaloníki and laid siege to Ioánnina. The Ottomans lost all their territories in Europe, except a small strip around Constantinople. On December 3 an armistice was concluded. Peace negotiations opened in London on December 16.

The victories of the Balkan allies affected many Austo-Hungarian interests. Vienna reacted vehemently, demanding the withdrawal of Serbian troops from the Albanian coast where an Albanian state had been proclaimed on November 28, 1912. The Austro-Serbian conflict automatically developed into an Austro-Russian one.

The crisis was settled at a conference of ambassadors in London in December 1912 that recognized the new Albanian state and obliged Serbia to withdraw its troops from the Adriatic. But at the end of January, 1913, after a coup d'etat in Constantinople by the nationalistic Young Turks, the war with the Ottomans was resumed. The allies were again victorious: Ioánnina fell to the Greeks, and Adrianople to the Bulgarians. Another crisis arose when the Montenegrins refused to leave Shkodër, which the London ambassadors' conference had given to Albania. The Montenegrins were forced to yield under the threat of a European naval blockade of their coast. A peace treaty, signed in London on May 30, 1913, gave all the territory west of the Enez–Midye line to the Balkan allies. Crete was united with Greece.

Serbia and Greece against Bulgaria

The territorial settlement produced discords among the Balkan allies. Serbia refused to give up the parts of Macedonia assigned by the 1912 treaty to Bulgaria on the ground that it had already been forced to withdraw from the Adriatic. A bitter struggle then ensued between the Greeks and the Bulgarians over Thessaloníki and Thrace.

Romania, as a price for remaining neutral, demanded from the Bulgarians a part of the Dobruja. Both Serbia and Bulgaria were reluctant to accept Russian arbitration. Austro-Hungarian diplomacy sought to undermine the Balkan alliance. Serbia and Greece allied themselves against Bulgaria on June 1, 1913. King Ferdinand of Bulgaria, backed by army circles, ordered his troops to attack Serbia and Greece in Macedonia on June 30. But the Bulgarian armies were defeated by the Serbs and Greeks. At the same time the Romanians entered the Dobruja and the Ottomans recaptured Adrianople. An armistice was concluded on July 31 and a peace treaty signed in Bucharest on August 10, 1913.

Results of the wars. As a result of the Balkan Wars, Greece obtained Thessaloníki, Kaválla, and a large coastal part of Macedonia; Serbia gained the northern

and central part of Macedonia; Montenegro acquired a portion of the sanjak of Novi-Pazar, establishing a common frontier with Serbia; Bulgaria retained a part of eastern Macedonia; and Romania procured its part of Dobruja. The long decline of Ottoman rule in the Balkans had ended.

The political consequences of the Balkan Wars were considerable. Apart from Turkey, the real loser was Austria-Hungary. The partitioning of the sanjak of Novi-Pazar between Serbia and Montenegro made it impossible, in the subsequent crisis of June–July 1914, for Austria-Hungary to intervene in the Balkans by occupying the sanjak. The success of Serbia and Montenegro stimulated the Yugoslav movement for union in the Habsburg Empire. The wars similarly altered the structure of alliances in the Balkans. Dissatisfied, Bulgaria henceforth looked to Austria-Hungary for support, while Romania tended to move away from its allies and toward Russia.

The most alarming result was the growth of tension between Austria-Hungary and Serbia. Serbia had extensive claims upon Albanian territory. Having obtained an assurance of German support, Austria-Hungary delivered an ultimatum in October 1913 to compel Serbia to withdraw from the Albanian borderlands. This, however, did not solve the Southern Slav question for Austria-Hungary, and it emerged once again in an acute form with the assassination of the archduke Francis Ferdinand on June 28, 1914, in Sarajevo, Bosnia. This event was followed by Austria-Hungary's ultimatum and by its declaration of war on Serbia (July 28, 1914) and the outbreak of general war in Europe in August (see WORLD WARS: *Origins*). (D.V.D.)

III. The Balkans after 1914

WORLD WAR I AND THE PEACE SETTLEMENTS, 1914–23

The role of the Balkan states in the war. The World War of 1914–18 was triggered by Balkan revolutionary nationalism. Gavrilo Princip, who shot and killed Archduke Ferdinand, heir apparent to the Habsburg throne, was one of many young Serbs who pinned so much faith upon the advantages of national unification as to risk their lives and flout existing political authorities, both in Serbia itself and in the adjacent lands of Bosnia, Hercegovina, Dalmatia, and southern Hungary, where Serbian populations lived under Habsburg rule.

Breakup of traditional life-styles

Nationalist movements. The breakup of traditional peasant styles of life among the South Slav peoples—Slovenians, Croats, Serbs, and Macedonians—fuelled this revolutionary movement. Population growth made subdivision of peasant holdings necessary; but, when a father had to divide his land among several sons, the new families could not hope to live as their parents had. This pushed innumerable young men off the land and into revolutionary activities. The pattern was as follows: as life on the farm became impossible, ambitious persons tried to get enough formal education to qualify for a desk job in town. But even after several years of secondary schooling, desk jobs were hard to come by, and many young men who had gone that far by desperate effort were not willing to wait patiently until something turned up. Instead, they listened eagerly to those who preached extreme revolutionary action.

According to Serbian nationalist agitators, justice, freedom, and a decent regard for Serbian dignity required that all speakers of the South Slav tongue who were also of the Orthodox faith should belong to the same state. The fact that the end of Habsburg rule over Serbian populations would inevitably mean more government jobs for educated Serbs was an attractive additional advantage.

Some thought that Muslim and even Roman Catholic speakers of the South Slav language should join their Orthodox brethren in a new South Slav state. But this Yugoslav (*Yug*, "South") ideal had little appeal for most Serbs. It attracted support mainly in Dalmatia, where rural Serbs (Orthodox South Slavs) and Croats (Roman Catholic South Slavs) found it easy to cooperate against the Italians, who had long dominated town life along the Adriatic.

Despite Serbia's tiny size compared to the vastness of the Habsburg monarchy, many high Austrian officials concluded that intransigent Serbian nationalism constituted a serious threat to their state. The power of the nationalist ideal in the Balkans had been demonstrated in 1912 by the First Balkan War, which all but drove the Ottoman Empire from Europe and added substantial new territories to Serbia. This success fanned the Serbian nationalist ambition which was already at white heat, to complete the task of liberation by disrupting the Habsburg state.

What made such a program so frightening to the Austrians was that other nationalities within the Habsburg Empire shared in some degree the ambition to win greater control over their own affairs; a few even dreamed of achieving complete national independence. But in 1914 nationalist movements among the Czechs, Germans, Italians, Poles, Magyars, Slovenes, and Croats were less emotionally intense and, therefore, less immediately threatening to constituted authority than was the case among the Serbs.

Outbreak of war. Austrian officials, therefore, felt that a showdown was desirable. They decided to seize upon Archduke Ferdinand's assassination to settle accounts with Serbia. Preliminary investigation failed to turn up definite evidence that the Serbian government had been connected with the assassination; but historians have since shown that the Serbian premier, Nikola Pašić (*q.v.*) knew what was going on and tried indirectly to warn Austrian authorities of the plot. Col. Dragutin Dimitrijević, chief of intelligence for the Serbian general staff and leader of the Black Hand—a secret society that planned the assassination and armed Princip (with several others)—was one of Pašić's political enemies and rivals. In hinting to the Austrians of what was afoot, Pašić did as much as he dared to thwart Dimitrijević's risky, revolutionary plans. But the Austrian authorities failed to take the hint. The Archduke was assassinated, official Europe was horrified, and on July 23, 1914, the Habsburg government delivered an ultimatum to the Serbs requiring suppression of patriotic societies and the establishment of a joint commission to investigate and punish those persons who were responsible for organizing the assassination.

Austrian reaction to the assassination of Archduke Ferdinand

The ultimatum was designed to be unacceptable. Despite a conciliatory reply, the Austrians declared war against Serbia on July 28, exactly a month after the assassination itself. Within a week Europe's alliance system swung creakily into action, pitting the Triple Entente—Russia, France, and Great Britain—on Serbia's side against the Central Powers—Germany and Austria-Hungary.

Russia's entry into the war upset Austrian plans for crushing Serbia. Austrian troops had to be diverted to the Russian front, and, when the Austrians were finally ready to attack the Serbs, on August 13, they were repulsed. A Serbian counteroffensive soon petered out, however, and by the end of 1914 the battle line stood very close to the prewar frontiers.

The outbreak of hostilities provoked intense diplomatic–military activity elsewhere in the Balkans. On August 11, 1914, two German cruisers that had been trapped in the Mediterranean Sea at the beginning of the war arrived in Constantinople. A fictitious sale transferred them to the Turks, and in October these vessels sailed into the Black Sea to bombard Russian coastal towns. The Allies (Entente) promptly declared war against Turkey (November 4–5, 1914).

Both the Entente and the Central Powers sought to rally support for their cause among the three remaining uncommitted Balkan states—Bulgaria, Romania, and Greece (Albania was in chaos and lacked a central government). Bulgaria wanted the parts of Thrace and Macedonia that had been annexed by the Serbs and Greeks after the Second Balkan War in 1913; Romania wanted the Habsburg territories of Transylvania and ad-

jacent regions in Bukovina and the Banat; Greece had ambitions in Anatolia and, above all, desired to possess Constantinople (later Istanbul).

The Central Powers were able to promise the Bulgars most of what they desired, because Serbia would be the main loser. Similarly, the Entente was able to appease the Romanian appetite at the expense of the Habsburgs. Greece's ambitions were more difficult, however, because Russia, too, aspired to possess Constantinople, and so did the Bulgars.

Courtship of the Balkan states

The work of diplomats and intelligence agents in lining up allies in the Balkans for one side and the other came slowly to fruition in 1915–17. The Bulgars were the first to commit themselves, by allying with the Central Powers in September 1915. By then the strategic situation in the Balkans had altered greatly. The first important move was British. In February 1915 the Royal Navy bombarded Turkish forts in the Dardanelles, and a month later British warships tried unsuccessfully to force their way through the straits. Then, on April 25, 1915, British troops went ashore on the Aegean side of the Gallipoli Peninsula in order to take the Turkish defenses of the Dardanelles in the rear and open a way to Constantinople for the Royal Navy; but once again the Turks were able to stop the British advance before it could achieve strategic success.

The next major move came from Italy. Despite a defensive alliance with Germany and Austria-Hungary, the Italian government remained neutral in 1914, arguing that, because Austria had attacked Serbia, the terms of the alliance had not been fulfilled. Italian nationalists wished to add Dalmatia and other Austrian provinces to their country; despite Serbian objections, the Allies agreed to most of the Italian demands in the secret Treaty of London (signed in April 1915). Accordingly, in May the Italians declared war and opened a new front against Austria in the Alps. Italian troops also crossed the Adriatic to occupy Albania.

The intervention of Italy, plus Austrian commitments on the Russian front, forced the Austrians to postpone large-scale action against the Serbs until fall; but by the first week in October everything was ready for a major assault. The Bulgars saw in this their opportunity to take Macedonia from Serbia, and they prepared to join the attack.

In a last-minute effort to aid the Serbs, French and British troops landed at the Greek city of Thessaloníki on October 3. This touched off a major crisis inside Greece, pitting Prime Minister Eleutherios Venizelos, champion of the Allies, against King Constantine, who favoured continued neutrality, at least until it was clearer which side would win the war. (In the end, by bombarding the royal palace in Athens the Allied powers were able to compel Constantine to abdicate in June 1917; and Venizelos, who took command of Greek affairs, promptly caused Greece to declare war against the Central Powers.)

A combined Austrian and German force attacked Serbia on October 6, 1915, with overwhelming strength. Allied troops in Salonika were too few to check the simultaneous Bulgar advance from the east. In November, the Serbian Army began a painful retreat through the mountain passes of Albania. A remnant 125,000 strong found refuge on the Greek island of Corfu, where the Serbian government, still being led by the aged and ailing King Peter I, with Nikola Pašić as prime minister, established a temporary headquarters (January 1916) in what had formerly been the German kaiser's holiday palace.

Meanwhile, the British withdrew their troops from Gallipoli, transferring most of them to the Thessaloníki front, which soon extended westward to link up with the Italians in Albania. Trench warfare then set in along a battle line extending all the way from the Adriatic coast to Kaválla on the Aegean. Neither side could break through the other's prepared defenses.

Stalemate of 1916

This stalemate was demonstrated in 1916, when the last Balkan neutral, Romania, entered the war on the Allied side on August 27. This move was planned to coincide both with a Russian offensive against Austria and with a major push against Bulgaria along the Thessaloníki front. Despite substantial reinforcement by rested and re-equipped Serbian troops transferred to Thessaloníki from Corfu, the offensive failed. The Romanian Army proved ineffective, and by January 1917 most of Romania was in the hands of the Central Powers.

The year 1917 saw no large-scale military action in the Balkans, but revolutions in Russia changed the realities of power profoundly. The Bolsheviks publicly renounced Russian claims on Constantinople; instead, Lenin appealed over the heads of all governments to the peoples of Europe to rise against their exploiters and inaugurate Socialism. Balkan response to Lenin's revolutionary summons was slight, partly because the Western Allies forestalled the Bolshevik appeal by endorsing a different revolutionary formula—national self-determination. The war thus became far more ideological than before, pitting nationalist revolutionary ideals against Socialist revolutionary ideals through the whole of eastern Europe.

The most complex nationality issue in the Balkans centred around Serbia's relationship to the other South Slav peoples of the Habsburg Empire. On July 20, 1917, the Serb prime minister Pašić signed a document declaring that the Serbs, Croats, and Slovenes should form a single state after the war, under the Serbian Karageorgević dynasty but with appropriate local autonomies. Exiled Dalmatian politicians, claiming to represent the Croats and Slovenes, also signed this Pact of Corfu. In April 1918 a Congress of Oppressed Nationalities met in Rome and, with Italian blessing, reiterated the idea that Serbs, Croats, and Slovenes belonged together, despite the fact that the three nationalities distrusted one another profoundly and that most Croats remained loyal to the Habsburg cause.

End of the war. The long military stalemate in the Balkans ended on September 30, 1918, when the Bulgars decided to sue for an armistice. From the Thessaloníki front, Allied troops under French command marched northward to the Danube. As the Allied forces approached, the Romanians, who had signed a peace with the Central Powers in May 1918, re-entered the war on November 8, just in time to count as an Allied and victorious power at the peace conference.

The Ottoman government followed the example of the Bulgarians by suing for an armistice on October 30, 1918. The armistice terms allowed a British force to advance through the Dardanelles and to occupy Constantinople on November 13. Amid the crash of falling empires, the Habsburg monarch also signed an armistice on November 3; but events had stripped the Emperor of his power to influence affairs. The Romanians (already in possession of the former tsarist province of Bessarabia) hastened to take possession of as much of Transylvania, Banat, and Bukovina as possible; meanwhile, Serbian troops were moving into the former Habsburg territory from the south, while the victorious Italians also sought to get control of as much of the Adriatic coastlands as they could.

Under these circumstances the Slovenes and Croats had little room for manoeuvre. On October 29, 1918, a national council meeting in Zagreb proclaimed the independence of "Yugoslavia" (meaning the former Habsburg lands in which the South Slavs lived). Before a stable settlement with the Serbs could be achieved—a preliminary agreement reached at Geneva on November 9 was later repudiated—the Zagreb National Council broke apart.

A faction opted for immediate union with Serbia; and, accordingly, on December 1, 1918, the Serbian monarch formally proclaimed a new Kingdom of Serbs, Croats, and Slovenes from his capital, Belgrade. A political coup unseated the Prince of Montenegro, whose state was also merged with the new South Slav state. But whether the new state would be federal or unitary and the question of how Serbs and Croats would come to an understanding with one another remained completely unset-

Kingdom of Serbs, Croats, and Slovenes

tled. (For additional information see WORLD WARS: *World War I.*)

Results of the peace conferences. The Paris Peace Conference that began in January 1919 drew up separate treaties for each defeated enemy state. By the Treaty of St. Germain (signed September 10, 1919) Austria ceded Slovenian and Dalmatian territory to the new Kingdom of Serbs, Croats, and Slovenes; by the Treaty of Neuilly (signed November 27, 1919) Bulgaria lost a strip of the Aegean coast (acquired in 1912) to Greece and surrendered small border territories to Serbia; by the Treaty of Trianon (signed June 4, 1920) Hungary transferred Transylvania and part of the Banat to Romania and surrendered Croatia, Slavonia, and the rest of the Banat to the new South Slav state; lastly, by the Treaty of Sèvres (signed August 10, 1920), Turkey assigned most of Thrace as well as the hinterland of Smyrna (Izmir) in Asia Minor, to Greece.

From L. Stavrianos, *The Balkans Since 1453;* Holt, Rinehart and Winston, Inc.

The Balkans after World War I.

These treaties settled many of the territorial questions that had long distracted Balkan politics and in a comparatively enduring way. But "national self-determination" proved a difficult formula to apply in lands where mixtures of nationalities were the rule rather than the exception. Some issues, such as the delineation of the Italian–Yugoslav boundary, were never resolved at the peace conference; instead, bilateral negotiation eventually (1924) defined a frontier that satisfied neither side.

Albania's borders were not fixed until 1926, when an international commission, established in 1912, finally concluded its labours. This settlement, which left large Albanian populations inside the new South Slav state, made little difference politically until after World War II, because Albanian national self-consciousness was weakened by traditional loyalties to rival kindred groupings, on the one hand, and by religious (Muslim, Orthodox, Roman Catholic) and linguistic (Gheg, Tosk) differences on the other.

Turkish and Tartar minorities along the Black Sea coast in Bulgaria and Romania shared the Albanians' prepolitical status; and Jews, important mainly in Romania and at Thessaloníki offered no systematic resistance to the new masters of the Balkans. The case was far different, however, with other Balkan nationalities. Those who had formerly enjoyed a leading position in society and government found it all but impossible to accept willingly the loss of former privileges. The victors often retaliated by subjecting German, Magyar, Turkish, and (in Dalmatia) Italian minorities to flagrant administrative discrimination.

Hence, the territorial settlement of 1919–20 had the effect of transferring to Romania and the new Kingdom of Serbs, Croats, and Slovenes many of the nationality problems that had plagued the Habsburg and Ottoman empires before 1914. In Romania, Magyar, German, Jewish, Ukrainian, Bulgarian, and Turko-Tartar minorities amounted to at least 4,500,000 in a total population of about 18,000,000; but the Romanian majority did give a solid core to the new state. The situation in the Kingdom of Serbs, Croats, and Slovenes was less stable, for, although the Serbs constituted the largest single nationality, they were still a minority in the state considered as a whole.

Continuing nationality problems

German, Magyar, Albanian, and Romanian minorities totalled over 1,600,000; about 1,300,000 Muslims (mostly speaking Serbo-Croatian) constituted another distinct bloc; Slovenes (about 1,100,000) formed a self-conscious, distinct nationality, too; but the really critical matter was the relation between the Croats (about 3,500,000) and the Serbs (about 5,500,000). A new constitution went into effect on January 1, 1921, establishing a unitary state on democratic lines. Croats felt that the Corfu Declaration of 1917 had committed the Serbs to federalism, and they refused to accept the new arrangement. This was especially dangerous for the new state, because the Italian government was dissatisfied with the peace settlement in the Adriatic and set out actively to encourage disruptive forces. The death of King Peter in 1921 made small difference; his heir, King Alexander I (reigned 1921–34), had already exercised the royal powers for several years.

The southern Balkans were even more distracted in the first postwar years. A Turkish nationalist movement, headed by Kemal Atatürk, refused to accept the terms of the Treaty of Sèvres. The Greeks, seeking to make good their claim to even more extensive territories in Asia Minor, invaded the interior in hope of forcing the Turks to yield; in 1921 they met defeat, and the angry Turks forced all Greeks and other Christian inhabitants from the land. About 1,500,000 survivors fled across the Aegean in 1921–22.

A new peace, agreed to at Lausanne, Switzerland, in 1923, provided for the systematic exchange of populations between Greece and Turkey under League of Nations supervision. Greek and other Christian inhabitants of Constantinople were exempted from this exchange; in return, Greece promised to allow Turkish peasants in western Thrace to remain on their land. This treaty provided that the Greeks relinquish their claim to Asia Minor entirely and retroceded eastern Thrace to Turkey.

Exchange of population with Bulgaria was also arranged by a separate agreement. The result, by about 1927, when major transfers ceased, was the sorting out of the populations of Greece, Bulgaria, and the western parts of Turkey by nationality.

No politically important national minorities remained in the southern and eastern Balkans. This radical surgery allowed nationality frictions to subside slowly in later decades. In the northern Balkans, however, such frictions continued to constitute a major axis of politics during the interwar years.

INTERWAR DEVELOPMENTS, 1923–39

The upheavals of World War I did little to solve the underlying problems of Balkan society. It is not strange, therefore, that revolutionary discontent found new chan-

nels of expression after the war. Success for certain nationalities (Serbs, Romanians) automatically meant frustration for others (Bulgars, Magyars, Croats, Macedonians), so that in some regions of the peninsula old-fashioned nationalist conspiracy and agitation continued as before, but now directed against the new masters of the land.

But national self-determination lost much of its glamour as it became clear that old problems were not really relieved by the changes in political boundaries and shifts in dominating nationalities that had occurred in 1918–19. Two new revolutionary movements, therefore, surged to the fore: peasantism and Communism.

New revolutionary movements. The three main bearers of the peasantist idea were the Peasant Party of Bulgaria, led by Aleksandŭr Stamboliyski; the Croatian Peasant Party, led by Stjepan Radić; and the Romanian Peasant Party, led by Iuliu Maniu. The latter, based mainly in Transylvania, opted for parliamentary and peaceable agitation and, even when Maniu briefly became prime minister (served 1928–30), accomplished little to reform rural conditions. The Croatian Peasant Party quickly became identified with Croat nationalism, thanks to Radić's unbending opposition to Serbian preponderance in the new Kingdom of Serbs, Croats, and Slovenes; by boycotting the parliament, Radić showed how shaky the new state really was, but his policy, too, accomplished no positive ends. Stamboliyski, on the other hand, came to power in 1919 on a wave of revolutionary feeling; but his efforts to end bureaucratic oppression and overthrow the parasitic classes that fattened on peasant labour only succeeded in putting crude former peasants and party men into administrative roles they were poorly equipped to handle; in 1923 a coup d'etat led to Stamboliyski's assassination and to the establishment of a shaky parliamentary regime, closely controlled from behind the scenes by royal, military, and semi-military manipulators.

Peasantism

The basic reason for the failure of peasant parties to achieve their ends lay in their programs. Men who wished to destroy the so-called social parasites (*i.e.*, everyone who did not work with his hands and raise his own food) could not take power without themselves becoming that which they wished to abolish: bureaucrats and paper shufflers.

Opposition to those who ruled was the only role such parties and movements could accept comfortably. Only in this way, in fact, could they hope to remain faithful to the perennial distrust their peasant constituencies felt toward government in any form and toward city people generally.

The other new revolutionary movement, Communism, was better equipped ideologically and organizationally. Communist parties had arisen in each Balkan state by 1921. In Bulgaria and Yugoslavia, the new parties met with rapid initial success but subsided into small, quarrelsome groups of hunted revolutionaries when the two governments officially outlawed Communist agitation, in 1921 (Yugoslavia) and 1923 (Bulgaria). In Romania, Greece, and Albania, Communist organizers met with only slight response in the 1920s, but they did succeed in creating revolutionary cadres ready and willing to operate outside the law.

Rise of Communist parties

The frustration of peasantist aspiration and the prevalance of nationalist revolutionary sentiment among such groups as the Macedonians seemed in 1924 to offer Communists a chance to unite all the disaffected elements of Balkan society into a grand alliance. The Comintern (Communist International, formed in 1919 to help in spreading Leninism around the world) approved the formula of Balkan federation as a solution for the peninsula's political and economic ills and instructed each national party to form "popular fronts" with any and all available groups. Radić flirted openly with Moscow; so did leaders of the Internal Macedonian Revolutionary Organization (IMRO).

But these incompatible bedfellows soon parted. IMRO leaders who cooperated with the Communists were killed by rivals within the organization. Radić became a cabinet minister for a brief period (1925–26), but in 1928, during a session of the parliament, he was shot and killed by a Montenegrin Serb. This assassination provoked a strong reaction among the Croats against any kind of cooperation with the Serbs. King Alexander, therefore, decided to scrap the constitution, which had done so little to heal the fissures within his kingdom; he proclaimed a dictatorship, dissolved the political parties, and officially renamed the state Yugoslavia.

Government reactions. By resorting to authoritarian government, Alexander openly admitted the breakdown of effective government by consent. The same thing had also happened in Bulgaria, Romania, and Albania; but in those countries the pretense of parliamentary elections and the rituals of party coalitions were preserved, and they sometimes registered real adjustments in public mood.

This was the case, for instance, when Maniu forged a coalition of peasant parties in Romania and emerged as premier in 1928. In Greece, too, the parliamentary elections that returned Venizelos to power in 1928 registered public feeling quite accurately; but Greek electoral politics were frequently punctuated by coups d'etat (1922, 1925, 1933, 1935), that were sometimes successful, sometimes not.

Official efforts to cope with the problems of Balkan society and to meet the new revolutionary thrusts directed against existing governments were not entirely fruitless. They took three forms: land reform, industrialization, and police repression.

Efforts to solve social problems

Land reform. Widespread redistribution of land shifted ownership toward the peasant families who actually worked the soil. Such reforms went fastest and farthest when land could be taken from owners of a different nationality. Thus, Magyar estates in the north and Turkish estates in the south disappeared at once. Gradual reapportionment took place elsewhere, too, so that by 1939 large estates had almost disappeared from the Balkans, surviving only in those parts of Romania where the landlords were politically powerful Romanian nationals.

Industrialization. The new owners of small peasant plots were often unable to cultivate the soil as efficiently as had the large-scale operators. Redistribution of land was no solution to the ills of Balkan overpopulation and underdevelopment. Each of the Balkan states recognized this fact by attempting to forward industrialization. Romania, building upon an oil industry that had arisen in the 19th century, made by far the most substantial progress in this direction; Bulgaria made almost none. Tariff protection, subsidy, and state enterprise were the devices used to develop industry. But shortage of capital and a generally low level of skills made progress painfully slow.

The only important policy difference in the interwar period with respect to industrialization was about how to treat foreign capital. Romania tried to finance industrial development from internal sources and actively discouraged further foreign investment in the oil industry, fearing that control and the real benefits of such expansion would pass exclusively to the foreign capitalists. Albania, under Ahmed Zogu (president, 1925–28; king, 1928–39), on the other hand, depended wholly on Italian capital for whatever modernization was achieved. Greece and Yugoslavia gave an ambivalent welcome to foreign investment, but political instability in these countries kept the flow of foreign capital to modest proportions. Bulgaria was more xenophobic and attracted almost no foreign funds.

Repression. The third major official response to the problems of Balkan society was repression. High-handed police action was common; elections were often "made" to suit the interests of those in power by overt use of army and police personnel; and sharp legal restriction, if not outright prohibition, was generally imposed on revolutionary political organizations and propaganda. Such measures were generally successful, even when the revolutionaries received systematic encouragement from abroad.

Alliances. The Soviet Union provided at least moral support for Communists throughout the period. Fascist Italy spun a web of intrigue aimed against Yugoslavia; by the late 1920s Mussolini's agents had entangled the Bulgaria-based IMRO, extreme Croat nationalists (Ustachi) based in Rome, and some elements of the Hungarian government in plots to dismember King Alexander's state.

In Romania, too, a Fascist movement, founded in 1927 (renamed the Iron Guard in 1928) by Corneliu Codreanu, rose quickly to prominence; it owed little to foreign patronage, however, because Codreanu based his appeal mainly upon harsh anti-Semitism, for which the ground was already well prepared.

The Balkan governments took steps to counter the foreign threat. A diplomatic alliance of Czechoslovakia, Romania, and Yugoslavia—the so-called Little Entente—dated from 1921. In 1934 a new Balkan Pact allied Greece, Yugoslavia, Turkey, and Romania. Such treaties were aimed mainly against Hungarian (Little Entente) and Bulgarian (Balkan Pact) aspirations for frontier revision. In the background, France played the role of great-power patron vis-à-vis Romania and Yugoslavia, rivalling Italy, the patron of Bulgaria and Hungary; Britain, the patron of Greece; and the Soviet Union, the pan-Balkan patron of Communists.

The Balkans in the 1930s. The economic depression that settled upon world trade in the early 1930s put the Balkan countries at a great disadvantage. Farm prices plummeted, making it all but impossible for high-cost Balkan peasant producers to compete on world markets. Hardship and a pervasive sense of failure and confusion in official quarters encouraged revolutionary sentiment, especially among the young. But the enhanced power of revolution, especially in Communist guise, provoked more ruthless repression. Democratic and parliamentary government seemed to have failed everywhere, especially after 1933, when the rising influence of Nazi Germany began to make itself felt in the Balkans.

The effects of the world depression

German trade policy, as a matter of fact, brought an effective solution to the economic crisis that had paralyzed the Balkan markets since 1930. The Nazis offered to buy agricultural products from the Balkans, at prices fixed through bilateral negotiation, and offered manufactured goods in exchange, again at prices fixed by interstate bargaining. Germany often drove a hard bargain in these trade negotiations, but the fact was that only in Germany could high-cost Balkan farm products find any kind of sale. Hence, these exchanges—administered by state trading agencies and kept track of through blocked accounts managed by state banks—benefitted all parties. Romania and Bulgaria, in particular, began to market substantial surpluses in Germany.

By the late 1930s the resulting economic improvement allowed precarious political stabilization in both countries. Thus, for example, King Boris III of Bulgaria pulled IMRO's teeth by condoning, if not instigating, a coup d'etat in 1936, which brought to power a military group that dispersed IMRO's gunmen and drove its leaders from the country. Similarly, in 1938 King Carol II of Romania was able to have Codreanu killed and to repress the Iron Guard through unscrupulous and high-handed police methods; the king owed his success to the fact that, despite the strong appeal of its anti-Semitism, trade revival had taken the cutting edge from the Iron Guard's revolutionary agitation.

Greece followed a similar route. The early 1930s saw a rising political crisis, with abortive coups d'etat in 1933 and 1935. A "managed" plebescite in 1936 led to the recall of King George II from exile; but new elections resulted in a parliamentary deadlock between royalists and republicans. A handful of Communist deputies held the balance of power, being in a position to make or break any parliamentary majority. King George reacted to this situation by entrusting the government to Gen. John Metaxas, who ruled without a parliament until his death in 1941.

In Albania, however, King Zog's regime collapsed in 1939, and Italians took over direct administration of the country. This allowed Mussolini to threaten both Yugoslavia and Greece across a new frontier. Such an advance of Italian power was profoundly disturbing to both Balkan governments. Ever since 1934, when King Alexander of Yugoslavia had been assassinated in Marseilles by an IMRO gunman (supported by Hungary and Italy), Yugoslavia's internal problems had offered the Italians a promising field of action. Prince Paul, brother of the assassinated Alexander, took over the reins of government as regent for the heir, King Peter II, who was still too young to rule. Paul, like other Balkan monarchs, experimented with authoritarian rule and worked diligently for diplomatic rapprochement with both Bulgaria and Italy.

Italian control of Albania

In the late 1930s Paul decided that the kingdom could survive only by coming to a basic understanding with the Croats. Prolonged negotiations led to an agreement, in August 1939, by which a generously defined Croatia would enjoy extensive autonomy; the Croatian Peasant Party accepted this arrangement, and only certain extremists (the Ustachi) remained irreconcilable. This drastically weakened the Italian leverage inside Yugoslavia; but it did not solve the state's problems, because most Serbs balked at the prospect of giving the Croats control over territory in which large numbers of Serbs lived. Yet nothing less would satisfy Croatian ambitions. As a result, the federal structure for Yugoslavia as promised in the 1939 agreement had not been fully implemented when the flood tide of World War II overwhelmed the Balkan Peninsula.

WORLD WAR II, 1939–45

Axis victories and occupation. Stalin's cooperation with Hitler against Poland (September 1939) turned previously proferred Anglo-French guarantees of Polish and Romanian territorial integrity into worthless scraps of paper. The Romanian government had to yield Bessarabia and Bukovina to the Soviet Union (June 1940), part of Transylvania to Hungary (August 1940), and the southern Dobruja to Bulgaria (September 1940). King Carol, discredited by such losses, fled the country, and Gen. Ion Antonescu became dictator. Antonescu invited German troops to enter Romania in October 1940. The Romanian government remained a loyal and relatively enthusiastic ally of the Nazis in their struggle against the Soviet Union until 1944.

The Italian government, jealous of Germany's successes in Poland, Scandinavia, and France, decided to make Greece into a dependency. When the Greek dictator Metaxas refused to yield to Mussolini's ultimatum (October 1940), Italian troops crossed the Albanian frontier, expecting to meet only token opposition. To their surprise and discomfiture, the politically divided Greeks joined ranks against the Italians and drove the attacking forces back across the Albanian border. Fearing the provocation of German military intervention, the Greek government reacted coolly to the British offers of air and naval support; these fears assumed new plausibility when Nazi troops moved secretly into Bulgaria in March 1941.

German advance into Bulgaria

The German move attempted to forestall Soviet influence in Bulgaria and to compel Greece and Yugoslavia to repudiate ties with Great Britain and align themselves with the Nazi cause. As a diplomatic prelude to their planned attack on the Soviet Union, the Germans demanded that each Balkan state adhere to the Tripartite Pact (concluded initially by Germany, Italy, and Japan in September 1940). Hungary and Romania did so in November 1940; Bulgaria followed suit on March 1, 1941; and the Yugoslavs reluctantly did the same a few weeks later (March 25). News of this act led Serbian radicals, already bitterly opposed to the deal the government had concluded with the Croats, to seize power in Belgrade. This act of defiance outraged Hitler, then at the summit of his diplomatic success; to safeguard his southern flank for the thrust against the Soviet Union, he determined to crush the Yugoslavs and Greeks in a lightning campaign.

Accordingly, on April 6, 1941, German forces attacked

and speedily overran Yugoslavia. A hastily assembled British expeditionary force scarcely reached Greece from North Africa when headlong retreat began. In May 1941 German parachutists invaded Crete, and by the end of the month they had won a costly victory there; German arms had thus chalked up yet another brilliant success, but it forced them to postpone by a few weeks the start of the campaign against the Soviet Union. Whether this delay actually helped the Soviets survive Hitler's assault can never be definitively decided; but Greeks and Yugoslavs easily convinced themselves that their nations' defeat was an essential precondition for the later Soviet victory.

Greece and Yugoslavia remained under Axis occupation until 1944–45. Bulgarian, Italian, and German troops carved out separate zones of occupation—most of Macedonia was incorporated into Bulgaria; an independent Croatia, ruled by the Ustachi and under Italian patronage, was proclaimed. Romania, too, staked out its territorial claims in Bessarabia and adjacent regions of the Ukraine.

The resistance movements. The first people who actively opposed these arrangements were Serbs, who had everything to lose and whose national tradition of heroic outlawry against the Turks inspired guerrilla action. Bands of demobilized Serbian soldiers—"Chetniks"—formed under the leadership of Col. Draža Mihailović and engaged in acts of sabotage. When the Germans sent fresh troops into Serbia and retaliated brutally against communities suspected of harbouring guerrillas, the Chetniks abandoned active operations, husbanding their strength against a future day of liberation when Germany's defeat would permit them to restore the Serbian nation to its accustomed and proper position in the Balkans.

After the Nazi attack on the Soviet Union (June 22, 1941), the Communist parties of the Balkans, which had previously cooperated with the Germans, made an abrupt about-face. Communist activity in Bulgaria remained marginal until 1944; in Romania the party was of trifling importance, being firmly identified with Jewish and other minority groups.

The popular fronts

But in Yugoslavia, Albania, and Greece the Communists rapidly built up powerful resistance organizations. The Communist Party line was to cooperate with all anti-Fascist elements in the population; hence, popular front, uniting Socialists, peasants, nationalists, and anyone else willing to cooperate with Communists, sprang into existence. Communist policy systematically played down Marxism and disguised the extent of party control over the network of political and military resistance organizations they created.

An essential strength of the Communists in this situation was the availability in each Balkan state of underground party cadres already accustomed to survival in face of police harassment. In addition, the Communists emphasized political organization in towns and countryside, thus providing the armed guerrilla bands responsive to their leadership with far firmer support than any rival organizations could offer. Finally, Communist policy aimed at helping the common cause of Socialist revolution by fighting Germans wherever they could be found; this simple policy had the effect of attracting the support of restless and active men throughout the western Balkans. Hence, by degrees the Communists were able to live down their traitorously antinational past and to far outdistance all rivals.

In Yugoslavia, when the Communist-led Partisans first took the field in the summer of 1941, they tried, in accord with popular front tactics, to cooperate with Mihailović's Chetniks. But violent quarrels soon broke out. Two points were at issue: whether to persist in active operations against the Germans and Italians, despite the cost to civilian populations, as Tito (Josip Broz), the Communist leader, desired, (Mihailović opposed this); and whether to welcome all Yugoslavs into the resistance, as Tito assumed, or accept only Serbs, as Mihailović felt was necessary.

Behind these disagreements lay rival visions of the future: Mihailović desired above all to protect Serbdom against Croat, Bulgar, and other threats, whereas Tito (*q.v.*) envisioned a revolutionary brotherhood of all Balkan nationalities, as projected by the Comintern ever since the 1920s. In the long-drawn-out struggle that ensued, advantage lay overwhelmingly with Tito; his policy of conducting active operations against the occupiers of his country won the backing of the British, American, and Soviet allies (Tehrán Conference, November 1943). In addition, as the war continued to bite into their daily lives the peoples of Yugoslavia more and more rallied to the only active transnational Yugoslav organizations in sight: Tito's Partisans and the Anti-Fascist Peoples' National Council (AVNOJ), the political voice and arm of the movement.

In Greece, the Communist resistance also took the form of an armed guerrilla organization, known by the acronym ELAS, and of a political organization, called National Liberation Front (EAM). British policy, however, never abandoned support for the Greek government in exile, headed by King George II. In Greece itself, anti-Communist guerrilla groups that were supported by British agents and supplies continued to divide the ground with ELAS.

The situation in Albania was similarly confused; rival Albanian resistance groups achieved effective organization only after 1943, when the surrender of the Italian government to the Allies in September put large stocks of arms into Albanian hands. The Italian surrender also allowed the resistance movements of Yugoslavia and Greece to acquire large quantities of Italian weapons and briefly to take possession of territories formerly policed by Italian troops.

Acquisition of Italian weapons

The Germans were able to reoccupy major cities and lines of communication in the former Italian zones of occupation; but by 1944 the continuing retreat of German armies in the Soviet Union made clear the ultimate outcome of the war. On August 23, 1944, when the advancing Soviet forces were close to the Romanian border, King Michael kidnapped General Antonescu and adroitly changed from the Axis to the Allied side. As a result, Soviet troops were able to advance rapidly toward the Danube, and Romanian units, formerly Hitler's allies, switched allegiances, turning their arms against the Germans.

The Bulgarians followed suit on September 9, as the Soviet advance guard neared their border. The Soviets then turned westward, passing through a corner of Yugoslavia (Belgrade was liberated, October 20, 1944) on their way to Budapest.

This abrupt military reversal compelled the Germans to withdraw what forces they could from the western Balkans. Isolated German garrisons, such as that in Crete, were left behind; but the main forces moved northward in good order, and at the end of the war (May 1945) much of Croatia still remained under German occupation.

The last Germans left Greece in October 1944, whereupon the royal Greek government returned to Athens (October 18) with the protection of a handful of British troops; quarrels soon broke out, however, and, during six bitter weeks (December 1944 to January 1945), fighting flared in Athens between British forces and the resistance guerrilla army, ELAS. (For further information see WORLD WARS: *World War II.*)

WORLD WAR II TO THE PRESENT

Postwar settlement, 1945–49. The armed collision between British- and Communist-led forces in the streets of Athens showed how hard it was, as the prospect of final victory over Germany came closer, for the great Allied powers to keep on cooperating. In May 1944 the United States had reluctantly approved a division of the Balkans into British and Soviet spheres of influence; this was confirmed and adjusted in favour of the Soviet Union when the British prime minister, Winston Churchill, visited Moscow that September to settle details of armistice arrangements with Romania and Bulgaria and to clear the way for the British landing in Greece.

British and Soviet spheres of influence

The Soviets were not unhappy to see the British resort to high-handed means to enforce their will in Greece. They hoped for a similar free hand in Romania, where the absence of any strong native Communist party made it particularly difficult for them to establish a government they could depend on. The Bulgarian Communist Party, though, was relatively strong and, operating through a "Fatherland Front," gave the Russians no cause for concern.

In Yugloslavia, however, where Tito easily took power as the Germans withdrew, the Soviets found it hard to restrain the Partisans' revolutionary enthusiasm. In the first flush of victory, Tito's followers were eager to put the Communist recipe for Balkan federation into effect and saw no reason to compromise with the "effete capitalist imperialists" of Britain and the United States over such an issue as control of Trieste. When the Soviets, in conformity to their deal with Churchill to divide the Balkans into spheres of influence, advised Tito to make conciliatory gestures towards the Royal Yugoslav government (in exile since 1940), the Yugoslav Communists reluctantly complied by allowing King Peter's representative, Ivan Šubašić, briefly to join the Cabinet. But the Partisans had come to power by taking risks and despising compromise; accordingly, many of Tito's followers were appalled at the Soviet Union's unwillingness to act upon revolutionary principles in the immediate postwar period.

The British, American, and Soviet foreign ministers slowly negotiated peace treaties with the former enemy states of the Balkans (1945–47). As long as the Anglo-Americans had not recognized the postwar Communist-dominated regimes of Bulgaria, Romania, and Hungary, the Soviets had a powerful argument for moderation; Stalin accordingly supported collaboration with all anti-Fascists and opposed further revolutionary adventures in the Balkans.

In Romania and Hungary there were strong practical reasons why out-and-out Communist Party dictatorships could not come to power—national feeling was distinctly anti-Soviet Union and, therefore, anti-Communist, and pre-existing Communist Party structures were extremely weak. But even where there were strong Communist parties, as in Bulgaria and Yugoslavia, until 1947 Soviet policy continued to support anti-Fascist popular fronts in which Communist preponderance was at least partially camouflaged.

Changes in Soviet policy toward the Balkans

In 1947 two events altered Soviet policy toward the Balkans. First, the United States and Great Britain signed peace treaties with Bulgaria, Romania, and Hungary in February. These treaties did not much alter interwar boundaries, although Romania did lose Bessarabia and Bukovina to the Soviet Union once again and ceded a small strip of Dobruja to Bulgaria; Greece acquired the Dodecanese Islands in the Aegean from Italy; and Yugoslavia annexed a strip of territory in the Istrian peninsula. The treaties did, however, disband the Allied armistice commissions, which had exercised some control over local affairs in both Bulgaria and Romania following 1944.

The cancellation of British and American legal claims to authority in these countries freed local Communists from what had been a real, if modest, hindrance. At the same time, because the treaties authorized the Soviets to maintain their forces in Romania as "lines of communication" troops to forward garrisons in Austria, the Communists retained what was still an essential guarantee of their hold over Romania.

The second event that altered Soviet policy occurred in March 1947, just a month after the peace treaties came into effect, when Pres. Harry S. Truman asked the United States Congress to authorize military and economic aid to Greece and Turkey, both of which were under Communist pressure. After prolonged debate, Congress voted to approve Truman's request and thereby endorsed the "Truman Doctrine," according to which the United States undertook to defend the rule of law internationally by coming to the aid of any government threatened with Communist subversion.

The U.S. decision to back the Greek government against a renewed Communist guerrilla movement signalized a sharp shift of American policy vis-à-vis the Soviet Union. Quarrels over the peace treaties, over Poland, over the occupation regimes in Germany and Japan, as well as over the rising tide of Communist power in China and several other parts of Asia, all contributed to the change of American public attitudes; but events in the Balkans were also important.

Spread of Communism. In 1945 and 1946, through a series of diplomatic notes, the Soviets tried to browbeat the Turks into giving them military bases on the straits between the Black Sea and the Aegean. In addition, Tito and other Balkan Communists, most notably Georgi Dimitrov of Bulgaria, set about actively implementing their ideal of Balkan confederation. A first step was to federalize Yugoslavia itself. A new constitution, closely modelled on that of the U.S.S.R., was accordingly promulgated in January 1946; it established six federal republics (Serbia, Slovenia, Croatia, Montenegro, Macedonia, Bosnia) and several autonomous regions. King Peter lost his throne, and Communist Party control came fully into the open.

Attempts to form a Balkan confederation

A second step was to bring a reliable Communist regime to power in Albania. The Yugoslavs sent troops and technical advisers to help Albanian revolutionaries seize firm control (January 1946). Soon the entire country began to behave much like another constitutive republic of Tito's emerging Balkan superstate.

The next item on the Communists' agenda was never realized: the creation of a united Macedonia that would combine the portions of that land belonging to Greece, Bulgaria, and Yugoslavia into a single whole. Bulgaria did in fact briefly cede Pirin Province to the new Macedonia, but the Greeks refused to cooperate. Accordingly, Tito sent Greek veterans of the wartime guerrilla force (who had retreated into Yugoslavia at the end of the war) back to Greece, where they formed the core around which fresh bands of guerillas quickly formed in 1946 and 1947.

The Greek government's efforts to repress this renewal of guerrilla activity were ineffective; British resources were too straitened at home to permit fresh involvement in Greece. Hence, for a few months—until the United States committed itself fully to stopping the Communist advance—Tito's revolutionary policy seemed on the verge of paying off.

Such heady prospects encouraged the Yugoslavs to be aggressive along their frontier with Italy, demanding further territory to unite all Slovenes in the new Slovene republic. They also entered into negotiations with the Bulgarians (and perhaps also with Romanian Communists) for merging their countries into the proposed Balkan federal state.

Tito's activity antagonized the United States and was a potent factor in persuading the U.S. Congress to support the embattled Greek government in 1947. Tito's effect on Soviet policy remains a matter for speculation; Stalin probably backed the idea of abandoning the popular-front tactic and the placing of out-and-out Communist regimes in power. Soviet diplomatic agents played the key role in driving King Michael from the Romanian throne (December 1947), thus instituting Communist Party dictatorship in that country. Bulgarian Communists needed no outside help to achieve the same result by the end of 1947. For further information see also INTERNATIONAL RELATIONS (1945 TO C. 1970).

Communist regimes in Romania and Bulgaria

Tito's break with the Soviet Union. Eventually, Tito's efforts to overthrow the royal government in Greece and to press ahead with Balkan federation alienated the Soviets. Perhaps Stalin feared Tito's independence or attributed the United States' involvement in Greece and Turkey to what he saw as Tito's recklessly revolutionary policies.

At any rate, in 1948 the Soviet dictator decided to call Tito to heel. With characteristic guile, Stalin set out to overthrow Tito by stirring up an intrigue within the ranks of the Yugoslav Communist Party. It did not work; Tito's prestige inside his own country was too

great for an outsider—even Stalin—to succeed in unseating him.

But when the quarrel between the Soviet Union and Tito came out into the open (June 1948), the entire strategic situation in the Balkans altered abruptly. Albanian Communists, warmly backed by the Soviet Union, broke away from Tito and unceremoniously evicted all the Yugoslav experts and advisers who had until then been running the country.

Bulgaria and Romania disclaimed all sympathy for Tito and hurried to participate in Stalin's economic blockade and propaganda war against the stubborn Yugoslavs (all the more energetically because of their previous associations with the new heretic).

In Greece, the Tito–Stalin split meant, first of all, the cessation of Yugoslav aid to the Greek guerrillas. This crippled the guerrilla cause. Then, in an effort to get the Macedonians to imitate the Albanians and secede from Tito's dominion, the Cominform (Communist Information Bureau, established in 1947) announced its program of a united Macedonia. Radio broadcasts failed to stir the Yugoslav Macedonians to action; but the news did create consternation in the ranks of the Greek guerrillas, who were unwilling to fight for a cause that, it now appeared, would lead, if successful, to the surrender of Greek territory to a Slav people. Greek Communist morale therefore collapsed, so that Greek government troops—equipped, advised, and assisted by a large American military mission—found it easy to win decisive victory in the summer of 1949.

Changes caused by the war. By August 1949, therefore, active military operations in the Balkans ceased; nearly a decade of war thus came to a conclusion. By that date Communist Party dictatorships were firmly established in all the Balkan countries except Greece and Turkey.

Yet, in spite of this fact, the changes World War II brought to the Balkans were distinctly less drastic than those that came during the 20th century's earlier decade of Balkan fighting, 1912–23. Boundaries shifted only slightly after 1945; and war or postwar population movements wiped out or greatly reduced the numbers of some national minorities—Germans and Jews in particular. The effect was to confirm and enhance the sorting out of Balkan populations into territorially defined national states, according to the patterns of 1918–19.

Confirmation of national states

From a political and social point of view the one-party regimes of the northern Balkans, set up by Communists, proved a little more ruthless and persistent in pursuit of the same goals than did the interwar Balkan governments: economic and political mobilization of the peasant mass—by police hectoring and controlled elections if need be—to hasten the development of industries and cities.

All in all, the major crisis of transition from a traditional peasant and premodern style of life apparently took place in the Balkans before and after World War I, whereas after 1949 somewhat more stable patterns of modernization and mobilization established themselves in Greece as much as in Communist lands. The waning force of revolutionary movements of every kind, a marked feature of the post-World War II Balkan scene, is an index of this basic transformation.

The 1950s and after. Though Balkan politics after 1949 were less tumultuous and also less bloody than was the case earlier, confusion and upheavals were not lacking. Among the Communist states, fluctuating relations with the Soviet Union defined major shifts of government policies.

Political and economic changes. From 1948 to 1953 all Stalin's satellites in eastern Europe purged real or suspected "Titoists"—*i.e.*, Communist leaders suspected of putting national interests ahead of subservience to the Soviet Union. The countries formerly closest to Tito were, not surprisingly, the most energetic in carrying out such purges.

Albania broke away from Yugoslavia and became for a while the Soviet Union's most enthusiastic satellite. The Bulgarian government staged a show trial against Titoists and used the occasion to implicate personnel of the United States embassy, with the result that official U.S.–Bulgarian relations were broken off in 1950, not to be resumed till 1966. Yet, in spite of a trade blockade and various kinds of subversive activity aimed against the Yugoslav regime, Tito's power remained unshaken. By cautiously accepting profferred American aid, the Yugoslavs managed to survive even Stalin's wrath.

After Stalin's death in 1953, the Soviet government tried to mend its fences with Tito. As a result, the Yugoslav government was able to balance itself between the Soviet Union and the United States—playing one off against the other and even getting economic and military aid from both great powers at once. The advantages of such an independent policy were obvious to other Balkan Communist states. But not until after 1961, when a quarrel between Chinese and Soviet Communists came into the open, did first the Albanians and then the Romanians venture to defy the Soviet Union.

Albania's policy was governed mainly by fear of a lasting Yugoslav–Soviet rapprochement; when that seemed likely in 1961, the Albanians threw out their Soviet advisers, as they had earlier ejected Yugoslavs from similar roles, and allowed the distant Chinese to become their new patrons.

Defiance of the Soviet Union

By the early 1970s Albania was expanding and normalizing its relations throughout the world. In 1971 diplomatic relations were either established or elevated to the ambassadorial level in Greece (with which country Albania had been in a technical state of war since 1940), Yugoslavia, and a number of other countries. Chinese influence, however, remained dominant in Albania, with China supporting numerous industrial enterprises under Albania's five-year plan for 1971–75.

A far more serious break in the Communist ranks occurred in 1964, when Romania declined to accept the role assigned to it by the Soviet Union in the Comecon (Council for Mutual Economic Assistance) plan for economic development of eastern Europe. Instead of concentrating on agriculture for export, the Romanian government wished to continue to emphasize industry, even if this meant duplicating Czech or East German factories. Romanian national feeling, always strongly anti-Soviet, surged to the surface in support of the government's stand.

In Greece, American policy played a dominating role after 1947. Until 1956 American funds continued to provide the Greek government with substantial aid for economic rehabilitation; the United States thus was able to control a number of important aspects of government policy.

After 1956, aid tapered off, and American diplomats deliberately tried to pull out of Greek politics. Such aloofness was all the more attractive to the United States because Greece seemed to have attained a relatively stable parliamentary regime under Marshal Alexandros Papagos—hero of the Albanian war of 1940 and of the guerrilla war of 1947–49—and, after his death (1955), Konstantinos Karamanlis, who survived three elections to remain prime minister for an unprecedentedly long period (1955–63).

Yet the fact that Greece had become a member of the North Atlantic Treaty Organization (NATO) in 1952 meant that American influence upon the Greek armed forces remained strong even after other forms of aid had stopped. And, because the political attitudes of the army mattered in Greek politics, American efforts to leave the Greek politicians alone were never very successful. Thus, in April 1967, when a clique of army officers seized power by coup d'etat, American agents were generally suspected of being responsible for what was probably planned in secret by a narrow and purely Greek circle. The policy of the new Greek government lent some colour to the charges, however, because the officers who emerged as rulers of the country combined an enthusiastic anti-Communism with an earnest courtship of private foreign (principally American) investment, which they needed to balance their international accounts.

Military coup in Greece

The authoritarian military dictatorship, headed by Col. Georgios Papadopoulos, lasted till 1974, when intrigues

aimed at bringing Cyprus into union with Greece miscarried and the military rulers of the country were discredited. Karamanlis was recalled from his self-imposed exile in Paris and organized new elections, thus restoring the legal forms of parliamentary democracy. In a national referendum in December 1974 the Greeks rejected the monarchy and became a republic. Relations with Turkey, which had nearly come to war over Cyprus, were not easily healed; and indignation at the failure of NATO commanders to support the Greek cause against Turkey led Karamanlis to cancel most of the agreements that had bound the Greek armed forces to NATO.

These political upheavals and the often noisy public debate that characterized Greece stood in sharp contrast to the strict controls on public discussion that Communist regimes enforced in other Balkan countries. This difference, however, should not disguise some important resemblances in the pattern of development pursued by all Balkan governments in the post-World War II era. Everywhere officials preferred industrial to agricultural investment and subjected most economic activities to elaborate, often cumbersome bureaucratic control. Everywhere, too, cities grew rapidly, offering scope for peasant sons and daughters to pursue new careers more attractive than those their parents had known. This permitted a general relaxation of political and economic dissatisfactions, despite the numerous unsolved problems that persisted within all the Balkan nations.

The only important difference in economic policies was that Greece continued to import private foreign capital and linked internal prices to world markets, whereas Communist countries maintained a command price system at home and regarded all private investment as detestable capitalist exploitation. When importing foreign capital, the Communist countries were willing only to borrow from other governments—a policy that seemed unlikely to make borrowers any less dependent on lenders.

Tangible increases of industrial output occurred in every Balkan state, with the possible exception of Albania. This did not mean, however, that problems of distribution and assortment of products to suit the consumers had been solved. Quite to the contrary, in the Communist lands shoddy goods and insufficient supplies of some commodities were still the rule; and many of the new factories, built as a result of political decisions, were distressingly inefficient when it came to costs. In Greece, unsolved problems were primarily those of income distribution among the different social classes, although inefficient and high-cost factories that sheltered behind tariff and quota protection were not absent.

Recognition of the difficulty of adjusting a command economy to consumer needs led the Yugoslavs to experiment with freer market prices on the one hand and with worker–management partnership in factory administration on the other. A new constitution, effective in 1963, gave enhanced power in economic matters to the federal republics in the hope that this, too, would bring planning and management closer to the people. Yugoslavia met some success in this effort at decentralization and bureaucratic simplification. But divisive tendencies among the various nationalities of the state were perhaps reinforced by allowing greater popular participation in management decisions. Nevertheless, on June 30, 1971, the federal government instituted new amendments that further enhanced the powers of the republics and municipalities, granting the right, for example, to initiate investment projects. The federal government reserved for itself sole power in the areas of defense, foreign policy, and general economic policies.

Political and economic growth

In spite of these and other unsolved problems, the political and economic history of the Balkans after 1949 must be rated an overall success, at least as compared to the experience of earlier decades of the 20th century and to the whole of the 18th and 19th centuries. Peace prevailed, as seldom before. Population and developed resources came more nearly into balance. Administrative and technical skills attained such a level that plans began to have reasonable relation to results. Mass mobilization, both politically and economically, was achieved, along with the enhancement of wealth and power usually expected from such successful modernization.

Effects of the changes. The costs were, of course, very great. As more and more young people left their village homes and managed to establish themselves in the expanding complex of administrative paper work, factory labour, construction work, etc., the fabric of traditional rural life altered profoundly in all the Balkan nations. Old peasant customs decayed; urban styles of dress and, still more, of expectations spread into the remotest villages; handicrafts survived, if at all, mainly on the strength of the tourist trade. The Balkan nations, in short, rapidly transformed themselves into provincial variants of the world-girdling Western style of civilization. Insofar as they were successful, new pains arose from the dissatisfactions of provincialism; but the far sharper psychological strains that had afflicted the generation of Balkan peasants who first witnessed the breakdown of their traditional village ways of life faded into the past. Proportionally, the fierceness of revolutionary aspiration dwindled, fed no longer by the agony of displaced young men who, like Gavrilo Princip in 1914, were glad to give their lives for a cause because only so could they transcend daily frustration and apparent failure.

Regarded as a case study of the interaction between premodern, traditional peasant styles of life and the aspiration for modernity, Balkan history after 1945 has wide significance. The majority of mankind launched itself upon a similar trajectory a good deal later than did the Balkan peoples and could perhaps be expected to follow a somewhat similar curve of historical development in the rest of the 20th century. (For additional information on contemporary affairs in the Balkans see ALBANIA; GREECE; ROMANIA; BULGARIA; and YUGOSLAVIA.)

BIBLIOGRAPHY

The Balkans to 1815: JOHN ALEXANDER, *Yugoslavia Before the Roman Conquest* (1972), a general summary of archaeology and protohistory of this country with emphasis on the early Iron Age; DUMITRU BERCIU, *Romania* (1967), archaeological survey from the Palaeolithic period to the Geto-Dacian civilization; STANLEY G. EVANS, *A Short History of Bulgaria* (1960), includes an outline of the early historical and cultural setting for the state; JOSEPH WIESNER, *Die Thraker* (1963), a detailed account of the Thracians to AD 600; MARIJA GIMBUTAS, "The Neolithic Cultures of the Balkan Peninsula," in *Aspects of the Balkans* (1972), a concise account of the Neolithic and Chalcolithic civilizations, 6500–3500 BC; *The Bronze Age Cultures in Central and Eastern Europe* (1965), a monograph that includes the Danubian region and Urnfield migrations; *The Slavs* (1971), an account of the beginning and early history of the Slavic peoples and their migrations to the Balkan peninsula; and the *Symposium* of the Centre d'Études Balkaniques, Sarajevo (1964), a collective work dedicated to the distribution and chronology of the prehistoric Illyrians. (*The Balkans in the Middle Ages*): National histories of the individual Balkan states are not always dependable for the medieval period. Two books on the Balkans as a whole, however, are quite reliable and up to date: GEORG STADTMULLER, *Geschichte Südosteuropas* (1950); and DIMITRY OBOLENSKY, *The Byzantine Commonwealth: Eastern Europe, 500–1453* (1971). The Byzantine context of the Balkan peninsula in the medieval period is well treated in the relevant chapters of *The Cambridge Medieval History*, 2nd ed., vol. 4 (1966); and on a more modest scale in GEORGE OSTROGORSKY, *Geschichte des byzantinischen Staates* (1965; Eng. trans., *History of the Byzantine State*, 2nd ed., 1968). On the Slavic states in the Balkans, see the two studies of FRANCIS DVORNIK, *The Slavs: Their Early History and Civilization* (1956) and *The Slavs in European History and Civilization* (1962). All these books have substantial bibliographies for further reading. (*The Ottoman era*): The best general discussion of the Balkans in the Ottoman era is to be found in L.S. STAVRIANOS, *The Balkans Since 1453*, ch. 3–12 (1958). The Ottoman conquest of the Balkans and its effects on European diplomacy are ably described in PAUL COLES, *The Ottoman Impact on Europe* (1968). Two excellent studies of dramatic events in this period are STEVEN RUNCIMAN, *The Fall of Constantinople, 1453* (1965); and THOMAS M. BARKER, *Double Eagle and Crescent: Vienna's Second Turkish Siege and Its Historical Setting* (1967). STEVEN RUNCIMAN, *The Great Church in Captivity* (1968), covers the patriarchate in Constantinople from the Turkish conquest until the 1820s.

The Balkans from 1815 to 1914: The period from the early-19th century till the 1950s is treated in RENE RISTELHUEBER, *Histoire des peuples balkaniques* (1950; Eng. trans., *A History of the Balkan Peoples*, 1971). A short review of the Balkans in the 19th century may be found in L.S. STAVRIANOS, *The Balkans, 1815–1914* (1963); and in CHARLES and BARBARA JELAVICH, *The Balkans* (1965). See also the relevant sections in Stavrianos' excellent general history, *The Balkans Since 1453*. The comparative method is applied in L.S. STAVRIANOS, *Balkan Federation* (1944); TRAIAN STOIANOVICH, *A Study in Balkan Civilization* (1967); CHARLES and BARBARA JELAVICH (eds.), *The Balkans in Transition* (1963); DIMITRIJE DJORDJEVIC, *Révolutions nationales des peuples balkaniques, 1804–1914* (French trans. 1965); DOREEN WARRINER (ed.), *Contrasts in Emerging Societies: Readings in the Social and Economic History of South-eastern Europe in the Nineteenth Century* (1965).

National histories: (*Yugoslavia*): Different aspects of Yugoslav development may be found in ROBERT J. KERNER (ed.), *Yugoslavia* (1949); and ROBERT F. BYRNES (ed.), *Yugoslavia* (1957). Short, condensed histories include: PHYLLIS AUTY, *Yugoslavia* (1965); A.W. PALMER, *Yugoslavia* (1964); MURIEL HEPPELL and FRANK B. SINGLETON, *Yugoslavia* (1961); Z. KOSTELSKI, *The Yugoslavs* (1952); STEPHEN CLISSOLD (ed.), *A Short History of Yugoslavia: From Early Times to 1966* (1966); and WERNER MARKERT (ed.), *Jugoslawien* (1954). The best social and economic history is JOZO TOMASEVICH, *Peasants, Politics, and Economic Change in Yugoslavia* (1955). The Yugoslavs in the Habsburg monarchy are studied in articles published in the *Austrian History Yearbook*, vol. 3, pt. 2 (1967). (*Greece*): The best, although very short history of 19th-century Greece is NICOLAS G. SVORONOS, *Histoire de la Grèce moderne* (1953). Surveys of Greek development in the same period may be found in JOHN CAMPBELL and PHILIP SHERRARD, *Modern Greece* (1968); W.A. HEURTLEY *et al.*, *A Short History of Greece, from Early Times to 1964* (1965); EDWARD S. FORSTER, *A Short History of Modern Greece, 1821–1956*, 3rd ed. (1958); JOHN N. MAVROGORDATO, *Modern Greece: A Chronicle and a Survey, 1800–1931* (1931); and C.M. WOODHOUSE, *The Story of Modern Greece* (1968). The standard work for diplomatic history is J. EDOUARD DRIAULT and MICHEL LHERITIER, *Histoire diplomatique de la Grèce de 1821 à nos jours*, 5 vol. (1925–26). See also GEORGE FINLAY, *A History of Greece, from Its Conquest by the Romans to the Present Time, B.C. 146 to A.D. 1864*, new ed., 7 vol. (1877, reprinted 1970); and WILLIAM MILLER, *A History of the Greek People, 1821–1921* (1922). (*Bulgaria*): Bulgarian 19th-century development is covered in D. KOSSEV, H. KHRISTOV, and D. ANGELOV, *A Short History of Bulgaria* (Eng. trans. 1963); and MERCIA MACDERMOTT, *A History of Bulgaria, 1393–1885* (1962). For internal Bulgarian politics, see CYRIL E. BLACK, *The Establishment of Constitutional Government in Bulgaria* (1943, reprinted 1970). IRWIN T. SANDERS, *Balkan Village* (1949), gives a description of post-World War I changes in Bulgarian rural life. (*Romania*): NICOLAE IORGA, *Histoire des Roumains et de la romanité orientale*, 5 vol. (1937), is still a basic general history, as is ROBERT W. SETON-WATSON, *A History of the Roumanians, from Roman Times to the Completion of Unity* (1934, reprinted 1963). The history of the unification of the country is presented by THAD W. RIKER in *The Making of Roumania* (1931); for recent developments, see STEPHEN A. FISCHER-GALATI, *Twentieth Century Rumania* (1970). (*Albania*): The best modern study of Albania is STAVRO SKENDI, *The Albanian National Awakening, 1878–1912* (1967). An older book is JOSEPH SWIRE, *Albania: The Rise of a Kingdom* (1929, reprinted 1971). The Soviet historian, ИРИНА ГРИГОРЬЕВНА СЕНКЕВИЧ, published (in Russian): *Албания в период восточного кризиса, 1875–1881* (1965); *Освободительное движение албанского народа в 1905–1912* (1959); and with a group of authors, *Краткая история Албании* (1965). A study of the 19th-century Albanian movements may be found in THEODOR IPPEN, "Beiträge zur inneren Geschichte Albaniens im XIX. Jahrhundert," in LUDWIG VON THALLOCZY (ed.), *Illyrisch-albanische Forschungen . . .*, vol. 1, pp. 342–385 (1916). (*Ottoman Empire*): Besides the standard works of WILLIAM MILLER, *The Ottoman Empire and Its Successors, 1801–1927*, 4th ed. (1936); and NICOLAE IORGA, *Geschichte des Osmanischen Reiches*, 5 vol. (1908–13), many modern studies deal with the reform activities in the Ottoman Empire: ERNEST E. RAMSAUR, *The Young Turks: Prelude to the Revolution of 1908* (1957); RODERIC H. DAVISON, *Reform in the Ottoman Empire, 1856–1876* (1963); ROBERT DEVEREUX, *The First Ottoman Constitutional Period: A Study of the Midhat Constitution and Parliament* (1963); FRANK E. BAILEY, *British Policy and the Turkish Reform Movement: A Study in Anglo-Turkish Relations, 1826–1853* (1942). Financial and economic aspects are discussed in DONALD C. BLAISDELL, *European Financial Control in the Ottoman Empire* (1929). EDWARD M. EARLE deals with the Ottoman Empire in the era of imperialism in *Turkey, the Great Powers, and the Bagdad Railway* (1923, reprinted 1966).

The Balkans after 1914: (*General works*): HUGH SETON-WATSON, *Eastern Europe Between the Wars, 1918–1941*, 3rd rev. ed. (1967); and *The East European Revolution*, 3rd ed. (1956); ROBERT L. WOLFF, *The Balkans in Our Time* (1956); R.V. BURKS, *The Dynamics of Communism in Eastern Europe* (1961); GHITA IONESCU, *The Politics of the European Communist States* (1967); YORICK BLUMENFELD, *Seesaw: Cultural Life in Eastern Europe* (1968); TRAIAN STOIANOVICH, *A Study in Balkan Civilization* (1967); C.A. (M.G./G.P.M./B.Je./C.J./D.V.D./W.H.McN.)

Balkhash, Lake

Situated in the eastern part of the Kazakh Soviet Socialist Republic, U.S.S.R., Lake Balkhash (Ozero Balkhash in Russian; Ozero Balchaš in the transliteration system of the Akademiya Nauk) is contained in the vast Balkhash–Alakol Basin, 1,115 feet (340 metres) above sea level and 600 miles east of the Aral Sea. It is 376 miles long from west to east. Its area varies within significant limits, depending on the water balance. In years in which there is an abundance of water, as at the beginning of the 20th century and in the decade 1958–69, the area reaches 6,900 to 7,300 square miles (18,000 to 19,000 square kilometres). In drought-afflicted periods, however (as at the end of the 19th century and in the 1930s and 1940s), the area of the lake decreases to 6,000 to 6,300 square miles. Such changes in area are accompanied by changes in the water level of about ten feet. Such variability is caused by the structure of the basin and the lake's location. Jutting far out into the lake is the Sarymsek Peninsula (Poluostrov), which divides Balkhash into two separate hydrological parts: a western part, wide and shallow, and an eastern part, narrow and relatively deep. Accordingly, the width of the lake changes from 46 to 17 miles in the western part and six to 12 miles in the eastern part. The depth of the western part does not exceed 36 feet, whereas the eastern part reaches 85 feet. The two parts of the lake are united by a narrow strait, the Uzynaral, with a depth of about 21 feet.

The variability of its area

Hydrology. The large Ili River, flowing in from the south, spills into the western part of the lake and contributes 75–80 percent of the total influx into the lake. Only such small rivers as the Karatal, Aksu, Ayaguz, and Lepsa feed the eastern part of the lake. With almost equal areas in both parts of the lake, this situation creates a continuous flow of water from the western section to the eastern section. The water of the western part is almost fresh (total mineralization 0.74 gram per litre) and suitable for industrial use and consumption; the water of the eastern part, however, is salty (about five grams per litre).

The east bank of the lake bears traces of a historically recent union (perhaps occurring only two or three hundred years ago) of the Balkhash Basin with the basin of Ozero (Lake) Alakol in the Dzungarian Gate to the east. The similarity between the fauna of Lake Balkhash and that of the Tarim River Basin in Central Asia and the dissimilarity of the faunas of the Aral Sea and Lake Balkhash suggest that formerly Lake Balkhash, through Lakes Alakol and Ai-pi, went into the system of lakes that formerly filled the Turfan Depression in the T'ien Shan (Celestial Mountains) and had no connection with the Aral Sea to the west.

The north banks of the lake are high and rocky, with clear-cut traces of ancient terraces. Farther north a dry steppe passes into the undulating Kazakh Plain. The south banks are low and sandy, and wide belts of them are covered with thickets of reeds and numerous small lakes. The low-lying banks, periodically flooded by the waters of the lake, are being continually transformed into the desert sands of the Sary-Ishikotrau and, further away, into the foothills of the Dzhungarsky Alatau.

Climate. Extremely harsh continental conditions prevail and significantly affect the whole regime of the lake. The average (1930–67) air temperature in the western part is 44° F (7° C), with an annual range of from 80° F (June) to −1° F (January; 27° C to −18° C) and, in the eastern part, 39° F (4° C) with a range of from 72° F (June) to −13° F (January; 22° C to −25° C). The water temperature in the western part of the lake is 50° F (10° C); in the eastern part it is 48° F (9° C). Average precipitation is approximately 17 inches. The predominant winds are from the northwest (in the west) and from the northeast (in the east). They are usually fairly strong, giving rise to constantly choppy water. The lake remains frozen from the end of November to the beginning of April.

Animal life. Carbonates predominate in the ground deposits of the lake. The fauna of the lake is rich, especially in regions dense with reeds. Different types of gulls and ducks and a large number of cormorants are most frequently found here. Now and then one can spot swans and pink pelicans. Among the brushwood on the banks, pheasants and partridges can be seen. Wild boars still forage among the reeds; and wolves, foxes, and hares inhabit the thickets. In the past tigers were not infrequent here; the last one was killed in the 1940s.

Twenty species of fish inhabit the lake, of which six are peculiar to the lake itself. The remainder were introduced to the lake by man and include the sazan, sturgeon, eastern bream, pike, and the Aral barbel. The main food fish are the sazan, pike, and Balkhash perch. Bottom life is poor, and the most important sources of food for the fish are benthos (Chironomidae), zooplankton, and the larvae of Tendipedidae. Pollution is only a problem insofar as it results from some of the natural biological processes, or enters the lake via the rivers.

Fish species

Economic activity. The economic importance of the lake has greatly increased during the Soviet period. Most significant is the fishing and fish breeding begun in the 1930s and now rapidly developing. A regular shipping service with a large freight turnover has developed. Of great importance to the economic development of the region was the construction of the Balkhash copper-refining plant, around which the large city of Balkhash grew on the north shore of the lake. A railway line connects Balkhash with all the major centres of Kazakhstan and Central Asia. Cattle breeding and rice growing in the lower reaches of the Ili River are of major economic importance to the region. In 1970 the Kapchagay hydroelectric power station began operations on the Ili River. As its reservoir began to fill, the regime of Lake Balkhash began to change radically. (A.V.S.)

Ballad

The ballad is a short narrative folk song whose distinctive style crystallized in Europe in the late Middle Ages and persists to the present day in communities where literacy, urban contacts, and mass media have not yet affected the habit of folk singing. The genre is not restricted to the English-speaking world: France, Denmark, Germany, Russia, Greece, and Spain possess impressive ballad collections, and at least one-third of the 300 extant English and Scottish ballads have counterparts in one or several of these continental balladries, particularly those of Scandinavia. In no two language areas, however, are the formal characteristics of the ballad identical. For example, British and American ballads are invariably rhymed and strophic (*i.e.*, divided into stanzas); the Russian ballads known as *byliny* and almost all Balkan ballads are unrhymed and unstrophic; and, though the Spanish *romances* and the Danish *viser* are alike in using assonance instead of rhyme, the Spanish ballads are generally unstrophic while the Danish are strophic, parcelled into either quatrains or couplets.

ELEMENTS

Narrative basis. Typically, the folk ballad tells a compact little story that begins eruptively at the moment when the narrative has turned decisively toward its catastrophe or resolution. Focussing on a single, climactic situation, the ballad leaves the inception of the conflict and the setting to be inferred or sketches them in hurriedly. Characterization is minimal, the characters revealing themselves in their actions or speeches; overt moral comment on the characters' behaviour is suppressed and their motivation seldom explicitly detailed. Whatever description occurs in ballads is brief and conventional; transitions between scenes are abrupt and time shifts are only vaguely indicated; crucial events and emotions are conveyed in crisp, poignant dialogue. In short, the ballad method of narration is directed toward achieving a bold, sensational, dramatic effect with purposeful starkness and abruptness. But despite the rigid economy of ballad narratives, a repertory of rhetorical devices is employed for prolonging highly charged mo-

ments in the story and thus thickening the emotional atmosphere. In the most famous of such devices, incremental repetition, a phrase or stanza is repeated several times with a slight but significant substitution at the same critical point. Suspense accumulates with each substitution, until at last the final and revelatory substitution bursts the pattern, achieving a climax and with it a release of powerful tensions.

Rhetorical devices

Then out and came the thick, thick, blood,
  Then out and came the thin,
Then out and came the bonny heart's blood,
  Where all the life lay in.

Oral transmission. Since ballads thrive among unlettered people and are freshly created from memory at each performance, they are subject to constant variation in both text and tune. Where tradition is healthy and not highly influenced by literary or other outside cultural influences, these variations keep the ballad alive by gradually bringing them into line with the style of life, beliefs, and emotional needs of the immediate folk audience. Ballad tradition, however, like all folk arts, is basically conservative, a trait that explains the references in several ballads to obsolete implements and customs, as well as the appearance of words and phrases so badly garbled as to show that the singer does not understand their meaning though he takes pleasure in their sound and respects their traditional right to a place in his song. The new versions of ballads that arise as the result of cumulative variations are no less authentic than their antecedents. A poem is fixed in its final form when published, but the printed or taped record of a ballad is representative only of its appearance in one place, in one line of tradition, and at one moment in its protean history. The first record of a ballad is not its original form, merely its earliest recorded form, and the recording of a ballad does not inhibit tradition from varying it subsequently into other shapes, because tradition preserves by re-creating rather than by exact reproduction.

COMPOSITION

Theories. How ballads are composed and set afloat in tradition has been the subject of bitter quarrels among scholars. The so-called communal school, led by two American scholars F.B. Gummere (1855–1919) and G.L. Kittredge (1860–1941), argued at first that ballads were composed collectively during the excitement of dance and song festivals. Under attack the communalists retreated to the position that although none of the extant ballads had been communally composed, the prototypical ballads that determined the style of the ballads had originated in this fashion. Their opponents the individualists, who included the British men of letters W.J. Courthope (1842–1917) and Andrew Lang (1844–1912) and the American linguist Louise Pound (1872–1958), held that each ballad was the work of an individual composer, not necessarily a folk singer, tradition serving simply as the vehicle for the oral perpetuation of his creation. According to the widely accepted communal re-creation theory, put forward by the American collector Phillips Barry (1880–1937) and the scholar G.H. Gerould (1877–1953), the ballad is conceded to be an individual composition originally. This fact is considered of little importance because the singer is not expressing himself individually, but serving as the deputy of the public voice, and because a ballad does not become a ballad until it has been accepted by the folk community and been remolded by the inevitable variations of tradition into a communal product. Ballads have also been thought to derive from art songs, intended for sophisticated audiences, which happened to filter down to a folk level and became folk song. This view, though plausible in the case of certain folk lyrics, is inapplicable to the ballads, for if the ballads were simply miscellaneous castoffs, it would not be possible to discern so clearly in them a style unlike anything in sophisticated verse.

Technique and form. Ballads are normally composed in two kinds of stanzas, a couplet of lines each with four stressed syllables, and with an interwoven refrain:

But it would have made your heart right sair,
  With a hey ho and a lillie gay
To see the bridegroom rive his haire.
  As the primrose spreads so sweetly

or a stanza of alternating lines of four stresses and three stresses, the second and fourth lines rhyming:

There lived a wife at Usher's Well,
  And a wealthy wife was she;
She had three stout and stalwart sons,
  And sent them o'er the sea.

Reference to the tunes show that the three-stress lines actually end in an implied fourth stress to match the pause in the musical phrase at these points. The interwoven refrain is a concession to the musical dimension of the ballad; it may be a set of nonsense syllables (Dillum down dillum, Fa la la la) or irrelevant rigmaroles of flowers or herbs. A few ballads have stanza-length burdens interspersed between the narrative stanzas, a technique borrowed from the medieval carols. The lyrical and incantatory effect of refrains during the ballad performance is very appealing, but in cold print they often look ridiculous, which is perhaps why early collectors failed to note them. In the first example above, it will be noted that the gaiety of the refrain is at odds with the mood of the meaningful lines. Not infrequently the ballad stanza satisfies the music's insistence on lyrical flourishes by repeating textual phrases and lines:

So he ordered the grave to be opened wide,
  And the shroud to be turned down;
And there he kissed her clay cold lips
  Till the tears came trickling down, down, down,
  Till the tears came trickling down

Kinds of repetition used in ballads

The refrain is just one of the many kinds of repetition employed in ballads. Incremental repetition, already discussed, is the structural principle on which whole ballads ("The Maid Freed From the Gallows," "Lord Randal") are organized, and many other ballads contain long exchanges of similarly patterned phrases building cumulatively toward the denouement:

"Oh what will you leave to your father dear?"
"The silver-shod steed that brought me here."
"What will you leave to your mother dear?"
"My velvet pall and my silken gear."
"What will you leave to your brother John?"
"The gallows-tree to hang him on."

Any compressed narrative of sensational happenings told at a high pitch of feeling is bound to repeat words and phrases in order to accommodate the emotion that cannot be exhausted in one saying, a tendency that accounts for such stanzas as:

Then He says to His mother, "Oh: the withy [willow], oh:
    the withy,
  The bitter withy that causes me to smart, to
    smart,
Oh: the withy, it shall be the very first tree
  That perishes at the heart."

Much repetition in ballads is mnemonic as well as dramatic. Since ballads are performed orally, the hearer cannot turn back a page to recover a vital detail that slipped by in a moment of inattention. Crucial facts in narrative, therefore, are incised in the memory by skillful repetition; instructions given in a speech are exactly repeated when the singer reports the complying action; answers follow the form of the questions that elicited them.

Conventional imagery

The exigencies of oral performance also account for the conventional stereotyped imagery of the ballads. For unlike the poet, who reaches for the individualistic, arresting figure of speech, the ballad singer seldom ventures beyond a limited stock of images and descriptive adjectives. Knights are always gallant, swords royal, water wan, and ladies gay. Whatever is red is as red as blood, roses, coral, rubies, or cherries; white is stereotyped as snow white, lily white, or milk white. Such conventions fall into place almost by reflex action, easing the strain on the singer's memory and allowing him to give his full attention to the manipulation of the story. The resulting bareness of verbal texture, however, is

more than compensated for by the dramatic rhetoric through which the narrative is projected. In any case, complex syntax and richness of language are forbidden to texts meant to be sung, for music engages too much of the hearer's attention for him to untangle an ambitious construction or relish an original image. Originality indeed, like anything else that exalts the singer, violates ballad decorum, which insists that the singer remain impersonal.

Music. A ballad is not technically a ballad unless it is sung; but though tunes and texts are dynamically interdependent, it is not unusual to find the same version of a ballad being sung to a variety of tunes of suitable rhythm and metre or to find the same tune being used for several different ballads. And just as there are clusters of versions for most ballads, so a given ballad may have associated with it a family of tunes whose members appear to be versions of a single prototypical form.

Ballad tunes are based on the modes (that is, the archaic tonal systems of medieval church music) rather than on the chromatic scales that are used in modern music. Where chromaticism is detected in American folk music, the inflected tones are derived from Negro folk practice or from learned music. Of the six modes, the preponderance of folk tunes are Ionian, Dorian, or Mixolydian; Lydian and Phrygian tunes are rare. The folk music least affected by sophisticated conditioning does not avail itself of the full seven tones that compose each of the modal scales. Instead, it exhibits gapped scales, omitting either one of the tones (hexatonic) or two of them (pentatonic). Modulation sometimes occurs in a ballad from one mode to an adjacent mode.

Most tunes consist of 16 bars with duple rhythm, or two beats per measure, prevailing slightly over triple rhythm. The tune, commensurate with the ballad stanza, is repeated as many times as there are stanzas. Unlike the "through-composed" art song, where the music is given nuances to correspond to the varying emotional colour of the content, the folk song affords little opportunity to inflect the contours of the melody. This limitation partly explains the impassive style of folk singing. Musical variation, however, is hardly less frequent than textual variation; indeed, it is almost impossible for a singer to perform a ballad exactly the same way twice. The stablest part of the tune occurs at the mid-cadence (the end of the second text line) and the final cadence (the end of the fourth line). The third phrase of the tune, corresponding to the third line of the stanza, proves statistically the most variable. Significantly, these notes happen to coincide with the rhyming words. The last note of the tune, the point of resolution and final repose, usually falls on the fundamental tone (*i.e.*, keynote) of the scale; the mid-cadence falling normally a perfect fifth above the tonic or a perfect fourth below it. To make for singability, the intervals in the melodic progression seldom involve more than three degrees. And since the singer performs solo or plays the accompanying instrument himself, he need not keep rigidly to set duration or stress but may introduce grace notes to accommodate hypermetric syllables and lengthen notes for emphasis.

Impassive style of folk singing

TYPES OF BALLADRY

The traditional folk ballad, sometimes called the Child ballad in deference to Francis Child, the scholar who compiled the definitive English collection, is the standard kind of folk ballad in English and is the type of balladry that this article is mainly concerned with. But there are peripheral kinds of ballads that must also be noticed in order to give a survey of balladry.

Minstrel ballad. Minstrels, the professional entertainers of nobles, squires, rich burghers, and clerics until the 17th century, should properly have had nothing to do with folk ballads, the self-created entertainment of the peasantry. Minstrels sometimes, however, affected the manner of folk song or remodelled established folk ballads. Child included many minstrel ballads in his collection on the ground that fragments of traditional balladry were embedded in them. The blatant style of minstrelsy marks these ballads off sharply from folk creations. In violation of the strict impersonality of the folk ballads, minstrels constantly intrude into their narratives with moralizing comments and fervent assurances that they are not lying at the very moment when they are most fabulous. The minstrels manipulate the story with coarse explicitness, begging for attention in a servile way, predicting future events in the story and promising that it will be interesting and instructive, shifting scenes obtrusively, reflecting on the characters' motives with partisan prejudice. Often their elaborate performances are parcelled out in clear-cut divisions, usually called fits or cantos, in order to forestall tedium and build up suspense by delays and piecemeal revelations. Several of the surviving minstrel pieces are poems in praise of such noble houses as the Armstrongs ("Johnie Armstrong"), the Stanleys ("The Rose of England"), and the Percys ("The Battle of Otterburn," "The Hunting of the Cheviot," "The Earl of Westmoreland"), doubtless the work of propagandists in the employ of these families. The older Robin Hood ballads are also minstrel propaganda, glorifying the virtues of the yeomanry, the small independent landowners of preindustrial England. The longer, more elaborate minstrel ballads were patently meant to be recited rather than sung.

Difference between minstrel and folk ballads

Broadside ballad. Among the earliest products of the printing press were broadsheets about the size of handbills on which were printed the text of ballads. A crude woodcut often headed the sheet, and under the title it was specified that the ballad was to be sung to the tune of some popular air. Musical notation seldom appeared on the broadsides; those who sold the ballads in the streets and at country fairs sang their wares so that anyone unfamiliar with the tune could learn it by listening a few times to the balladmonger's rendition. From the 16th century until the end of the 19th century, broadsides, known also as street ballads, stall ballads, or slip songs, were a lively commodity, providing employment for a troop of hack poets. Before the advent of newspapers, the rhymed accounts of current events provided by the broadside ballads were the chief source of spectacular news. Every sensational public happening was immediately clapped into rhyme and sold on broadsheets. Few of the topical pieces long survived the events that gave them birth, but a good number of pathetic tragedies, such as "The Children in the Wood" and broadsides about Robin Hood, Guy of Warwick, and other national heroes, remained perennial favourites. Although the broadside ballad represents the adaptation of the folk ballad to the urban scene and middle class sensibilities, the general style more closely resembles minstrelsy, only with a generous admixture of vulgarized traits borrowed from book poetry. A few folk ballads appeared on broadsheets; many ballads, however, were originally broadside ballads the folk adapted.

Broadside ballad as a source of news

Literary ballads. The earliest literary imitations of ballads were modelled on broadsides, rather than on folk ballads. In the early part of the 18th century, Jonathan Swift, who had written political broadsides in earnest, adapted the style for several jocular bagatelles. Poets such as Swift, Matthew Prior, and William Cowper in the 18th century and Thomas Hood, W.M. Thackeray, and Lewis Carroll in the 19th century made effective use of the jingling metres, forced rhymes, and unbuttoned style for humorous purposes. Lady Wardlaw's "Hardyknute" (1719), perhaps the earliest literary attempt at a folk ballad, was dishonestly passed off as a genuine product of tradition. After the publication of Thomas Percy's ballad compilation *Reliques of Ancient English Poetry* in 1765, ballad imitation enjoyed a considerable vogue, which properly belongs in the history of poetry rather than balladry.

SUBJECT MATTER

The supernatural. The finest of the ballads are deeply saturated in a mystical atmosphere imparted by the

presence of magical appearances and apparatus. "The Wife of Usher's Well" laments the death of her children so unconsolably that they return to her from the dead as revenants; "Willie's Lady" cannot be delivered of her child because of her wicked mother-in-law's spells, an enchantment broken by a beneficent household spirit; "The Great Silkie of Sule Skerry" begets upon an "earthly" woman a son, who, on attaining maturity, joins his seal father in the sea, there shortly to be killed by his mother's human husband; "Kemp Owyne" disenchants a bespelled maiden by kissing her despite her bad breath and savage looks. An encounter between a demon and a maiden occurs in "Lady Isabel and the Elf-Knight," the English counterpart of the ballads known to the Dutch-Flemish as "Herr Halewijn," to Germans as "Ulinger," to Scandinavians as "Kvindemorderen" and to the French as "Renaud le Tueur de Femme." In "The House Carpenter," a former lover (a demon in disguise) persuades a wife to forsake husband and children and come away with him, a fatal decision as it turns out. In American and in late British tradition the supernatural tends to get worked out of the ballads by being rationalized: instead of the ghost of his jilted sweetheart appearing to Sweet William of "Fair Margaret and Sweet William" as he lies in bed with his bride, it is rather the dead girl's image in a dream that kindles his fatal remorse. In addition to those ballads that turn on a supernatural occurrence, casual supernatural elements are found all through balladry.

Romantic tragedies. The separation of lovers through a misunderstanding or the opposition of relatives is perhaps the commonest ballad story. "Barbara Allen" is typical: Barbara cruelly spurns her lover because of an unintentional slight; he dies of lovesickness, she of remorse. The Freudian paradigm operates rigidly in ballads: fathers oppose the suitors of their daughters, mothers the sweethearts of their sons. Thus "The Douglas Tragedy"—the Danish "Ribold and Guldborg"—occurs when an eloping couple is overtaken by the girl's father and brothers or "Lady Maisry," pregnant by an English lord, is burned by her fanatically Scottish brother. Incest, frequent in ballads recorded before 1800 ("Lizie Wan," "The Bonny Hind"), is shunned by modern tradition.

The Freudian paradigm

Romantic comedies. The outcome of a ballad love affair is not always, though usually, tragic. But even when true love is eventually rewarded, such ballad heroines as "The Maid Freed from the Gallows" and "Fair Annie," among others, win through to happiness after such bitter trials that the price they pay seems too great. The course of romance runs hardly more smoothly in the many ballads, influenced by the cheap optimism of broadsides, where separated lovers meet without recognizing each other: the girl is told by the "stranger" of her lover's defection or death: her ensuing grief convinces him of her sincere love: he proves his identity and takes the joyful girl to wife. "The Bailiff's Daughter of Islington" is a classic of the type. Later tradition occasionally foists happy endings upon romantic tragedies: in the American "Douglas Tragedy" the lover is not slain but instead gets the irate father at his mercy and extorts a dowry from him. With marriage a consummation so eagerly sought in ballads, it is ironical that the bulk of humorous ballads deal with shrewish wives ("The Wife Wrapped in Wether's Skin") or gullible cuckolds ("Our Goodman").

Tabloid crime. Crime, and its punishment, is the theme of innumerable ballads: his sweetheart poisons "Lord Randal"; "Little Musgrave" is killed by Lord Barnard when he is discovered in bed with Lady Barnard, and the lady, too, is gorily dispatched. The murders of "Jim Fisk," Johnny of "Frankie and Johnny," and many other ballad victims are prompted by sexual jealousy. One particular variety of crime ballad, the "last goodnight," represents itself falsely to be the contrite speech of a criminal as he mounts the scaffold to be executed. A version of "Mary Hamilton" takes this form, which was a broadside device widely adopted by the folk. "Tom Dooley" and "Charles Guiteau," the scaffold confession of the assassin of Pres. James A. Garfield, are the best known American examples.

Medieval romance. Perhaps a dozen or so ballads derive from medieval romances. As in "Hind Horn" and "Thomas Rymer," only the climactic scene is excerpted for the ballad. In general, ballads from romances have not worn well in tradition because of their unpalatable fabulous elements, which the modern folk apparently regard as childish. Thus "Sir Lionel" becomes in America "Bangum and the Boar," a humorous piece to amuse children. Heterodox apocryphal legends that circulated widely in the Middle Ages are the source of almost all religious ballads, notable "Judas," "The Cherry-Tree Carol," and "The Bitter Withy." The distortion of biblical narrative is not peculiarly British: among others, the Russian ballads of Samson and Solomon, the Spanish "Pilgrim to Compostela" and the French and Catalonian ballads on the penance of Mary Magdalene reshape canonical stories radically.

Historical ballads. Historical ballads date mainly from the period 1550–1750, though a few, like "The Battle of Otterburn," celebrate events of an earlier date, in this case 1388. "The Hunting of the Cheviot," recorded about the same time and dealing with the same campaign, is better known in a late broadside version called "Chevy Chase." The details in historical ballads are usually incorrect as to fact because of faulty memory or partisan alterations, but they are valuable in reflecting folk attitudes toward the events they imperfectly report. For example, neither "The Death of Queen Jane," about one of the wives of Henry VIII, nor "The Bonny Earl of Murray" is correct in key details, but they accurately express the popular mourning for these figures. By far the largest number of ballads that can be traced to historical occurrences have to do with local skirmishes and matters of regional rather than national importance. The troubled border between England and Scotland in the 16th and early 17th century furnished opportunities for intrepid displays of loyalty, courage, and cruelty that are chronicled in such dramatic ballads as "Edom o Gordon," "The Fire of Frendraught," "Johnny Cock," "Johnie Armstrong," and "Hobie Noble." Closely analogous to these are Spanish *romances* such as "The Seven Princes of Lara," on wars between Moors and Christians.

Disaster. Sensational shipwrecks, plagues, train wrecks, mine explosions—all kinds of shocking acts of God and man—were regularly chronicled in ballads, a few of which remained in tradition, probably because of some special charm in the language or the music. The shipwreck that lies in the background of one of the most poetic of all ballads "Sir Patrick Spens" cannot be fixed, but "The Titanic," "Casey Jones," "The Wreck on the C & O," and "The Johnstown Flood" are all circumstantially based on actual events.

Outlaws and badmen. Epic and saga heroes figure prominently in Continental balladries, notable examples being the Russian Vladimir, the Spanish Cid Campeador, the Greek Digenes Akritas, and the Danish Tord of Havsgaard and Diderik. This kind of hero never appears in English and Scottish ballads. But the outlaw hero of the type of the Serbian Makro Kraljević or the Danish Marsk Stig is exactly matched by the English Robin Hood, who is the hero of some 40 ballads, most of them of minstrel or broadside provenance. His chivalrous style and generosity to the poor was imitated by later ballad highwaymen in "Dick Turpin," "Brennan on the Moor," and "Jesse James." "Henry Martyn" and "Captain Kidd" were popular pirate ballads, but the most widely sung was "The Flying Cloud," a contrite "goodnight" warning young men to avoid the curse of piracy. The fact that so many folk heroes are sadistic bullies ("Stagolee"), robbers ("Dupree"), or pathological killers ("Sam Bass," "Billy the Kid") comments on the folk's hostile attitude toward the church, constabulary, banks, and railroads. The kindly, law-abiding, devout, enduring steel driver "John Henry" is a rarity among ballad heroes.

Epic and saga heroes

Occupational ballads. A large section of balladry, especially American, deals with the hazards of such oc-

cupations as seafaring ("The Greenland Whale Fishery"), lumbering ("The Jam on Gerry's Rock"), mining ("The Avondale Mine Disaster"), herding cattle ("Little Joe the Wrangler"), and the hardships of frontier life ("The Arkansaw Traveler"). But men in these occupations sang ballads also that had nothing to do with their proper work: "The Streets of Laredo," for example, is known in lumberjack and soldier versions as well as the usual cowboy lament version, and the pirate ballad "The Flying Cloud" was much more popular in lumbermen's shanties than in forecastles.

BALLAD CHRONOLOGY

Singing stories in song, either stories composed for the occasion out of a repertory of traditional motifs or phrases or stories preserved by memory and handed down orally, is found in most primitive cultures. The ballad habit thus is unquestionably very ancient. But the ballad genre itself could not have existed in anything like its present form before about 1100. "Judas," the oldest example found in Francis James Child's exhaustive collection, *The English and Scottish Popular Ballads* (1882–98), dates from 1300, but until the 17th century ballad records are sparse indeed. As an oral art, the ballad does not need to be written down to be performed or preserved; in any case, many of the carriers of the ballad tradition are illiterate and could not make use of a written and notated ballad. The few early ballads' records survived accidentally, due to some monk's, minstrel's, or antiquary's fascination with rustic pastimes.

Precise dating almost impossible

The precise date of a ballad, therefore, or even any particular version of a ballad, is almost impossible to determine. In fact, to ask for the date of a folk ballad is to show that one misunderstands the peculiar nature of balladry. As remarked earlier, the first record of a ballad must not be assumed to be the ballad's original form; behind each recorded ballad one detects the working of tradition upon some earlier form, since a ballad does not become a ballad until it has run a course in tradition. Historical ballads would seem on the surface to be easily datable, but their origins are usually uncertain. The ballad could have arisen long after the events it describes, basing itself, as do the Russian ballads of the Kievan cycle and the Spanish ballads about the Cid, on chronicles or popular legends. It is also likely that many historical ballads developed from the revamping of earlier ballads on similar themes through the alteration of names, places, and local details.

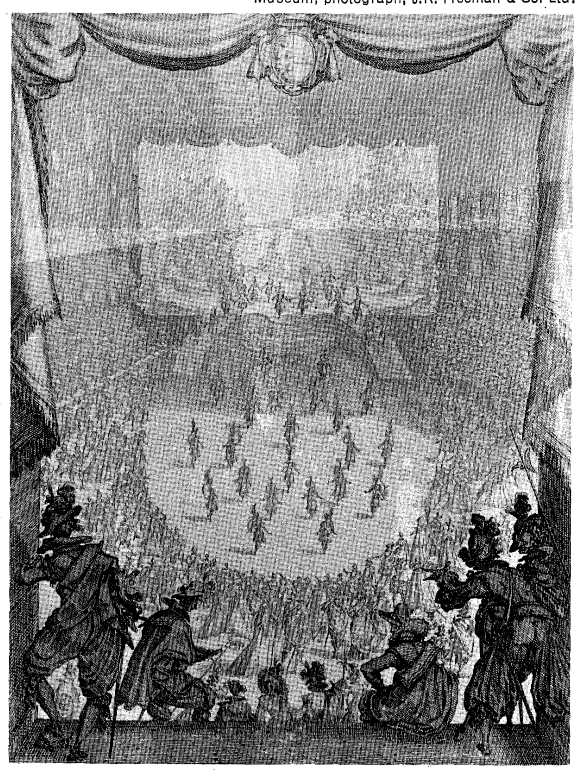
BIBLIOGRAPHY. F.J. CHILD (ed.), *The English and Scottish Popular Ballads*, 5 vol. (1882–98), is the canon of traditional balladry; the tunes for which are supplied in B.H. BRONSON (ed.), *Traditional Tunes of the Child Ballads*, 4 vol. (1959–71). Of the many broadside collections, the most important are *The Roxburghe Ballads*, ed. by W. CHAPPELL and J.W. EBSWORTH, 9 vol. (1871–99); and *The Pepys Ballads*, ed. by H.E. ROLLINS, 8 vol. (1929–32). For a comprehensive sampling of broadsides, see *The Common Muse: An Anthology of Popular British Ballad Poetry, XVth–XXth Century*, ed. by V. DE SOLA PINTO and A.E. RODWAY (1957). Broadside tunes are gathered in C.M. SIMPSON, *The British Broadside Ballad and Its Music* (1966). T.P. COFFIN, *The British Traditional Ballad in North America*, rev. ed. (1963); and G.M. LAWS, *Native American Balladry*, rev. ed. (1964), are valuable bibliographies. Ballad criticism and scholarship are analyzed in S.B. HUSTVEDT, *Ballad Books and Ballad Men* (1930); D.K. WILGUS, *Anglo-American Folksong Scholarship Since 1898* (1959); and A.B. FRIEDMAN, *The Ballad Revival: Studies in the Influence of Popular on Sophisticated Poetry* (1961). Key modern critical essays are C.J. SHARP, *English Folk-Song: Some Conclusions* (1907); G.H. GEROULD, *Ballad of Tradition* (1932); and M.J.C. HODGART, *Ballads* (1950). A.T. QUILLER-COUCH (ed.), *The Oxford Book of Ballads* (1910, reissued 1951); M. LEACH (ed.), *The Ballad Book* (1955); and A.B. FRIEDMAN (ed.), *Folk Ballads of the English Speaking World* (1956), are the standard anthologies.

(A.B.F.)

Ballet

A theatrical art, ballet consists of extremely stylized dancing, usually with musical accompaniment and with stage settings and costumes. A ballet may, through its dance, music, and design, unfold a dramatic plot, or it may be conceived without narrative content, as a visual interpretation of the music by means of dance.

The word ballet derives from the Italian *ballare*, "to dance," but ballet involves a very special kind of dancing and of spectacle. The art of ballet had its beginnings in the 15th and 16th centuries in the spectacular dramatic entertainments of the Italian nobility, who performed these dramas themselves, usually on a theme from antiquity, combining dance, mime, song, and recitation to a musical accompaniment and with lavish settings and costumes. These extravaganzas evolved toward an emphasis on dancing, which became ballet. They sought a "perfect" form of human vocalization and movement. Over the centuries both ballet and opera refined the techniques they inherited from Renaissance court spectacles, becoming widely esteemed as the most elite forms of dancing and singing in the West. Since the 18th century, ballet has been popular outside the circles of its birth. In the 20th century, particularly, it became more widespread through extensive tours by its greatest dancers and companies, through broadened technical and thematic repertoires, and through its presentation in film and on television. It attained unprecedented popularity even where the notion of an aristocracy had become an anathema.



Ballet interlude from the spectacular Florentine opera-ballet *La liberazione di Tirreno e d'Arnea*, engraving by J. Callot after a drawing by G. Parigi, c. 1616. After the formal performance, the cast, composed of nobles, and the court spectators combined for dances on the main floor.

THE AESTHETICS OF BALLET

The history of ballet reveals several shifts of taste between ballet as "pure dance," or the dazzling physical execution of a repertoire of techniques, and ballet as "dramatic dance," or the presentation of a story through the stylized movements of that repertoire. Classic ballet was fully developed during the period of the romantic ballet in the 19th century, even though the terms classic and romantic are generally considered to be opposing categories in the arts. In ballet, the first applies to dance technique, the second to the subject matter of the ballets.

Like the art dance of such nations as India, Japan, and

Indonesia, ballet is based not on random exercises but on a limited collection of positions and movements that must be learned absolutely by the performer before he can add the nuances of his particular skill and personality. This technique developed much like a language. Dancers and choreographers who added to its vocabulary or enriched its subtlety of expression first mastered its existing language. It is not coincidental, therefore, that ballet was transmitted through master-to-pupil sequences.

Periods in which sheer technical virtuosity predominated were generally looked upon as decadent by ballet historians, who tended to favour dramatic expression within a narrative framework. Ballet was in such a "decadent" state when Jean-Georges Noverre, the renowned French choreographer and teacher, published in 1760 his *Lettres sur la danse, et sur la ballet*. These theories, as well as his work, were pivotal in the development of the art. Noverre called for the elimination from ballet of the meaningless gestures that had become conventions and of the leather masks worn by the dancer to indicate love, hatred, and other emotions. About the composition of ballet he wrote

Noverre's dictums

> A well-composed ballet . . . must be expressive in all its detail and speak to the soul through the eyes; . . . Steps, the ease and brilliance of their combination, equilibrium, stability, speed, lightness, precision, the opposition of the arms and legs—these form what I term the mechanism of the dance. When all these movements are not directed by genius, and when feeling and expression do not contribute their powers sufficiently to affect and interest me, I admire the skill of the human machine, I render justice to the strength and ease of movement, but it leaves me unmoved . . . Dancing is possessed of all the advantages of a beautiful language, yet it is not sufficient to know the alphabet alone. When a man of genius arranges the letters to form words, and the words to form sentences, it will cease to be dumb; it will speak with both strength and energy; and then ballets will share with the best plays the merit of affecting and moving, and of making the tears flow, and, in their less serious styles, of being able to amuse, captivate and please. (J.-G. Noverre, *Letters on Dancing and Ballets*, trans. by C.W. Beaumont, C.W. Beaumont, London, 1930.)

The basic principles that Noverre laid down were still considered valid by practitioners and critics of ballet in the late 20th century. The public for ballet, however, was by then so broad as to embrace extremes of both pure and narrative ballet.

Noverre's distinction between the means and the ends of ballet—that is, between technical virtuosity and dramatic experience—is relevant to the concepts of the classic and the romantic in ballet. The term classic ballet refers essentially to the means of all ballet since the 19th century, to the movements and positions that are its formal language—just as the metre, rhyme, number of lines, and closing couplet are an essential language of the Shakespearean sonnet. The dancer and choreographer, like the poet, provide the specific words and their sequence to spell out their thought.

Concepts of classic and romantic in ballet

The term romantic ballet, on the other hand, refers to the ballet, in favour during much of the 19th century, that dramatized tales of nymphs and other forest spirits and was an ideal expression of the ideals of the time. The romantic ballet was deeply influenced by Noverre and his direct descendants, in both technique and subject matter, and during its reign in the 19th century the dancer-choreographer-teachers Carlo Blasis and Enrico Cecchetti were among those who codified the technique of classic ballet as it came to be practiced and taught.

Apart from its theory, ballet is a practical art produced to a rigid schedule of performance by many highly and variously skilled professionals. A fuller picture of the art will emerge from a description of what each of these artists—dancer, composer, librettist, designer, and choreographer—contributes to the finished ballet.

The dancer. The dancer is both the instrument and the instrumentalist of ballet. His or her body must possess a special form of beauty, a physical beauty that an audience will find pleasing and expressive to watch and that can respond to the rigorous physical demands of the art. The height of a female dancer rarely exceeds five feet six inches (168 centimetres), and she must have an attractive and finely proportioned head well set on the shoulders and well-shaped arms and legs. Other essential features include a foot with a fine instep and toes that will serve as a platform for toe (*pointe*) dancing and the ability to turn out a 90° angle from the hips and to achieve a high extension of the legs. The male dancer, taller but rarely over six feet (183 centimetres), must have a finely built body and great strength that is not too much in evidence. He must have the grace of the efficient male athlete, a grace that is not effeminate.

There are different types of dancers. Best known are the ballerina, the pure classic dancer and the most delicate in build, and her male equivalent, the *danseur noble*. The *demi-caractère* dancer is capable of dancing soubrette or supporting roles of great variety. Finally, the "character dancer" undertakes comic or elderly roles or roles that often involve folk dance.

In addition to physical dexterity, the dancer requires a high degree of musicality, and he must be expressive from head to foot. Balletic acting is a thing apart from dramatic acting; it emerges from the dancer's translation of music into visual form as well as from his interpretation of character, period, and situation. The dancer's personality, too, is important; its quality, nearly indefinable in words, becomes obvious when the viewer senses the dancer's movements as controlled by a will rather than by a puppeteer's wires.

The art of balletic acting

The 18th-century French author Voltaire gave as one of his reasons for loving ballet that it was both a science and an art. Only after a dancer has mastered technique, the science of ballet, can he develop as an artist. Toward this mastery serious training usually begins around the age of ten or 11—not, as was once thought, at four or five. The dancer's training is at the same time both exhausting and exhaustive.

The composer. In addition to providing accompaniment to the dancers' movements, music for narrative ballet must also set the scene and provide counterpoint for the action, in effect writing the libretto in musical form. In all the most successful ballets, the score—whether especially commissioned or an existing work—corresponds inevitably to the movement on stage. Ballets have been attempted without music, but, despite their occasional success, such works are regarded largely as tours de force. Many successful ballet scores now exist in their own right as concert works.

In many long-lasting ballets, the composer and choreographer have worked closely together. Outstanding composer–choreographer relations included those of Peter Tchaikovsky with Marius Petipa in the 19th century and in the 20th century of Igor Stravinsky with Michel Fokine and George Balanchine. Working with the impresario Sergey Diaghilev in the 1920s, the French composers Francis Poulenc, Henri Sauguet, and Georges Auric wrote music that was direct and unpadded, that did not attempt to overwhelm the other elements of ballet. Music composed for an existing ballet, such as J.E. Szyfer's percussive accompaniment to Sergey Lifar's *Icare* (1935), was rare.

Among works that have used scores originally written for the concert hall are Michel Fokine's *Sylphides* (1909), which used an orchestrated version of Chopin's piano music; Léonide Massine's *Présages* (1933), to Tchaikovsky's *Fifth Symphony*, his *Choreartium* (1933), to Brahm's *Fourth Symphony*, and his *Symphonie fantastique* (1936), to Berlioz' work of that name. All were controversial but received strong support, as did *Les Sylphides*. Other creators of the so-called abstract ballet (using choreography without narrative lines) include Frederick Ashton, with *Symphonic Variations* (1946), to César Franck's music, and *Enigma Variations* (1968), based on Sir Edward Elgar's work. George Balanchine, long a specialist in this direction, produced many ballets based on existing orchestral or chamber works. The difficulty in all these cases has been to meet the choreographer's requirements without destroying the shape of the original score.

The librettist. Writers on ballet often neglect its dramatic or poetic content. The serious limitations of its narrative capacities can become sources of great strength if properly used.

Limitations of balletic communication

Ballet can speak only in the present tense. Its story must be comprehensible from the stage portrayal alone, not from program notes. Ballet can say, for example, "X did this, Y did that," but so simple a statement as "X is Y's brother-in-law" is beyond its power. In characterization, a man can only display such extreme states as hatred or love, or be jealous or generous, kind or cruel, haughty or subservient, sad or gay: the list is severely limited. Attempts to inject psychological interpretation into ballet have rarely been successful. Since the disappearance of the conventional mask and miming of early ballet, the dancer has been forced to be totally expressive within the limits of the silent medium; and the librettist, communicating only through the movement of the dancer and the music, is in constant danger of being either obvious or obscure.

Ballet can be, however, an art of great subtlety, whether telling a story or suggesting a mood or an atmosphere. The typical romantic ballet of the 19th century told a dramatic narrative, as in *Giselle*, whereas the neoromantic ballets of the early 20th century suggested an aura of romance through, for example, the suite of dances making up *Les Sylphides*. A narrative ballet such as *Petrushka* (1911) can be regarded as a simple child's story, the awakening of a soul, or even a hidden Marxist message. Its creators, Stravinsky and Fokine, repeatedly refused to offer definitive explanations of its "meaning."

The term abstract ballet is much used to describe ballet that is based solely on music rather than on a narrative line. The term is inherently ambiguous, however, for the dancers being human, every *pas de deux* (dance for two performers) may be interpreted as a courtship dance. It is best applied, perhaps, only to the kind of purely rhythmic exercise exploited in certain types of classic Indian dance, like the *bhārata-nāṭyam*.

In the 20th century, the role of the librettist has become less and less significant as choreographers have become more and more inclined to devise their own scenarios. His is now the total conception, and something may have been lost through the exclusion of the poet from the balletic domain.

The designer. The designer must understand the dance intimately. His costumes must be of the correct weight and balance for the steps to be performed, and he must plan the effect of light on materials and the mixture of colours in the choreographer's groupings. Finally, he must be in sympathy with the music, for colour and sound can easily counteract one another. The designer–composer alliance between Marie Laurencin and Poulenc in Bronisława Nijinska's *Biches* (1924), between Pablo Picasso and Manuel de Falla in Massine's *Three-Cornered Hat* (1919), and between Georges Rouault and Prokofiev in Balanchine's *Prodigal Son* (1929) was, in each case, a total artistic collaboration. Many ballets of the recent past and today have no scenery. Many of Balanchine's works, for instance, depend solely on lighting to set the mood.

Contribution of dancers to costuming

Dancers themselves contributed much to the evolution of ballet costuming. The 18th-century ballerina Marie Camargo altered the earlier long, cumbersome skirts to make leg movement easier as well as more visible. In 1729, Marie Sallé and her partner danced without the leather masks that had been customary, but only in the 1770s, under Noverre's influence, was the mask finally abandoned. Around 1838 dancing tights were invented. Although they allowed maximum freedom of movement, they were considered immoral and their acceptance was not immediate. Marie Taglioni was among the earliest dancers to use the shoes with blocked toes, invented around 1820, that permitted *pointe* dancing. In *Giselle* she introduced the midcalf-length skirt that was the prototype for the very short tutu devised by Italian ballerinas in the 1880s.

The choreographer. The choreographer is the direct descendant of the dancing master of the Renaissance, who refined the peasant dances for the courts and taught the nobles grace and style in their movements. The choreographer also recalls early ballet masters like Pierre Beauchamp, who worked with Molière and the composer Jean-Baptiste Lully to produce ballets for the court of Louis XIV of France. In the 20th century his role has become a little like that of the stage or film director, although the choreographer must first fashion what he is going to direct.

Little has been written about the science or art of choreography since 1760, when Noverre wrote his *Lettres* that outraged the leadership of the Paris Opéra, then the centre of European ballet. A seminar on choreography held in Moscow in 1969 confirmed the lack of universally agreed upon standards, but certain attributes have found general acceptance.

Nearly without exception, the choreographer is or has been a dancer, for he must be thoroughly familiar with the vocabulary of classic ballet and with the potentialities and limitations of the human body. Some choreographers collaborate with their dancers to develop a work, others present the fully conceived work almost from the first rehearsal. In either case they must work with dancers each of whom has a distinctive will, personality, and set of performing characteristics. Any important change of cast may significantly alter the work. Even if dance notations were universally accepted, therefore, it would neither alter this situation significantly nor eliminate the need for constant polishing of performances by the choreographer.

Collaboration of choreographer and dancers

The choreographer must also be a well-grounded musician. He must be familiar with the arts and styles of many cultures, primitive and advanced, contemporary and historical. In working with music he must be aware that the eye and the ear respond at different speeds. Petipa's notebooks reveal how close a working relationship he established with Tchaikovsky, who during the choreographing of *The Sleeping Beauty* sat at the piano indicating the exact length of passages.

The rules of composition pertaining in the visual arts govern its choreography: there is constant interaction of foreground and background, of colour and line, and of moving dancers and immobile scenic design. Even static moments in the dance must be expressive, not simply breaks in movement. Ballet choreography requires realism within the limits of its conventions, but stylization is essential. If a river has been established at one part of the stage, the dancers must not walk but make swimming movements at that place. On the other hand, however, if a ballet is set in China, the dancers may use *pointe* dancing even though it is not Chinese.

Finally, the subject selected by the choreographer must be effective theatre and capable of better expression through ballet than any other theatrical medium. If ballet uses subjects from other theatrical forms, it must find original perspectives in them and translate them radically to fit the conventions and means available to the dancer.

HISTORICAL DEVELOPMENT

Origins in the Renaissance. The visual arts of the Renaissance in Italy strove for an idealization of the human body. The courts of the nobility, such as those of the Medici in Florence, vied to outdo one another in their magnificence.

This desire for opulence and the quest for idealization were combined to produce spectacular entertainments for distinguished guests, often several hours in length and consisting of a series of entrées, or pageants of music, poetry (sung or declaimed), pantomime, and dancing hung loosely upon a classical theme. Costumes were lavish, and the settings, whether in a garden or in the centre of the banquet hall, were splendidly designed. One such spectacle, produced in Tortona in 1489, has been called the first actual ballet. Between courses of the feast, members of the nobility presented the story of Jason and the Golden Fleece; the dances were based on the formal styles of the court.

Renaissance ballets

Another candidate for designation as the first ballet was the *Ballet comique de la reine* (1581), presented by Cath-

erine de Médicis, who had brought her musicians from Italy when she became queen of France. The *Ballet comique* told of Ulysses' escape from Circe's wiles, a mythological source typical of ballet librettos for centuries. The word *comique* referred to the gaiety of the occasion (a betrothal) and to the dance's happy ending. The ballet was devised by Catherine's director of court festivals, Baltazarini di Belgioioso, an Italian known in France as Balthazar de Beaujoyeulx. He left a long account of the work, which he referred to as "a geometrical arrangement of many persons dancing together under a diverse harmony of instruments."

Renaissance court ballet.
(Top) The prologue from the *Ballet comique de la reine*, choreographer, Balthazar de Beaujoyeulx, engraving by J. Patin, 1581. Three-dimensional sets representing Circe's garden and palace (arranged around the ballroom) moved on rollers in order to be seen from at least three sides. (Bottom) English masque as seen in the portrait of Sir Henry Unton, oil on a panel by an unknown artist, c. 1596. In the National Portrait Gallery, London.

This statement might serve as a partial definition of choreography at the time. It was a period in which the idealizations of the earlier Renaissance assumed in the visual arts an extreme stylization that became known as mannerism. Ballet, certainly, was mannered. Belgioioso's stress on geometry was of interest. The long, cumbersome costumes limited the dancers, and without the elevations, toe steps, and leaps developed by future generations, attention was focussed on the ground patterns.

The *Ballet comique* cost 3,600,000 francs and represented a great change from the banquet intermezzi. For the next century such court entertainments were danced by aristocratic amateurs under the direction of ballet masters. Louis XIII injected bawdy humour into the productions. In England, the Italian masquerades introduced during the reign of Henry VIII evolved into the masque. This form was closely akin to the French ballet; its master librettist, the poet and dramatist Ben Jonson, owned a copy of the *Ballet comique*. In 1632 performances were opened for the first time to the general public.

17th century. In France, the building of the Palais Cardinal (1636) changed ballet history. The dance moved from the ballroom to the theatre, and both the audience's angle of vision and the placement of stage scenery were permanently altered.

Louis XIV's influence on ballet

A number of circumstances turned an aristocratic pastime into a profession. The young Louis XIV, the future "Sun King," was bored with opera, for he loved dancing and at 13 had performed a leading role. He gathered about him outstanding artists from many mediums: the dramatist Molière, the poet Isaac de Benserade, the composer Jean-Baptiste Lully, and his own dancing master and intimate, Pierre Beauchamp. Molière demanded complete devotion to dancing, but he was often forced to introduce awkward intermissions for costume changes so he could use his few trained dancers in several roles. In 1661, Louis created the Académie Royale de Danse, comprising the dancing masters of the nobility with Beauchamp as chairman.

The preamble to the letters patent of the Académie's foundation, written by Louis, was the first full recognition of the art of ballet.

> Although the art of dancing has always been recognized as one of the most honourable and most necessary for the training of the body . . . many ignorant persons have tried to disfigure and spoil it . . . so that we see few among those of our court and suite who would be able to take part in our ballets . . . Wishing to establish the said art in its perfection and to increase it as much as possible, we deemed it opportune to establish in our good town of Paris a Royal Academy of Dancing.

The members of the new Académie, most of them illiterate, left no written records, but they systematized the techniques recognized at that time. The success of the undertaking prompted Louis to set up the Académie Royale de Musique in 1669 and a dancing school in 1671. These institutions, combined as the Académie de Musique and known as the Paris Opéra, were the major cradle of ballet and remained a centre of ballet production through succeeding centuries.

Innovations of the Académie

The school rapidly brought about many changes. Originally the ladies of the court took part only as a decorative background; as in the Elizabethan theatre, female roles were performed by men. Women first appeared professionally in Lully's *Triumph of Love* (1681); its ballerina, Mlle Lafontaine, was quickly acclaimed "queen of the dance." There was also an extension of balletic techniques. Pierre Beauchamp, who had danced in *The Triumph*, clarified styles of turns and elevation and codified the five positions of the feet that remained basic to ballet.

The form of ballet also received attention. The French ballet was still a mixture of dance and music with singing and declamation, whereas the English masque had taken the path of poetic drama, and in Italy singing predominated. In 1708, at a fete given by the Duchess du Maine, Françoise Prévost and Jean Balon (Ballon) danced and mimed without words the last act of *Les Horaces*, based on Pierre Corneille's tragedy *Horace;* the audience is said

Pierre Beauchamp's *The Triumph of Love*, 1681, with set and costumes by Jean Berain, and music by Jean-Baptiste Lully, engraving by Daniel Marot (1663–1752). Originally Beauchamp danced the feminine role in a *pas de deux* with Louis XIV, but later gave his part to the first ballerina, Mlle Lafontaine.

to have been moved to tears. At about the same time, John Weaver was making similar experiments in dramatic dancing in England. Probably influenced by the pantomimes of John Rich, a famous Harlequin and rival producer, Weaver staged such narrative ballets as *The Cheats of Scapin, or, The Tavern Bilkers* (1702) and *The Loves of Mars and Venus* (1717).

18th century. The rivalry of Marie Camargo and Marie Sallé in the first half of the 18th century increased public interest in the dance. Both ballerinas altered ballet technically and aesthetically. The shortened skirts and heelless slippers of "la Camargo" permitted leg extensions not previously possible, as well as the perfection of the *entrechat*, a leap during which the feet are crossed rapidly. Her favourite vehicle was the plotless divertissement, a series of solo minuets, courantes, sarabands, gigues, and other dances in contrasting styles.

In contrast to Camargo's balletic agility, Marie Sallé emphasized the dramatic potentialities of the dance. She studied with Rich in London and, in 1734, danced in the dramatic ballet *Pygmalion* with a loosely draped costume and flowing hair. Sallé's attempts to unify music, costume, and dance, as well as her interest in the dramatic, anticipated Noverre's reforms by a quarter of a century.

Technical virtuosity of 18th-century dancers

Camargo's dances of purely decorative beauty and virtuosity and Sallé's dances seeking the utmost dramatic expression were typical of the polarities in 18th-century ballet. The dancers at the Paris Opéra, including such brilliant performers as the three Dumoulin brothers, Jean-Barthélemy Lany, and Louis Dupré, continued to perfect their techniques. Appearances by Italian acrobats and comic dancers in Paris further stimulated an emphasis on physical display. Gaetano Vestris perfected the broad, high leap, or *grand jeté*, and elaborated on the multiple turn known as the *pirouette*. By 1800 male dancers were executing spectacular leaps and series of *pirouettes*.

This dazzling virtuosity presented a danger noted as early as 1741 by St. Mard in his *Reflections sur l'Opéra:* the dancers, he complained, lacked both variety and intelligence and were like "cardboard that is made to move like machines." Despite such strictures and the work of such ballet masters as Jean Baptiste de Hesse, who staged pantomimic ballets at the Théâtre Italien, Paris, and trained his students as dance actors, the Opéra became by the middle of the 18th century a bastion of technical purity. Its dancers offered entertainment without involvement.

Noverre, the teacher of a generation of great dancers, published his *Lettres* in 1760. His ideas were rejected at the Opéra, and he spent 16 years choreographing in Stuttgart, London, Vienna, and Milan. A curious Gaetano Vestris observed him in Stuttgart, danced in his ballets, and brought a version of his *Medée et Jason* to the Opéra in 1770. When Vestris discarded the leather mask as Jason, other dancers soon followed. Despite opposition, Noverre's ideas prevailed and he was called to the Opéra in 1776. There he found an ideal interpreter of his *ballets d'action* in the ballerina Madeleine Guimard. His pupils Jean Dauberval and Charles Le Picq carried his ideas throughout Europe. In 1789 Dauberval produced *La Fille mal gardée*, which was still in the ballet repertoire of the late 20th century and, next to Vincenzo Galeoti's *Whims of Cupid and the Ballet Master* (1786), was the oldest work in performance.

Although Noverre was the most influential innovator, the Italians Gasparo Angiolini and Salvatore Viganò also furthered dramatic, narrative ballet. Angiolini, who concurred with Noverre's theories but thought his ballets obscure, collaborated with the German composer Christoph Willibald Gluck in the ballets *Don Juan* (1761) and *Semiramide* (1765) and choreographed the dances for the opera *Orfeo ed Euridice* (1762). Gluck's experiments in opera were further aided by work with Noverre himself on *Iphighénie en Tauride* (1779). Viganò, a nephew of the composer Luigi Boccherini and a student of Dauberval, worked mainly at La Scala theatre in Milan, where he built the roles of his dancers in the manner of a stage director, assigning them individual characteristics. Typical of his heroic works, which were designed on a grand scale, was *Otello* (1818). For Viganò Beethoven composed his only ballet score, *The Creatures of Prometheus* (1801).

Romantic and classical traditions in the 19th century. The Romantic spirit found in the arts of the early 19th century was expressed in the dance with the production of *La Sylphide* at the Paris Opéra in 1832. This ballet, danced by Marie Taglioni and choreographed by her father, Filippo Taglioni, permanently changed the art and

Medée et Jason, choreography by Gaetano Vestris in 1770, adapted from the original ballet by Jean-Georges Noverre, engraving by John Boydell, 1782. Vestris as Jason (centre), Adelaide Simonet as Medea (right), and Giovanna Baccelli as Creusa (left) appear without the traditional leather masks in Boydell's caricature of the tragic ballet.

ushered in what has been called the "golden age of ballet."

"After *La Sylphide*," wrote the French critic Théophile Gautier,

> . . . the Opéra was given over to gnomes, undines, salamanders, nixes, wilis, peris—to all that strange and mysterious folk who lend themselves so marvellously to the fantasies of the ballet master.

Greek mythology and sunlight gave way to the spirit-haunted, moonlit, and mist-covered forests of Europe. Costuming underwent rapid change to accommodate the new subjects and the seemingly disembodied dancing of Taglioni and her successors, and the music came into closer rapport with the action. The most drastic innovation of the age was dancing *sur les pointes*, on the tips of the toes, essential for the portrayal of sylphs, naiads, and bird-women.

Gautier, who became high priest of the movement, condemned the male dancer as essentially coarse and unromantic. With some notable exceptions the male was virtually swept from the ballet stage outside Russia and Denmark. Consequently, audiences of the period watched ballerinas, many of whom became legends. Taglioni and Fanny Elssler reproduced the Camargo–Sallé rivalry of a century earlier. Carlotta Grisi created the title role in *Giselle* (1841), usually considered, with *La Sylphide* and Saint-Léon's *Coppélia* (1870), the finest achievement of the romantic ballet outside Russia. In 1845, together with the equally renowned dancers Fanny Cerrito and Lucile Grahn, Taglioni and Grisi appeared in London in Perrot's *Pas de quatre*, a gathering of brilliance rare in any period.

Contributions of Carlo Blasis

In Italy, Carlo Blasis, a prolific writer as well as a choreographer, codified the techniques of classic ballet in his *Elementary Treatise Upon the Theory and Practice of the Art of Dancing*, published in 1820. Ten years later, his *Code of Terpsichore* advised young dancers of the rigours demanded by the dance and of the vitality their work must exhibit. His school at La Scala, which he conducted from 1837, attracted both students and such famous dancers as Cerrito and Grisi.

Ballet historians regard the last third of the 19th century as a period of decadence in the art, much like the one that Noverre had first denounced and then transformed. The romantic subject matter, new in *La Sylphide* and *Giselle*, was endlessly repeated, as Greek mythology had been before. The replacement of square-blocked shoes by the satin slippers made ballet and toe-dancing synonymous, and the neglect of ensemble dancing for the brilliant virtuosity of the ballerina deprived ballet of artistic unity.

Only Denmark and Russia were immune from these excesses. Antonio Sacco and Vincenzo Galeotti had established dramatic ballet on the Danish stage before 1800, but the prime architect of the Royal Danish Ballet was Auguste Bournonville. A native Dane, Bournonville in 1829 brought to Copenhagen the preromantic style of the Paris Opéra, which emphasized masculine virtuosity and expressive mime. The tradition was meticulously preserved by Bournonville and his successors.

Early history of Russian ballet

On the continent of Europe, however, empty formulas might have destroyed ballet as a serious art had it not been for the Russian ballet. The westernization of Russia begun by Peter the Great in the early 18th century brought the European court dance to the newly founded capital city of St. Petersburg. The old-guard nobles, who held one masquerade lasting a week, were compelled by the Emperor to modify their costumes and dance the minuet with the court ladies. The early history of French ballet was repeated, and again it was only a short step from court to theatre. In 1734 the empress Anna brought Jean-Baptiste Landé from France to organize a school, "to give instruction to the young people under his charge, to teach them with honesty, sincerity, seriousness and all the qualities of a good man." His pupils were the children of the poor.

By 1740 the Imperial School of Ballet was established at the Winter Palace, and Russian soloists appeared in a fully established company. Such teachers and choreographers as Franz Hilverding—Noverre's successor at Stuttgart—Angiolini, and Le Picq were brought to Russia by Catherine the Great and Alexander I. The half million rubles expended on the scenery for one ballet suggested the exuberance of the Russian balletomane. Ivan Valberg became the first Russian choreographer, but it was the Frenchman Charles Didelot who, after 1801, created the grand spectacles that remained hallmarks of Russian ballet. The Taglionis as well as Elssler, Cerrito, Grahn, and Grisi appeared in St. Petersburg. There is some evidence that the ballerina Mariya Danilova, who died at 17, was the first Russian to use *pointes*.

The vigour of the Russian ballet, even throughout the period of decline elsewhere, was attributable in some part to its assimilation of native Russian materials. Apart from the imperial companies, nobles sponsored companies composed of their serfs. To them, the Russian folk dance, not the foreign, was the living reality. The Imperial Russian Ballet constantly renewed itself, by purchase and legacy, from these companies. In 1829 the Moscow ballet, now the Bolshoi Ballet, founded in 1825, acquired 21 dancers from a Mr. Rzhevsky, and after 1824 serfs of the imperial theatres were emancipated, nearly 50 years before emancipation became general.

The allegation that Russian ballet was the product of foreigners thus requires modification, for it was very Russian in character from the start of the 19th century. The indigenous dance influenced the foreign teachers themselves, most notably the Russianized Auguste Poirot, who spent 30 years studying Russian dance and incorporating it into ballet. The ballerina Ylena Andreyanova, who rivalled Taglioni when she danced in Paris and Milan, lent a special quality to *Giselle* in 1842. Gautier praised the serious outlook of the Russian dancers. Critics pointed to the softening influence of the Russian temperament on the brilliant but sometimes brittle Italian dancers.

Petipa's influence on the Russian ballet

The major foreign influence on Russian ballet came from the Frenchman Marius Petipa, the Swede Christian Johansson, and the Italian Enrico Cecchetti. Petipa, whose brother Lucien was one of the few outstanding male dancers of the romantic period, came to Russia in 1847. He became virtual dictator of Russian ballet from his appointment as choreographer in 1862 until his return to France in 1910. His output included 57 full-length ballets, 34 opera ballets, and 17 revivals. His greatest triumphs were the Tchaikovsky ballets, although some of

their most effective passages were the work of a Russian, Lev Ivanov. Petipa's original choreography of *Swan Lake* (1895)—Act II was Ivanov's work—and *The Sleeping Beauty* (1890), and his versions of *Giselle* and *Coppélia* remained in the repertoire of most ballet companies in the U.S.S.R. and elsewhere.

Christian Johansson, trained by Bournonville, came to St. Petersburg in 1841 as a dancer. His major contribution was as principal teacher at the Imperial School of Ballet, where he formed an entire generation of ballerinas. The international character of ballet is nowhere so clear as in the case of Cecchetti. He first visited Russia in 1874 and returned 13 years later with an Italian company for a summer of dancing. The technical brilliance of his dancers dazzled the Russians, who were accustomed to the gentler grace of their Franco-Russian ballet. Pierina Legnani created the role of Odette in *Swan Lake*, and Cecchetti himself danced the bluebird in *The Sleeping Beauty*. He remained for 15 years as dancer and teacher before going on to Warsaw and London.

Early 20th century. When the initial impetus for a great movement slows down, innovation may cease and inspiration may become a formula. This occurred toward the end of Petipa's reign, certainly by 1903, when his *Magic Mirror* was a failure. The audiences of St. Petersburg were connoisseurs of the dance, critical of each step but no longer interested in choreography.

The Diaghilev period. A new direction was provided by Sergey Diaghilev, a man who was neither dancer, composer, poet, designer, nor choreographer. As a law student in St. Petersburg, Diaghilev became part of a group of avant-garde writers, painters, and musicians who called themselves "the Pickwickians of the Neva." They aimed to take the best in the Russian arts to the West and to overturn the academicism that insisted that every picture tell a story. Not at first concerned with ballet, they were redirected by two events. The first was the dancing of the Italian Virginia Zucchi, which demonstrated to "Pickwickian" Alexander Benois the potentiality of a great dancer given the right work. The second was the appearance in Russia of the American Isadora Duncan, dancing in flowing costumes to the music of the great composers. She aroused fierce controversy between the connoisseurs and the reformers. Diaghilev led ballet on a middle path, and Duncan became a major force behind what came to be known as modern dance.

Role of Isadora Duncan

In 1909, Diaghilev organized a troupe of Russian dancers to present a season in Paris. As choreographer he chose Michel Fokine, whose student work had been acclaimed but who found himself denied the limelight that Petipa still commanded. As early as 1904 Fokine had restated Noverre's principles and elaborated them. Ballet would no longer be broken into separated dances but would flow without interruption, like Wagnerian opera. Dancing would vary in style with the demands of the theme and be the sole means of expression, disdaining conventionalized mime. Most important, the several arts of ballet were to be equal partners and the style was to be consistent in all elements. As a result, the full-length ballet, with its padding and its dances interpolated to show off a particular ballerina, was abandoned.

The French public was accustomed to isolated stars and to buxom women dancing male roles, but not to the homogeneous ensemble dancing of the Polovtsian warriors in the fierce *Prince Igor* nor to the reintroduction of the leading male dancer by Vaslav Nijinsky in *Petrushka*. This first phase of Diaghilev's life as impresario consisted of the neoromantic choreography of Fokine in those and such other works as *The Firebird* (1910), *Scheherazade* (1910), and *Le Spectre de la rose* (1911). All of them were intensely Russian and had the scenic design of Alexandre Benois, Léon Bakst, and others.

Dancing and choreography of Nijinsky

A bridge in Diaghilev's career occurred when Nijinsky became a choreographer as well as a dancer. The scandal of his *Afternoon of a Faun* (1912) was dwarfed by that of *The Rite of Spring* (1913), when Stravinsky's music, considered incomprehensible, caused a fashionable Parisian audience to riot.

Following the disruptions of World War I and tours through America and southern Europe, the choreography of Léonide Massine provided a new aesthetic direction. Varying national styles assimilated in the travels of the Diaghilev troupe appeared in such Massine works as *The Three-Cornered Hat* (1919) and *Pulcinella* (1920). Cut off from Russia by the Revolution, Diaghilev made Paris his artistic centre, commissioning designs from such painters as Picasso, Rouault, Matisse, and Derain.

Original design by Léon Bakst for *Scheherazade*, 1910. In the Musée des Arts Décoratifs, Paris. The other artists contributing to this Diaghilev production were: Michel Fokine, choreographer; Nikolay Rimsky-Korsakov, music; Alexandre Benois, book; Ida Rubinstein, Vaslav Nijinsky, and Enrico Cecchetti, principal dancers.
Marc Garanger

Diaghilev animated a group and reformed an art; he had a counterpart who popularized ballet and inspired a generation of dancers. The solitary genius Anna Pavlova left Russia in 1907 and toured her company over the globe. Tirelessly dedicated to the dance, she performed on stages large and small, good and bad, in villages and capitals, bringing ballet to people who had never suspected its existence. It has been said that she, rather than Diaghilev, was the guardian of the traditions of ballet.

(A.L.H.)

Ballet since Diaghilev. The immediate heirs of Diaghilev were René Blum, who was in charge of the ballet in Monte-Carlo from Diaghilev's death in 1929 until the Nazi invasion of France in 1940, and Colonel W. de Basil, who formed a rival Russian ballet company in Paris, went into partnership with Blum in 1932, and later separated from him again. From the early 1930s until after World War II, these and various other allegedly Ballets Russes companies toured the world. The Blum–de Basil company first visited the United States in 1933, and a rival company run by Sergey Denham made its home there during and after the war. Such Diaghilev choreographers as Fokine and Massine worked with these companies and new Russian dancers emerged. In particular the de Basil company became famous for its teenage "baby" ballerinas—Irina Baronova, Tatyana Ryabushinska, and Tamara Toumanova—who were all trained by the former St. Petersburg ballerina Olga Preobrajenska in Paris. The Ballets Russes were instrumental in bringing ballet to many new audiences and in keeping the love of ballet alive. One of de Basil's dancers, Édouard Borovansky, eventually settled in Australia and started the first ballet company there. After his death in 1959 the company was run by Dame Peggy Van Praagh, who was later joined by Sir Robert Murray Helpmann.

The days of privately run touring ballet companies were, however, numbered, and the more influential heirs of Diaghilev were those who created or directed permanent national companies in London, Paris, and New York. It took all the genius of a Diaghilev to maintain creativity and artistic integrity without a permanent home or a public subsidy; recent imitators, including the late Marquis de Cuevas in France and Rebekah Hark-

ness in the United States, though they succeeded in running popular companies at their own expense, did not contribute anything lasting to the art of ballet.

The French national ballet

The French national ballet, which had fallen into decline, received a new lease of life from Sergey Lifar, one of Diaghilev's stars, who was principal dancer, choreographer, and artistic director at the Paris Opéra from 1932 until 1958. His choreography did not on the whole find much favour outside France, but during his reign ballet gained an important status in Paris. A large number of dancers trained at the Opéra became international stars, in some cases going on to form companies of their own. Roland Petit, for example, left the Opéra in 1944 to form Les Ballets des Champs-Elysées. For some time he was regarded as the most important young choreographer in western Europe, producing *Les Forains* (1945), *Le Jeune Homme et la mort* (1946), and *Carmen* (1949), among other works. Unfortunately, French ballet went back into decline toward the end of Lifar's regime.

Great Britain and the United States. In Britain and the United States, on the other hand, ballet can be said virtually to have been born after the death of Diaghilev. British ballet was largely the creation of two remarkable women, Dame Marie Rambert and Dame Ninette de Valois. Neither was English—Rambert was born in Poland and de Valois in Ireland. Both had served their apprenticeships with Diaghilev and benefitted from the appetite for ballet he had created, though they suffered at first from the public's belief that ballet must be Russian. Rambert did not have the ability, or maybe the will, to create a large organization, but her Ballet Rambert nurtured the two most important choreographers in the first decade of British ballet, Frederick Ashton and Antony Tudor, and many of the dancers she trained went on to become stars elsewhere. De Valois had the apparently hopeless vision of creating a British national ballet. Later, she had the satisfaction of watching the tiny Vic-Wells Ballet she started in 1931 grow into the Sadler's Wells Ballet and then into the present Royal Ballet, based at the Royal Opera House, Covent Garden, London, and recognized as one of the world's major companies. The Vic-Wells started with British dancers inherited from Diaghilev, notably Dame Alicia Markova and Anton Dolin; de Valois soon acquired the services as choreographer of Frederick Ashton, and she also did choreography for the company herself, her *Rake's Progress* (1935) being an outstanding work in a truly English idiom. Tudor spent most of his later career in the United States, though his early British ballet *Lilac Garden* (produced for Marie Rambert's Ballet Club, 1936) is still his most successful and best known work.

Balanchine's role in American ballet

In the United States, another Diaghilev protégé, George Balanchine, founded the School of American Ballet in 1934. Since then, in close association with Lincoln Kirstein, a businessman, he has directed various ballet companies, culminating in the New York City Ballet, formed in 1948. Just as the Sadler's Wells Ballet achieved international recognition when it appeared at the Metropolitan Opera House, New York, in 1949 on the first of what were to become almost annual visits, so New York City Ballet took its place among the world's leading companies when it appeared in London at Covent Garden in 1950. It acquired a permanent home in 1964 at the new New York State Theater in New York City's Lincoln Center for the Performing Arts.

The distinctive styles of the Royal Ballet and of New York City Ballet are the result of years of work with their respective resident choreographers, Ashton and Balanchine. The other major American company, Ballet Theatre (now the American Ballet Theatre), founded in 1939 by Lucia Chase and Richard Pleasant, has always had a more eclectic repertoire and a wider range of styles, making it closer to the Ballets Russes tradition. During and immediately after World War II, Ballet Theatre was the most important American company, and it was the first one to dance at Covent Garden and in the U.S.S.R. But it never had a permanent home and always depended on private finance. In 1971 it became one of the official companies in residence at the new John F. Kennedy Center for the Performing Arts in Washington, D.C.

Not only have Ashton and Balanchine created vast and varied repertoires for their own companies; they have also influenced the whole development of ballet in the Western world. Ashton's style might be described as a romantic approach to classicism. His most popular work, *La Fille mal gardée*, is a re-creation of a French ballet first staged in 1789. He has also made three-act works to Prokofiev's scores for *Cinderella* and *Romeo and Juliet* and to Hans Werner Henze's especially commissioned *Ondine*. Among his most successful short ballets have been abstract works like *Symphonic Variations* and *Monotones*, lighthearted divertissements like *Les Rendezvous, Les Patineurs*, and *Jazz Calendar*, and narrative ballets like *Daphnis and Chloë* and *Enigma Variations*. He played a crucial part in the development of Margot Fonteyn, the first ballerina to emerge from within de Valois' organization, and he created many roles with lyrical and technically demanding *pas de deux* for her and her successive partners, Sir Robert Helpmann, Michael Somes, and Rudolf Nureyev.

Ashton's choreographic style

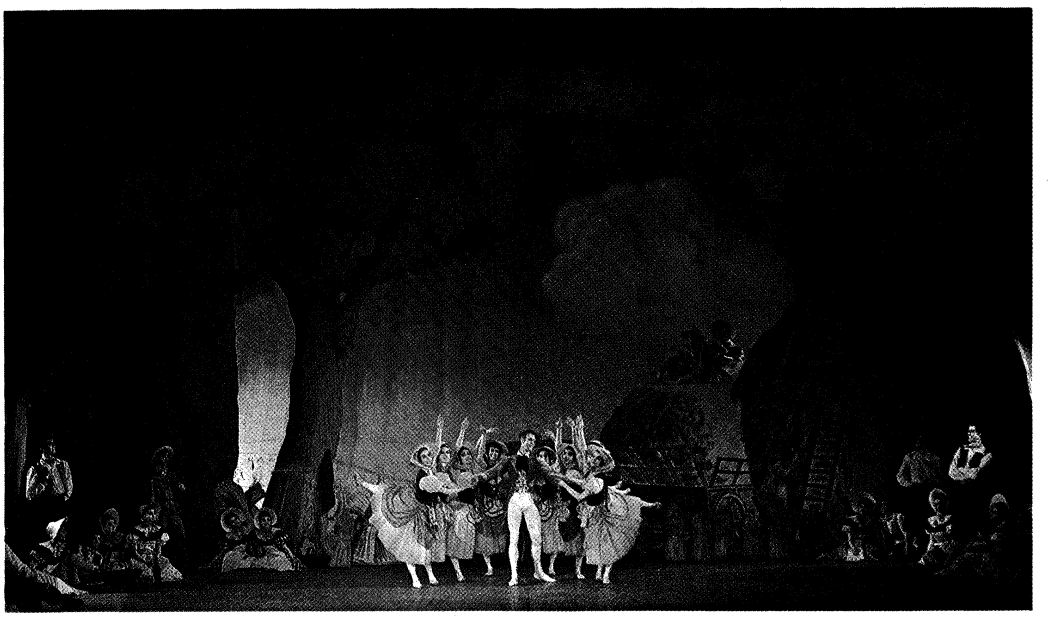
Ashton's success in making three-act ballets, which had not previously been attempted by Western choreographers, influenced the younger British choreographers John Cranko and Kenneth MacMillan to follow the same path. Cranko made *The Prince of the Pagodas* to an especially commissioned score by Benjamin Britten, and in Stuttgart, where he became director of the ballet in 1961, he created several full-length ballets. MacMillan created *Romeo and Juliet* and *Anastasia* for the Royal Ballet, of which he succeeded Ashton as director in 1970.

The creation of new full-length works, and new versions of 19th-century classics, is one of the surprising developments in ballet since the early 1950s. The other is the great popularity of abstract, pure dance works, largely inspired by Balanchine. (Nineteenth-century classics and the idea of dance for its own sake were once thought to have been killed by the Diaghilev–Fokine revolution.) Although Balanchine has created full-length story ballets, he is mainly associated with plotless works in which dancers simply move to music. His genius lies in his ability to make every sort of music—from Bach, Mozart, Tchaikovsky, and John Philip Sousa to Charles Ives, Anton von Webern, and Yannis Xenakis—seem as if it were written for ballet. His special sympathy and close friendship with Igor Stravinsky resulted in a long series of ballets and led him to devise new styles of movement to match the percussive, nonmelodic scores of the composer's later period. One of Balanchine's favourite devices was to choreograph a symphony or concerto using different dancers for each movement. He was generally more interested in choreography for women than for men, and there developed a "Balanchine-type" of ballerina—young, long-legged, fast-moving, technically brilliant, but usually rather lacking in personality. In general, Balanchine's works were more coolly classical, less sentimentally romantic, than Ashton's.

Heirs of Ashton and Balanchine

Just as Ashton's heirs are Cranko and MacMillan, so Balanchine's are Jerome Robbins and a number of younger American choreographers, especially John Clifford, Eliot Feld, and John Neumeier. Robbins first achieved prominence in 1944 with *Fancy Free*, a ballet derived from the style of Broadway musicals. He is perhaps best known for his direction and choreography of the musical *West Side Story*, but he also created abstract classical ballets, among them *Dances at a Gathering* and *Goldberg Variations*. Clifford, working with New York City Ballet, Feld with his own American Ballet Company, and Neumeier, in Frankfurt, West Germany, all created promising works in this style.

These are just some of the choreographers who contributed to the mid-20th-century ballet boom. In the West, it centred on Britain and the United States, where regional ballet began to flourish. Classical companies, often working in association with Balanchine, were especially successful in Washington, Philadelphia, Boston, and Salt Lake City, but there were also many others, and dance departments were established in many American univer-



La Fille mal gardée. Sir Frederick Ashton created a new version of the 18th-century Dauberval ballet in 1960, with the music of François-Joseph Hérold adapted by John Lanchbery, and decor by Osbert Lancaster. Performed by the Royal Ballet.
Houston Rogers

sities. In Britain, small regional companies were set up in Glasgow and Manchester. There were also touring companies in both countries. In the U.S., the City Center Joffrey Ballet had an eclectic repertoire of standard 20th-century works and new ones—including some multimedia experiments—by Robert Joffrey and Gerald Arpino, the company's directors. In Britain, London's Festival Ballet relied mainly on the classics.

Modern European ballet. The ballet boom extended to many other countries. Classical ballet companies were attached to virtually every German opera house, and, under Cranko, the Stuttgart company won international recognition. British influence was also dominant in establishing the Australian Ballet and the National Ballet of Canada. British ballet masters worked in Scandinavia, Turkey, Israel, Argentina, and many other countries. Balanchine lent the ballet in Geneva, Switzerland, ballet masters and dancers, and he also advised the company in West Berlin.

In Belgium, the French-born choreographer and producer Maurice Béjart staged large-scale dance spectacles in sports arenas and circuses as well as in the opera house. Béjart directed a large company of talented dancers with a particular appeal to young audiences. The ballet companies at La Scala, Milan, and the Vienna State Opera have inevitably taken second place to the opera, but even these companies gained status in recent years.

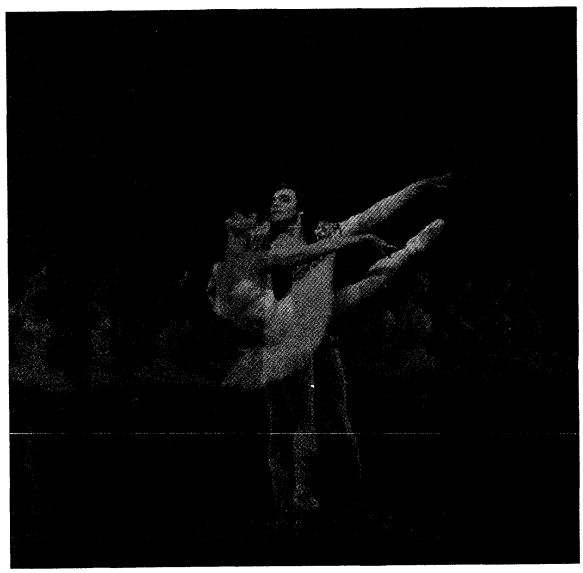
Members of the street gang the "Sharks" dance the choreography of Jerome Robbins to the music of Leonard Bernstein in *West Side Story*, film version, 1961.

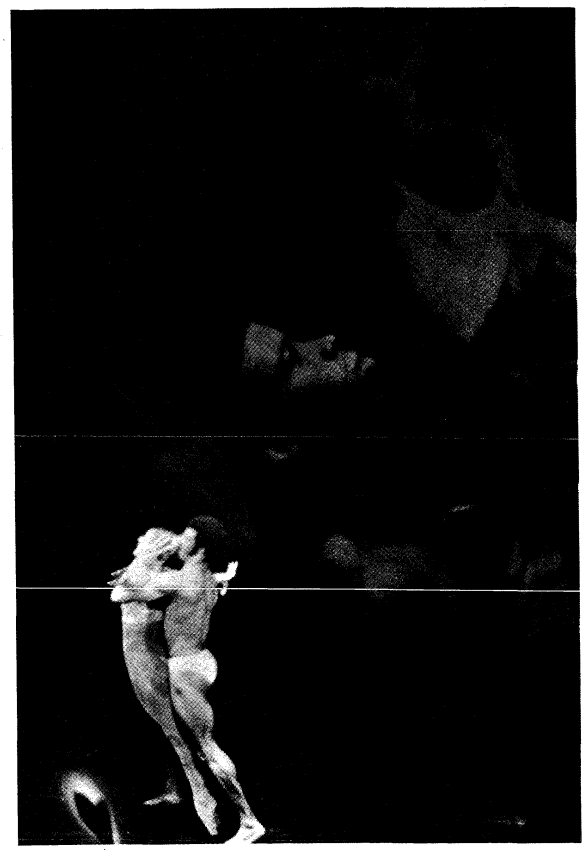
The Scandinavian companies

Great efforts were made to revive and strengthen the ballet companies in Norway, Finland, and Sweden; the Royal Swedish Ballet, one of the oldest companies in the world, benefitted from regular work with the British ballet mistress Mary Skeaping, the choreographer Antony Tudor, and the Danish *premier danseur* Erik Bruhn, who was director of the company from 1967 to 1971. The Royal Danish Ballet is even older than the Swedish and is the only Scandinavian company in the top international class. It preserves the charming and romantic 19th-century works created for it by Auguste Bournonville. Under its director, Flemming Flindt, the Royal Danish Ballet broadened its repertoire to include representative modern works in all styles, as well as preserving and sometimes restaging the Bournonville works.

Modern ballet in Soviet Russia. The Soviet government encouraged ballet companies in many provincial cities of the U.S.S.R. and helped to establish and maintain ballet in the east European Communist countries. Soviet companies made frequent visits to the West, and the Soviet style of dancing—more flamboyant and acrobatic than the traditional style inherited from Petipa—influenced Western dancers and choreographers. The former Leningrad dancer Rudolf Nureyev played a vital role in raising standards of male dancing and in staging various works by Petipa that had been forgotten outside Russia.

Immediately after the Revolution, ballet masters in the U.S.S.R. experimented with avant-garde styles and tried to give political content to their work, but under Stalin Soviet ballet reverted to a more traditional form. It concentrated on the 19th-century classics and on such neoclassical works as *Romeo and Juliet* and *Cinderella.* Soviet choreographers have attempted to modernize the classics by replacing conventional mime with naturalistic acting and by giving the principal male characters more dancing. Soviet productions of *Swan Lake* often end with the Prince killing Rothbart and "living happily ever after" with Odette, as the arts in the U.S.S.R. are intended to be uplifting and Russian audiences today are not supposed to believe in life after death. One recent full-length work, Yury Grigorovich's version of *Spartacus* (1968), succeeded in telling a revolutionary story entirely through dance and exploited the virility and athleticism of Russian male dancers in a new and exciting way.





Classical and experimental ballet in the 20th century.
(Left) The Bolshoi Ballet performs Aleksandr Gorsky's 1911 restaging of the 1895 version of *Swan Lake*, with choreography by Marius Petipa and Lev Ivanov and music by Peter Ilich Tchaikovsky. (Right) *Astarte*, Robert Joffrey's psychedelic *pas de deux*, was composed in 1967 as a multimedia work combining ballet with film, light, and rock music. Performed by the City Center Joffrey Ballet.

Experiment of a more determinedly avant-garde kind became common in the West during the late 1960s and early 1970s. Especially in the United States, Britain, Belgium, and The Netherlands, producers and choreographers used electronic and concrete music, tried to achieve psychedelic effects with stroboscopic and projected lighting, and combined speech, song, and technical effects in an effort to break down the barriers between dance and other forms of theatre. In accordance with similar trends in the theatre and cinema, dancers were presented in the nude and realistic imitations of various sexual activities were devised. It is not yet clear whether these trends will lead to the emergence of a new form of ballet, or a new art form, or whether they will be largely forgotten like the similar experiments of the 1920s. It may be significant that the world's leading ballet companies and choreographers still preferred evolution to revolution and still put their faith in traditional styles and techniques and that audiences continued to flock to see their work. (O.Ke.)

BIBLIOGRAPHY. The most comprehensive general reference books on ballet are: ANATOLE CHUJOY and P.W. MANCHESTER (eds.), *The Dance Encyclopedia* (1967); and G.B.L. WILSON (ed.), *A Dictionary of Ballet*, rev. ed. (1961). Histories of ballet include books covering the entire history as well as those devoted to ballet in specific countries or historical periods. Some authoritative general histories are: ARNOLD L. HASKELL, *Ballet* (1938), *A Picture History of Ballet* (1954), and *Ballet Retrospect* (1964); LINCOLN KIRSTEIN, *Dance: A Short History of Classical Theatrical Dancing* (1935); and JOAN LAWSON, *A History of Ballet and Its Makers* (1964).

Books on ballet history that are devoted to single countries and periods include: CYRIL W. BEAUMONT, *A History of Ballet in Russia, 1616–1881* (1930); V.M. BOGDANOV-BEREZOVSKII, *Ulanovna and the Development of the Soviet Ballet* (1952; orig. pub. in Russian, 1949); EDWIN DENBY, *Looking at the Dance* (1949), essays on ballet in the United States; THEOPHILE GAUTIER, *The Romantic Ballet As Seen by Théophile Gautier* (Eng. trans. 1932); IVOR GUEST, *The Ballet of the Second Empire*, 2 vol. (1953–55), a study of ballet in 19th-century France; PETER LIEVEN, *The Birth of the Ballets Russes* (1936); JOHN MARTIN, *The World Book of Modern Ballet* (1952), mainly on the United States; DEIRDRE PRIDDIN, *The Art of the Dance in French Literature from Théophile Gautier to Paul Valéry* (1952); NATALIA ROSLAVLEVA, *Era of the Russian Ballet, 1770–1965* (1966); MARY GRACE SWIFT, *The Art of the Dance in the U.S.S.R.* (1968); and WALTER TERRY, *The Dance in America* (1956).

Interesting works that approach ballet history by focussing on its major figures, either as biography or reminiscence, include: ALEXANDRE BENOIS, *Reminiscences of the Russian Ballet* (1947); VICTOR DANDRE, *Anna Pavlova* (1932); ARNOLD L. HASKELL and W. NOUVEL, *Diaghileff: His Artistic and Private Life* (1935); TAMARA KARSAVINA, *Theatre Street*, rev. ed. (1950); DERYCK LYNHAM, *The Chevalier Noverre: Father of Modern Ballet* (1950); LILLIAN MOORE, *Artists of the Dance* (1938); ROMOLA NIJINSKY, *Nijinsky* (1933); and LYDIA SOKOLOVA, *Dancing for Diaghilev* (1960).

Valuable discussions of ballet technique are in: ERIK BRUHN and LILLIAN MOORE, *Bournonville and Ballet Technique* (1961); JEAN GEORGES NOVERRE, *Lettres sur la danse sur les ballets et les arts*, rev. ed. (1803; Eng. trans., *Letters on Dancing and Ballets*, 1930); and AGRIPPINA VAGANOVA, *Fundamentals of the Classic Dance*, trans. and ed. by ANATOLE CHUJOY (1946).

Stories of ballet libretti are contained in: GEORGE BALANCHINE, *New Complete Stories of the Great Ballets* (1968); CYRIL W. BEAUMONT, *Complete Book of Ballets* (1937), and *Ballets, Past and Present* (1955); and WALTER TERRY, *Ballet: A New Guide to the Liveliest Art* (1959).

(A.L.H.)

Ballistics

Ballistics is the subject concerned with the phenomena and laws of projectiles, their propulsion, flight, and impact. These three aspects of the field can be studied separately when applied to guns and are called individually interior (or internal), exterior (or external), and terminal ballistics, respectively, and a wide range of phenomena is subsumed under them. Rocket propulsion in free flight involves the special problem of interior and exterior ballistics at the same time because the thrust of the projectile and its aerodynamics are interdependent during flight. Ballistics beyond the atmosphere (that is, space flight) is a subcategory of exterior ballistics known as geoballistics. The ballistics of cartridge-actuated devices concerns the use of propellants to move heavy loads short distances, or to work against large resistance in short periods of time. Still another branch of study is hydroballistics, the study of projectiles moving through the

water. The general effects treated in ballistics are reproducible muzzle velocity; the lowest gun pressure that will produce the desired velocity within a given length of the gun barrel; the stability of the projectile in flight; long and reproducible trajectories; and maximum interaction with a selected target. In this article "ballistic" is used to apply to all the properties, behaviour, reactions, etc., of projectiles of any sort—under any and all conditions.

HISTORY OF BALLISTICS THEORY

Ballistics theory depends on many scientific disciplines. Interior ballistics involves the application of theories of chemical combustion, compressible gas dynamics, and mechanics; exterior ballistics theory is built on a knowledge of mechanics, aerodynamics, and, sometimes, geodesy—the shape and physical character of the Earth; terminal ballistics draws on the theories of explosive technology, metallurgy, solid-state physics, and mechanics. Because all ballistic phenomena occur at extremely high rates, and a great complexity of interactions between them develops, the fastest and most capacious computers, microsecond photography, supersonic wind tunnels, and pressure gauges capable of measuring several thousand megabars (a megabar is equivalent to about one million atmospheres of pressure) in microseconds are required in ballistic study.

Ballistics problems have always challenged the most powerful and sophisticated scientific techniques available and have stimulated new ones. Among the prominent early contributors to ballistics were Leonardo da Vinci, Galileo, and Newton. Men like Leonhard Euler, a Swiss astronomer and mathematician; Pierre-Simon Laplace, a French physicist and astronomer who became Examiner of the Royal Artillery; and Antoine-Laurent Lavoisier, the French father of chemistry and director of the French National Powder Factory, also made vital contributions. The first hurled object was a problem in ballistics. The advantages of being able to hurl farther or harder led to devices for extending the arm, slings and throwing sticks. Further increases in effectiveness were achieved with the bow, which combined increased mechanical advantage and the accuracy derived from a more stable platform than provided by the human in the act of throwing. Arrows could reach the parapets of a defensive structure, but breeching the walls or causing internal structural damage necessitated the invention of the ballista from which ballistics derives its name. Ballistics shares an etymological root with the word diabolic, or devilish, both deriving from the Greek word *ballein*, "to throw." *Diaballein* means to throw across or, alternatively, to calumniate. The intimate relationship between the human body and ballistics in propulsion by throwing or using the ordinary bow makes it doubtful that hunters and warriors felt a need for an intellectual ballistics principle. With the advent of the ballista, however, the intimate sense of feel and the integration of arms and eyes are absent. The ballista propelled missiles in one of three ways: through torque, equipoise dropping of weights, or flexure. Its capacity was determined by the tension, lever, and weight values applied to the device. By the time of Leonardo da Vinci, the principles of levers were well known, so that methods of increasing initial velocity of various weights could be understood characteristically, if not analytically. Because Leonardo and his contemporaries had mistaken views of the magnitude of gravitational effects, the effective use of the ballista required experiments to test the range of each missile and each variation in the ballista's design and setting; a completely empirical set of data, therefore, had to be obtained for accurate use of the machine. Knowledge of terminal ballistics was also empirical, although the chemical formulation of Greek fire was a refined and highly secretive art.

The work of Leonardo da Vinci

Prior to the advent of guns, then, principles of ballistics included the application of the principles of levers to ballista and of geometry to aiming.

It might also be noted that although Leonardo had an excellent knowledge of static mechanics, his version of dynamics was empirical and theoretically incorrect. He incorrectly deduced that force is directly proportional to velocity, rather than a change of velocity with time; that is, he did not seem to comprehend that force is directly proportional to acceleration. Thus, he could have no correct theory of interior or exterior ballistics. He did write on the trajectory of cannon shot, and it is not surprising that a sculptor would have an interest in the cannon foundry. Leonardo, as a late 15th-century Florentine, lived only a century after the discovery or invention of gunpowder and guns, and knew only their early use in warfare—two centuries before the English began to regulate the propulsive properties of gunpowder.

Until the first half of the 16th century it was assumed that a projectile travelled in a straight line to the zenith of its trajectory, and then fell on the other leg of an isosceles triangle. It was observed that flight was curved, but the principle applied was simply to approximate the curvature of flight with a circular arc in the upper portion of flight. No concept of drag is included in this description, and it was 1740 before Benjamin Robins, an English mathematician and engineer, first measured with any accuracy the loss of projectile velocity in flight. His results were incredible to scientists of that time. It had been thought that the influence of drag was about the same as that of gravity; but experiments have shown it to be many times greater. The measuring device that Robins invented was a ballistic pendulum that operated on the principle that the swing of a pendulum of large mass, when struck by a projectile with less mass, can be used to calculate the impact velocity.

Gunpowder. Muscle and gravity were eventually replaced by gunpowder, but there is dispute over its origin. It could have been imported from China, though Marco Polo never mentioned such a curiosity in his writings; or it could have been invented in Italy, because chemicals of the proper quality were mined there; or it could have been discovered by Sir Francis Bacon. Whatever the source, gunpowder provided a human experience with dynamical forces far, far beyond the effects of muscle, levers, or weights. There were no theoretical tools in chemistry, physics, or mathematics with which to begin a theory of gun ballistics, but the history of science since that time is replete with mathematical, physical, and chemical discoveries that were made in a search for solutions to problems in ballistics.

PRINCIPLES OF BALLISTICS

Interior ballistics. *General considerations.* It is useful to begin with the simplest ballistic case—a bullet fired from a gun. The bullet is driven along the barrel by the gas pressure generated when the gunpowder propellant burns at extreme rate in a chamber (called the breech) at the rear of the gun. The process is analogous to that of a piston in an internal-combustion engine, the projectile being the piston. The gross variables of this process are the weight and cross-sectional piston area of the projectile, the gas pressure applied to its base, and the length of travel in the gun along which the propellant gases can exert force. If a mathematical relationship can be found for these factors, then the ballistic behaviour of any bullet fired from any gun using any propellant can be approximated.

In the broadest sense, the classical laws of motion are applicable to any moving object: the force (F), causing the mass (m) to accelerate (a), is equal to the product of the mass and the acceleration; that is, $F = ma$. Since the projectile's mass is usually constant throughout the period defined by interior ballistic period, its acceleration will result from the applied force. That force is the sum of: (1) the gas pressure (p) working on an area (A) (effectively, the cross-sectional area of the gun bore that is normally taken as a constant), and (2) the resistance to motion resulting from starting forces, friction, and spin (in the case of rifled gun barrels). The latter forces are small relative to that derived from the pressure, but are required in useful formulations of the interior ballistic trajectory—especially the shot-start pressure (pressure at instant of firing) required to engrave the projectile's soft metal band, usually of copper, that then rotates the pro-

jectile along the grooves of the barrel. By using classical physics, the foregoing ballistic data is related in an equation such that the acceleration (a) equals the pressure (p) times the area (A) plus the resistant force (f), divided by the mass (m), the equation being written: $a = \frac{pA + f}{m}$.

The principal variable in this process is the pressure on the projectile base; if it can be measured, then the acceleration can be calculated. The pressure that is effective on the base of the projectile depends on the propellant's properties, on the amount of it that is burned, and on the spatial distribution of gas down the bore. The outcome of these variables is a pressure that is usually measured by instrumentation at a fixed location—the breech end of the gun.

Chemistry of propellants. Propellants are substances that ignite and burn extremely fast, producing voluminous quantities of gas in a very short time. In general, the burning process is a chemical reaction involving oxidation, an oxidizing agent being any substance that removes electrons. The shorter the period during which a given mass of propellant burns, the more explosive will be the production and expansion of the gas. Thus, propellants are mixtures of chemical compounds that contain both fuel and oxidizer, in contrast with internal-combustion engines into which a mixture of fuel vapour and atmospheric oxygen are metered. Propellants must be chemically and physically stable in ordinary environments, and must react only to specific conditions that can be reproduced acceptably. They are ignited by a primer propellant that has been in turn ignited by heat either from an electrical-resistance wire or from an explosive percussion primer. Properly manufactured, prepared, placed, and ignited, the propellant material burns at a rate that depends on the pressure of the product gases and, secondarily, on the temperature of the unburnt material. The higher the temperature, the faster will be the reaction. This burning rate, usually expressed in terms of length burned per unit time, is determined by burning a strand of the material at various controlled pressures. When the strand is inhibited from burning along its sides and made to burn evenly across its face, the linear rate of burning is measured and an equation is derived in which an exponent of the pressure varies from 0.1 to 1, with conventional propellants; such a range of values makes determination of this variable a critical factor in calculating the ballistic behaviour of any particular gun or projectile.

Geometry of propellant grains

The propellant charge in a gun is composed of many small pieces, or grains, that are ideally of the same shape, and, thus, the weight of propellant consumed is a function of the accumulated linear consumption at any time in the combustion process. The actual shape of the grains is an important factor and, therefore, the problem is a geometric one. Solid cylindrical grains present a smaller and smaller area as they burn and represent a regressive geometry. Cylinders with central perforations along their length present a nearly constant surface, representing a neutral geometry. With a number of longitudinal perforations (usually seven) that expand, the amount of propellant burned increases as the cylinder burns away up to the point at which the expanding perforations meet. This is called a progressive geometry. The ballistic advantage of the latter is that it generates gas at a lower rate, initially when the total volume behind the projectile is small, and produces gas at an accelerated rate as the projectile gathers velocity and creates volume behind it at an increasing rate.

Behaviour of gases. The chemistry of propellants involves the so-called equation of state of the material; *i.e.*, the relationship between pressure, volume, and temperature of a gas. If p is pressure, V the volume available to the gas, n the number of moles of the gas (weight in grams equal to the molecular weight), R the universal gas constant, and T its temperature (in degrees absolute), then the product of pressure and volume will equal the product of the number of moles, the gas constant, and the temperature, thus: $PV = nRT$.

Since the gas itself must be accelerated down the gun bore behind the projectile, it is distributed at any time in such a way that local pressure decreases from the breech to the projectile's base as the latter travels. The average pressure along the gun behind the projectile can be used to calculate the instantaneous rate of burning. The energy for the work done in moving the propellant gas itself is obtained from the total pressure generated, and the projectile, therefore, receives that much less. Accordingly, acceleration can be estimated by dividing the force of the combustion (the mean pressure of the combustion times the effective area of the bullet) by the mass of the bullet plus one-third the weight of the propellant. The thermodynamic, or heat, efficiency of the system is also reduced by any gas leakage past the projectile, by potential work available in the gas remaining when the projectile leaves the muzzle, and by heat lost to the gun itself. When all these factors are considered, what is left for the kinetic energy in the projectile is about one-third of the potential chemical energy contained in the propellant charge.

There is clearly an exceedingly intricate relationship between the rate of propellant consumption, the pressure at which the propellant burns, and the volume of gas behind the projectile; the relationship is expressed in several simultaneous differential equations which are frequently programmed on an analogue computer to provide curves of gas pressure and projectile travel versus time. These vary for each assembly of devices, but when for any one system enough measurements have been made, the formula can be used to predict desired factors (for example, the amount of a propellant needed to move a certain projectile at a desired acceleration).

Projectiles are often given a spin in order to obtain a more stable and uniform flight pattern. This rotational acceleration of projectiles, as well as other secondary variables, such as frictional resistance to motion and leakage of gas, must be taken into account in a full development of interior ballistics. Although they use, collectively, only about 5 percent of the energy consumed in the whole process, they can affect projectile performance significantly and are, thus, important to ballistic calculations. For example, the inferred empirical value for shot-start pressure is vital in establishing the conditions for burning during projectile travel. Some ballistic devices have been designed with leakage as a critical parameter. If a salvo of several projectiles is to be fired at once with a particular pattern of impact ranges, this can be accomplished either by pre-aiming several barrels with appropriate firing angles relative to one another to achieve the pattern or by making the barrels with various effective lengths; the same effect is achieved with barrels of identical length that leak gas after the projectile has travelled different distances in the bore.

Absence of a satisfactory ignition theory

No theory has been satisfactorily developed for ignition of propellants. Ignition has remained a facet of technology in which the aims are to ignite reliably and quickly at all propellant temperatures and without high rates of pressure rise.

As noted above, the propellant gas is accelerated down the gun bore behind the projectile. Since the weight of the propellant charge is usually of the same order of magnitude as the projectile weight, a considerable amount of the propellant energy is expended on its own acceleration. The predominant products of combustion are usually oxides of nitrogen and carbon, with molecular weights on the order of 30 or higher. If the propelling gas is much lighter, as, for example, hydrogen is, then much higher velocities of gas and projectile are feasible. For research experiments two-stage guns using a light gas have been built, and projectile velocities of five to ten kilometres per second (three to six miles per second) have been achieved at their muzzles.

Gun wear. An undesired product of the interior ballistic cycle is gun wear. Chemical corrosion from the gases and erosion from heat and friction steadily enlarge the bore diameter of a gun mostly near its ends. The effects of this wear include different initial conditions for projectile motion, leakage, and even projectile instability

in the bore. The gun tube, as a pressure vessel, must be designed at each position along its length to withstand the maximum pressure it will receive, increased by a suitable safety factor. To the extent that the pressure pulse the gun receives is below the design level the gun is inefficient. A pressure gauge at any point along a gun measures a pressure that rises quickly to a maximum and then decays slowly, the gun at that point being able to withstand the design maximum pressure for the entire interior ballistic cycle. The ratio of the mean pressure on the projectile to the maximum pressure is called piezometric efficiency. Its value taken at breech pressure is normally between 0.5 and 0.75.

The interior ballistic portion of the total ballistic trajectory ends with the velocity, spin, and direction imparted to the projectile at the gun muzzle as well as to the projectile's angle of attack to its direction of motion.

Exterior ballistics. Exterior ballistics is concerned with the flight of projectiles through the atmosphere, and of primary interest are: the manner in which projectiles are slowed as a result of a factor called drag; how they maintain a consistently favourable attitude (a variable factor called stability), and how they are influenced by variations in interior ballistics and by their flight environment.

General considerations. First, the interaction between the projectile and the medium through which it passes must be examined and measurements made in terms of coefficients that indicate the amount of changes in the projectile's behaviour as the conditions change. The aerodynamics of a nonspinning projectile are represented in terms of three dimensionless parameters which appear as coefficients of drag, of lift, and of moment (a moment measures the forces tending to turn an object) in equations describing how a projectile is slowed by the air, how it is moved laterally (lifted or depressed) by the aerodynamic pressure distribution over the projectile in flight, and how the projectile tends to tumble because of an overturning aerodynamic moment. These coefficients are all functions of the speed of the projectile and properties of the air such as density and elasticity. They are expressible as functions of projectile velocity divided by the local speed of sound (that is, Mach number; Mach 1 being a speed equal to the velocity of sound in the same medium) and of the so-called Reynolds number (based on the velocity at which streamlined flow of a fluid becomes turbulent) of the air or fluid through which the projectile is passing. The theory of the Reynolds number is complex, and a good approximation to conventional ballistics can be obtained by ignoring it and regarding the three coefficients as functions of Mach number only. (This is not the case for high speed—hypersonic—or hydroballistics. For those the change in Reynolds number is sufficient to require its use in conversion of experimental data.) These coefficients are also different for different projectile shapes. Specifically, for typical shapes the drag coefficient is near 0.08 at low velocities, increases very sharply to about 0.2 at the speed of sound, and decreases slightly at higher velocity. The coefficients are normally determined experimentally either from direct force measurements in a wind tunnel on a fixed projectile shape with air blown over it, or by inference from fitting flight trajectory data to a mathematical model. If ρ is the air density, d the projectile diameter, v the projectile velocity, and δ the angle of yaw—or the angle between the projectile's long axis and its direction of motion—and K_D, K_L, K_M are coefficients of drag, lift, and moment, and these forces are combined into the following linearized equations, then drag equals density times diameter squared times velocity squared times the drag coefficient; lift equals the same factors but substituting the coefficient of lift for the coefficient of drag, times the sine of the angle of yaw; and the moment equals the product of the density, diameter cubed, velocity squared, the coefficient of moment, and the sine and cosine of the angle of yaw. Written out symbolically, the equations are

Mach and Reynolds numbers

$$\text{Drag } D = \rho d^2 v^2 K_D$$
$$\text{Lift } L = \rho d^2 v^2 K_L \times \sin \delta$$
$$\text{Moment } M = \rho d^3 v^2 K_M \times \sin \delta \times \cos \delta.$$

Drag and spin. The drag effect at zero yaw can be broken up into three influences: that due to pressure of the atmosphere on the bow of the projectile resulting in a backward force component; that due to skin friction of the atmosphere along the body of the projectile and varying with its surface roughness and minor convolutions; and that due to base drag resulting from the turbulence induced in the atmosphere at the rear of the projectile. At usual projectile velocities, say 300 to 900 metres per second (1,000 to 3,000 feet per second), pressure drag is reduced by sharpening and shallowing the curve of projectile noses, frictional drag by body smoothness, and base drag by drawing the base more toward a conical shape.

Factors in stable flight

In stable projectile flight the orientation of lowest drag is presented to the airstream. Unstable flight leads to high drag, short range, and reduced accuracy. Static stability is achieved when the centre of pressure (resulting from combination of forces including drag) acting on the body is behind its centre of gravity. This is sometimes achieved by the use of fins as on bombs, mortar shells, and nonspinning rockets; the fins acquire the centre of pressure, whereas the centre of gravity remains somewhere around the midsection of the projectile. Dynamic stability is achievable even when the centre of pressure is forward of the centre of gravity by spinning the projectile and thereby inducing a gyroscopic action that counterbalances the wobbling or tumbling that the pressure would induce. Thus, unless suitable fins are provided, spinning the projectile is necessary for the stability of its longitudinal axis in flight. Too much spin will make a projectile so stable at high angles of fire that it will resist following its velocity vector near the zenith of its trajectory and assume an increasingly sideways orientation, and eventually it will tumble. The mathematical treatment of spinning projectiles introduces complex variable notation to the force system described above; a number of separately indentifiable torques (or moments) and forces result that are expressible as functions of the same basic parameters that are identified without spin, with the addition of the spin parameter and new dimensionless coefficients. These coefficients are also empirical. The cross forces and moments, which result from spinning in the airstream, are called Magnus forces or Magnus moments. To make the mathematical problems tractable, projectile yaw is assumed to be small, and a linearized theory is used. There has been some analytical development of nonlinear yawing motion.

Experiments with projectiles in flight are of two kinds. In one, flight is simulated in wind and water tunnels by making air or fluid flow past a stationary projectile that is hooked up to instruments. Alternatively, projectiles can be fired down dark tunnels called spark ranges where flash photographic images are taken. The measurements obtained in either case are complex, but the equations developed from such data can then be used for approximate solutions of problems in exterior ballistics.

Geoballistic factors. Over long ranges of flight, including an "infinite" range postulated by Newton (*i.e.*, that of orbital satellites), effects that can be neglected in conventional ballistic systems become prominent and, at extreme altitudes, the significance of aerodynamic effects are reduced. For very long ranges and times of flight, the spinning of the Earth imposes a small force, called the coriolis force, which causes projectiles in the Northern Hemisphere to have a rightward curving flight, and in the Southern Hemisphere a leftward curving flight. The explanation of this is that since the surface of the Earth, spinning on its axis, moves at different speeds at different Earth latitudes (a point on the Equator moves faster than any point north or south because the circumference at the Equator is greatest; while a point at either pole is stationary), when trajectories cover a range of latitudes this must be accounted for. Moreover the oblate nonspherical configuration of the Earth affects orbital trajectories as does, to lesser degree, local variation in the magnitude and direction of gravity forces. The forces resulting from the attractions of Sun and Moon are negligible. All these effects are treated in a modern branch of ballistics called geoballistics.

Nonspinning projectiles. Bombs are fin stabilized and are dealt with as nonspinning projectiles. The problem of aiming a bomb introduces the problem of locating a release point from a moving platform in order to make the bomb's trajectory intersect a target. Since a bomb-carrying aircraft counteracts air drag with its engine thrust while the falling bomb does not, after its release, the bomb immediately trails the aircraft while it falls. To select the point at which to release the bomb requires mathematical manipulations of data, and the aim is to find the most efficient way of mechanizing the selection of release conditions. While being carried and during its release, the bomb is subjected to complicated airflow conditions around the aircraft. The effects of this are not well understood.

Aiming bombs

Meteorological effects. Corrections for variation from standard, of either gun muzzle velocity or of projectile weight, are supplied by exterior ballistics. A more difficult correction problem is posed by the meteorological conditions. Wind speed, direction, and air density vary with altitude and horizontal distance from the gun. Measurements are not generally available for the specific flight path intended, but, rather, one must use data gathered at a more or less nearby location and at an earlier time. Internationally agreed-upon standard atmospheres are used as a first approximation in standard ballistics tables giving range and time of flight for various gun elevations and selections of ammunition. Meteorological differentials are then applied, either for a single "average" value of wind and density variation from standard, or even for variations with altitude.

Ideal shape for projectiles. The ideal projectile for interior ballistic performance differs from the exterior ballistic ideal. The latter has a long finely pointed nose and tail for low drag and is heavy for a high ballistic coefficient. Best interior ballistic performance is attained with projectiles that are lighter, have higher muzzle velocities, and have a nearly cylindrical shape which provides better bearing surfaces through the gun bore for low wear. The terminal ballistic ideal may be different from both of these, since usually what is wanted is a large payload weight but low accelerations in the gun. The practical design is a compromise.

Rocket ballistics. *General considerations.* The general principles underlying rocketry involve propellant combustion in a chamber that has some suitable aerodynamic shape and that expels the gaseous products of the combustion through one or more nozzles at the rear of the chamber. If the rocket is well designed, the internal combustion pressure remains nearly constant during burning. Otherwise, the pressure vessel must be designed for the maximum pressure generated and at lesser pressures the extra protection is wasted; the design is then inefficient. The rocket nozzle is designed to effect a smooth flow of gas from the combustion chamber, accelerating the escaping gas velocity to the local speed of sound at its most constricted point (throat), and expanding it to nearly atmospheric pressure and supersonic velocity. According to Newton's second law of motion, the speed of change of the momentum of the gas leaving the rocket represents a force, and, according to his third law, this force is reacted against by a thrust in the opposite direction. It is this thrust that drives the rocket forward. Clearly, the thrust is increased with higher velocity and increasing propellant gas density. Thrust is the change in the product of mass (m) and velocity (V) of the gas divided by the change in time. This is written as $\frac{dm\,V}{dt}$, the d indicating an infinitesimal change.

For well designed rockets the exhaust velocity is substantially constant. Since the rocket mass includes the steadily reducing mass of the propellant, which is used up during burning, and since the rocket is accelerating, both mass and velocity are changing. The thrust of a rocket is approximately proportional to the product of the smallest cross section area in the nozzle and the chamber pressure, with a factor of proportionality between one and two depending on the expansion ratio.

Propellants. The propellant may be solid or liquid. When liquids are used the fuel is usually stored separately from the oxidizer (that is, the substance that "burns" it), and the two are mixed in proper proportion at rates designed to cause them to ignite spontaneously and burn evenly. Examples of fuels are liquid hydrogen and ammonia. Liquid oxygen, nitric acid, and fluorine have been used as oxidizers. Solid rockets require that the grain of the propellant have a geometry designed to present a nearly constant surface area as it burns away, and that the grains have a suitable rate of burning. Rocket thrust is a function of time, varying from the instant of ignition through flight, and it can be measured on a gauge that indicates force. The ideal curve derived in this fashion rises quickly to a pressure plateau and, at the end of burning, drops quickly. Another factor affecting flight is the fact that rocket propellants burn at a rate that depends on the propellant temperature. Fortunately, the conduction of heat through a mass of rocket propellant is low in relation to the actual linear rate of burning so that the temperature tends to remain constant during burning. That is, the propellant burns before the heat of combustion can spread ahead of the flame. Higher initial temperature of the propellant, however, increases the rate of burning and, thus, the thrust is raised to a value higher than the designed value. Finally, although curves for rocket thrust versus time may vary from the roughly trapezoidal form referred to above, it is the integral which corresponds to final rocket velocity at burn out, and the latter tends to be less variable than individual values of thrust during burning.

When a rocket is ignited inside a gun barrel, with or without an independent cartridge charge, another variable must be taken into account. Gas pressure difference across the exhaust nozzle of the rocket is considerably lower within the gun barrel than in free air. This application of rocketry is efficient only if short, high-velocity trajectories are desired.

Special problems. Problems peculiar to rocketry arise during flight. Thrust malalignment may occur either because the thrust is at an angle relative to the longitudinal axis of the rocket or is along a line displaced from, but parallel to, the rocket axis. The latter is called linear malalignment. Angular malalignment gives the thrust a sideways component that must be reacted against by the rocket body and fins. Linear malalignment produces a torque moment (a tendency to turn due to uneven forces acting on different parts of the body) relative to the centre of mass. The peculiarities of rocket flight also include the fact that a yawing rocket has a thrust component along the direction of its attitude as compared with its direction of motion. Subjected to a crosswind, finned rockets tend to weathercock or turn into the wind and to fly upwind. After burnout the weathercocking is still present, but drag due to the atmosphere results in a downwind motion. The reaction to a changing angle of rocket attack as reflected in the angular change in gas momentum is a yaw damping in the rocket called jet damping torque.

Weathercock effect

Rockets may be given spin stability by canting two or more nozzles relative to the centreline of the rocket. This angular and linear malalignment, if properly designed and constructed, results in a rolling moment, or spin, being applied to the rocket without also adding pitch and yaw.

Rocketry is a most efficient technique when low reactions by the launcher are required, as is the case with a light platform, and also when the weight of the gun pressure vessel exceeds that which is ordinarily allowable. Although these advantages are not always realizable in practice, another advantage of rockets has been important in achieving space flight: beyond the Earth's atmosphere drag is negligible and the propulsive energy of the rocket can be used efficiently. Rockets also provide the capability of delivering heavy loads to targets thousands of miles away and, with onboard guidance systems, achieving a high degree of accuracy in that application.

A combination of effects is achieved in recoilless guns.

By venting propellant gas through a suitable nozzle at the rear, or breech, of the gun, the gun is effectively a rocket receiving a forward thrust. This tends to counteract the projectile's momentum (that is, to work against the recoil). It is an obviously inefficient use of propellant in order to reduce the weight of the gun platform.

A disadvantage of rockets as compared with guns is that they are not normally re-usable, while the gun is. Nozzle erosion in most rocket designs significantly affects efficiency so that reloading, even if the rocket were recovered, would require replacement of the nozzle as well as the propellant and usually would also require repairs to the motor case.

Terminal ballistics. *General considerations.* Of the various events that occur when a projectile hits a target, the simplest to discuss is penetration of the target by the projectile. Attempts to state analytically the three-dimensional process of penetration accounting for the material properties of target and missile have been only partially successful. Even the simplest two-dimensional attempts have encountered considerable computational difficulty. The phenomenology of penetration has evolved out of experimental observations and known characteristics of material failure under shock loading. It is most easily approached through projectile impact on a single plate of some thickness. Penetration completely through the plate is called perforation. Partial penetration that pushes whatever is left of the surface at the rear face clear of the plate around the penetration path is called scabbing. If the projectile's impact causes a pressure shock of sufficient amplitude in the plate, and if the plate thickness and its material permit it, a piece of the plate, thinner than the plate thickness, may be separated and driven by shock from the rear face of the plate without the projectile penetrating an appreciable distance. This

Spallation

piece, called a spall, is split off the plate by the extreme tensile force within the plate, caused by the rarefaction pulse which results when the shock front is reflected from the rear surface of the plate that is not penetrated. A theoretical description of spallation can be given from the impact geometry and velocity and from the equation of state of the materials. The depth of penetration for a projectile that survives impact without fracture is roughly proportional to the impact velocity and the projectile length, and it increases with the density of the penetrator, which may not be identical with the density of the projectile before impact. As the angle of impact on the plate varies from the right angle to the plate, the possibility of ricochet increases. The impact angle at which half of the projectiles in a series being tested ricochet is called the ricochet angle.

Explosive projectiles. Projectiles may contain high explosives which cause the shell casing of the projectile to fragment before or after impact with a target. Fragmentation increases the region affected, called the lethal volume, if the fragments resulting from impact cause the kind of damage sought. The process of fragmentation is understood primarily from empirical data but the reproducibility of material failure under shock loading suggests that fragmentation is a more uniform process than any that could occur under very slow loading rates; *i.e.*, slow increase in pressure. The projected fragments are characterized by their masses, velocities, and directions. The terminal ballistic process for fragmenting projectiles is then completed by impact of fragments with the target.

Effects of shaping charges

Different kinds of action can be achieved with high-explosive projectiles by preforming and shaping the interfaces between explosive and metal, as is done, for example, in the case of the so-called rod warhead. If the ends of metal rods are properly attached in a cylindrical bundle around the explosive, the rods can be caused to expand into a hoop shape, with a resulting cutting action. Another kind of action is achieved with a cylinder filled with explosive and terminated at one end in a metal cone the apex of which is in the explosive. This is called a conical-shaped charge. Detonation at the apex end of the charge drives the cone material forward and toward its axis, and the collision can be explained in terms of fluid mechanics. The resulting jet of metal achieves velocities above 3,000 metres per second (10,000 feet per second). The fluid properties of this system result in jet elongation that, up to the point of separation and dispersal, increase penetration. The laws of penetration regarding the velocity and length of the penetrator indicate greatly increased penetration for such devices and experiments verify it. Similar techniques are used for fragment accelerators to study the effects of meteoroid impacts in space.

Theory of terminal ballistic impact. A theory of terminal ballistic impact is now evolving as a result of simulation using digital computers, based on a number of hydrodynamic representations (considering the materials under high pressure as fluids). By the use of computer graphics, a picture of the fluid can be presented as it is being compressed or rarefied and as its geometry changes. This is done by calculating and plotting a lattice of connecting points of the fluid as a function of time. Initially, the lattice may look like a section of graph paper, but then with time the lattice is seen to distort and change configurations just as would the fluid when disturbed. Indeed, it is a motion picture of its history. Inputs in such computations include impact velocity and physical variables of projectile and target, such as density, speed of sound in the materials, material strengths, and equation of state, all relating pressure and density in the material. Output variables include dimensional deformation and internal pressure distributions. Varying impact conditions in the formulations beyond the range of available experimental evidence can suggest new directions, but the validity of computed extrapolation beyond experience is questionable until verified by experiment. The great speed and analytical ability of the digital computer nevertheless allows some success in attempts to smooth projectiles for flight, to increase muzzle velocity, and to penetrate the target more deeply. Thus, in all areas of ballistics, a process of computer-simulated experimentation supported by selected physical experiments has become useful.

Theory of terminal ballistics. A theoretical structure for terminal ballistics is a relatively current development, having begun about 1960. Although all fields of ballistics are centuries old, in an experimental sense, terminal ballistics is in its theoretical youth and has considerable promise in explaining physical relationships in materials at very high pressures.

RECENT DEVELOPMENTS

Cartridge-actuated devices

Since World War II, propellants and explosives have found increasing use in applications other than conventional guns. Devices that take advantage of the large amounts of potential chemical energy stored in small-volume propellant cartridges to do work in an emergency or in a place remote from large power supplies are called cartridge-actuated devices. They are widely used in aircraft personnel escape systems and in aircraft bomb and missile ejectors, as well as for attaching and detaching structure, inflation, emergency positioning, cutting, and electrical switching.

The ballistic properties of cartridge-actuated devices differ from those of guns in both degree and kind. Many cartridge-actuated devices move weight or move against a resisting force in a substantially closed system so that only interior ballistic theory is applicable. The action of explosive separators is best described by terminal ballistic principles as in shock-separated explosive bolts and linear-shaped charge for cutting aircraft escape capsules away from the rest of the aircraft.

Differences in degree and kind can be seen in comparing pilot ejection catapults with guns. In the late 1940s, when aircraft performances exceeded the pilot's ability to bail out safely, the pilot ejection seat was developed. The system employed a catapult gun powered by gun propellant. Early catapult guns shot man and seat away from the aircraft at a velocity of about 18 metres per second (60 feet per second), achieved in about one metre of travel. The prime ballistic constraints in such a system are the ejection velocity necessary for the ejection seat to clear the aircraft's vertical stabilizer and the maxi-

mum acceleration below the level that the human spine can sustain (about 25 times the force of gravity, or 25 g). Although the system can be regarded as a simple gun, its exterior ballistic properties are special with regard to the high initial yaw of the "projectile," a large overturning moment at the muzzle, and its unusual ballistic shape. The terminal ballistic problem is to deploy a parachute at the right time and at the right attitude of the "projectile." The interior ballistic factors are also unusual for a gun: operating at perhaps 3 percent of the usual maximum pressure over about 20 percent of the usual barrel length against 10 times more projectile weight than is conventional to achieve muzzle velocities one-fiftieth of the usual.

In more extreme interior ballistic situations, aircraft ejectors employ propellant charges to thrust against as much as 50,000 times their weight over distances on the order of 15 centimetres (six inches).

Many cartridge-actuated devices burn gun propellants at pressures much lower than desirable for uniform combustion. Also, as described above, pressure is dependent upon the projectile mass, which can vary by a factor of 10 in the same cartridge-actuated device. This can lead to inefficient and non-reproducible ballistics. However, if the propellant is burned in a chamber separated from the working piston and cylinder by a wall perforated with holes of suitable size, the propellant can be burned in a reproducible way, the flow of gases through the perforations will be sonic, and the pressure exerted in the working cylinder will be roughly independent of initial temperature and projectile weight.

As a family, cartridge-actuated devices experience heat loss during the interior ballistic cycle of 15 to 20 percent of the potential propellant heat energy, as compared with 5 percent in guns. This factor must be accounted for in the interior ballistic theory of cartridge-actuated devices.

Ballistic theory is applicable to guns, mortars, rockets, and any thrown, hurled, or freely propelled missile, as well as to closed systems that use stored or generated gas as a source of energy. Consequently, the principles are widely applied in space exploration as well as in many of man's Earth-bound activities. Examples include the inflation of flexible containers by propellant gas, which activates life rafts and crash-protection bags in motor vehicles, and explosive devices for welding, the forming of complex metal shapes, and emergency cutting. The principles that have evolved from studies of terminal ballistics have civilian as well as military application; police control measures, for example, include the use of rubber bullets to reduce the incidence of human injury.

New uses for ballistic theory and devices

Baltic Languages

The Baltic languages form a branch of the Indo-European language family and are more closely related to Slavic, Germanic, and Indo-Iranian (in that order) than to the other branches of the family. They comprise modern Lithuanian and Latvian (Lettish), the languages of the Balts inhabiting the eastern coast of the Baltic Sea, as well as the now extinct Old Prussian language, Yotvingian (also spelled Yatvingian, Jotvingian, Jatvingian), Curonian (Kurish), Semigallian, and Selonian (Selian); the speakers of this group are here referred to as the B-Balts. There also existed languages and dialects of the Balts (D-Balts) who lived east of the above-mentioned groups in the areas of the upper reaches of the Dnepr River.

Languages of the group. Because its dialects are more archaic in their forms than those of the other living Indo-European languages, Lithuanian is of particular importance in the study of comparative Indo-European linguistics. The language has 2,507,000 speakers in Lithuania (1970) and several thousand speakers in Belorussia and Poland, and until 1945 there were several thousand Lithuanians in East Prussia as well. More than 500,000 Lithuanians live abroad, mostly in the United States. Lithuanian is sharply divided into dialects whose differences are quite marked. The two major ones are Low (or Western) Lithuanian, with three subdialects, and High (or Eastern) Lithuanian, with four subdialects. The Low dialect is spoken by the Lowlanders, who live in the west and along the Baltic Sea; High Lithuanian is spoken by the Highlanders, who live in the eastern (and greater) part of Lithuania. Standard Lithuanian, formed at the end of the 19th and the beginning of the 20th century, is based on the southern subdialect of West High Lithuanian.

Lithuanian, most archaic living Indo-European language

The language most closely related to Lithuanian is Latvian, spoken by 1,342,000 speakers in Latvia (1970) and about 370,000 abroad, mostly in the United States. Latvian is divided into dialects, the major ones being the Central dialect, Livonian (also called Tahmian, or West Latvian), and High (or East) Latvian. Standard Latvian, established at the end of the 19th and the beginning of the 20th century, is based on the Central dialect.

By the 16th century the Selonians, Semigallians, and Curonians, who lived in areas of Latvia and Lithuania, had completely lost their national identities and were assimilated by the Latvians and the Lithuanians. They left no written records. Nor did the Yotvingians (or Suduvians), who lived in southwest Lithuania and farther to the south (in the territory of the present-day Poland). They became extinct around the 16th–17th century, being assimilated by the Lithuanians in the north and the Slavs in the south. Information on the extinct Baltic languages is extremely scarce (mostly place-names). Only Old Prussian, of all the extinct Baltic languages, left any written records, and they are quite poor. The Prussians lived in East Prussia (*i.e.,* between the lower reaches of the Vistula and Neman [Lithuanian Nemunas] rivers on the Baltic coast). They became extinct (*i.e.,* were assimilated by the Germans) at the beginning of the 18th century.

Extinction of several Baltic languages

Linguistically, the Yotvingians were very closely related to the Prussians. They made up one ethnic Baltic group, commonly called the Western Balts, as opposed to the so-called Eastern Balts—the Lithuanians, Latvians, Selonians, Semigallians, and Curonians. The traditional terms Western Balts and Eastern Balts are inaccurate when used for all of the Balts—*i.e.,* including the Balts for whose languages there are no records (the D-Balts). These Balts, who were assimilated by Slavs in the 7th–14th century, lived in the upper reaches of the Dnepr.

Historical survey. Proto-Baltic, the ancestral Baltic language from which the various known languages evolved, developed from the dialects of the northern area of Proto-Indo-European. These dialects also included the Slavic and Germanic protolanguages (and possibly also Tocharian). The quite close historic relationship of the Baltic, Slavic, and Germanic languages is shown by the fact that they alone of all the Indo-European languages have the sound *m* in the dative plural ending (*e.g.,* Lithuanian *vilkā-m-s* "wolf," Common Slavic **vilko-m-ŭ,* Gothic *wulf-am*). (An asterisk [*] indicates that the following sound or word is unattested and has been reconstructed as a hypothetical linguistic form.) This relation-

Features common to Baltic, Slavic, and Germanic

ship is suggested not only by the morphology and word-formation but also by the vocabulary—*e.g.*, Lithuanian *draũgas* (Latvian *dràugs*) "friend," Old Church Slavonic *drugŭ*, Gothic *driugan* "to fulfill military service"; Lithuanian *vãškas* (Latvian *vasks*) "wax," Russian *vosk*, Old High German *wahs*. Probably the earlier close contact of the Balts and the Slavs with the Germanic tribes broke off around the 2nd millennium BC, when the Balts moved from the south (not, however, losing contact with the Slavs) and settled a large area of the eastern coast of the Baltic Sea and the upper reaches of the Dnepr.

Relationship between Baltic and Slavic. Because contact between the Balts and Slavs from the time of Proto-Indo-European was never broken off, it is understandable that Baltic and Slavic should share more linguistic features than any of the other Indo-European languages. Thus, Indo-European **eu* passed to Baltic *jau* and Common Slavic **jau* (which became *ju*)—*e.g.*, Lithuanian *liáudis* "people," Latvian *làudis*, Old Church Slavonic *ljudije*. Tonal correspondences are found between Lithuanian and Serbo-Croatian (a Slavic language of Yugoslavia), and there are also similarities in stress; *e.g.*, Lithuanian *dū́mai* "smoke" and Russian *dym* have the stress on the root, as do Lithuanian *rañką* "hand" (accusative singular) and Russian *rúku*, while both Lithuanian *rankà* "hand" (nominative singular) and Russian *ruká* are stressed on the second syllable.

Baltic and Slavic have specific morphological features in common. Among them, for example, is the genitive plural form. In Lithuanian, *mū́sų* "of us" (= Latvian *mūsu*), evolved from the older form **nūsōn*, which comes from Baltic **nōsōn* and corresponds to the genitive plural form in Common Slavic, **nōsōn*, from which developed Old Church Slavonic *nasŭ* "of us." Baltic also shares some syntactic features with Slavic; *e.g.*, the genitive case is used in place of the accusative with verbs expressing negation (Lithuanian *jis* nieko *nežino* "he does not know anything," Latvian *viņš* nekā *nezin*, Russian *on* ničego *ne znajet*). There are also many lexical items common to Baltic and Slavic. More than 100 words are common in their form and meaning to Baltic and Slavic alone, among them Lithuanian *bėgu* "I run," Latvian *bēgu*, Old Church Slavonic *bĕgǫ*; Lithuanian *líepa* "linden tree," Latvian *liēpa*, Old Prussian *lipe*, Old Church Slavonic *lipa*; Lithuanian *rãgas* "horn," Latvian *rags*, Old Prussian *ragis*, Old Church Slavonic *rogŭ*.

In addition to these features common to all the Baltic and Slavic languages, there are certain quite archaic features that Slavic has in common with Lithuanian and Latvian but not with Old Prussian. The most striking example is the genitive singular ending in Lithuanian *vil̃k-o* = Latvian *vìlk-a* "of a wolf," which comes from Baltic **-ō*, historically paralleled by the genitive singular ending in Common Slavic **vĭlk-ā*. Old Prussian, however, has a different ending for the same inflection (*deiw-as* "of God"). In certain instances the Slavic languages, differing from Lithuanian and Latvian, come closer to Old Prussian; *e.g.*, the Prussian possessive pronouns *mais* "my, mine," *twais* "your, yours," *swais* "one's own" are different from Lithuanian *mãnas, tãvas, sãvas* and from Latvian *mans, tavs, savs* but similar to Old Church Slavonic *mojĭ, tvojĭ, svojĭ*.

It is possible to conclude that there was close contact between the Baltic and Slavic protolanguages at the time when they began to develop as independent groups (*i.e.*, from about the 2nd millennium BC) and that the Proto-Slavic area might have been a part of peripheral Proto-Baltic, although a specific part. That is, Proto-Slavic at that time was in direct contact with both the corresponding dialects of the peripheral Proto-Baltic area (*e.g.*, with Proto-Prussian) and the corresponding dialects of the central Proto-Baltic area. All this shows that the Proto-Slavic area of that time (south of the Pripyat River) was much smaller than the Proto-Baltic area. Proto-Slavic began to develop as a separate linguistic entity in the 2nd millennium BC and was to remain quite unified for a long time to come. Proto-Baltic, however, besides developing into an independent linguistic unit in the 2nd millennium BC, also began gradually to split. Among other things, the size of the Proto-Baltic area had an influence on the development of Proto-Baltic in that it considerably reduced contact between its dialects (see also SLAVIC LANGUAGES).

Development of the individual Baltic languages. By the middle of the 1st millennium BC, the Proto-Baltic area was already quite sharply split into dialects. From the middle of the 1st millennium AD, the Baltic language area began to become considerably smaller; at that time the greater part of Baltic territory, the eastern part, began to be inhabited by Slavs migrating from the south. The Balts there became gradually assimilated by the Slavs; complete assimilation probably occurred around the 14th century. One of these Baltic tribes, the Galindians (Goljadī), is mentioned in a chronicle as late as the 12th century. The protolanguage of the so-called Eastern Balts split into Lithuanian and Latvian (Latgalian) around the 7th century. The other languages of the so-called Eastern Balts became separated probably at the same time. Selonian and Semigallian could have been transitional languages between Lithuanian and Latvian. Only Curonian, which some consider to be a transitional language between East and West Baltic, might have developed somewhat earlier. Moreover, the name of the Curonians occurs in historical sources earlier (AD 853: Latin Cori) than the names of the other tribes of the so-called Eastern Balts.

Split between Lithuanian and Latvian

Old Prussian. In historical sources the Prussians are called Aistians from the 1st century AD (by Tacitus) until the 9th century AD (by the Anglo-Saxon seafarer Wulfstan). They are referred to by their own name (by a Bavarian geographer using the form Bruzi, "Prussians") for the first time in the 9th century AD. About 1230 the Teutonic Order began to plunder the lands of the Prussians and finally conquered the Prussians and the Yotvingians (Suduvians) in 1283. From that time the slow extinction of the two Baltic groups began, with the Germanization of the Prussians being completed at the beginning of the 18th century.

The earliest Old Prussian (and, for that matter, Baltic) written record is a German–Prussian vocabulary—the so-called Elbing vocabulary, compiled about 1300 and extant in a copy dated around 1400. This vocabulary, consisting of 802 Old Prussian words (and the same number of German words), was written in a South Prussian dialect (in Pomesania). Somewhat poorer than the Elbing vocabulary is the vocabulary compiled by Simon Grunau, consisting of 100 Old Prussian (and German) words, written between 1517 and 1526. The most important Old Prussian written records are the three catechisms of the 16th century based on the dialects of Sambia and translated from the German; the first two catechisms, which are very short and anonymous, date from 1545, and the third catechism, or *Enchiridion*, dates from 1561 and was translated by Abelis Vilis (Abel Will), a pastor of the church at Pobeten (Pabečiai; modern Romanovo). The language of all the Old Prussian catechisms is rather poor: the translations are excessively literal, and there are many errors in language and orthography. In spite of this, it is from these Old Prussian catechisms that scholars can learn most about the Old Prussian language.

Lithuanian. Lithuanians are first mentioned in historical sources in AD 1009. Old Russian (more precisely, an East Slavic language based primarily on Belorussian), Latin, and Polish were used in official matters in the Grand Duchy of Lithuania, which was established in the mid-13th century and lasted until the 18th century. Lithuanian writings begin to appear in the 16th century, first in East Prussia (where many Lithuanians lived) and, somewhat later, in the Grand Duchy of Lithuania. In East Prussia, a quite uniform written Lithuanian language, based on the West High Lithuanian dialect, had already been established by the second half of the 17th century. In Lithuania, however, a uniform written Lithuanian came into use only at the end of the 19th and the beginning of the 20th century—*i.e.*, when a standard Lithuanian language, based on the (Southern) West High Lithuanian dialect (spoken in both East Prussia and Lithuania), was established. Martynas Mažvydas (died 1563),

Establishment of uniform written Lithuanian

who published the first Lithuanian book (a catechism) in Königsberg (Lithuanian Karaliaučius; modern Kaliningrad) in the year 1547, is purported to be the first person to use Lithuanian as a written language. Others, in particular Baltramiejus Vilentas, Jonas Bretkūnas, and the pastor-poet Kristijonas Donelaitis, also took part in the formation and standardization of a written Lithuanian language in the 16th–18th century in East Prussia. Great influence was exerted by the first grammars of Lithuanian, by Danielius Kleinas (1653 and 1654), and the works of Donelaitis (1714–80), the first Lithuanian writer to become well known. In the Grand Duchy of Lithuania the first to use Lithuanian as a written language is held to be Mikalojus Daukša (died 1613), who published a catechism in 1595 and a prayer book (*Postilė*) in 1599. Among later writers who helped to standardize written Lithuanian were Konstantinas Sirvydas, who prepared the first dictionary of Lithuanian (1629), Jonas Jaknavičius (1598–1668), and Saliamonas Slavočinskis (17th century). The works of Daukša and Sirvydas in particular, based on the Middle and East High Lithuanian dialects, did much toward establishing the practice of drawing on the various dialects in the creation of a written Lithuanian. This tradition became weakened in the 18th century but was again revived at the beginning of the 19th, when the formation of a standard Lithuanian was undertaken. The practice became most apparent at the end of the 19th and the beginning of the 20th century, during the establishment of Standard Lithuanian. The process of the mixing and levelling of the Lithuanian dialects started at the beginning of the 20th century because of the influence of a standard language, and it was especially intensified after the creation of the Lithuanian Soviet Socialist Republic in 1940. Standard Lithuanian is the official language of the Lithuanian S.S.R., as it was of the Republic of Lithuania (from 1918).

Latvian. The Latvian (Latgalian) people achieved a separate identity around the 16th century AD, when they completely assimilated the other Balts, as well as a greater part of the Livs (also called Livonians, Livians), who are of Finnic descent and live on Latvian territory. As a result of the conquering of Latvian territory by the German Knights of the Sword by 1290, close contact between all of the so-called Eastern Balts (the Latvians with the Lithuanians as well) was considerably weakened for a long period of time. The first Latvian book was the *Catechismus Catholicorum* of 1585. In 1638 the first Latvian (–German) dictionary, by Georgius Mancelius, appeared; the first grammar of the Latvian language, by Johann Georg Rehehausen, was published in 1644; and a Latvian translation of the Bible was published in 1685. The Latvian writings of the 16th–18th century are translations of religious works, as are the Lithuanian. The language of these Latvian works, however, is somewhat poorer than that of the Lithuanian writings of the same period. The works of the Latvians Juris Alunāns (1832–64) and Atis Kronvalds (1837–75) exerted a great influence on the development of a standard Latvian language, based on the Central dialect, at the beginning of the 19th century. Standard Latvian was finally established at the end of the 19th and the beginning of the 20th century, and the levelling influence of this standard language on the Latvian dialects began at this time. Standard Latvian is the official language of the Latvian S.S.R.

Early Latvian books

Characteristics of the Baltic languages. All of the Baltic languages are inflected. Old Prussian is the most archaic of the recorded Baltic languages (although it also has innovations of its own), and it differs considerably from Lithuanian and Latvian.

Old Prussian. In contrast to Lithuanian and Latvian, Old Prussian retained the Baltic diphthong *ei*—Old Prussian *deiws* "God," Lithuanian *diẽvas*, Latvian *dìevs;* Old Prussian *deinan* "day" (accusative singular), Lithuanian *dienà*, Latvian *dìena*. In place of Lithuanian *š* and *ž* (from Indo-European **ḱ*, **ǵ*, and **ǵh*), however, Old Prussian, like Latvian (as well as Curonian, Semigallian, and Selonian), has *s* and *z*—thus, Old Prussian *assis* "axle," Latvian *ass*, Lithuanian *ašìs;* Old Prussian *(po)sinnat* "to confess," Latvian *zināt*, Lithuanian *žinóti* "to know." The cluster *s* + *j* (and *z* + *j*) in Old Prussian, as in Latvian, passed to *š* (and *ž*): Old Prussian *schan* (from **sjan*) "this" (accusative singular feminine), Latvian *šùo* "this," Lithuanian *šią*. In contrast to Lithuanian and Latvian, Old Prussian did not replace the clusters *t* + *j* and *d* + *j* with affricate sounds (begun with complete stoppage of the breath stream from the lungs and released with incomplete closure and friction): Old Prussian *median* "forest," Lithuanian *medžias*, Latvian *mežs*.

Word stress was free in Old Prussian, as it is in Lithuanian (in contrast to Latvian, in which the stress is predictable and falls on the first syllable). Old Prussian also made use of intonations (tones), the character of which is similar to that of the Latvian (*i.e.*, more archaic than that of Lithuanian intonations). The Proto-Baltic circumflex intonation corresponds to the falling tone in Old Prussian, while the acute intonation corresponds to the rising tone.

Old Prussian morphology

Old Prussian, moreover, had a substantive neuter gender, lost by Lithuanian and Latvian: Old Prussian *assaran* "lake," Lithuanian *ežeras*, Latvian *ezers;* Old Prussian *lunkan* "bast," Lithuanian *lùnkas*, Latvian *lūks*. It differs in morphology from Lithuanian and Latvian in more than one instance—*e.g.*, in the genitive singular ending, Old Prussian *deiw-as* "of God" (Lithuanian *dievo* = Latvian *diev-a*) and, in the dative singular, Old Prussian *tebbei* "to you" (Lithuanian *tavi* = Latvian *tev*), among others. Old Prussian did not have the dual number, only the singular and plural. Nouns were declined according to seven types. There were five cases: nominative, genitive, dative, accusative, and vocative. All verbs had three separate forms in the plural, but not in the singular. The 3rd person was the same in both the singular and the plural. There were three tenses: present, preterite, and future.

In vocabulary Old Prussian is quite similar to Lithuanian and Latvian (closer to Lithuanian than Latvian). It should be emphasized, however, that Old Prussian differs from Lithuanian and Latvian in that it retained a greater number of archaisms than either.

Comparison of Lithuanian and Latvian. The differences between Lithuanian and Latvian can be summarized in very broad terms by saying that Lithuanian is far more archaic than Latvian and that modern written Lithuanian could in many instances serve as a "protolanguage" for it. For example, Lithuanian has quite faithfully preserved the old sound combinations *an, en, in, un* (the same is true of Old Prussian, Curonian, Selonian, and, possibly, Semigallian), while they have passed in every case to *uo, ie, ī, ū* in Latvian; thus, Lithuanian *rankà* (Old Prussian *rancko*) = Latvian *rùoka* "hand," Lithuanian *peñktas* (Old Prussian *penckts*) = Latvian *piekt(ai)s* "fifth," Lithuanian *pìnti* = Latvian *pīt* "to weave, to twine," and Lithuanian *jùngas* = Latvian *jūgs* "yoke." The diphthongs *ei* (as well as *ai*) and *au* in final position were monophthongized and later shortened in Latvian—*e.g.*, Lithuanian *ved-eĩ* (2nd person singular preterite) = Latvian **ved-ie*, which became *ved-i* "you led"; Lithuanian *med-aũs* = Latvian **med-uos*, which became *med-us* "of honey." Long vowels at the end of polysyllabic words have been shortened in Latvian, and short vowels have been dropped—*e.g.*, Latvian *sak-a* "says" (which derives from **-ā*) = Lithuanian *sāk-o*, Latvian *pel-e* "mouse" (from **-ē*) = Lithuanian *pel-ẽ*, Latvian *vìlk-u* "wolf" (from **-uo*) = Lithuanian *vilk-ą*, Latvian *daikts* "thing" (from **-ăs*) = Lithuanian *dáiktas*, and Latvian *nakts* "night" (from **-ĭs*) = Lithuanian *naktìs*. Palatalized *k* and *g*, formed with the blade of the tongue closer to the hard palate than nonpalatalized *k* and *g*, were retained in Lithuanian (as in Old Prussian and Semigallian) but changed to *c* (pronounced like *ts*) and *dz* in Latvian (as in Selonian and Curonian): Lithuanian *ãkys* "eyes" (Old Prussian *ackis*) = Latvian *acis*, and Lithuanian *gérvė* "crane" (Old Prussian *gerwe*) = Latvian *dzeŗve*. The change of the old clusters *t* + *j* and *d* + *j* progressed further in Latvian. Most Lithuanian dialects have *č* (as *ch* as in "church") and *dž* (as *j* in "jam"), whereas Latvian has *š* (as *sh* in "shore") and *ž* (as *z* in "azure")—*e.g.*, Lithuanian *trẽčias* = Latvian

trešs "third"; Lithuanian *bríedžiai* = Latvian *briēži* "elks." Another difference between Lithuanian and Latvian is that, instead of Lithuanian *š* and *ž*, Latvian (like Selonian, Semigallian, Curonian, and Old Prussian) has *s* and *z* sounds—*e.g.*, Lithuanian *širdìs* = Latvian *sirds* "heart"; Lithuanian *žiemà* = Latvian *zìema* "winter." Proto-Latvian (and Prussian) *s* + *j* and *z* + *j* have passed to *š* and *ž*: Latvian *šūt* "to sew" = Lithuanian *siūti;* Latvian *eža* "of a hedgehog" (from Latvian **ezjā*) = Lithuanian *ežio*. Lithuanian has retained the initial clusters *pj* and *bj*, which in Latvian (and similarly in Slavic) have passed to *pļ* and *bļ*—*e.g.*, Lithuanian *piáuti* (*pi* is pronounced as *pj*) = Latvian *pļaũt* "to cut"; Lithuanian *biaurùs* = Latvian *bļaũrs* "hideous, nasty."

Stress and tone in Lithuanian and Latvian

Lithuanian has a free stress in contrast to Latvian fixed stress, which occurs on the first syllable. Latvian is more archaic than Lithuanian in the intonations inherited from Proto-Baltic: the Proto-Baltic circumflex intonation has preserved its falling character in Latvian (it became rising in Lithuanian), and the Proto-Baltic acute intonation retained its rising character (it is falling in Lithuanian), although in some cases (because of stress retraction) it has been changed to the broken intonation; *e.g.*, Latvian *pìrsts* "finger" = Lithuanian *piřštas* (falling in Latvian and rising in Lithuanian from the Proto-Baltic circumflex), Latvian *vārna* "crow" = Lithuanian *várna* (the rising or extended intonation in Latvian and the falling intonation in Lithuanian from the Proto-Baltic acute intonation), Latvian *zâle* "grass" (the Latvian broken intonation from the Proto-Baltic acute intonation through stress retraction).

There are really no differences in the older morphological features between Lithuanian and Latvian if one does not take into account innovations such as the Latvian debitive verb form (*man ir jāmācās* "I must study" or "it is necessary for me to study") and the Lithuanian frequentative past (*jie eidavo* "they used to go"). Lithuanian and Latvian have two grammatical genders (masculine and feminine) and two numbers (singular and plural), while some Lithuanian dialects also have the dual number. Both Lithuanian and Latvian have seven cases—nominative, genitive, dative, accusative, instrumental, locative, vocative. Standard Lithuanian has five declensions of nouns with 12 inflectional types; Latvian has six declensions with eight inflectional types. Lithuanian adjectives have three declensions, Latvian adjectives have one. The comparison of adjectives in the two languages is different. Both Lithuanian and Latvian have indefinite adjectives (Lithuanian *mãžas*, masculine, *mažà*, feminine, "a small one" = Latvian *mazs*, *maza*) and definite adjectives (Lithuanian *mažàsis*, *mažóji* "the small one" = Latvian *mazais*, *mazā*) with their own specific inflection. The verb in Lithuanian and Latvian has three conjugations (genetically different). There are three persons, the third of which is the same (apparently from the time of Proto-Indo-European) in both the singular and the plural (as well as the dual); for example:

Lithuanian		Latvian
Singular		Singular
1. *kertù*	("I cut, I strike")	1. *certu*
2. *kertì*	("you cut, you strike")	2. *certi*
3. *kerřta*	("he cuts, he strikes")	3. *cert*
Plural		Plural
1. *kerřtame*	("we cut, we strike")	1. *certam*
2. *kerřtate*	("you cut, you strike")	2. *certat*
3. *kerřta*	("they cut, they strike")	3. *cert*

Verb forms

The verb in Lithuanian and Latvian has three tenses (present, preterite, future)—*e.g.*, Lithuanian *kertù*, Latvian *certu* (present); Lithuanian *kirtaũ*, Latvian *cirtu* (preterite); Lithuanian *kiřsiu*, Latvian *ciršu* (future). In contrast to Latvian, Lithuanian also has a frequentative past tense—*e.g.*, *kiřsdavau* "I used to cut, strike." Lithuanian and Latvian have many compound tense forms, compounded from the forms of the verb *būti* "to be" and participles. There are several moods in both languages, although they are different. The system of participles (active and passive) in Lithuanian and Latvian is quite similar, although complicated—*e.g.*, Lithuanian *kertą̃s*, Latvian *certuošs* (present active); Lithuanian *kerřtamas*, Latvian *certams* (present passive). Lithuanian and Latvian sentence word order is quite free, and, in general, the syntax of both languages is quite similar.

Words are formed in Lithuanian and Latvian basically by means of suffixes, prefixes, and compounding. The languages are very similar in their early vocabulary, and the differences that do occur tend to be more of a semantic nature—e.g., Lithuanian *móša* "husband's sister" = Latvian *māsa* "sister"; Lithuanian *žam̃bas* "corner, angle (acute)" = Latvian *zùobs* "tooth." Some older lexical differences do occur, however (*e.g.*, Lithuanian *kraũjas* = Latvian *asins* "blood"; Lithuanian *sūnùs* = Latvian *dēls* "son"). In the newer vocabulary, there are now many differences between Lithuanian and Latvian.

Loanwords in Baltic. The Baltic languages have loanwords from the Slavic languages (*e.g.*, Old Prussian *curtis* "hunting dog," Lithuanian *kùrtas*, Latvian *kuřts* come from Slavic [*cf.* Polish *chart*]; Lithuanian *muĩlas* "soap" [*cf.* Russian *mylo*]; Latvian *suods* "punishment, penalty" [*cf.* Russian *sud*]). There are also a few loanwords from Gothic (*e.g.*, Old Prussian *ylo* "awl," Lithuanian *ýla*, Latvian *īlens*) and possibly from Scandinavian, and many from German, especially in Old Prussian and Latvian, as a consequence of the German colonization of the Prussians, Latvians, and, in part, of the Lithuanians in the 13th century.

Relation between the Baltic and Finnic languages

The Balts first came in close contact with their northern neighbours, the Baltic Finns, about 2000 BC. This contact left traces in both the Baltic and the Finnic languages, perhaps most clearly in the vocabulary. Baltic has very few early loanwords from Finnic, but Finnic has many early loans from Baltic. Latvian, with many loanwords from Livian (Livonian) and Estonian (both Finnic languages), has been more influenced by Finnic than has any other recorded Baltic language.

Orthography. The Lithuanian alphabet is based on the roman (Latin) alphabet. It has 33 letters, several employing diacritical marks (*ą, č, ę, ė, į, š, ų, ū, ž*), and is phonetic (*i.e.*, written as it is pronounced). In linguistic literature ′ is used for falling tones, and ~ for rising tones; the grave accent (`) is used for short, stressed vowels. The Latvian alphabet has 33 letters, 11 with diacritical marks: *ā, č, ē, ģ, ī, ķ, ļ, ņ, š, ū, ž*. A macron (¯) over a vowel indicates that it is long. In linguistic literature the following accents are used for the Latvian intonations: ` (falling), ~ (extended, or rising), ˆ (broken).

The Old Prussian orthography is almost wholly based on the German orthography of that time and is quite inconsistent. Furthermore, every Old Prussian written record has its own specific orthography.

BIBLIOGRAPHY. There are very few works on the Baltic languages in English aside from LEONARDAS DAMBRIUNAS, ANTANAS KLIMAS, and WILLIAM R. SCHMALSTIEG, *Introduction to Modern Lithuanian* (1966); TEREZA BUDINA LAZDINA, *Teach Yourself Latvian* (1966); and JANIS ENDZELINS, *Baltų kalbų garsai ir formos* (1957; Eng. trans., *Comparative Phonology and Morphology of the Baltic Languages*, 1971). *Baltic Linguistics*, ed. by THOMAS F. MAGNER and WILLIAM R. SCHMALSTIEG (1970), is a collection of papers on various aspects of Baltic linguistics.

The following publications are written in German, Lithuanian, Latvian, and Polish. REINHOLD TRAUTMANN, *Die altpreussischen Sprachdenkmäler* (1910); JOHANN ENDZELIN, *Lettische Grammatik* (1922; trans. into Latvian, 1951); KAZIMIERAS BUGA, *Lietuvių kalbos žodynas* (1924–25), the introduction to this dictionary contains much valuable information on the history of the Baltic languages; *Rinktiniai raštai*, 3 vol. (1958–61); JANIS ENDZELINS, *Senprūšu valoda* (1943; trans. into German, 1944, without a glossary); *Ievads baltu filoloģijā* (1945), an introduction to Baltic linguistics, in Latvian; ERNST FRAENKEL, *Die baltischen Sprachen* (1950), a general introduction; ALFRED SENN, "Die Beziehungen des Baltischen zum Slavischen und Germanischen," *Zeitschrift für vergleichende Sprachforschung*, vol. 71 (1954), discusses the relationship of Baltic to Slavic and Germanic; *Mūsdienu latviešu literārās valodas gramatika*, 2 vol. (1959–62), a grammar of the modern Latvian literary language; ARTURS OZOLS, *Veclatviešu rakstu valoda* (1965), treats Old Latvian; JAN OTREBSKI, *Gramatyka języka litewskiego*, 3 vol. (1956–65), a Lithuanian grammar, in Polish; MARTA RUDZITE, *Lat-*

viešu dialektologija (1964), treats Latvian dialectology; *Lietuvių kalbos gramatika,* 2 vol. (1956, 1971), the most authoritative grammar of the Lithuanian language; ZIGMAS ZINKEVICIUS, *Lietuvių dialektologija* (1966), a valuable treatment of Lithuanian dialectology; CHRISTIAN S. STANG, *Vergleichende Grammatik der Baltischen Sprachen* (1966), the only scholarly comparative grammar of the Baltic languages; VYTAUTAS J. MAZIULIS (comp.), *Prūsų kalbos paminklai* (1966), contains and discusses all the photographed Old Prussian texts; ALGIRDAS SABALIAUSKAS, "Lietuvių kalbos leksikos raida," *Lietuvių kalbotyros klausimai,* 8:5–140 (1966), treats the development of the vocabulary of Lithuanian; JONAS PALIONIS, *Lietuvių literatūrinė kalba XVI–XVII a.* (1967), a treatment of the Lithuanian literary language in the 16th and 17th centuries; JONAS KAZLAUSKAS, *Lietuvių kalbos istorinė gramatika* (1968), the only historical grammar of Lithuanian; VYTAUTAS MAZIULIS, *Baltų ir kitų indoeuropiečių kalbų santykiai* (1970), treats the relationship of Baltic and the other Indo-European languages.

The largest dictionaries of Baltic languages are: K. MULENBACHS, *Latviešu valodas vārdnīca,* 4 vol. (1923–32); *Lietuvių kalbos žodynas,* 8 vol. (1941–70); and ERNST FRAENKEL, *Litauisches etymologisches Wörterbuch,* 2 vol. (1955–65).

(V.J.M.)

Baltic Religion

The term Baltic religion covers the religious beliefs and practices of the Balts, ancient inhabitants of the Baltic region of eastern Europe, who spoke languages belonging to the Baltic family of languages.

SOURCES AND PROBLEMS IN THE STUDY OF BALTIC RELIGION

Problems. The study of Baltic religion has developed as an offshoot of the study of Baltic languages—Old Prussian, Latvian, and Lithuanian (see BALTIC LANGUAGES). These form a separate group—the oldest one—of the Indo-European languages, which are closely related to the ancient Indian language Sanskrit.

Although the study of Baltic languages is important in the study of Indo-European linguistics, the study of Baltic religion has not assumed a similar level of importance in the study of comparative religion. In 1875 it was shown that the religious concepts of the Balts, when compared with those of other European peoples, are found to be marked by many older features that agree with Vedic (ancient Indian) and Iranian ideas. At least one scholarly reconstruction of ancient Indo-European religion depended mainly on Baltic religious traditions. International research in Baltic religion has, however, been greatly hindered by the fact that the languages of these small Baltic countries (Latvia and Lithuania) are but little known and because Baltic scholars have been able to work in this field only relatively recently. Thus, a comprehensive review of Baltic religion is possible only on the express understanding that many findings are only hypothetical and require further research. But, as will be seen below, even under these circumstances Baltic religious concepts help greatly in understanding the formation and structure of the oldest phases of Indo-European religion.

Sources of data. There are four main sources of data, each with its own relevance and each requiring its own specific methodology: archaeological material, historical documents, linguistics, including toponymy (the study of the place-names of a region or language), and folklore. Since the last half of the 19th century, archaeological material has furnished much information about burial and sacrificial rites. The remains of sacral buildings have also been found. This material is of special interest in that it corroborates old religious traditions preserved by folklore, which gives added reliability to both of these sources. But archaeological material can at best furnish only a partial and incomplete picture, even though it is meaningful in some respects. Historical documents, already partially compiled and published, could be expected to yield much more information. Their value, however, is made problematic by the fact that all such documents were written by foreigners, mainly Germans who, in the course of their centuries-long eastward expansion, subjugated the Baltic peoples and exterminated some of them. Since the conquerors did not understand the Baltic languages, many documents contain the names of gods and other divinities that are without basis in fact. Baltic religion was viewed dogmatically and negatively in the light of Christian interpretations. Linguistic source material, also compiled by foreigners, shows fewer signs of interpretation, especially in regard to toponymy. Baltic folklore—one of the most extensive folklores of all European peoples—contains the greatest amount of material, especially in the form of *dainas* (short folk songs of four lines each) and folktales. Folklore is especially valuable because it contains many concepts that elsewhere have been lost under the influence of Christianity. Old religious beliefs have persisted because the Germans, after conquering the Baltic lands in the 13th and 14th centuries, made practically no attempt at Christianization and contented themselves with only economic gains. The positive result of this policy is the preservation of old traditions and religious beliefs; some researchers have also noted the similarity between the metrical structure of the *dainas* and that of the Old Indian short verses in the Ṛgveda (a Hindu sacred scripture).

The student of Baltic religion still encounters two difficulties. First, as has been noted, since written documents were established in Christian times, Christian influences in them are inescapable. Such influences cause difficulties and make a critical approach mandatory. Second, after the establishment of political independence of the Baltic countries following World War I, there arose a certain national romanticism that has attempted to identify Baltic culture with that of the ancient Indo-Europeans. Thus, an uncritical approach has led even to the introduction of "gods" that are actually only etymological derivations from the names of Christian saints. On the other hand, those western European scholars who are unfamiliar with the special historical and social circumstances of the Balts have assumed Baltic folklore to be on a level with the thoroughly Christianized western European folklore and thus have underestimated its importance.

MYTHS AND GODS

Cosmology. In the traditions of the Baltic peoples, there are no epic myths about the creation of the world and its structure. This fact is explained by the historical and social circumstances mentioned above, which either have hindered the formation of these types of myths or, more likely, have simply made their preservation possible. Furthermore, there has been no significant research concerning Baltic myths and their intrarelationships. Fragmentary evidence found exclusively in folklore indicates only two complexes of ideas with any certainty: the first concerns the structure of the world, the second the enmity between Saule (the Sun) and Mēness (Latvian; Lithuanian Mėnulis; the Moon).

There is disagreement as to whether the Balts pictured the world as consisting of two regions or of three. The two-region hypothesis seems to be more plausible and is supported by a dualism found frequently in the *dainas*: *šī saule* (literally "this sun") and *viņa saule* (literally "the other sun"). The metaphor *šī saule* symbolizes ordinary everyday human life, while *viņa saule* indicates the invisible world where the sun goes at night, which is also the abode of the dead.

The two-region hypothesis

The evidence does not show conclusively whether it is located in the direction of the setting sun or under the earth, beneath which the sun travels back to the east. The sky is considered to be a mountain, sometimes of stone, and is the residence of the sky gods. Saule rides over the sky in a chariot drawn by a varying number of horses, Mēness rides to be married, and Pērkons (Latvian; Lithuanian Perkūnas; the Thunderer) makes weapons and jewelry in the sky.

The concept that Saule, unseen during the night, makes her way from west to east under the earth so that she can start her course anew over the sky mountain is also familiar. It is also possible to see here the ancient idea of a world ocean on which the earth, as a round plate, swims, an idea that has disappeared under the influence of Christianity.

The notion of a sun tree, or world tree, is one of the most important concepts regarding the cosmos. This tree grows at the edge of the path of Saule, and the setting sun (Saule) hangs her belt on the tree in preparation for rest. It is usually considered to be an oak but is also described as a linden or some other kind of tree. The tree is said to be located in the middle of the world ocean or generally to the west.

The gods. *Dievs.* The Baltic words Latvian *dievs*, Lithuanian *dievas*, and Old Prussian *deivas* are etymologically related to the Indo-European *deiu̯os;* among others, the Greek Zeus is derived from the same root. It originally meant the physical sky, but already in Old Indian and other religions the sky became personified as an anthropomorphic deity. Dievs, the pre-Christian Baltic name for god, was used by Christian missionaries (and still is) to denote the Christian God. The etymology of the word indicates that the Balts preserved its oldest forms, which is also true of the functions and attributes of the personified Baltic sky god Dievs, who lives on his farmstead on the sky mountain but does not participate in the work of the farm. Importantly, Dievs is a bridegroom who rides together with the other gods to a sky wedding in which his bride is Saule. Dievs' family is a later development; in the family, Dieva dēli (God's Sons) play the primary role. Thus Dievs is pictured as the father of a family of sky gods. Besides such anthropomorphic characteristics, another characteristic that gives Dievs a universal significance may be observed: he appears as the creator of order in the world on the one hand, and as the judge and guardian of moral law on the other. From time to time he leaves the sky mountain and actively takes part in the everyday life of the farmers below. His participation in various yearly festivals is vividly described. In spite of this, the Baltic Dievs is similar to the Old Indian Dyaus, the Greek Zeus, and other personifications of the sky. Such divinities have a tendency, in comparison with other gods of their religions, to recede into a secondary role.

The sky god

Pērkons. In Baltic, as in other Indo-European religions, there is, in addition to Dievs, the Thunderer (Latvian Pērkons, Lithuanian Perkūnas) with quite specific functions. Pērkons is described in the oldest chronicles and in poetic and epic folklore, but, though he is a primary divinity there is no reason to believe that he is the main god. His abode is in the sky, and, like Dievs, he sometimes descends from the sky mountain. He has two main characteristics. First, he is a mighty warrior, metaphorically described as the sky smith, and the scourge of evil. His role as adversary of the devil and other evil spirits is of secondary importance and has been formed to a great extent under the influence of Christian syncretism. Secondly, he is a fertility god, and he controls the rain, an important event in the life of farmers. Various sacrifices were made to him in periods of drought as well as in times of sickness and plague. No other god occupied a place of such importance at the farmer's table during festivals, especially in the fall at harvest time. Like the other sky gods, he also has a family. Even though his daughters are mentioned occasionally, originally he had only sons, and myths depicting sky weddings portray his role vividly, as a bridegroom and as the father in his sons' weddings.

Saule. The sun, Saule, occupies the central place in the pantheon of Baltic gods. The divinity of the sun has been recognized all over the world, and the Balts were no exception. The Baltic description of the sun as divinity is so complete and specific that it was one of the first to be studied by scholars. Of greatest importance is the similarity in both functions and attributes of Saule and the ancient Indian god Sūrya. Similarities between the two gods are so great that, were not the two peoples separated by several thousand miles and several millennia, direct contact between them would be indicated instead of only a common origin.

The sun goddess

The representation of Saule is dualistic in that she is depicted as a mother on one hand, and a daughter on the other. Her attributes are described according to the role she plays. As a daughter she is mentioned only when she is a bride to the other sky gods. But as her daughters frequently are in the same role, it is difficult to differentiate between them. As a mother, however, she is depicted much more extensively and completely. Her farmstead on the sky mountain borders that of Dievs, and both Dieva dēli and Saules meitas (Daughters of the Sun) play and work together. Sometimes Dievs and Saule become enraged at each other because of their respective children, as, for example, when Dieva dēli break the rings of Saules meitas or when Saules meitas shatter the swords of Dieva dēli. Their enmity lasts three days, which some scholars explain through natural phenomena; *i.e.*, the three days before the new moon when Dievs, a substitute for the moon, is not visible.

That Saule, richly described in mythology, also had a cult devoted to her is suggested by the many hymns in her honour. They contain either expressions of thanks for her bounty or prayers seeking her aid, not only in relation to agriculture but to life in general. In agriculture Saule is a sanctifier of the fertility of the fields; in the life of the individual she is a typical sky goddess, interfering in her omniscience. She has human moral characteristics and punishes the immoral and aids the suffering. Though the question of where Saule's places of worship were located is not solved, the occasions for rituals pertaining to Saule have been definitely established, the most important of which was the summer solstice. Besides song, recitative, and dance, a central place in the ceremonies was occupied by a ritual meal, at which cheese and a drink brewed with honey (later beer) were consumed.

The moon god

Mēness. Mēness, the moon, also belongs to the sky pantheon. Detailed analysis only recently has shown that he has a role as a war god in Baltic religion. Such a role is indicated not only by his dress and accoutrements but especially by his weapons and expressions used in times of war. The influence of syncretism, however, has erased the outlines of his characteristics so far as to make a description of his role and any cult he may have had very difficult. The sky wedding myths furnish a somewhat more complete picture in which he is represented as a conflict-creating rival suitor of Auseklis (the Morning Star).

Auseklis, his sons, Dieva dēli, and Saules meitas form a separate group of divinities. Although they are mentioned in the sky myths, they have remained only as personifications of natural phenomena, characterized by the most beautiful metaphors.

It is notable that a common characteristic of the sky gods, and, in fact, of all Baltic divinities, is the express tendency for each to have a family.

All the divinities mentioned above are closely associated with horses: they either ride or are drawn in chariots across the sky mountain and arrive on earth in the same fashion. The number of horses is indeterminate but usually varies from two to five or more. This trait also confirms the close ties between Baltic and Indo-Iranian religions.

Although males form the majority of the sky gods, the chthonic (underworld) divinities are mostly female. In both Latvian and Lithuanian religions the earth is personified and called Earth Mother (Latvian Zemes māte, Lithuanian Žemyna). But the Lithuanians also have Žemėpatis, Earth Master. Latvians in general refer to mothers, Lithuanians to masters. Zemes māte is the only deity in addition to Dievs who is originally responsible for human welfare. Based on the writings of the Roman historian Tacitus, it has been asserted that she is the mother of the other gods, but there is no support for this view in other sources. Under the influence of Christian–pagan syncretism, the Virgin Mary has assumed some of the functions of Zemes māte. Furthermore, some of these functions have been acquired and differentiated by various other later divinities, who, however, have not lost their original chthonic character. Thus, a deity of the dead has developed from Zemes māte, called in Latvian Smilšu māte (Mother of the Sands), Kapu māte (Mother of the Graves), and Veļu māte (Mother of the Ghosts). Libations and sacrifices were offered to Zemes māte.

Such rituals were also performed in connection with the other divinities at a later stage of development. The fertility of the fields is also guaranteed by Jumis, who is symbolized by a double head of grain, and by various mothers, such as Lauka māte (Mother of the Fields), Linu māte (Mother of the Flax), and Mieža māte (Mother of the Barley).

Forest and agricultural deities. A forest divinity, common to all Baltic peoples, is called in Latvian Meža māte (Mother of the Forest, Lithuanian Medeinė). She again has been further differentiated into other divinities, or rather she was given metaphorical appellations with no mythological significance, such as Krūmu māte (Mother of the Bushes), Lazdu māte (Mother of the Hazels), Lapu māte (Mother of the Leaves), Ziedu māte (Mother of the Blossoms), and even Sēņu māte (Mother of the Mushrooms). Forest animals are ruled by the Lithuanian Zvėrinė opposed to the Latvian Meža māte.

The safety and welfare of the farmer's house is cared for by the Latvian Mājas gars (Spirit of the House; Lithuanian Kaukas), which lives in the hearth. Similarly, other farm buildings have their own patrons—Latvian Pirts māte (Mother of the Bathhouse), Rijas māte (Mother of the Threshing House); Lithuanian Gabjauja.

Gods of natural phenomena

Because natural phenomena and processes have often been raised to the level of divinities, there is a large number of beautifully described lesser mythological beings whose functions are either very limited or completely denoted by their names. Water deities are Latvian Jūras māte (Mother of the Sea), Ūdens māte (Mother of the Waters), Upes māte (Mother of the Rivers), and Bangu māte (Mother of the Waves; Lithuanian Bangpūtys), while atmospheric deities are Latvian Vēja māte (Mother of the Wind), Lithuanian Vėjopatis (Master of the Wind), Latvian Lietus māte (Mother of the Rain), Miglas māte (Mother of the Fog), and Sniega māte (Mother of the Snow). Even greater is the number of those beings related to human activities, but only their names are still to be found, for example Miega māte (Mother of Sleep) and Tirgus māte (Mother of the Market).

Goddess of destiny. Because of peculiarities of the source materials, it is difficult to determine whether the goddess of destiny, Laima (from the root word *laime*, meaning "happiness" and "luck"), originally had the same importance in Baltic religion as later, or whether her eminence is due to the specific historical circumstances of each of the Baltic peoples. In any case, a wide collection of material concerning Laima is available. The real ruler of human fate, she is mentioned frequently together with Dievs in connection with the process of creation. Although Laima determines a man's unchangeable destiny at the moment of his birth, he can still lead his life well or badly within the limits prescribed by her. She also determines the moment of a person's death, sometimes even arguing about it with Dievs.

The devil. The devil, Velns, has a well-defined role, which is rarely documented so well in the folklore of other peoples. Besides the usual outer features, several characteristics are especially emphasized. Velns, for instance, is a stupid devil. In addition, the Balts are the only colonialized people in Europe who have preserved a large amount of folklore that in different variations and situations portrays the devil as a German landlord. Another evil being is the Latvian Vilkacis, Lithuanian Vilkatas, who corresponds to the werewolf in the traditions of other peoples. The belief that the dead do not leave this world completely is the basis for both good and evil spirits. As good spirits the dead return to the living as invisible beings (Latvian *velis*, Lithuanian *vėlės*), but as evil ones they return as persecutors and misleaders (Latvian *vadātājs*, Lithuanian *vaidilas*).

PRACTICES, CULTS, AND INSTITUTIONS

Temples and other holy places. Recent archaeological excavations have indicated the existence of temples made of wood. The only remains of these temples are postholes. Such temples were circular, approximately five metres in diameter, in the centre of which a statue of a god may have been erected. At present, however, the existence of such temples must be regarded only as conjecture within the realm of probability. On the other hand, the existence of open-air holy places or sites of worship among the Balts is confirmed by both the earliest historical documents and folklore. Such places were holy groves, called *alka* in Lithuanian. Later the word came to mean any holy place or site of worship (Lithuanian *alkvietė*). Considerable research has shown that the usual sites were little hills, where the populace gathered and sacrificed during holy festivals, all of which supports the idea that wooden buildings could have been built at these sites.

Sites of worship

Other holy places were also recognized. The most important of these appear to be bathhouses, whose function some researchers have compared to that of churches in Christianity. A large amount of evidence indicates that religious–magical rites, from birth ceremonies to funerals, were performed in such bathhouses. There are various opinions as to whether the so-called holy corner (*heilige Hinterecke*); *i.e.*, the dark corner of a peasant's house in which a deity or patron lives, belongs to pre-Christian concepts or not. On the other hand, various places in the house proper, such as the hearth and the doorstep, were considered to be abodes of spirits. In general, the more important work sites each had its own guardian spirit. Sacrifices were performed at each spot to assure successful completion of work. Because they supplied the farmstead with water, streams and rivers were also especially important.

Religious personages. There is no reliable information that the Balts had a priestly class, let alone religious hierarchy. The 11th-century German historian Adam of Bremen, in describing conflicts between Christian missionaries and Latvians, said that "every house is filled with seers, augurers, and necromancers," which indicates that the Balts had sacral persons, probably the patriarchs of large extended families or heads of clans. As even 18th-century church inspection records show, the Christian Church had great difficulty in curbing their influence, especially within their clans. Their religious functions were twofold. First, they were responsible for the welfare and means of existence of the people through the performance of appropriate rites both at work sites and during the holy festivals. Second, they assured that the proper procedure would be followed in rituals connected with the important occasions of human life, such as birth, marriage, and death. In the syncretistic amalgam of Christianity and the religion of the Balts, those persons were called sorcerers (*Zauberer*) and, according to church records, were treated by the Balts with the same reverence as bishops were by Christians.

Sacred times. Special rites evolved for the festivals of the summer solstice and the harvest, while other rites were used specifically for beginning various kinds of spring work. Such spring work included sending farm animals to pasture or horses to forage for the first time, plowing the first furrow, and starting the first spring planting. The birth of a child was especially noted; it usually took place in the bathhouse or some other quiet spot. Laima was responsible for both mother and child. One birth rite, called *pirtīžas*, was a special sacral meal in which only women took part. Marriage rites were quite extensive and corresponded closely to similar Old Indian ceremonies. Fire and bread had special importance and were taken along to the house of the newly married couple. These rites persisted until quite late and were to be seen even at the end of the 19th century, though in many cases only as games. In this connection, fire in general occupied a central place in Baltic religion. Considered holy, it was worshipped, and sacrifices were offered to it.

Death rites and customs

It seems unbelievable that even as late as 1377 and 1382, respectively, the Lithuanian king Algirdas and his brother Kęstutis could still be buried according to the old traditions in a Christian Europe; dressed in silver and gold, they were burned in funeral pyres together with their best possessions, horses, hunting dogs, birds, and weapons. In spite of a ban by the church and subsequent persecution, this rite still persisted in the 15th century. The tenacious preservation of this ancient Indo-European

ritual casts light on other features of Baltic religion. Chronicles relate that Lithuanians, after losing a battle, joyfully committed suicide; this was also true of the widows of soldiers killed in battle. Such voluntary immolation and the articles buried with the dead are evidence of a belief in life after death. It is said that at the funeral of a nobleman his companions threw lynx and bear claws into the fire to aid his climb up the mountain to God, an indication of Christian influence. Archaeological excavations have also yielded evidence of fire funeral rites: the bones of men and animals, metal jewelry, and weapons found at the sites of the funeral pyres.

In funeral rites several different phases are discernible during the period between death and burning. The deceased was laid out in his house for a longer or shorter period depending on his social position and the size of his estate. During this time a meal lasting several days was held for the deceased's relatives and friends. In the course of the festivities the participants conducted fights on horseback. Lamentations, leave-takings, and praises of the deceased, as well as wishes for a safe journey to the world of the dead, accompanied the corpse on the way to the funeral pyre. In spite of persecution by the church, the tradition of lamentation has lasted until modern times, though in a somewhat modified form. One of the peculiarities of Baltic funeral rites was their similarity to wedding ceremonies. The corpse and a partner selected from the living were dressed in elaborate wedding costumes, wedding songs were sung, and dancing took place. The basis of these ceremonies was the belief that the dead anticipate a new companion with the same joy as the living do a new in-law. The corpse's living partner was a symbolical substitute for the new comrade awaited by the dead.

The above suggests a dominant concept in Baltic religious thought, namely, that the boundary between the worlds of the dead and the living was not real. The dead continued to live invisibly and were present at all important occasions. A place was set for them at the festival table and no one else might sit there. The extensive practice of feeding the dead was a consequence of the concept that the living were responsible for their welfare. Originally, their food must have been placed at the hearth. In later development, meals for the dead were also placed in other buildings, such as the threshing house or the bathhouse. Under the influence of Christianity, these living dead (Latvian *vēlis*, Lithuanian *vėlės*) have been confused with the devil. A widespread view was that the souls of the dead dwell in the *zalktis* (Latvian; Lithuanian *žaltys;* "green snake"); thus special care was taken in its feeding. But the *zalktis* was also closely associated with fertility and sexual symbolism.

SUMMARY AND CONCLUSIONS

Three main characteristics

Three main characteristics are discernible in Baltic religion. First, it is a typical astral religion in which the personified sky and main heavenly bodies play a major role. Saule, Mēness, Auseklis, and other gods have their own traits, frequently based on counterparts in nature. Although they are all related as one family, their roles within the family are varied. Depending on the cult or the plot of the myth, each divinity can assume various functions; religious man, in general, does not experience such fluctuations as a contradiction. The second main characteristic is personified happiness, luck, and fate, Laima, who has assumed the role of a goddess of destiny. Because happiness is not an external, datable event, other gods besides Laima can help determine happiness in human life. The differentiation of Laima's functions has led to the establishment of some of her functions as independent entities with sometimes a poetic, sometimes a religious, meaning. The concept of destiny in Baltic religion has not, however, resulted in passive resignation or quietism but rather full exploitation of opportunities within the limits set by it. The third characteristic is the fertility cult. Here the primary force is the personified earth, called Mother, with all her functions and characteristics. It must be understood that the concept of a fertility cult entails a wider meaning, that of the assurance of human welfare in general.

These three main typological traits hardly describe Baltic religion in all of its details and nuances. The religion can also be analyzed as having two strata: one, expressed in the above three features, can be called the stable surface layer. The second, visible below the first, contains only the outlines of undifferentiated, fluid mythological and religious beings that, because of their vague character, appear in various guises and have no stable role. They are the countless house, field, and wood spirits of the nature myths.

Baltic religion, typologically, is an agricultural religion, and it is useless to speculate whether any other basis—such as nomadism, hunting, or fishing—can be found for it, because no information regarding such possibilities can be derived from any source. The amorphous agricultural clan defines the nature of Baltic religion. The farmer's gods are also farmers, though they live in great glory on their farmsteads on the sky mountain, from which they descend to help their lesser image—man. If necessary, Dievs, Saule, and Laima dress themselves in farmer's clothes and walk his fields with him. This religion does not recognize contemplation or mysticism but rather exhibits a healthy rationalism. Just as the gods are part of the cosmic order and are responsible for its maintenance, so man obeys it and becomes a part of the divine rhythm of life set by the gods. In this way, man crosses the boundary that otherwise separates him from the world of the gods. Various specific historical circumstances explain why the Balts, in their language as well as in their religion, have preserved many elements undoubtedly belonging to the oldest phase of Indo-European religion.

BIBLIOGRAPHY. H. BERTULEIT, "Das Religionswesen der alten Preussen mit litauischlettischen Parallelen," in *Prussia*, vol. 25 (1924), is the only complete review of the Old Prussian religion. A critical examination of sources and research may be found in HARALDS BIEZAIS, "Die Religionsquellen der baltischen Völker und die Ergebnisse der bisherigen Forschungen," *Arv*, 9:65–128 (1953). The most important and complete bibliography is ZENONAS IVINSKIS, *Senoves lietuviu religijos bibliografija* (1938). For a comprehensive collection of historic records of the Prussian, Lithuanian, and Lettish religion, see W. MANNHARDT, *Letto-Preussische Götterlehre* (1936). HARALDS BIEZAIS, *Die Hauptgöttinnen der alten Letten* (1955), *Die Gottesgestalt der lettischen Volksreligion* (1961), and *Die himmlische Götterfamilie der alten Letten* (1972), are devoted to central problems of Baltic religion, with exhaustive bibliographies. MARIJA GIMBUTAS, *The Balts*, pp. 179–204 (1963), gives a concise summary. For essays on all conceptions, see the *Wörterbuch der Mythologie*, fasc. 7, pp. 373–454 (1965).

(H.Bi.)

Baltic Sea

As the largest expanse of brackish water in the world, the semi-landlocked and fairly shallow Baltic Sea is of conspicuous interest to scientists, while to historians it represents the economic core of the Hanseatic League, the great medieval trading group of north European ports. The many names for the sea—Ostsee (German); Östersjön (Swedish); Morze Bałtyckie (Polish); Baltiyskoye More (Russian); Itämeri (Finnish)—attest to its strategic position as a meeting place of many nation-states.

General description and location

The Baltic Sea is roughly finger-shaped, covering 160,000 square miles (420,000 square kilometres) and extending northeast on the eastern side of the Scandinavian peninsula from latitude 54° N to very near the Arctic Circle. The catchment area drained by the rivers bringing fresh water into the Baltic is about four times as large as the sea itself. Its major axis, from eastern Denmark to south Finland, is just over 1,000 miles long, with an average width of about 120 miles. The western Baltic is connected to the North Sea by the channel known as the Skagerrak, a deep inlet that separates southern Norway from the tip of the Jutland peninsula; to the immediate east of the Skagerrak, but, at a right angle to it, the shallower Kattegat separates northeast Denmark from Sweden. The large islands of Bornholm

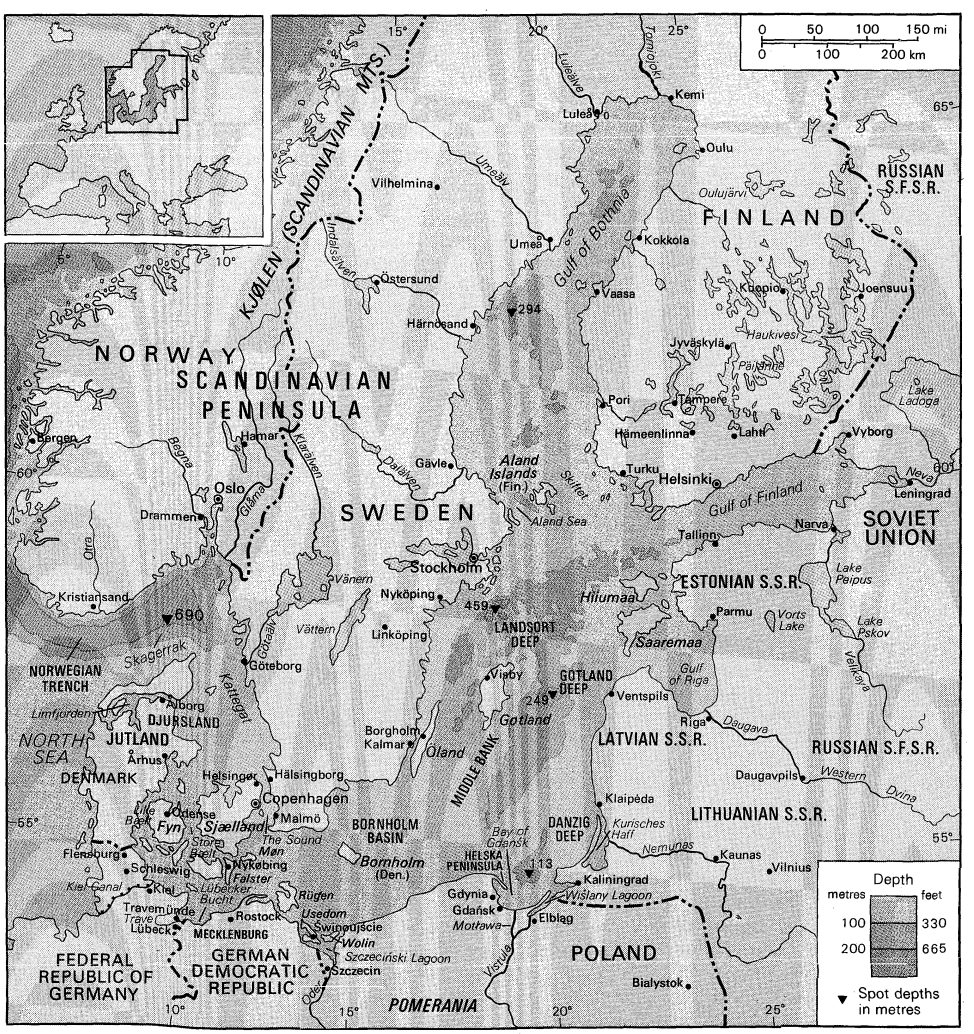
(Denmark) and then Öland and Gotland (Sweden) lie in the western Baltic while the Aland Islands (Finnish Ahvenanmaa; Swedish Åland), further north, rise from a narrows between Sweden and Finland and mark the entrance to the arm of the Baltic, known as the Gulf of Bothnia (Swedish Bottenhavet). Just to the south of the Aland Islands, the narrow Gulf of Finland stretches eastward between Finland and the Soviet Union, with Leningrad at its head. Proceeding clockwise from the west, the states bounding the Baltic are Norway; Sweden; Finland; four of the constituent republics of the Soviet Union (the Russian Soviet Federated Socialist Republic and the Estonian, Latvian, and Lithuanian S.S.Rs.); Poland; the German Democratic Republic; the Federal Republic of Germany; and Denmark. (For history, see BALTIC STATES, HISTORY OF THE, and SCANDINAVIA, HISTORY OF; for economic aspects, see HELSINKI; LENINGRAD; and STOCKHOLM; see also the articles on the states bordering the Baltic.)

The Baltic Basin. *Physical evolution.* The Baltic Sea is a shrunken remnant of the water-covered region that emerged as the melting Scandinavian Ice Sheet retreated toward the Arctic at the close of the Ice Age. In 12000 BC, ice covered all of northern Europe as far as the present German–Polish coastline; by 7700 BC glacial meltwater had formed the Yoldia Sea, which stretched east from the present Skagerrak across what is now lake-strewn southern Sweden as far as the present Lake Ladoga, beyond the bend of the Gulf of Finland. A thousand years later, only limited areas of stagnant ice remained in northern Sweden, leaving the freshwater Ancylus Lake stretching from Arctic Sweden and Finland to the present southern Baltic. Later changes around 4500 BC led to a breach of the land bridge between the present Baltic and North seas, forming The Sound (Øresund), the Store Bælt (Great Belt), and the Lille Bælt (Little Belt), which fragment the Jutland peninsula. Today there is a rise in sea level equivalent to several feet per century in the Stockholm region—a feature absent in southern Sweden and along the Danish coast—while, on the other hand, deposition is building up the head of the almost tideless Gulf of Bothnia.

Features of the sea floor. The shallowest part of the Baltic is the continental shelf, from which rise the islands of the Danish archipelago. Here the Lille Bælt divides east Jutland from the island of Fyn (Funen), which is itself separated from Sjælland (Zealand) by the deeper Store Bælt. The narrow channel of The Sound between Denmark and Sweden is too shallow for ocean-going vessels, so that Göteborg is the Swedish transatlantic shipping terminal on the coast of the Kattegat. The greatest deeps (over 1,500 feet) lie off the southeast coast of Sweden between Nyköping and the island of Gotland and also in the Gulf of Bothnia in the Aland Sea between Sweden and the Aland Islands. A deep-water channel also extends along most of the Gulf of Finland. The Baltic Sea proper contains a series of basins (*e.g.*, in the Zatoka Gdańska [Bay of Gdańsk]) divided by shallow shelves.

Hydrography. *Salinity and ice formation.* The Baltic Sea is so nearly land-locked (and its outlet so shallow) that its waters are remarkably fresh. Its longest rivers, the Vistula and the Oder, drain regions of temperate continental climate; swollen by spring snowmelt they have low evaporation rates, thus further reducing the salinity. The highest salinity is recorded in the west Baltic, where the figure is about 10‰ (parts per thousand) at the surface and about 15‰ near the bottom, while the

Factors influencing low salinity



The Baltic Sea.

lowest is at the head of the Gulf of Bothnia, where it is less than a third of this amount. The low salinity and the shallow coastal waters cause pack ice to accumulate at the head of the Gulf of Bothnia and off Finland in most winters, sometimes banked up in pressure ridges almost 50 feet high. Drift ice forms at and north of the Aland Islands area and also in the inner reaches of the Gulf of Finland, reaching a depth of about a yard. Navigation between Stockholm, Turku, and Helsinki is, however, possible, except in the most severe winters. Along the Polish and German coasts, ports are normally closed by ice for at least four weeks a year. In summer, the surface waters remain cool, while Arctic temperatures persist at lower depths.

Tides and currents. The Baltic, sheltered from the strong North Sea tides, is remarkable for the general absence of tidal currents, although the great influx of river water and surface runoff, including spring snowmelt, causes an outflow of surface water into the North Sea, while a deeper countercurrent of more dense salt water flows into the Baltic. Strong northeasterly winds may cause high waves along the southern shores, resulting in coastal flooding; conversely, prevalent southwesterly winds have aided the accumulation of sand dunes along the German and Polish coasts and also cause a piling up of water in the northern Baltic.

Coastal features. The coasts of Sweden and Finland are highly fretted and generally rocky, whereas those of the southern Baltic are flat and rather featureless. Where the crystalline rocks of the ancient rock mass known as the Fennoscandian Shield outcrop along the northern coasts, partly obscured by glacial drift and marine deposits, they are often fringed by the low, rocky, islands known as a skerry guard. These are most numerous in the Saltsjön between Stockholm and the open waters of the Gulf of Bothnia and, again, off the southwest coast of Finland. Off southeast Sweden, the narrow, elongated island of Öland and also Gotland formed of ancient limestone, partly covered by sandy drift deposits. Off southern Sweden, the rectangular island of Bornholm is formed of a detached fragment of granite, and its high cliffs were shaped by faulting and shearing of the rock strata.

Glaciation and sea-level changes

The coastal features of eastern Denmark are the outcome of Ice Age glaciation and of subsequent changes in sea level. The east coast of Jutland, north of the Djursland peninsula, is smooth and low-lying. To the south are shallow bays, or *viks*, divided by low promontories. In the area around Schleswig, shallow, straight-sided inlets known as *Förden* occur, and the Flensborg Fjord (Flensburger Förde) forms part of the boundary between Denmark and West Germany. The islands of the Danish archipelago have a broken coastline, with a number of shallow inlets and also bars, notably, the Odense bar on the island of Fyn. Where terminal moraines (deposits marking the farthest extent of glaciers) reach the sea, low promontories are formed. Solid rock seldom outcrops except along the coast of Møn Island where chalk rock forms a moderate cliff feature known as Møns Klint.

The short length of Baltic coastline within West Germany is one of shallow *Förden* and bays. Kiel lies at the head of one such inlet, south of the entrance to the Kiel (Baltic–North Sea) Canal, which runs through German territorial waters. To the east is the Lübecker Bucht (Bay of Lübeck) at the head of the Trave estuary, where Travemünde—a ferry port for Copenhagen and Sweden—combines the functions of a seaport and tourist resort. Beyond the frontier of East Germany, the coast of Mecklenburg is flat and low-lying. A series of long shingle bars, capped by moving sand dunes, has been built up here, cutting off the distinctive shallow lagoons from the open sea. Distinctive examples are the west–east spit of Darsser-Ort, on the island of Rügen, and the link (near Świnoujście) between the islands of Usedom and Wolin, which isolate the lagoon of Das Haff from the open sea. Beyond the Polish frontier, the port of Szczecin lies at the mouth of the Oder River. Solid rock outcrops conspicuously only on the island of Rügen, where the remarkably irregular coastline includes the chalk cliff known as the Königstuhl.

East of Szczecin, the coast of Pomerania (Pomorze) is generally flat and featureless, with sand dunes and spits bounding brackish lagoons. Beyond the Ikin spit of the Mierzeja Helska (Helska Peninsula) the Vistula Delta drains into the Baltic through a number of distributaries, and the historic city of Gdańsk lies on the most westerly of these, the Motława. To the east, spectacular *Haff* and *Nehrung* ("lagoon" and "shingle bar") features have developed: the region is well-known for the classic development of these features, the names of which have been applied to similar areas throughout the world. Sand dunes, covering an elongated shingle spit, almost enclose the famous brackish Frisches Haff, at the northeastern end of which lies Königsberg, the historic German outpost founded by the Order of the Teutonic Knights. Once the chief city and port of East Prussia, it is now the Russian port of Kaliningrad. Northward, the cliff coast of Uzlovoye is noted for its amber, a fossilized resin that formed a valued item of medieval trade throughout the Baltic and as far afield as Venice, which was reached by the "amber route" via Kraków and Vienna. At the northern end of the triangular inlet of the Kurisches Haff, at the mouth of the Neman, lies Klaipėda (German Memel), the most northeasterly city of Germanic origin in the Baltic. Cutting off the lagoon from the Baltic is the 60-mile-long shingle bar (the classic Nehrung), capped by low fixed dunes fringed by high moving dunes of white sand.

Haff and *Nehrung* features

The Soviet Baltic coast consists of rather monotonous features. Glacial deposits cover solid rock, and the coast is broken by broad bars, such as those on which the Latvian port of Riga lies. At the head of the Gulf of Finland is Peter the Great's "window on the Baltic," the city of St. Petersburg, renamed Leningrad in 1924, with its white buildings in classical style lining the waterfront of the Neva.

Economic resources. The Baltic Sea is no longer the major highway of trade that it was in the Middle Ages, when it flourished as the main means of communication between the ports (Lübeck, Rostock, Visby, and Gdańsk) of the Hanseatic League. The German Hansa merchants traded mainly in fish, notably, salted herring and stockfish (the dried cod from Norway and Iceland), and also in softwood timber for shipbuilding, hemp for ropes, flax for sailcloth, and grain. Forest products traded included honey and furs, notably, from Russia and Finland, as well as Stockholm tar, while amber was a semiprecious commodity. Overfishing of the herring, the opening up of trade to the New World following the Age of Discovery, and the increase in the size of sailing ships led to the decline of the Hanseatic League. Copenhagen, however, continued to prosper on the profits from tolls exacted from passing shipping during the period when both shores of The Sound were under Danish rule. Following the Reformation and the rise to political ascendancy of Sweden as the dominant Baltic power of the 17th century, Stockholm began to supersede older Swedish trading centres such as Kalmar and Visby. The later rise of Russia under Peter the Great and the empress Catherine, however, saw a corresponding decline in the economic importance of both Sweden and Denmark. Finland became a grand duchy under Russia by the Treaty of Hamina (1809), and its independence was only proclaimed in 1917. Poland ceased to exist as an independent state until resurrected in 1918, though Gdańsk (formerly German Danzig) thrived as a port. The present political and economic structure of the states bordering the Baltic in the south and east is largely a reflection of post-World War II changes, and traditional trading patterns have been amended accordingly. Timber and fish are the main items in modern Baltic trade. Softwood timber is Finland's "green gold," and it is also a major export from a large number of Swedish ports, as well as from the Soviet Union. Processed wood—including woodpulp, cellulose, paper, and hardboard from Sweden and Finland—is of growing importance. Sweden exports iron ore during the summer months from the Arctic

port of Luleå, as well as from the older port of Gävle in the south. Both Finland and Denmark have developed shipbuilding industries and marine engineering, especially since the end of World War II, Finland paying reparations to the Soviet Union in the form of ice breakers. Copenhagen, Helsingør, and Odense build motor ships. The Swedish port of Göteborg now manufactures cars and has a number of light engineering industries using high-grade steel, notably, in the manufacture of ball bearings.

Fisheries

The fisheries of the Baltic, once so rich, no longer compare in value with those of the North Sea, which are far more abundant in marine life. The shipment of fish on ice and as factory-packed frozen fish is nevertheless of growing significance to both Sweden and Denmark, the fisheries of the Kattegat, notably, those for plaice, cod, and herring, yielding the greatest returns. The traditional trade in smoked and salted herring remains important, especially with Germany. On the island of Bornholm, the traditional method of smoking the herring is over open wood fires. In Denmark, the island of Falster has offshore oyster beds, and in summer crayfish and prawns are caught off the coast of southern Sweden. In the warmer waters of the southern Baltic, herring, cod, and a variety of flatfish make up the catch off the Polish and German coasts. Gdynia (part of greater Gdańsk), Szczecin, and Elbląg are also commercially important, as are the German ports of Travemünde and Rostock.

BIBLIOGRAPHY. W.R. MEAD, *An Economic Geography of the Scandinavian States and Finland* (1958), provides economic coverage of the northern Baltic states. W.R. MEAD and HELMER SMEDS, *Winter in Finland* (1967), gives a detailed, illustrated account of the Finnish winter and its effect in the Baltic Sea. A.C. O'DELL, *The Scandinavian World* (1957), includes descriptions of the Baltic Sea and its surrounding lands. AXEL SOMME (ed.), *A Geography of Norden*, rev. ed. (1968), provides a full and illustrated account of the geography of the Scandinavian states and Finland with reference to the Baltic Sea. JOHANNES HUMLUM and KNUD NYGARD, *Danmark-Atlas* (1961), is a useful compilation of maps. See also the national atlases of Denmark, Finland, and Sweden.

Baltic States, History of the

The Baltic states comprise the present-day Soviet republics of Lithuania, Latvia, and Estonia, on the eastern shores of the Baltic Sea. While, in some respects, they have a common history, they are ethnically and linguistically diverse. The Lithuanian and Latvian languages belong to the Baltic branch of the Indo-European linguistic family. The Estonian people, on the other hand, belong to the Finno-Ugric family of peoples, and their ancestors migrated to the Baltic probably as early as the 3rd millennium BC, coming from the wooded regions west of the Ural and from the middle Volga.

Diverse backgrounds of the Baltic peoples

FROM EARLIEST TIMES TO THE 18TH CENTURY

In prehistoric times these lands were inhabited by many different tribes. The Estonians and Livs lived in the northern and western areas bordering on the sea. The Latvians and Lithuanians, consisting of several related but independent tribes, inhabited the southern and inland areas. The western part of what is now Latvia, bordering the sea, was settled by seafaring people known variously as Kurs, Cours, or Couronians. During the 10th and 11th centuries these tribes were subject to a double pressure: Russian penetration from the east, and a Swedish push toward the shores of Courland and Estonia from the west.

The political-social structure of the various tribes showed certain differences. The Estonians and Cours of the coastal regions were peasant and seafaring peoples led by "elders." They were influenced by the Scandinavian vikings. The Latgallians, Semigallians, Selonians, Livs, and Lithuanians, who had connections with the Russo-Varangian principalities (Polotsk, Pskov), had a more developed, almost feudalistic social structure. The Lithuanians, who very early developed a warrior class, were far superior to their neighbours in military prowess. At the beginning of the 13th century all of these tribes were still entirely rural; there were markets, seaports, and castles, but cities in the European sense did not yet exist. Some trades, particularly that of the smith, were remarkably advanced, but building with stones and mortar was still unknown. There was no writing. The religion of these tribes was nature worship, with dimly anthropomorphic figures representing the sky, sun, moon, thunder, and other forces of nature.

The German conquest of Latvia and Estonia. The Latvians and Estonians were conquered and made Christians by the Germans. Traders began visiting the estuary of the Daugava River in the latter part of the 12th century. Coming in contact with the Livs first—they are today absorbed by the Latvians—the Germans named the country Livland, a name rendered in Latin as Livonia. Missionaries followed the traders, but their efforts had little success. Berthold, appointed bishop of Livonia, decided to use the sword and was killed in battle in 1198. His successor, Albert of Buxhoevden, was more successful. With the permission of Pope Innocent III he organized a crusade against the "treacherous Livs." In 1201 he founded the city of Riga, and in 1202 the Order of the Knights of the Sword was formed.

The Knights of the Sword

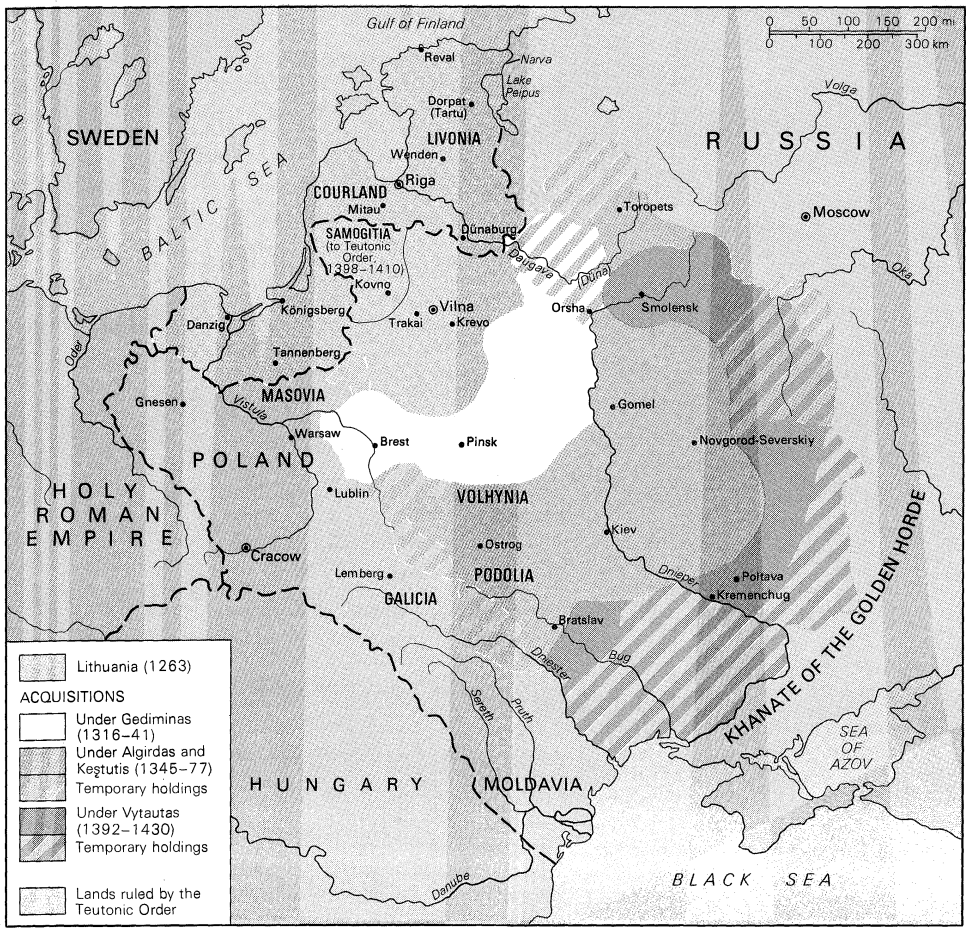
By 1208 the Knights were firmly established on both banks of the Daugava, and Albert proceeded northward to the conquest of Estonia. In a major battle in 1217, the crusaders defeated the Estonians; their commander Lembitu was killed. Albert then concluded an alliance with King Valdemar II of Denmark, who in 1219 landed with a strong army on the northern coast, on the site of present-day Tallinn. By 1227 the conquest was complete.

In 1237 the Knights of the Sword joined the Teutonic Order, which now assumed control of Livonia. Northern Estonia was under Danish rule; the greatest part of Livonia—that is, Southern Estonia and Latvia—was shared between the Teutonic Order and the bishops.

The conquered tribes, particularly the Estonians, were restive; a number of revolts occurred. The imposition of a new class of feudal overlords upon them reduced the Estonians, the Latvians, and the Livs to a state of serfdom. Their superficial conversion to Christianity was of little help; occasional attempts by the papal curia to intercede on behalf of their rights were of no effect. Personal freedom was greater in the cities, such as Riga, Dorpat (Tartu), and Reval (Tallinn), where men could support themselves in the trades. Much of the urban population consisted of German settlers, but the countryside remained native. The various indigenous nationalities retained their folklore and their language, while the German overlordship brought the Latvians and Estonians as a whole into the cultural sphere of the West. The borderline along the Narva River and Lake Peipus (Peipsi) became a cultural dividing line between the Roman Catholic West and the Russian Byzantine East.

Independent Lithuania. While the Latvians and Estonians were losing their independence in the 13th century, the Lithuanians succeeded in retaining theirs and in subsequently establishing a state that extended far beyond the ethnographic borders of the original nation. The Lithuanians in the early 13th century were ruled by a lower warrior nobility and the boyars (higher nobles). The first leader to unite the nation was Mindaugas, who in 1236 succeeded in bringing Lithuania proper, Samogitia, and the adjoining Belorussian territories under his single rule. In order to consolidate his regime he declared himself ready to accept Christianity and to relinquish his claim upon the contested province of Samogitia in the northwest in return for peace with the knights of the Livonian branch of the Teutonic Order. Mindaugas was crowned king by the authority of Pope Innocent IV in 1253. His peace with the Livonian knights did not last, however, because of continuing conflict in Samogitia. He and his two sons were murdered in 1263, and Lithuania returned to paganism.

The country was not unified again until 1290, when the grand duke Vytenis was recognized as absolute ruler. He was succeeded in 1316, by his younger brother Gediminas, who ruled until 1341. Gediminas extended Lithu-



Lithuania and the lands ruled by the Teutonic Order in the 14th and 15th centuries.

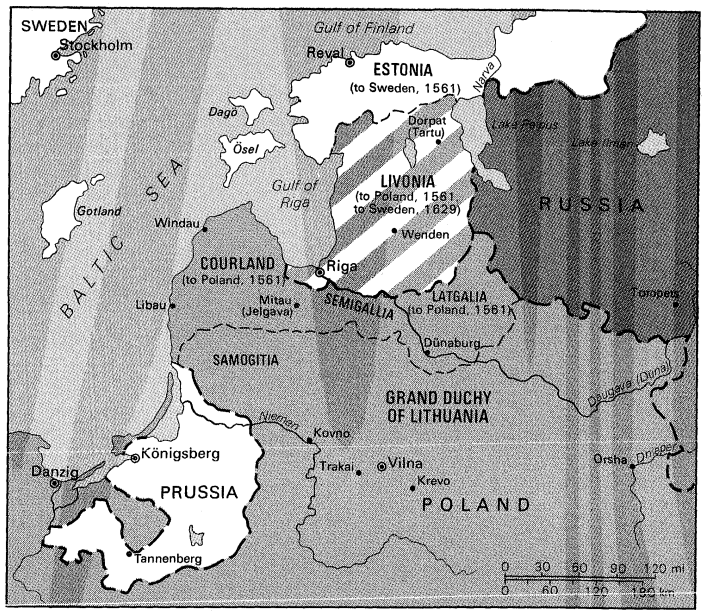
The Lithuanian Empire

ania's territories from the Baltic Sea southward almost to the Black Sea and eastward to the Dnieper. Lithuania became a major power. Under Gediminas' sons Algirdas and Kęstutis the Grand Duchy expanded to include Kiev in the east. The expansion was a product of political conditions in eastern Europe. The Tatar conquest of Kiev had destroyed the influence of the Kievan state over the other Russian principalities, which then tended to gravitate toward the west. This gave Lithuania an opportunity to expand to the east and southeast, while at the same time fighting off the Teutonic Order on its western frontiers. That a small non-Christian state was able to conquer and maintain control over such an extended area was partly the consequence of skillful diplomacy (including political marriages). The conquered Russian principalities were allowed to keep their autonomy and their Orthodox religion. The business of the state was conducted in a Slavic language (a kind of Belorussian Church Slavonic). Germans were brought into the east to build trade and commerce, and many Jews also settled there.

In 1385 Jogaila, the son of Algirdas, concluded an agreement to unite Lithuania and Kievan Russia with the Polish crown if he could marry the 12-year-old Queen Jadwiga of Poland and become king of Poland himself. He went to Cracow, was baptized on February 15, 1386, receiving the name Władysław II Jagiełło, married Jadwiga, and on March 4 was crowned king of Poland (see POLAND, HISTORY OF). The Lithuanians were baptized in 1387, and Władysław granted the Lithuanian boyars, or gentry, great privileges. Władysław's cousin Vytautas became grand duke of Lithuania. In 1410 the Polish-Lithuanian forces inflicted a crushing defeat on the Teutonic Order at Tannenberg (Grünwald). Samogitia returned to Lithuania. The grand duke Vytautas renewed the policy of eastward expansion under the sovereignty of his cousin King Władysław, and during this time Lithuania reached its largest expansion. When Vytautas, often called "the great," died at the age of 80 in 1430, the heroic epoch of medieval Lithuania ended.

With the acceptance of Roman Catholicism, Lithuania was drawn culturally toward the West. The Teutonic Order ceased to be a menace, but in the East the rise of Muscovy posed a threat to Lithuania's Belorussian conquests. The federal union between Lithuania and Poland was of no advantage to the Lithuanian and Belorussian peasantry. The culturally more advanced Polish nation tended to assimilate the Lithuanians, so that the legal equalization of the aristocracy of both countries resulted in the Lithuanian and Belorussian nobility becoming polonized; they began to consider themselves an integral part of the Polish nation. The Lithuanian and Belorussian peasantry now met with a fate similar to that of the Latvians and Estonians before them; isolated under the rule of an aristocracy that did not speak their language, they were restricted to farming and a rustic mode of life. Lithuanian and Belorussian became the language of peasants. In 1569 the personal union between the dynasties of Poland and Lithuania was changed to a union of the two countries, and Lithuania was reduced to a subsidiary land under the Polish crown. In the 18th century, when Poland was partitioned among Prussia, Austria, and Russia, Lithuania was annexed by Russia.

Livonia, Estonia, and Courland from the 16th to the 18th century. Medieval Livonia was a loose confederation of feudal ecclesiastical states, whose sovereigns, the bishops, were princes of the Holy Roman Empire. The responsibility for the defense of the confederation against the growing power of the Grand Duchy of Moscow was assumed predominantly by the Master of the Teutonic Order. While the power of the sovereigns decreased, the importance of the corporations of the landed nobility (*Ritterschaften*) and of the free cities increased. The towns enjoyed prosperity through the commercial



Baltic States from 1561 to 1721.

activity of the Hanseatic League, predominantly in the trade with Russia (Novgorod). As early as 1522–24 the teachings of Martin Luther began to gain ground among the German ruling class of Livonia. This was to prove important in the history of the non-German population, for the evangelical ministers did much to foster written literature in the Estonian and Latvian languages. With the establishment of Lutheranism, the ecclesiastical states became anachronisms.

Partition of Livonia in the 16th century

When the Russian tsar Ivan IV the Terrible advanced claims on Livonia in order to secure access to the Baltic Sea, the Livonian confederation broke down before the violent onslaughts of the Russian and Tatar troops. The sovereigns, the nobles, and the magistrates of the cities were forced to apply for protection to the kings of Sweden and Poland-Lithuania. Livonia broke up into three "duchies" of Livonia. Estonia, and Courland, the borders of which were different from the original Estonian and Latvian settlements; they remained the administrative divisions until 1917. Estonia, with its capital, Reval, came under Swedish rule; Livonia, with its capital, Riga, became a part of Lithuania; while Courland became a hereditary duchy to be held as a Polish fief. The nobility and the magistrates of the free cities retained their privileges; German was recognized as the official language; and German law and German administration remained.

The division of Livonia between Poland-Lithuania and Sweden did not ensure a lasting peace. In 1592 the lands became the object of the first Swedish–Polish war and of the struggle between Protestantism and Catholicism. In 1629 Poland was forced to cede Livonia with Riga to Sweden, retaining only the southeastern province of Latgale.

The Swedish kings, particularly Gustavus II Adolphus (reigned 1611–32) and Charles XI (reigned 1660–97), were accustomed to a free peasant class in their own country. They sought to raise the Estonian and Latvian peasants from the serfdom into which they had been thrust. Under Charles XI the levies and payments of the peasants were regulated in accordance with a general land registration. The Bible was translated into Latvian and Estonian. There were numerous administrative, judicial, educational, and ecclesiastical reforms in favour of the peasantry, but they fell short of their intended accomplishments because of the frequent, devastating wars. The Swedish crown needed the support of the landed nobility and rewarded their services with estates and with concessions of autonomy. Despite this, the association with the Swedish Empire has traditionally been regarded by the Estonians and Latvians as one of the better periods of their history.

In Courland the last master of the Teutonic Order of Livonia had preserved its independence as a duchy under the formal suzerainty of Poland. His grandson Jacob, the ablest of all the dukes of Courland (sole ruler 1642–82), developed local industry, fostered foreign trade, and created not only a sizable merchant marine but also a navy of warships. He also acquired two colonies: the island of Tobago in the West Indies, and Gambia on the West African coast at the mouth of the Gambia River. His ambitions were cut short because the country was unavoidably drawn into the European power struggle. In the third partition of Poland in 1795, Courland became a province of Russia.

THE BALTIC COUNTRIES UNDER RUSSIA (UNTIL 1918)

With his victory over Sweden in the Great Northern War (1700–21), the Russian tsar Peter I the Great gained both Livonia and Estonia. He thus succeeded in his aim of "opening the window to Europe" for his country. The other Baltic lands passed into Russian hands at the first and third partitions of Poland in 1772 and 1795. For the Germans of the Baltic lands—particularly the nobility—their incorporation into Russia opened up great opportunities for advancement in the service of the tsar. For the peasants it brought a deterioration of legal status and increased exploitation.

Social changes under the tsars

Not until the 19th century did a process of social and national emancipation begin. Under the tsar Alexander I the Estonian and Latvian peasants were given their personal freedom (1816–19), but without the right to own land. By the middle of the century, however, they were allowed to acquire leased land as their personal property. The Estonian and Latvian provinces thus began to develop an agrarian structure quite different from that in Russia. However, as the big landed estates remained untouched, most of the peasants were not able to acquire enough land to be self-supporting. In consequence, many Estonians and Latvians migrated to the Russian interior where land was available for settlement. In Lithuania the peasantry was not liberated before 1861—when the emancipation of the Russian serfs took place—and there was no consolidation of individual holdings, before the beginning of the 20th century; the Lithuanian emigration of the late 19th century went westward to Canada and the United States.

Advances in education

Some progress was made in education, with the development of elementary schools teaching in the native tongues. By the end of the century there was almost no illiteracy in Estonia and Latvia. A German-language university was established in Dorpat (Tartu) in Estonia in 1802. By the middle of the 19th century it had become a focal point for national revival among the Estonians and Latvians. A Polish-language university founded at Vilna (Vilnius) in 1803 served in a similar way for the Lithuanians. Educated Latvians, Estonians, and Lithuanians began to grow conscious of their national origins, whereas previously they had been germanized or polonized. Starting with an interest in the past and with the study of the national languages, the movement inevitably developed a political tendency.

The Lithuanian national movement had to fight particularly hard for its aims. The Lithuanians took part in the Polish rebellions of 1830–31 and 1863 and suffered the same repression afterward. From 1864 to 1905 the policy of russification extended to every part of Lithuanian public life: it was forbidden to publish newspapers, periodicals, or books in Polish or Belorussian, while books in Lithuanian could be printed only if the Russian alphabet was used; Russian was the only language of teaching in the schools; and the Roman Catholic religion was persecuted. The Lithuanian resistance was able to capitalize on the fact that Lithuanian was also spoken in the eastern part of East Prussia, and the national movement flourished there under the leadership of Lutheran clergymen and teachers. It was there, on Germany territory, that the first Lithuanian daily newspaper was published, and Lithuanian books were printed to be smuggled into Russia.

Beginning in the 1880s the Lithuanian resistance to russification also received strong support from the Catholic clergy, which sided with the national middle class and the growing class of intellectuals. Both of these classes had developed out of the peasantry and sought to emancipate themselves from the lower nobility and the owners of the large estates, who were naturally interested in maintaining their association with the Poles and the Polish language.

In the Baltic provinces the Russian government introduced a series of liberal reforms during the 1860s and 1870s, but after the assassination of the tsar Alexander II in 1881 a general strategy of systematic russification began that lasted until 1905. The russification extended to the whole educational system, the courts, and governmental administration. At the same time, however, it did much to strengthen the Baltic nationalities, particularly the Latvians and Estonians. It released many of them from their provincial, patriarchal environment and gave them careers as civil servants in Russia; it also brought them into contact with the developing Russian revolutionary movement. The provinces became part of the giant Russian Empire. Railroad lines were built from the Baltic seaports to the Russian hinterland. Riga became a world port, its population growing to 290,000 in 1900 and to 530,000 in 1914. Riga, Tallinn, and Narva became important industrial centres. These developments changed the character of the city populations. The Baltic Germans, who had never comprised more than 10 percent of the population, declined in number and importance. Although the German influence remained strong in the sciences (through the University of Dorpat), as well as in the Lutheran Church, in the large landed estates, in wholesale trade, and in industry, banking, and the professions, the advancing Estonians and Latvians crowded the Germans out of the middle class trades, business, and the civil service. Many of the German academicians emigrated to Germany, where they were successful as scientists and writers, while the number of Estonian and Latvian academicians grew steadily. The percentage of Estonians in the population of Tallinn rose from 51.8 in 1867 to 88.7 in 1897, and the percentage of Latvians in the population of Riga rose in the same period from 23.5 to 41.6.

Marxism appeared in the Baltic provinces at the turn of the century. The Latvian Social Democratic Party, founded in 1904, joined forces with the Russian Social Democratic Workers' Party in 1906. An independent Estonian sister party was established in 1906. Both parties maintained connections with the German Social Democratic Party. A Lithuanian Social Democratic Party was founded in 1895, but in that agrarian, Catholic country it could not flourish.

The Russian Revolution of 1905 was felt strongly in the Latvian and Estonian provinces. Bourgeois politicians, together with radical revolutionaries, raised the demand for national autonomy. When revolutionary bands spread into the countryside, looting and burning the manor houses, the government in St. Petersburg sent troops to put down the uprising. A total of 908 Latvians and Estonians were court-martialed and shot, and a number of leading politicians fled abroad. As elsewhere in Russia, the Revolution was followed by concessions from the tsar in the way of liberal reforms, particularly in education and cultural and economic life. The Baltic regions were allowed to send elected representatives to the new imperial Duma (legislature).

LIBERATION AND INDEPENDENCE (1917–40)

Liberation (1917–20). At the end of World War I a chaos of events occurred in the Baltic states. Allowing for many differences, there was a common pattern. Following the Bolshevik Revolution of October 1917 (November in the present calendar), Soviet regimes were proclaimed in Latvia and Estonia; they were swept away with the advance of the German armies. After the defeat of Germany independent non-Communist (bourgeois) governments were set up with the support of the Allies. The government of Soviet Russia tried in vain to overthrow them and in 1920 signed peace treaties with independent Estonia, Lithuania, and Latvia, which survived as sovereign states until World War II.

The rise of bourgeois governments

Estonia. The Russian Revolution of March (February, old style) 1917 overthrew the tsar and brought a brief period of political autonomy for Estonia. On April 12 the Russian provisional government passed a decree providing that all districts with an Estonian majority were to be united into one province; Jaan Poska, the National Liberal mayor of Tallinn, was appointed commissioner for Estonia and an Estonian national council was planned. Elections to the council (*maapäev*) took place in June.

The October coup d'etat by the Bolsheviks in Petrograd was immediately felt in Estonia. The bourgeois majority parties of the *maapäev* decided to break away from the crumbling Russian Empire, but the Bolsheviks appointed a Communist government for Estonia. In February 1918 German forces advanced to Estonia. The Communists fled from Tallinn, and on February 24 the *maapäev* declared Estonia's independence and formed a provisional government. This collapsed the following day when German troops entered Tallinn. On March 3, 1918, the Brest-Litovsk Treaty was signed, effectively transferring sovereignty over the Baltic countries to Germany.

Germany capitulated on November 11, 1918. The Estonian provisional government once more proclaimed the independence of Estonia. But the Soviet government declared the Treaty of Brest-Litovsk null and void. On November 28 the Red army took Narva and started the invasion of Estonia, which had been denuded of all arms by the retreating Germans. The government of Konstantin Päts was successful in obtaining weapons and war materiel from the Allies. With the aid of a British naval squadron and a Finnish voluntary force of 2,700 men, the commander in chief Col. (later General) Johan Laidoner was able to open a counteroffensive in January 1919. By the end of February all of Estonian territory had been freed, and the Estonian Army penetrated into Soviet and Latvian territory.

Repulse of the Red army

Latvia. In Latvia the struggle for independence was even more difficult than in Estonia. The Latvian People's Council, representing peasant, bourgeois, and Socialist groups, proclaimed independence on November 18, 1918. A government was formed by the leader of the Farmers' Union, Kārlis Ulmanis. The Soviet government established a Communist government for Latvia at Valmiera, headed by Pēteris Stučka. The Red army, which included Latvian units, took Riga on January 3, 1919, and the Ulmanis government moved to Liepāja (Libau), where it was protected by a British naval squadron. But Liepāja was still occupied by German troops whom the Allies wished to defend East Prussia and Courland (Kurzeme) against the advancing Red army. Their commander, Gen. Rüdiger Graf von der Goltz, demanded the control over the Latvian units as well. He intended to build a German-controlled Latvia and to make it a German base of operation in the war against the Soviets. This intention caused a conflict with the government of independent Latvia supported by the Allies. Von der Goltz had at his disposal—besides his German troops—the *baltische Landeswehr*, a combat-ready unit of predominantly Baltic-German volunteers including also Latvian units. On May 22 these forces took Riga. Pushing northward, the Germans were stopped near Cēsis by the Estonian army which included 2,000 Latvians. The British general, Sir Hubert de la Poer Gough, head of the Allied military mission, negotiated an armistice. The Germans had to abandon Riga, to which the Ulmanis government returned in July. In the meantime, the Red army, finding itself attacked from the north by the Estonians, had withdrawn from Latvia.

In July Gough demanded that the German troops should retreat to East Prussia. But von der Goltz now raised a "West Russian" army, systematically reinforced by units of German volunteers. These forces, headed by an adventurer, Col. Bermondt-Avalov, were to fight the Red army, co-operating with the other "White Russian" armies of Kolchak, Denikin, and Yudenich, supported

by the Allies. But on October 8 Bermondt attacked the Latvian troops and occupied the suburbs of Riga south of the river. By November 10, however, the Latvians, helped by the artillery of an Anglo-French naval squadron, cooperating with Estonian forces, defeated von der Goltz's and Bermondt's troops, attacked finally also by the Lithuanians. Until December 1919 all German troops had abandoned Latvia and Lithuania. Only Latgale remained in Red hands; but this province was cleared by 33,000 Latvians under Gen. Jānis Balodis, 20,000 Poles under Gen. Édward Smigły-Rydz, and 6,000 men of the *Landeswehr*, which had been put under the command of the British Lieut. Col. H.R.L.G. Alexander (later Earl Alexander of Tunis).

Lithuania. During World War I the Germans occupied a great part of historic Lithuania. An independent state of Lithuania was recognized by Germany after Brest-Litovsk in March 1918, with the proviso of a "perpetual alliance" of Lithuania with Germany. On November 11, 1918, a government was formed by Augustinas Voldemaras. As the German armies withdrew, the Red army occupied Vilnius on January 5, 1919, and installed a Communist government. The Germans remained in western Lithuania until December 1919. The Lithuanian Army took the offensive against the Reds in February 1919, and by the end of August the country had been cleared of Soviet troops.

A dispute with Poland had developed, however, over the possession of the capital city of Vilnius and the district of Vilna. The city was largely Polish in population, while the district of Vilna was predominantly Lithuanian. Jósef Piłsudski the head of the restored Polish state, proposed two alternatives: an independent state without Vilnius and its region or a larger state including Vilnius but federally linked to Poland. On April 20, 1919, the Polish Army led by Piłsudski took Vilnius from the Red army, which enabled the Lithuanians to re-enter Kaunas. Even though the Lithuanians were able to regain the region in July of 1920, during the war between the Soviet Union and Poland, the territorial issue remained in dispute for some time and was revived by Poland in 1938.

Consolidation. The Estonians signed the very favourable Treaty of Tartu with the Soviet Union on February 2, 1920, in which the Soviets recognized "without reservations" the independence of Estonia and "relinquished for all time" all rights of sovereignty over Estonian territory. Peace treaties between the Soviets and Lithuania and Latvia were signed later in the same year, on July 12 and August 11, respectively. The province of Latgale returned to Latvia, and the Soviet Union recognized the claim of Lithuania to the region of Vilna.

Political and social reforms

The internal problems faced by all three republics were largely the same: to reorganize their semifeudal agrarian structures, to adapt their economies to the new conditions, and to establish constitutions. In Estonia and Latvia the governments had promised the distribution of land parcels to the combatants during the war. Now both republics solved their agrarian problem with the expropriation of all the holdings of large landed estates (10,600,000 acres), thus destroying the economic and political power of the Baltic-German nobility whose corporations were dissolved. Tens of thousands of the rural proletariat were given land. The expropriated forest lands remained the property of the state and became an important source of income from lumber exports.

In Lithuania the large estates were mainly in the hands of Poles. The land reforms, less radical than in Latvia and Estonia, left the owners with maximum holdings of 370 acres. The government sponsored cooperatives to handle the collection and marketing of farm produce.

Constitutional reform. The constitutional reorganization in all three countries was radically parliamentarian in character, the legislative body clearly predominating over the executive branch. In Estonia, for example, there was a single-chamber parliament with a system of proportional representation, and the prime minister was also the chief of state.

Estonia and Latvia had a three-party structure. There were the conservative Farmers' Party, the National-Liberal Centre Party, and the Social-Democratic Party. The Farmers' Party was of particular importance since the two countries were predominantly agricultural, and it participated in almost all of the government coalitions. In Estonia the National Centre Party had its power base in the university city of Tartu. The Communist Party was outlawed in Estonia after an attempted coup in Tallinn on December 1, 1924. The trials and executions that took place before and after the coup did not improve Estonia's already delicate relationship with the Soviet Union.

Lithuania also had a three-party system. The conservative Christian Democratic Party was the strongest. The second strongest party was the left-liberal People's Socialists (Liaudininkai), and the third was the Social Democratic Party.

The economy. In seceding from the Russian Empire, the Baltic states had lost their economic hinterland. The result was unemployment, particularly in the metal-processing and textile industries. Estonia developed an entirely new industry with the opening up of the rich oil shale fields in the northeast. The timber and related industries increased slowly in importance, as did the export of meat, dairy, and poultry products. Great Britain became the principal market for all three countries, with Germany a close second. Trade with the Soviet Union remained slight. By 1930 employment in manufacturing accounted for 17.4 percent of the labour force in Estonia and 13.5 percent in Latvia, while Lithuania, with only 6 percent, remained almost entirely agricultural.

Education and culture. Freed from outside restriction, cultural life expanded. Schools of all kinds increased. The russified University of Dorpat (Yurev) in Estonia became the State University of Tartu; in Latvia the Riga Polytechnic Institute was enlarged to become a complete university; in Lithuania, since Vilnius was in Polish hands, the government established the Vytautas University in Kaunas in 1922. Literature, music, and the fine arts reached the level of the rest of Europe. Cultural policy was strongly Western in its orientation; English was the first foreign language taught in the schools. The problem of national minorities was settled best in Estonia by means of the law on cultural self government in 1925.

Political tendencies in the 1920s and 1930s. For many Estonians, Latvians, and Lithuanians the independent, democratic, national state had long appeared to be the goal of their historical development. When it was finally attained, however, some serious problems appeared. Political experience and democratic traditions were lacking, as well as institutions that would have protected the interests of the state against those of particular groups. The radical parliamentary constitutions drawn up in the first hours of independence hampered the creation of stable governments. By the end of 1926 an authoritarian presidential regime had been established in Lithuania, similar to that of Piłsudski in Poland. This happened when the small Nationalist Party, with the consent of the Christian Democratic Party, overthrew a left-democratic regime in December 1926.

Problems of establishing democratic governments

The numerous political parties in Estonia and Latvia prevented the formation of stable coalitions and led to frequent governmental crises during the 1920s. The lifespan of the governments of Estonia during the years 1919–1933 averaged eight months and 20 days. The political problem became even more pronounced in 1930, when the world economic crisis brought financial difficulties and unemployment that emphasized the need for stable government. Voices demanding constitutional reform were heard in both countries. In Estonia the movement was led by the "Vaps" (Vabadussõjalaste Liit, or League of Freedom Fighters), which had grown from a group of war veterans into an anti-Communist and anti-parliamentary mass movement. The proposal of the Vaps won a majority of 72.7 percent in a referendum of October 1933. The acting president Konstantin Päts was expected to prepare for the election of a new president. Instead, he declared a state of emergency on March 12, 1934; the Vaps was dissolved, its leaders were arrested, and the parliament was soon also dissolved. After that Päts ruled by decree until 1938.

In Latvia a similar development occurred on May 15th, 1939. After attempts at constitutional reform had failed and the country had become increasingly polarized between the far right and the far left, the prime minister Karlis Ulmanis declared a state of emergency. He formed a government of national unity from representatives of almost all the important parties. From then on he governed without the parliament.

In neither Estonia nor Latvia was there any significant resistance to the suppression of parliamentary government. Quite a few party representatives were even ready to support the authoritarian regimes. These regimes drew their main support from the well-to-do and the peasants, from the army and the home guard. Both heads of state based their coups d'etat on the need to prevent the interference of foreign powers in state affairs. Both were also successful in diminishing the power of the radical right. Both strove to reorganize the society by setting up representative bodies of the professions.

But there were marked differences in their styles of leadership. The moderate Estonian president regarded his authoritarian regime as a "regency for the restoration of the endangered democracy" and worked for a conservative reform of the state. He had his regime legalized by a plebiscite in 1936 in order to elect a constituent assembly to draft a new constitution. The candidates were chosen from the ranks of the Patriotic League that he had founded in February 1935. The new parliament that convened in 1938 had in its lower chamber 63 members of the Patriotic League and a token opposition of 17.

In Latvia the energetic "leader of the people" K. Ulmanis did not bother to legalize his regime by popular referendum or even to organize a unified following. In 1936 he combined the office of prime minister with the office of president of state and adopted the nationalistic theme of "a strong and Latvian Latvia." He also enlarged the state-run sector of the economy, predominantly at the expense of the German minority. In consequence, the younger generation of Germans felt themselves to be losing out to the Latvian majority, and German National Socialism found an increasing number of supporters among them. In both Latvia and Estonia the liberal intellectuals chafed under the restraints put upon speech and press. The rural population and the business interests, on the other hand, favoured the authoritarian regime because it brought prosperity; foreign trade showed a steady increase.

Rise of the one-party state in Lithuania

In Lithuania a nationalistic one-party state emerged. The dictatorial tendencies of prime minister Voldemaras aroused opposition among conservative-ecclesiastical circles, which led to his removal by the president, Antanas Smetona, in 1929. Smetona now cast himself as a "people's leader" with the Nationalist Party in full control of the state, supported by some of the Christian Democrats. His regime also had the support of the army, the home guard, and the state-sponsored youth organization, Young Lithuania. The obvious model for the regime was Fascist Italy.

A continuing issue in Lithuanian politics was the city of Memel (Klaipėda) and the surrounding region on the right bank of the Memel River (Nemunas), which had been taken from Germany after World War I and given to Lithuania. The Lithuanian government had been required to grant autonomy to Memel. The nationalist leaders in Lithuania aspired to Lithuanianize the territory, whose inhabitants were mostly of Lithuanian descent, although the sentiment in Memel was for reunion with Germany. Following a German ultimatum, Lithuania was forced to restore Memel to Germany on March 23, 1939. (After World War II, Memel was absorbed by the Lithuanian Soviet Socialist Republic.)

The end of independence. The Baltic states had won their independence at a time when both Russia and Germany were defeated in war. They retained it as long as the two powers remained weak. Endeavouring to remain neutral, the Baltic republics refrained from aligning themselves with political blocs in the 1930s. The likelihood of reaching an understanding with the Germany of Hitler or the Soviet Union of Stalin seemed so remote that the governments of the Baltic states never considered it in their plans. Proposals for ties with Finland and Poland ran aground on the unreconcilable differences between Lithuania and Poland and on the refusal of Finland to engage in affairs south of the Gulf of Finland. An Estonian–Latvian defense alliance was signed in 1923 and renewed in 1934, which also provided for cooperation in foreign policy. When Lithuania joined the alliance in 1934 it became known as the Baltic Entente. All three of the states signed nonagression pacts with the Soviet Union. They differed, however, as to whether the greater danger lay in the West or in the East. While influential circles in Latvia inclined toward the idea that Germany was the graver danger, the Estonians were clearly preparing to meet a possible attack from the Soviet Union. In the summer of 1939 the Baltic question was one of the issues in the ill-fated Anglo-French negotiations with Moscow.

The geographic plight of the Baltic states

In a secret protocol to the German–Soviet pact of August 23, 1939, Estonia and Latvia were recognized as belonging to the Soviet sphere of interest. In September, after the German victory over Poland, Lithuania was put in the same category. Moscow then demanded that the Baltic states should sign mutual assistance pacts with the U.S.S.R. and allow the construction of Soviet military bases on their territory. Completely isolated, the governments of the Baltic states realized that military resistance was useless. The agreement between Berlin and Moscow for a resettlement of Baltic Germans in Germany made it abundantly clear to the Balts that Hitler had left their states at the mercy of Stalin. The alacrity with which the ethnic Germans of Estonia, Latvia, and Lithuania departed for the *Reich* showed that they had little doubt as to the fate impending for those states. On October 10 the Soviet Union returned the Vilnius region to Lithuania.

The Soviets were at first satisfied to observe the limits of their bases, watching with growing distrust the economic infiltration of Germany into the Baltic states as well as attempts to activate the Baltic Entente. When the Germans took Paris in June 1940, Stalin demanded that the governments of the Baltic states admit more Soviet troops. After the Soviet Army had established itself in the countries, pro-Soviet governments were set up. These held rigged elections on July 14–15 in which only single lists of Soviet-sponsored candidates were allowed to stand. The new parliaments immediately voted for the incorporation of their countries into the U.S.S.R.; the proposals were officially accepted by the Supreme Soviet on August 3, 5, and 6.

Arrests and deportations

Many political leaders were arrested or fled to the West. In the first year of Soviet occupation mass deportations took place in June 1941 and many people were arrested and executed. Estonia lost more than 60,000; Latvia about 35,000; and Lithuania about 45,000. Those deported included politicians, military personnel, higher officials, writers and publishers, and businessmen, together with their families.

After the German attack on the U.S.S.R. in June 1941, the Baltic states became part of a larger Ostland in which Belorussia was also included. Many Estonians, Latvians, and Lithuanians were by that time ready and willing to cooperate with the Germans. But they found that it gained them neither their national independence nor the return of their nationalized property. Whereas the Soviets had sought to extirpate the "class enemy," the Nazis tried to wipe out the Jews; they killed about 190,000 Jews in Lithuania, about 90,000 in Latvia, and about 4,500 in Estonia.

In the fall of 1944, as the Germans retreated and the Soviets returned, large numbers of people fled before the advancing Soviet Army. About 30,000 Estonians escaped by sea to Sweden and 33,000 to Germany. About 115,000 Latvians fled to Germany and Sweden, and about 70,000 Lithuanians to Germany. After the Soviets had restored Communist governments in the three countries there were new deportations. Estimates of the numbers deported in the years 1941–49 run to about 500,000, including large numbers of peasants who were deported for

resisting the collectivization of their farms. About 25–30 percent of these persons are said to have returned to their native countries after Stalin's death (1953).

THE BALTIC STATES AS UNION REPUBLICS OF THE U.S.S.R.

Soviet policies

After the victory over Germany the Soviet authorities resumed their previous efforts to integrate the Baltic states into the U.S.S.R. Most of the Communist leaders of the early days were replaced by officials who had grown up in the U.S.S.R. or been trained there.

Collectivization and industrialization. The rural population was forced into the *kolkhozy*, or collective farms, without regard for the consequences to agriculture. Resistance by partisans or guerrillas, which persisted longest in Lithuania, was ultimately broken by special forces of the security police. Collectivization eliminated the independent farming class, which had been the political basis of the Baltic states.

The *kolkhozy* as a rule included about 150 families and had an average area of from 5,000 to 6,000 acres. They were run, like all Soviet collective farms, on the principle of common cultivation; members were paid out of the proceeds of the farm according to the number of work units they had performed. Every household was allotted a plot of land for its own use. There were also state farms, or *sovkhozy*, in which workers were paid wages. The Baltic regions concentrated on dairy farming and cattle breeding; in the 1950s and 1960s Estonia and Latvia held first place among the union republics of the U.S.S.R. in milk production per cow.

The economies of the Baltic republics were integrated into the Soviet system of economic planning and development. This resulted in considerable growth in production, as a result of Soviet investment in the Baltic region. Some outstanding projects of the 1950s and 1960s included the development of the Estonian oil shale industry, which supplies gas for Leningrad and Tallinn. The oil shale also serves as fuel for the giant power stations, to generate electricity, as do the dams built on the Narva and Daugava rivers. Living standards remained relatively low. One reason was the preference given to industrial goods over consumption goods in economic planning; another was that the Baltic republics, which were far more productive than the Soviet average, were expected to share their surplus with other republics. The standard of living nevertheless remained considerably higher than in other parts of the Soviet Union.

Demographic changes. These industrial and agricultural policies worked a fundamental change in the social structure of the Baltic republics. From predominantly rural societies they became predominantly urban. In 1939, 65 percent of the Latvians lived in rural areas, as did 66 percent of the Estonians; but by 1966 the ratio was reversed, and more than 60 percent of the Latvians and Estonians were urban dwellers. The change in Lithuania was not pronounced: from 61 percent rural in 1959 to 55 percent in 1966. The larger cities grew as follows: Riga from 347,800 in 1939 to 667,800 in 1966; Tallinn from 143,384 in 1939 to 327,800 in 1965; and Vilnius from 236,100 in 1959 to 304,700 in 1966.

Russian immigration

Another demographic change was the immigration of Russians. In 1970 more than half the population of Riga was estimated to be Russian; Tallinn was 40 percent Russian; and in Liepaja, an important military base, the Russians comprised about 65 percent of the population as early as 1960. Many Russians were brought in to work in the Estonian oil shale industry and in the Narva region. The proportion of Latvians in the total population of Latvia declined from 75 percent in 1935 to 62 percent in 1959, and to 56.8 percent in 1970; Estonians in Estonia decreased from 88 percent in 1934 to 75 percent in 1959, and to 68.2 percent in 1970; and Lithuanians in Lithuania from 84 percent to 79 percent between 1923 and 1966. But according to the results of the census of 1970 the proportion increased anew to 83 percent.

An important part of the Baltic peoples now lives in countries outside the Soviet Union, most of them in Sweden, the United States, Canada, and Australia. Their total numbers in 1970 were estimated at 102,800 Estonians, 180,000 Latvians, and almost 800,000 Lithuanians. The population of Estonia in 1959 was 1,197,000; in 1970, 1,356,000; the population of Latvia in the same years, 2,093,000 and 2,363,000; the population of Lithuania rose from 2,711,000 to 3,128,000.

Religion, education, and culture. Under Soviet rule, the activities of the formerly influential Lutheran and Roman Catholic churches have been severely limited. They are forbidden to print and disseminate religious literature, and the training of new clergymen is discouraged. Church attendance has declined markedly.

Education and culture in the Baltic republics have been "national in form, socialist in content." The native languages and literature, theatre and music, popular customs and national histories have all been promoted, but as part of a multinational Soviet culture and in terms of Soviet ideology. The severance of ties between the Baltic states and Russia after 1918 is regarded as the work of Western imperialism, and the forced integration into the Soviet Union as a "liberation from the yoke of imperialism."

In 1971 the incorporation of the Baltic states into the Soviet Union had still not been recognized by the United States and many other countries, although some governments have accorded it de facto recognition.

(A.v.T./Ed.)

Baluchistan

Baluchistan (Balūchestān) is the westernmost province of Pakistan. It is bordered on the west and northwest by Iran and Afghanistan; on the north and east by the Pakistani provinces of Northwest Frontier, Punjab, and Sind; and on the south by the Arabian Sea. With an area of 134,050 square miles (347,188 square kilometres), it is the largest Pakistani province, but it is the most sparsely populated, with an estimated 2,409,000 inhabitants. The provincial capital of Quetta is located in the north.

The name Baluchistan is derived from the words Balūch and *estān* and literally means "place, or abode, of the Baluch people," who inhabited most of the contemporary provincial area by the end of the 15th century. Baluchistan as the name of the area was in use in the 15th century, but it was not the official designation of the region until the 19th century.

The least developed of the Pakistani provinces, Baluchistan is primarily a pastoral region. Its rich mineral wealth awaits exploitation, and the expansion of agriculture depends upon increased irrigation projects. Industrial activity is minimal, and development is hampered by the lack of adequate transport and communications facilities.

History. Archaeological remains have confirmed that prehistoric Baluchistan passed through the Stone and Bronze ages. The materials of the Quetta, Togho, Kulli, and Nal sites represent a fairly widespread level of cultural achievement and indicate that Baluchistan served as an intermediary link between the cultures of South Asia and the Middle East. Little is known of the region's early history, but it may have been subject to the Assyrians and the Medes. It was subjugated and annexed as part of the 14th satrapy of the Persian Empire under Darius I (522–486 BC); but, with the defeat of Darius III by Alexander the Great in 330 BC, the area came under the Greek supremacy.

The chronology of the succeeding powers suggests that, after Alexander's death, the territories of Baluchistan became a part or were under the political influence of the empires of Seleucus I Nicator and Candragupta Maurya (305 BC), the Indo-Greeks and the Parthians (3rd–2nd century BC), the Scythians (100 BC–AD 200), and the Sāsānids (3rd–7th century AD). The Hephtalite Turks controlled central and northeastern Baluchistan from AD 470 to 520, leaving the southern coastal area to the Sāsānids. As Sāsānid power weakened during the 7th century, the Brahmin rulers of Sind extended their influence into western Baluchistan.

Arab invasions of the 7th century

Baluchistan emerges into recorded history with the advance of the Arab armies in the 7th century. With the final conquest by Muḥammad ibn al-Qāsim in 711, most of Baluchistan became part of the Sind province of the Umayyad and the ʿAbbāsid empires. From the 11th century, the region fell under the control of various powers and formed part of the Mughal Empire from about 1595 to about 1638.

The first Baluch people to arrive in Baluchistan were mainly of the Brahui group. They set up the principality of Kalāt in the central portion of the region in the 14th century. In the 15th century, Kalāt was overrun by the last great migrating body of the Rind–Lāshār Baluch. Naming the new ruler of Kalāt, the Rind and the Lāshār moved onward; the former founded the principality of Sibi with its capital at Fatehpur and the latter the principality of Kachhi with its capital at Gandāvá. As a result of the 30-year Rind–Lāshār War (*c.* 1490–1520), most of the Rind and Lāshār migrated further to the Punjab, Sind, and Gujarāt.

The Brahui regained control of their principality, and the khanate of Kalāt, which became the future nucleus of Baluch power, was founded in 1666. Nasīr Khān (1750–93) welded together the region's different ethnic stocks, organized the military and socio-political institutions of the Baluch, aligned himself with Nāder Shāh of Iran and Aḥmad Shāh Durrānī of Afghanistan, and succeeded in creating a political unit independent of neighbouring Sind, Iran, and Afghanistan.

The British influence in Baluchistan commenced with the mission of the British administrator Sir Robert Sandeman to Kalāt in 1875 and the subsequent occupation of Quetta in 1877. By the Treaty of Gandamak with Afghanistan in 1879 and other treaties with the *khāns* of Kalāt, the territories acquired were constituted into British Baluchistan Province and Tribal Areas by 1896, while Kalāt became a protected princely state. Baluchistan Province became part of Pakistan in 1947, and Kalāt state acceded to Pakistan one year later. The various parts of the former British Baluchistan Province (settled districts, native states, and tribal areas) became a more integrated single administrative unit after 1947. In 1955, Baluchistan was merged into the newly created "Province of West Pakistan" which was abolished on the 1st of July 1970 when Baluchistan was reestablished as a separate province in its present form.

The natural environment. *Relief, drainage, and soils.* Baluchistan can be divided into four physical regions. The upper highlands of the central and northeastern regions are traditionally known as the Khorāsān country. The area is bounded by the Sulaimān Range to the east and the Toba Kākar Range to the northwest. To the north of the central Sulaimān Range is an oblong massif known as Kaisargarh (Kasi-barh) that reaches an altitude of 11,290 feet (3,441 metres). A series of hills curve westward from the Sulaimān Range to the broad mountain arc that abuts the Quetta-Pishīn uplands. Peaks in this region include Khalifat, which rises to 11,434 feet (3,485 metres) south of Ziārat, and Zarghūn, which attains 11,738 feet (3,578 metres) northeast of Quetta.

Four physical regions

The great break in the mountains formed by the Bolān and Khojak passes separates the upper highlands from the lower highlands. The lower highlands include the eastern slopes of the Sulaimān Range; the lower ranges of Makrān, Khārān, and Chāgai on the west; and the Pab and Kīrthar ranges on the southeast.

The third region consists of the extensive flat plains along the coast that extend northward into the mountains. In the east, the plain stretches along the eastern slopes of the Kīrthar Range as far north as Sibi. In the northwest are the arid deserts of Chāgai, Khārān, and Makrān and the swamps of Lora, near the Afghanistan border; and Māshkel, near the Iran frontier.

The upper highlands drain into the Indus River, while the lower highlands drain northward into the swamps or southward to the Arabian Sea. The main rivers are the Zhot in the northeast, Nāri in the southeast, Dasht in the extreme southwest, and Hingol, Porāli Nai, and Hab in the western Las Bela district.

The variety of soils is related to the region's physical features. Saline soils are found along the coast, around the swamps and lakes, and in some of the low-lying arid areas. Sandy soils occur in the three main desert areas and in parts of the plains. The valleys of the lower and upper highlands contain soft rocky soils, while stony soils dominate the vast waterless flats between the hills. There are deep deposits of alluvial soils in the plains of Sibi, Kachhi, and Las Bela.

Climate, vegetation, and animal life. There are three climatic zones. The climate is temperate along the coast, with a mean annual temperature of 86° F (30° C). The inland deserts and arid zones are hot, with a mean annual temperature of 98° F (37° C), while the submountainous region is cold, with a mean of 76° F (24° C). Outside the influence of the monsoon, most of the province is dry and experiences the extremes of heat and cold. The coastal plains become extremely hot during the long summer from April to September, with temperatures at Sibi rising to 122° F (50° C). The plateaus of Kalāt and Quetta-Pishīn receive some snowfall and experience severe cold during winter from October to March, the temperature falling to several degrees below freezing. Rainfall is irregular and scanty; it ranges from an average of four to 11 inches on the coast to between six and 16 inches in the hilly region.

The upper highlands of Kalāt, Quetta-Pishīn, and Ziārat support such trees as the juniper, pistachio, olive, ash, edible pine, poplar, and willow. The flats remain

covered with saxual and sagebrush, while the mountain valleys have a variety of fruit trees. The hillsides abound in herbaceous and bulbous plants, and the Ziārat and Kalāt uplands support such plants of economic value as cumin, hyssop (a European mint), and licorice. The perennial herb that is the source of asafetida occurs in Koh-i-Sultān, and wild rhubarb is found in the Khwāja Amrān range. Dwarf palms grow in the hilly tracts, and tamarisk, acacia, and wild caper (a low prickly shrub) occur on the plains. The valley of the Dasht River abounds in date-palm trees of the best variety, and the grasses in the Khārān region yield seeds that for centuries have been used as food grain during periods of famine.

Vegetation and animal life

The straight-horned markhor (a wild goat) and mountain sheep are found in the higher hills and the Sind ibex (a wild goat) in the lower highlands. Leopards and black bears are occasionally found in the western hilly regions, while the wild ass, the Persian gazelle, and the wolf occur in the deserts. The jackal, fox, and hyena are more common. Baluchistan has been a natural habitat for various breeds of sheep, cattle, and horses.

Typical game birds are the *chikōr* (a colourful bird of the partridge family) and *sisi* (of the same family, but smaller and dusty brownish in colour). The black and white *shakūk* (a larger bird with a longer tail) struts around in summer. There are waterfowl, bustards, and other migratories, while the raven, lammergeier (a large bird of prey), and golden eagle are among the permanent bird population. The deserts and plains abound in a vast variety of reptiles and insects. The horned snake, *kingarmār*, is typical of the Khārān region. The tortoise is common, and the skink (a lizard) occurs in the sandhills of Chāgai. Crocodiles are found in the Hingol River, and the coastal belt is rich in fish and mollusks (such as snails, limpets, mussels, and cuttlefish). A large variety of marine fish include shark and skate, as well as pomfret, sole, and sardine.

The population. The Baluch and Pathan peoples constitute the two major and more distinct ethnic groups; the mixed ethnic stock, mainly of Sindhian origin, forms the third major group. There are minor ethnic communities of Meds along the coastal belt, Lurs in the predominantly Baluchi areas, and Jāṭs in the Sibi, Kachhi, and Las Bela districts.

The Pathan and Baluch peoples

The Pathans, divided into 13 subgroups, are believed to be of Turko-Iranian origin. Pathan tradition claims northern Baluchistan immediately west of the Sulaimān Range to be their ancient home, and the Pathans are still concentrated in the contemporary Zhob, Loralai, and Quetta-Pishīn districts.

The Baluch are concentrated in the Kalāt Division and in the Sibi and eastern Loralai districts of the Quetta Division. Their tradition, irrespective of the languages spoken by the various subgroups, traces their origin back to the ancient Babylonian homeland of Aleppo, Syria. Baluchi tradition and scholarship support the theory that the Baluch are Chaldean descendants of Belus, identified as the Babylonian king Nimrod.

Baluchistan is a multilinguistic region; a majority of its inhabitants are bilingual, and there is a sizable trilingual population. Baluchi, Brahui, and Sindhi are the principal languages of the Kalāt Division, while Pashto, Baluchi, Sindhi, and Seraiki are the main languages of the Quetta Division. Baluchi has eastern and western dialects, and Pashto is spoken in its southern dialect as distinct from the northern Pashto of Northwest Frontier Province. Sindhi has four dialects, and Seraiki has two dialects. Persian, in the Dehwari dialect, is spoken by the Dehwar communities of Kalāt and Mastung, and a mixed dialect, the Mokāki, is spoken by the Lurs in the Kalāt Division. Punjabi is spoken by the settlers from Punjab, mainly in the urban areas, while Urdu is used as a lingua franca.

The Baluchis and Pathans are mostly Sunnī Muslims, although some communities profess the Shīʿite doctrine. Some of the Baluchi communities and peoples of Makrān and Las Bela districts profess to be the followers of the 16th-century messiah Mīrān Muḥammad Mahdī of Jaunpur and constitute a sect by themselves. Hindus, Parsis (Zoroastrians), and Christians constitute minority communities, the latter two living mainly in Quetta city.

The vast rural areas are mostly barren, and semi-arid lands are visited by nomads in the rainy season. The few green areas have pastoral concentrations, while the coastline has clusters of fishing villages. Though some mining settlements have sprung up in the interior, the bulk of the rural population remains nomadic.

Settlement patterns

Nomadism and ruralism traditionally have been the dominant features of the Baluchistan population. Since 1947, however, the process of urbanization has increased in response to industrialization and the greater educational and employment opportunities in urban areas. The major towns are Fort Sandeman, Hindubāgh, Chaman, Mastung, Mach, Sibi, Kalāt, Khuzdār, Panjgūr, Turbat, Bela, Sonmiāni, and Gwādar. Since 1951 there has been a marked increase in the urban population; in seven of the province's ten districts, the increase has been more than 75 percent. Immigration from other Pakistani provinces has also been responsible for this increase, particularly in Quetta city.

Administration and social conditions. The province is headed by a governor, who is appointed by the central government. Each of its two divisions of Quetta and Kalāt are under a commissioner. The divisions are subdivided into ten districts, which are headed by deputy commissioners, political agents (Zhob and Chāgai districts), or deputy commissioner-cum-political agents (Sibi and Loralai districts), depending upon the degree of political control exercised within their jurisdiction. Quetta-Pishīn, Sibi, Loralai, Zhob, and Chāgai districts constitute the Quetta Division, while the Kalāt Division includes Kalāt, Kachhi, Las Bela, Makrān, and Khārān districts. The districts are subdivided into tahsils headed by *tahsildār*s, and the tahsil is further subdivided for purposes of revenue into *ḥalqah* and *maḥāl*, the smallest administrative unit, headed by a revenue officer.

Health facilities, though inadequate, have been extended to the whole province. Each of the ten districts has hospitals, dispensaries, and mobile dispensaries or rural health centres. There are also two tuberculosis clinics. Medical personnel include doctors, specialists, health visitors, and nurses. The major health problems are infant mortality, smallpox, eye diseases and blindness, and stomach troubles and kidney stones due to the non-availability of clean water.

Traditional education includes an indigenous community-supported Islāmic system of *maktab*s (primary schools) and *madrasah*s (secondary and higher institutions) situated in towns and larger settlements. Classes are taught in Persian and Arabic, and the religious studies are the main educational objective. Western education was introduced in 1882, when the first government school was established by the British in Quetta. In the early 1970s, there were more than 1,460 primary schools, 150 middle schools, 60 high schools, seven colleges, and five vocational, commercial, or polytechnic institutes. Enrollment is much higher in the primary and secondary schools than in the post-secondary schools, and there are more male than female students. The University of Baluchistan in Quetta was established in 1970. Government policy aims at providing more education funds to extend and improve primary schools, to expand the scope of science education, to introduce "marketable skills" in the school curriculum, and to orient the university program to technical education.

Educational facilities

Social-welfare work commenced with the sanction of 13 urban–rural community development projects, six of which were functioning in 1970. A provincial Social Welfare Council administers the program through voluntary social-welfare agencies. Among the projects run by the agencies are homes for industrial workers, orphanages, schools for the deaf and dumb, clinics and health centres, social services, and vocational training centres.

Rural development through the Rural Works Program is geared to the overall economic goal of increasing production. It includes the expansion of employment opportunities and the creation of new sources of income.

As a measure against drought, a food-storage scheme has been devised to construct grain-storage facilities in central areas. During the early 1970s funds were provided for the construction of such facilities at Quetta, Chaman, Nushki, Mastung, Mach, and Turbat.

The economy. *Resources and their exploitation.* Baluchistan's major economic potential lies in its mineral wealth, marine fisheries, livestock, fruit farming, irrigated agriculture, and scope for industrial growth. Development costs of water and power resources and communication facilities, however, remain prohibitive.

Mineral wealth

The province has proved reserves of coal, chromite, sulfur, marble, limestone, gypsum, emery stone, magnesite (native magnesium carbonate), natural gas, barites (the barium sulfate mineral), fluorite, onyx, and manganese. There are deposits of copper, bauxite, lead, antimony, iron ore, laterite, and brucite. Several of these minerals, such as coal, chromite, marble, sulfur, limestone, gypsum, barites, emery, and magnesite, are mined for export. The natural gas found in 1952 at Sui has contributed to industrial growth by the production of almost half the nation's electric power.

The coastal belt has large fishing potential. Fishing cooperatives are supplied with motor launches, and facilities are being extended at the ports of Sonmiāni, Ormāra, Kalmat, Pasni, and Jīwani. There is a cold-storage plant and an ice factory at Gwādar, where a new fishing harbour is to be constructed by 1975.

The sheep industry engages more than 90 percent of the population and utilizes more than 95 percent of the provincial acreage. The sheep raised produce high-quality wool, most of which is exported. Cattle and other animals yield hides and skins for the local leather industry and export.

Agriculture remains limited for want of water, power, and adequate communications. Of the total cultivable area of 17,000,000 acres, less than 3,000,000 acres are cultivated, mainly in areas of scanty rainfall. With the extension of irrigation from the Indus River to Sibi and Kachhi districts, acreage and production have increased. Major crops include wheat, rice, barley, millet, fruit, and vegetables.

The province contains less than 1 percent of the nation's industry. In the early 1970s, large-scale industry consisted of one pharmaceutical plant, one cotton-spinning mill, one woollen mill, one distillery, and a charcoal plant. Small industry comprises fruit and vegetable processing, grain milling, light-engineering workshops, and hand-embroidery units. Two large industrial estates in the Quetta area are to be established by 1975 at Usta Muhammad in Sibi District and Uthal in Las Bela District.

Transport. Baluchistan has almost 1,000 miles of railway and about 7,000 miles of roads, of which 950 miles are metalled. Modest fair-weather roads connect the important towns. The main highways are the Quetta–Mirjāveh road leading to Iran, the Quetta–Chaman road to Afghanistan, and the Quetta–Sibi road to Karāchi and Lahore. A shorter road from Quetta to Karāchi was under construction in the early 1970s as part of an international highway connecting Pakistan, Iran, and Turkey.

The railway system

The railway system radiates from Quetta to Zāhedān, Iran; Chaman on the Afghanistan border; Sibi through the Bolān Pass to Karāchi and Lahore; Fort Sandeman in the north; and Loralai in the northeast. Pakistan International Airlines provides daily domestic services between Quetta, Karāchi, Lahore, and Rāwalpindi. Small ships, launches, and boats ply along the coast, linking the ports of Sonmiāni, Jīwani, Pasni, and Gwādar with Karāchi and the Persian Gulf.

The expansion of transport facilities is basic to future economic development. There are proposals to link the mining area centre of Sepzand with Quetta and to link the town of Uthal—a proposed industrial site and headquarters of Las Bela district—with Karāchi by rail.

Cultural life. The Baluch and Pathan peoples are organized on the basis of *qawm* or *qabīlah*, "community" or "tribe." Depending upon its strength and standing, a community headed by a *sardār* or *khān* may be composed of various divisions and groups, each with its own headman. The nucleus of a Pathan community is characterized by blood bonds and homogeneity, while that of a Baluch community is characterized by "common weal and woe" and heterogeneity. In the Marri community of the Baluch, land is the common property of all and is divided among the three main clans every tenth year. *Riwāj* ("custom"), specific to each community, has served the function of unwritten law. The Balūchī Dīwān serves as a legislative assembly for the Baluch, while the *jirgah* serves as a judicial tribunal among both the Baluch and Pathan communities. *Mayār* or *nang* is the traditional Baluch code of honour, based on blood feud and chivalry. Marri society includes the *rāhzan*, who conducts the attack in war, and the *rhezwār shāʿir*, or community poet laureate, who ennobles their deeds and defends their actions.

Horse racing, wrestling, religious holidays, *melās* (fairs), and marriage feasts are the main festivals.

Baluch communities have professional minstrels who sing from *Balūchī daptar*, known as the great epic of the 30-year Rind–Lāshār War. Stories of valour and romance such as "Shay Murīd and Ḥānī" and "Bivargh and Gran Naz" originated from this epic. Other well-known romantic stories indigenous to Baluchistan include *Sammi-Dodā*, *Shīrīn-o*, *Dūstīn*, *Shadad-Mahnāz*, and *Lallah-Gran Naz*.

Zahīrūk songs of the western Baluchi area, *Lailee-Moar* of the central Brahui-speaking area, and *dehis* and *dastānaghs* of the eastern Baluchi area are the typical regional folk songs. Others are the *balūchī shiʿar*, ballads pertaining to the themes of war and valour; *līkū*, the traditional caravan song of the cameleer; *hallū-hālū*, *laylaṛṛū*, *lādū*, *lāṛṛū*, *sa'ot*, and other marriage songs; cradlesongs and lullabies such as *nāzīnk* for girls and *lolī* for boys; and *mūdik* or *muhthik*, elegies and dirges over the dead. Among the Pathans, the *landai* form of folk song in the *kākarrī* style is the most popular singing style. The Kāḵar community has a rich variety of folk songs; *babū lāla* and *de shīn khāl-o naare* ("song of the blue mole") are their typical marriage songs, while *de atanṛ naare* are common songs for women.

The Baluchi Academy, the Brahui Adabī Dīwān, and the Pashto Academy—all centred in Quetta—are engaged in the investigation and preservation of the Baluchi, Brahui, and Pashto cultural and literary traditions of Baluchistan.

BIBLIOGRAPHY. ARRIAN, *Anabasis*, ed. by A.G. ROOS (1907) and *Indica*, ed. by RUDOLF HERCHER (1885), contain an account of Alexander's conquests in India; the *Futūḥ al-Buldân*, by AHMAD IBN YAHYA, AL-BALADHURI, is available in translation but the original Arabic text edited by M.J. DE GOEJE (1866), gives an early and most authentic account of the Arab conquest. For discussions of the origin and history of the Baloch people, see M.K.B. MARRI BALOCH, *The Balochis Through Centuries: History Versus Legend* (1964); M.S. KHAN, *History of Baluch Race and Baluchistan* (1958) and *The Great Baluch* (1965). An account of the Brahui and their language is contained in SIR DENYS DE SAUMAREZ BRAY, *The Brahui Language*, pt. 1, *Introduction and Grammar* (1909), pt. 2, *The Brāhūī Problem*, and pt. 3, *Etymological Vocabulary* (1934). The *Census of India 1901*, vol. 5 and 5-A, *Baluchistan*, contains statistical data and an informative introduction on all aspects of the country. The *Population Census of Pakistan, 1961*, vol. 1 (1962), contains the latest comparative tables for the country, and the *Baluchistan District Census Reports*, present the latest descriptive and statistical information about each district of Baluchistan. For economic material see the various reports of the government of Baluchistan.

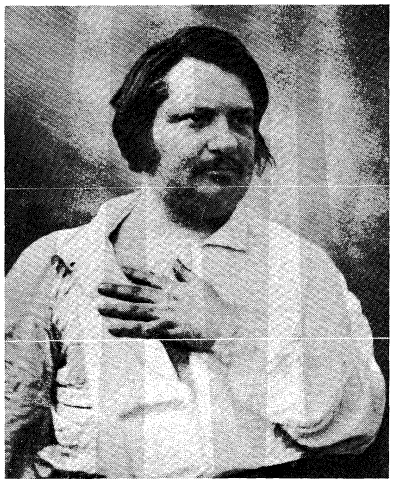
(N.A.B.)

Balzac, Honoré de

Recognized as one of France's greatest writers and as a genius in the novel, Honoré de Balzac drew inspiration from models as diverse as the French writers François Rabelais, Molière, Pierre-Augustin Caron de Beaumarchais, Alain-René Lesage, Denis Diderot, and Jean-Jacques Rousseau; the English writers Tobias Smollett, Henry Fielding, Samuel Richardson, and Laurence Sterne; and the U.S. novelist James Fenimore Cooper;

but, above all, the Scottish Romantic novelist Sir Walter Scott. He converted what had been styled "romance" into a genuine and convincing record of human experience. His vast life work, *La Comédie humaine* ("The Human Comedy"), written from 1829 to 1847, is exceptional in the history of fiction, so much the more so because he claimed at once to be a philosopher—even a seer—who explained man to himself, a historian (a "secretary" of society), a sociologist, and a psychologist.

J.E. Bulloz



Balzac, daguerreotype, 1848.

Balzac was of southern peasant stock, though in fact he was born in Tours on May 20, 1799. His father had made a career in the civil service, mainly based in Paris, but he was in Tours from 1798 to 1814. He had no right to the aristocratic particle *de*, which first he, then his son, assumed. Honoré's mother was of bourgeois stock, her family being cloth makers. Of neurotic temperament, she never understood her son, but it was probably thanks to her that he became attached to the various kinds of pseudo-science and occultism—mesmerism, magnetism, somnambulism, physiognomy, phrenology, and Illuminism (a belief in a special, supernaturally derived wisdom) —that permeated his thought. His sister Laure (later de Surville) was his only childhood friend, and she became his first biographer.

He spent nearly six years at the Collège des Oratoriens at Vendôme. This experience provided material for the novel *Louis Lambert* (1832–35). At Napoleon's downfall his family moved to Paris, where Honoré went to school for two more years and then spent three more as a lawyer's clerk, thus acquiring experience of the law and its victims, to be drawn upon in *Le Colonel Chabert* and *Un Début dans la vie* (*A Start in Life*). He aimed, however, at a literary career: as a writer of tragedy (*Cromwell*, 1819) he had no success. He turned to the novel: the results were sentimental, mystic, reminiscent of Rousseau. In addition, he linked up with hack writers and turned out potboilers—Gothic, humorous, historical novels—written under composite pseudonyms. He was learning his trade, but scholars and critics have found promise of his later achievements in what he himself called "this literary hogwash." He turned his attention to social skits—"physiologies" and "codes," parodies of scientific and legalistic compilations. Then he tried a business career as publisher, printer, and typefounder. By 1828 he was on the verge of bankruptcy and pulled out—the beginning of a lifetime of debt. He returned to writing, and his literary apprenticeship was over.

Early career, 1829–33. Two works of 1829 brought Balzac to the brink of success. *Les Chouans*, the first novel published under his own name, is a historical novel about Breton peasants called Chouans and their part in royalist guerrilla warfare in western France in 1799; in it he showed that women can be more full-blooded than Sir Walter Scott's characters Rebecca and Rowena. The other, *La Physiologie du mariage* (*The Physiology of Marriage*), was anonymous and, on the surface, humorous and satirical: the subject was cuckoldry, encompassing both its causes and cure. It betrayed a fundamental sympathy for and understanding of women that he was immediately to unfold in fiction and thereby began to establish his reputation.

Balzac's parents had retired to Versailles, while he himself spent most of his time in Paris: the man from Tours was already a Parisian and settled in a flat in the rue Cassini. A boisterous, somewhat vulgar person, avid for fame, fortune, and love, but above all conscious of genius, he decided to conquer not only the world of letters but also fashionable and artistic society. His knowledge of women was no longer secondhand. The almost brotherly affection he had for Zulma Carraud, a friend of his sister, lasted his whole life: an affectionate and admiring counsellor, critic, and hostess, she often welcomed him at her home, first at Angoulême (where he gathered material for one of his greatest novels, *Illusions perdues* [*Lost Illusions*]), then at Frapesle, near Issoudun. In 1822 he became enamoured of Madame Laure de Berny, a lady whom he assiduously wooed and won, who gave him his first experience of passionate love—and also a tender affection that, because she was old enough to be his mother (there was almost always a mother-oriented tendency in Balzac's loves), became more and more maternal until her death, in 1836. Between 1828 and 1831 Laure Junot, Duchesse d'Abrantès, widow of Andoche Junot, a Napoleonic general, partly occupied his attention.

Determination to conquer fashionable and artistic society

Other loves were to follow. Madame de Berny—"la Dilecta" ("The Beloved")—was, however, the most important. No doubt it was she who helped him come to an understanding of the mature woman, which inspired *La Femme abandonnée* (*The Deserted Woman*), *La Femme de trente ans* (*A Woman of Thirty*), and *Le Lys dans la vallée* (*The Lily of the Valley*). In addition, he helped Laure d'Abrantès with her memoirs and perhaps drew much information from her about the Napoleonic period, which he used in such works as *Une Ténébreuse Affaire* (*A Murky Business*).

Indeed, between 1828 and 1834 Balzac led a characteristically tumultuous existence, spending his earnings in advance as a dandy and man-about-town, exciting some general hilarity by his sartorial extravagances, his two-wheeler and groom, his gaudy walking stick, and other adornments. As a fascinating raconteur, he was fairly well received in society. But social ostentation then and later was, above all, a relaxation from phenomenal bouts of work—14 to 16 hours at his table in his white, quasi-monastic dressing gown, with his goose-quill pen and his exorbitant drinking of coffee. He was keen to make money but was already upbraiding his age for worshipping it ("money, the only god we now believe in"). He was exigent with editors and publishers. Everything, however, was genuinely subservient to a tremendous creative urge within him and a desire to put his century to rights —to be a Napoleon in the literary sphere. It is in his activity during these years that the key to his purpose can be found.

The journalist. The reigns of Louis XVIII and Charles X witnessed an upsurge of polemical and satirical journalism. Cheap dailies, such as *La Presse* and *Le Siècle* (to which Balzac was to contribute many serial novels), did not begin to appear until 1836, while the great organs, such as *Le Journal des Débats* and *Le Constitutionnel* were not so much involved as smaller and generally scurrilous sheets bent on attacking the increasingly reactionary ministries. Balzac wrote frequently for some of these between 1829 and 1831 and even helped to found one, *La Caricature*. They were mostly liberal, but by this time Balzac was no longer liberal-minded. He moved over rapidly to the absolutist view and wrote in 1832 for the royalist *Le Rénovateur*. Furthermore, he began to restrict his journalistic writing to such reputable periodicals as *La Revue de Paris*. Even with these, however, he quarrelled repeatedly, just as he did with his publishers. He thus began to nourish a rancour against the press that was later to burst into flame in, for exam-

ple, *Un Grand Homme de province à Paris* (*A Distinguished Provincial in Paris*), Part II of *Illusions perdues*. Balzac's scathing attacks on the periodical press are truly memorable.

Growing contempt for parliamentarian government

The politician. His collaboration with the *Rénovateur* came about chiefly through his friendship with a royalist leader, the Duc de Fitz-James; his growing contempt for parliamentary government was no doubt stimulated by his infatuation for the duke's niece, Henriette-Marie, marquise (later duchesse) de Castries. He was on very affectionate terms with her until she refused to become his mistress in the summer of 1832—a humiliation for which he avenged himself in *La Duchesse de Langeais*, which forms the second part of a trilogy called *L'Histoire des Treize* (*The Thirteen*). Even without this rebuff, however, his withdrawal from the unintelligent aristocratic party would have been inevitable. He gave up a whim he had entertained of standing for the Chamber of Deputies; *Le Médecin de campagne* (*The Country Doctor*), expresses his by then quite independent views in favour of authoritarian government, to which he henceforth consistently adhered.

The social historian. Balzac worked at high pressure in his rue Cassini flat until in 1835 the pursuit of creditors drove him to a house in Chaillot, a suburb of Paris, where he adopted a series of ingenious schemes for evading writ servers. He looked upon the novel as a variety of drama, and between 1829 and 1830 he produced his first six *Scènes de la vie privée* ("Scenes from Private Life"). They are classified as *nouvelles*, long short stories of predominantly psychological import, a genre that, thanks to his peculiar method of composing, expanding on and emending proofs, he was apt to develop into full-blown novels. These first *scènes* were mainly about girls in conflict with parental authority. As, for instance, in *La Maison du chat-qui-pelote* (*At the Sign of the Cat and Racket*), the minute attention he gave to domestic background already had earned him a reputation as an emulator of the Dutch painters and had also given promise of his later Parisian studies. Further items in this series (1831–32) reveal his compulsive interest in women of maturity.

New productions of this period of special importance include *Le Curé de Tours* (*The Vicar of Tours*) and *Eugénie Grandet*. He paid many visits to the country, particularly to the château de Saché near Tours, the home of Jean de Margonne, a friend of the family (where he often retired to write), and also to the house of his friends the Carrauds. The two novels show him working toward a second kind of *scène*—that of provincial life. At the same time, *Le Colonel Chabert* also brought him nearer to Parisian life; *e.g.*, *Ferragus* (Part I of *L'Histoire des Treize*) shows him very interested in Parisian topography and types of citizens. *La Fille aux yeux d'or* (*The Girl with the Golden Eyes*—Part III of *L'Histoire des Treize*), besides being a study of lesbianism, contains, in addition, an evocation of Paris as a kind of Dantesque inferno.

The philosopher. Simultaneously Balzac was staking his claim as a thinker, in a series of *Romans et contes philosophiques* ("Philosophical Novels and Tales"). Many of these are fantastic and fascinating, but the philosophic novels of this period are all-important. *La Peau de chagrin* (*The Wild Ass's Skin*) denounces the unscrupulous acquisitiveness and anarchical individualism of his age and tells the story of a magic talisman, possession of which confers upon its owner the fatal power of having all his wishes granted. In *Louis Lambert*, Balzac, making his most intensive effort to justify an enduring belief in the oneness of mind and matter, attempts to reconcile positive science with occultism. *Séraphîta* tries to conciliate the "two worlds" theosophy of Emanuel Swedenborg with Catholicism, by then Balzac's official creed. Of these three novels, *La Peau de chagrin* relates most closely to his future work. The talisman symbolizes an idea, basic to his psychology, of the destructive power of thought (a term embracing not only cerebration but also emotion, passion, imagination, and exercise of the will)—destructive both of the individual and of society: "the blade wears out the scabbard," as Lord Byron had succinctly observed.

With this idea is linked the notion of a vital "ethereal" fluid, a store of energy—concentrated inside the man—that he may husband or squander as he will, thereby lengthening or shortening his vital span. A supremely important feature in Balzac's characters—and in himself—is that most are spendthrifts of this vital force, a fact that explains the monomaniacs who abound in his work from the very beginning: Gobseck, in the *nouvelle* of that title, a usurer gloating over his sense of power; a miser obsessed with gold in *Eugénie Grandet;* a fanatical chemist in *La Recherche de l'absolu* (*The Quest of the Absolute*); an idolatrous father, the King Lear of *Le Père Goriot;* and many others until his life's end.

"La Comédie humaine." The year 1834 marks a climax in Balzac's career, for by then he was totally conscious of his great plan to group his work so that it should form one whole. There were to be three general categories: *Études analytiques* ("Analytic Studies"), dealing with the principles governing human life and society; *Études philosophiques* ("Philosophical Studies"), revealing the causes determining human action; *Études de moeurs* ("Studies of Manners"), showing the effects of those causes, and now to be divided into six kinds of *scènes*—private, provincial, Parisian, political, military, and country life. The *Études analytiques* were unfortunately to remain undeveloped (*La Physiologie du mariage*, *Petites misères de la vie conjugale* [*Conjugal Life*], some fragmentary and projected works); even in the *Études de moeurs*, political and military life were ill catered for.

This entire project resulted in a total of 12 volumes (1834–37), the first volume of *Études philosophiques* (December 1834) being preceded by an explicative preface, of primary importance, which was written by a friend, Félix Davin. By 1837 Balzac had, naturally, written much more, and by 1840 he had hit upon a Dantesque title for the whole: *La Comédie humaine*. He negotiated with a consortium of publishers for an edition under this name, 17 volumes of which appeared between 1842 and 1848, including a famous foreword written in 1842. In 1845, having new works to include and many others in project, he began preparing for another complete edition. The 17 volumes were republished posthumously, with three supplementary volumes, in 1855. A "definitive edition" was published, in 24 volumes, between 1869 and 1876.

Also in 1834 the idea of using "reappearing characters" matured. He was to establish, as it were, a pool of characters from which he would constantly draw, thus adding a sense of solidarity and coherence to the imaginary world he was superimposing on the real world. A certain character would reappear—now in the forefront, now in the background, of different fictions—in such a way that the reader could gradually form a full picture of him. He first applied the device in *Le Père Goriot*, a masterpiece of realism. It may perhaps be considered an artificial technique, but its effect is to give the reader a convincing sense of being in contact with human experience. Furthermore, Balzac's use of this device places him among the originators of the modern novel cycle.

The middle and final years, 1834–50. "My life-story," Balzac wrote in 1841, "is the story of my work." He must then be pictured continuing his threefold activities as writer, as social lion, and, more specially still, as collector of emotional experience. In 1832 he became friendly with Éveline Hanska, a Polish countess who was married to an elderly Ukrainian landowner. She, like many other women, had written to Balzac expressing admiration of his writings. Thus began a lifelong liaison, born of romantic dreams and intensified by passionate ambitions. They met twice in Switzerland in 1833, the second time in Geneva, where they became lovers; then again in Vienna in 1835. They agreed to marry when her husband died, and so they continued to correspond; the *Lettres à l'étrangère* ("Letters to a Foreigner"), which appeared posthumously (4 vol., 1889–1950), are an important

Use of specific people as characters

source of information for the history both of Balzac's life and work. A striking feature of his work is the way he so ostensibly yet so subtly used his knowledge of specific people, especially women, in conceiving his characters. In 1834 he met another woman who, notwithstanding his increasing devotion to Madame Hanska, was to be his mistress, friend, and patroness for a number of years: Sarah Frances Lowell, the English wife of an eccentric Italian, Count Guidoboni-Visconti . . . "la contessa." In 1835 he also made momentary contact with the beautiful Jane Digby, Lady Ellenborough, and it is typical of his creative technique that in *Le Lys dans la vallée*, a novel contrasting platonic with sensual love, the presence of four women can be detected: "La Dilecta," Éveline, "La Contessa," and Lady Ellenborough. Other women who were not mistresses are traceable elsewhere: the admirable Zulma Carraud, for instance, as Renée de Maucombe in *Mémoires de deux jeunes mariées* (*The Two Young Brides*); his friend the novelist George Sand as the literary celebrity Camille Maupin in *Béatrix* and other works; Marie de Flavigny, Comtesse d'Agoult, mistress of the composer Franz Liszt, in the same novel. Of course, there is always fusion and transformation. It would be superfluous to complete the count of his loves. He was highly sexed, a fact that caused Madame Hanska many transports of jealousy.

Further highlights in Balzac's life include his unsuccessful ventures as editor of *La Chronique de Paris* (1836) and *La Revue Parisienne* (1840); culturally profitable journeys to Italy in 1836 and 1837 on a commission for "la Contessa" and her husband, which resulted in such interesting works as the musical fantasies *Gambara* (1837) and *Massimila Doni* (1839); an abortive expedition to Sardinia in 1838 on a mining quest that might have produced results had Balzac not been born, financially speaking, under an unlucky star; the building in 1838 of a rather fantastic house near Versailles called Les Jardies, which increased his debts and which he left in 1840, taking a house in Passy, another Paris suburb (now the Balzac Museum); from 1839 onward, renewed but frustrated bids for success in the theatre (with, for example, *Vautrin*, 1840); in 1839, efforts on behalf of authors' copyright as president of the Société des Gens de Lettres ("Society of Men of Letters"); vain attempts to save a former fellow journalist from the guillotine for murder; the signing of the contract for the *La Comédie humaine* in 1841; and failure to obtain election to the Académie Française.

In January 1842 Balzac learned of the death of Wenceslas Hanski. He now had good expectations of marrying Éveline, but there were many obstacles, not the least being his inextricable indebtedness. She in fact held back for many years, and the period of 1842–48 shows Balzac continuing and even intensifying his literary activity in the frantic hope of winning her, though he had to contend with increasing ill-health. He joined her again in St. Petersburg in the summer of 1843. After that, his life, apart from his writing and wrangles with publishers or editors, was a story of new meetings and holidays together in western Europe; of a longed-for paternity and miscarriage (1846); of anxiety, anguish, and misgivings: the tragedy of an ailing man longing to find stability. His literary productivity, however, did not visibly flag: *Les Parents pauvres* (*Poor Relations*—consisting of *La Cousine Bette* and *Le Cousin Pons*) is among his greatest works.

In the autumn of 1847 he went to Madame Hanska's château at Wierzchownia and remained there until February 1848. He returned again in October to stay, mortally sick, until the spring of 1850. Then at last Éveline relented. They were married in March and proceeded to Paris to live in a house that Balzac had bought and lovingly furnished. He lingered on miserably until his death on August 18, 1850.

Reputation. Until well into the 20th century, Balzac was chiefly regarded as the creator of realism, or naturalism, in the novel; as a man obsessed with the positive and sordid aspects of life; of limited vision, of too coarse a fibre to understand the aristocracy (though Marcel Proust did not accept this estimation), leaving the working classes out of account though acutely perceptive of every aspect of bourgeois life from the professional classes downward; as giving a vivid picture of artistic and bohemian circles and a grim view of the peasantry; obsessed also with the power of money (everywhere in his work, but above all in *César Birotteau*, and *La Maison Nucingen* [*The Firm of Nucingen*]); intensely sympathetic with, though critical of, the young men of his time who were desperately struggling for recognition and success (as in *Le Père Goriot* and *Illusions perdues*). Balzac's reputation and influence have been worldwide. On the whole, readers have more appreciated his human understanding than his harsher critical qualities. In England and the United States he has had great admirers, including Oscar Wilde, Henry James, W. Somerset Maugham.

His perception of bourgeois life

Balzac is openly acknowledged as one who established the technique of the orthodox classical novel, in which consequent and logically determined events are narrated by an all-seeing observer and characters are coherently presented.

The study of Balzac, however, has taken a new turn. Less attention is now given to him as a scientifically minded determinist, an ardent admirer of both the naturalists Georges Cuvier and Geoffroy Saint-Hilaire, and their differing theories of evolution, and more instead to Balzac the visionary (a quality discerned by his young contemporary the poet Charles Baudelaire): to the man claiming "second sight," the philosopher and the illuminate. Perhaps some critics have gone to extremes in this respect, but justice had to be done to such fascinating works as *La Peau de chagrin*, *Le Chef-d'oeuvre inconnu* (*The Unknown Masterpiece*), *La Recherche de l'absolu*, and *Ursule Mirouët*.

Certainly Balzac had exceptional powers of observation and a photographic memory, but he also had a sympathetic, intuitive capacity to get inside other people's skins. Even in thinking of him as an observer and determinist, it is difficult to decide how far he carried the principle of causation: whether he was in effect a convinced materialist or a mystically oriented idealist. His *Études philosophiques* are of help in resolving this problem, but in all the great "realistic" novels (*Le Père Goriot*, *Le Contrat de mariage* [*The Marriage Settlement*], *La Rabouilleuse* [*A Bachelor's Establishment*], *Les Parents pauvres*) he was bent on illustrating the relation between cause and effect, background and character. This preoccupation explains the main features of his novelistic technique; his long preparative descriptions of antecedents and environment—locality, architecture, houses, atmosphere, furniture, clothes, personal physiognomy—from which his characters emerge. His ambition was to "compete with the civil register," exactly picturing his contemporaries in their class distinctions and occupations. In this he certainly succeeded; but he went even further in his efforts to show that the human spirit has power over men and events—to become, as he has been called, "the Shakespeare of the novel."

Balzac's style has been both praised and disparaged. He is a master of the French language, though perhaps too exhaustive in description and often too emotionally hyperbolic when he tries to soar into the higher reaches of spiritual experience. His conscious wit and humour are questionable—not everyone can stomach the Rabelaisian coarseness of the *Contes drolatiques* (*Droll Stories;* not forming an integral part of *La Comédie humaine*). He is probably at his best in the dry, sardonic mood that he favours above all for winding up his narrations. Brought up on the Gothic novel, he never wholly succeeded in eliminating the lurid and melodramatic from his work. The basic question is to ask how deep did his understanding of human nature go. Most of his readers would answer that it reached rock bottom.

MAJOR WORKS

La Comédie humaine

ETUDES DE MOEURS: (*Scènes de la vie privée*): *La Maison du chat-qui-pelote* (1830); *La Bourse* (1832); *Modeste Mignon* (1844); *Un Début dans la vie* (1842); *Albert Savarus* (1842); *La Vendetta* (1830); *Une Double Famille*

(1830); *La Paix du ménage* (1830); *Madame Firmiani* (1832); *Étude de femme* (1830); *La Grenadière* (1832); *La Fausse Maîtresse* (1841); *Une Fille d'Ève* (1839); *Le Message* (1832); *La Femme abandonnée* (1832); *Honorine* (1843); *Beatrix* (1839); *Gobseck* (1830–35); *La Femme de trente ans* (1831–34); *Le Père Goriot* (1834–35); *Le Colonel Chabert* (1832); *La Messe de l'athée* (1836); *L'Interdiction* (1836); *Le Contrat de mariage* (1835); *Autre étude de femme* (1842).

(SCENES DE LA VIE DE PROVINCE): *Ursule Mirouët* (1841); *Eugénie Grandet* (1833); *Les Célibataires: Pierrette* (1840); *Le Curé de Tours* (1832); *La Rabouilleuse* (1841–42). *Les Parisiens en province: L'Illustre Gaudissart* (1833); *La Muse du département* (1843); *Les Rivalités–La Vielle Fille* (1837); *Le Cabinet des antiques* (1836–38, 1839). *Illusions perdues:* [*Les Deux Poètes*, 1837; *Un Grand Homme de province à Paris*, 1839; *Les Souffrances de l'inventeur*, 1843].

(SCENES DE LA VIE PARISIENNE): *Histoire des Treize-* [*Ferragus*, 1833; *La Duchesse de Langeais*, 1833–34; *La Fille aux yeux d'or*, 1834–35]; *Histoire de la grandeur et de la décadence de César Birotteau* (1834–37); *La Maison Nucingen* (1838). *Splendeurs et misères des courtisanes* (in four parts, 1839–47); *Les Secrets de la Princesse de Cadignan* (1839); *Facino Cane* (1836); *Sarrasine* (1830); *Pierre Grassou* (1840); *Les Parents pauvres* [*La Cousine Bette*, 1846; *Le Cousin Pons*, 1847]; *Un Homme d'affaires* (1845); *Un Prince de la Bohème* (1840); *Les Employés* (1837); *Gaudissart II* (1844); *Les Comédiens sans le savoir* (1846); *Les Petits Bourgeois* (1845–56). *L'Envers de l'histoire contemporaine: Madame de la Chanterie* (1842); *L'Initié* (1848).

(SCENES DE LA VIE POLITIQUE): *Un Épisode sous la Terreur* (1830); *Une Ténébreuse Affaire* (1841); *Le Député d'Arcis* (1847); *Z. Marcas* (1840).

(SCENES DE LA VIE MILITAIRE): *Les Chouans* (1829); *Une Passion dans le désert* (1830).

(SCENES DE LA VIE DE CAMPAGNE): *Les Paysans* (1844); *Le Médecin de campagne* (1833); *Le Curé de village* (1839); *Le Lys dans la vallée* (1835–36).

ETUDES PHILOSOPHIQUES: *La Peau de chagrin* (1831); *Jésus-Christ en Flandre* (1831); *Melmoth réconcilié* (1835); *Massimilla Doni* (1839); *Le Chef-d'oeuvre inconnu* (1831); *Gambara* (1837); *La Recherche de l'absolu* (1834); *L'Enfant Maudit* (1831–36); *Adieu* (1830); *Les Marana, 1832–33; Le Réquisitionnaire* (1831); *El Verdugo* (1830); *Un Drame au bord de la mer* (1835); *Maître Cornélius* (1831); *L'Auberge rouge* (1831); *Sur Catherine de Médicis* (1841); *L'Élixir de longue vie* (1830); *Les Proscrits* (1831); *Louis Lambert* (1832); *Séraphîta* (1834–35).

ETUDES ANALYTIQUES: *La Physiologie du mariage* (1829); *Petites misères de la vie conjugale* (1830, 1840, 1845).

The above arrangement of the *Comédie humaine* is that of the Conard edition (40 vol., 1912–40). The dates after the titles are the printed publication dates.

OTHER WORKS: *Contes drolatiques* (1832–37). (PLAYS): *Le Faiseur* (1844, produced 1851); *Vautrin* (1840); *Les Ressources de Quinola* (1842); *Paméla Giraud* (1843); *La Marâtre* (1848).

ENGLISH TRANSLATIONS: Balzac's works have been extensively translated. There have been two collected editions in English: Dent, 40 vol. 1895–98; Caxton, 53 vol. 1895–1900. The former is the better of the two, but neither is accurate and the language used is archaic. Many novels in these translations have been revised and issued separately, and an 18-vol. reprint series by Books for Libraries Press appeared in 1971. Several individual translations that aim at accuracy and modernity of language have been produced by Penguin Classics, Everyman's Library, and other publishers.

BIBLIOGRAPHY. Balzacian archives, mostly collected in the last half of the 19th century by Vicomte Charles V. Spoelberch de Lovenjoul, are kept at the Chantilly Museum. LOVENJOUL'S *Histoire des Oeuvres de Honoré de Balzac* (1879, reprinted 1967), is still indispensable for Balzacian research. See also WILLIAM H. ROYCE, *A Balzac Bibliography* (1929, reprinted 1969); and CHARLES B. OSBURN (comp.), *The Present State of French Studies* (1971).

Editions of complete works: There are many excellent ones. For convenience: Pléiade, *La Comédie humaine*, ed. by M. BOUTERON, 11 vol. (1935–59); Editions du Seuil, *La Comédie humaine*, ed. by PIERRE CITRON, 7 vol. (1965–66); Bibliophiles de l'Originale, *Oeuvres complètes*, ed. by JEAN DUCOURNEAU (1967–), with facsimiles of the original edition; see especially PIERRE BARBERIS, *Aux sources de Balzac: Les romans de jeunesse* (1965). There are many special critical editions. The partly critical editions of the Classiques Garnier are especially useful.

Letters: ROGER PIERROT (ed.), *Correspondance*, 5 vol. (1960–69) and *Lettres à Madame Hanska*, 4 vol. (1967–71) a complete, compact collection.

Periodicals: *Les Cahiers Balzaciens*, ed. by M. BOUTERON, 8 vol. (1923–28); *Le Courrier Balzacien*, 10 vol. (1948–50); *Les Études Balzaciennes*, 10 vol. (1951–60); *L'Année Balzacienne* (1960–).

Biographies: (*Classical presentations*): LAURE DE SURVILLE, *Notice biographique* (1858); THEOPHILE GAUTIER, *Honoré de Balzac* (1859); EDMOND WERDET, *Portrait intime de Balzac* (1859) by Balzac's one-time editor; LEON GOZLAN, *Balzac en pantoufles* (1869); FERDINAND BRUNETIERE, *Honoré de Balzac, 1799–1850* (1906). (*Later biographies*): ANDRE BILLY, *Vie de Balzac*, 2 vol. (1944); H.J. HUNT, *Honoré de Balzac: A Biography* (1957, reprinted 1969, with a corrigendum sheet bringing it up to date); ANDRE MAUROIS, *Prométhée: ou, La vie de Balzac* (1965; Eng. trans., *Prometheus: The Life of Balzac*, 1965).

General presentations: SAMUEL ROGERS, *Balzac and the Novel* (1953), a very thoughtful work; SOMERSET MAUGHAM, *Ten Novels and Their Authors* (1954; U.S. title, *The Art of Fiction*, 1955); H.J. HUNT, *Balzac's Comédie Humaine* (1959), a complete historical and analytical study that shows the work's expansion and the 1964 ed. brings the Balzac bibliography up to date to that year; JULES BERTAUT (ed.), *Balzac* (1959), includes a highly interesting tribute by MICHEL BUTOR; PHILIPPE BERTAULT, *Balzac* (1962; Eng. trans., *Balzac and The Human Comedy*, 1963), a judicious general study by a great Balzacian scholar; HARRY LEVIN, *The Gates of Horn: A Study of Five French Realists* (1963), a valuable assessment; MAURICE BARDECHE, *Une Lecture de Balzac* (1964), a subtle introduction; F.W.J. HEMMINGS, *Balzac: An Interpretation of La Comédie Humaine* (1967), a perceptive analysis of Balzac in relation to his times; STEFAN ZWEIG, *Balzac* (1946; Eng. trans., 1946), a competent assessment.

Special studies: MARCEL BARRIERE, *L'Oeuvre de Honoré de Balzac* (1890), an early analysis of each work in relation to Balzac's general scheme; MAURICE BARDECHE, *Balzac, romancier*, rev. ed. (1940, reprinted 1967), an initial inquiry into Balzac's evolution up to 1834; ALBERT BEGUIN, *Balzac visionnaire* (1946), follows Curtius (below) in reacting against the view of Balzac as a mere "realist"; PHILIPPE BERTAULT, *Balzac et la religion* (1942), the definitive work on this subject; OLIVIER BONARD, *La Peinture dans la création balzacienne* (1969), describes Balzac's dependence on visual and artistic models for his initial inspirations; RENE BOUVIER and EDOUARD MAYNIAL *Les Comptes dramatiques de Balzac* (1938), the basic inquiry into Balzac's financial affairs; E.R. CURTIUS, *Balzac* (1923), an early perception of Balzac's philosophic importance; E.P. DARGAN and BERNARD WEINBERG, *The Evolution of Balzac's Comédie Humaine* (1942); W.L. CRAIN (ed.), *Le Secret des Ruggieri: A Critical Edition* (1970), is an admirable example of the Chicago "school" of research; J.H. DONNARD, *Balzac: Les Réalités économiques et sociales dans la Comédie Humaine* (1961), a corollary to Bouvier and Maynial; HENRI EVANS, *Louis Lambert et la philosophie de Balzac* (1951), the first serious appreciation of this novel; H.U. FOREST, *L'Esthétique du roman balzacien* (1950), an illuminating study; BERNARD GUYON, *La Pensée politique et sociale de Balzac*, 2nd ed. (1967), a fundamental work; his *La Création littéraire chez Balzac* (1951) initiated the study, now much pursued, of Balzac's method of composition as revealed in manuscripts, successive proofs, and editions; JEAN POMMIER, *L'Invention et l'écriture dans la Torpille d'Honoré de Balzac* (1957), has been very active in this field; SOPHIE DE KORWIN-PIOTROWSKA, *Balzac et le monde slave* (1933) and *Balzac en Pologne* (1933), basic works for Balzac's relations with Madame Hanska; PIERRE LAUBRIET, *L'Intelligence de l'art chez Balzac* (1961), an important thesis; M. LE YAOUANC, *Nosographie de l'humanité balzacienne* (1960). For Balzac's knowledge of pathology, see also J. BOREL, *Médecine et psychiatrie balzaciennes* (1971); FERNAND LOTTE, *Dictionnaire biographique des personnages fictifs de La Comédie Humaine* (1952, with supplementary vol., *Anonymes*, 1956), supersedes the pioneer *Répertoire de la Comédie Humaine de Honoré de Balzac* by ANATOLE CERFBERR and JULES CHRISTOPHE (1887; Eng. trans., *Repertory of the Comédie Humaine*, 1902); FELICIEN MARCEAU, *Balzac et son monde* (1955; Eng. trans., *Balzac and His World*, 1966), a complete study of Balzac's characters, weakened by some lack of historical sense; D.Z. MILATCHITCH, *Le Théâtre inédit d'Honoré de Balzac* (1930), the pioneer study. See also PIERRE DESCAVES, *Balzac dramatiste* (1960); PER NYKROG, *La Pensée de Balzac dans La Comédie Humaine* (1965), perhaps takes the study of Balzac's philosophy too far; DANIEL VOUGA, *Balzac malgré lui* (1957); ADRIEN PEYTEL, *Balzac, juriste romantique* (1950), studies Balzac's very considerable knowledge of the law; M.H. FAILLIE, *La Femme et le code civil dans La Comédie Humaine d'Honoré de Balzac* (1968); GEORGES POULET, *Études sur le temps humain*, vol. 2, *La Distance intérieure* (1956; Eng. trans., *Studies in Human Time*, vol. 2,

The Interior Distance, 1959), examines Balzac's sense of time values; A. PRIOULT, *Balzac avant La Comédie Humaine* (1936), important as a pioneer study of Balzac's "apprentice" works.

(H.J.H.)

Bangkok

Bangkok is the capital and chief port of Thailand. With a population of more than 3,000,000 it is the only cosmopolitan city in a country of small towns and villages; it is also the centre of Thailand's cultural and commercial activity.

One of the most colourful of Eastern cities, Bangkok is located on the delta plain of the Mae Nam Chao Phraya (River of Chao Phraya), about 25 miles (40 kilometres) from the Gulf of Thailand (Gulf of Siam). It was formerly divided into two municipalities—Krung Thep on the east bank and Thon Buri on the west—connected by three bridges. In 1971, the two were united as a single city-province with a single municipal government. Krung Thep is considered as Bangkok proper. It has a low architectural profile, punctuated by tall pagodas, radio and television masts, and occasional high-rise buildings. It is a bustling, crowded city, with temples, factories, shops, and homes standing juxtaposed along its roads and *khlongs* (canals).

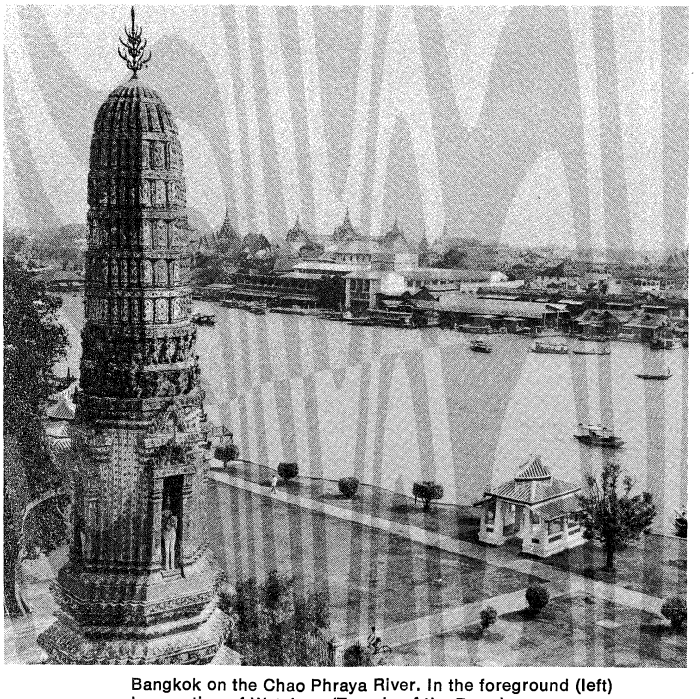
The name Bangkok, used commonly by foreigners and older provincials, is, according to one interpretation, derived from a name that goes back to the time before the city was built—the village or district (*bang*) of wild plums (*makok*). Most Thais call their capital Krung Thep (City of Angels), which is the first part of its mellifluous 27-word official name.

HISTORY

Bangkok became the capital of Siam (as Thailand was previously known) in 1782, when General Chakkri, on assuming the throne as Rama I, moved the citadel from the west to the east bank of the Chao Phraya. The move appears to have been dictated by strategic considerations, because the new site drew an advantage from the wide westward bend in the river that constituted a wide moat guarding the northern, western, and southern perimeters of the citadel. To the east stretched the vast, swampy delta plain, called the Sea of Mud, that could be traversed only with extreme difficulty. Rama I built a city that was intended as far as possible to be the equal in its grandeur of ancient Ayutthaya, 40 miles to the north, and capital of the kingdom for more than 400 years. By the end of the reign of Rama I the city was established, and the walled Grand Palace complex including Wat Phra Kaeo, which housed the most sacred Emerald Buddha, as well as Wat Po, and the city wall were completed. The wall, perhaps the most imposing structure, skirted the river and Khlong Ong Ang to the east; it was four and a half miles long (7 kilometres), 10 feet (three metres) thick, 13 feet (four metres) high, and had 63 gates and 15 forts. The area enclosed amounted to one and a half square miles (4 square kilometres), half of which was occupied by the Grand Palace.

Strategic location of the city

H. Armstrong Roberts



Bangkok on the Chao Phraya River. In the foreground (left) is a portion of Wat Arun (Temple of the Dawn).

More Buddhist monasteries were built during the reigns of Rama II (1809–24) and Rama III (1824–51). They served as schools, libraries, hospitals, and recreation areas, as well as religious centres. During these years Wat Arun, noted for its tall spire, Wat Yan Nawa, and Wat Bowon Niwet, were completed, Wat Po was enlarged, and Wat Sutat was begun. There were, however, few other substantial buildings and fewer paved streets; the river and the network of interconnected khlongs served as roadways.

Rama IV (1851–68) developed the city while continuing, at a reduced rate, the traditional building of *wats*. The Grand Palace was improved, a number of substantial dwellings constructed for members of the royal family, several new streets laid down, and a reduction made in the large number of floating houses anchored along the river front. A new route, Charoen Krung (New Road), leading southward was constructed and a new city moat, Khlong Phadung Krung Kasem, parallel to the city's first canal, was dug and fortified; a long canal led from it to the present port area (Khlong Toei), thus allowing small boats to bypass the big bend in the river immediately south of the city. A pony path, now Phra Ram Thi 4 Road, was laid atop the mud beside this waterway.

The transformation of the city under Rama V

The long reign of Rama V, King Chulalongkorn (1868–1910), saw the city transformed through a program of public works. This great triple-spired Chakkri Building in the Grand Palace was completed by 1880; later the Dusit Palace and an ancillary garden city were built beyond the Wall, being connected to the Grand Palace by European-inspired Ratchadamnoen Boulevard. A road- and bridge-building program was embarked on in earnest, for King Chulalongkorn, an early automobile enthusiast, foresaw the effect that the motor vehicle would have on city development. Most of the now obsolete city wall was pulled down to build the roads, but two forts, a large gate, and a section of the wall were preserved. A post and telegraph service was organized in 1885, an electric tram service instituted on New Road in 1892, and the first line of the State Railway, running from Bangkok to Ayutthaya, opened in 1900. Nor were aesthetic considerations forgotten, for other new buildings included the marble temple of Wat Benchamabopit (1900), elegant bridges in the French style, and the Italian-inspired Throne Hall (now the National Assembly Hall). King Chulalongkorn's reign was also one of population growth. By 1910 the inhabitants numbered about half a million.

Rama VI (1910–25) continued the program of public works. He established Chulalongkorn University in 1916, built a system of locks to control the level of waterways throughout the city, and gave the public their first and largest recreational area—Lumphini Park. During Rama VII's reign (1925–35), municipal areas were delimited as part of a general administrative reorganization aimed at decentralization. In 1937 Bangkok was formally divided into the municipalities of Krung Thep and Thon Buri; at the time of their establishment, the two municipalities, approximately equal in area, together covered about 37 square miles (97 square kilometres). The city's population had grown to over 650,000, four-fifths of whom lived in Krung Thep.

Since World War II, Bangkok—and particularly Krung Thep—has grown with unprecedented rapidity; the population doubled between 1960 and 1970 and the area of Krung Thep has been extended three times—in 1942, 1955, and 1965—to include more than 90 square miles

(238 square kilometres). Extended twice, in 1955 and 1966, Thon Buri now covers 20 square miles (52 square kilometres). With their union in 1971, the Bangkok-Thon Buri metropolis had a total area of 110 square miles (290 square kilometres). Since this growth had not been anticipated and since there is as yet no policy governing the use of or speculation in urban land, it is not surprising that the facilities of the city are now overtaxed, while problems associated with unregulated urban growth affecting transportation, communication, housing, water supply, drainage, and pollution are becoming acute.

THE CONTEMPORARY CITY

Climate. The climate is hot throughout the year, ranging from 77° F (25° C) in the "cold" season in December to 86° F (30° C) at the height of the hot season in April. The mean annual rainfall totals 60 inches (1,500 millimetres), four-fifths of which falls in brief torrential downpours during the late afternoons of the rainy season, which lasts from mid-May through September; the dry season lasts from December to February. Mean monthly humidity varies from a low of 70 percent in the "cold" season to well over 80 percent during the rains.

The city layout. Bangkok is not a planned city and is now undergoing rapid, if not chaotic, changes. The city is becoming much more closely packed in areas long built-up and, at the same time, is sprawling outward into the surrounding agricultural areas. Some districts, however, are evolving into functional units as the inner city becomes more clearly institutional and commercial, and the outer city more residential and industrial.

Principal districts of the city

The government district contains the central administrative offices, which are massed around the Grand Palace and also line Ratchadamnoen Boulevard. A number of large camps around and north of the National Assembly Hall compose the military area. The Chinese quarter of Sam Peng is the main commercial district. Both banks of the river just south of Sam Peng are the site of the city's warehouses, while industry is located at Sam Rong, south of the port. The rich live in Bang Kapi, the squatters in the Klong Toei area, and the poor and not so poor at the Din Daeng and Hua Mak welfare housing estates. Entertainment is concentrated on Pat Pong Road and along Phet Buri Road. The financial district straddles Silom Road.

Traditional areas. Two of the city's identifiable neighbourhoods—the governmental and commercial districts—occupy traditional sites. Government offices were first housed in the Grand Palace and, by the late 19th century, occupied surrounding palaces or palatial mansions. The bureaucracy then spread out into nearby colonial-style or Thai-style office buildings and homes along Ratchadamnoen Boulevard. Severe, multistoried buildings are now being erected to meet the ever-increasing demand for space, and the traditional government compounds are becoming overbuilt.

When the citadel was moved to the east bank of the river in the 18th century, Chinese merchants and tradesmen occupying the site were displaced and moved a short distance southward to the area now known as Sam Peng. Business was at first carried on in one-story wood and thatch houses of diverse shape and size. By the early 1900s a number of streets had been lined with two-story masonry shop-houses. Today, the ever-expanding district contains rows of shop-houses that are sometimes five or more stories high and that are so crowded together that often access is possible only on foot. The area may be likened to a huge department store in which the counters are represented by city blocks fronted by innumerable shops, and the aisles are crowded streets and alleyways.

Transportation. Bangkok's transportation system was originally based on water travel. The city's maze of khlongs connected with the river earned it the name of the Venice of the East. The advent of the automobile, however, brought drastic changes. The number of vehicles in the city has increased to nearly 260,000—including three-wheeled taxis, private cars, and buses that are colour coded according to the region of service—and a shortage of road space has developed. The problem was met first by filling in most of the smaller and a number of the larger canals; this proved to be more than an aesthetic loss because the waterway system had served to drain the deltaic waterlogged city site. Furthermore, though it afforded temporary relief, the measure did not solve the problem of lack of space; traffic today is so congested that movement is increasingly difficult.

Lines of communication radiate outward from the city. Roads run north to Laos and Chiang Mai, east to Cambodia, and south to Malaysia; railways run to the borders of Laos and Malaysia, to Chiang Mai in the north and to Ubon Ratchathani and Nong Khai in the east. Bangkok airport is utilized by 35 international airlines.

The port of Bangkok, located on the Chao Phraya, is connected to the sea by a channel dug through the sandbar at the river mouth some 17 twisting miles (27 kilometres) downstream. The port now handles nearly all of the nation's imports and seven-tenths of its exports. About 30 percent of all inbound cargo is sent elsewhere in the country, while the rest remains in Bangkok to be consumed or processed further.

Demography. The population's outstanding demographic characteristics—its youth and the low proportion of non-Thais—are due to a high rate of natural increase, and restrictive foreign immigration quotas adopted after World War II. Half the residents are under 20 years of age, while another fifth are not yet 30. About 90 percent of the 3,000,000 citizens are Thai, and of the remainder nine percent are Chinese, 0.02 percent are Indians, and 0.02 percent are Americans; the remainder constitute a mixed group of European and Asian nationals.

Despite their small size, the foreign communities tend to live in certain areas. The Chinese concentrate in and around the commercial area of Sam Peng, the Indians gather around mosques in the Wang Burapha section, and the Western community enjoys the affluence of the modern, eastern section of the city.

Of the foreign groups, the Chinese enter the most intimately into city life. They appear to assimilate readily, and intermarriage is the rule rather than the exception. Their offspring are Thai citizens, many families take Thai surnames, and many Chinese are naturalized.

Labour statistics reflect the city's commercial and industrial importance. Thirty percent of those employed are craftsmen and factory workers, 31 percent are sales workers, 19 percent are engaged in services, 10 percent are clerical workers, and 10 percent are administrators or professionals.

Population densities are highest in the Chinese district of Sam Peng where they reach about 390,000 persons per square mile (150,000 per square kilometre). They then diminish rapidly and regularly from this centre to about 25,000 persons per square mile (10,000 per square kilometre) in the more recently built-up outer portions of the city. Approximately half of the population live at densities of less than 50,000 per square mile (20,000 per square kilometre), while no more than one-fifth reside at densities of more than 130,000.

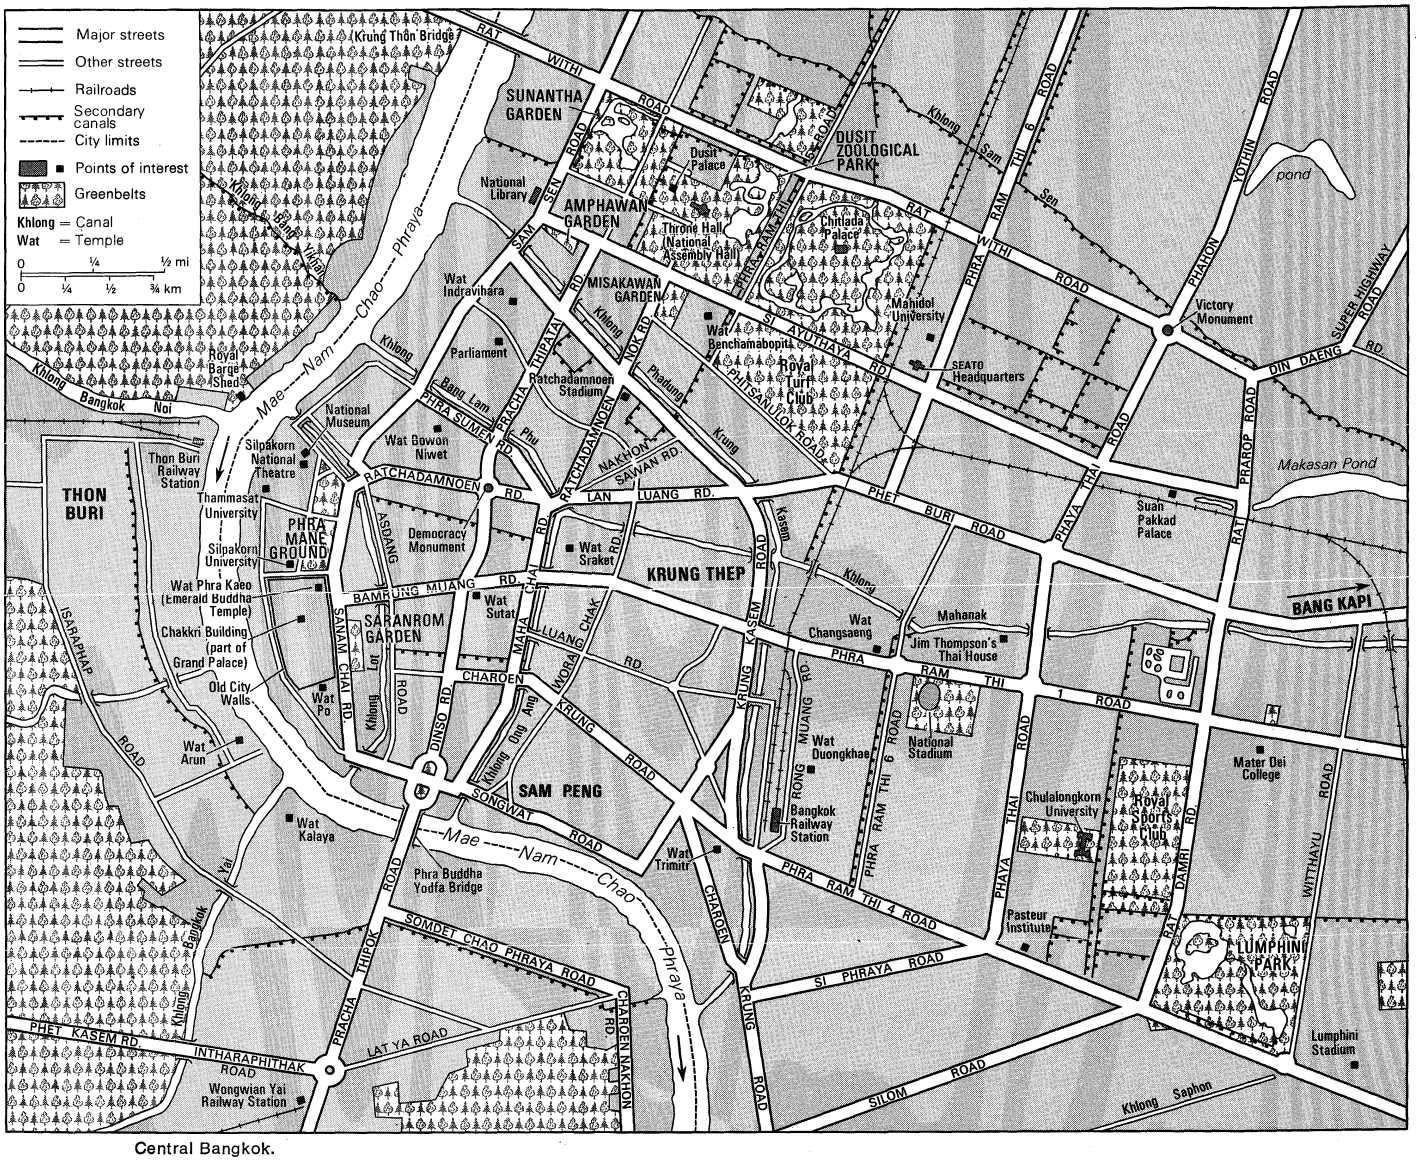
Housing. Homes for the most part consist of small, one- or two-story wooden structures standing close together. Most of these are overcrowded because there are far too few of them to house the ever-expanding population. Government housing programs are insufficient to meet the growing housing shortage; it is estimated that another 100,000 housing units are needed. Fewer than 9,000 units have been built in six public welfare housing projects, and many of these have replaced former homes. At Din Daeng, the largest project, high-rise concrete buildings of 50 to 80 apartments have been constructed.

Housing shortage

The government allows squatters temporarily to occupy unused public land. The number of squatters is small; most of them are concentrated around the port.

Private real estate developers are preoccupied with providing homes for middle-income groups, and many government agencies provide "estates" for their employees. Homes may be crowded onto small lots provided with elementary sanitation facilities. These developments spread out haphazardly on the periphery of the city.

Housing for the rich—mostly for the wealthy foreign



Central Bangkok.

community—usually takes the form of large, modern, two-story masonry structures equipped with separate servants' quarters and kitchens and set in spacious, landscaped compounds. So many of these homes have been built in Bang Kapi that the area has become a maze of dead ends and narrow, sharp-angled lanes. The shops offer Western goods, the modern office buildings house foreign firms and all manner of modern services are available.

Economy. *Industry.* There are many factories in the metropolitan area, the majority of them operating on a small scale. Larger plants are located in the vicinity of the port so as to be near the warehouses that store imported materials. Manufacturing is chiefly confined to food-processing, textiles, and the production of building materials. The city houses the Thai Chamber of Commerce and the Association of Thai Industries. Although trade unions were abolished in 1958, there are 14 specialized trade associations in Bangkok.

Commerce. Bangkok houses about one-third of the country's banking units, holding 75 percent of all deposits. There are 18 Thai banks and 14 branches of foreign banks, as well as the Industrial Finance Corporation of Thailand (IFCT) and the Office of the Board of Investment. The Bangkok Stock Exchange and several insurance companies are also located in the city.

Governmental and international institutions. Prior to their union in 1971, both of the municipalities—Krung Thep and Thon Buri—had a mayor and a municipal assembly whose members were elected by direct voting. The municipal councils were chosen by the assemblies from their members and had executive advisory functions. The government of the newly combined metropolis was to be administered by a governor and two deputies. The governor was to act as mayor of Bangkok–Thon Buri municipality and was to be appointed by the Interior Ministry. Governmental activities are greatly restricted, however, and developmental responsibilities rest with a large number of independent governmental agencies.

In addition to housing the headquarters of the United Nations Economic Commission for Asia and the Far East (ECAFE), Bangkok also houses various other United Nations agencies, including branch offices of the World Health Organization (WHO), the International Labour Organization (ILO), and the International Bank for Reconstruction and Development (World Bank). It is also the headquarters of the Southeast Asia Treaty Organization (SEATO).

Public utilities. Most of the water supply is drawn from the Chao Phraya and is then chemically treated at the municipal plant; nonchlorinated water is then added from deep wells. The supply is uncertain, and some areas are without water during periods of heavy demand.

Sanitation facilities consist of open sewage storm drains and the canals; large buildings are often equipped with septic tanks. Bangkok consumes about 85 percent of the country's electric power. It houses the National Energy Authority and its pilot nuclear plant.

Health and safety. Bangkok benefits by containing most of the country's health facilities. In the late 1960s there were more than 40 government-run general hospitals, 80 private hospitals, and several private clinics in operation. Special services are offered for patients with tuberculosis and venereal disease, and there are government homes for the indigent, handicapped, and aged. The Pasteur Institute supplies vaccines and antivenins.

The metropolitan police are a separate unit within the national police department. About 6,000 strong, it is divided into three sections—North Bangkok, South Bangkok, and Thon Buri—that are patrolled 24 hours a day. The traffic police division also provides mounted escorts and guards for the King. There is a police fire brigade; a detective-training school is located in the city.

Education. Because of its high proportion of school-age citizens, Bangkok's educational facilities are overburdened. In 1968 there were over 660,000 students in Bangkok and Thon Buri. There are too few schools, and the standard of instruction varies. Many of the government-built preprimary and primary schools are located on *wat* grounds. Private primary and secondary schools run by foreign religious missions—including Bangkok Christian College and Mater Dei College—train the children of the elite. There are about 100 private Chinese primary schools and night schools.

Universities

The city houses five universities—Chulalongkorn University (founded 1916), Kasetsart University (1943), Mahidol University (formerly the University of Medical Sciences), Silpakorn University (1943), and Thammasat University (1933).

Cultural life. The most important cultural feature is the *wat*, or Buddhist monastery. There are more than 300 such temples, representing classic examples of Thai architecture. Most *wat*s are enclosed by walls. However, many *wat*s have leased a portion of their grounds for residential or commercial use. Important monasteries are Wat Po (Temple of the Reclining Buddha), Wat Phra Kaeo (Temple of the Emerald Buddha), and Wat Trimitr (Temple of the Golden Buddha).

The National Museum houses prehistoric, Stone Age, and Bronze Age art relics, as well as royal objects dating back to the 6th century AD. The city also has 12 libraries, including the National Library and the Thai National Documentation Centre. Jim Thompson's Thai House, named for an American entrepreneur and devotee of Thai culture, is composed of five traditional Thai mansions; it contains the country's largest collection of 17th-century Thai religious paintings. There are also collections of Dhavaravadti and Khmer sculpture and of Thai and Chinese pottery and porcelain.

The media. All of the country's daily newspapers and most of its weeklies and monthlies are published in Bangkok. The press is tightly controlled by the government, and the number of newspapers on the stands changes rapidly. In 1971 there were 22 dailies, 20 weeklies, and several biweekly, monthly, and bimonthly publications. Newspapers are printed in Thai, English, and Chinese. The more important papers are the *Thai Rath*, which has the largest circulation; and the *Sri Nakorn*, one of the largest of the Chinese papers.

Radio and television are controlled by the public relations department of the Office of the Prime Minister and by the Royal Thai Army. More than one-half of the nation's 160-odd radio stations are located in or near Bangkok. The four television stations, two of which transmit in colour, broadcast about 100 hours a week. Most programs are in Thai, but some special programs are in English and Chinese.

Recreation. Motion pictures are extremely popular, with about 70 percent of the population attending the films at least once a week. There is a thriving Thai cinema industry but films are also imported from the U.S., Hong Kong, and the U.K. and are subject to governmental censorship. There are also many nightclubs. Fairs, festivals, and kite-flying contests are held at the three large public parks; the Ratchadamnoen and Lumphini stadiums present exhibitions of Thai boxing. Silapakorn National Theatre presents dancing, drama, and music.

(La.S.)

Bangladesh

Bangladesh is an independent Asian state located in the delta of the Ganges and Brahmaputra rivers in the northeastern part of the Indian subcontinent. Until 1971 it was East Pakistan, one of five provinces of Pakistan, which was separated from the other four provinces by 1,100 miles of Indian territory. Bangladesh has an area of 55,126 square miles (142,776 square kilometres) and is one of the most densely populated areas in the world. In about 4 percent of the area the density exceeds 2,000 persons per square mile. The total population in the early 1970s was more than 73,000,000. Bangladesh is bounded by the Indian states of West Bengal to the west and north, Assam to the north, Meghalaya to the north and northeast, and Tripura to the east, and by the Indian union territory of Mizoram to the east, Burma to the southeast, and the Bay of Bengal to the south. The capital is Dacca.

Bangladesh is fringed on the south by the huge expanse of marshy deltaic forest known as the Sundarbans, the abode of the famous royal Bengal tiger. The Bay of Bengal is known for its cyclonic storms, which whip up its waters, sending them crashing onto the coastal areas and the offshore islands, occasionally causing flooding.

Relations with West Bengal

Throughout history the territory's relations with what is now the neighbouring Indian state of West Bengal have been marked by ambiguity. Although in certain periods the two areas were administratively united, their differences have remained: the riverine eastern part (the province) with its Muslim majority and the relatively dry western part (West Bengal) with its predominantly Hindu population. (For associated physical features, see BAY OF BENGAL; BRAHMAPUTRA RIVER; GANGES RIVER. For historical aspects, see INDIAN SUBCONTINENT, HISTORY OF THE.)

PHYSICAL GEOGRAPHY

Physiography. *The rivers.* The most significant feature of the landscape is provided by the rivers, which have molded not only its physiography but also the way of life of the people. The rivers may be divided into five systems—(1) The Ganges, or Padma, as the united streams of the Ganges and Brahmaputra are known, and their deltaic streams; (2) the Meghna and the Surma river system; (3) the Brahmaputra and its adjoining channels; (4) the North Bengal rivers; and (5) the rivers of the Chittagong Hill Tracts and the adjoining plains.

Five major river systems

The Ganges is the pivot of the deltaic river system of Bengal. The river and its tributaries enclose a large area, covering the districts of Kushtia, Jessore, Khulna, Faridpur, Patuākhāli, and Bakerganj. The Ganges Delta itself covers about 20,000 square miles. The Padma enters Bangladesh at the western extremity of the Rājshāhi district and forms, for about 90 miles, the international boundary between Bangladesh and West Bengal (India).

The Meghna, another mighty river, is formed by the union of the Sylhet-Surma and Kusiyāra rivers. These two rivers are branches of the Barāk River, which rises in the Nagar-Manipur watershed in India. The main branch of the Barāk, the Surma, is joined near Ajmiriganj in the Sylhet district by the Kālni and farther down by the Kusiyāra branch. The Dhaleswari, a distributary of the Jamura River, joins the Meghna a few miles above the junction of the Ganges and the Meghna. As it meanders south, the Meghna grows larger after receiving the waters of a number of rivers, including the Burhi Ganga and the Sitallakhya.

The Brahmaputra and its adjoining channels cover a large area from the eastern parts of the districts of North

Bengal to the Meghna River in the southeast. The Brahmaputra (Jamuna) receives waters from a number of rivers, especially on its right bank. The river, with its notoriously shifting channels, not only prevents permanent settlement along its banks but also inhibits communication between the northern area of Bangladesh and the eastern part, where Dacca, the capital, is situated.

The Tīsta is the most important water carrier of the northern districts of Bangladesh. Rising in the Himalayas near Darjeeling (India), it flows southward. After the floods of 1787, however, the Tīsta changed its course, moving southeastward to join the Brahmaputra. That shift caused the rivers of North Bengal to be cut off from the upland waters and led to the deterioration of the natural drainage. Similarly, a number of small and medium-sized rivers in the southwest are silting up, adversely affecting the economic life of that region.

Four main rivers constitute the river system of the Chittagong Hills and the adjoining plains—the Feni, the Karnaphuli, the Sangu, and the Mātāmuhari. Flowing generally west and southwest across the coastal plain, they empty into the Bay of Bengal.

Three main types of soils

Soils. There are three main categories of soils: the old alluvial soils, the new alluvial soils, and the hilly soils, which have a base of sandstone and shale. The fertile new alluvial soils, found mainly in flooded areas, are usually pale brown, sandy, micaceous, and chalky clays and loams. They are deficient in phosphoric acid, nitrogen, and humus but not in potash and lime. The old alluvial soils in the Bārind and Madhupur jungles are dark-brown clays and loams. They are sticky during the rainy season and hard during the dry. The hilly soils support dense forest growth.

Natural regions. Physical geographers, utilizing topographic criteria, have divided Bangladesh into as many as 20 regions; the following 11 are generally regarded as the most important.

The Bārind Tract. The Bārind Tract comprises the districts of Rājshāhi division, between the Ganges and Brahmaputra. The soil of this region is hard, reddish clay, and the region is comparatively elevated.

The Bhar Basin. The depression southeast of the Bārind Tract is called the Bhar Basin. It includes parts of Rājshāhi and Pābna districts, with its centre in the vast marshy area called the Chalan Bīl (bīl, "lake").

The Brahmaputra floodplains. The floodplains of the Brahmaputra (Jamuna) stretch from Bhurungamāri in Rangpur district in the north to Bera in Pābna district in the south. The eastern limit of this zone extends from Dewanganj to Jamālpur in Mymensingh district, while in the west it extends across the Indian border. The area is dominated by the Brahmaputra, which frequently overflows its banks in devastating floods.

The Madhupur Tract. The Madhupur Tract in the east consists of an elevated plateau, with hillocks varying in height from 30 to 60 feet. The valleys, mostly flat, are cultivated. The Madhupur Jungle contains sal trees, whose hardwood is second to teak in value.

The Northeastern Lowland. The southern and southwestern parts of Sylhet district and the northern part of Mymensingh district compose the Northeastern Lowland. It is characterized by a large number of lakes.

The Sylhet Hills. The Sylhet Hills in the east consist of a number of small hills and hillocks ranging from 100 feet to more than 1,100 feet in height. Among the northern Sylhet Hills, Kesara Pahar (500 feet, or 150 metres), Lubhachara (over 300 feet, or 90 metres), and Chatal Tila (over 400 feet, or 120 metres) stand out. A number of hills jut into southern Sylhet from India.

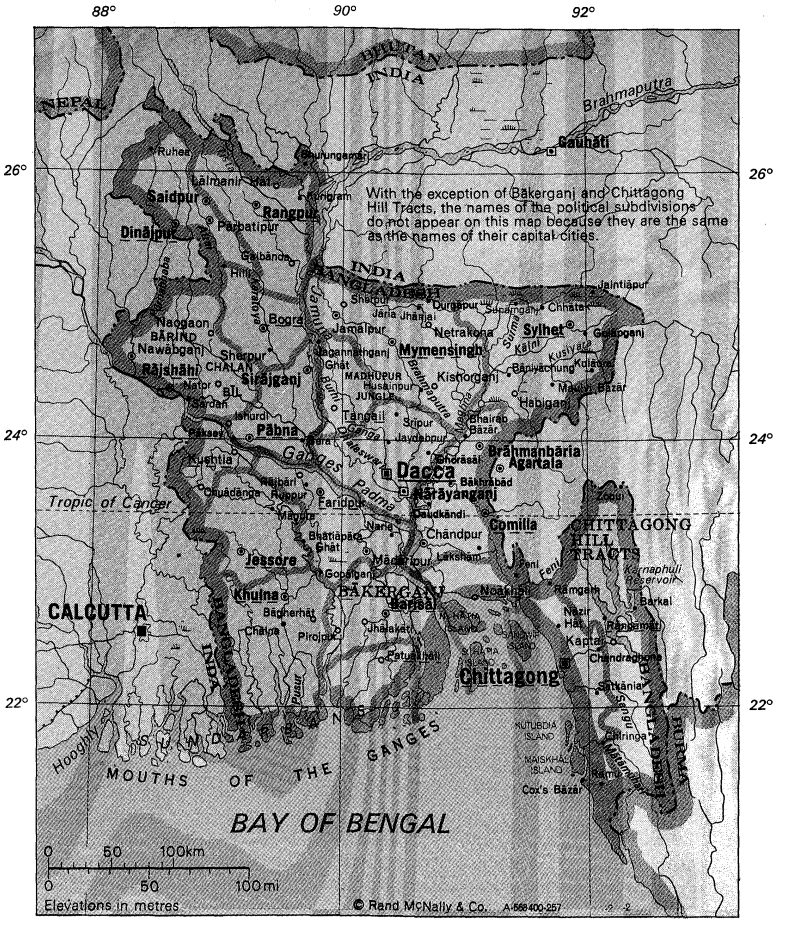
The Meghna Flood Basin. The Brahmaputra River in its old course built up the Meghna Flood Basin, which includes the low and fertile Meghna-Lakkhya Doāb, enriched by the Titās distributary, as well as the *diaras* and *chars* (land areas formed and changed by the deposition of silt and sand in riverbeds) of the Meghna, especially between Bhairab Bāzār and Daudkāndi.

The Central Delta Basin. The Central Delta Basin includes the extensive lakes in the central part of the Bengal Delta in Farīdpur district. The basin's total area is about 900 square miles (2,300 square kilometres).

The Immature Delta. The belt of land in southern Bangladesh bordering the Bay of Bengal constitutes the Immature Delta. The belt—a lowland of some 3,000 square miles (7,800 square kilometres)—contains, in addition to the vast forest known as the Sundarbans, the reclaimed and cultivated lands to the north of it. That area in southern Khulna and southwestern Bakerganj is crisscrossed by a network of streams that flow around roughly oblong islands.

The Active Delta. The Active Delta includes the Dhaleswari-Padma Doāb (*i.e.*, the land between those rivers) and the estuarine islands of varying sizes that are found from the Pusur River in Khulna district in the west to the island of Sandwīp in Chittagong district in the east.

The Chittagong region. Lying to the south of the



BANGLADESH

Feni River, the Chittagong region is full of hills, hillocks, valleys, and forests and is quite different in aspect from other parts of Bangladesh. The coastal plain is partly sandy and partly composed of saline clay; it extends from the Feni River to Cox's Bāzār and varies in width from one to 10 miles. In the south, the plain is narrowed by the Jaldi and Khurushkul hills. The region has a number of offshore islands and one coral island, St. Martin's, off the coast of Burma.

Climate. Bangladesh has a typical monsoon climate characterized by rain-bearing winds, moderately warm temperatures, and high humidity. In general, maximum temperatures in the summer months, from April to September, range between 91° and 96° F (33° and 36° C). April is the warmest month in most parts. January is the coldest month in the winter season, which lasts from about November to March.

The conditions of lowest atmospheric pressure occur all over Bangladesh in June and July, the storm season. Winds are mostly from the north and northeast in winter, blowing gently at a rate of one to two miles per hour in northern and central areas and two to four miles per hour near the coast. During the period of the nor'westers (March to May), wind speeds may rise to 30 or 40 miles per hour.

Rainfall

Bangladesh receives heavy rainfall; except for some parts in the west, it generally exceeds 60 inches (1,500 millimetres) annually. Large areas of the south, southeast, north, and northeast receive from 80 to 100 inches (2,500 millimetres), and the northern and northwestern areas of Sylhet district receive from 150 to 200 inches. The maximum rainfall occurs during the monsoon period, from June to September or early October.

In the early summer (April and May) and late in the monsoon season (September to November), storms of very high intensity often occur; they may create winds with speeds of more than 100 miles (160 kilometres) per hour, piling up the waters of the Bay of Bengal to crests as high as 20 feet (six metres) that crash with tremendous force onto the coastal areas and the offshore islands, inundating them and causing heavy losses of life and property. One such cyclone and tidal wave that battered the coastal areas in November 1970 killed at least 250,000 people and rendered millions destitute.

Vegetation and animal life. *Vegetation.* About 16 percent of the land surface is covered with forests. Most of them are situated in the districts of Chittagong, Chittagong Hill Tracts, Sylhet, and Khulna, but there are also forests in the districts of Dacca and Mymensingh. Bangladesh in general possesses a luxuriant vegetation, with villages appearing to be virtually buried in groves of mango, jackfruit, bamboo, betel nut, and date palm.

Bangladesh has four different areas of vegetation. The northeastern zone, consisting of parts of Sylhet and Chittagong districts, has many low hills covered with jungles of bamboo and rattan (a species of climbing palm). The commonest plant is a large kind of bamboo that is the basis of the country's paper industry. The central zone, covering parts of Dacca and Mymensingh districts, contains a large number of lakes and swampy vegetation. The soil of part of this zone is laterite, which produces the Madhupur jungles. The area lying to the northwest of the Brahmaputra and to the southwest of the Padma forms a flat plain, the vegetation of which consists mostly of cultivated plants and orchards. Babul (*Acacia arabica*) is the most conspicuous plant. The southern zone, comprising the districts of Khulna and Barisāl, contains the Sundarbans, with their distinctive mangrove vegetation. Many commercially valuable trees, such as the *sundri*, after which the Sundarbans are named (*Heritiera fomes* or *minor*); *gewa*, or *gengwa* (*Excoecaria agallocha*), a softwood tree used for making newsprint; and *goran* (*Ceriops roxburghiana*), a kind of mangrove, grow in this vast forest.

Among the common flowers are marigolds, Bengal roses, water lilies, gandharaj (a tuberose), bokul (*Mimusops elengi*) and kamini (orange jasmine).

Animal life. Bangladesh is said to have about 200 species of mammals, 750 of birds, 150 of reptiles, and about 200 species of marine and freshwater fishes. Elephants are found in the Chittagong Hill Tracts living in herds ranging from less than a dozen to about 100. They are the so-called Indian elephants that can be captured and trained. Buffalo, both wild and domesticated, are also found. The domesticated, or water, buffalo are used for plowing and pulling carts. Of the different kinds of deer, the barking deer, the barosinga, or 12-horned deer, and the sambar deer, with its maned neck, are well-known. The barosinga, which reach a height of about four feet at the shoulders, mostly inhabit the Sundarbans. The sambar, which lives in the eastern jungles of the province, attains a height of four and a half feet and a length of six to seven feet. By comparison with these, the spotted deer, the barking deer, and the hog deer are smaller.

The elephant herds of the Chittagong Hill Tracts

Of the carnivores, the Bengal tiger is the best known. The famous denizen of the Sundarbans measures nine to ten feet from head to tail and feeds mostly on small animals. The leopard, though smaller than the tiger, is more active and is capable of climbing trees. The clouded leopard, dark gray and with spots that are oval or oblong in form, is smaller than the leopard. The leopard cat, about the size of the domestic cat but with longer legs, is ferocious.

Of the three types of bear usually seen—the sloth bear, the Himalayan black bear, and the Malayan bear—the sloth bear is the most numerous. Usually black and about two and a half feet high at the shoulder, the sloth bear is nocturnal and feeds on fruits, insects, and honey from beehives. The Malayan bear is smaller in size. The jackal is a common animal; it feeds on carrion of all kinds and is adept at stealing lambs and poultry from homesteads. Its eerie howling at night is a familiar sound in Bangladesh. The mongoose, grayish brown and about two and a half feet long, including the tail, feeds on rats, mice, lizards, and insects and also kills snakes. The Bengal, or rhesus, monkey is the commonest of primates in the province.

The common house crow is found everywhere, and its shrill cries are detested by the people, who regard them as a bad omen. The bulbul is a beautiful, small, smokey-brown bird. The colour of the magpie robin is a mixture of black and white. A wide variety of warblers are found; some are migrants that appear only in winter. Several kinds of flycatchers also occur. There are also myna birds of several kinds. Other species include the common game birds, cuckoos, hawks, owls, kingfishers, hornbills, and woodpeckers, as well as vultures, which act as scavengers. Among the eagles, the crested serpent eagle and the ring-tailed fishing eagle are the most common. There are also hoopoes, herons, storks, ducks, and wild geese.

POPULATION

Ethnic composition and distribution. Ethnically, Bangladesh is a melting pot of races. The following groups are the most important:

The proto-Australoids, sometimes called Veddas, who were longheaded, flat nosed, and dark brown in complexion, were one of the earliest groups to enter the area. According to some ethnologists, they were followed by longheaded Mediterranean caucasoids (whites), also known as Aryans. Short-headed or broad-headed Armenoids (of Indo-European stock) are believed to have entered as well. It is presumed that the process known as Aryanization began in the first millennium before Christ.

With the coming of the Muslims in the 8th century AD, new elements were introduced. Persons of Arab, Persian, and Turkish origin moved in large numbers to the subcontinent and gradually at different times entered what is now Bangladesh. The contention that Bengali Muslims are all descended from lower caste Hindus who were converted to Islām is incorrect; a substantial proportion are the descendants of the Muslims who reached the subcontinent from elsewhere.

The peoples known as the Santāls and the Khāsis possibly belong to the proto-Australoid group—the former living in the Bārind area in the districts of Rājshāhi and Dināj̄pur and the latter in the Khāsi Hills near the border with Assam. The Mongoloid element is represented by the Gāro, Hajang, Kachari, and Tipera groups. The Gāros live in the Susang Hills region; the Hajang are a branch of the Gāros. The Kacharis live mainly in the district of Kachar in Assam (India), but some of them are found in the Sylhet district of Bangladesh. The Tiperas mostly live in the Chittagong Hill Tracts.

Apart from these tribes, the rest of the people are Bengalis—an ethnic as well as a linguistic group. The Bengalis, however, are not homogeneous in origin. Differences in head shapes and in skin colour are found among them. In general, the people of the coastal areas with whom the Muslim merchants of the Middle East were in close touch show physical features that seem to be the result of the admixture of local peoples with peoples of Turkish and Semitic origin.

The Bengalis

Linguistic pattern. Bengali, the language spoken in Bangladesh, belongs to the Indo-Aryan group of languages. Like Pāli and various other forms of Prākrit in ancient India, Bengali originated beyond the influence of the Brahmin society of the Aryans. The Pāla rulers of Bengal, who were Buddhists and whose religious language was Pāli, did not inhibit the emergence of a colloquial tongue; it was known as the Gaudiya Prākrit, the language from which Bengali is derived.

Bengali is spoken by about 98 percent of the people. The remainder, largely immigrants who came to Bangladesh, then East Pakistan, after 1947, generally speak Urdu. English is an important means of communication with West Pakistanis, who speak four other languages.

While literary Bengali is the same all over Bangladesh, there are slight dialectal differences from region to region. The dialects of the districts of Sylhet, Noākhāli, and Chittagong are the most markedly different. Bengali contains a large number of loanwords from Portuguese, English, Arabic, Persian, and Hindi. Words derived either directly or indirectly from Sanskrit, however, predominate in the literary idiom.

Religious affiliations. An overwhelming majority—more than 80 percent—of the population profess the religion of Islām. The advent of a handful of Muslims to Bengal at the beginning of the 13th century and the rapid expansion of their rule permanently changed the character and culture of the area. When the Muslims first arrived, the Hindus were in an overwhelming majority; there were also some Buddhists and a few animists. The Hindus remained in the majority throughout the Turko-Afghan and Mughal periods. Even as late as 1872 there were more than 18,000,000 Hindus in Bengal, compared to about 16,000,000 Muslims. From the 1890s onward, however, the balance began to tilt in favour of the Muslims, and they have since remained in the majority.

There are several reasons for the increase in the Muslim population. Perhaps the most significant was the activity of ascetic divines and Ṣūfī (mystics), who won converts among the lower castes of the Hindus. Second, there was an influx of Muslims from northern India as well as from outside India. Third, the Muslims had a higher birthrate than that of the Hindus, since, for religious reasons, Hindu widows were not allowed to remarry.

The majority of the Muslims belong to the Sunnī sect. There is, however, a small sprinkling of Shīʿite Muslims, mostly descendants of immigrants from Persia.

Hindus are divided into two broad groups—high-caste and low-caste. The high caste Hindus constitute almost 9 percent of the population and the low castes almost 10 percent. The Buddhists, numbering about 400,000, form less than 1 percent of the population. Of the tribes in the Chittagong Hill Tracts, the Chakma, Chak, Magh, and the Mru are mostly Buddhists. The Kumi and some of the Mru are animists. While most of the Bon, Kuki, and Lushais are Christians, the Tiperas are high-caste Hindus, and the majority of the Piangs are low-caste Hindus.

The pattern of rural and urban settlement. The economy is predominantly agrarian. At the time of the first census, in 1872, the population of the area now forming Bangladesh totalled about 22,000,000; it rose steadily to 35,000,000 in 1931, 50,000,000 in 1961, and more than 73,000,000 in 1971.

Urban settlement. Bangladesh is one of the least urbanized areas in South Asia. There are only three cities, although there are more than 80 towns of varying sizes. In 1951 the urban population numbered 1,800,000 —about 4 percent of the total population. By the early 1970s about 3,000,000 lived in cities—still only 4 percent of the total. Dacca, the capital, is the biggest city and in 1972 was estimated to have a population of about 960,000. Ten miles from Dacca is the town of Nārāyanganj, the centre of the jute industry. Dacca and Nārāyanganj are sometimes conjointly referred to as Greater Dacca City, with a combined population of nearly 1,400,000.

Major cities

Chittagong is the second most important city. Once a sleepy little river port, since 1947 it has been the most important port in the territory. In 1972 Chittagong's population was estimated at 488,000. A number of industrial areas, such as Kalurghat, Sholāshahar, and Faujdār Hat are developing around Chittagong.

Khulna, in the southwest, is becoming a commercial and industrial centre; the opening of the port of Chālna nearby and the growth of the Daulatpur industrial area have increased its population to more than 200,000 inhabitants.

The houses in the towns and cities are mainly of one or two stories. It is common for a new town to grow around an older, historical one, as at Dacca. Industrial development has prompted migration to the cities from the rural areas.

Rural settlement. The rural area throughout the province is so thickly populated that it is difficult to distinguish any well-defined pattern of settlement. There are, however, some noticeable features. The inundation of most of the fields during the rainy season makes it necessary to build homes on higher ground. Continuous strings of settlements along roads are very common in the districts of Kushtia, Jessore, and Faridpur, in parts of Khulna, Bakerganj, and Patuākhāli, and in the floodplains of the Mahānanda, Tīsta, Jamuna, Ganges, and Meghna rivers. Similar settlements are also to be found in the hilly regions of southern Sylhet and in the Chittagong region. Settlements are more scattered, however, in parts of Khulna, Bakerganj, and Patuākhāli districts, in the floodplains of the Brahmaputra, in eastern and southern Sylhet, in Comilla district, and in parts of Chittagong district. In the Haor Basin of Sylhet and in the Chittagong Hill Tracts, settlements occur in a nucleated, or clustered, pattern.

The villages are composed of thatched bamboo huts. There is an adequate water supply, and the buildings within the settlements are scattered.

THE ECONOMY

Agriculture. Bangladesh is overwhelmingly agricultural, with more than 80 percent of the population engaged in farming. Of Bangladesh's total land area of 36,000,000 acres (15,000,000 hectares), about 23,000,000 acres are cultivated. The soil is fertile and has been so for centuries. Travellers from the 7th century onward consistently testified to the richness of Bengal's soil and the abundance of its harvests. Jute and rice are the most important agricultural products. Before 1971, the territory produced about half the world's supply of jute. The total yield in an average year was more than 5,000,000 bales (of 400 pounds each); the total area devoted to jute cultivation was over 2,000,000 acres. The average yield is 1,000 pounds of jute per acre. Other important agricultural products are pulses (leguminous plants, such as peas, beans, and lentils), potatoes, oilseeds of various kinds, sugarcane, tobacco, and fruit.

Jute and rice production

Agriculture has in the past been wholly dependent upon the vagaries of the monsoon. A poor monsoon always meant poor harvests or none and the threat of famine. Among the remedial measures adopted in recent years have been the construction of a number of irrigation projects designed to control floods and to conserve rainwater for use in the dry months. The most important are the Karnaphuli Multipurpose Project, the Tīsta Barrage Project, and the Ganges–Kobadak Project. The first is in the Chittagong district in the southeast, the second is in the north, and the third will serve the districts of Kushtia, Jessore, and Khulna.

Fisheries. Bangladesh, a riverine area, has great possibilities in pisciculture (the breeding and raising of fish). Its rivers and seacoast offer opportunity for the operation of the usual type of fisheries. There are approximately 2,200,000 acres of inland fishery waters and 20,000,000 acres of marine fishery waters, mostly in the estuaries of the Bay of Bengal. It has been estimated that the annual yield from inland fisheries is around 240,000 tons and from marine fishing over 58,000 tons. Among the varieties of fish caught are the marine rupchanda, or pomfret, and the freshwater hilsa, a relative of the shad.

Industry. Excessive—until recently almost exclusive—dependence upon agriculture in an area in which during the monsoon period no work in the fields is possible has led to seasonal unemployment among peasants, as well as to a low standard of living. To counteract this imbalance, a policy of industrialization was adopted after 1947 and, until 1971, was pursued through the successive five-year plans. The main obstacle to its fulfillment has been the comparative lack of mineral resources.

Power resources. Oil in marketable quantities has not been struck anywhere in Bangladesh; vigorous prospecting has, however, been in progress. The consumption of petroleum products in the territory rose from 70,000 tons in 1948 to more than 1,000,000 tons in 1968. Bangladesh is also dependent upon imports for coal. Two coalfields have been discovered, one at Sylhet and the other at Bogra, but commercial exploitation has not yet begun.

Natural gas holds more promise. It has been found at Harīpur, Chhātak, Kailash-Tila, Rashīdpur, and Shahi Bāzār (all in the district of Sylhet), as well as at Brāhmanbāria and Bakherabad, in Comilla district. The Harīpur field is estimated to have a reserve of about 180,000,000,000 cubic feet, with gas of fairly good quality. The Harīpur field and the gas fields of Rashīdpur and Kailash-Tila supply the Fenchuganj Natural Gas Fertilizer Factory, which is also in Sylhet. The Titās field in Brāhman-

bāria began supplying gas to industrial consumers in Dacca and its suburbs in 1968.

The output of electricity

In 1947 the territory had an installed capacity of 21,000 kilowatts of electricity. This rose to 173,000 in 1960 and to about 535,000 in 1970. Thermal power stations have been built at Ghorāsāl, in Dacca district, and at Chittagong, producing, 110,000 kilowatts and 60,000 kilowatts, respectively; a few other similar projects have also been constructed. The annual per capita consumption of electricity was about 13 kilowatt-hours in 1970. A nuclear-power station is under consideration at Ruppur, in the district of Pābna.

Industrial development. Industrial policy after 1947 was to give priority to industries based on indigenous raw materials such as jute, cotton, hides, and skins. Up to 1971, the principle of free enterprise in the private sector was accepted, subject to certain conditions including the national ownership of public utilities. The policy also aimed to develop as quickly as possible consumer-goods industries with a view to avoiding dependence on imports. Attempts were also being made to establish heavy industries, such as steel.

To promote this policy, various institutions were established. Some of the important ones were the East Pakistan Industrial Development Corporation (EPIDC), the East Pakistan Small and Cottage Industries Corporation, the Industrial Development Bank of Pakistan, the Equity Participation Fund, and the Pakistan Industrial Credit and Investment Corporation.

The actual task of establishing industries rested on the EPIDC, which sponsored new industrial units producing jute textiles, paper and board, sugar, cotton textiles, nonmetallic mineral products, basic metals, chemicals and fertilizers, and fuels and minerals, as well as engineering and shipbuilding plants.

Manufacturing and other industries. Since the export of raw jute was not very remunerative, efforts were made to establish mills to produce and export jute products and thus earn foreign exchange. About 45 percent of the jute produced was processed in the territory; the balance was exported raw.

The abundance of bamboo in the Chittagong Hill Tracts and the various softwood trees growing in the Sundarbans provide excellent raw material for papermaking. There are paper mills at Chandraghona (Chittagong) and at Pāksey, in Pabna district, as well as a paper and board mill at Khulna.

Bangladesh has several fertilizer factories and one cement factory, which is located at Chhātak, in the district of Sylhet, and which, although it has a capacity of 250,000 tons, is quite unable to meet the growing demand for cement. A shipyard has been opened at Khulna for repairing and reconstructing ships. Two dry docks—one at Chittagong and one at Khulna—were under construction in 1970.

Cottage industries

By far the most important cottage industry centres on the production of yarn and textile fabrics. More than 300,000 people produce coarse and medium-quality fabrics. Another cottage industry produces cigarettes known as *bidis* and employs more than 20,000 workers. Carpets, ceramics, and cane furniture are also products of cottage industries. (S.S.H.)

ADMINISTRATION AND SOCIAL CONDITIONS

Administration. The administration of Bangladesh began in a *de facto* manner on December 16, 1971, after the surrender of the Pakistan army in Bangladesh. During much of 1972 the new administration had to cope with the confusion engendered by the 1971 civil war, which had resulted in the country's independence. Thus reliable statistics, as opposed to rapid assessments, were not available. The administrative structure, however, remained substantially the same in form as it had been before the civil war, although certain policies and many of the personnel were not the same.

The constituent assembly. In late 1972 the draft of the Bangladesh Constitution was completed for submission to the constituent assembly, a body comprised at that time of 403 members. The Assembly approved the draft, and it became effective on December 16, 1972, establishing a parliamentary form of government and dissolving the Assembly. Sheik Mujibur Rahman, leader of the Awami League political party, which had won a landslide victory in the 1970 elections, formed a Bangladesh government. His cabinet was composed primarily of persons who before independence had been members of the government-in-exile, and he administered the affairs of state through the office of the presidency by means of presidential ordinances and orders. The Cabinet under the new constitution was to consist of members of the Parliament to be elected in March 1973. In 1972 the president was the titular head of the People's Republic of Bangladesh, and he acted upon the advice of the prime minister.

Post-war problems. The new administration faced a formidable combination of social, economic, and sometimes political problems arising out of the 10-month civil war. The restoration of law and order, for example, posed a major problem; weapons had to be recalled from youths who had joined the liberation forces; citizens accused of "war crimes" had to be arrested and detained in an orderly fashion; members of communities of non-Bengali origin (Biharis) were frequently open to charges of "collaboration"; and the army and police forces required major reorganization. The administrative tasks arising from these circumstances were made more difficult by the shocked and emotional state in which the people emerged from a civil war that had produced many inhuman acts, including systematic terrorization and massacres of civilians.

The refugee problem

Approximately 8,000,000 to 10,000,000 refugees, most of whom were Hindus, had fled across the border to India; substantial numbers of Muslims, including students, Awami League supporters, and others, were, however, also among them. The number of those who were displaced from their homes but remained within the territory that is now Bangladesh could not be reliably assessed; figures of between 10,000,000 and 20,000,000 were frequently assumed. The refugees returned in early 1972, but their physical and financial resources were at a low ebb, and many of them returned to derelict farms or businesses, and to ruined houses.

The difficulties of administering adequate supplies of relief and rehabilitation materials, and of providing necessary services, were compounded by the destruction of road and rail communications (particularly bridges), the obstruction of major ports and channels by sunken vessels, and by increases in the price of essential items on the open market at a time when employment opportunities were scarce, and when smuggling and hoarding were financially profitable. The normal fixed-price ration shop distribution system was unable to meet the acute demand for some time, although the United Nations Relief Operation in Dacca gave technical assistance, particularly with transport facilities. The quantities of foodstuffs that had to be imported was variously estimated at between two and three or more million tons up to the end of 1972. (The lower figure also represented the territory's normal shortfall in food production.) The United Nation's Children's Fund (UNICEF) sponsored a nationwide child feeding program to combat malnutrition. Wherever possible the Bangladesh government pursued a policy of "Test Relief," using imported, donated, or locally acquired foodstuffs as payment in kind to needy persons for manual work on public projects. Although the incidence of malnutrition inevitably increased in the worst-affected communities, widespread famine did not prevail.

The civil service. The civil service was modelled upon the pre-1947 Indian Civil Service, whose members were at the apex of the administration. Civil servants were appointed by the Civil Service Commission, and selection was made by competitive examinations. The administrative structure had two broad categories—the Secretariat, and the "field officers." The former was the administrative policy-making body, while the latter was organized into a pyramidical hierarchy with a well-defined chain of command. During the civil strife, many depart-

ments functioned in only a token manner, and were often completely dependent upon military exigencies. At the conclusion of the civil war, the civil service continued as a national institution of substantially the same character as it had been previously. The four area divisions, previously subdivided into 19 districts and 62 subdivisions, in 1972 were reorganized as 62 new district units, thus promoting the decentralization of administrative authority. At a lower level, however, the former administrative structure of "circles" (*thanas*), each having a population of between 100,000 and 200,000, was continued. Each unit was headed by a "circle officer" responsible for revenue collection and for certain developmental functions. In each of these units there were also police officers, serving side by side with the civil servants responsible for administration.

The autonomous corporations. Under the Pakistani administration, new types of autonomous corporations were developed over the years to deal with industrial development, water and sewerage management, the development of forest industries, and road transportation. The Bangladesh government in 1972 nationalized these corporations, and then established 12 new corporations to manage the nationalized enterprises. At the same time, the government revealed its intention of having these corporations managed by personnel with professional and commercial experience, rather than relying on civil servants, as had formerly been the practice.

Justice. Bangladesh has continued with substantially the same judicial system as had been in operation when the territory was a province of Pakistan, and which owed its origins to the system in operation under the British Raj before 1947. The Supreme Court of Pakistan had previously existed at the apex of the system as the final court of appeal for three types of jurisdiction: original, appellate, and advisory. High Court judges were appointed by the President of Pakistan, and could not be removed except on charges of misconduct. Although the judiciary was comparatively free, the separation of judicial and executive powers was not fully achieved, and officials from one power had at times been appointed to the other. After the civil war, the Bangladesh Supreme Court became the highest court in the land. The 1972 constitution divided the Supreme Court into Appellate and High Court divisions and envisaged a complete separation of the judiciary and executive branches.

In rural areas, district courts were situated in town centres, where district judges tried both civil and criminal cases. The district magistrates were of different classes, corresponding to the seriousness of the cases that they were allowed to hear, and to the limits of punishment that they could impose.

In general, the concept of justice suffered greatly during the civil war; the Pakistan army considered that the continued unity of the country as an Islamic state was the paramount consideration. The military were assisted by ad hoc "peace committees" which were established in most localities, purportedly to help restore normalcy and actively to cooperate with military administrators and commanders in the field operating against the Mukti Bahini (nationalist guerrillas) and their sympathizers. Many of those who cooperated with the military were later arrested, and shared the blame for the tragic excesses of killing and destruction that took place. The trials of "war criminals" and "collaborators" was a major issue in the earlier period of Bangladesh politics. A tribunal of the type employed at the Allied War Crimes trials at Nürnberg after World War II was mooted, especially for those Pakistani officers who were captured.

The "peace committees"

Local government. Although the tradition of local self-government through *panchayats* (councils of village elders) throughout the subcontinent goes far back into history, it was only in 1880 that, under British administration, the system was organized along modern lines. After 1947, under the initial Pakistan administration, the functions of local self-government that were obligatory covered such public services as primary education, local road construction and maintenance, sanitation, drainage, water supply, lighting, slaughterhouses, markets, and local health services, as well as the power to hear petty criminal and civil cases. These functions were administered under a Department of Local Self-Government through district boards or municipalities, and with "union councils" as the lowest unit in the administrative hierarchy. In 1958, after the introduction of martial law, a system known as "Basic Democracy" was substituted; this partly reflected a gradualist approach to democracy, and also promoted community development and change through greater citizen participation. Each "Basic Democrat" was elected by a population of between 1,000 and 1,500 (roughly one village), and ten such representatives, together with an additional five who were nominated to serve, made up one "union council." These councils had municipal, judicial, and community organization functions. At the next level in the hierarchy were the "*thana* councils," which were primarily concerned with developmental activities within their respective areas. Half of the *thana* council members were chosen by indirect elections conducted in the union councils, while the other half were *ex-officio* government servants. While the system of unions and *thanas* that Bangladesh has inherited has remained, the political concept of "Basic Democracy," and the councils as such, have been abolished.

"Basic Democracy"

Social conditions. *Education.* The foundation of the educational system was laid down during the period of British rule; the system has three tiers—the primary, secondary, higher educational levels. Primary education, which was not compulsory, was for children up to about ten years old. Fewer than half of the children of primary school age attended; although tuition was free, books were not. (In 1972 it was the intention of the Bangladesh government to issue free books up to a certain level.) Secondary education was subdivided into three levels—junior secondary, high school, and higher secondary (intermediate college)—with public examinations being held at the conclusion of each level of schooling. Both primary and secondary schools varied greatly in quality in different areas; those in cities and towns were generally better staffed and financed than those in rural areas, where the quality of teaching left much to be desired.

Higher education was in two stages—college and university. There were some 250 colleges, most of them affiliated with one of three universities—the University of Dacca, the University of Rājshāhi, and the University of Chittagong. Apart from these universities, there was an agricultural university at Mymensingh, a rural academy at Comilla, and a university of engineering and technology at Dacca. There were also more than 20 technical schools, which trained high school graduates.

From 1963 onward, intensive efforts were made to promote literacy. In 1972 the literacy rate among the general population was approximately 20 percent.

The educational system was greatly disrupted by the civil war; schools and colleges ceased to function, there was a massacre of the staff and students at Dacca University, and Bengali intellectuals were generally considered a target group. In its first budget (1972–73), the Bangladesh government allocated 20 percent of budget revenue to education. Bengali, and occasionally English, are the languages of instruction; Urdu has lost the prominence it formerly enjoyed under Pakistani administration. The policies of secularism and Bengali nationalism were expected, in the early 1970s, to be reflected in changes of emphasis and curricula.

Health. The aims of the health services under the Pakistani administration were: the provision of essential health services for all, the intensification of the fight against such diseases as malaria and tuberculosis, and the improvement of sanitation and nutritional standards. There were about 8,000 doctors of all categories in the territory—a ratio of about one doctor for every 8,500 people. There was also a shortage of trained nurses. Rural health centres were established, but there was a reluctance on the part of some doctors to go to remote rural areas. Malaria constitutes the most serious threat to health. Before the civil war, tuberculosis affected about 4 percent of the population; subsequent privations, however, are known to have raised the incidence of this

Prevalent diseases

disease. There have also been periodic outbreaks of cholera, which can assume plague proportions after natural disasters, such as the cyclone and tidal wave that occurred in 1970. Both smallpox and cholera were spread in Bangladesh in 1972 by refugees returning from exile, where they had been obliged to live in squalid camp conditions. A cholera research laboratory in Dacca, however, has evolved an effective approach, which is both suitable and inexpensive, to treatment of this disease. In the early 1970s it was estimated that there were more than 65,000 cases of leprosy in the territory; measures for leprosy control, including the establishment of clinics, were undertaken.

Welfare. Under the Pakistani administration, most social services were provided by private agencies. Public projects included community development projects, schools for handicapped children, youth centres, orphanages, training institutes for social workers, and other units. In 1972 the government of Bangladesh welcomed voluntary agency assistance in its task of relief and rehabilitation after the successive disasters of the 1970 cyclone, the 1971 civil war, and the floods that occurred in 1972; more than 50 international agencies had responded to this appeal by 1972. (A.C.Cl.)

CULTURAL LIFE

Music. There are four main types of music in Bangladesh—classical, light-classical, devotional, and popular. Classical music has many forms, of which *dhrupad*—Hindustani devotional songs—and *khayal*—a blending of the Perso-Arab and Indian musical systems—are the best known. The *thumri* and *tappa* forms belong to the light-classical variety. Devotional music also is represented by *qawwāli* and *kīrtan*. These forms are part of the common musical heritage of the subcontinent. It is, however, in the field of popular music that the territory can best claim originality. The forms known as *bhatiali, bhawaiya, jari, sari, marfati,* and *baul* have no exact equivalents outside the country. While they may appear to lack the sophistication and artistry of the classical forms, they are characterized by a spontaneity and vigour wholly missing in classical music. They combine, in some respects, the vigour of jazz, the pathos of Negro spirituals, and the unpredictability of pop.

Music in Bengal made great advances during the period of the independent rulers. Sultan Ghiyās ud-Dīn A'zam Shāh (who ruled in the late 14th and early 15th centuries) was a great patron of music, as was 'Alā'-ud-Dīn Ḥusayn Shāh who ruled from 1493 to 1518. During the Mughal period, regular and constant cultural contact was maintained between northern India, the seat of classical music, and Bengal. Noted musicians accompanied the Mughal viceroys to Bengal, and classical music flourished in the region through the centuries; the *rāga-pradhan* Bengali music of modern times is an important form of classical music.

Between the rigid and formal classical music and free modern songs are found the songs called *rabindra sangeet.* They represent an experiment in mixed beats. Another significant form of modern Bengali music is the *nazrul geeti.*

Dance. Apart from such classical dances as *kathākali* and *bhārata-nāṭya*—forms that are popular all over the subcontinent—the territory has evolved highly original indigenous dances. The best known are the *dhali, baul, manipuri,* and snake dances. Each form expresses a particular aspect of tribal or communal life and is danced on particular occasions. In popular music and dancing alike, improvisation has been traditional. With the increasing commercialization of the arts, however, improvisation has been on the wane, and stereotypes have become the order of the day.

Painting. Painting in the territory is a recently introduced art form. The main figure behind the art movement was Zainul Abedin, whose sketches of the Bengal famine of 1943 first attracted attention. He was able, after 1947, to gather around him a school of artists who have experimented with various forms, both orthodox and original.

The media. *The press.* There are several daily newspapers published in Dacca and Chittagong in Bengali and English. There are also numerous Bengali and English weeklies, biweeklies, and periodicals.

Radio and television. Broadcasts are made from Dacca, Rājshāhi, Chittagong, Khulna, Sylhet, and Rangpur. Programs are presented in more than 20 languages, including English, Urdu, and Bengali. Limited television service is broadcast from Dacca.

BIBLIOGRAPHY. Comprehensive studies of the history, geography, economy, and culture of the territory are not readily available. NAFIS AHMAD, *An Economic Geography of East Pakistan,* 2nd ed. (1968), is one of the few broad surveys of the country's economic resources in relation to its geography. K. AHMED, *Agriculture in East Pakistan* (1965); and MOHAMMAD AFSARUDDIN, *Rural Life in East Pakistan* (1964), provide useful information. Demographic and agricultural statistics are available from government publications such as *East Pakistan on the March* (1963) and *Abstracts of Agricultural Statistics of East Pakistan* (annual). The history of industrialization is traced in *Some Aspects of Rural Capital Formation in East Pakistan: A Systematic Regional Geography and Its Deade of Industrial Progress* (1968), a government of Pakistan publication; and *Planning in Pakistan: A Review by a Panel of Economists* (1968). For further study, see HAROUN ER-RASHID, *East Pakistan: A Systematic Regional Geography and Its Development Planning Aspects* (1965); WARREN C. ROBINSON, *Studies in the Demography of Pakistan* (1967); and SUBHASH C. KASHYAP *et al.* (eds.), *Bangla Desh* (1971). M. RASHIDUZZAMAN in his *Pakistan: A Study of Government and Politics* (1967), analyzes current political problems. KAMRUDDIN AHMAD, *The Social History of East Pakistan* (1967), presents a historical survey of the growth and development of the area. *Folk Tales of East Pakistan* by JASIMUDDIN (1953), is a translation of some of the best known popular stories of Bangladesh. S. SAJJAD HUSAIN, *Contemporary Writing in East Pakistan* (1958), provides detailed information on modern writing in Bengali.

(S.S.H.)

Bankruptcy, Laws Concerning

Bankruptcy legislation is designed to provide an orderly and equitable liquidation of the estate of an insolvent debtor. This has always been the principal purpose of the institution of bankruptcy. Because in earlier times it was frequently coupled with the imposition of penalties and loss of civil rights upon fraudulent debtors, the designation bankrupt came to be associated with dishonesty. Eventually, however, bankruptcy legislation was extended to a broader scope to permit the rehabilitation of embarrassed estates and to provide judicial proceedings for the adjustment of debts so as to avoid bankruptcy. Modern bankruptcy laws, therefore, include various types of arrangement and reorganization proceedings to prevent the liquidation of estates that have run into financial difficulties.

In addition, bankruptcy laws of England, the United States, and some British Commonwealth countries came to include provisions for the discharge of the unpaid portion of debts incurred prior to bankruptcy in order to give honest but unfortunate debtors a new start in life. The bankruptcy laws of the European continent and of most of Latin America, by contrast, do not have such provisions. The staggering number of bankruptcies in the United States may be explained by those provisions for the discharge of hopeless debts, coupled with the possibility of voluntary proceedings by nonmerchants. Thus, the number of proceedings under the Bankruptcy Act of the United States commenced during the fiscal year of 1969 totalled 184,470. This figure included 154,054 voluntary petitions in straight bankruptcy, of which 140,530 were consumer cases filed for the purpose of obtaining a discharge, while the remaining 13,524 cases were voluntary business bankruptcy proceedings.

Since bankruptcy laws aim at the liquidation or rehabilitation of insolvent estates, bankruptcy proceedings involve all nonexempt assets of the debtor; all creditors entitled to share in the proceeds of liquidation of the estate are called upon to participate. Hence bankruptcy proceedings are general or universal collection procedures, as distinguished from individual collection remedies

available to particular creditors for the enforcement of their claims.

HISTORY OF BANKRUPTCY LAW

Early developments

Modern bankruptcy law has been formed from a number of distinct historical strands. In ancient Roman law, an unpaid judgment creditor could have his debtor's estate sequestered (*missio in bona*) and sold for the benefit of all creditors (*venditio bonorum*). Proceedings of this type caused loss of civil rights. To alleviate this hardship a debtor was given the privilege of relinquishing voluntarily his assets to his creditors by petitioning a magistrate (*cessio bonorum*).

During the Middle Ages both institutions underwent a revival and development. The Italian medieval cities enacted statutes dealing with the assets of debtors, especially merchants, who had absconded or fraudulently caused insolvency. Such "bankrupts" (*rumpentes et falliti*) were subjected to severe penalties, and their estates were liquidated. In addition, medieval Spanish law restored the judicial *cessio bonorum*. The famous Siete Partidas, a codification published by authority of Don Alfonso X the Wise, king of Castile and León, during the second half of the 13th century, contained detailed provisions relating to insolvent debtors, applicable to merchants and nonmerchants alike, enabling them to secure a voluntary liquidation of their assets under judicial supervision. An unpaid creditor could insist on either payment or assignment by the debtor of his estate to all creditors.

Laws dealing with the property of absconding and fraudulent debtors, modelled after the statutes of the medieval Italian cities, spread throughout western Europe. Provisions of this type were adopted in the commercial centres of France, Brabant, and Flanders during the 15th and 16th centuries.

The customs of Antwerp, printed in 1582, contained comprehensive rules on the treatment of bankrupts and their estates. The emperor Charles V, as count of Flanders, inserted stringent provisions for the repression of bankruptcies in his Decree for the Administration of Justice and Good Order of 1531. There can be no doubt that the first English "acte againste suche persones as doo make Bankrupte" passed in 1542/43 was inspired by the northern European models, as the very title reproduces the Flemish expression. It governed proceedings instituted against absconding or concealed debtors. It was superseded by a more detailed act of 1571 that applied only to merchants and other traders. Voluntary proceedings were not provided in England until 1844 and not in the United States until 1841.

In France, national rules on insolvency and bankruptcy were inserted into the celebrated Ordonnance du Commerce of 1673. It regulated both voluntary assignments for the benefit of creditors made by merchants (Title X) and the proceedings and effects flowing from bankruptcy (Title XI). It was interpreted to restrict bankruptcy proceedings to merchants only, and the laws of many other countries followed the French lead. Thus in Spain the limitation of bankruptcy to merchants was adopted by the famous Ordinances of Bilbao, which were sanctioned in 1737 and subsequently applied in Latin America, especially Argentina.

The restriction of bankruptcy legislation to persons engaged in commerce created a need for liquidation proceedings applicable to other debtors. As mentioned before, the Siete Partidas contained provisions for voluntary liquidation proceedings applicable to all classes of debtors. On that basis a Spanish jurist of the 17th century, Salgado de Somoza, elaborated detailed rules for the initiation and conduct of voluntary judicial liquidation proceedings, which were styles concourse of creditors. His tract, entitled *Labyrinthus Creditorum*, influenced the course of Spanish law and also had great impact on the common law of Germany. As a result, Spanish law developed two classes of liquidation proceedings, one for merchants and one for nonmerchants. A similar approach was adopted in Portugal, Argentina, and Brazil. Other countries, including Germany, Austria, the United States, and England, brought nonmerchants under their bankruptcy laws. France and Italy, however, as well as some Latin American countries, still do not provide true insolvency procedures for ordinary debtors.

Consequences of bankruptcy

The dire consequences of bankruptcy for the debtor, such as the loss and liquidation of his assets, criminal penalties, and loss of civil rights, resulted in the need for procedures avoiding such sanctions. A remedy was found in the right of a deserving debtor to reach an agreement for an extension or reduction of his debts with a majority of his creditors that was binding on dissenters. The cradle of this institution was again the statutes of the medieval cities. Provisions to that effect were also contained in the Siete Partidas mentioned before. In England, similar procedures were developed by the Privy Council through bills of conformity, but this practice ended with the abolition of the council's civil jurisdiction in 1641. In France the Ordonnance du Commerce of 1673 recognized majority compositions as a legitimate means of handling the estates of insolvents without liquidation. The Commercial Code of 1807, however, and following it the laws of other countries, restricted them to a method of terminating rather than preventing bankruptcy proceedings. Preventive compositions were resumed as legitimate means of dealing with embarrassed or insolvent estates only during the second part of the 19th century; they are now recognized in most countries as important devices for economic rehabilitation.

At one time all bankrupts were considered defrauders and criminals. They were subjected to severe social and professional sanctions, including even a degrading form of dress. In recent times, however, great efforts have been made to remove the disgrace attached to bankruptcy. Even the terms bankrupt and bankruptcy (or their equivalents in other languages) are used less and less frequently in the statutory language. Modern French legislation, for example, totally suppresses the traditional term *faillite* as the name of liquidation proceedings and restricts it to special procedures entailing the loss of civil rights by insolvents guilty of commercial misconduct.

LIQUIDATION OF INSOLVENT ESTATES

Most nations with private enterprise economies possess legislation providing for the liquidation of hopelessly insolvent estates. The socialist countries, with the exception of Yugoslavia, handle financial difficulties of their economic organizations in a different manner, aiming at rehabilitation rather than elimination. Liquidation proceedings are often referred to as "straight" bankruptcy, to distinguish them from arrangements and other rehabilitation proceedings.

The existing bankruptcy laws of the major commercial nations are of diverse vintages. The following list gives the dates of some currently operating bankruptcy laws, disregarding subsequent amendments but including the dates of the codes of civil procedure in nations such as Portugal and Spain in which the governing procedural rules are contained in these codes: Germany 1877, Spain 1881, Switzerland 1889, Austria 1914, England 1914, India 1920, Sweden 1921, Japan 1922 and 1952, Chile 1931, Peru 1932, Argentina 1933, United States 1938, Italy 1942, Mexico 1942, Brazil 1945, Canada 1949, Portugal 1961, Australia 1966, France 1967, New Zealand 1967, Colombia 1969. Some of these laws, especially those of the United States, Canada, and Mexico, were undergoing revision at the beginning of the 1970s.

Although liquidation laws differ greatly in policies and details, they all deal with six well-defined major problems: the persons subject to judicial liquidation of their estates; the persons entitled to initiate judicial liquidation proceedings and the prerequisites of an order for liquidation; the assets encompassed in liquidation proceedings and the effect of such proceedings upon prior dispositions by the bankrupt; the creditors entitled to share in distribution and the priorities among them; the role of the court, the administrator, and the creditors in the conduct of the proceedings; and the effect of liquidation on unpaid or partially unpaid debts.

Persons subject to estate liquidation. Bankruptcy or insolvency laws vary considerably in their applicability to

Differences in coverage of laws

particular classes of persons. The German act and, following its example, the Austrian and Japanese acts extend bankruptcy proceedings to all natural and juristic persons, whether or not they are engaged in commerce and without differentiating between petitions by the bankrupt himself or by creditors. In the United States and Canada the bankruptcy acts likewise have a very broad sweep. In the United States, individuals, whether merchants or nonmerchants, as well as private corporations, with the exception of certain financial institutions, are subject to the Bankruptcy Act. Involuntary petitions, however, cannot be filed against low-income wage earners, farmers, and nonprofit corporations. Canada likewise applies its act to individuals and corporations. It excludes, however, not only certain financial institutions but, in addition, nonbusiness corporations in general. In England the Bankruptcy Act covers only individuals, whether merchants or not. Registered companies are liquidated under the winding-up provisions of the Company Law. A great number of the provisions of the Bankruptcy Act, however, are made applicable in such proceedings. The same system governs in Australia, New Zealand, and India. A number of nations, following the model of the French law of 1838, extend their bankruptcy laws only to persons qualifying as merchants or engaging in trade but do not differentiate between individuals and corporations. To that class belong the bankruptcy laws of Italy (with the exception of small enterprises), Spain, Portugal, Switzerland, and a number of Latin American countries, including Argentina, Brazil, Colombia, Mexico, and Venezuela. Chile and Peru, however, chose to follow the German pattern and subjected to their bankruptcy laws all individuals and corporations, whether merchants or not. A number of the countries that restrict bankruptcy to merchants have, however, inserted provisions for insolvency proceedings governing nonmerchants in their Codes of Civil Procedure. France extends its new insolvency law to merchants and all juristic persons even if not merchants.

Persons entitled to initiate liquidation. Modern bankruptcy laws provide for the initiation of liquidation proceedings upon petition by either the bankrupt himself or his creditors. There are differences as to the number of creditors who must join in a creditor's petition. A great number of laws are satisfied with a petition by a single creditor regardless of the amount of his claim, the total number of creditors, or the amount of the outstanding indebtedness, so long as the debtor is unable to meet his current payments or has committed a so-called act of bankruptcy. Petition by a single creditor suffices according to the law of Germany and, following it, of Japan; the laws of Austria, France, Italy, Portugal, Spain and Switzerland; and the laws of such Latin American countries as Argentina, Brazil, Chile, and Mexico. In Austria at least one other creditor must exist, although he need not join in the petition; but the sufficiency of one unpaid creditor is provided expressly in the Chilean and Mexican acts.

A somewhat different regime exists in the common-law countries. In England, Canada, Australia, and New Zealand, as well as India, a single creditor may be a petitioner if the unsecured part of his claim equals or exceeds a specified amount. Otherwise, other creditors must join until the aggregate amount of their claim equals the requisite sum. In the United States in 1971, the total indebtedness of the bankrupt had to be at least $1,000, and a petition by three or more creditors with unsecured claims aggregating at least $500 was required if the total number of creditors was 12 or more; otherwise one or two creditors with claims totalling at least that amount might be petitioners.

In some countries the initiation of liquidation may also be decreed by the court ex officio or upon petition by public officials. Ex officio action by the court is provided, for example, in Italy and France. Italy, Portugal, and Mexico authorize public officials to file petitions for the liquidation of bankrupt estates. In a number of countries, following in that respect the traditional French approach, a bankrupt debtor is under a duty to file a petition, and his initiation is not left to his own judgment as in the common law countries.

Prerequisites of involuntary liquidation

Legal systems differ widely as to the substantive conditions that must be met in order to justify a decree for compulsory adjudication. In England, the United States, Canada, Australia, New Zealand, and India, a creditor's petition requires that the debtor have committed an "act of bankruptcy" or an "act of insolvency" within a specified period prior to the petition. The acts of bankruptcy are specifically defined in the applicable bankruptcy laws, their definitions and numbers varying from country to country. They include public manifestations of insolvency as well as certain conduct that endangers the collection of debts by ordinary means or entails preferential treatment of certain creditors. The laws of Germany and Italy, as well as the legislation of other countries influenced by them such as Austria and Japan, do not include a special catalog of acts of bankruptcy but condition bankruptcy upon inability of the debtor to meet his obligations or upon his state of insolvency. Cessation of payment is deemed to be an important manifestation of this condition. In France and Argentina a cessation of payments is made the grounds for the decree of liquidation, and not only an appropriate manifestation of insolvency. A number of countries have mixed systems. Liquidation is decreed if the creditor proves that the debtor has either proceeded to a cessation of payments or has committed other specified acts of bankruptcy. Systems of this type exist in Portugal, Spain, Switzerland, Brazil, and Chile. Mexico lists a number of acts that result in a rebuttable presumption of a cessation of payments. In Chile cessation in the payment of one commercial obligation justifies adjudication.

Postadjudication and preadjudication dispositions

Assets subject to distribution. One of the most important aspects of bankruptcy legislation is the determination of the assets to be seized and sold for the purpose of distributing the proceeds among the creditors as so-called dividends. Various legal systems have vastly different approaches. The disparities relate mainly to the status of assets acquired by the bankrupt subsequent to his adjudication or conveyed away by him prior to that date.

In Germany all nonexempt assets belonging to the bankrupt at the date of the adjudication form the bankrupt estate. Assets that are no longer owned by the bankrupt at the time of the adjudication are not included in the bankrupt estate unless their alienation is voidable under special rules permitting the avoidance of fraudulent or preferential transactions. The Bankruptcy Law of the United States follows a similar approach, except that the "date of cleavage" is not the date of the adjudication but is the date of the filing of the petition. Postpetition acquisitions are part of the bankrupt estate under the U.S. law only if they constitute narrowly defined "windfalls," such as inheritances or bequests vesting in the bankrupt within six months from the filing date. On the other hand, many other bankruptcy laws include within the estate subject to distribution all nonexempt assets acquired after the adjudication and during the period of the proceedings. The English Bankruptcy Act declares expressly,

> The property of the bankrupt divisible amongst his creditors . . . shall comprise . . . all such property as may belong to or be vested in the bankrupt at the commencement of the bankruptcy, or may be acquired by or devolve on him before his discharge.

Hence the bankrupt estate is formed by assets owned by the bankrupt when he commited an act of bankruptcy within the three months preceding the filing of the petition, or vesting in him after that time until his discharge. Similar rules apply in other Commonwealth countries, such as Australia, New Zealand, and Canada. In Canada, however, the so-called relation-back doctrine has been restricted and the date of cleavage is not that of the commission of the relevant act of bankruptcy but that of the filing of the involuntary or voluntary petition.

In many civil-law countries the bankrupt estate likewise includes property acquired during the course of the proceedings. Rules to this effect govern in Austria, Switzerland, France, Italy, Portugal, Spain, Argentina, and Bra-

zil. Chile, however, restricts the inclusion in the bankrupt estate of after-acquired assets to those acquired by gift, bequest, or inheritance and leaves assets purchased by the bankrupt to his own disposition.

The bankruptcy acts of England, the United States, and the Commonwealth countries vest the title to the assets forming the bankrupt estate in a trustee or assignee in bankruptcy. The bankruptcy laws of most of the other countries, however, leave the title in the bankrupt and transfer only the power of administration and disposition to a third party; as a result, the relation-back doctrine of the common-law countries, which dates the vesting of the title of the assignee to a date of cleavage prior to the adjudication, is inapposite in the countries whose bankruptcy laws do not affect the title. In some of these countries, however, parallel doctrines have been developed. The model for that approach has been the French commercial code of 1807. It required the decree of adjudication to fix the date of the cessation of payments and provided that transactions by the bankrupt after that date and before the adjudication (called the critical or suspect period) were ineffective against the estate. In 1838 France relinquished the general relation-back theory and replaced it with a catalog of different transactions, mostly various kinds of preferential transfers, that are rendered ineffective against the estate if made during the critical period. In 1967 that period was limited to a maximum of 18 months prior to the adjudication. In the early 1970s Spain seemed to be the only civil-law country that still provided for a general avoidance of acts of the bankrupt from the cessation of payments until the adjudication.

Preferential transfers

One of the cardinal principles governing the liquidation of insolvent estates is the equal treatment of creditors—the classical *par conditio creditorum*. Debtors on the eve of bankruptcy, either on their own volition or under pressure, may accord preferential treatment to certain creditors. The bankruptcy laws of all countries, therefore, contain special rules aiming at the reintegration of the insolvent estate through the avoidance of such preferences given after insolvency or cessation of payments or even earlier. These provisions are either in addition to or in lieu of a general relation-back of the date of the loss of title or power of disposition produced by the adjudication. Again, the laws of the different nations vary greatly with respect to the elements that must be present to make a transfer voidable as a preference. In the United States a transfer of property to a creditor is voidable by the trustee as a preference if it was made on account of a pre-existing debt and perfected within four months preceding the petition at a time when the bankrupt was insolvent and if, in addition, the recipient knew or should have known of the insolvency. In England a preference given by an insolvent to a creditor is subject to avoidance if it was made within six months prior to the filing of the bankruptcy petition and if it was made with a view to giving the recipient a preference. Canadian law is similar to the English in its approach, except that the critical period ordinarily covers only three months prior to the petition but is extended to 12 months if the recipient creditor is related to the bankrupt; moreover, if the transfer had a preferential effect, it is presumed that it was made with a view to giving a preference. In Australia the critical period commences six months prior to the filing of the petition. Preferential transfers by an insolvent to a creditor during this time are voidable unless the creditor had no reason to suspect that the debtor was insolvent at the time of the transfer and that the transfer gave him a preference over other creditors. In New Zealand the critical period extends to two years preceding the adjudication. Any transfer made during this time by an insolvent debtor to his creditor with a view to giving him a preference can be avoided by the trustee. In addition, all preferential transfers made by an insolvent during the month preceding his adjudication are voidable regardless of intent.

In France and a number of other civil-law countries, certain classes of preferential transfers are ineffective regardless of the intent of the debtor or the creditor's knowledge of the financial embarrassment of the debtor, provided that the transfer was made after cessation of payments or after the date when the debtor became insolvent. This critical date is usually fixed in the order of adjudication; usually, it may not antedate the adjudication or initiation of the bankruptcy proceedings by more than a fixed period. Systems of this type have been adopted by Argentina, Brazil, Chile, and Mexico. The length of the permissible period varies from country to country, being a maximum of two years in Chile but only 60 days in Brazil. Transactions considered preferential and ineffective are payments of debts made before their maturity; payments of matured debts by means other than cash, commercial paper, or securities; and grants of security interests for antecedent debts.

In Germany and in countries influenced by the German approach, preferential transfers are only voidable if the recipient knew the transfer to be preferential; in certain cases the trustee may rely on a presumption of such knowledge. Thus, in Germany, transfers granting a creditor a security or satisfaction to which he was not then entitled are voidable if made after the tenth day prior to the cessation of payments or the filing of the petition, unless the recipient is able to show that he knew neither of the cessation of payments or the petition nor of a preferential intent. If the payment or the grant of a security interest was made in performance of an existing obligation, it is voidable if its date is subsequent to the cessation of payments or the filing of a petition. In that case, however, the burden of proof of the recipient's knowledge of these facts is on the trustee. Voidability on the ground of the creditor's knowledge of the cessation of payment cannot be claimed if the transfer was perfected at a date preceding the filing of a petition by more than six months. The same system governs in Japan except that the ten-day period in cases of prepayment or newly granted security is extended to 30 days and the special limitation period of six months is lengthened to one year. The Portuguese bankruptcy law likewise contains a catalog of voidable preferences differentiating the length of the critical period preceding adjudication according to various classes of preferential transactions; voidability is aided by a rebuttable presumption of a preferential intent. Comparable provisions govern in Austria and Italy. Switzerland authorizes the avoidance of payments of debts prior to their maturity or of grants of security interests for pre-existing debts if such preferences were given when the bankrupt was insolvent, unless the creditor can show that he did not know of that circumstance. In addition, in Switzerland all transfers made with preferential intent known to the creditor are voidable within five years.

Distribution of proceeds

Claims to the estate. One of the principal objectives of liquidation is the distribution of the proceeds of the estate among the creditors. The designation of the classes of claims entitled to share in such distribution and the regulation of the procedures for their establishment form an important ingredient of modern bankruptcy legislation. Entitlement to "dividends" by reason of a "provable claim" must be distinguished from the right by means of "reclamation proceedings" and from the right to regain specific property to recover the proceeds from certain assets by a lien claimant. Except for the rules governing fraudulent or preferential transfers, bankruptcy does not affect existing consensual or statutory security interests although their enforcement may come within the jurisdiction of the bankruptcy court. In a number of countries, however, for example in Italy, Argentina, and Brazil, creditors holding security interests in assets belonging to the estate must file proof of the claims so secured in order to assert their rights to the proceeds from the collateral.

Provable claims are held by creditors of the bankrupt. Creditors who have become such as a result of acts in, or expenditures for, the administration of the estate are not creditors of the bankrupt and are entitled to payment ahead of such creditors. Provable claims result from transactions or events that took place prior to a specific phase of the bankruptcy proceedings. The controlling date in the United States and Canada is usually the time

of the filing of the petition. In England the dividing date is that of the issuance of the receiving order that precedes the formal adjudication, while in Australia it is that of the sequestration order or of a voluntary petition that renders the debtor a bankrupt. In New Zealand the crucial date is that of the adjudication, a rule also governing in continental European and South American countries and in countries influenced by continental European laws, such as Austria, France, Germany, Italy, Portugal, Spain, Argentina, Brazil, Chile, and Japan.

Under most bankruptcy laws provable claims include all classes of pre-bankruptcy obligations, whether matured or unmatured, liquidated or unliquidated, unconditional or contingent. A provable unliquidated liability may be based not only on contract but also on the infliction of personal injury or damage to property. Systems providing for such a broad spectrum of provability exist in most of the civil-law countries and also in Canada and New Zealand. In England and Australia, however, claims for unliquidated damages arising otherwise than by reason of contract are not provable. Hence personal injury claims, not reduced to judgment or settled by compromise, are not provable. In the United States a similar exclusion exists, except that claims for the negligent infliction of personal injuries are provable if such an action was pending at the time of the petition. In Brazil the view is held that a creditor with an unliquidated claim cannot prove it in bankruptcy proceedings but may only demand the setting apart of a reserve.

Although in principle bankruptcy laws aim at equality among creditors, priorities traditionally are given to certain creditors. Generally speaking, such priorities exist for taxes or other debts owed to the state and certain public entities and for wage claims and other private liabilities deserving preferential treatment. In some civil-law countries the system of priorities is full of complexities. In Spain, for example, proceeds from personal property are distributed according to priority rules that differ substantially from those governing proceeds from real property.

Creditors not entitled to priorities are designated as general creditors. Secured creditors whose claims are not covered by their security are entitled to dividends for the unsecured portion of their debt.

Release of debts

Discharge. An English statute of 1705 provided for a discharge (release) of all debts owed by the bankrupt and due at the time of bankruptcy provided the bankrupt had faithfully complied with his statutory duties. Since that time, relief of the honest but unfortunate bankrupt from his provable debts has become one of the main objectives of the bankruptcy laws of the English-speaking countries. The right to a discharge, however, is not unqualified. A bankrupt may forfeit his right to a discharge by certain reprehensible conduct or by neglect of special duties. Moreover, certain debts are excepted from the operation of a discharge, as, for example, liabilities for support or debts resulting from fraudulent dealings.

In England, Canada, Australia, and New Zealand, the court has the power to grant suspended or conditional discharges. In the first three countries the court may not grant an immediate and absolute discharge if the bankrupt has been guilty of certain acts listed in a statutory catalogue. In New Zealand the discretion of the court in deciding the character of the discharge is not restricted. Conversely, in the United States, conditional or suspended discharges are not permitted, and the grounds barring a discharge are absolute. Japan introduced discharge provisions modelled after the law of the United States in 1952. Most civil-law countries do not provide for discharges in liquidation proceedings and leave the discharge of debts to subsequent agreement among the parties. An exception is the bankruptcy law of Brazil. In that country payment of dividends in excess of 40 percent of the provable debts entails the release of the balance; the unpaid balance is extinguished after five years from the closure of the proceedings, unless the bankrupt was convicted of a bankruptcy crime.

Conduct of bankruptcy proceedings. Since bankruptcy aims at a judicially supervised liquidation of the insolvent estate, the proceedings must be initiated in a court, which in some measure controls the proceedings. The bankruptcy laws of the various countries, however, vary considerably with respect to (1) the jurisdiction of the bankruptcy court and (2) the relative roles assigned to the judicial officers, the creditors, and others participating in the liquidation.

The "force of attraction" theory

Jurisdiction of the bankruptcy court. During the formative period of bankruptcy law in Europe, the courts developed a theory of the "force of attraction," in the sense that all litigation involving the creditors or assets was to be concentrated in the bankruptcy court. Modern bankruptcy laws are still under the influence of this idea, but the jurisdiction of the bankruptcy court differs greatly from country to country. The statutes of England, the United States, Australia, Canada, and New Zealand contain very broad grants of jurisdiction to the bankruptcy courts; extensive jurisdictional powers of the bankruptcy courts exist likewise under the acts of a number of civil-law countries, as for example in Italy and Argentina. Conversely, the bankruptcy law of Germany and to a lesser degree the bankruptcy legislation of countries influenced by German law, such as Austria, have left the settlement of individual controversies to the ordinary courts—*i.e.*, in such matters as the rights of the estate to certain assets or the determination of contested provable debts.

In many countries a vast array of functions of the bankruptcy court are conferred upon special judicial officers who may be either actual members of the judiciary (as in France) or judicial officers without full judicial status. In England, Registrars in Bankruptcy have jurisdiction over the initiation of bankruptcy proceedings and a long catalog of matters not requiring hearings in open court. Similar rules apply in Canada and New Zealand. In the United States the Referee in Bankruptcy may exercise practically all judicial functions. In Australia, for constitutional reasons, the law authorizes only the delegation of functions of an administrative nature. In Germany, conversely, a wide range of judicial bankruptcy functions are delegable to judicial officers outside the regular judiciary, called *Rechtspfleger*.

Growing powers of the courts

The roles of the court, the creditors, and others. Creditors have traditionally played an important part in the conduct of bankruptcy proceedings. In most countries, however, they are no longer the dominant parties; the courts, assisted by official administrators, have emerged as key figures. In England, creditors gained an active role with the legislation of 1706; they have been vested with important powers except for an interval from 1831 to 1869, when a system of "officialism" governed. It was followed by a system of creditor autonomy. In 1883, however, shared responsibility was instituted. Creditors retained the power of selecting the trustee, who was subjected to supervision by a creditors' committee as well as by the Board of Trade. English law also provides for official receivers who act as trustees until one is appointed either by the creditors or, in default of such action, by the Board of Trade. In Canada the position of judicial and administrative officers in liquidation proceedings is even stronger. There the trustee is appointed initially either in the court's receiving order, issued upon an involuntary petition, or by an official receiver in the case of a voluntary assignment. The creditors, however, may replace such a trustee by one of their choice. Official receivers in Canada are special officers of the court, appointed by the governor general, who are charged with a general supervision of bankruptcies in their districts as well as the examination of bankrupts in individual cases. Creditors exercise supervisory powers over the actions of the trustees. Similarly, in Australia, official receivers serve as initial trustees but may be replaced by registered trustees selected by the creditors. Under the New Zealand Insolvency Act of 1967, the administration of bankrupts' estates is in the hands of official assignees appointed under the State Services Act. The creditors may appoint experts or committees to assist in the administration. In the United States creditors have preserved a greater power over the conduct of the proceedings, al-

though the bankruptcy judge is in control of them. No official trustee or administrative control is provided. In France and Italy the creditors are almost totally deprived of any voice in the proceedings; creditors' meetings in liquidations have been abolished in France and are convoked in Italy only for the establishment of provable debts. In both countries creditors are represented through a creditors' committee selected by the judge. Its establishment is mandatory in Italy but only optional in France. In Chile and Switzerland the actual liquidation is entrusted to administrative officials. In Chile, bankrupt estates are liquidated by official trustees, constituting the staff of a central governmental agency called Sindicatura General de Quiebras. In Switzerland, bankruptcy offices are established for each of the bankruptcy districts created by the individual cantons. The bankruptcy office is in charge of the progress of the proceedings and acts as trustee, unless the creditors select one of their choice.

REHABILITATION OF INSOLVENT ESTATES

Liquidation is a wasteful and socially undesirable way of disposing of insolvent estates. For that reason most bankruptcy laws establish procedures aiming at the rehabilitation of the estate by means of an arrangement with a qualified majority of the creditors. Such an arrangement, if it meets statutory requirements and has the approval of the court, becomes binding upon dissenters. An arrangement may provide merely for a deferment of payments (extension agreement) or for a scaling down of the indebtedness (composition). During the 19th century the bankruptcy laws of many countries recognized such arrangements only as a method of terminating pending bankruptcies. In more recent statutes, however, arrangement proceedings have been established for the avoidance of liquidation proceedings. In England, after an experiment with preventive compositions outside bankruptcy, composition proceedings were permitted by the Bankruptcy acts of 1883 and 1914 only after a petition in bankruptcy had been filed either before or after the adjudication. In France, likewise, arrangement proceedings constitute a mandatory phase after the filing of a petition and before adjudication. In the United States, preventive compositions prior to the initiation of liquidation proceedings were introduced in 1933 and greatly expanded by the Chandler Act of 1938. Canada reintroduced preventive "proposals" in 1949, and similar provisions have been adopted in New Zealand. Systems of preventive arrangements exist also, for example, in Austria, Germany, Italy, Portugal, Argentina, Brazil, Chile, Mexico, Japan, and Spain. Australia authorizes preventive compositions among other preventive arrangements. Usually compositions affect only the rights of the unsecured creditors. In the case of corporate enterprises, however, effective rehabilitation frequently requires that the whole debt structure be reconstituted; in some countries, therefore, including the United States, Canada, and Japan, special provisions for corporate reorganization affecting also secured creditors have been adopted.

Avoidance of liquidation proceedings

The United States has also enacted special provisions permitting wage earners to work out plans for a reduction of their indebtedness and payment of their creditors from their earnings. Canada authorizes nonbusiness insolvents to arrange for the orderly payment of their debts by means of consolidation orders. Proceedings of this kind, however, do not afford protection against an involuntary bankruptcy petition.

INTERNATIONAL ASPECTS

Perhaps the majority of countries extend their bankruptcy proceedings to all foreign assets of a resident debtor without differentiating between personal and real property. This is done, for example, in England, the United States, and Switzerland. Japan, on the other hand, applies its law solely to property located in that country. Only a few nations, among them the United States and Austria, provide for adjudication of nonresidents merely because they have assets in the national territory. Germany follows a similar rule with respect to nonresidents who maintain a business branch or operate a farm in that country but restricts the proceedings to local assets. A number of countries expressly refuse to recognize foreign adjudications and leave the domestic assets to individual executions; these include Argentina, Germany, Japan, and Portugal. Other countries permit foreign trustees to reach property in their territory, especially if the foreign adjudication has been recognized by special procedures to that effect.

Normally countries will not differentiate between foreign and domestic creditors in proceedings involving residents, at least if reciprocity exists. Provisions to that effect exist in the laws of Germany and Japan and by implication in Italy. A number of countries, however, especially in Latin America, give priority to local creditors if there are concurring bankruptcies.

Even greater complexities exist with respect to the extraterritorial effects of releases flowing from compositions or discharges in bankruptcy.

Because of the above difficulties, some groups of countries have regulated the subject among themselves by multipartite treaty, in particular the five Scandivanian countries (by a treaty of November 7, 1933) and 15 Latin American countries (by a treaty of February 20, 1928; the so-called Bustamante Code of Private International Law). The Common Market countries had by 1971 prepared a draft convention governing liquidation, composition, and extension proceedings in their respective territories, accompanied by the draft of a uniform law governing fraudulent and preferential transfers and certain other matters.

BIBLIOGRAPHY. While the general aims and features of the bankruptcy law of most countries are similar, the substantive and procedural rules vary greatly. The following works are commentaries on, or proposals for, reform of the laws of particular countries: *Argentina:* FRANCISCO GARCIA MARTINEZ, *El concordato y la quiebra*, 4th ed., 3 vol. (1962–63). *Australia:* ARNDELL LEWIS and DENNIS ROSE, *Lewis' Australian Bankruptcy Law*, 5th ed. (1967). *Austria:* HANS SABADITSCH (ed.), *Die Konkurs-, Ausgleichs- und Anfechtungsordnung*, 5th ed. (1970). *Brazil:* WALTER T. ALVARES, *Direito Falimentar* (1966); J.C. SAMPAIO DE LACERDA, *Manual de Direito Falimentar*, 4th ed. (1967). *Canada:* LEWIS DUNCAN and JOHN D. HONSBERGER, *Bankruptcy in Canada*, 2nd ed. (1961); *Report of the Study Committee on Bankruptcy and Insolvency Legislation* (1970). *Chile:* ARTURO DAVIS, *Código de comercio: origenes concordancias, jurisprudencia*, vol. 4, *Ley de quiebras* (1966). *England:* R.V. WILLIAMS, *William's Law and Practice in Bankruptcy*, 18th ed. (1968). *France,* GILBERT BORD, *Règlement Judiciaire et liquidation des bien* (1969). *Germany:* ERNST JAEGER, *Konkursordnung, mit Einführungsgesetzen*, 2 vol., 8th ed. (1958–70). *India:* RAMESHWAR DIAL, *The Provincial Insolvency Act*, 3rd ed. (1969). *Italy:* FRANCESCO FERRARA, *II Fallimento*, 2nd ed. Banks and Banking

The principal types of banking in the modern industrial world are commercial banking and central banking. A commercial banker is a dealer in money and in substitutes for money, such as checks or bills of exchange. He also provides a variety of financial services. The basis of

his business is borrowing from individuals, firms, and occasionally governments—*i.e.*, receiving "deposits" from them. With these resources and also with his own capital, the banker makes loans or extends credit and also invests in securities. The banker makes his profit by borrowing at one rate of interest and lending at a higher rate and by charging commissions for services rendered.

A bank must always have cash balances on hand in order to pay its depositors upon demand or when the amounts credited to them become due. It must also keep a proportion of its assets in forms that can readily be converted into cash. Only in this way can confidence in the banking system be maintained. Provided it honours its promises (*e.g.*, to convert notes into gold or provide cash in exchange for deposit balances), a bank can create credit for use by its customers by issuing additional notes or by making new loans, which in their turn become new deposits. The amount of credit it extends may considerably exceed the sums available to it in cash. But a bank will only be able to do this as long as the public believes the bank can and will honour its obligations, which are then accepted at face value and circulate as money. So long as they remain outstanding, these promises or obligations constitute claims against that bank and can be transferred by means of checks or other negotiable instruments from one party to another. These are the essentials of deposit banking as practiced throughout the world today, with the partial exception of Soviet-type institutions.

Another type of banking is carried on by central banks. Central banks are bankers to governments and "lenders of last resort" to commercial banks and/or other financial institutions. They are often responsible for formulating and implementing their country's monetary and credit policies, usually in cooperation with the government. In some cases—*e.g.*, the U.S. Federal Reserve System—they have been established specifically to lead or regulate the banking system; in other cases—*e.g.*, the Bank of England—they have come to perform these functions through a process of evolution.

Some institutions often called banks, such as finance companies, savings banks, investment banks, trust companies, and home-loan banks, do not perform the banking functions described above and are best classified as financial intermediaries. Their economic function is that of channeling savings from private individuals into the hands of those who will use them, in the form of loans for building purposes or for the purchase of capital assets. These financial intermediaries cannot, however, create money (*i.e.*, credit) as the commercial banks do; they can lend no more than savers place with them.

The article is divided into the following sections:

I. The development of banking systems

Money changers and merchant bankers

Banking is of ancient origin, though little is known about it prior to the 13th century. Many of the early "banks" dealt primarily in coin and bullion, much of their business being money changing and the supplying of foreign and domestic coin of the correct weight and fineness. Another important early group of banking institutions was the merchant bankers, who dealt both in goods and in bills of exchange, providing for the remittance of money and payment of accounts at a distance but without shipping actual coin. Their business arose from the fact that many of these merchants traded internationally and held assets at different points along the trading routes. For a certain consideration, a merchant stood prepared to accept instructions to pay money to a named party through one of his agents elsewhere; the amount of the bill of exchange would be debited by his agent to the account of the merchant banker, who would also hope to make an additional profit from exchanging one currency against another. Because there was a possibility of loss, any profit or gain was not subject to the medieval ban on usury. There were, moreover, techniques for concealing a loan by making foreign exchange available at a distance but deferring payment for it to a later date so that the interest charge could be camouflaged as a fluctuation in the rate of exchange.

Another form of early banking activity was the acceptance of deposits. These might derive from the deposit of money or valuables for safekeeping or for purposes of transfer to another party; or, more straightforwardly, they might represent the deposit of money in current account. A balance in current account could also represent the proceeds of a loan that had been granted by the banker, perhaps based on an oral agreement between the parties (recorded in the banker's journal) whereby the customer would be allowed to overdraw his account.

English bankers in particular had by the 17th century begun to develop a deposit banking business, and the techniques they evolved were to prove influential elsewhere. The London goldsmiths kept money and valuables in safe custody for their customers. In addition, they dealt in bullion and foreign exchange, acquiring and sorting coin for profit. As a means of attracting coin for sorting, they were prepared to pay a rate of interest, and it was largely in this way that they began to supplant as deposit bankers their great rivals the "money scriveners." The latter were notaries who had come to specialize in bringing together borrowers and lenders; they also accepted deposits.

It was found that, when money was deposited by a number of people with a goldsmith or a scrivener, a fund of deposits came to be maintained at a fairly steady level; over a period of time, deposits and withdrawals tended to balance. In any event, customers preferred to leave their surplus money with the goldsmith, keeping only enough for their everyday needs. The result was a fund of idle cash that could be lent out at interest to other parties.

About the same time, a practice grew up whereby a customer could arrange for the transfer of part of his credit balance to another party by addressing an order to the banker. This was the origin of the modern check. It was only a short step from making a loan in specie or coin to allowing customers to borrow by check: a loan account would be debited with the full amount borrowed and the amount credited to a current account against which checks could be drawn, or the customer would be allowed to overdraw his account up to a specified limit. In the first case, interest was charged on the full amount of the debit, and in the second the customer paid interest only on the amount actually borrowed. A check was a claim against the bank, which had a corresponding claim against its customer.

Origin of the check

Another way in which a bank could create claims against itself was by issuing bank notes. The amount actually issued depended on the banker's judgment of the possible demand for specie, and this depended in large part on public confidence in the bank itself. In London, goldsmith bankers were probably developing the use of the bank note about the same time as that of the check. (The first bank notes issued in Europe were by the Bank of Stockholm in 1661.) Some commercial banks are still permitted to issue their own notes, but in most countries this has become a prerogative of the central bank.

Bank money or credit

In Britain the check soon proved to be such a convenient means of payment that the public began to use checks for the larger part of their monetary transactions, reserving coin (and, later, notes) for small payments. As a result, banks began to grant their borrowers the right to draw checks much in excess of the amounts of cash actually held, in this way "creating money"—*i.e.*, claims that were generally accepted as means of payment. Such money came to be known as "bank money" or "credit."

Excluding bank notes, this money consisted of no more than figures in bank ledgers; it was acceptable because of the public's confidence in the ability of the bank to honour its liabilities when called upon to do so.

When a check is drawn and passes into the hands of another party in payment for goods or services, it is usually paid into another bank account. Assuming that the overdraft technique is employed, if the check has been drawn by a borrower, the mere act of drawing and passing the check will create a loan as soon as the check is paid by the borrower's banker. Since every loan so made tends to return to the banking system as a deposit, deposits will tend to increase for the system as a whole to about the same extent as loans. On the other hand, if the money lent has been debited to a loan account and the amount of the loan has been credited to the customer's current account, a deposit will have been created immediately.

One of the most important factors in the development of banking in England was the early legal recognition of the negotiability of credit instruments or bills of exchange. The check was expressly defined as a bill of exchange and thus recognized as a negotiable instrument. In continental Europe, on the other hand, limitations on the negotiability of an order of payment prevented the extension of deposit banking based on the check. Continental countries developed their own system, known as Giro payments, whereby transfers were effected on the basis of written instructions to debit the account of the payer and to credit that of the payee.

II. The structure of modern banking systems

The banking systems of the world have many similarities, but they also differ, sometimes in quite material respects. The principal differences are in the details of organization and technique. The differences are gradually becoming less pronounced because of the growing efficiency of international communication and the tendency in each country to emulate practices that have been successful elsewhere.

Unit banking and branch banking

Banking systems may be classified in terms of their structure as unit banking, branch banking, or hybrids of the two. For example, unit banking prevails in large areas of the United States, which in 1971 had nearly 14,300 banks but only about 24,600 bank branches (in relation to a population of 205,000,000). In other countries it is more usual to find a small number of large commercial banks, each operating a highly developed network of branches. In England and Wales, for example, there were in 1971 only six clearing banks (four of which are very much larger than the other two), which carried on nearly all the domestic banking business through more than 14,300 branch offices (in relation to a population of 49,000,000). Examples of hybrid systems include those of France, West Germany, and India, where banks that are national in scope are supplemented by regional or local banks. Some of these hybrid systems are slowly changing their character, the banks becoming fewer in number and individually larger, with a larger number of branches.

UNIT BANKING: THE U.S.

Bank organization in the United States during the years after World War II was still passing through a phase of structural development that many other countries had completed some decades earlier. Development in the U.S. has been subject to constraints not found elsewhere. The federal Constitution permits both the national and state governments to regulate banking. Some states prohibit branch banking, largely because of the political influence of small local bankers, thus encouraging the establishment and retention of a large number of unit banks. (In Australia, which also has a federal constitution, the national government has more power to regulate banking generally; consequently, there have been no legal impediments to the spread of branch banking, and the system has for a number of years been well developed.)

Even in its early years the United States had an unusually large number of banks. As the frontiers of settlement were pushed rapidly westward, banks sprang up across the country. One reason for this was the demand for capital in the expanding frontier economy. There was also an obvious need for a large number of banks to serve the diverse and rapidly expanding demands of a growing and constantly migrating population. It must be remembered, too, that at this time communications between the frontiers of settlement and the established centres of commerce and finance were still inadequately developed.

As long as communications remained imperfect, the existence of large numbers of competing institutions is not difficult to explain. The subsequent failure of bank mergers or amalgamations to produce a concentration of financial resources in the hands of large banking units can be attributed in part to the character of the federal Constitution as noted above. Among the people, moreover, there was a widespread distrust of monopoly and a deep-rooted fear that a "money trust" might develop. This went hand in hand with a political philosophy that emphasized the virtues of individualism and free competition; restrictions on branching, merging, and on the formation of holding companies were a feature of both the state and the federal banking laws. Where permitted, however, bank branches are numerous in the U.S. (especially in California, where branching is statewide, and in New York); in states in which branching is prohibited, one often finds local bank monopolies in small towns. The banking system of the United States would not work without a network of correspondent bank relationships, which are more highly developed there than in any other country.

The U.S. concern for competition

BRANCH BANKING: GREAT BRITAIN

If the United States banks can be taken as representative of a unit banking system, the British system is the prototype of branch banking. Its development was linked to the growth of transportation and communications, for otherwise banks cannot clear checks drawn on other banks and effect remittances speedily and efficiently. The Scots favoured branch banking from the very beginning (the Bank of Scotland was founded in 1695), but at first they were not very successful—largely because of poor communications and the difficulty of supplying branches with adequate amounts of coin. Not until after the Napoleonic Wars, when the road system of Scotland had been greatly improved, did branch banking begin to develop vigorously in Scotland. As the Industrial Revolution progressed and as the size of businesses increased, the structure of English banking underwent a corresponding change. Greater resources were required for lending, and banks also needed more extensive interconnections in order to provide an increasing range of services. Where banks remained small, they were frequently unable to take the strain of the larger demand; they tended to become overextended and often failed.

The growth in size of banks was also greatly encouraged by legislation that encouraged joint-stock ownership, beginning in 1826. Joint-stock ownership, which reduced the risk to any particular individual, must be distinguished from limited liability, which did not become widely accepted until the failure of the City of Glasgow Bank in 1878 demonstrated the need for a legal device that would protect the stockholder. The early joint-stock banks tended to remain somewhat localized in their business interests, and it was only gradually (along with the spread of limited liability and disclosure of accounts) that amalgamations began to convert the banking system in England and Wales into its highly concentrated modern form. The main movement was completed before World War I, though there was to be a further degree of concentration in the years after World War II. By these means, the British banks were able to attract deposits from all parts of the country and also to spread the banking risk over a wide range of industries and areas.

HYBRID SYSTEMS

A third group of banking systems differs from the unit-banking system of the United States and also from the

branch-banking systems of countries that have followed the British model (such as Australia, Canada, New Zealand, and South Africa). This group is characterized by the existence of a small number of banks with branches throughout the country, holding a significant part of total deposits, along with a relatively large number of smaller banks that are regional or local in emphasis. Such systems exist in France, West Germany, Italy, and India. Japan has a small number of large city banks with branch networks but a larger number of local banks.

France. Banking institutions in France were classified after World War II into three main groups: deposit banks, *banques d'affaires* (or investment banks), and institutions that were either specialized or operated mainly outside France. New banking legislation in 1966 greatly reduced the importance of the distinction between deposit banks and *banques d'affaires;* the main distinction is now between commercial banks on the one hand and a range of other banking and financial institutions on the other. Along with this there has been (1) a further concentration of banking resources, as a result of several large mergers and also of greater financial integration through share-exchange agreements and interlocking directorates, and (2) the conversion of a number of *banques d'affaires* into deposit banks, which have hived off their investment interests into separate investment or holding companies.

Integration in France

The main reason for this development was the relative superfluity of deposit bank funds, along with a scarcity of funds at the disposal of the *banques d'affaires.* There had always been a bigger demand for capital than the *banques d'affaires* themselves were able to provide, but, so long as a high proportion of medium-term commercial notes were rediscountable at semipublic institutions or at the Bank of France, the *banques d'affaires* could turn over their funds fairly frequently by rediscounting; this was now no longer possible on the same scale. In consequence, the *banques d'affaires* had to seek deposits more actively. Meanwhile, the deposit banks had begun to attract an increasing proportion of their funds from private individuals (who were making much less use of notes), and these banks sought to hold such business by expanding their retail banking facilities (*e.g.*, personal loans and mortgage lending). But they were also permitted to carry more time deposits, and these funds are now used to finance their medium-term lending; hence, they have less need to rediscount.

In 1970 there were about 330 banks registered in France, a decrease of more than 200 since 1945. The thinning-out process affected primarily the deposit banks, which in 1970 consisted of the three nationalized banks (with branches throughout the provinces and accounting for well over one-half of total deposits), four relatively large non-nationalized banks (one of them strictly a Parisian bank that heads a group of regional banks), about 20 regional banks (very few of which are now independent of Paris, one of them being the sixth-largest deposit bank in the country), 75 Parisian deposit banks, and 70 local banks operating in departmental centres. Most of the reduction in numbers was among the local banks, and the rest was among the Paris deposit banks. The number of regional banks remained virtually unchanged.

All of the regional banks and some local banks have branches. The balanced character of the regional economies often provides these banks with a good portfolio of risks; they serve not only a prosperous agriculture but a number of local industries. Some of the local banks are also very sound institutions, despite their small size.

The survival of a hybrid system in France, despite the long-run trend toward centralization, reflects certain characteristics of French society. These included, until recently, a strong emphasis on small business, together with a preference for the individual and personal service that only the small bank could provide. Particularism in some parts of France manifests itself in support for local institutions, and the local banker also often has an advantage because of his special knowledge of local industries and people, which enables him to accept risks that the big banks decline. Until recent years, moreover, the large French banks preferred to open branches in new areas rather than to absorb local and regional banks.

West Germany. An even more direct conflict between the forces favouring concentration and those working against it may be seen in the Federal Republic of Germany. Before 1848, when the first joint-stock bank was established, there was little industrial development. Banking grew in the latter part of the 19th century along with industry; a number of the banks established after 1848 were from the beginning specifically linked with the promotion of industrial enterprises. For this reason, the banks were inclined to rely mainly on their own capital resources and did not at first try to attract deposits from the public. Not until 1874 did the Deutsche Bank A.G. begin to seek deposits through offices specially opened for the purpose. This was done to provide cheap finance for traders, the deposits being invested in mercantile bills that were regarded as both safe and liquid.

This was an important period in the evolution of German banking, when the principles of deposit banking on the British model were combined with long-term financing of the kind done by the French *banques d'affaires.* In pursuit of deposits, the banks built up a widespread network of branch offices, which were also used to establish and maintain industrial contacts throughout the country. The unification of Germany in 1871 removed the political obstacles to a more integrated banking system, and the selection of Berlin as the capital made that city the country's financial centre. Four of the largest banks were already established there; the new Reichsbank was set up in 1876. In addition, the larger and more enterprising of the provincial banks were now attracted to the capital. The Berlin stock exchange rapidly displaced Frankfurt am Main as the country's leading securities market.

The Berlin banks

The Berlin banks extended their influence throughout the provinces. They did this initially by developing correspondent relationships and subsequently by acquiring a financial interest in the provincial banks and being represented on their boards. Sometimes a provincial bank might acquire an interest in a Berlin bank, but almost invariably it was the provincial bank that lost some of its independence. Each of the big Berlin banks came to be associated with a group of provincial banks more or less under its control. At the same time, all of the banks, Berlin and provincial alike, expanded their business by opening branches, usually by absorbing a private banking business or by buying up the assets of a provincial bank that had been forced into liquidation.

During World War I the degree of centralization increased; by 1918, the big Berlin banks held over 65 percent of total deposits. In the early 1920s there were amalgamations, and branch systems became much larger. Bank failures and the financial crisis of 1931 resulted in further consolidation until the German banking system was dominated by three giants. Under the Nazis, it became virtually an instrument of the state.

But there were countervailing forces. Probably the most important of these was the establishment of publicly owned banking institutions, such as the communal savings banks, which became of increasing importance after World War II. In 1970 the three largest banks held only about one-fifth of total demand deposits (repayable on sight or demand) and about 10 percent of savings bank deposits. The other big commercial banking group included the regional banks, holding less than 15 percent of sight deposits. The commercial banks also accepted time deposits (repayable after a period of time). But sight and time deposits together were much less than savings deposits; indeed, the savings banks (some of which were bigger than certain of the regional banks) constituted the chief competition of the commercial banks. They attracted an even larger volume of sight deposits than did the commercial banks—over 35 percent of the total—and almost 60 percent of the much larger sum of savings deposits. On the lending side, also, the competition was quite significant; in the long-term lending field (in which the big banks were small), the savings banks extended about one-quarter of the total amount loaned, and their

central institutions, the *Girozentralen*, extended a further one-sixth. Even the specialist long-term lending of the private and public mortgage banks amounted to something less than 30 percent of the total.

The savings banks offer a wide range of services, especially to lower income groups and smaller businesses. The large commercial banks have concerned themselves more with big business and with wealthy individuals. The savings banks now compete in wholesale banking as well. A number of them, together with their *Girozentralen*, are to all intents and purposes "universal banks," like the Big Three and the larger regional banks. The Big Three remain unchallenged only in stock exchange and foreign banking business.

There were also about 170 private bankers in 1970, though only about half a dozen were of any size. The bigger private banks are important in the fields of investment and wholesale banking, while the smaller ones flourish in the leading stock exchange cities, such as Düsseldorf and Frankfurt am Main. Many of these private bankers, however, are not bankers in the true sense; they subsist mainly on stock transactions, investment services, portfolio management, and insurance and mortgage brokerage. There are also consumer finance institutions, mortgage and other specialist banks, and a large number of cooperatives.

The German banking system is a reflection of the decentralized nature of the country, with its numerous provincial cities. Economic and cultural life is dispersed. Some strong banks thrive upon regional sentiment. The belief in economic competition also remains very strong and is encouraged. At the same time, the influence of the Big Three is more important than the foregoing figures indicate. Regional and private banks are often within the sphere of influence of the Big Three. In some cases the latter have a financial interest in these banks, and in some cases they own them. The Big Three also have shares in certain of the private mortgage banks. There are also "cooperation agreements," and a number of mergers have taken place. In these several ways, much more integration exists than appears on the surface. While banking in West Germany remains a hybrid system, a trend toward greater concentration is evident.

Italy. The large Italian banks began, as in a number of other European countries, by operating as "mixed banks." After the crisis of the early 1930s, however, short-term banking operations were separated from the various types of medium- and long-term banking by the Banking Law of 1936, which reserved each kind of business specifically for a separate type of organization. Italian arrangements thus contrast strongly with the West German concept of a "universal" bank, the tendency in Italy being to specialize. The specialization has been somewhat blurred in recent years as credit terms have lengthened and as the ordinary banks have expanded their security portfolios.

Wholesale and retail banking in Italy

The big banks have tended to function as wholesalers of credit, operating on a national scale, and to do business mostly with the large and medium-sized firms. They have had branches mainly in the capital towns of the provinces and in busy centres of industry and commerce. The medium-sized and smaller banks have traditionally catered to medium-sized and smaller customers. As indicated, there have been changes in recent years. The big banks, stimulated partly by the growth in middle-range personal income, have begun to develop a retail banking business, especially in the field of personal loans; while certain of the medium-sized banks, as well as some of the savings banks, have grown sufficiently in size and importance to attract business even from very large concerns. In addition, the big banks now operate in such fields as agricultural credit, requiring a nationwide network of branches, and have extended their branching arrangements accordingly, sometimes by taking over smaller banks.

Although there is some concentration of banking resources, much of Italian banking is still decentralized, a pattern stemming from the time when Italy consisted of a number of separate states and kingdoms. Regionalism is still evident. Only in northern and central Italy is banking strongly integrated, though the economic development of the south will doubtless lead to further integration. As in other countries, some large banks have taken control of smaller banks without proceeding to a merger, so that the degree of actual concentration is greater than it appears.

In 1970 there were about 1,200 banks in Italy. Five of them were major banks, and another five might be described as large. There was also one major savings bank. Many of the others, including ordinary credit banks, cooperative people's banks, savings banks, and rural and artisan banks, were quite small. About 345 banks accounted for 97 percent of total deposits.

The major banks concentrate almost entirely on commercial banking, foreign banking, and the securities business. They also have subsidiaries that provide industrial credit and real estate financing. But the other banks offer a greater variety of services and therefore attract a greater share of the business.

For a long time the Italian government sought to stem the movement toward concentration and the absorption of small banks. By the late 1960s, however, the official attitude toward bank mergers had changed; the government recognized a need for rationalization and automation, as well as a need to spread risks more widely, and began to encourage the merging of smaller banks into larger units.

India. Until the 1950s, banking in India was carried on by a large number of small banks. India is still primarily an agricultural country, with an economic and social structure based largely on the villages. The integration of banking has been impeded by poor communications, by illiteracy, and by the barriers of language and caste. Banking and credit have remained largely in the hands of the so-called indigenous banker and the village moneylender. Although their influence has been greatly reduced in recent years, they still remain important in many an up-country area. The indigenous banker, who is also a merchant, offers genuine banking services: accepting deposits and remitting funds; making loans quickly and with a minimum of formality; and by means of the *hundi* (a credit instrument in the form of a promissory note) financing a still significant, if declining, portion of India's internal trade and commerce.

Problems in the integration of banking in India

Efforts were made to eliminate the moneylender by developing a network of rural credit cooperatives. When progress proved to be slow, a more successful alternative was found in requiring banks to open "pioneer" branches in rural areas. The first branches were those of the semi-public Imperial Bank of India and its nationalized successor, the State Bank of India (and its subsidiaries). Many smaller banks began to disappear, sometimes by merger and sometimes as a result of failure. The number of "reporting" banks fell from 517 in 1952 to 66 in 1970. Of these, 22 had been nationalized, including the State Bank, its seven subsidiaries, and the 14 large joint-stock banks taken over after 1969. The foregoing figures do not, of course, include the indigenous bankers and moneylenders.

The main path of banking development in India is now the expansion of bank branches into the under-banked areas. The authorities have sought to expand the number of branches but to avoid their concentration in the larger towns and cities and, in particular, to provide the rural areas with adequate facilities. The ultimate objective is to enable the mobilization of deposits on a massive scale throughout the country and a stepping up of lending to weak sectors of the economy. This is a massive undertaking in a country of 550,000 villages. In 1970, despite years of encouragement, there were only about 10,000 commercial bank offices in India.

City banks and local banks in Japan

Japan. Banking business in Japan is largely concentrated in the hands of the big banks (some of which are specialized), though a number of small banks still survive. At the end of 1971 there were 85 banks operating in Japan. Of these, 14 were city banks (over half with head offices in Tokyo and three in Osaka), three were special long-term credit banks, 61 were local banks, and

seven were trust banks. There were also 71 mutual loans and savings banks, 484 credit associations, and 528 credit cooperatives. The city banks have widespread networks of branches, though some are more regional in their interests than others. Some of the local banks, which on occasion are similar in size to city banks, also have a number of branches, making them really more regional than local. At the end of 1971 there were some 8,000 bank offices in Japan; about 2,400 belonged to the city banks, about 4,300 to the local banks, 262 to the trust banks, and 36 to the long-term credit banks. Thus, despite the concentration of business in the hands of the city banks, which at the end of 1971 held about 60 percent of total deposits, the Japanese system may be classed with the hybrid system.

It should be noted that the distinction between city banks and local banks has no legal basis; it rests on the fact that the city banks are under the supervision of the Department of Banks, while the local banks are regulated mainly by the Local Boards of Finance; both the city and the local banks belong to the Federation of Bankers' Associations of Japan; the local banks also belong to the Local Banks Association. The city banks service mainly manufacturing industry and commerce, particularly the big firms, while the local banks operate in and around a single city or in the rural areas, collecting deposits, lending to local business and the smaller firms, but also investing in securities and in the call-money market.

The local banks have city bank correspondents, not only to hold surplus balances but also for assistance in investing their funds, especially in the call-money market. In addition, a city bank may introduce certain of its large customers to a local bank (*e.g.*, a big company having a local factory) with a view to a loan from the local bank to the customer concerned. City correspondents in Japan do not, however, provide the wide range of ancillary services that is common in the United States.

Since World War II there has been much stability in Japanese banking, but there are many in Japan who are anxious to see changes. This is particularly true of the city banks, which have suffered a relative decline in the importance of their business in competition with other institutions. This has been true in particular of the agricultural cooperatives, which attract the larger part of the Treasury's payments on account of government purchases of the rice crop; there has also been a relative increase in the importance of the life insurance companies and the trust funds, which have attracted sizable funds from the general public.

Because the need for radical overhaul had become so apparent, the problem was referred to the Committee on Financial System Research, set up to advise the Minister of Finance in 1966. As a result, two laws were passed in 1968, the first of which was concerned to revise arrangements relating to mutual loans and savings banks and to improve the financing of small business, and the second to permit mergers and conversions of status between different types of financial institutions. In 1967, the committee began to investigate the system of private financial institutions (other than those for small businesses and agriculture) with an eye to the possible diversification of commercial bank business, the promotion of efficiency in banking (and the possible introduction of a deposit insurance scheme), and arrangements for financing foreign trade within the context of a changing international monetary environment. In order to sustain stable economic growth, the committee recommended in 1970 that greater resort be made to interest rates (including interest rates on deposits) as a means of influencing business activity; that greater strength be imparted (*e.g.*, through mergers, but on the initiative of the institutions concerned) to financial institutions serving the national economy; that, although specialization was to be favoured, there should be some flexibility in the choice of business undertaken, thereby helping to stimulate "fair competition" (*e.g.*, in medium-term financing); and that a deposit insurance scheme should be introduced (relevant legislation was enacted in 1971).

A major banking merger took place in 1971. In the short run, extension of existing cooperation agreements is the more likely pattern (*e.g.*, for sharing Telex services among local banks, the joint use of electronic computers, resort to mutual credit cards, and so on). In due course these agreements will almost certainly lead to interlocking capital holdings, on which basis their more complete integration will tend to follow. In this way, banks in the provinces may well build themselves up into units large enough to compete directly even with merged city banks.

BANKING IN PLANNED ECONOMIES

The Soviet Union. The present-day Soviet banking system was established by the credit reforms of the early 1930s, which centralized practically all short-term credit in the hands of the Gosbank (State Bank, established in 1921). There was much restructuring of banking during succeeding years, mainly to ensure that the system became an effective instrument for carrying out the national economic plan. The Gosbank's control over payments flows was also tightened in order to maintain stability of prices. The activities of the Gosbank are by no means limited to purely financial operations. For example, Gosbank economists are also employed, on a voluntary basis, by organs of the Communist Party and the government to assist in regulating activity in a wide range of economic sectors and to conduct investigations into the business and financial activities of the enterprises that are their customers.

Functions of the Gosbank

The Gosbank was originally concerned with the provision of short-term credit; a number of other banks were created to finance capital investment in the socialized economy. Even in the 1930s there was a tendency to consolidate these banking units, and this continued into the postwar period. In 1959 there were further mergers and a reallocation of activity, as a result of which the Investment Bank (Stroibank) emerged as the means of canalizing state budgetary appropriations into capital investment. The savings bank system, with over 76,000 branches, became part of the Gosbank in 1963. The only other banking institution remaining in existence is the Bank for Foreign Trade (Vneshtorgbank), whose field of operations was considerably expanded in 1961. Originally concerned mainly with the provision of currency for tourists and diplomatic missions and with remittances from abroad, the Bank for Foreign Trade came to handle all foreign-exchange transactions, including those relating to trade.

Since the functions of the Investment Bank are essentially administrative (supervising the disbursement of budgetary grants), the Gosbank is the only domestic bank servicing the cash, credit, and payment needs of a population exceeding 240,000,000. The organization of the Gosbank is as follows: it has a policy-making head office and principal offices in the various Soviet republics. There are also regional offices and a network of about 4,000 local branches; the latter are the bank's main points of contact with a variety of economic enterprises, collective farms, and lower level government units. To serve the needs of the urban population, the Gosbank also maintains numerous collection offices (part of the network of communal banks abolished in 1959), which collect rent, taxes, and other compulsory payments and contributions. It maintains a small number of special cash service agencies in large industrial establishments and at construction projects. Seasonal agencies are operated at remote places where large purchases of farm products are made at certain times of the year.

Organizational structure of the Gosbank

In the industrial area, the Gosbank services hundreds of thousands of state enterprises that operate on the basis of cost accounting; each of these enterprises has its own working capital and prepares a balance sheet and a statement of income; it may borrow regularly or occasionally, depending on its needs. In addition, there are tens of thousands of collective farm accounts. But the Gosbank has hundreds of thousands of other customers comprising party, trade union, cultural and other organizations, and individuals. Most of the accounts held by individuals are loan accounts for financing homes.

The aggregate balances maintained by Gosbank customers are small in comparison with the cash balances held by business and government accounts in the United States.

The operation of a centralized payments system in a country the size of the Soviet Union gives rise to many problems. The system of payments, based mainly on documentary drafts, involves the processing of a very large number of items, an operation that in recent years has been to some extent automated. Changes in several sectors of the economy have greatly increased the complexity of the bank's operations.

Transactions of individuals. Although consumer loans are extended by stores rather than by banks, there has also been a rapid increase in the transactions of individuals. This has resulted from rising incomes, an increase in savings, and the provision of facilities for crediting wages to savings accounts and making periodic payments from them. Housing loans and tourism have also been growing in importance. As savings bank offices handle virtually all the accounts and transactions of individuals, the considerable increase in the volume of these transactions was probably the main reason for absorbing the savings bank system into the Gosbank in 1963.

Transactions of collective farms. An even greater problem has been created by the rise in transactions involving the collective farms. Before 1953 the collectives paid in kind for the services performed by the state-owned tractor and farm-machinery stations; they were also required to deliver to the state a large part of their output. Since 1953 these transactions have gradually shifted from payment in kind to payment in cash. As a first step, the tractor and machinery stations were closed down and their equipment sold to the collectives. The farms now had to pay in cash for all machinery and fuel, as well as for building materials, fertilizers, and other supplies. Subsequently, they were enabled to sell their output to the state for money.

Farm labour likewise has come to be remunerated in cash rather than in kind. In 1953 only one-third of the "compensation" for work contributed by members of the collectives was in cash; five years later the proportion had risen to more than half, and by 1963 it was nearly three-quarters. In 1965 the flow of money income to the farm population was increased further by the introduction of state pensions for collective farmers. In the summer of 1966, it was decided to make minimum monthly payments to the members of collective farms, and this resulted in an even greater use of money in the farm sector.

The growth of money flows and of bank lending in rural areas, as well as the need to service a growing clientele in the villages, greatly added to the complexity of Gosbank operations, which had been geared primarily to the needs of industry and government. The Gosbank attempted to resolve its problems by simplifying payments procedures, though its efforts to work out a system of offsetting mutual claims were not initially very successful. The settlements mechanism remained one of the major operating problems of the Gosbank.

Interest rates in the U.S.S.R.

In the Soviet economy, interest rates serve primarily to pay the operating expense of the Gosbank. After the credit reforms of 1930–32, a uniform system of interest rates was applied to all short-term credits, irrespective of the purpose of the loan or the financial condition of the borrower. Higher rates were charged as a penalty on overdue loans. In the 1960s there was a move to differentiate rates, it being accepted as a matter of principle that bank funds should be more expensive than an enterprise's own working capital and that borrowings made necessary by shortcomings of management (*e.g.*, excessive inventories or the erosion of working capital) should carry higher rates than loans to finance normal needs. Penalty rates for overdue loans and for late payments were also increased, and collection was more vigorously enforced. But the rate of interest was employed only to a very limited extent as a means of allocating resources among alternative uses.

Yugoslavia. The banking system that had emerged in the Socialist Federal Republic of Yugoslavia by 1971 represented an evolution away from the highly centralized institutional arrangements of the Soviet-type system. It also differed from the Western capitalist model. In Yugoslavia, management is ultimately in the hands of the depositors, these consisting mainly of enterprises or sociopolitical bodies having large deposits in the bank.

Before World War II Yugoslavia's banking system had consisted of a number of private and state banks. When the Communists came to power, the private banks disappeared, and the state banks were reorganized. The National Bank, a descendant of the Serbian National Bank founded in 1883, was retained. The former State Mortgage Bank became the State Investment Bank, and the Agricultural Bank founded in 1929 continued to operate. An Industrial Bank was also established to assist in implementing the ambitious program of industrialization, and there were six regional banks. In 1946, all the existing banks were merged into the National Bank and the State Investment Bank; the former was to engage in short-term transactions, while the other handled investments and foreign loans. The National Bank also issued currency, provided general banking and agency facilities for the government, and served as a clearing house for the entire economy. In 1948 the system was expanded again, with the formation of 89 communal banks and six regional state banks for lending to agricultural cooperatives. Though it was not deemed appropriate in a socialist system to charge interest for the use of capital, a commission of 1 percent was charged for bank services. Additional changes came in the early 1950s, when the communal banks were abolished and the others merged with the National Bank. A "reasonable" rate of interest was instituted so that credit would be used economically. In 1954 the National Bank experimented with credit auctions as a means of allocating funds among borrowers, but the less profitable enterprises tended to offer the highest rates; in 1955 the bank returned to the practice of evaluating every application for credit separately.

In another revolt against overcentralization, the communal banks were re-established, though they were required to keep substantial reserves with the National Bank. Two-thirds of each bank's managing board was to be nominated by workers' councils of the enterprises located in its area. Three specialized federal government banks were also set up—a Foreign Trade Bank, an Investment Bank, and an Agricultural Bank.

The banking reforms of 1965 in Yugoslavia

These continued to operate until the reforms of 1965, when the National Bank was given the power to regulate the commercial banks (formerly the federal government banks and the communal banks) by varying their reserve requirements, limiting the amounts they could borrow from it, and sometimes imposing a ceiling on commercial bank lending. The National Bank was also empowered to vary the special credits granted to the commercial banks, used to finance about half the short-term credits extended by the commercial banks to their customers. Three types of bank credit were contemplated: investment, commercial, and consumer. Investment banks were established to finance the capital requirements of enterprises; commercial banks to provide short-term credit; "mixed banks" that served as both investment and commercial banks; and savings banks. In principle, all banks could operate throughout the country. These changes were followed by a marked concentration of banking: in November 1964 there had been 217 banks (206 communal banks, eight republican investment banks, and the three specialized federal banks); by June 1967 there were only 111 banks (61 commercial banks, 39 "mixed banks," and 11 investment banks), and by the end of 1968, the number of banks had been further reduced to 74.

The biggest change, however, was in the organization and operation of the banks. Banks were now established by enterprises in partnership with sociopolitical communities (federal, republican, and local). Each bank had its own capital, or "credit fund." The founders invested their capital in the credit fund of the bank and became shareholders. No single shareholder was entitled to more than

10 percent of the total number of votes in a bank's assembly of shareholders (which also contained representatives of the bank's personnel). No enterprise or sociopolitical community could be refused the right to invest in a bank and to take part in its management. Shareholders were entitled to dividends, depending on profitability, but these tended to be invested in the bank as new capital. Management was placed in the hands of an executive committee appointed by the assembly of shareholders.

The decentralization of the banking system was offset to some extent by mergers, some of which produced several very large banks. A number of banks entered into agreements with foreign banks as a means of encouraging greater foreign participation in the Yugoslav economy. In the field of banking, as in economic affairs generally, the Yugoslavs were prepared to experiment on a broad scale.

III. The business of banking

The business of banking consists of borrowing and lending. As in other businesses, operations must be based on capital, but banks employ comparatively little of their own capital in relation to the total volume of their transactions. The purpose of capital and reserve accounts is primarily to provide an ultimate cover against losses on loans and investments. In the United States capital accounts also have a legal significance, since the laws limit the proportion of its capital a bank may lend to a single borrower.

FUNCTIONS OF COMMERCIAL BANKS

The balance sheet

The essential characteristics of the banking business may be described within the framework of a simplified balance sheet. A bank's main liabilities are its capital (including reserves) and deposits. The latter may be from domestic or foreign sources (corporations and firms, private individuals, other banks, and even governments). They may be repayable on demand (sight deposits or current accounts) or repayable only after the lapse of a period of time (time, term, or fixed deposits and, occasionally, savings deposits). A bank's assets include cash (which may be held in the form of credit balances with other banks, usually with a central bank but also, in varying degrees, with correspondent banks); liquid assets (money at call and short notice, day-to-day money, short-term government paper such as treasury bills and notes, and commercial bills of exchange, all of which can be converted readily into cash without risk of substantial loss); investments or securities (substantially medium-term and longer term government securities—sometimes including those of local authorities such as states, provinces, or municipalities—and, in certain countries, participations and shares in industrial concerns); loans and advances made to customers of all kinds, though primarily to trade and industry (in an increasing number of countries, these include term loans and also mortgage loans); and, finally, the bank's premises, furniture, and fittings (written down, as a rule, to quite nominal figures).

All bank balance sheets must include an item that relates to contingent liabilities (*e.g.*, bills of exchange "accepted" or endorsed by the bank), exactly balanced by an item on the other side of the balance sheet representing the customer's obligation to indemnify the bank (which may also be supported by a form of security taken by the bank over its customer's assets). Most banks of any size stand prepared to provide acceptance credits (also called bankers' acceptances); when a bank accepts a bill, it lends its name and reputation to the transaction in question and, in this way, ensures that the paper will be more readily discounted.

Deposits. The bulk of the resources employed by a modern bank consists of borrowed money (that is, deposits), which is lent out as profitably as is consistent with safety. Insofar as an increase in deposits provides a bank with additional cash (which is an asset), the increase in cash supplements its loanable resources and permits a more than proportionate increase in its loans.

An increase in deposits may arise in two ways. (1) When a bank makes a loan, it may transfer the sum to a current account, thus directly creating a new deposit; or it may arrange a line of credit for the borrower upon which he will be permitted to draw checks, which, when deposited by third parties, likewise create new deposits. (2) An enlargement of government expenditure financed by the central bank may occasion a growth in deposits, since claims on the government that are equivalent to cash will be paid into the commercial banks as deposits. In the first instance, with the increase in bank deposits goes a related increase in the potential liability to pay out cash; in the second case, the increase in deposits with the commercial banks is accompanied by a corresponding increase in commercial bank holdings of money claims that are equivalent to cash.

The way in which deposits may be increased

Taking one bank in isolation, an increase in its loans may result in a direct increase in deposits. This may occur either as a result of a transfer to a current account (as above) or a transfer to another customer of the same bank. Once again, there is an increase in the potential liability to pay out cash. On the other hand, if there has been an increase in loans by another bank (including an increase in central bank loans to the government), this may give rise to increased deposits with the first bank, matched by a corresponding claim to cash (or its equivalent). For these reasons a bank can generally expect that, if there is an increase in deposits, there will also be some net acquisition of cash or of claims for receipt of cash. It is in this way that an increase in deposits usually provides the basis for further bank lending.

Except in countries where banks are small and insecure, banks as a whole can usually depend on their current account debits being largely offset by credits to current account, though from time to time an individual bank may experience marked fluctuations in its deposit totals, and all banks in a country may be subject to seasonal variations. Even when deposits are repayable on demand, there is usually a degree of inertia in the deposit structure that prevents sharp fluctuations; if money is accepted contractually for a fixed term or if notice must be given before its repayment, this inertia will be greater. On the other hand, if a significant proportion of total deposits derives from foreign sources, there is likely to be an element of volatility arising from international conditions.

In banking, confidence on the part of the depositors is the true basis of stability. Confidence is steadier if there exists a central bank to act as a "lender of last resort." Another means of maintaining confidence employed in some countries is deposit insurance, which protects the small depositor against loss in the event of a bank failure. Such protection was the declared purpose of the "nationalization" of bank deposits in Argentina between 1946 and 1957; banks receiving deposits acted merely as agents of the government-owned and government-controlled central bank, all deposits being guaranteed by the state.

Maintaining liquidity

Reserves. Since the banker undertakes to provide his depositors with cash on demand or upon prior notice, he must hold a cash reserve and maintain a "safe" ratio of cash to deposits. The safe ratio is determined largely through experience. It may be established by convention (as it was for many years in England) or by statute (as in the United States and elsewhere). If a minimum cash ratio is required by law, a portion of a bank's assets is in effect frozen and not available to meet sudden demands for cash from the bank's customers. In order to provide more flexibility, required ratios are frequently based on the average of cash holdings over a specified period, such as a week or a month. In addition to holding part of his assets in cash, a banker will hold a proportion of the remainder in assets that can quickly be converted into cash without significant loss. No banker can safely ignore the necessity of maintaining adequate reserves of liquid assets; some prefer to limit the sum of loans and investments to a certain percentage of deposits (*e.g.*, 70 percent), not allowing their loan–deposit ratio to run for any length of time at too high a level.

Unless a bank holds cash covering 100 percent of its demand deposits it could not meet the claims of depositors if they were all to exercise in full and at the same time their rights to demand cash. If that were a common phe-

nomenon, deposit banking could not long survive. For the most part, the public is prepared to leave its surplus funds on deposit with the banks, confident that they will be repaid if needed. But there may be times when unexpected demands for cash exceed what might reasonably have been anticipated; therefore, a bank must not only hold part of its assets in cash but also must keep a proportion of the remainder in assets that can be quickly converted into cash without significant loss. Indeed, in theory, even its less liquid assets should be self-liquidating within a reasonable time.

A bank may mobilize its assets in several ways. It may demand repayment of loans, immediately or at short notice; it may sell securities; or it may borrow from the central bank, using paper representing investments or loans as security. Banks do not precipitately call in loans or sell marketable assets because this would disrupt the delicate debtor–creditor relationships and increase any loss of confidence, probably resulting in a run on the banks. Ready cash may be obtainable in this way only at a very high price. Banks must either maintain their cash reserves and other liquid assets at a high level or have access to a "lender of last resort," such as a central bank, able and willing to provide cash against the security of eligible assets. In some countries the commercial banks have at times been required to maintain a minimum liquid assets ratio. This has been common, for example, in some of the western European countries, in England, Australia, Canada, and in several of the new African countries. But central banks impose such requirements less as a means of maintaining appropriate levels of commercial bank liquidity than as a technique for influencing directly the lending potential of the banks (see below).

Kinds of assets of commercial banks

Among the assets of commercial banks, investments are less liquid than money-market assets such as call money and treasury bills. By maintaining an appropriate spread of maturities, however, it is possible to ensure that a proportion of a bank's investments is regularly approaching redemption, thereby producing a steady flow of liquidity and in that way constituting a secondary liquid assets reserve. Some banks, particularly in the United States and Canada, favour a "dumbbell" distribution of maturities, a significant proportion of the total portfolio being held in long-dated maturities with a high yield, a small proportion in the middle ranges, and another significant proportion in short-dated maturities. Following redemption, the banks usually reinvest all or most of the proceeds in longer term maturities that in due course become increasingly short-term. Investments and money-market assets merge into each other. The dividing line is arbitrary, but there is an essential difference: the liquidity of investments depends primarily on marketability (though sometimes it also depends on the readiness of the government or its agent to exchange its own securities for cash); the liquidity of money-market assets, on the other hand, depends partly on marketability but mainly on the willingness of the central bank to purchase them or accept them as collateral for a loan. This is why money-market assets are more liquid than investments.

INDUSTRIAL FINANCE

Long-term and medium-term lending. Banks that do a great deal of long-term lending to industry must ensure their liquidity by maintaining relatively large capital funds and a relatively high proportion of time deposits, as well as valuing their investments very conservatively. Such banks, notably the French *banques d'affaires* and the West German commercial banks, have developed special means of reducing their degree of risk. Every investment is preceded by a thorough technical and financial investigation. The initial advance may be an interim credit, later converted into a participation. Only when market conditions are favourable is the original investment converted into marketable securities, and an issue of shares to the public is arranged. One function of these banks is to nurse an investment along until the venture is well established. Even assuming its ultimate success, a bank may be obliged to hold such shares for long periods before being able to liquidate them. In addition, they often retain an interest in a firm as an ordinary investment as well as to ensure a degree of continuing control over it.

The long-term provision of industrial finance in Britain and the Commonwealth countries is usually handled by specialist institutions, with the commercial banks providing only part of the necessary capital. In Japan, the long-term financial needs of industry are met partly by special industrial banks (which also issue debentures as well as accepting deposits) and partly by the ordinary commercial banks. In West Germany the commercial banks customarily handle long-term finance.

Term loans

Since World War II, the commercial banks in the United States have developed the so-called term loan, especially for financing industrial capital requirements. The attempt to popularize the term loan began in the economic depression of the 1930s, when the banks tried to expand their business by offering finance for a period of years. Most term loans have an effective maturity of little more than five years, though some run for 10 years or more. They are usually arranged between the customer and a group of lending banks, sometimes in cooperation with other institutions such as insurance companies. Banks in other countries, including Britain and Australia, began during the 1960s to give term loans both to industry and to agriculture.

Short-term lending. Short-term loans are the core of the banking business even in countries where commercial banks make long-term loans to industry. Much short-term lending consists in the provision of working capital, but the banks also provide temporary finance for fixed capital development, aiding a customer until he can find long-term finance elsewhere.

Overdrafts

Much of this short-term lending is done by overdraft, particularly in Britain and a number of the Commonwealth countries, in The Netherlands and Norway, and—on the basis of somewhat similar arrangements—in Austria, Denmark, and Switzerland. The overdraft permits a depositor to overdraw his account up to an agreed limit. In theory, overdrafts are repayable on demand or after reasonable notice has been given, but often they are allowed to run indefinitely, subject to a periodic review. An advance is reduced or repaid whenever the account is credited with deposits and recreated when new cheques are drawn upon it, interest being paid only on the amount outstanding.

An alternative method of short-term lending is to debit a loan account with the amount borrowed, crediting the proceeds to a current account; interest is usually payable on the whole amount of the loan, which normally is for a fixed period of time. (In Britain arrangements are sometimes more flexible, and the term of the loan may be set by oral agreement.)

Discountable paper

In some countries, including the United States, France, West Germany, and Japan, short-term finance is often made available on the basis of discountable paper—commercial bills or promissory notes. Some of this paper is usually rediscountable at the central bank, thus becoming virtually a liquid asset, unlike a bank advance or loan.

Credit may be offered with or without formal security, depending on the reputation and financial strength of the borrower. In many countries a customer may use a number of banks, and these institutions usually freely exchange information about joint credit risks. In Britain and The Netherlands, however, most concerns tend to use a single banking institution for most of their needs.

Liability management

Traditionally bankers took the view that the liabilities of a bank (and, in particular, its deposits) were more or less stable and concerned themselves primarily with the investment of these funds. In recent years, however, especially in North America, there has been a change of emphasis. During the late 1950s and 1960s the banks found it more difficult to obtain deposits. Interest rates rose to high levels, and banks were obliged to compete with each other and with other institutions for funds. At the same time, there was little point in paying a high rate of interest for money unless it could be employed profitably. Bankers began to relate the cost of borrowed money directly to the return on investments. Previously the main limitation on a bank's expansion had been its

ability to find profitable new business, but now the determining factor became the availability of funds to lend out. The essence of liability management, as it came to be called, was deciding what kinds of new money to buy and what to pay for it. There was an incentive to borrow at longer term or to borrow money in forms that were less volatile than demand deposits had become: savings deposits, time deposits (including certificates of deposit, which could be sold by the lender to someone else if he wanted his funds before they matured), federal funds in the United States (entitlements to balances at a Federal Reserve Bank, the excess supplies of which were regularly traded throughout the United States), and even Eurodollars (entitlements to dollar balances usually held outside the United States, chiefly in Europe). In short, if loan demand was strong and the business likely to be profitable, the banks would seek to buy new money to meet these demands. To some extent banks tended to relate the periods for which money was borrowed to the periods for which it was to be lent. Since large banks generally found it easier to obtain money, they tended to become larger; the smaller banks, on the other hand, felt more directly than larger institutions the impact of central bank restrictions, which they could not so easily circumvent.

IV. The principles of central banking

The need for a central bank

The principles of central banking grew up in response to the recurrent British financial crises of the 19th century and were later adopted in other countries. Modern market economies are subject to frequent fluctuations in output and employment. Although the causes of these fluctuations are various, there is general agreement that the ability of banks to create new money may exacerbate them. Although an individual bank may be cautious enough in maintaining its own liquidity position, the expansion or contraction of the money supply to which it contributes may be excessive. This raises the need for a disinterested outside authority able to view economic and financial developments objectively and to exert some measure of control over the activities of the banks. A central bank should also be capable of acting to offset forces originating outside the economy, although this is much more difficult.

RESPONSIBILITIES OF CENTRAL BANKS

The first concern of a central bank is the maintenance of a soundly based commercial banking structure. While this concern has grown to comprehend the operations of all financial institutions, including the several groups of nonbank financial intermediaries, the commercial banks remain the core of the banking system. A central bank must also cooperate closely with the national government. Indeed, most governments and central banks have become intimately associated in the formulation of policy.

The central bank as "lender of the last resort"

Relationships with commercial banks. One source of economic instability is the supply of money. Even in relatively well controlled banking systems, banks have sometimes expanded credit to such an extent that inflationary pressures developed. Such an overexpansion in bank lending would be followed almost inevitably by a period of undue caution in the making of loans. Frequently the turning point was associated with a financial crisis, and bank failures were not uncommon. Even today, failures occur from time to time. Such crises in the past often threatened the existence of financial institutions that were essentially sound, and the authorities sometimes intervened to prevent complete collapse.

The willingness of a central bank to offer support to the commercial banks and other financial institutions in time of crisis was greatly encouraged by the gradual disappearance of weaker institutions and a general improvement in bank management. The dangers of excessive lending came to be more fully appreciated, and the banks also became more experienced in the evaluation of risks. In some cases, the central bank itself has gone out of its way to educate commercial banks in the canons of sound finance. In the United States, the Federal Reserve System examines the books of the commercial banks and carries on a range of frankly educational activities. In developing countries such as India and Pakistan, central banks have also set up departments to maintain a regular scrutiny of commercial bank operations.

The most obvious danger to the banks is a sudden and overwhelming run on their cash resources in consequence of their liability to depositors to pay on demand. In the ordinary course of business, the demand for cash is fairly constant or subject to seasonal fluctuations that can be foreseen. It has become the responsibility of the central bank to protect banks that have been honestly and competently managed from the consequences of a sudden and unexpected demand for cash. In other words, the central bank came to act as the "lender of last resort." To do this effectively, it was necessary that the central bank be permitted either to buy the assets of commercial banks or to make advances against them. It was also necessary that the central bank have the power to issue money acceptable to bank depositors. But if a central bank was to play this role with respect to commercial banks, it was only reasonable that it or some related authority be allowed to exercise a degree of control over the way in which the banks conducted their business.

Role of central banks in the banking system

Most central banks now take a continuing day-to-day part in the operations of the banking system. The Bank of England, for example, has been increasingly in the market to assure that the banks have a steady supply of cash, even during periods of credit restriction. It also lends regularly to the discount houses, supplementing their resources whenever the commercial banks feel the need to call back money they have on loan to them. In the United States the Federal Reserve System has operated in a similar way by buying and selling securities on the open market and by lending to dealers in government securities on the basis of repurchase agreements. The Federal Reserve may also discount paper submitted by the commercial banks through the Federal Reserve banks. The various techniques of credit control used in the United States, Great Britain, and other countries are discussed in greater detail below.

The evolution of those working relations among banks implies a community of outlook that in some countries is relatively recent. The whole concept of a central bank as responsible for the stability of the banking system presupposes mutual confidence and cooperation. For this reason, contact between the central bank and the commercial banks must be close and continuous. The latter must be encouraged to feel that the central bank will give careful consideration to their views on matters of common concern. Once the central bank has formulated its policy after a full consideration of the facts and of the views expressed, however, the commercial banks must be prepared to accept its leadership. Otherwise, the whole basis of central banking would be undermined.

The central bank and the national economy. *Relationships with other countries.* Since no modern economy is self-contained, central banks must give considerable attention to trading and financial relationships with other countries. If goods are bought abroad, there is a demand for foreign currency to pay for them. Alternatively, if goods are sold abroad, foreign currency is acquired that the seller ordinarily wishes to convert into his own currency. These two sets of transactions usually pass through the banking system, but there is no necessary reason why, over the short period, they should balance. Sometimes there is a surplus of purchases and sometimes a surplus of sales. Short-period disequilibrium is not likely to matter very much, but it is rather important that there be a tendency to balance over a longer period, since it is difficult for a country to continue indefinitely as a permanent borrower or to continue building up a command over goods and services that it does not exercise.

Maintaining the balance of foreign payments

Short-period disequilibrium can be met very simply by diminishing or building up balances of foreign exchange. If a country has no balances to diminish, it may borrow, but normally it at least carries working balances. If the commercial banks find it unprofitable to hold such balances, the central bank is available to carry them; indeed,

it may insist on concentrating the bulk of the country's foreign-exchange resources in its hands or in those of an associated agency.

Long-period equilibrium is more difficult to achieve. It may be approached in three different ways: price movements, exchange revaluation (appreciation or depreciation of the currency), or exchange controls.

Price levels may be influenced by expansion or contraction in the supply of bank credit. If the monetary authorities wish to stimulate imports, for example, they can induce a relative rise in home prices by encouraging an expansion of credit. If additional exports are necessary in order to achieve a more balanced position, the authorities can attempt to force down costs at home by operating to restrict credit.

The objective may be achieved more directly by revaluing a country's exchange rate. Depending on the circumstances, the rate may be appreciated or depreciated, or it may be allowed to "float." Appreciation means that the home currency becomes more valuable in terms of the currencies of other countries and that exports consequently become more expensive for foreigners to buy. Depreciation involves a cheapening of the home currency, thus lowering the prices of export goods in the world's markets. In both cases, however, the effects are likely to be only temporary, and for this reason the authorities often prefer stability in exchange rates even at the cost of some fluctuation in internal prices.

Quite often governments have resorted to exchange controls (sometimes combined with import licensing) to allocate foreign exchange more or less directly in payment for specific imports. At times, a considerable apparatus has been assembled for this purpose and, despite "leakages" of various kinds, the system has proved reasonably efficient in achieving balance on external payments account. Its chief disadvantage is that it interferes with normal market processes, thereby encouraging rigidities in the economy, reinforcing vested interests, and restricting the growth of world trade.

Whatever method chosen, the process of adjustment is generally supervised by some central authority—the central bank or some institution closely associated with it—which can assemble the information necessary to ensure that the proper responses are made to changing conditions.

Moderating booms and slumps

Economic fluctuations. As noted above, monetary influences may be an important contributory factor in economic fluctuations. An expansion in bank credit makes possible, if it does not cause, the relative overexpansion of investment activity characteristic of a boom. Insofar as monetary policy can assist in mitigating the worst excesses of the boom, it is the responsibility of the central bank to regulate the amount of lending by banks and perhaps by other financial institutions as well. The central bank may even wish to influence in some degree the direction of lending as well as the amount.

An even greater responsibility of the central bank is that of taking measures to prevent or overcome a slump. Recessions, when they occur, are often in the nature of adjustments to eliminate the effects of previous overexpansion. Such adjustments are necessary to restore economic health, but at times they have tended to go too far; depressive factors have been reinforced by a general lack of confidence, and, once this has happened, it has proved extremely difficult to stimulate recovery. In these circumstances, prevention is likely to be far easier than cure. It has therefore become a recognized function of the central bank to take steps to preclude, if possible, any such general deterioration in economic activity.

For the central bank to be effective in regulating the volume and distribution of credit so that economic fluctuations may be damped, if not eliminated, it must at least be able to regulate commercial bank liquidity (the supply of cash and "near cash") because this is the basis of bank lending. There is now little dispute about the broad objectives, though the techniques of control are various and depend to some extent on environmental factors. It would be incorrect to suppose, however, that the actions of the central bank can, unaided, achieve a high degree of stability. It can by wise guidance contribute to that end, but monetary action is in no sense a panacea; at all times, the degree to which it is likely to be effective depends on the provision of an appropriate fiscal environment (see FISCAL AND MONETARY POLICY).

Developing the banking system

Banking services. Another responsibility of the central bank is to ensure that banking services are adequately supplied to all members of the community that need them. Some areas of a country may be "under-banked" (*e.g.*, the rural areas of India and the northern and more remote parts of Norway), and central banks have attempted, directly or indirectly, to meet such needs. In France, this need underlay the early extension of branches of the Bank of France to the *départements*. In India, as noted above, the authorities encouraged the opening of "pioneer" branches by the former Imperial Bank of India and its successor, the State Bank of India, as well as the extension of bank branches to rural and semirural areas. In Pakistan, officials of the State Bank of Pakistan played an active part in the foundation of the semipublic National Bank of Pakistan.

A different sort of problem arises when the business methods of existing banks are unsatisfactory. In such circumstances, a system of bank inspection and audit organized by the central banking authorities (as in India and Pakistan) or of bank "examinations" (as in the United States) may be the appropriate answer. Alternatively, the supervision of bank operations may be handed over to a separate authority, such as France's Banking Control Commission or South Africa's Registrar of Banks.

In developing countries, central banks may undertake to encourage the establishment and growth of specialist institutions such as savings institutions and agricultural credit or industrial finance corporations. These serve to improve the mechanism for tapping existing liquid resources and to supplement the flow of funds for investment in specific fields.

The central bank as a public institution

Responsibilities to the government. Central banks have over the years acquired a number of well-defined responsibilities to their respective national governments. Some, notably the Bank of England, developed into central banks after being, in origin, bankers to the government. More recently it has become a matter of course for a new central bank to accept responsibility for the financial affairs of its government. The reasons are self-evident. Government transactions have become of increasing importance in influencing the workings of the economy, and the institution that holds the government's account is in a strategic position to cushion the commercial banks against the impact of large movements of cash originating in this way. As banker to the government, furthermore, the central bank has an obvious responsibility to provide routine banking services, such as arranging loan flotations and supervising their service, renewal, and redemption. The central bank also usually issues the currency.

Equally important are its responsibilities as an adviser on the probable monetary consequences of any proposed action. In this role the central bank should scrutinize the government's proposals with a certain amount of objectivity and state its point of view with vigour. One may cite a now-famous dictum of Montagu Norman as governor of the Bank of England:

> I think it is of the utmost importance that the policy of the Bank and the policy of the Government should at all times be in harmony—in as complete harmony as possible. I look upon the Bank as having the unique right to offer advice and to press such advice even to the point of "nagging"; but always of course subject to the supreme authority of the Government.

Many central banks are now nationalized, reflecting the increasingly general recognition of the central bank as a servant, if not a creature, of the government. This is also, in a way, a final recognition of the central bank as a responsible public institution, whose function it is to serve the community as a whole, untrammelled by narrow dictates of profit and loss. Most central banks, nevertheless, make very handsome profits.

TECHNIQUES OF CREDIT CONTROL

Central banks have developed a variety of techniques for influencing, regulating, and controlling the activities of commercial banks. These may be divided into (1) the so-called classical, or indirect, techniques and (2) various "direct" controls. The classical techniques make use of open-market purchases or sales by the central bank of certain types of assets, invariably associated with changes in interest rates. Direct or quantitative credit controls are used to influence the cash and liquidity bases of commercial bank lending by freezing or unfreezing their liquid resources; sometimes ceilings are imposed on bank loans.

Purchases and sales of securities by the central bank

Open-market operations. The way in which open-market operations influence the cash reserves and, through them, the general liquidity of the commercial banks is essentially simple. If the central bank buys securities in the open market, the cash it offers in exchange adds to the reserves of the banks; if the central bank sells securities in the open market, the cash necessary to pay for them is either withdrawn from the banks' reserves or obtained by diminishing holdings of other assets (with the possibility of capital losses in consequence of these sales). It does not matter whether this buying and selling takes place between the central bank and the commercial banks directly or between the central bank and other financial sectors, including the public at large, since these are the customers of the commercial banks.

Open-market operations are invariably associated with related changes in one or more "strategic" rates of interest, the most influential of these rates being the minimum rate at which the central bank does business (the bank rate, or the discount rate), since other rates tend to move in sympathy with it. The central bank seeks to achieve an appropriate and consistent structure of interest rates. If a particular rate structure is desired (*e.g.*, prior to a new issue of government securities or in order to change the emphasis of institutional investment between, say, long-term and short-term securities), it may be necessary to precondition the market by means of open-market operations. To achieve its purposes the central bank must possess (if it is selling) or be willing to absorb (if it is buying) the appropriate types of securities.

In London, the specialist banks known as discount houses effectively put to work the revolving fund of cash that circulates through the British banking system. If temporarily there is an inadequate supply of cash, the Bank of England either lends on a short-term basis or buys some of the assets held by the discount market. Alternatively, the Bank of England may buy assets from the clearing banks (the large joint-stock banks), which then make the relevant moneys available to the market. On the other hand, if the discount market is oversupplied with funds, the Bank of England sells treasury bills, in this way mopping up the excess of cash. These transactions are known as smoothing-out operations.

Not all Bank of England transactions in securities are in treasury bills. Even for smoothing-out purposes, first-class acceptances and government bonds with a maximum maturity date of not more than five years are eligible. In addition, the Bank of England is also responsible for managing the national debt, and, whether the object is to influence the flows of money or not, such transactions in fact have monetary effects.

The Open Market Committee of the Federal Reserve

In the United States the Federal Reserve System regulates the money supply. Within the Federal Reserve System, the Federal Open Market Committee is the most important single policy-making body. It is presided over by the chairman of the Board of Governors, with the president of the Federal Reserve Bank of New York as its permanent vice chairman. The main responsibility of the Open Market Committee is to decide upon the timing and amount of open-market purchases or sales of government securities. Since open-market operations must obviously be consistent with other aspects of monetary and credit policy, it is in the committee that broad agreement is reached on matters such as changes in discount rates or reserve requirements.

One of the big differences between London and New York is that the central banking authorities in New York maintain direct relationships more or less continuously with the nonbank government securities dealers as well as with the commercial banks. The Federal Reserve Bank of New York may make temporary accommodation available to nonbank dealers under a repurchase agreement, whereby securities are sold to the bank under an agreement that they be repurchased after a stipulated time. These agreements are made only for the purpose of supplying reserves to the banking system, but from the dealer's standpoint they are helpful in financing portfolios. Since early 1966, the bank has also been prepared to mop up money by undertaking reverse repurchase agreements, in which the nonbank dealers act as intermediaries for large commercial banks with temporarily surplus money that they are prepared to place against bills, subject to the bank's repurchasing them a few days later; the commercial bank concerned lends the dealer the money to finance the holding of the bill. Similar arrangements are also made by the Federal Reserve directly with bank dealers.

All member banks of the Federal Reserve System have direct access to the discount service of their Federal Reserve Bank, of which there is one in each of 12 districts. This is a privilege, however, and not a right. In the early years of the system the banks would sell discountable paper to the Federal Reserve, but now they usually borrow against a pledge of government securities held in safe custody with the Federal Reserve Bank in question. The Federal Reserve lends for a number of purposes but always at a time of general stress. It is assumed that, as the pressure abates, borrowing banks will repay their indebtedness as quickly as possible. Under ordinary conditions, the continuous use of Federal Reserve credit by a member bank over a considerable period is not regarded as appropriate.

In the latter half of the 1960s, the Federal Reserve subjected its discount arrangements to an intensive three-year scrutiny and decided to make them more flexible. Open-market operations were to remain the main tool of monetary policy, but the proposed changes in discount operations were expected to lead to a generally higher level of borrowing by the commercial banks. This higher level of borrowing would not mean a corresponding increase in total reserves, since the increased borrowing would tend to be offset by correspondingly smaller Federal Reserve purchases of securities in the open market.

Direct controls. The so-called classical techniques of credit control—open-market operations and discount policy—can only be employed where there is a sufficiently developed complex of markets in which to buy and sell assets of the type that commercial banks ordinarily hold. Direct credit controls have a wider range of application. They may be used either as a substitute for the classical techniques or as a supplement to them. Direct controls are more likely to be resorted to when the money market is undeveloped, because then a central bank can only impose its authority by means of direct action. This is often the situation facing a newly established central bank. Rather than wait for the slow evolution of a money market, the authorities may provide the central bank from the start (as in Pakistan, the Philippines, Sri Lanka [formerly Ceylon], and Malaysia) with very full powers to control the banking system.

The aim in imposing a direct, quantitative regulation of credit is to curb inflationary pressures that may result from an expansion of commercial bank lending. This can be done in four main ways: (1) the commercial banks may be required to maintain stated minimum reserve ratios of cash to deposits, a stated liquid assets ratio, or some combination of both; (2) part of the cash resources of the commercial banks may be immobilized at the discretion of the central bank; (3) ceilings may be imposed on the amount of accommodation to be made available to the commercial banks at the central bank (sometimes referred to as "discount quotas"); and (4) a ceiling may be prescribed for commercial bank lending itself.

Variations in reserves

Minimum reserve requirements. The variation of minimum cash reserve requirements as a direct means of

quantitative credit control has become increasingly general in recent years. The practice has largely derived from experience in the United States. In its origin the U.S. insistence on stated minimum reserve requirements for commercial banks was simply a means of prescribing minimum standards of sound behaviour. Only later did such ratios come to be seen as a useful supplementary quantitative credit control. The history has been similar elsewhere (as in India and New Zealand).

The power granted by the Banking Act of 1935 to the Federal Reserve System to vary the cash reserves of the commercial banks in the United States was employed for the first time during the boom of 1936–37, and periodic variation of minimum reserve requirements subsequently came to be recognized as an appropriate technique for controlling the money supply. The Federal Reserve Board's decisions were sometimes subject to considerable criticism, but, as it became more experienced in the use of this technique, variation in reserve requirements combined with other measures came to be regarded as a useful means of cushioning the economy against a recession. The variation of reserve requirements did not prove as effective in preventing inflation, largely because of the government's insistence that the Federal Reserve simultaneously support the prices of government bonds through open-market operations. This insistence was abandoned after an "accord" between the Treasury and the Federal Reserve Board in March 1951. Since then, much greater emphasis has been placed on the use of open-market operations, which had become more effective, and the variation of minimum reserve requirements as a means of controlling the credit base has diminished in the U.S. The technique is still widely used, however, in many countries.

In some countries the authorities require the maintenance of minimum liquid assets ratios. This is often combined with minimum requirements for cash reserves, as in India, Pakistan, and West Germany, though not always (in France, for example, until 1967 there were no minimum cash reserve requirements). Where prescribed minima relate to liquid assets and not to cash as such, reserves are held in the form of earning assets—an important distinction from the point of view of the commercial banks.

Cash ratios and special deposits in England

After 1946 the clearing banks in England (but not the Scottish banks) observed a more or less fixed cash ratio of 8 percent; the convention of a 30 percent minimum liquid assets ratio (of which the 8 percent was part) became officially recognized in 1955. It was lowered to 28 percent in 1963. A new element was introduced in 1960, when the Bank of England launched its system of "special deposits" as a means of reinforcing other methods of credit control. Calls were now made from time to time on the London clearing banks to deposit with the Bank of England by a specified date some specified percentage of their gross deposits; similar arrangements applied to the Scottish banks, but the calls were smaller. In 1971, however, a new system was introduced whereby the banks were required to keep a uniform minimum reserve ratio of 12.5 percent of their "eligible liabilities" (primarily sterling deposits of up to two years' maturity, including sterling certificates of deposit) and, when called upon to do so, to place special deposits with the Bank of England. The assets representing the 12.5 percent included balances with the Bank of England (other than special deposits), treasury bills, company tax reserve certificates, money at call with the London money market, local authority bills eligible for rediscount at the Bank of England, commercial bills, and government securities. They did not include cash in till. (Member banks in the United States were allowed to include "vault cash" in their minimum reserves after 1959.)

The use of variable minimum reserve requirements as a means of credit control can, if carried far enough, produce results, especially when the requirements include the holding of cash balances. It is more useful as an anti-inflationary weapon than as a means of countering recession, since it cannot overcome a possible unwillingness of the banks to lend or of their customers to borrow. It is a somewhat clumsy technique, however, and cannot make adequate allowance for the special needs of different institutions.

Immobilization of cash resources. A second group of direct quantitative credit controls involves keeping a portion of the cash resources of commercial banks immobilized at the discretion of the central bank. Two leading examples of this technique were the use of the Treasury Deposit Receipt (TDR) in Great Britain during and after World War II and the "special account procedure" adopted in Australia in 1941. Both were means of immobilizing the increased liquidity deriving from wartime government expenditure.

The direct issue of Treasury Deposit Receipts at a nominal rate of interest to banks in the United Kingdom began in July 1940. They were not negotiable in the market nor transferrable between banks, but they could be tendered in payment for government bonds (and tax certificates); hence, during the war years they had a limited degree of liquidity. The Bank of England communicated to the banks collectively the amount of the weekly call, which was divided among them in proportion to their deposits. After the war, TDR's were replaced by treasury bills; in order to reduce the consequent high liquidity of the banks, there was a "forced funding" of £1,000,000,000 of treasury bills in November 1951, which were required to be invested in Serial Funding Stocks.

Special accounts in Australia

The special account procedure introduced in Australia in 1941 had a similar objective. The surplus investable funds of the Australian trading banks, defined as the amount by which each bank's total assets in Australia at any time exceeded the average of its total assets in Australia in August 1939, were required to be placed in special deposit accounts with the Commonwealth Bank (then the central bank) at a nominal rate of interest. A bank was not to withdraw any sum from its special account except with the consent of the Commonwealth Bank; during the war years, the bank generally directed the trading banks to lodge in their special accounts each month an amount equal to the increase in their total assets in Australia during the preceding month, although as a rule a lodgment was not required if it was known that a rise in assets would be followed by an early fall. Legislation in 1945 adopted the special account procedures as a means of general credit control (*e.g.*, to curb inflation), but the provisions were made more flexible. In 1953 a more complicated formula was introduced, and in 1960 the system was abandoned in favour of minimum reserve ratios.

Accommodation ceilings. Some countries have tried placing a limit on the amount of accommodation that the central bank may make available to the commercial banks. The difficulty in this type of quantitative credit control is to make it effective while at the same time allowing for changes in the economy; its most obvious use is as a means of checking inflation, but if the upward pressures on prices are strong, there is a temptation to increase the ceilings so that the restraint then becomes little more than a temporary check.

Usually, it is only when a control begins to be felt and to affect bank profits that the banks become really sensitive to changes in credit policy and the implementation of the control becomes truly effective. The postwar experience of France is a case in point. *Plafonds*, or "ceilings," were first introduced in France in 1948. Rediscount ceilings (or discount quotas) were fixed for each bank, though some categories of paper were excluded. Ceilings could be increased or (after 1957) reduced.

The French *plafonds*

From the authorities' point of view, the chief difficulty in operating this control was the persistent building up of pressure against the ceilings. This was met partly by upward revisions in the ceilings themselves and partly by instituting a number of safety valves. The degree of elasticity required constituted the chief weakness of the ceiling technique. The central bank was constantly under pressure to adjust the ceilings upward. Some upward revisions were unavoidable, but the problem was to decide which claims were legitimate and which not. Much bilateral bargaining took place between the Bank of France

and individual commercial banks, but the banks continued to complain that the strictness of the control was excessive and that the technique lacked flexibility.

The inadequacies of the *plafonds* technique in its original form became apparent when prices began to rise rapidly during the Korean War boom, and even the built-in safety valves failed fully to accommodate the pressures on bank liquidity. The need to strengthen the mechanism was obvious, and this was attempted in 1951. Previously, rediscounts had frequently exceeded the ceilings during the course of the month and were only brought within the *plafonds* by special action (*e.g.*, by purchase through the open market). The situation was brought under control by introducing a secondary ceiling to which a penalty rate of interest was applied. This was extended in 1958 to permit rediscounts even beyond the secondary ceiling, provided a further penalty was paid; each application, however, was scrutinized by the Bank of France. The system lasted until about the spring of 1964, though it did not finally disappear until 1968, when it was largely replaced by Bank of France operations in the open market. After early 1967, the banks were also subject to minimum reserve requirements.

Plafonds have also been employed in West Germany. They were introduced in 1952 and greatly strengthened in 1955. Quotas may be reduced from time to time (after 1964 they were also used to discourage institutions from borrowing abroad). Again there were safety valves (although less generous than in France) and the possibility of extra accommodation (Lombard credits) at a higher rate. In certain circumstances, supplementary quotas might be approved for periods of up to six months. A bank might also raise funds through the money market, though very likely at higher cost.

General ceilings on credit. Attempts have been made to prescribe a general ceiling within which the quantity of commercial bank lending must be held. This is even more difficult to achieve. One example of an attempt to place a ceiling on bank loans was the adoption of a "rising ceiling" by Chile in 1953. All banks were required not to expand the volume of their loans to businesses and individuals by more than 1.5 percent a month, using as their basis the average of a bank's advances on selected dates in 1953. Certain types of loans were forbidden, and bank resources were to be directed to productive and distributive activities that really contributed to the expansion of the national economy. The banks were also placed under an obligation to provide information on the destination of their loans. In succeeding years, adjustments were made on several occasions in the maximum permitted credit increase, expressed either as a percentage of advances or sometimes simply as a total for the banking system as a whole. In 1959 all quantitative credit restrictions were removed and banks were permitted to advance funds up to their financial capacity, provided they operated within the general banking law. There was no evidence that the controls had been effective, but the major problem in Chile was budgetary rather than monetary. A temporary ceiling on loans was imposed by agreement in Canada in 1951–52; in The Netherlands in 1957–58; and in France in 1958–59.

Ceilings on bank advances in Britain

Great Britain has had the most experience with this type of ceiling, introducing it as a temporary measure in 1955, when the banks were asked to bring their advances down by an average of 10 percent. Later an attempt was made to impose a true ceiling, requiring that bank advances not exceed the average of the period October 1956 to September 1957. This ceiling was continued until July 1958. Again, in 1961, the authorities indicated that the banks must aim at checking the rate of rise in bank advances; this came to be interpreted as a request that the level of advances at the end of 1961 be no higher than in the previous June. The banks were also not to encourage an increase in the volume of commercial bills. The request was modified in May 1962 and largely withdrawn in October, but it was made again in May 1965, when the clearing banks were requested not to increase their advances to the private sector at an annual rate of more than about 5 percent in the 12 months to mid-March 1966 (likewise with commercial bills). Other financial institutions were requested to observe a comparable degree of restraint. For 12 months after March 1966, advances and discounts, allowing for seasonal factors, were not permitted to rise above the levels set for March 1966. This represented an intensification of the credit squeeze because prices were rising. The credit restriction led to a falling off in business confidence, and, consequently, toward the end of 1966 bank lending was well below the official ceiling. In April 1967 the authorities announced a change in techniques, with an emphasis on making calls to special deposits (see above), but the ceilings returned again in November 1967. There was to be no increase in bank advances to the private sector (excluding exports and shipbuilding) except for seasonal reasons. In May 1968 a new ceiling was instituted for all such lending (including that for exports and shipbuilding); the clearing banks were now asked to restrict the total of this lending, after seasonal adjustment, to 104 percent of the November 1967 figure, with priority to be given to finance for exports and for activities directly related to improving the balance of payments. The restrictions also extended to other types of credit. Credit became even tighter (in March 1969) when the ceiling was reduced to 98 percent of the November 1967 level. The banks experienced considerable difficulty in meeting this new requirement and agreed merely to "do their best." Advances increased above the ceiling, and as a penalty the interest paid by the Bank of England on special deposits was halved. Not until late autumn 1969 did it become clear that the authorities were prepared to abandon their long campaign to get bank loans down to the target figure. By 1971 the ceiling had been replaced by the new reserve requirements described above. The system of quantitative credit control requires, for its successful implementation, the full cooperation of the banking community. In the United Kingdom, where banks base much of their lending on the overdraft technique under which customers can overdraw their accounts up to prearranged limits, the system was very unpopular.

Selective controls on credit

In addition to regulating the quantity of credit, central banks have sometimes attempted to influence the directions in which the commercial banks lend. A loose system of control prevailed in the United Kingdom during World War II and afterward, based initially on directives from the Capital Issues Committee and later on requests from the Bank of England. A highly formalized technique was employed in Australia during the war and earlier postwar years; detailed and specific instructions were given to the trading banks, marginal cases being referred to the central bank. The system of Voluntary Credit Restraint in the United States in 1951 was similar. The more formal controls seemed to be no more effective than the looser system employed in the United Kingdom.

Selective controls have been imposed on consumer installment finance in the United States and elsewhere (*e.g.*, by stipulating the percentage of deposit required and the length of the term over which repayments may be made). In the U.S., under the Securities Exchange Act of 1934, the Federal Reserve can vary the margins that purchasers of securities must pay in cash, thereby limiting the amount of credit available for this purpose.

Baptists

Baptists are Protestant Christians who share the basic beliefs of most Protestants and first received their name from their insistence on baptizing believers only and on Baptism by immersion only rather than by sprinkling or pouring. (This view is, however, shared by others who are not Baptists.) While Baptists do not constitute a single church or denominational structure, most of them adhere to a congregational form of church government. Some Baptists lay stress upon having no human founder, no human authority, and no human creed.

In the late 1960s there were nearly 28,000,000 Baptists in the world, with the vast majority of them concentrated in the United States, where they constitute the largest Protestant community. The 27 Baptist bodies in the United States have an inclusive total of 24,500,000 members. Of these, the large majority are included in four major conventions: the Southern Baptist Convention, with nearly 10,500,000 members; the National Baptist Convention, U.S.A., Inc., with 5,500,000 members; the National Baptist Convention of America, with over 2,500,000 members; and the American Baptist Convention, with nearly 1,500,000 members. The multiplicity of Baptist groups in the United States is accounted for in part by the 19th-century controversy over slavery, in part by racial and nationality differences, and in part by divergence of opinion on questions of doctrine and organization. Baptists also have a basic suspicion of super-congregational ecclesiastical organizations as valid expressions of the church.

Outside the United States, major Baptist communities are found in the U.S.S.R. (545,000 members), India (508,000), Brazil (243,000), Zaire (228,000), Burma (223,000), and Canada (177,000).

HISTORY

Origins. Some Baptists believe that there has been an unbroken succession of Baptist churches from the days of John the Baptist and the Apostles of Christ. Others trace their origin to the Anabaptist movement (16th-century radical Protestant movement) on the European continent. While differing in their estimate of the possible Anabaptist influence, most scholars agree that Baptists as an English-speaking denomination originated within 17th-century Puritanism (a church reform movement that attempted to "purify" the remaining vestiges of Roman Catholicism from the Church of England) as an offshoot of Congregationalism. There were two major currents in early Baptist life: the Particular Baptists adhered to the doctrine of a particular atonement—that Christ died only for an elect—and were strongly Calvinist (following the Reformation teachings of John Calvin) in orientation; the General Baptists held to the doctrine of a general atonement—that Christ died for all men and not only for an elect—and represented the more moderate Calvinism of Jacobus Arminius (a 17th-century Dutch theologian who advocated the priority of divine grace and free will).

Particular Baptists and General Baptists

The two currents were also distinguished by a difference in churchmanship related to their respective points of origin. The General Baptists emerged from among the English Separatists (see below), whereas the Particular Baptists had their roots in non-Separatist independency (see below). Both the Separatists and the non-Separatists were congregationalist. They shared the same convictions with regard to the nature and government of the church. They believed that church life should be ordered according to the pattern of the New Testament churches, and to them this meant that churches should be self-governing bodies composed of believers only.

The point at which they differed was with regard to their attitude toward the Church of England. The Separatists took what is commonly described as a sectarian position; they contended that the Church of England was a false church and insisted that the break with it must be complete and uncompromising. The non-Separatists, more ecumenical in spirit, sought to maintain some bond of unity among Christians. While they believed that it was necessary to separate themselves from the corruption of parish churches, they also believed that it would be a breach of Christian charity to refuse all forms of intercourse and fellowship with them. While many non-Separatists withdrew and established a worship of their own, they would not go so far as to assert that the parish churches were devoid of the marks of a true church.

Most scholars find no evidence of decisive influence having been exerted upon the English Baptists by the continental Anabaptists, but they acknowledge that the General Baptist wing of the English Baptists exhibits Anabaptist influence at several minor points.

Growth in England and abroad. Although the Particular Baptists were to represent the major continuing Baptist tradition, the General Baptists were first in the field. In 1608 religious persecution had induced a group of Lincolnshire Separatists to seek asylum in Holland. One contingent settled in Amsterdam with one John Smyth (or Smith) a Cambridge graduate, as their minister; another moved to Leiden under the leadership of one John Robinson. When the question of Baptism arose during a debate on the meaning of church membership, Smyth came to the conclusion that, if the Separatist contention that "the churches of the apostolic constitution consisted of saints only" was correct, then Baptism should be restricted to believers only. This, he contended, was the practice of the first New Testament churches, for he could find no scriptural support for the baptizing of infants. Smyth published his views in *The Character of the Beast* (1609) and in the same year proceeded to translate them into action by baptizing first himself and then 36 others who joined him in forming a Baptist Church. Shortly thereafter. Smyth became aware of the

The question of Baptism

existence of a Mennonite (Anabaptist) community in Amsterdam and began to question his procedure in baptizing himself. Such an act could be justified, he concluded, only if no true church existed from which a valid Baptism could be obtained. After some investigation, Smyth arrived at the conviction that the Mennonites did constitute a true church, and he recommended union with them. This was resisted by Thomas Helwys and other members of the group, who returned to England in 1611 or 1612 and established a Baptist Church in London. The parent group in Amsterdam soon disappeared.

The Particular Baptists stemmed from a non-Separatist church that was established in 1616 by Henry Jacob at Southwark across the Thames from London. In 1638 a number of its members withdrew under the leadership of John Spilsbury to form the first Particular Baptist Church.

The two decades from 1640 to 1660 constituted the great period of early Baptist growth, for the Baptist preachers found their great opportunity to win adherents around the campfires of the Puritan leader Oliver Cromwell's army. The greatest gains were made by the Particular Baptists, and the General Baptists actually suffered numerous defections to the Quakers. After the Restoration of the Stuarts in 1660, both groups were subjected to severe disabilities, being forced to go underground until the Act of Toleration of 1689—in which the idea of a comprehensive Church of England was abandoned and "Nonconformists" were permitted to have their own places of worship—granted them a measure of relief.

During the following decades, the vitality of the General Baptists was drained away by the inroads of skepticism, and their churches generally dwindled and died or became Unitarian. The Particular Baptists took an opposite course, retreating into a defensive, rigid hyper-Calvinism that prevented any effective evangelism.

Survival and expansion of Particular Baptists

Among the Particular Baptists in England, renewal came as a result of the influence of the Evangelical Revival, a new surge of growth initiated by the activity of the English Baptist clergymen Andrew Fuller, Robert Hall, and William Carey. Carey, in 1792, formed the English Baptist Missionary Society—the beginning of the modern foreign missionary movement in the English-speaking world—and became its first missionary to India. A New Connection General Baptist group, Wesleyan in theology, was formed in 1770, and a century later, in 1891, it united with the Particular Baptists to form the Baptist Union of Great Britain and Ireland.

By the end of the 19th century, Baptists, together with the other Nonconformist churches, were reaching the peak of their influence in Great Britain, numbering among their preachers several men with international reputations. Baptist influence was closely tied to the fortunes of the Liberal Party, of which the Baptist David Lloyd George was a conspicuous leader. After World War I, English Baptists began to decline in influence and numbers.

Baptist churches were first established in Australia (1831) and New Zealand (1854) by missionaries of the English Baptist Missionary Society. In Canada, Baptist beginnings date from the activity of one Ebenezer Moulton, a Baptist immigrant from Massachusetts who organized a church in Nova Scotia in 1763; Baptist work there, and in the 13 Atlantic seaboard colonies, was nurtured by the Philadelphia Baptist Association (see below). In Ontario, the earliest Baptist churches were formed by United Empire Loyalists who crossed the border following the American Revolution, while other churches were established by immigrant Baptists from Scotland and by missionaries from Vermont and New York. The Baptists of Canada are united in the Baptist Federation of Canada.

Development in the United States. Baptist churches in the English colonies of North America were largely indigenous in origin, being the product of the leftward movement that was occurring among the colonial Puritans at the same time as that in England. While some migrated to the new world as Baptists, it was more typical for Baptist views to be adopted after arrival in the colonies, as happened in the case of Henry Dunster, the first president of Harvard, and Roger Williams.

Colonial period. The first Baptist Church in the American colonies was established at Providence in 1639 by Roger Williams shortly after his banishment from the Massachusetts Bay Colony. While Williams' general Calvinist theological position was roughly analogous to that of Spilsbury, prior to becoming a Baptist, he had adopted the narrower Separatist view of the church. Williams soon came to the conclusion that all existing churches, including that newly established at Providence, lacked a proper foundation, and that this defect could be remedied only by a new apostolic dispensation, in which new apostles, divinely commissioned, would appear to re-establish the true church.

The defection of Williams left the church with no strong leadership and thus made it possible for it to be reorganized on a General Baptist platform in 1652. There was scattered General Baptist activity throughout the colonies, but the only real cluster of General Baptists was in Rhode Island, where the churches formed themselves into an association, or yearly meeting, in 1670. The early General Baptists never gained great strength. Most of their churches decayed, and some, including the Providence church, were reorganized as Particular Baptist churches. The half-dozen churches that survived never entered the main stream of American Baptist life and exerted no real influence upon its development.

The earliest strong Particular Baptist centre in the colonies was at Newport, Rhode Island, where, between 1641 and 1648, a church that had been gathered by the physician and minister John Clarke adopted Baptist views. Except for a church that had a brief existence at Kittery, Maine, there were only two other Particular Baptist churches in New England for the better part of a century. One of these was at Swansea, Massachusetts, where a church was formed by a group of Welsh immigrants under the leadership of John Myles, who had previously attempted to found a church near Plymouth but had been arrested, tried, and fined on a charge of conducting a public meeting without having first obtained permission to do so; the other was organized at Boston in 1665. Another Particular Baptist church was established at Charleston, South Carolina, in 1683 or 1684.

The great centre of Particular Baptist activity in early America was in the Middle Colonies. In 1707 five churches in New Jersey, Pennsylvania, and Delaware united to form the Philadelphia Baptist Association, and through the association they embarked upon vigorous missionary activity. By 1760 the Philadelphia association included churches located in the present states of Connecticut, New York, New Jersey, Pennsylvania, Delaware, Virginia, and West Virginia; and by 1767 further multiplication of churches had necessitated the formation of two subsidiary associations, the Warren in New England and the Ketochton in Virginia. The Philadelphia association also provided leadership in organizing the Charleston Association in the Carolinas in 1751, and this in turn fostered the formation of the Kehukee Association in North Carolina in 1765.

Philadelphia Baptist Association

While this intercolonial Particular Baptist body provided leadership for the growth that characterized American Baptist life during the decades immediately preceding the American Revolution, that growth was largely a product of an 18th-century religious revival known as the Great Awakening. Though they participated directly in the Awakening only during its last phase in the South, Baptists attracted large numbers of recruits from among those who had been "awakened" by the preaching of others. In addition to strengthening and multiplying the "regular" Baptist churches, the Awakening in New England produced a group of revivalistic Baptists, known as Separate Baptists, who soon coalesced with the older New England Baptist churches. In the South, however, they maintained a separate existence for a longer period of time. Shubael Stearns, a New England Separate Baptist, migrated to Sandy Creek, North Carolina, in 1755 and initiated a widespread revival that quickly penetrated the entire Piedmont region. The churches he organized

were brought together in 1758 to form the Sandy Creek Association. Doctrinally, these churches did not differ from the older "regular" Baptist churches, but what the older churches saw as their emotional excesses and ecclesiastical irregularities created considerable tension between the two groups. By 1787, however, a reconciliation had been effected.

In several of the colonies, Baptists laboured under legal disabilities of varying severity. The public whipping of one, Obadiah Holmes, in 1651 for refusing to pay a fine imposed for holding an unlawful meeting in Lynn, Massachusetts, caused John Clarke to write his *Ill News from New England* (1652). Fourteen years later Baptists of Boston were fined, imprisoned, and denied the use of a meetinghouse they had erected. Payment of taxes for support of the established church was a cause of continuing controversy in New England, while the necessity to secure licences to preach became an inflammatory issue in Virginia.

In the 19th century. The problem of travel had made it difficult for the Philadelphia association to serve as a bond uniting Baptists, and the rapid multiplication of churches made it impossible. It has been estimated that immediately before the American Revolution there were 494 Baptist congregations; 20 years later, in 1795, Isaac Backus estimated the number at 1,152. The initial expedient of the Philadelphia association had been to organize subsidiary associations, but during the war the churches, left to their own devices, proceeded to organize independent associations. By 1800 there were at least 48 local associations, and the great problem was to fashion a national body to unite the churches. The final impetus in this direction came from an interest in foreign missions. The first missionaries of the newly organized Congregational mission board were Adoniram Judson and Luther Rice, who had been sent to India. On shipboard they became convinced by a study of the Scriptures that only believers should be baptized. Upon arrival at Calcutta, Judson went on to Burma, while Rice returned home to enlist support among American Baptists. As a result of Rice's efforts, a General Convention of the Baptist denomination was formed in 1814. Its scope was almost immediately broadened to include, in addition to the foreign mission interest, a concern for home missions, education, and the publication of religious periodicals. In 1826 the General Convention once again was restricted to foreign mission activities, and in the course of time it became known as the American Baptist Foreign Mission Society. Other denominational interests were served by the formation of additional societies with similar specialized concerns, such as the American Baptist Home Mission Society and the American Baptist Publication Society.

Formation of General Convention

The unity that was achieved through these societies was partially disrupted as a result of the slavery controversy. During the decade prior to 1845, various compromises between the proslavery and antislavery parties in the denomination were attempted, but they proved to be unsatisfactory. As a result, a Southern Baptist Convention was organized at Augusta, Georgia, in 1845. Although its constitution provided for boards of home and foreign missions, education, and publication, its energies were devoted largely to foreign missions. Consequently, the American Baptist Home Mission Society and the American Baptist Publication Society continued to operate in the South after the Civil War and enjoyed a large measure of support from the churches. Toward the close of the 19th century, however, the Southern Baptist Convention began to develop its own home mission and publication work and to protest the intrusion of the older societies in the South. The final separation between Baptists of South and North was formalized in 1907 by the organization of the Northern Baptist Convention (after 1950 called the American Baptist Convention), which brought together the older societies and accepted a regional allocation of territory between the northern and southern conventions.

Development of Negro churches. Negro churches constitute an important segment of American Baptist life. Following the Emancipation Proclamation (1863)—an edict freeing the slaves of the United States—and the close of the Civil War, Negro Baptists began to organize their own churches. A state convention of Negro Baptist churches was formed in 1866 in North Carolina, and in 1880 the National Baptist Convention of America was organized. A dispute over the control of property and publications led to a division in 1916. The smaller of the two factions retained the original name, while the larger body became the National Baptist Convention, U.S.A., Inc.

National Baptist Convention

Developments in education. From the beginning, American Baptists have displayed an interest in an educated ministry, and their interest in higher education increased steadily as they grew in numbers. The Philadelphia association in the 18th century collected funds to help finance the education of ministerial candidates. Hopewell Academy was established in 1756, and in 1764 Brown University was founded in Rhode Island midway between Nova Scotia and Georgia. Eight other institutions were established before 1825, 25 more were established between 1825 and 1850, 39 between 1851 and 1875, and 70 between 1876 and 1900. The educational advance culminated in 1891 in the founding of the University of Chicago, which was intended to be a great national Baptist superuniversity that would tie together the smaller Baptist colleges.

In the North, regional education societies were the usual channels through which support was given to education, while in the South the institutions more often were sponsored directly by state conventions or by the Southern Baptist Convention. After the Civil War, the American Baptist Home Mission Society established a number of Negro Baptist colleges in the South. These came to be administered by Negro boards of trustees, with the cooperation of the American Baptist Home Mission Society and the Board of Education and Publication of the American Baptist Convention.

During the 20th century. After 1900 Baptists were troubled by theological controversies that led to the formation of several new Baptist groups. Some of the tensions arose over questions of structure of church organization, some arose over refusals to adopt an authoritative creedal statement, and some were the product of dissatisfaction with the affiliation of the American Baptist Convention with interdenominational and ecumenical bodies. Questions of organizational structure were involved in the formation of the American Baptist Association in 1905 by churches located primarily in Oklahoma, Texas, and Arkansas. Two other groups were products of the Fundamentalist controversy: the General Association of Regular Baptist Churches, organized in 1932; and the Conservative Baptist Association of America (1947).

A phenomenon of the post-World War II period was the abandonment by the Southern Baptist Convention of its regional limitations. Because of increasing mobility of population, the Southern Baptist Convention felt it necessary to follow its members to the growing urban centres of the North and West; by the second half of the century Southern Baptist churches were to be found in almost every part of the United States.

Growth outside the U.S. While Baptists have been troubled by divisive tendencies during the 20th century, a parallel tendency has been toward greater unity and cohesiveness through the Baptist World Alliance. The 19th century was the great period of Baptist missionary endeavour. The penetration of Asia was led by William Carey in India, Adoniram Judson in Burma, and Timothy Richard in China, and by the late 1960s there was a Baptist community of nearly 1,000,000 adherents in Asia, chiefly in India, Burma, and mainland China. The initial Baptist presence in Africa began in 1793 when David George, a former slave from South Carolina, reached Sierra Leone by way of Halifax, Nova Scotia. More organized activity was initiated in 1819 by Negro Baptists of Richmond, Virginia, who sent Lott Cary to Sierra Leone in 1821 and then shifted his base of operations to Liberia in 1824. By 1970 Baptists in Africa numbered a half million communicants, with major concentrations in the Republic of Zaire, Nigeria, and Camer-

oon. Of later origin is the Baptist community of 600,000 in Latin America.

The pioneer Baptist on the Continent of Europe was Johann Gerhardt Oncken, who organized a church at Hamburg in 1834. Oncken had become acquainted with Barnas Sears of Colgate Theological Seminary, who was studying in Germany, and with six others he was baptized by Sears. From this centre, evangelistic activity was extended throughout Germany, and missions were established in Austria, Hungary, Romania, Bulgaria, Switzerland, Belgium, The Netherlands, Denmark, Poland, and Russia. Baptist activity was initiated independently in France, Italy, and Spain. Swedish Baptist beginnings date from the conversion of Gustaf W. Schroeder, a sailor baptized in New York in 1844, and Frederick O. Nilsson, also a sailor, who was baptized by Oncken in 1847. From Sweden, Baptists penetrated Norway and Finland. Excluding the British Isles but including the U.S.S.R., there were nearly 870,000 European Baptists in the late 1960s.

It was this expansion of the Baptist community in Asia, Africa, Latin America, and Europe that led to the formation of the Baptist World Alliance at London in 1905. The purpose of the alliance is to provide mutual encouragement, exchange of information, coordination of activities, and consciousness of the larger Baptist fellowship. Periodic world congresses are held, and a headquarters secretariat is maintained in Washington and London.

Developments in Russia

The most notable growth occurred in Russia, where a Russian Baptist Union was formed in 1884 as the result of influences stemming from Oncken. Another Baptist body, the Union of Evangelical Christians, was organized in 1908 by a Russian who had come under the influence of English Baptists. Persecution of Baptists, which had been severe, was relaxed in 1905, and within the remaining disabilities a moderate growth occurred. The Revolution of 1917, with its proclamation of liberty of conscience, ushered in a period of astonishing advance: by 1927 the Russian Baptist Union numbered some 500,000 adherents, while the Union of Evangelical Christians embraced more than 4,000,000. The Soviet constitution of 1929 subjected them to pressure once again, however, and in the late 1960s the two groups, which had combined in 1944 to form the All-Union Council of Evangelical Christians and Baptists in the U.S.S.R., reported 545,000 baptized believers.

ORGANIZATION, WORSHIP, AND DOCTRINE

Organization. Baptists insist that the fundamental authority, under Christ, is vested in church life in the local congregation of believers, which admits and excludes members, calls and ordains pastors, and orders its common life in accord with what it understands to be the mind of Christ. These congregations, which are manifestations of the whole church of Christ, are linked together in cooperative bodies, to which they send their delegates or messengers—regional associations, state conventions, and national conventions. The larger bodies, it is insisted, have no control or authority over a local church; they exist only to implement the common concerns—missionary, educational, philanthropic—of the local churches.

The pattern of organization of the local church has been undergoing change during the 20th century. Traditionally, the pastor was the leader and moderator of the congregation; more recently, there has been a tendency to regard him as the employed agent of the congregation and to elect a lay moderator to act in his stead at corporate meetings of the church. Traditionally, the deacons' functions were to assist the pastor and to serve as agents to execute the will of the congregation in matters both temporal and spiritual; more recently, there has been a tendency to multiply the number of church officers by the creation of boards of trustees, boards of education, boards of missions, and boards of evangelism. Traditionally, decisions were made by the congregation in a church meeting; more recently, church meetings have become less and less frequent, and there has been a tendency to delegate decision making to various boards. The relationship of local churches to the cooperative bodies has been undergoing similar change, and this has occasioned continuing discussion among all Baptist groups.

Worship. Baptist worship is hardly distinguishable from the worship of the old Puritan denominations (Presbyterians and Congregationalists) of England and the United States. It centres largely around the exposition of the Scriptures in a sermon, and an emphasis upon extemporaneous, rather than set, prayers. Apart from the centrality of the sermon, hymn singing is one of the most characteristic features of worship. Communion, received in the pews, is customarily a monthly observance. Baptism is by immersion.

Doctrine. *History.* Initially, Baptists were characterized theologically by strong to moderate Calvinism. The dominant continuing tradition in both England and the United States was Particular Baptist. By 1800 this older tradition was beginning to be replaced by evangelical doctrines fashioned by the leaders of the evangelical revival in England and the Great Awakening in America and further elaborated by subsequent New England divines and frontier revivalists. By 1900 the older Calvinism had almost completely disappeared, and Evangelicalism was dominant. The conciliatory tendency of Evangelicalism and its almost complete preoccupation with heart-religion and the conversion experience largely denuded it of any solid theological structure opening the door to a new theological current, which in its later phases became known as Modernism. Modernism, which was an attempt to adjust the Christian faith to the new intellectual climate, made large inroads among the Baptists of England and the United States during the first two decades of the 20th century, and Baptists provided many outstanding leaders of the movement, including Shailer Mathews and Harry Emerson Fosdick. To many, these views seemed to pose a threat to the uniqueness of the Christian revelation, and they precipitated a counterreaction that became known as Fundamentalism (a movement emphasizing biblical literalism).

As a result of the controversy that followed, many Baptists developed a distaste for theology and became content to find their unity as Baptists in promoting denominational enterprises. By 1950 both Modernists and Fundamentalists were becoming disenchanted with the positions into which they had been forced in the heat of controversy, and it was from among adherents of both camps that a more creative theological encounter began to take place. While the majority of Baptists remained non-theological in their interests and concerns, there were multiplying signs that Baptist leadership was increasingly recognizing the necessity for renewed theological inquiry.

Contents. The unity and coherence of the Baptists is to be found in six distinguishing, although not necessarily distinctive, convictions they hold in common.

Central aspects of Baptist doctrine

1. The supreme authority of the Bible in all matters of faith and practice. Baptists are a non-creedal people, and their ultimate appeal always has been to the Scriptures rather than to any confession of faith that they may have published from time to time to make known their commonly accepted views.

2. Believer's Baptism. This is the most conspicuous conviction of Baptists. They hold that if Baptism is the badge or mark of a Christian, and if a Christian is one in whom faith has been awakened, then Baptism rightly administered must be a Baptism of believers only. Furthermore, if the Christian life is a sharing in the life, death, and resurrection of Christ, if it involves a dying to the old life and a rising in newness of life, then the act of Baptism must speak in these terms. The sign must be consonant with that which it signifies. It is for this latter reason that Baptists were led to insist upon immersion as the apostolic form of the rite, in addition to their initial insistence upon the Baptism of believers only.

3. Churches composed of believers only. Baptists reject the idea of a territorial or parish church and insist that a church is composed only of those who have been gathered by Christ and who have placed their trust in him. Thus, the membership of a church is restricted to those who—in terms of a charitable judgment—give clear evidence of their Christian faith and experience. The basis

of their church life is a church covenant wherein they covenant with God and one another to walk together in Christian obedience.

4. Equality of all Christians in the life of the church. By the doctrine of the priesthood of all believers, Baptists not only understand that the individual Christian may serve as a minister to his fellows, but they believe that it also confers upon each member of a church equal rights and privileges in determining the affairs of the church. The church officers—pastor and deacons—have special responsibilities, derived from the consent of the church, which only they can discharge, but they do not have a priestly unique status.

5. Independence of the local church. By this principle Baptists affirm that a properly constituted congregation is fully equipped to minister Christ and need not derive its authority from any source, other than Christ, outside its own life. Baptists, however, have not generally understood that a local church is autonomous in the sense that it is isolated and detached from other churches. The local church is but one manifestation of the Catholic Church, and as individual Christians are bound to pray for one another and to maintain communion with one another, so particular churches are under like obligation. Thus, the individual churches testify to their unity in Christ by forming associations and conventions through which they can seek counsel and advice and cooperate in common concerns.

6. Separation of church and state. From the time of Smyth, Baptists have insisted that a church must be free to be Christ's church, determining its own life and charting its own course in obedience to Christ without outside interference. Thus Smyth asserted that the

> magistrate is not by virtue of his office to meddle with religion or matters of conscience, to force and compel men to this or that form of religion or doctrine, but to leave Christian religion free to every man's conscience.

Baptists were in the forefront of the struggle for religious freedom in both England and America, they cherish the liberty established in early Rhode Island, and they played an important role in securing the adoption of the "no religious test" clause in the U.S. constitution and the guarantees embodied in the First Amendment.

Few Baptists have been willing to become so sectarian as to deny the Christian name to other denominations. With the exception of the Southern Baptists, the vast majority of Baptists cooperate fully in interdenominational and ecumenical bodies, including the World Council of Churches.

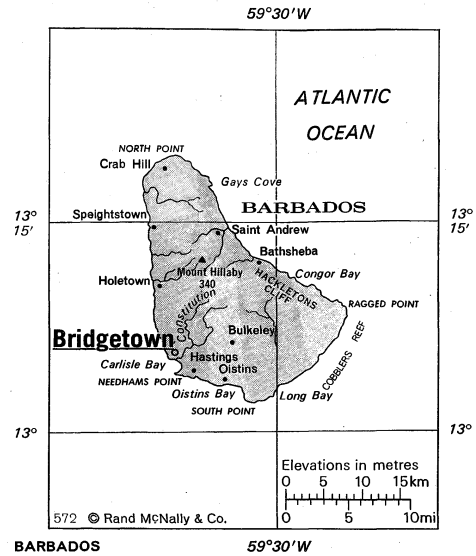
UNDERWOOD, *A History of the English Baptists* (1947), gives major attention to Baptist beginnings. W.L. LUMPKIN (ed.), *Baptist Confessions of Faith* (1959), is a compilation of documents. W.S. HUDSON, *Baptist Concepts of the Church* (1959), provides useful perspectives and interpretations. N.H. MARING and W.S. HUDSON, *A Baptist Manual of Polity and Practice* (1963), gives details of ecclesiastical organization. Additional references may be found in E.C. STARR (ed.), *A Baptist Bibliography* (1947–); statistical information in *The Baptist Handbook, 1969.*

(W.S.H.)

Barbados

Barbados is an independent island in the West Indies situated about 100 miles (160 kilometres) east of the Windward Islands. Approximately triangular in shape, it has an area of 166 square miles (430 square kilometres) and a population of about 240,000. Its capital is Bridgetown, the only seaport.

Strictly speaking, Barbados does not form part of the Lesser Antilles island chain, although it is sometimes grouped with this archipelago. Its geographic position has profoundly influenced the island's history and culture. In the era of sailing ships, the prevailing winds made the island difficult of access; if outward-bound ships from Europe did not gain the island while heading west, they found it difficult indeed to turn and reach its shores by sailing eastward. As a result of this circumstance, conquest of the island was impracticable, and it remained a British possession without interruption from the 17th century to November 30, 1966, when it attained independence and membership in the Commonwealth of Nations. It has also developed a proto-British culture, thus earning the nickname Bimshire, or Little England; to many "Bajans" (as Barbadians sometimes refer to themselves) the fact that Barbados lies about 4,750 miles southwest of London is more significant than the fact that it is about 300 miles northeast of Venezuela. Its many British customs, however, provide an attraction for tourists; tourism has strengthened the island's economy at a time when the production of sugar—its main crop—has been declining.



The landscape. *Geology.* The rocks underlying Barbados consist of sedimentary deposits, including thick shales (laminated sediments in which the particles are predominantly of clay), clays, sands, and conglomerates, laid down approximately 70,000,000 years ago. Above these are chalky deposits, which were capped with coral before the whole island rose to the surface. A layer of coral, up to 300 feet thick, now covers the island, except in the northeast (a physiographic region known as the Scotland District) where erosion has stripped off the coral cover.

The coral surface

Relief. Mt. Hillaby, the highest point in Barbados, rises to 1,115 feet in the north central part of the island. To the west the land drops down to the sea in a series of terraces, many of which are green and gently rolling. East from Mt. Hillaby, the land declines sharply to the rugged upland of Scotland District. Southward, the highlands again descend steeply to the broad St. George River Valley; between the valley and the sea the land rises to 400 feet to form Christ Church Ridge. Coral reefs surround most of the island.

Climate. The climate is generally a pleasant one. The temperature does not usually rise above 86° F (30° C) or fall below 72° F (22° C). There are two recognized seasons of the year: the dry season, from early December till May, and the wet season, which lasts the rest of the year. The average rainfall is about 60 inches a year, but, despite the smallness of the island, it varies markedly from district to district. Barbados lies in the southern border of the West Indian hurricane zone. Hurricanes in 1780 and 1831 caused great devastation, and others of lesser intensity have visited the island—including one in 1955 that was the first in 57 years.

Vegetation and animal life. Only about 40 acres of the original vegetation remain; the pale green of sugarcane is the characteristic colour of the landscape. Tropical trees—including the flamboyant tree, or poinciana, and the frangipani—are widespread, while flowering shrubs adorn parks and gardens.

The few existing wild animals—such as monkeys, hares,

raccoons, and mongooses—constitute a pest to local cultivators. Resident birds include the dove, hummingbird, and sparrow. The waters are alive with dolphins, barracuda, bream, and sprats (small European herring), and the tree frog punctuates the night with its constant piping or whistling.

The landscape under human settlement. Since over four-fifths of the farmland is the property of estates or of big landowners, there is little land that the poor can own. As a result, "tenantries" are much more common than villages. These are clusters of wooden houses—locally known as chattel houses—which are to be seen on the borders of the large estates; they are usually owned by the occupier but stand on rented ground from which they may easily be removed. Some of them have electric light; toilet facilities are outdoors, and water is obtained from a village pump, locally called a standpipe. Sheep, goats, and cows graze nearby. Children and young men often lounge around, talking, playing cards or cricket, and, on Sunday mornings, cutting each other's hair. A "cum rum" (a grocer's shop with a license for the sale of rum) is normally the only social amenity and is shared by tenantry and village alike. The villages are usually rows of houses—including the stone houses of the middle class—aligned along the main roads.

The only sizable town is Bridgetown, the national capital, which had a metropolitan population of about 97,000 in 1970. In its commercial and administrative centre, new multistoried buildings are replacing the 19th-century town, which once resembled a Victorian print. Donkey carts, bicycles, and old wooden buses, however, still dispute their right-of-way with English and American cars, while old women hucksters sit on the pavement selling mangoes and straw hats.

History. Although most of the island's early history is unknown, existing remains indicate that there was once a considerable population of Arawak Indians. The first contact with Europe probably came in 1518, when the Spanish landed to seek slaves for their colony of Hispaniola. By the mid-16th century no Indians appear to have remained, and Spanish claims to the territory had lapsed.

When the first English colonists landed in the early 17th century, their settlement was uncontested. Barbados became the third West Indian island to be occupied by the British—Bermuda having been occupied in 1612, and St. Kitts in 1623. The settlers brought in slaves to supply the large amount of labour needed for the production of sugarcane.

Effects of slavery

The decision in favour of slavery had momentous social consequences. In 1640 the population numbered 30,000, of whom only a few hundred were slaves. Five years later there were 6,000 slaves on the island, and by 1685 there were 46,000. The white population, however, began to decline; by 1700 it was reduced to 12,000—about what it was at the start of the 1970s.

Slavery was abolished in 1834. On other Caribbean islands emancipation all but ruined the sugar industry. In Barbados, however, sugar fared better, partly because there were fewer absentee landlords and partly because there were fewer places for the freed slaves to go. The central problem, however, was how to create a new community of free men at a time when the government represented the interests of a tiny oligarchy of planters and merchants. No immediate solution was found, but during the next 100 years democratic processes were gradually introduced.

At the end of the 1930s, rapid population growth and the worldwide economic depression led to rioting throughout the British West Indies. The Moyne Commission was sent by the British Parliament in 1937 to investigate. The enfranchisement of women, adult suffrage, the ministerial system, and the development of trade unionism and political parties were the fruits of this epoch. Barbados housed the headquarters of the Development and Welfare Organization for the West Indies from 1942 to 1958 and produced the first federal prime minister of the Federation of the West Indies in 1958. In 1965, however, Barbados broke away from the federation. On November 30, 1966, Barbados achieved independence, remaining a member of the Commonwealth of Nations at its own request.

Population. The population in 1970 numbered over 238,000, having increased annually at an average rate of less than 3 percent between World War II and 1960 and remained at a virtual standstill between 1960 and 1970 because of emigration losses. The density of over 1,400 persons per square mile was very high for a rural community. About 90 percent of the population was black, about 4 percent white, and about 6 percent mixed. There were about 4 percent more women than men. Marriage is statistically uncommon in the island, and more than 70 percent of the population is illegitimate.

The religion is Christian, with Anglicans accounting for more than half the population. Protestant sects combined make up nearly a quarter of the rest, while the Roman Catholic Church accounts for less than 3 percent.

Economy. Traditionally, sugar and its by-products—rum and molasses—have dominated the economy, constituting in 1970 about 50 percent of its domestic exports. In recent years, efforts have been made to diversify the economy and to provide a greater degree of employment. Fishing has been encouraged, and a number of light industries have sprung up, including food processing, textiles, the manufacturing of glass bottles and furniture, and local handicrafts. It is tourism, however, that is most likely to change the economy. Since 1968 the tourist trade has brought in more foreign currency than the production of sugar. Between 1965 and 1970 the amount of money spent by tourists more than tripled, land prices rose considerably, and numerous new hotels and apartment houses were built.

The tourist industry

The sugar industry, on the other hand, has been undergoing one of the recurrent crises which have marked its long history. It is short of the capital necessary to mechanize its operations, while strikes, malicious cane fires, and the growing disinclination of Barbadians to work on the land prevented the industry on three occasions in the 1960s even from fulfilling the annual quota of 163,000 tons for Britain and Canada. The situation is further complicated by a sharply rising cost of living and a national debt that quadrupled during the decade of the 1960s. Foreign trade—both import and export—is mainly conducted with the United Kingdom, the United States, and Canada. Commerce with fellow members of the Organization of American States is rising annually.

The monetary unit is the East Caribbean dollar. The government plans, however, to withdraw from the East Caribbean Currency Board and print its own currency.

Transport and communications. The island is provided with a network of good roads. The deepwater harbour at Bridgetown is the only port of call, but several international airlines and British West Indian Airways

run regular services to Seawell Airport near the south coast. The headquarters of the eastern Caribbean fishing fleet and receiving and transmitting stations of Cable and Wireless Ltd. are also located on Barbados.

Administration and social conditions. Queen Elizabeth II is the head of state. The British crown is represented by a governor general who acts on the advice of the island's Cabinet. Parliament consists of an upper and a lower house. The upper house, called the Senate, contains 21 government-appointed members; 12 are chosen by the prime minister, two by the leader of the opposition, and seven by the governor general. The House of Assembly consists of 24 members elected by universal adult suffrage. There is a prime minister's Cabinet, a High Court, and a Privy Council.

Education. The provision of state education compares favourably with that of Jamaica and Trinidad. The majority of the student population is educated at state schools, of which two grammar schools—Harrison College and Lodge School—enjoy reputations that extend throughout the eastern Caribbean. The government's expenditure on education is between a quarter and a fifth of the annual budget. According to the 1960 census, over 80 percent of the male population over 15 had completed primary school education, and 16 percent had obtained a secondary school education. There is a liberal arts college, founded in 1963 as part of the regional University of the West Indies, as well as a teacher-training college, a centre for multiracial studies financed by the University of Sussex, and an Anglican theological college.

Cultural life. The island has both a museum and a good public library. There is one daily newspaper, a serious literary magazine, and local radio and television stations. It is in sport, however, that Barbados can claim pre-eminence. Since 1950 the island has produced at least two cricketers of international reputation—Sir Frank Worrell and Gary Sobers—and a disproportionately large number of the members of the West Indian Test Match cricket teams.

Prospects. Political control is in black hands. Socially, however, Barbados is a rigidly stratified society, composed of a tiny planter and merchant class, mainly white; an equally small group of retired, rich foreigners—winter residents; and a professional group consisting of foreign doctors, engineers, hotel managers, and business people on contract. There is also a slightly larger black middle class of doctors, lawyers, teachers, and civil servants; the black working class represents 80 percent of the population. Economic power is in private—usually white and often foreign—hands. The economy is dependent upon sugar and tourism, both highly vulnerable industries. Granted reasonable good luck and a government that can preserve a reputation for honesty and prudent social spending, however, the two-party government system may survive, and the sharp distinctions of class and colour become softened with time.

BIBLIOGRAPHY. The *Barbados Census for 1960* is detailed and useful, but it is difficult to assess its accuracy. The *Report on Vital Statistics and Registrations* is concise and clear. Both the MINISTRY OF EDUCATION report, *Barbados 1967/68*, and the *Economic Survey 1969*, prepared by the Economic Planning Unit, are brief, but useful. JOHN H. PARRY and PHILIP M. SHERLOCK, *A Short History of the West Indies* (1958), is an orthodox, middle-of-the-road, general history that is mainly dependent on secondary sources; G.K. LEWIS, *Growth of the Modern West Indies* (1968), a stimulating, carefully researched, left-wing, idiosyncratic account; and JOHN MACPHERSON, *Caribbean Lands*, 2nd ed. (1967), an engagingly written, straightforward, geographical account of the area—well illustrated with photographs. F.A. HOYOS, *The Rise of West Indian Democracy* (1963), contains local history dealing with the rise of Sir Grantley Adams' party in Barbados. For ethnography, see M.G. SMITH, *The Plural Society in the British West Indies* (1965). Vegetation and animal life of Barbados are discussed in E.G.B. GOODING, A.R. LOVELESS, and G.R. PROCTOR, *Flora of Barbados* (1965); J.A. ALLAN, *The Grasses of Barbados* (1957); I. BAYLEY, "The Whistling Frogs of Barbados," *J. Barbados Mus.*, 17:161–170 (1950); and GARTH UNDERWOOD, *Reptiles of the Eastern Caribbean* (1962). For the economy, see JEANETTE BETHEL, *A National Accounts Study of the Economy of Barbados* (1960).

(C.S.J.)

Barcelona

The major Spanish port and commercial centre on the Mediterranean Sea, Barcelona, capital of the province of the same name in the region of Catalonia in northeast Spain, is a city of great individuality not only because of its physical surroundings, which, with its backdrop of mountains, are as fine as any on the Mediterranean, but also because of its Catalan cultural heritage and the proud independence of its people.

The city's geographical location, together with a mild and agreeable climate, its broad, busy avenues, and the attractions of its old buildings in the Gothic quarter—including the cathedral and the church of Santa Maria

Josip Ciganovic—FPG

Puerta de la Paz, Barcelona. The Columbus monument stands at left, and the Reales Atarazanas, a 14th-century arsenal housing the maritime museum, is at right.

del Mar—and its modern exemplars in the exuberant architecture of Antonio Gaudí, make Barcelona one of the most interesting and pleasant cities on the Mediterranean. In spite of residual pockets of poverty, the city's economic dynamism, cultural activity, and tourist attractions enhance a deeply rooted cosmopolitan character, joining old traditions with a good measure of modern progress.

History. *Foundation and medieval growth.* By tradition, Barcelona was founded by the ancient Phoenicians or Carthaginians and the name may be derived from the famous ruling Carthage family, the Barcas. During the Roman epoch it received the name Colonia Faventia Julia Augusta Pia Barcino, later called Barjalūnah by the Moors. Toward the end of the 3rd century the first city wall was built. After the domination (begun in AD 415) of Visigothic invaders, Barcelona fell, around 717, under the sway of the Islāmic world. In 801 the Carolingian emperor Louis I the Pious expelled the Arabs and added the city to his domains, ending centuries of instability. With the Muslim frontier kept at a prudent distance, the city prospered while the counts of Barcelona made themselves independent and, during the 10th and 11th centuries, consolidated their influence over the rest of Catalonia. The union, in 1137, of Catalonia and Aragon was followed by the rise to political importance of the wealthy merchant class, from which were elected the members of the municipal council, Consell de Cent (Council of 100). Barcelona now grew to be one of the foremost trading cities of the Mediterranean, the rival of Genoa and Venice, and its 13th-century maritime code, *Llibre del consolat de mar* (Consulate of the Sea), was for long widely recognized as authoritative.

Origin of name

Epidemics of plague, which decimated the population, brought a period of decline in the 14th century. Barcelona also lost ground when Naples became the political capital of the Catalan-Aragonese monarchy, in its stead, in 1442. Abroad, in the 16th century, the growing power of the Turks and the colonization of the New World caused Barcelona's former commercial influence in the Mediterranean to diminish. At home, from 1615, Catalonia's relations with the court in Madrid suffered progressive deterioration: Catalonia was excluded from commerce with America, and, until 1778, monopolistic control was granted to Andalusia.

The modern era. In 1705, during the War of the Spanish Succession, the archduke Charles III of Austria, contending for the Spanish throne, established his court in Barcelona. When, however, Philip V won the throne and his forces captured the city in 1714, he swiftly brought its self-government to an end.

By the time the city had recovered from its subjection under Napoleon (1808–13), industrialization in Spain was getting under way and the city's first steam-powered textile factory was put into operation in 1832. Because of its cotton industry, Barcelona became in this period the kingdom's most important city, attracting large numbers of the working class. Not surprisingly, its subsequent history was marked by episodes indicative of social, industrial, and political unrest. Especially serious were the uprisings of 1835, when 11 convents were destroyed, and of 1909, when more than 60 churches and religious buildings disappeared from the city's architectural inheritance.

19th-century industrialization

Barcelona was the stronghold of the Catalonian separatist movement and, following the outbreak of the Spanish Civil War in 1936, it became the seat of an autonomous Catalonian government and the main centre of Republican strength and suffered some damage from bombing. Its fall, in January 1939, led to the Republican government's final surrender. By the 1950s, however, Barcelona prospered again.

The contemporary city. *Layout and boundaries.* Barcelona is built on a gentle slope facing southeast to the Mediterranean. It lies in a fertile plain between the Rivers Besós, to the northeast, and Llobregat, to the southwest, and is backed by an amphitheatre of mountains that culminates in the Tibidabo (1,745 feet; 532 metres). The fortified hill of Montjuich (630 feet) rises from the sea and separates the city from the mouth of the Llobregat. The municipal area is 35 square miles (91 square kilometres) and the perimeter 27 miles. The city is a remarkably homogeneous urban unit, residential and commercial, centred on the core of the old city with its surrounding municipalities and its industries extended at the perimeter.

The main axis of the old town is formed by the Ramblas, a series of successive wide, tree-lined avenues, leading north to the Plaza de Cataluña, the largest square and commercial centre, and south to the Paseo Marítimo and seafront. The Ramblas, a favourite promenade renowned for its charm, has seats beneath the trees down both sides of the wide pavement and many stalls where birds and flowers are sold. To the north is the new town, the Ensanche (Extension), laid out in squares and crossed by wide avenues. The old town and the more modern part west of the Ramblas are enclosed in a semicircle by the Rondas, peripheral avenues occupying the ground where the fortifications once stood. At the northernmost part of the Rondas in the Plaza de la Universidad, through which runs the broad Avenida de José Antonio, with a bullring at either end. The other great thoroughfare, the Avenida del Generalísimo Franco is a residential street running southwest–northeast across the upper part of the town to the slopes of Pedralbes, where a 14th-century monastery stands on the hillside.

Architectural features. The oldest part of the city is built on a small hill, Monte Taber, the Roman walls being still visible in some streets. In the centre of the old city stands the cathedral. The present structure was built between 1289 and the late 15th century, and the west front was added in the 19th century. Excavations, however, brought to light the remains of a 6th-century basilica. Close by, in the Plaza del Rey, and the chapel and great hall of the Palacio Real Mayor, the royal palace of the counts of Barcelona (mainly 14th-century but with earlier parts) and the 16th-century palace housing the archives of the crown of Aragon. South of the cathedral are the archdeacon's house (16th century), containing the city's archives, and the episcopal palace. In the Plaza de San Jaime are the Provincial Diputación (congress hall), which was built in the 15th and 16th centuries and contains the Capilla de San Jorge and the Orange Tree Court. The Gothic town hall is a 14th- and 15th-century building with a modern facade.

The core of the city

In the Puerta de la Paz, the Columbus monument towers 197 feet high and overlooks the port; there also the Reales Atarazanas, a 14th-century arsenal, houses the maritime museum.

Perhaps the most remarkable of all Barcelona's monuments is the huge and elaborate unfinished church, Templo Expiatorio de la Sagrada Familia, begun in the 1880s, whose fantastic openwork spires dominate the city. It is the best known work of the Catalan architect and sculptor Antonio Gaudí, who designed many other notable structures in Barcelona, among them the Park Güell and the Casa Batlló.

The people. With more than 1,750,000 inhabitants in 1971, Barcelona proper has one of the highest population densities in the world. In relation to its suburbs, the city constitutes the main part of a metropolitan area (District of Barcelona) that comprises 27 municipalities with a total area of 188 square miles and a total population of over 2,650,000. It has been estimated that because of immigration from poorer regions of Spain, the population of the metropolitan area would continue to swell in the 1970s and beyond. The municipal birth rate and death rate were 17.07 and 8.76 per 1,000, respectively at the end of the 1960s.

Economic life. Three-quarters of the industrial establishments in Catalonia are concentrated in the Barcelona area, which contributes 20 percent of Spain's industrial output. The metal and chemical industries were, in the 1970s, gaining in importance over the once-dominant textile industry. Chief products are automobiles (including industrial vehicles), heavy machinery, office machines, and chemicals.

Decline of the textile industry

Barcelona's stock exchange is active, and the city is a

centre for Spanish and foreign banks, savings banks, and other financial institutions.

Government and services. The head of the municipal administration is a mayor appointed by the head of state for a six-year period, which is renewable. The mayor appoints six delegates who, with him and with six of the 36 councilmen and three deputy mayors, form the Executive Municipal Commission. The municipality is divided into 12 districts, with a District Board that serves as a coordinating link.

City transportation is provided by buses, subways, suburban railroads, and cable cars. City streetcars disappeared in 1971. The total number of passengers using collective transportation is about 600,000,000 annually. In 1970 some 350,000 private automobiles were in use in Barcelona. In 1969 the first toll freeways were opened, linking Barcelona with neighbouring towns. Later, an urban belt of rapid transit and three tunnels under the Tibidabo were under construction: these would permit the expansion of Barcelona beyond its surrounding mountain chain. The metropolitan subway (opened in 1924) had 19 route miles in 1971, with additional construction underway in the early 1970s to provide an eventual 49 mile, 108 station system by 1978. The Prat Airport, seven miles west of the city in the plain of Llobregat, serves international airlines. Railways connect Barcelona with the rest of Spain and with France.

The port of Barcelona, at first little more than an open roadstead, was improved in 1474 by the construction of a mole, the Moll de Santa Creu, but the harbour proper dates from the 17th century. It was subsequently greatly enlarged. The present port has 7.4 miles of docks and three special quays for gasoline and oil tankers; it also has silos, warehouses, and terminals for containers. In 1970 the traffic amounted to 9,100,000 tons, of which 2,500,000 tons were carried by oil tankers. There are over 130 regular shipping lines that link the port with other world ports.

The city receives electric energy from the zone of the Pyrenees, from other Spanish zones, and from the south of France. In 1970, Catalan Gas and Electricity set in operation a regional network of distribution for natural gas by installing a receiving terminal in the port of Barcelona. Nuclear energy was to come in the 1970s from the Vandellós Central Plant in the province of Tarragona.

Increasing consumption of water causes supply problems, since some sources and the Llobregat and Besós rivers do not have sufficient volume to cover the needs of the industrial and urban agglomeration. Water from the Ter River in the province of Gerona has been channelled to Barcelona.

The Catalan language

Cultural life. Barcelona is more than a cultural centre for Spain as a whole. It nurtures as well a long historic tradition that is given cohesion and a means of expression through the language of Catalonia: Catalan. This linguistic peculiarity, which has deeply marked the political, social, and cultural history of Catalonia, did not produce a closed provincial culture but one open to international currents, especially to those of Europe.

The outstanding museums are: the Fine Arts Museum of Catalonia (Romanesque and Gothic painting); the Federico Marés Museum (12th–18th-century sculpture); the Picasso Museum (enriched with important donations from the painter, who had spent nine years of his youth in Barcelona); and the Maritime Museum.

The University of Barcelona (founded in 1450 by Alfonso V the Magnanimous) and the technical colleges that occupy a large group of buildings on the edge of the city near Sarria had about 16,000 students by the early 1970s. In 1968 the Autonomous University of Barcelona was created, with more academic and administrative independence, to meet the growing demand for advanced education and research.

The general and specialized libraries (Central Library of Catalonia, the University Library, and the Municipal Periodical Library) and the scientific and artistic institutions are reinforced by many civil associations dedicated to varied cultural, recreational, or civic purposes.

Barcelona was one of the first Spanish cities to have a printing press and one of the first in Europe to publish a newspaper (*Diario de Barcelona*, 1792), which still appears. The city has ten daily newspapers and many periodicals. There are many radio stations, a television station connected to the state network, and three movie studios.

Opera and ballet have their headquarters in the Gran Teatro del Liceo (founded in 1847). The Barcelona International Festival of Music, celebrated in October, is the chief musical event of the year.

Recreation. There are many sports grounds, and among the events that are particularly popular are international automobile races, swimming contests, tennis matches, and association-football matches. The Barcelona Football (soccer) Club, founded in 1899, has more than 50,000 members and a stadium with a capacity for 100,000 spectators.

As a cultural centre Barcelona has nurtured the traditional Catalan dances, such as the well-known *sardana* round dance, the region's national dance. It also offers the attractions characteristic of a large city, such as amusement parks (Montjuich and Tibidabo and the Ciudadella Park, with its zoo), and all kinds of other entertainments (there are more than 130 movie theatres, 14 playhouses, two bullrings, and more than 100 dance halls).

BIBLIOGRAPHY. Three classic works deal with the history of Barcelona: ANDRES AVELINO PI Y ARIMON, *Barcelona antigua y moderna*, 2 vol. (1850–54), which describes Barcelona from its foundation to modern times; F. CARRERAS CANDI, *Geografía general de Catalunya*, vol. 6, *La ciutat de Barcelona* (n.d.); and ANTONIO DE CAPMANY, *Memorias historicas sobre la marina, comercio y artes de la antigua ciudad de Barcelona* (1779). A three-volume, re-edited edition, with commentary, was published in 1961. This latter book deals more with economic aspects of the city's development. ARMANDO SAEZ BUESA, *La Población de Barcelona en 1863 y 1960* (1968), is a comparative analysis of the urban demography of Barcelona, using as a base a series of unedited publications from 1863. *Ayuntamiento de Barcelona*, published by the Estadistica municipal, is an annual résumé (begun in 1936) and a primary statistical source. A more general view is found in ROLAND COURTOD and ROBERT FERRAS, *Les Grandes villes du monde Barcelona* (1969). The best guides to outstanding landmarks in the city include: CARLOS SOLDEVILA ZUBIBURU, *Guía de Barcelona* (1951); *Barcelona, la ciudad, los museos, la vida* (1962); and ALEXANDRE CIRICI, *Barcelona pam a pam* (1971). English-language works are: JAIME MIRAVALL, *Barcelona* (1951; Eng. trans. 1964); PASCUAL MAISTERRA, *Barcelona* (1967); CLIFFORD KING, *Barcelona* (1968); JAMES MORRIS, *Barcelona* (1967); and ROBERT GOLDSTON, *Barcelona, the Civic State* (1969).

(J.M.C.I.)

Barents Sea

A major outlying sea of the European sector of the Arctic Ocean, the Barents Sea lies to the northeast of the Scandinavian peninsula, separating the northern European Soviet Union from the great archipelagoes of Spitsbergen (and hence the Arctic Basin proper) and Franz Josef Land to the north, and the long, narrow, island of Novaya Zemlya (and hence the Kara Sea) on the east. The strait between Svalbard and Bjørnøya (Bear Island), halfway between Norway and Spitsbergen, leads to the neighbouring Greenland Sea, and the Norwegian Sea lies to the southwest. An irregular southern inlet forms the White Sea. The Barents Sea's area is 542,000 square miles (1,405,000 square kilometres)—larger than South Africa—and its average depth is 750 feet (229 metres), plunging to a maximum of 2,000 feet. The sea was known to Vikings and medieval Russians, its early frequenters, as the Murmean Sea and first appeared under its modern name in a chart published in 1853, thus honouring a 16th-century Dutch seeker of a northeast passage to India, Willem Barents. A German meteorologist, after an 1848 expedition, suggested that Atlantic waters penetrated the sea. The subsequent corroboration of this hypothesis was followed by the Russian academician A.F. Middendorf's important discovery of the warm North Cape Current, streaming in around the northern tip of Scandinavia. Further valuable research stemmed

History of exploration

from an 1898–1905 Russian expedition, charting warm and cold currents, the studies of the explorer F. Nansen (reported in *Northern Waters*, 1906), and the detailed reports of a number of Soviet research institutes. For related information see ARCTIC OCEAN; SOVIET UNION; and RUSSIAN SOVIET FEDERATED SOCIALIST REPUBLIC.

Physical characteristics. The Barents Sea covers a relatively shallow continental shelf fringing the Eurasian landmass. In Tertiary times (65,000,000 to 2,500,000 years ago) this region was land, with powerful rivers coursing over its surface. During the Pleistocene Ice Age (ending only 10,000 years ago) glaciers covered the surface, which later sank, though retaining older relief patterns. The floor—which is covered by sands, silts, and a sandy-silt mixture—is traversed from east to west by the major Bear Island Trench, 1,600 to 2,000 feet deep, and the smaller South Cape, Northern, and Northeastern trenches. The Central and Perseus elevations make for shallower relief in the north, and there are fishing banks and shallows to the southeast. The only island (apart from those on the periphery) is the oval Kolguyev Island, which lies in the southeast. The western portion of the mainland coast, as far as Cape Svyatoy Nos, is elevated, with abrupt shores pierced near the Soviet–Norwegian border by the deep, glacier-widened drowned valley inlets known as fjords. East of the Kanin Peninsula, which lies at the entrance to the White Sea, the coast is low-lying, with a number of shallow bays and inlets. Away from the mainland, the bleak coasts of the various archipelagoes are steep and high, with glaciers frequently plunging down to the sea and accumulations of moraines (glacier-carried debris) in the hollows.

The climate is sub-Arctic, with winter air temperatures averaging −13° F (−25° C) in the north and 23° F (−5° C) in the southwest; summer temperatures in the same regions are, respectively, 32° F (0° C) and 50° F (10° C). Absolute maxima and minima nevertheless range from −40° F (−40° C) off Novaya Zemlya to 87° F (31° C) off Murmansk. Annual precipitation is 20 inches (500 millimetres) in the south but only half this amount in the north. In years when Atlantic cyclones (low pressure areas) bring in cloudy weather, sunshine decreases and air and water temperatures exceed the norm; the converse applies when the clear, cold weather brought by Arctic anticyclones (high pressure areas) predominates.

Warm currents in the sea derive from the North Cape and Spitsbergen branches of the Norway Current, but heat is lost in mixing with colder waters. Salinity is high, at 34 parts per thousand; but ice forms in winter, although fields are thin and icebergs do not linger long. In summer, the edge of the ice is far to the north, sometimes beyond the sea, but some icebergs break from the great archipelagoes and drift as far south as Murmansk. The tidal amplitude varies greatly, especially in narrow coastal zones. Tidal current direction also varies; an important mixing of water layers thus occurs. Ice-free ports are the Soviet ports of Murmansk and Teribyorka, and the Norwegian port of Vardø.

Biological characteristics. Nutrients in the sea are facilitated by the influx of the North Cape and South Spitsbergen currents. The microscopic forms of phytoplankton produced feed, among others, a number of deep-sea invertebrates, a wide range of small, shrimp-like crustaceans, bivalves, and sponges. These in turn support fish (including cod, herring, salmon, plaice, and catfish), sea mammals (seals and whales), and land mammals (polar bears and Arctic foxes). There are also different types of sea gulls and, in warm weather, ducks and geese. Underwater flora is very rich in the shallow southern regions; and brown, red, and green algae are widespread. About 20 to 40 percent of the coastline contains shrubs, mosses, and lichens, whereas the rest is rock and stones. Grasses are rare, although vegetation increases on the continental mainland.

Sea nutrients

Fishing flourishes, with yield in the southern areas reaching a peak of 1,104,500 metric tons in 1967, followed by a sharp decline because of over-hunting. The hunting of harp seals in the southeast is now strongly regulated; fishermen from Norway and the Soviet Union take only about 30,000 specimens a year.

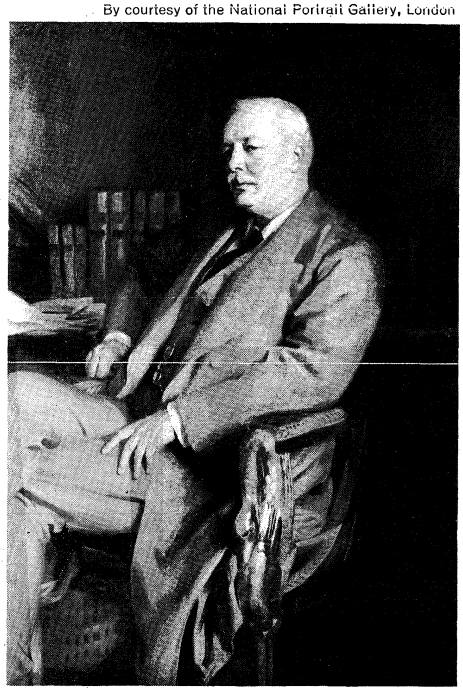
Baring, Evelyn, 1st Earl Cromer

An army officer, administrator, and diplomat, Evelyn Baring, 1st Earl Cromer, is best known as one of the last great proconsuls who served imperial Britain. For 24 years he represented his country as British agent and consul general in Egypt. He exerted a decisive influence on that country's development as a modern state, and his impressions of and attitudes toward Egypt were mainly responsible for Britain's imperial policy of a long-term commitment there.

By courtesy of the National Portrait Gallery, London



Baring, oil painting by John Singer Sargent, 1902. In the National Portrait Gallery, London.

Born on February 26, 1841, of a family distinguished in politics and banking, Evelyn Baring received his training at the Royal Military Academy, Woolwich, from which he graduated at the age of 17. He received a commission in the Royal Artillery and served in Corfu (where he met his first wife Ethel Errington Stanley), Malta, and Jamaica. He then entered the Staff College and a year later in 1869 he graduated first in his class. For a while he served in the War Office, but military life was not to his taste, and when in 1872 his cousin, Lord Northbrook, just named viceroy to India, offered to take him along as his private secretary, Baring accepted.

Career in India

In India Baring rapidly made his mark. His administrative qualities were obvious and highly appreciated by his superiors. His colleagues, however, dubbed him "Vice-Viceroy" and "Over-Baring," nicknames which clearly bespoke his self-assured efficiency and ability to command—traits invaluable in a leader of men, though not necessarily conducive to popularity among his equals. His manner was gruff to his equals, condescending and patronizing to his subordinates and to the people he chose to describe as the "subject races." Imbued with immense common sense and a profound belief in himself

and his country, he could not abide cant or hypocrisy. He was the typical Victorian colonial administrator, eminently fair and just but with little to endear him save an occasional flash of humour.

It was in India that Baring buried his early notions of self-determination for colonial peoples and decided that strong rule accompanied by reform programs was the only way to help the downtrodden peasant. His later experiences in Egypt strengthened his views on the tyranny of native rulers and the need for reform by the British. Reform became translated into one enduring principle which governed all his administrative actions—the need for a sound financial system.

Baring first went to Egypt in 1877 when he served as representative of the British holders of Egyptian bonds on the recently created Egyptian Public Debt Commission. The Commission was designed to help the Egyptian viceroy, the khedive Ismāʿīl Pasha, out of his financial difficulties, and also to safeguard the interest of the bondholders. Egyptian finances, however, were in a worse state than Baring had imagined, and he was the prime mover behind the creation of a Commission of Inquiry into Egyptian finances. When his advice was turned down by the khedive Ismāʿīl Pasha he resigned and returned to England, but when Ismāʿīl Pasha was deposed in 1879 he was invited to return to Egypt as British controller of the debt. In 1880 he became the financial member of the Viceroy's council in India where he remained for three years. After the British occupation of Egypt in 1882, he returned to Egypt once more in 1883 as British Agent and consul general with plenipotentiary powers, having in the interim been knighted.

Baring's mandate in Egypt

Baring's mandate in Egypt was to carry out wide-scale administrative reforms in a country that was bankrupt and had just gone through the upheavals of a popular revolution and a foreign occupation, and eventually to effect the evacuation of the British forces stationed there. Quite quickly he came to the conclusion that reforms and evacuation were incompatible, that reforms were of more lasting value to the mass of the Egyptians, and that evacuation should come only in the distant future when the Egyptians had been taught self-rule. He therefore instituted a form of government that came to be called the Veiled Protectorate whereby he ruled the rulers of Egypt, with the assistance of a group of English administrators trained in India, who were placed in key positions as advisers to the Egyptian government. Until his resignation in 1907 he remained the real ruler of Egypt. The system worked well during the first ten years, for the khedive Tawfīq Pasha was a weakling who abdicated all responsibility to the English. Egypt was made financially solvent by 1887, and after the British forced the Egyptian government to give up its attempt to reconquer the Sudan —wrested from its control by the religious rebellion of the *Mahdī*—there followed a period of peace and stability that allowed the country to recover from the chaos of the previous decade. Baring's parsimony in public spending and his encouragement of public irrigation works and other agricultural projects soon resulted in increased prosperity.

In 1892, a young new ruler, ʿAbbās Ḥilmī II, struggling to divest himself of the onus of the Veiled Protectorate, gave encouragement to a budding nationalist movement. Baring, who had been raised to the peerage as Lord Cromer, was as inflexible in his dealings with the young Khedive as he had been with his predecessor and succeeded in intimidating him quite thoroughly.

Throughout his years in Egypt, Cromer won the respect and admiration of the many men who occupied the foreign office and who usually deferred to his judgment in matters concerning Egypt. An exceedingly hard worker, his day began at sunrise and continued well after sunset with a two-hour break in the afternoon for physical exercise, which he pursued with as much deliberation as the rest of his duties. During his periods of relaxation he steeped himself in the classics he so admired. As a young officer he had learned Greek and Latin as well as French and Italian: he was later to learn Turkish, the language of the Turco-Circassian elite in Egypt. Yet in spite of his long stay in Egypt, he never attempted to learn Arabic and was never able to communicate either with the peasant whom he claimed to know so well, nor with the middle class that was to produce a new breed of nationalists. He had little liking for the Oriental mind, which he termed "slipshod," and even less understanding of it, despite his claims to the contrary. With age his aloofness increased and he dismissed the young nationalist movement as unimportant. Instead he worked hard at effecting the Entente Cordiale of 1904 with France, which set the seal on the permanent occupation of Egypt. His first wife, Ethel Errington, died in 1898. He married a second time in 1901, to Lady Katherine Thynne, the daughter of the 4th Marquess of Bath.

Retirement

In 1907 an incident in an Egyptian village, Dinshwai, in which a British officer was killed, resulted in brutal sentences being passed on the Egyptian peasants involved. Public outrage created a storm both in Egypt and in the British House of Commons and led the new Liberal cabinet under Prime Minister Sir Henry Campbell-Bannerman to adopt a more accommodating attitude toward Egypt. Cromer, who had little to do with the sentences since he was on home leave at the time, realized that a change was impending and, as his health had deteriorated, resigned office in 1907.

On his return to England he spent his time writing and in the House of Lords, where he was the foremost exponent of free trade. In 1916 he presided over the Dardanelles Commission, but the strain proved too taxing and he died on January 29, 1917.

BIBLIOGRAPHY. Among Baring's published works are: *Modern Egypt*, 2 vol. (1909), an account of his work and years in Egypt; *Abbas II* (1915), a somewhat snide and inaccurate telling of his relationship with the Khedive; and his annual reports on Egypt (1884–1906). LORD ZETLAND, *Lord Cromer* (1932), is his official biography. He is also mentioned in ALFRED M. MILNER, *England in Egypt* (1892), and showered with praise for his work in Egypt; also in RENNELL RODD, *Social and Diplomatic Memoirs, 1884–1893* (1922). AFAF LUTFI AL-SAYYID, *Egypt and Cromer* (1968), presents a modern Egyptian view of Cromer's work in Egypt; JOHN MARLOWE, *Cromer in Egypt* (1970), a modern British view of Cromer's life.

Barmakids

The Barmakids (popularly known as the Barmecides) were a priestly family of Iranian origin, from the city of Balkh in Khorāsān, who achieved prominence in the 8th century as scribes and viziers to the early ʿAbbāsid caliphs. Their ancestor was a *barmak*, a title borne by the high priest in the Buddhist temple of Nawbahār. The Barmakids were also known for their patronage of literature, philosophy, and science and for their tolerant attitude toward various religious and philosophical issues. They promoted public works—such as canals, mosques, and postal services—but also squandered money on building magnificent palaces by the Tigris.

Origin of the family

When Balkh, the native town of the Barmakids, fell to the Arabs *c.* 663, Khālid ibn Barmak and his brothers moved to the garrison city of Basra in Iraq, where they converted to Islām.

Khālid ibn Barmak. Khālid ibn Barmak is the first Barmakid about whom much is known. He first appears in the mid-8th century as a supporter of the revolutionary movement that established the ʿAbbāsid caliphate. In 747 Khālid was put in charge of the distribution of spoils when the ʿAbbāsid army moved toward Iraq. Afterward, he was sent to Dayr Qunnā to administer the district. Under the ʿAbbāsid caliph Abū al-ʿAbbās as Saffāḥ, Khālid shared ministerial authority with Abū al-Jahm and was entrusted with the army and the collecting of the land tax.

Khālid's intimacy with the caliph reached the extent that the latter entrusted him with the upbringing of his daughter. During the reign of al-Manṣūr, Khālid was appointed governor of Fars, and in 765 he was among the delegates to obtain Prince ʿIsā's renunciation of succession to the caliphate. Khālid then was nominated governor of Ṭabaristān, where coins were struck in his name

between 767–771. There, he distinguished himself by capturing Ustūnā Wand and building a town called Manṣūrah. Because of political intrigues and rivalry, al-Manṣūr dismissed Khālid in 775 and imposed a heavy fine upon him. Al-Khayzurān, prince al-Mahdī's wife, helped him to raise the money. Subsequently Khālid was sent to Mosul to suppress Kurdish disturbances while his son Yaḥyā was put in charge of Azerbaijan. The Barmakids were endowed with more privileges during al-Mahdī's reign, when Khālid, helped by his son Yaḥyā, was appointed governor of Fars.

Yaḥyā. Khālid died in 781/782. Yaḥyā, well trained by his father and already undertaking various administrative jobs, was nominated in 778 as secretary-tutor to the caliph's son Hārūn. As secretary, he played a decisive role in ensuring the succession of his ward to the caliphate. In 779/780 the caliph appointed Hārūn, accompanied by Yaḥyā, to lead the expedition against the Byzantines. On his return Hārūn was put in charge of the western provinces, with Yaḥyā as his adviser. In 781 Hārūn was proclaimed second in succession after his brother Mūsā, but a little later—and due to al-Khayzurān's and Yaḥyā's influence—the caliph intended to deprive Mūsā of his rights as an heir apparent but died before accomplishing his scheme. Hārūn decided not to put up any opposition to the new caliph Mūsā al-Hādī. This wise decision, inspired by Yaḥyā, perhaps saved the empire from civil war.

Yaḥyā's influence on Hārūn ar-Rashīd

Al-Hādī, in turn, confirmed Yaḥyā's position with Hārūn. This was, no doubt, a tactical error by al-Hādī, for when he decided to nominate his own son to the caliphate, Hārūn would have given in had Yaḥyā not objected. Yaḥyā tried in vain to convince the caliph that the violation of an oath after so short a time would have disastrous consequences. Hārūn and Yaḥyā were jailed. At this point, however, al-Hādī suddenly died in obscure circumstances.

Thus Hārūn ar-Rashīd (786–809) was raised to power, not by his own efforts but by the machinations of the queen mother al-Khayzurān and Yaḥyā the Barmakid. It was, therefore, no surprise that he put the whole administration in the hands of Yaḥyā and his sons. Yaḥyā received the title of *wazīr*, and his sons al-Faḍl and Ja'far were placed in charge of the caliph's personal seal.

Al-Faḍl and Ja'far. Al-Faḍl and Ja'far also bore the title *wazīr*. Ja'far, the younger brother and ar-Rashīd's favourite, was known for his eloquence and for his love of pleasure and parties. He rarely left the court, but when, in 796, the caliph sent him to control a disturbance in Syria, Ja'far succeeded in quieting the situation. On his return, he was appointed director of the bureaus (*dīwāns*) of the post, textiles, and mint. In the latter office Ja'far minted coins in his name in various provinces. Al-Faḍl, unlike his brother, distinguished himself by his competence and seriousness. When in 792 the 'Alid Yaḥyā ibn 'Abd Allāh rebelled in Daylam, al-Faḍl, through diplomacy and promises, persuaded him to give in. In 793 al-Faḍl was appointed governor of Khorāsān; he was able to put an end to the disturbances in Kābul. In 797 al-Faḍl took over the central government from his father, who resided at Mecca. Al-Faḍl, besides, was a tutor to ar-Rashīd's elder son and heir apparent al-Amīn.

The fall of the Barmakids. The Barmakids' influence lasted 17 years, but they were extirpated at the peak of their power and fortune. Ja'far, only 36 years old, was executed in 803 and parts of his body displayed on the bridges of Baghdad. Other Barmakids, with the exception of Muḥammad ibn Khālid, were imprisoned and their property confiscated. Yaḥyā and al-Faḍl died in prison in 805 and 808 respectively. A number of their partisans were accused of heresy and executed.

Assessment

The Barmakids' fall was sudden and brutal. Many accusations were made against them at the time, but the Barmakids' disgrace is to be attributed, first, to their overmighty influence in the court, administration, and society. Second, they seized every opportunity to enrich themselves (which accounts for their ostentatious generosity). Thirdly, they showed a certain degree of liberalism toward various religious and political sects, which the caliph considered as a danger to his authority. The Barmakids' role ended but their fame survived. They became the subject of controversies among historians. Contradictory traditions, marred by the obvious flattery or prejudice by which they are inspired, represent an attempt by narrators to exalt or discredit the Barmakids' character, thus obscuring their true historical role. Late Muslim literature, especially Persian literature, is inclined to visualize the Barmakid period as an ideal period in the history of the caliphate. These traditions even consider the Barmakids' Zoroastrian by faith and trace their descent to the Sāsānid period. Be that as it may, their downfall was to be considered the end of the theory that ministers were initiators of policy and not merely heads of administration; it also marked the caliph's reaction against the liberal tendency current at the time.

The expression "Barmecide feast," for an imaginary banquet, comes from "The Barber's Tale of His Sixth Brother" (*The Arabian Nights' Entertainment*), where a Barmakid has a series of empty dishes served to a hungry man to test his sense of humour.

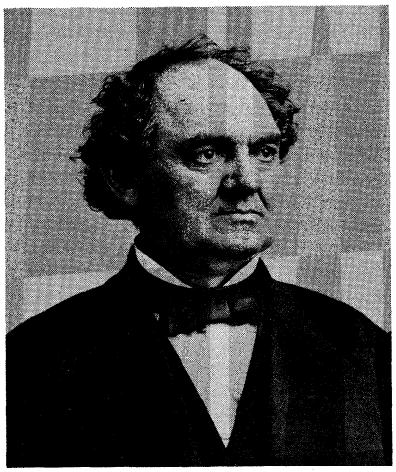
Barnum, P.T.

In a flamboyant career that spanned half of a century, Phineas Taylor Barnum established himself as the most innovative and celebrated showman ever to flourish in the United States. It was Barnum who popularized for mass audiences such amusements as the public museum, the musical concert, and the three-ring circus. In doing so, he created techniques of presentation and publicity that were to become widely imitated in vaudeville, motion pictures, and television variety shows of the 20th century. When he died, *The Times* of London echoed the press of the world in its final tribute. ". . . He created the *métier* of showman on a grandiose scale. . . . He early realized that essential feature of a modern democracy, its readiness to be led to what will amuse and instruct it. . . . His name is a proverb already, and a proverb it will continue."

Barnum was born in Bethel, Connecticut, on July 5, 1810. Although driven at the outset of his career by a desire for wealth and fame, Barnum may have been basically motivated by less selfish reasons. "This is a trading world," he wrote, "and men, women and children, who cannot live on gravity alone, need something to satisfy their gayer, lighter moods and hours, and he who ministers to this want is in a business established by the Author of our nature."

Early notoriety. Barnum was 15 years old when his father died, and the support of his mother and his five sisters and brothers fell largely upon his shoulders. After holding a variety of jobs, he became publisher of a Danbury, Connecticut, weekly newspaper, *Herald of Freedom*. Arrested three times for libel, he enjoyed his first taste of notoriety.

In 1829, at the age of 19, Barnum married a 21-year-old Bethel girl, Charity Hallett, who was to bear him four daughters. In 1834 he moved to New York City, where he found his vocation as a showman one year later when he successfully presented Joice Heth, a wizened black



Barnum.
By courtesy of the Library of Congress, Washington, D.C.

lady whom he advertised as the 161-year-old nurse to Gen. George Washington. This human relic, on her death, was exposed as a hoax.

Casting about for a legitimate undertaking, Barnum outmanoeuvred wealthier bidders to acquire John Scudder's American Museum, in New York City, a five-story marble structure filled with stuffed animals, waxwork figures, and similar conventional exhibits. The new owner rapidly transformed the museum into a carnival of live freaks, dramatic theatricals, beauty contests, and other sensational attractions. Playing upon the public's interest in the unusual and bizarre, Barnum scoured the world for curiosities, living or dead, genuine or fake. By means of outrageous stunts, repetitive advertising, and exaggerated publicity, Barnum excited international attention and made his showcase of wonders a landmark.

Barnum's museum

Between 1842, when he took over the American Museum, and 1868, when he gave it up after fires twice had all but destroyed it, Barnum's gaudy showmanship enticed 82,000,000 visitors into his halls, among them Henry and William James, Charles Dickens, and Edward VII, then prince of Wales.

Barnum's first successful exhibit in the museum was the Feejee Mermaid, which had a seemingly human head topping the finned body of a fish and was, of course, found later to be a fake. Among the genuine curiosities were Chang and Eng, Siamese twins who were connected by a ligament below their breastbones. It was, however, Charles S. Stratton, a midget only 25 inches tall who was discovered by Barnum, that proved to be his most profitable exhibit. Ballyhooing his midget as General Tom Thumb, Barnum sold 20,000,000 tickets to the museum. After being received by President Abraham Lincoln, Barnum and Tom Thumb enjoyed a triumphal tour abroad, during which the midget gave a command performance before Queen Victoria.

From promoter to impresario. Eager to change his image from promoter of freaks to impresario of artistic attractions, Barnum risked his entire fortune by importing Jenny Lind, a Swedish soprano whom he had never seen or heard and who was almost unknown in the United States. Dubbing Miss Lind "The Swedish Nightingale," Barnum mounted the most massive publicity campaign he had ever attempted. Jenny Lind's opening night in New York, before a capacity audience of 5,000, and her nine months of concerts across the United States earned immense sums.

At the peak of his career, Barnum's own appearance was nearly as familiar to the public as the exhibits he promoted. An impressive figure six feet two inches tall, semibald, with blue eyes, a bulbous nose, and potbelly, he called himself the "Prince of Humbugs." He dwelt in a three-story Oriental mansion, named Iranistan, on a 17-acre estate in Bridgeport, Connecticut, where he played host to such notables as Mark Twain, Horace Greeley, and Matthew Arnold. Close friends regarded him as good-natured, thoughtful, and kind, as well as parsimonious and egotistical.

His avocations were politics and writing. After serving two terms in the Connecticut state legislature, he was elected mayor of Bridgeport, in which post he fought prostitution and union discrimination against Negroes. In 1855 he published his autobiography, *The Life of P.T. Barnum, Written by Himself;* and because he frankly revealed some of the deceits he had employed, he was harshly taken to task by the majority of critics. Stung, Barnum continually modified the book in many revised versions, which, he claimed, sold a total of 1,000,000 copies. By 1884, more anxious for publicity than for profit, Barnum placed his autobiography in the public domain, allowing anyone to print and sell it without copyright infringement. Though the cynicism "There's a sucker born every minute" has long been attributed to Barnum, there is no proof that he ever wrote or spoke these words.

Barnum's family life was not entirely happy. One daughter had died in childhood; another was dropped from his will for committing adultery. Disappointed because he had no male heir, Barnum left a sizable bequest to a grandson on the condition that he agree to use the name of Barnum as part of his name. After 44 years of marriage, Charity Barnum died in 1873. The following year, Barnum, who was then 64, took the 24-year-old Nancy Fish, the daughter of a British admirer, for his second wife.

"The greatest show on earth"

Although his name has been popularly linked with the circus, Barnum did not, in fact, become a circus showman until he was past the age of 60. Barnum did not invent the modern circus, but, in partnership with the retiring, efficient James A. Bailey, he did give the American spectacle its gigantic size, its most memorable attractions, its widest popularity, attempting to make it what he called "the greatest show on earth." Barnum capped his circus career by purchasing a six-and-a-half ton elephant named Jumbo, who quickly earned back his purchase price during his first season under the big top.

In his 81st year, Barnum fell gravely ill. At his request, a New York newspaper published his obituary in advance so that he might enjoy it. Two weeks later, on the morning of April 7, 1891, after inquiring about the box office receipts of the circus, Barnum died in his Connecticut mansion.

Barth, Karl

One of the most influential theologians of the 20th century, Karl Barth initiated a radical change in Protestant thought. He developed a "theology of the Word of God" in opposition to the anthropocentric (man-centred) theological writings of the 19th century that took their point of departure from man's reason and his innate religious and moral consciousness.

He was born May 10, 1886, in Basel, Switzerland, the son of Fritz Barth, a Reformed professor of church history and New Testament at Bern, and Anna Sartorius. He attended the Free Gymnasium at Bern, where as a young student he displayed a keen interest in history and military matters. Although there is no account of his conversion, the pastor under whom he was confirmed suggested that he take up the study of theology. At the age of 18 he began his studies: first at Bern, then at Berlin, Tübingen, and Marburg—the last three in Germany—during which time he was greatly influenced by the leaders of liberal theology, notably Adolf von Harnack and Wilhelm Herrmann.

Barth, 1965.
Horst Tappe—EB Inc.

For two years Barth served as an assistant minister in Geneva (1909–11) and then from 1911–21 as minister in the farming and working-class congregation in Safenwil (Aargau canton). In 1913 he married Nelly Hoffman, a talented violinist. Their children were a daughter, Franziska (1914); Markus (1915), a professor of New Testament; Christoph (1917), a professor of Old Testament; Mathias (1921), a theology student who died as a result of a mountain-climbing accident in 1941; and Hans Jakob (1925), a landscape architect. While at Safenwil, in close cooperation with Eduard Thurneysen, a lifelong friend and fellow theologian, Barth began to think through the situation of the church and theology burdened with the liberalism of 19th-century Protestantism. Shocked by the failure of the theology of his teachers in the face of social questions and World War I, he joined the Religious Socialist movement and sought to organize the workers of his congregation. Deeper reflection upon the real task of theology and the church led in 1919 to the publication of *Der Römerbrief* (*The Epistle to the Romans*), which, in six successive editions, shocked theologians of the early 1920s out of their complacency. During that period Barth stressed the "wholly otherness of God" in contrast to the rationalism, historicism, and psychologism that prevailed in liberal Protestantism.

The publication of *Der Römerbrief*

The sensation created by this book brought the young Barth, who had never taken an earned doctoral degree, to the attention of academic theologians, and he was subsequently appointed to the chairs of theology at Göttingen (1921), Münster (1925), and Bonn (1930). Another result of the attention gained by the publication of *Der Römerbrief* was the formation of the "Dialectical school," composed of Thurneysen, Rudolf Bultmann, Friedrich Gogarten, Emil Brunner, and Georg Merz, all theologians who became influential in Protestantism and beyond, and the founding of the periodical *Zwischen den Zeiten* ("Between the Times"). Differences concerning the basis of evangelical theology began to appear among the members of the school, and a crisis eventually occurred with the rise of Adolf Hitler to power in January 1933.

From the outset Barth was a vigorous opponent of National Socialism and of the "German Christian" party within the German Evangelical Church. Through his pamphlet *Theologische Existenz heute* ("Theological Existence Today"), the first in a series under that name, he clarified the basic theological issues and rallied churchmen to resistance. With Martin Niemöller, an anti-Nazi church leader, and others he organized the Synod of Barmen (May 1934) at which was adopted the Barmen Declaration that became the confessional basis of the Confessing Church, which claimed to be the "evangelical church in Germany," in opposition to the established church that did not oppose National Socialism. The text of the declaration was almost entirely Barth's work. Its first article epitomized his theological position:

> Jesus Christ, as He is attested for us in Holy Scripture, is the one Word of God which we have to hear and which we have to trust and obey in life and in death.

Refusal to take an unconditional oath of allegiance to Hitler led to Barth's suspension at Bonn and was the occasion of his accepting a chair of theology at Basel. From there he continued his fight against Nazism. Prior to and during World War II he wrote letters of encouragement and admonition to the churches and their leaders in many lands and voluntarily enlisted for service in the Swiss army.

At Basel, Barth continued to work on *Church Dogmatics*, which he had begun at Bonn. Although never completed, it runs to four volumes (13 parts) of over 9,000 pages. A truly ecumenical work, filled with new insights and a wealth of exegetical, historical, philosophical, and dogmatic material, it is regarded by many Protestant and Roman Catholic scholars as the classical theological work of the century. Basic to all his writings has been his concern with the task of the preacher who from Sunday to Sunday is called to proclaim not man's word but the Word of God. He delivered over 500 sermons, most of which are yet to be published posthumously. In his later years he preached almost exclusively in the Basel prison as "a prisoner among prisoners."

Political and social views

Even before the collapse of the Third Reich near the end of World War II, Barth was among the first to champion friendship with defeated Germany. Symbolic of this friendship were lectures he delivered in 1946 and 1947 amid the ruins of the University of Bonn, but he did not withhold the sharpest criticism of the development of German history from Frederick the Great, king of Prussia in the 18th century, to Otto von Bismarck, founder and first chancellor of the German Empire in the 19th century, and to Adolf Hitler, founder of the Third Reich. Indeed, he declared that the German people "suffers from the legacy of the greatest Christian German: from the error of Martin Luther with respect to the relation of law and Gospel, of temporal and spiritual power, by which its natural paganism has not been so much limited and restrained as it has been ideologically transfigured, affirmed and strengthened."

Soon thereafter, Barth's polemic was directed against those inside and outside the church who were advocating what amounted to an "anti-Communist crusade." He took a stand for peace, for the abolition of the "iron curtain" between East and West, against equating the totalitarianism of the Soviet Union with that of Nazi Germany, and against the use of nuclear bombs—not because he had a love of Communism but because he had a penetrating insight into the Phariseeism (legalism and belief in a moral superiority) of anti-Communism. He anticipated by 20 years a changed stance of the Roman Catholic and Protestant churches toward Communism and the political thawing of the cold war.

International reputation and influence

Indicative of his international reputation and influence, as well as of the ecumenical significance of his work, Barth's travels took him to France, Italy, The Netherlands, England, Scotland, Hungary, Romania, Czechoslovakia, and, in 1962, the United States. In 1948 he delivered one of the major addresses at the opening of the first meeting (in Amsterdam) of the World Council of Churches and, following the second Vatican Council (1962–65), made a special trip to Rome in order to be better informed about the renewal of the Catholic Church. Barth was the recipient of honorary degrees from the universities of Münster, Glasgow, Edinburgh, St. Andrews, Oxford, Budapest, Geneva, Strasbourg, Paris, and Chicago and was honorary senator of the University of Bonn, honorary professor of universities in Hungary and Romania, an honorary member of the British and Foreign Bible Society and of the Académie des Sciences Morales et Politiques of the Institut de France, and holder of the British King's Medal for Service in the Cause of Freedom.

Characteristics of the man were an uncompromising devotion to the Gospel of Christ and kindliness even toward those with whom he sharply disagreed, an insatiable intellectual curiosity combined with a probing, criti-

cal mind, and a humility and cheerfulness born of a sense of the goodness of the Creator and his creation—reflected in a childlike enjoyment of the music of Mozart. For Barth, theology was "a peculiarly beautiful science" and a joyful task because its object is the indescribably good news of "the beauty of the Lord our God" in the humiliation and exaltation of Jesus Christ. And—in the words of Keats—"a thing of beauty is a joy forever; its loveliness increases." On December 9/10, 1968, Karl Barth died in Basel, his native city.

MAJOR WORKS

THEOLOGICAL WRITINGS: *Das Wort Gottes und die Theologie* (1924; *The Word of God and the Word of Man*, 1957); *Die Theologie und die Kirche* (1928); *Fides quaerens intellectum: Anselms Beweis der Existenz Gottes* (1931; *Anselm: Fides quaerens intellectum*, 1960); *Kirchliche Dogmatik* (1932; *Church Dogmatics*, 1961); *Credo: Die Hauptprobleme der Dogmatik dargestellt im Anschluss an das Apostolische Glaubensbekenntnis* (1935; *Credo: A Presentation of the Chief Problems of Dogmatics with Reference to the Apostles' Creed*, 1936); *Evangelium und Gesetz* (1935); *Gotteserkenntniss und Gottesdienst nach reformatorischer Lehre* (1938; *The Knowledge of God and the Service of God According to the Teaching of the Reformation*, 1938); *Dogmatik in Grundriss* (1947; *Dogmatics in Outline*, 1949); *Christus und Adam nach Röm 5* (1952; *Christ and Adam: Man and Humanity in Romans 5*, 1957).

BIBLICAL EXEGESIS: His best known commentaries include *Der Römerbrief* (1919; *The Epistle to the Romans*, 1933); and *Erklärung des Philipperbriefes* (1927; *The Epistle to the Philippians*, 1962).

BIBLIOGRAPHY. KARL KUPISCH, *Karl Barth in Selbstzeugnissen und Bilddokumenten* (1971), although only 156 pages in length, is the fullest account of Barth's life and work extant and is supplied with copious quotations from his letters and books, and with documentary pictures. GEORGES CASALIS, *Portrait de Karl Barth* (1960; Eng. trans. with an introduction by ROBERT MCAFEE BROWN, 1963), is not so much a biography as a portrait of the man and his work. See also the articles on Barth by W. MATTHAIS in *Evangelisches Kirchenlexikon*, vol. 1 (1956); and by G. GLOEGE in *Die Religion in Geschichte und Gegenwart*, 3rd ed., vol. 1 (1957). T.H.L. PARKER, *Karl Barth* (1970), is an account of Barth's spiritual pilgrimage and of the development of his theological method. A definitive biography is being projected by the Karl Barth Foundation in Basel, together with some 40 volumes of unprinted material that Barth left to the executors of his literary estate. A complete edition of his works will run to some 70 volumes, exclusive of the *Church Dogmatics*.

(A.C.C.)

Bartók, Béla

The significance of Béla Bartók lies in four major areas of music—composition, performance, pedagogy, and ethnomusicology. As a composer, of a stature equalled by few in the first half of the 20th century, he fused the essence of Hungarian and related folk music with traditional music to achieve a style that was at once nationalistic and deeply personal. As a pianist he gave concerts in Europe and America, disseminating the newer Hungarian music. As a teacher he helped train generations of pianists, both Hungarian and foreign. And as an ethnomusicologist he was one of the first to examine folk music with attention to its historical and sociological implications, and he helped to lay the foundations for the study of comparative musical folklore in Hungary.

Career in Hungary. Bartók was born in 1881 in Nagyszentmiklós, a small town then in Hungary and now in Romania. He spent his childhood and youth in various provincial towns. Studying the piano with his mother and later with a succession of teachers, he began to compose small dance pieces at the age of nine. Two years later he played in public for the first time, including a composition of his own in his program.

Following the lead of another eminent Hungarian composer, Ernő Dohnányi, Bartók undertook his professional studies at the Royal Hungarian Academy of Music in Budapest rather than in Vienna. He developed rapidly as a pianist but less so as a composer. After writing no music at all for two years, he resumed composing in 1902 under the stimulus of his discovery of the music of Richard Strauss. At the same time a spirit of optimistic

nationalism was sweeping Hungary, inspired by Ferenc Kossuth and his Party of Independence. As other members of Bartók's generation demonstrated in the streets, the 22-year-old composer wrote a symphonic poem, *Kossuth*, portraying in a style that was reminiscent of Strauss, though with a Hungarian flavour, the life of the great patriot Lajos Kossuth, Ferenc's father, who had led the revolution of 1848–49. Despite a scandal at the first performance, occasioned by a distortion of the Austrian national anthem, the work was received enthusiastically.

Shortly after Bartók completed his studies in 1903, he and the Hungarian composer Zoltán Kodály, who collaborated with Bartók, discovered that what they had considered Hungarian folk music and drawn upon for their compositions was instead the dilettante music of city-dwelling gypsies. A vast reservoir of authentic Hungarian peasant music was subsequently made known by the research of the two composers. The initial collection, which led them into the remotest corners of Hungary, was begun with the intention of revitalizing Hungarian music. Both composers not only transcribed many folk tunes for the piano and other media but incorporated into their original music the melodic, rhythmic, and textural elements of peasant music. Ultimately, their own work became suffused with the folk spirit.

Uncovering authentic peasant music

Bartók was appointed to the faculty of the Academy of Music in 1907 and retained that position until 1934, when he resigned to become a working member of the Academy of Sciences. His holidays were spent collecting folk material, which he then analyzed and classified, and he soon began the publication of articles and monographs.

At the same time, Bartók was expanding the catalog of his compositions, with many works for the piano, a substantial number for orchestra, and the beginning of a series of six string quartets that was to constitute one of his most impressive achievements. The first quartet (1908–09) shows few traces of folk influence, but in the others that influence is thoroughly assimilated and omnipresent. The quartets parallel and illuminate Bartók's stylistic development; in the second quartet (1915–17), Arab elements reflect his collecting trip to North Africa; in the third (1927) and fourth (1928), there is a more intensive use of dissonance; and in the fifth (1934) and sixth (1939), there is a reaffirmation of traditional tonality.

In 1911 Bartók wrote his only opera, *Duke Bluebeard's Castle*, an allegorical treatment of the legendary wife murderer, with a score permeated by characteristics of old Hungarian folk song, especially in the speechlike rhythms of the text setting. The technique is comparable to that used by the French impressionist composer Claude Debussy in his opera *Pelléas et Mélisande* (1902), and Bartók's opera has other impressionistic qualities as well. A ballet, *The Wooden Prince* (1914–16), and a pan-

tomime, *The Miraculous Mandarin* (1918–19), followed; thereafter he wrote no more for the stage.

Unable to travel during World War I, Bartók devoted himself to composition and the study of the collected folk music. During the short-lived proletarian dictatorship of the Hungarian Soviet Republic in 1919, he served as member of the Music Council with Kodály and Dohnányi. Upon its overthrow Kodály was removed from his position at the Academy of Music; but Bartók, despite his defense of his colleague, was permitted to remain.

Period of greatest activity

His most productive years were the two decades that followed the end of World War I in 1918, when his musical language was completely and expressively formulated. He had assimilated many disparate influences: in addition to those already mentioned—Strauss and Debussy—there were also the 19th-century Hungarian composer Franz Liszt and the modernists Igor Stravinsky and Arnold Schoenberg. Bartók arrived at a vital and varied style, rhythmically animated, in which diatonic and chromatic elements are juxtaposed without incompatibility. Within these two creative decades, Bartók composed two concertos for piano and orchestra and one for violin; the *Cantata Profana* (1930), his only large-scale choral work; and a number of important chamber scores, including the *Music for Strings, Percussion, and Celesta* (1936), and the *Sonata for Two Pianos and Percussion* (1937). The same period saw Bartók expanding his activities as concert pianist, playing in most of the countries of western Europe, the United States, and the Soviet Union.

U.S. career. As Nazi Germany expanded its sphere of influence in the late 1930s, and Hungary appeared in imminent danger of capitulation, Bartók found it impossible to remain there. After a second concert tour of the United States in 1940, he emigrated there later the same year. An appointment as research assistant in music at Columbia University enabled him to continue working with folk music, transcribing and editing for publication a collection of Serbo-Croatian women's songs, a part of a much larger recorded collection of Yugoslav folk music. With his wife, the pianist Ditta Pásztory, he was able to give a few concerts. His health, however, was never very strong and had begun to deteriorate even before his arrival in America. His last years were marked by the ravages of leukemia, which often prevented him from teaching, lecturing, or performing. Nonetheless, he was able to compose the *Concerto for Orchestra* (1943), the *Sonata for Solo Violin* (1944), and all but the last measures of the *Third Piano Concerto* (1945). When he died in New York on Sept. 26, 1945, his last composition, a *Concerto for Viola and Orchestra*, was left an uncompleted mass of sketches.

Bartók's heritage. During his life Bartók published several important book-length studies of Hungarian and Romanian folk music. His three-volume study of Romanian folk music was issued only in 1967; the first of three volumes on Slovakian folk music appeared in 1959. These contributions loom large in the field of musical ethnology, and it may be argued that they overshadow Bartók's legacy as composer.

Though his music was infrequently performed outside Hungary during his lifetime, many of his compositions, including the string quartets and the *Concerto for Orchestra*, later entered the standard concert repertory. Bartók's compositions within a quarter century after his death were ranked among the classics of Western music.

MAJOR WORKS

Orchestral music

Kossuth, symphonic poem (1903); *Suite No. 1*, op. 3, for large orchestra (1905); *Suite No. 2*, op. 4, for small orchestra (1905–07); *Music for Strings, Percussion and Celesta* (1936); *Divertimento*, for string orchestra (1939); *Concerto for Orchestra* (1943).

CONCERTOS: *Violin Concerto No. 1* (1907–08), *No. 2* (1937–38); *Piano Concerto No. 1* (1926), *No. 2* (1930–31), *No. 3* (unfinished, 1945); *Viola Concerto* (unfinished, but completed by Tibor Serly, 1945).

Chamber music

STRING QUARTETS: *No. 1*, op. 7 (1908–09); *No. 2*, op. 17 (1915–17); *No. 3* (1927); *No. 4* (1928); *No. 5* (1934); *No. 6* (1939).

MISCELLANEOUS: *Piano Quintet* (1904); *Sonatas for Violin and Piano No. 1* (1921), *No. 2* (1922); *Rhapsodies for Violin and Piano No. 1 and 2* (1928); *Forty-four Duos*, for two violins (1931); *Sonata for Two Pianos and Percussion* (1937; transcribed as *Concerto for Two Pianos and Orchestra*, 1940); *Contrasts*, for violin, clarinet, and piano (1938); *Sonata for Solo Violin* (1944).

PIANO SOLOS: *Rhapsody*, op. 1 (1904; also arranged for piano and orchestra and for two pianos); *Fourteen Bagatelles*, op. 6 (1908); *For Children* (1908–09); *Allegro barbaro* (1911); *Sonatina* (1915); *Suite*, op. 14 (1916); *Sonata* (1926); *Out of Doors*, suite (1926); *Mikrokosmos*, 153 progressive pieces for piano (1926–39).

Vocal music

STAGE WORKS: *Duke Bluebeard's Castle*, op. 11, an opera, libretto by Béla Balázs (Budapest, 1918); *The Wooden Prince*, op. 13, ballet, libretto by Béla Balázs (Budapest, 1917); *The Miraculous Mandarin*, op. 19, pantomine, libretto by Menyhért Lengyel (Cologne, 1926).

CANTATA: *Cantata Profana: The Nine Enchanted Stags*, for double mixed chorus, tenor and baritone soloists, and orchestra (1930).

SONGS: A large number of settings of Hungarian and other folk songs, including *Five Village Scenes*, for voice and piano (1924).

BIBLIOGRAPHY. A listing of the Bartók compositions and papers held by the Béla Bartók Archives in New York appears in VICTOR BATOR, *The Béla Bartók Archives: History and Catalogue* (1963). The composer's letters have been collected and edited by JANOS DEMENY in *Bartók Béla levelek* (1948), and *Bartók Béla levelei* (1951 and 1955); in *Ausgewählte Briefe* (1960); and in *Bartók Letters* (1971). HALSEY STEVENS, *The Life and Music of Béla Bartók*, rev. ed. (1964), is a biographical study and critical examination of all published works, with a catalog of compositions and an extensive bibliography.

(H.Ss.)

Baseball

Baseball (originally written "base ball") is a contest between two teams of nine players each. Four bases are laid out at angles of a 90-foot (27.4-metre) square at one end of a broad field of play. Teams alternate as batters ("ins") and fielders ("outs"), exchanging places when three of the batting side are "put out." As batters, players attempt to hit a ball served by a pitcher out of reach of the fielding side, and to run from base to base counterclockwise. A complete circuit counts one run, and victory goes to the side tallying the most runs at the end of nine innings (times at bat) for each team.

Baseball is played in most countries of the world, but is most popular in Latin American countries, Japan, and the United States, where it is, by tradition alone, accepted as the national game. As such, it is played informally by schoolboys on their playgrounds and in organized leagues, by teams representing community groups —schools and colleges, churches, department stores, employed personnel of factories, shipyards, mines, railroads, etc.—and by teams representing service units of the armed forces. While in the case of business firms some of the players receive financial compensation for playing, the term professional baseball player applies only to athletes employed as players by teams that are members of leagues subscribing to the authority and regulations governing what is known as organized baseball.

Baseball belongs to the extensive genus of civilized athletic competitions stemming perhaps from the primitive play urge to hit a fragment of rock, a piece of wood, or other object with a club. Two boys with one stick of wood and a rubber ball portray baseball in its essence when they mark two fixed points on their playground with a couple of flat stones as bases and take turns hitting the ball with the bat. One, armed with the bat, stands at one of the bases. The other stands an agreed distance away and tosses the ball to the batter, who drives it as far as he can. How many times the batter must run between bases before he is credited with a run, or a score, is usually agreed upon between the two contestants. Each keeps count of his runs and, after each has had the same number of turns at batting, the one who has scored the most runs is the winner.

Description of the game

Baseball in all the leagues, in the big city stadiums with

attendances of 50,000 or more, is but a refined and more intense form of the same competition. Nine-man teams oppose each other instead of just two individuals. There are four bases instead of two. In scoring a run, a batter must go to each of the other three bases before returning to his starting point to complete his run, but he may perch temporarily on a base on his way around until the opportunity is offered to continue his course.

Just as each batter has eight teammates to help him, there are nine players to pursue the batted ball instead of only the boy who in the playground miniature game had to be both thrower and retriever.

The official baseball rules, uniformly in force internationally and unchanged in any conspicuous feature since 1920, prescribe the dimensions and markings of the playing field, the conditions under which the teams function when at bat and when in the field, and the law of the game as it has evolved to cover every conceivable eventuality of the sport; variations in playing conditions in individual parks are provided for by local ground rules.

Innings and completion, termination, and suspension of games

The visiting team always has the first inning at bat in modern baseball, the home team's inning coming second. In common parlance, "inning" includes an inning at bat for each team. Originally a game was described as consisting of nine innings for each side. Usage has erased the last three words. A game, in modern baseball language, consists of nine innings, and a team's inning, for example, the sixth, is now its "half of the sixth." In written accounts of ball games a play is said to have occurred "in the first half of the sixth," or "in the top of the sixth," which conveys to the reader the information that the visiting team was at that time at bat in its sixth inning. If the home team was batting, the writer would place the play "in the last half of the sixth," or, more likely, "in the bottom of the sixth."

Whichever team has scored the most runs at the completion of a game is the winner. A game is completed at the end of nine innings if either team has scored more runs than the other, or at the end of 8½ if the home team is ahead at that point. If the score is even after nine full innings, play continues until one side has more runs than the other in equal innings at bat. Starting with the latter half of the ninth inning, if the home team acquires one run more than the visiting team, the game terminates at the moment the winning run is scored—unless that run is driven in by a home run, in which case any runners on base at that time may score ahead of the home run hitter, whose run becomes the final transaction of the game. A game may be terminated by the umpire because of rain, darkness, or other causes that in his judgment interfere with further play. If at least five equal innings have been played, the umpire may declare the game a tie or a decided game, depending on the score. A game may be suspended if there is light failure, if a curfew requires play to stop, or if league time limits are reached, and the suspended game is then completed at a later date.

The balance of this article deals primarily with the sport as played professionally in the United States. Following are the main sections and subsections of this article:

I. History of baseball

ORIGIN OF THE GAME

Evolution from rounders. In the early days of modern U.S. baseball, no one who wrote of it seemed to doubt that it was an evolution from an English children's game known then and thereafter as rounders. A simple change in the rules, according to these authorities, transformed it into a man's game. In rounders, as then played, the fielder put out a runner running for a base, or caught off base, by throwing the ball at him and hitting him with it. This precluded the use of a hardball and, since a softball cannot be batted very far, limited both the size of the field and the activity of the players. Then, presumably about 1840, some American had the idea of putting out the runner by tagging him—touching him with the ball or with the hand holding it. It became immediately possible to use a hardball—at first, a kind of miniature cricket ball. And the game suddenly grew up. The rules of the pioneer Knickerbocker Baseball Club of New York, drawn up in 1845, constitute the earliest known documentary record of this change.

But many of the old-time players, and especially A.G. Spalding, who had made a fortune out of sporting goods, refused to entertain the thought that a foreign nation could have had anything to do with inventing a great U.S. institution such as baseball. Hence the Spalding Commission, composed not of skilled investigators but of baseball men assisted by a United States senator, was appointed ostensibly to investigate the origins of the game but really to prove its exclusively U.S. origin. In 1908 this commission reported in the official *Baseball Guide* that the game, including the essentials of the modern rules, the dimensions of the field, and even the name, was invented in 1839 at Cooperstown, New York, by Abner Doubleday—afterward General Doubleday, a hero of the Battle of Gettysburg—and that the foundation of this invention was an American children's game called one old cat. As most of the pioneer players were dead before 1908, this report caused so little controversy at the time that gradually even the standard reference books accepted its conclusions as seasoned history. Effective attempts to refute its data did not begin until 1939, the centenary of the alleged invention, when Robert W. Henderson, of the New York Public Library, issued a pamphlet embracing some scholarly researches of his own, all casting doubt on the Doubleday theory and strengthening the case for an English origin. Others have since added corroborative details.

The main points in support of this contention are as follows: the word baseball to designate some popular English game has been traced back to the first half of the 18th century. In the *Letters* of Mary Lepel, Lady Hervey, there occurs a passage under the date of November 14, 1748, referring to ". . . base-ball, a play all who are, or have been, schoolboys, are well acquainted with." In *Northanger Abbey* (written about 1798) Jane Austen remarks of her heroine, "It was not very wonderful that Catherine . . ., should prefer cricket, base ball, riding on horseback, and running about the country, at the age of fourteen, to books."

Evidences of English origins

But before this, the name and presumably the game were already known in America. In 1744 *A Little Pretty Pocket-Book* was published in England. Illustrated with crude woodcuts, it pictures and describes in doggerel quatrains 26 children's sports, one for each letter of the alphabet; and *b* is represented by "Base-Ball." The text records that the batter hits the ball and runs from base to base. The illustration, which comprises only part of the field, shows a player at the plate, holding a bat with a curious flat, fanlike end; a catcher behind him; a pitcher preparing to throw a small ball underhand; and two bases, marked by posts instead of bags, with a baseman beside each of them. This book, extremely popular in England, was reprinted twice in America—in New York City (1762) and Worcester, Massachusetts (1787).

Other later references present good documentary evidence of an American game of this kind. The journal of George Ewing, a soldier, written at Valley Forge in 1778, tells of "playing at base." Some boys "playing at ball" in the Wall Street region of New York abandoned their game to join one of the riots that preceded the American Revolution. In 1787 the faculty of Princeton College forbade the students to "play with balls and sticks in the back common of the college." Thurlow Weed, editor and politician of Rochester, New York, mentioned in his memoirs "a baseball club organized about 1825." Corroborating this, a newspaper item dating from the 1820s states that the Rochester Baseball Club, with about 50

members, was in practice for its season's activities. The elder Oliver Wendell Holmes (Harvard 1829) mentioned to an interviewer that he had played a good deal of baseball while in college at Cambridge, Massachusetts. These are only a few selected references from a number discovered incidentally and accidentally. Systematic search of books, documents, and records before 1830 would probably reveal many others.

Then came an unpretentious document that ties English rounders to American baseball in their primitive forms. *The Boy's Own Book*, a treatise on boys' sports and their rules, published in London in 1828, was so popular that it ran through many editions, the second of which includes a chapter entitled "Rounders," with a note that the game is called "feeder" in London. As there described, it bears a far closer family resemblance to modern U.S. baseball than does rugby football to its acknowledged offspring, U.S. intercollegiate football. It was played on a diamond with a base at each corner, the goal or fourth base being identical with the plate beside which the batter stood. The batter might run whenever he hit the ball across or over the diamond; if he hit it in any other direction, this constituted a foul, and he was not permitted to run. If he struck at it and missed it three times, he was out. A batted ball caught on the fly constituted an out. When a runner made the circuit of the bases, it counted one point or tally for his side. Then came the one vital difference that distinguished this from modern baseball. When a grounder was fielded, the fielder put the runner out by throwing the ball at him and hitting him with it. The same rule applied to a runner caught off base. The woodcut accompanying the article bears a strong resemblance to that illustrating the rhyme "Base-Ball" in *A Little Pretty Pocket-Book*. Even the bat is the same strange-looking implement. Objects that look like flat stones serve as bases, however, and there seems to be a second catcher to range for fly fouls.

The game in America. Many English immigrants to America in colonial times were from those south counties of which Mary Lepel and Jane Austen were residents. That the old game was called baseball in that region, as it was called feeder in London and rounders in western England, and that south-county immigrants took both the name and the game to America seems a tenable hypothesis. There would seem to be little doubt that modern-day baseball evolved from such sport just as so many other present pastimes did from games of bygone eras.

As for the "old cat" versions, the critics of the Spalding report hold that in the 18th century those games were what they are today—substitutes for baseball when the boys did not have enough players for two full teams. In one old cat there was one base, one pitcher, one catcher, and one batter. The more men available the higher goes the number of "old cats"—two, three, etc. "Town ball" seems to have been only another American name for rounders, feeder, or old-time baseball, and near Boston the sport was known as the "Massachusetts game" at the turn of the 19th century. Reminiscences in the sporting periodicals of the 1850s and 1860s prove that the game was played in New England even before 1833, when Philadelphia had a town ball club and drew up written rules. New England, however, unlike Philadelphia, distinguished between fair and foul balls. On the other hand, in part of New England, home base and batter's plate were not identical, but stood a few feet apart from each other, so that the lineup included a fourth baseman. Henderson's writings reveal that the first U.S. book on baseball was *The Book of Sports*, written by Robin Carver in Boston in 1834. In it the author credits much of his material to the London publication *The Boy's Own Book*, published six years earlier. Carver's book goes into details of the game of rounders, including an illustrated diagram for the placing of the posts (bases) in the shape of a diamond. Carver copied the English rules of rounders almost word for word, and yet he called his game base, or goal ball. Doubleday, Alexander J. Cartwright, a New York surveyor and amateur ballplayer, Harry Wight, who played as an amateur with the New York Knickerbockers and became a professional player and manager (Cincinnati and Boston), and Spalding have each been referred to as the "father of baseball." Doubleday no doubt did much to promote interest in the sport, probably while a cadet at West Point, for some sports historians place his years at the military academy as 1838–42. Unfortunately, the notes, statements, and affidavits gathered by the Spalding Commission were afterward lost in a fire, and only the finished report is extant. In this, an old resident named Abner Graves figured as the chief witness; and he testified that in the game Doubleday taught in Cooperstown, the fielder put out the runner by hitting him with the ball. This means, of course, that Doubleday's game was still much like the old English version and renders unlikely the statement that Doubleday laid out a diamond with the exact dimensions of the modern playing field, for any ball light and soft enough to be thrown full force against a player's head or body without danger of inflicting serious injury could scarcely have been batted out of an infield so large. Cartwright, who long had played the game with society friends about New York, became discouraged with the haphazard manner in which contests were conducted and organized a group to formulate a code of standard rules in 1845. Drawing heavily on Carver's book, the group submitted a set of regulations, which were adopted in September 1845; much of that original code is applicable today. It was then that tagging out a runner was adopted, which no doubt paved the way for the introduction of the hardball that is the key factor of modern baseball.

From a few of the 1845 rules it may be seen how closely they paralleled those in force in organized baseball of today; for example: (1) a ball knocked outside the range of first or third (outside foul lines today) is foul; (2) three balls being struck at and missed, and the last one caught is a hand out (one out), but if not caught, it is considered fair and the striker is bound to run; (3) three hand outs, all out (batting side retired); and (4) a player running the bases shall be out if the ball is in the hands of an adversary on the base and the runner is touched by the ball before he makes his base, it being understood, however, that in no instance is the ball to be thrown at him (a definite departure from rounders).

With the introduction of the new rules by the New York Knickerbockers, the sport gained quickly in popularity. The "Knicks," who were about to be ousted from their Manhattan playing field, found a new site across the Hudson River in Hoboken, New Jersey, and made it their home field for the 1846 season. Their rules soon were taken up by such clubs as the Gothams, Eagles, Empires, and Mutuals. The Olympic Club of Philadelphia, although it had been playing town ball since 1833, did not switch to the Cartwright code until 1860. At about the time the new version of baseball was being popularized around the New York area, the old softball variety had a sudden spurt in popularity in Boston. Until the U.S. Civil War, the game was called, respectively, Boston baseball and New York baseball. During the Civil War, however, the New York and New Jersey regiments taught their own versions of the sport to other Federal soldiers, and when the war ended the more rugged and adult New York game held the field as the sport for grown men.

The original code of rules

One old cat and town ball

LATER HISTORY

Emergence of organized clubs. From 1845 until 1854 baseball was played according to rules first written for the game. In 1854 a revision provided specifications for the size and weight of the ball. On March 10, 1858, the first attempt was made at organization of clubs, their number having greatly increased and the game having expanded throughout the territory about New York City, extending to Philadelphia. Massachusetts still played town ball. In 1859 Washington, D.C., organized a baseball club, followed in 1860 by Lowell, Massachusetts, Allegheny, Pennsylvania, and Hartford, Connecticut. From that time the game became more widespread, going to Maine, Kentucky, and in 1866 to Portland, Oregon. Baseball was played in towns and hamlets other than the cities mentioned during this period, but the clubs

First attempts at organization

were considered to be town or minor clubs as compared with organized clubs, a distinction that has since followed the progress of professional baseball. The National Association of Base Ball Players, organized in 1858, embraced 16 clubs in New York City. The Knickerbocker playing rules were amplified, and the ball and bat were made to conform to measurements approximating those of the present day. In 1863 the rules were further amplified. From 1861 to 1865 baseball languished except in the armies of the Civil War. In 1865 a convention was held in New York at which 91 clubs were represented, including those from the cities of St. Louis, Missouri; Chattanooga, Tennessee; Louisville, Kentucky; Washington, D.C.; Boston; and Philadelphia. It was strictly an amateur organization without schedules for games, and its purpose was to preserve the stability of the rules and the amateur status of the sport.

Appearance of professionalism. In 1865 and 1866 professionalism began to make an appearance. Even then, players did not derive their livelihood from baseball, but the more expert accepted sums of money as members of any club that would engage them for occasional games. This was a new development, somewhat unexpected, and it seriously perturbed the amateur players. Gentlemen players openly avowed their objection to what they expressed in caustic language as deterioration. In addition to the disposition of some players to accept hire for their services, open pool selling and bribery by gamblers, some of which was successful, outraged many amateur players and organizers of clubs. This conflict between amateurism and professionalism eventually led to a professional organization, the first of its kind, which was a puny affair compared with the later great associations of clubs in leagues.

In 1867 the Nationals of Washington made the first trans-Allegheny tour, going as far west as St. Louis. In that year the Rockford, Illinois, club began the practice of paying salaries to some of its players. In 1868 the Cincinnati team was organized on what were known as semiprofessional lines, a characterization of athletes peculiar to the United States. A semiprofessional does not play baseball for a living, but is hired for occasional games.

The first all-professional team

In 1869 the Cincinnati team was hired as an outright professional organization and made a successful tour of the United States from New York to San Francisco. The Cincinnati team did not lose a game that year and was undefeated until June 14, 1870. During the successful career of the Cincinnati team, rival clubs became imbued with an eager desire to win from it, throwing aside all restraint of policy relative to being amateurs in order to engage the best players available. Most of the important clubs abandoned every attempt to preserve an amateur standing, despite the fact that they were members of the National Association, which was an amateur body. Once professionalism had entered the game, it was impossible to keep the professional and amateur exponents of the sport reconciled. The organization of the professional Cincinnati team was followed by that of another professional team at Chicago, and in 1870 the National Association of Base Ball Players was disrupted, the pure amateurs withdrawing from the annual meeting. A new amateur organization was effected in 1872 but dissolved in 1874, the last of the concerted attempts to keep the control of the game within amateur influence. In 1871 the National Association of Professional Base Ball Players was organized in New York. This embraced the Athletics of Philadelphia; Bostons of Boston; White Stockings of Chicago; Eckfords of Brooklyn, New York; Forest Citys of Cleveland; Forest Citys of Rockford, Illinois; Haymakers of Troy, New York; Kekionagas of Fort Wayne, Indiana; Olympics of Washington, D.C.; and Mutuals of New York. The affairs of the organization were loosely conducted. The circuit was not preserved intact. Many scheduled games never were played. Gambling and contract breaking became so repulsive to players of higher principle and to certain owners that they withdrew. The association dissolved in 1876 when the National League of Professional Base Ball Clubs came into existence with the seceders from the association backing it. It was organized in New York City, February 2, 1876, with a membership made up of Philadelphia, Hartford, Boston, Chicago, Cincinnati, Louisville, St. Louis, and the Mutuals of New York City.

William A. Hulbert, who became president of the league in 1877, expelled four ballplayers found guilty of dishonesty from baseball for life; and from that time, confidence was established in the professional branch, and amateur baseball grew with the revived interest in professional baseball. Hulbert remained president of the league until his death in 1882. During his administration baseball developed sufficiently to be regarded as an institution.

Formation of leagues. In 1882 the American Association was formed in cities not members of the National League circuit. National League owners attempted to equalize salaries of players, regardless of cities and local conditions, by a uniform scale of hire. The players opposed the plan, and in 1890, after forming a league known as the Players' League, took the field against the National League. In one year the player organization was wrecked. In 1891, the American Association engaged the National League in open rivalry, a venture hopelessly destined to failure; finally, in the winter of 1891 the American Association was merged with the National League into a 12-club organization having a monopoly of major league baseball.

As "the" major league, the National operated with 12 clubs from 1892 to 1899, inclusive. Falling off of patronage in Baltimore and Cleveland, mainly due to the weakening of the two teams' lineups by trades, resulted in the return to the eight-club membership, starting with the 1900 season. Baltimore, Washington, Cleveland, and Louisville were dropped as National League cities, leaving Boston, Brooklyn, Chicago, Cinncinnati, New York, Philadelphia, Pittsburgh, and St. Louis. This resumption of an eight-club setup by the one and only major league in existence led to the rise of a rival circuit, the Western League, organized as a minor league in 1893, with membership of Midwest cities covering about the same territory as the present-day American Association.

In 1900 Charles A. Comiskey, then owner of the St. Paul, Minnesota, club of the Western League, moved his team to Chicago, and renamed it the Chicago White Sox, although Chicago was a member of the National League, with continuous membership from the league's inception in 1876, when its team had been known as the Chicago White Stockings. In the same year, the Western League shifted its Grand Rapids, Michigan, team to Cleveland, one of the cities abandoned by the National League after 1899.

The move to Chicago by Comiskey received the assent of the National League, but when permission was sought to place teams for the 1901 season in Baltimore and Washington, the National League refused.

The baseball "war" in the early 20th century

Two years of baseball "war" followed. Having changed its name to the American League, the militant former Western Leaguers moved their Indianapolis (Indiana), Kansas City (Missouri), Minneapolis (Minnesota), and Buffalo (New York) clubs to Baltimore, Washington, D.C., Philadelphia, and Boston for the start of the 1901 season.

The American League withdrew from the National Agreement, the body of rules governing relations between all professional leagues, major and minor, including their transfers of players from one league to another and their territorial restrictions in the operation of clubs. Its 1901 lineup of eight cities included—besides the newly invaded four eastern cities—Chicago, Detroit, Cleveland, and Milwaukee to the west. In 1902 the Milwaukee club was moved to St. Louis, invading National League territory there; and in 1903 the Baltimore franchise was shifted to New York, establishing the American League's roster of cities as it remained through 1953.

In the "war" years, the American League made inroads on the National's galaxies of star players to such a degree that it became firmly established as a major league. When peace was made between the two leagues in January, 1903, the new agreement entered into by both gave each

of the two leagues equal importance. The agreement forbade the consolidation of two clubs occupying one city into one ownership, prohibited shifting of teams from one city to another by either league without the consent of the other, set rules for transfers of players from one major league to another, and reestablished the rules dealing with securing minor league players.

The "war" brought into prominence two men whose names became baseball tradition, Connie Mack (Cornelius McGillicuddy) and John J. McGraw. In 1900 Mack, a former National League catcher and manager of the Pittsburgh Pirates in 1894–96, was manager of Milwaukee when the Western League changed its name. In 1901 he was placed at the head of the American League's new Philadelphia team, the Athletics. In 1902 he won the first of a long line of championships with his Athletics. The success of the American League's rise to major-league status was largely attributed to his leadership and inspiration.

McGraw, a star third baseman of the Baltimore Orioles —National League pennant winners three straight years in the middle 1890s—was manager of Baltimore's American League club starting the 1902 season. In June, a National League countermove to the raids on its ranks by the American League induced McGraw to jump back to the National as manager of the New York Giants. For the next quarter of a century, McGraw and his Giants were headliners in the National League comparable in prominence to Mack and his Athletics in the American League.

The Federal League

During the period when organized baseball was governed by the National Commission (1903–21), there was one attempt by outside interests to conduct championship baseball on a major-league level independent of organized baseball. This outlaw organization was the Federal League, which conducted pennant races in 1914 and 1915.

Baltimore, Brooklyn, Buffalo, Chicago, Indianapolis, Kansas City, Pittsburgh, and St. Louis were represented in the 1914 season, with Indianapolis winning the pennant. In 1915 the Indianapolis team was transferred to Newark, New Jersey. Chicago won the 1915 pennant. The Federal League not only placed teams in organized baseball territory but also offered contracts to the outstanding players and managers of the two major leagues. Its raids were not as successful in securing stars as those of the American League had been. After the 1915 season came another "peace treaty," and the Federal League passed out of existence. Two of the men who had heavily backed the outlaw league joined the major leagues as owners of the Chicago National League and the St. Louis American League clubs, respectively. Players developed by Federal League clubs and not previously the "property" of organized baseball found places in organized baseball. Those who had left organized baseball to join up with the "Feds" returned to the clubs from which they had jumped.

Survival and growth of the game. The administrative structure of baseball and its future as a national game were severely tested in the period from 1919 through 1921. During these years eight members of one of the game's greatest teams of all time, the Chicago White Sox of 1919, were accused of accepting bribes to throw the World Series of that year. The incident became known as the "Black Sox" scandal. In September 1920, all were indicted on a charge of fraud. The presiding judge for the grand jury was Kenesaw Mountain Landis, who one year later was named baseball's first commissioner. Comiskey suspended the eight players for the 1921 season. In August of that year all were found not guilty by a jury, but Landis, then commissioner, banned them from organized baseball for life.

During this period George Herman ("Babe") Ruth was becoming baseball's newest hero. He began hitting balls a greater distance than any other hitter the game had known, and was a tremendous factor in arousing the fans' desire to see a new idol who would go down in history as the greatest of all home-run hitters. About fifty years later, Ruth's career record of 714 major league home runs, not counting All-Star and World Series games, had been challenged by Willie Mays—who retired in 1973 after hitting 660 homers with the New York and San Francisco Giants and the New York Mets—and finally broken in 1974 by Hank Aaron of the Atlanta Braves, whose total reached 745 by the end of 1975.

Black players

Mays and Aaron were among the dozens of Negro players to rise to stardom in the 1950s and 1960s. In 1947 infielder Jackie Robinson had become the first Negro player in the major leagues since Welday and Moses Walker, brothers, played in 1884 for Toledo in the American Association, then a major league. Robinson, brought into organized baseball by Branch Rickey, president of the Dodgers, then in Brooklyn, helped the Dodgers win the pennant in his first year and received the National League's Most Valuable Player Award in his third. The Cleveland Indians followed Rickey's lead with Larry Doby, slugging outfielder, and, in 1948, with Leroy ("Satchel") Paige, then past 40, famous pitching star of the Negro leagues.

Within a few years all of the major-league teams had added Negroes to their rosters, and there were also many in the minor leagues. This integration was accepted by the players and fans alike; for example, there was virtually no mention in the press when the Pittsburgh Pirates started a game with Negroes at all of the nine positions on September 1, 1971. Moreover, Negro players had won every possible individual honour. In addition to Mays and Aaron, others to earn superstar status were pitcher Bob Gibson of the St. Louis Cardinals, first baseman Willie McCovey of the San Francisco Giants, first baseman Ernie Banks of the Chicago Cubs, and outfielders Roberto Clemente of the Pittsburgh Pirates and Frank Robinson of the Los Angeles Dodgers.

Negroes had been barred from the major leagues for more than a half century; nonetheless, there were many Negro baseball players. Some of them—such as Josh Gibson, Bill Yancey, John Henry Lloyd, Andrew ("Rube") Foster, and "Cool Papa" Bell—most certainly would have been major-league stars of the first magnitude if they had been white. Gibson, a catcher who died in 1947 when Jackie Robinson was a rookie with the Brooklyn Dodgers, was an extraordinary power hitter in the same class with Babe Ruth. Gibson was credited with hitting 89 home runs in one season and 75 in another, many of them against semipro competition, however. According to one legend, Gibson hit a ball so high and far that no one saw it come down. The umpire, after scanning the sky for a few minutes, called it a home run.

There had been several Negro players in the minor leagues in the 19th century, and in the 20th century many Negroes played winter ball in Cuba, Mexico, and Venezuela. The first professional Negro team, the Cuban Giants, of Long Island, was organized in 1885. A number of other Negro teams were formed, and the Negro National League was set up in 1920 and the Negro Eastern League in 1921, inaugurating a world series in 1924; but these failed in 1932 because of the depression. A second Negro National League, founded in the late 1930s, was dissolved in 1952. The Negro American League, founded in 1936, formed an eastern and a western division in 1952 to conduct the annual Negro East–West Game.

After World War II, the Negro leagues suffered the decline in attendance and revenue that affected the minor leagues of organized baseball, accentuated by the loss of outstanding players to formerly all-white teams.

ORGANIZED BASEBALL

The major leagues. Baseball's most skillful players are professionals who perform, under exclusive contract, for one or another of the clubs that make up the major leagues. In the early 1970s, salaries for the season, which begins in early April and closes in early October, ranged from $12,750 (minimum) to more than $225,000. While not more than nine players may be used at any one time in a game, each club carries a complement of 25 players during normal periods of the season.

Traditionally all clubs were named for the cities in

which they operated. Beginning in the 1960s some have been named for states—the Minnesota Twins (Minneapolis–St. Paul), the California Angels (Anaheim–Los Angeles), and the Texas Rangers (Dallas–Fort Worth). All are members of one of the two major leagues, the National and the American. New York and Chicago have clubs in both leagues, each with its own stadium for play and severely independent of the other. Other professional leagues, known as minor leagues, operate in smaller cities and towns and serve almost exclusively as player-development "farms" for major-league clubs.

Each major-league club fields a team whose goal is to win the league championship. Each league is split into two divisions, officially "East" and "West." Each team plays a 162-game league schedule, equally balanced between games at home and away from home, and including a specified number of interdivisional games.

Commercial operations

Operation of a major-league club is a highly coordinated commercial enterprise involving extensive investment in: real estate and accommodations for spectators (although many clubs now play in multi-million-dollar, municipally owned stadiums erected for the use of the club); park service employees; the operation of a nationwide scouting staff for the search, signing, and training in the minor leagues for the approximately 200 players who make up the club's reservoir of replacements for retiring major-league players; and spring-training camps at which the players are maintained in warm climates during the weeks before the season opens. There is also a large administrative staff, usually headed by a general manager.

Revenues are derived from admissions and from the sale of television and radio rights, of rights to vend food and beverages at the games, and of programs, car parking, and fence and scoreboard advertising.

Cities enter the major leagues through purchase or transfer of a franchise operating in another city or through the expansion of the leagues. Both leagues increased from eight clubs to ten in 1961–62 and from ten to twelve in 1969. A franchise refers to a club's official certificate of membership in a league and establishes the right of its team to compete for the league championship. It is frequently owned by one person or by a small group, though some franchises are publicly owned stock corporations and others are subsidiaries of large industrial organizations (Columbia Broadcasting System, Anheuser-Busch).

Divisional components in each major league at the start of the 1972 season were American East: Baltimore Orioles, Boston Red Sox, Cleveland Indians, Detroit Tigers, Milwaukee Brewers, and New York Yankees; American West: California Angels, Chicago White Sox, Kansas City Royals, Minnesota Twins, Oakland Athletics, and Texas Rangers; National East: Chicago Cubs, Montreal Expos, New York Mets, Philadelphia Phillies, Pittsburgh Pirates, and St. Louis Cardinals; and National West: Atlanta Braves, Cincinnati Reds, Houston Astros, Los Angeles Dodgers, San Diego Padres, and San Francisco Giants.

At the season's close, divisional winners, determined by best percentage of games won, meet in a best-of-five-games series for the league championships. These decided, American and National League champions meet in a best-of-seven-games series for the championship of the world (World Series).

The great interest of Americans in baseball is reflected in the fact that an estimated 63,000,000 people were tuned in for the fourth game of the 1971 World Series, which was played at night. Gate receipts for the seven World Series games in 1971, with admission prices ranging to $12 per ticket per game, exceeded $3,000,000. Under a schedule adopted in 1969, each player of the team winning the World Series is guaranteed a minimum of $15,000 in prize money, players of the losing team $10,000. Players of teams eliminated in league divisional playoffs receive $5,000.

While each club controls and sells television and radio rights of games played on its home field, the commissioner is vested with authority to sell such rights on a national network basis for the World Series, All-Star Game, and one game a week, selected by a network, during the regular season. In 1969 this package was sold for a three-year period for a total of $50,000,000, with $5,300,000 earmarked annually for the players' pension fund.

The constant influx of new talent comes principally from schools, colleges, and independent amateur teams of city and rural districts throughout North and South America. Twice annually, in January and June, the leagues hold a joint free-agent draft in which clubs (in prescribed order) select for contract eligible young players who have never played professionally. Players selected must be signed to contracts before the next draft session. If not signed, they become subject to selection in the next draft. Bonuses to youngsters for signing may include such compensation as an $8,000 college scholarship and, to exceptionally talented prospects, up to $100,000 in cash.

Canadian, Latin American, and Japanese leagues

Organized professional baseball in the United States includes clubs in both Canada and Mexico. The game is widely played in Cuba, Puerto Rico, Venezuela, and Panama. A number of Latin American players became stars in the U.S. major leagues. Cuba figured prominently in winter league play, and Havana operated a club in the International League until ties with the Americans were cut after the successful Castro revolution. Two independent 12-club leagues now operate in Cuba, and admission to all games is free. Baseball is also a major sport in Japan, and crowds upward of 50,000 have attended games at Koshien Stadium in Osaka. Two professional six-club leagues, the Pacific and the Central, play 130-game seasons climaxed by a Japan Series between pennant winners. All league clubs are owned by industrial concerns, and the Tokyo Giants, operated by the Yomiuri Shimbun newspaper, won the Japan Series for the tenth time in 1970.

The system of mutual agreement among the operators of professional teams representing cities and towns in leagues throughout the United States and in parts of Canada recognizes one central supreme authority, the commissioner, and subscribes to the body of rules administered by this authority. Most important, these rules regulate the transfer of players from one league to another and among teams in the same league. The provisions aim at protecting the individual player from exploitation, at the same time imposing restraint on his freedom of choice to the extent that at no time after signing up with any club in organized baseball can he, without the consent of his employer, obtain employment from any other club in organized baseball until he has received an unconditional release from the contract under which he plays in any given year.

The two major leagues and each of their member clubs are signatories to an agreement, called the Major League Agreement, the first article of which creates the office of commissioner and sets forth its functions. The two major leagues, acting as one party, and the National Association, representing the minor leagues as the other, are signatories to the Major–Minor League Agreement, the first clause of which recognized the office of commissioner as created by the Major League Agreement.

As an aftermath of the Chicago White Sox scandal in 1919, the Commissioner's Office in 1921 took the place of the National Commission, a three-man board of arbitration established in 1903 and made up of the presidents of the two major leagues and an elected chairman. The framework of the commission continued under the Commissioner's Office in the form of the Advisory Council, the two league presidents with the commissioner as chairman. Nearly all the authority formerly vested in the commission was transferred to the commissioner.

Realignment and expansion. The year 1953 saw the first break in a half century in the alignment of cities in the majors when Lou Perini, president of the Braves, succeeded in transferring his National League franchise from Boston to Milwaukee. The last previous change in the lineup of major-league clubs had occurred in 1903, when the Baltimore Orioles became the New York Highlanders and then the New York Yankees.

Transferring franchises

The St. Louis Browns figured in another major realign-

ment in September 1953, when the American League franchise of the Browns was sold to a Baltimore syndicate. Beginning with the 1954 season the former Browns became the Baltimore Orioles. Another change in cities was effected before the start of the 1955 season when the Philadelphia Athletics' franchise was shifted to Kansas City. The New York Giants and the Brooklyn Dodgers played in their respective cities for the last time in 1957. The National League approved a change in locations prior to the 1958 season: the Giants to San Francisco and the Dodgers to Los Angeles.

In 1961 the Washington Senators moved their American League franchise to Minneapolis–St. Paul and were renamed the Minnesota Twins. A franchise for a new team was granted in Washington and another in Los Angeles, giving the American League ten teams. In 1962 the National League also expanded to ten teams with franchises in New York and Houston. In 1966 the Braves moved from Milwaukee to Atlanta, Georgia, and in 1968 the Athletics moved from Kansas City to Oakland, California. Both moves evoked threats of congressional action to avoid the game's exemption from federal antitrust laws. A suit to block the move from Milwaukee was rejected by the Wisconsin Supreme Court. The move from Kansas City two years later evaded legal repercussions by an American League agreement to include that city in an expansion to 12 clubs in 1969. Seattle, Washington, was later awarded the 12th franchise. National League expansion followed soon after with admission of San Diego, California, and Montreal, Quebec, the latter being the first major-league franchise outside the United States. Following the 1971 season the Washington franchise was transferred to Dallas–Fort Worth, leaving the nation's capital without major-league baseball for the first time in 71 years.

Adding new teams

These two waves of expansion, from eight to ten teams and then from ten to 12, generally resulted in immediate attendance gains. Equally significant, they enabled the owners to enlarge their television and radio markets. The cities that were awarded new franchises or were given old ones being moved either had built new stadiums that were standing empty and ready for occupancy or had pledged such construction. Not all moves were successful. The Seattle franchise, a notable failure, was in operation for only the 1969 season. The owners insisted they had suffered large financial losses and asked the American League for permission to sell or move. Approval was granted, but the city of Seattle and the state of Washington immediately countered with injunctions and restraining orders. The owners finally declared bankruptcy, and the franchise was sold and transferred to Milwaukee, which had been abandoned four years earlier when the Braves moved to Atlanta.

The cost of the expansion franchises continually spiralled upward. In the first round of expansion, for example, the four new teams were obligated to spend approximately $2,000,000 for 28 to 30 players of lesser skill who had been placed in a pool by the eight existing major league teams. These player purchases, at inflated prices, were, in effect, the cost of the franchise. In 1968 the National League's new Montreal and San Diego franchises each required entry fees totalling $10,000,000. Simultaneously, the American League's Kansas City and Seattle franchises went for approximately $6,000,000, a comparative bargain, but nonetheless three times the cost of the 1961 expansion franchises.

With the exception of the California Angels, who finished in third place in 1962, their second year, the expansion franchises were unable to field representative teams. That had been anticipated because the players made available to the new clubs were largely either untested rookies or aging veterans in the twilight of their careers. Still, the teams stayed afloat. Many of them played in new stadiums such as the Astrodome in Houston, which itself was an attraction. Most of the teams also had the advantage of opening new major-league territories. California, for example, which was without a major-league club prior to 1958, now had five teams—in Los Angeles, Anaheim, San Francisco, Oakland, and San Diego.

The New York Mets, born in 1962, became the first expansion team to win a pennant and a World Series. Upon arrival, the Mets discovered an eager audience. Many of their rooters were old New York Giant and Brooklyn Dodger fans, starved for baseball since the Giants and Dodgers had fled to California. The Mets hired Charles Dillon ("Casey") Stengel, then 70 years of age, as their manager. He had been forced into retirement, against his wishes, a year earlier by the New York Yankees. In 12 seasons with the Yankees, Stengel had directed the team to ten pennants, including an unprecedented five in succession. The Mets, under Stengel, lost their first nine games, but the most inept players were lionized and the fans came out, not to see the Mets win, but to watch them lose. The Mets obliged. They solidified their comic image by losing a record 120 games in their maiden season. In 1965 Stengel was again forced into retirement by ill health. Gil Hodges, a one-time Brooklyn star and also one of the 22 original Mets (he was acquired in the expansion draft), was named manager prior to the 1968 season. One year later, Hodges completed the "Miracle of the Mets," directing them to the National League pennant and to a World Series victory over Baltimore, the first time a team soared from ninth to first place in one season. The Mets led the majors in home attendance in 1969, drawing 2,175,373 paid admissions. They led again in 1970 with a home gate of 2,697,479, only 57,705 short of the all-time one-team record set by the 1962 Los Angeles Dodgers.

Rise of the New York Mets

The minor leagues. A radical revision of the minor-league structure was effected following the close of the 1962 season. Once self-sufficient but now heavily subsidized by major-league clubs, the minors were classified by population into leagues designated AAA (or Triple-A), AA (Double-A), A, and Rookie leagues. Earlier there had been seven classifications, including B, C, and D leagues. Rookie leagues are limited to players in their first or second season of professional play. Also, the majors conduct winter instructional leagues for prospective players. In the 1940s about 60 minor leagues operated in more than 400 cities in the U.S., Canada, Mexico, and Cuba and attracted nearly 42,000,000 paid admissions. By the early 1960s the number had declined to 20 leagues in about 130 cities with 10,000,000 admissions. Player contracts, once the most valuable operating asset of minor-league clubs, were by the early 1970s virtually all owned or controlled by parent major-league clubs.

The Triple-A leagues are the International, Pacific Coast, and the American Association, each with eight clubs. Other minor leagues include teams from cities whose geographic locations are identified by their titles, such as Eastern League (AA), Southern League (AA), California League (A), Florida State League (A), and Appalachian League (Rookie). There are also four leagues in Mexico: Mexican (AAA), Mexican Center (A), Mexican Southeast (A), and Mexican Northern (A).

The grading of leagues from top to bottom is part of the mechanism in organized baseball for assuring a player's opportunity for advancement. The grading represents different levels of salary limit. An annual draft empowers higher classification leagues to select players at fixed prices from leagues lower in the rating. Transfers of players' contracts are on a buy-and-sell basis, not only among teams in the same league but also in interleague transactions. There are fixed prices applying at the various levels for the drafting process.

Drafting of players

Each year before the arrival of the draft deadline in October, players of unusual ability may be transferred to higher leagues by the sale of their contracts at prices higher than the fixed draft price that would be obtained if a player's club chose to keep his contract beyond the date of the draft deadline, on the chance that he would be overlooked by scouts seeking reinforcements for teams in higher rated leagues. This trading in players' contracts evolved out of the baseball wars of the 19th century. In the early years of organized baseball, rival clubs commonly raided each other's ranks and hired away each other's stars in free competition on an open market. In 1879, Arthur H. Soden, of the Boston club, effected the

adoption of a resolution by the National League by which five players of each club might be named who could not be approached for hire by any other team in the league. This was the beginning of the Reserve Rule (also known as the Reserve Clause), amplified in 1883 when Col. A.G. Mills, National League president, brought about an agreement among the National League and the American Association, the two major groups at the time, and the minor leagues then in existence.

The Reserve Rule. The Reserve Rule, requiring the observance of each team's rights to the services of the players on its reserve list, is said to be the cornerstone of organized baseball. The original list of five reserved players was increased to 11 as part of the 1883 agreement. The number of players permitted to be held on each club's reserve list was increased in all gradations of leagues in the intervening years. The modern maximum is 40. In an effort to eliminate excessive bonuses for promising new players, in 1964 the league adopted a free-agent draft with all college and other amateur players drawn from a common pool. The teams draft, by rounds, in reverse order of their final standings for the season.

In the 1940s major-league players chose representatives from their own ranks to discuss problems and air any grievances with the club owners and the league executive council. Higher travel allowances, pension plans, and other benefits are among the items handled by the athletes' spokesmen. The ownership of players resulted in a series of court fights in the 1950s stemming from the baseball clause that bans a player from bargaining on his own with any club while he is under contract to another team. Charges that baseball violated the federal antitrust laws went as far as the U.S. Supreme Court, which on November 9, 1953, reaffirmed a 1922 ruling that baseball was not a business within the purview of those laws. The House of Representatives Judiciary Committee, after an exhaustive survey of the monopolistic aspects of the sport, had issued a report in 1952 in which it found no grounds on which to recommend that the game be brought under antitrust regulations.

Challenges of the Reserve Rule

The club owners were confronted with still another antitrust challenge on January 16, 1970, when a $4,100,000 suit contesting the Reserve Clause was filed in New York City's Federal Court on behalf of Curt Flood, a star outfielder with the St. Louis Cardinals and a veteran of three pennant-winning Cardinal teams. Named as defendants were the baseball commissioner, the two major-league presidents, and the 24 major-league clubs. In essence, Flood objected to the fact that the Cardinals, in trading him to the Philadelphia Phillies without his knowledge or approval, had violated his rights as a citizen. Flood announced he would not report to the Phillies and that he would sit out the 1970 season. He did.

Unlike other previous court actions, this suit had the unanimous support of the Major League Baseball Players Association; moreover, the association provided financial help and hired Arthur Goldberg, the former U.S. Supreme Court justice and ambassador to the United Nations, to represent Flood. Judge Irving Ben Cooper heard the case without a jury. League officials and owners, predictably, expressed the belief that the Reserve Rule was necessary for an orderly arrangement, though one of the newer owners, Ewing Kauffman of Kansas City, admitted the reserve system did somewhat prohibit salary negotiations and that he, for example, would be willing to pay Flood $100,000 or $125,000 a year to play with his team. Judge Cooper, in a 47-page opinion, upheld the defense and ruled that the antitrust laws do not apply to baseball, citing the previous Supreme Court decisions. He did recommend, however, that modifications in the reserve system should and could be negotiated between the Players Association and the club owners. Flood's attorneys appealed, and in 1972 the U.S. Supreme Court heard the case. It rejected Flood's suit, reaffirming the 1922 and 1953 findings exempting baseball from the antitrust laws and calling on the Congress to correct any inequities under the existing system. In the meantime, Flood had been signed by the Washington Senators for the 1971 season, with the understanding that he would not be sold or traded without his consent; but in mid-season he left the team and the country to live in Spain.

Player revolts and unionism. By 1970, the players were organized as never before. The Players Association had 941 dues-paying members, including about 850 players, plus managers, coaches, and trainers. Only one eligible player had refused membership, not because of disagreement with association policies but because he did not believe in joining organizations of any type. Association dues were $2 a day for each day a player was on the active roster during the season, with a maximum payment of $344. The players received a like amount from the association's licensing and merchandising program, which, in 1971, produced revenues in excess of $250,000.

The first player union was the National Brotherhood of Base Ball Players, organized in 1885 by Billy Voltz, a sports editor and minor-league manager. It was originally a benevolent and protective association of about 200 players who were assessed $5 a month to aid sick and needy members and to provide death benefits. At first a secret organization, the brotherhood came out in the open and became a genuine bargaining union in 1886, when the National League adopted a $2,000 maximum salary rule. The leader of the brotherhood throughout its existence was John Montgomery Ward, a pitcher–shortstop who had paid his way through law school with his baseball earnings. Disappointed with conditions and low salaries, the brotherhood went into the baseball business and formed an "outlaw" Players' League. It collapsed in 1890 after one season.

History of players' associations

The Protective Association of Professional Baseball Players was organized in 1900 and lasted during the two years of the National–American League war. When National League owners ignored the requests of the Protective Association, the association drew up a long list of National League players and induced all but one of them to join the new American League. Later, the National League made concessions to the union in exchange for the promise that union members would honour their contracts, but the American League offered more money than the National did, and the union could not prevent its members from jumping. When the American was recognized as a major league in 1903, the Protective Association quietly died.

Next came the Baseball Players' Fraternity, organized in 1912 by David Fultz, a former player and at that time a lawyer in New York City. The fraternity grew out of an incident in the spring of that year when Ty Cobb of the Tigers was suspended indefinitely for punching a fan who had provoked him. Practically all of the major-league players and most of those in the higher minor leagues were members. Fultz once called a strike because of a squabble involving a minor-league player, but the dispute was settled the day before the strike was to begin. The Players' Fraternity lasted until World War I, when the War Department issued a "work or fight" order. It was never revived.

Raymond Cannon, a Milwaukee lawyer who represented some of the banned Chicago White Sox players in 1920 and later was a congressman, twice tried to organize the players after World War I, both times without success. Robert Murphy, a Boston attorney, organized the American Baseball Guild in 1946, which, in retrospect, was a successful failure. Though Murphy's guild did not grow to fruition, the very thought of its existence roused the owners to the adoption of a number of reforms the following season, including a players' pension fund.

Murphy claimed guild members in 12 of the 16 major-league teams and twice went before the National Labor Relations Board charging unfair labour practices against the players by the Pittsburgh and Washington clubs. The board refused to assume jurisdiction. Murphy called for a strike of the Pittsburgh players on June 7 because the club would not negotiate with him. While a game with the New York Giants was being held up, the players voted on the strike and decided against it. Later, the Pennsylvania Labor Relations Board ordered an election among the Pittsburgh players to determine if they wanted

guild representation. Prior to this vote, it was acknowledged that about 90 percent of the Pittsburgh players were in support of the guild; but the vote was 15–3 against the guild, with ten players refusing to vote.

The owners, cognizant of player unrest, approved reforms for the 1947 season. A minimum major-league salary of $5,000 was adopted, the first such minimum in history; it was agreed that no salary cut could be made on a player demoted to the minors during the course of a season; moving expenses up to $500 were allowed for players sold or traded; $25 in weekly spring-training expenses was provided (still referred to by the players as "Murphy money"); and annual cuts in player salaries were limited to a maximum of 25 percent. In addition, plans were made for the establishment of a players' pension fund and for player representation on the Executive Council.

The players then began electing representatives from each team to discuss problems and air grievances, not only with the Executive Council but also with the management of the individual clubs. The pension fund, however, was to be the solidifying factor. It started growing to significant proportions in 1950 when the owners, guided by Albert B. ("Happy") Chandler, then the commissioner, signed a six-year contract for the All-Star and World Series television and radio rights, with much of this money going into the pension fund. The television contract alone was for $6,000,000, or $1,000,000 a year.

Role of the pension fund

In 1953 the owners and players entered disputes about the pension money, and the players—then led by Ralph Kiner, a home-run-hitting outfielder, and pitcher Allie Reynolds—hired a legal adviser, J. Norman Lewis. With Lewis' help, and also because of the new Taft–Hartley legislation, it was agreed that thereafter the pension plan would be administered by a joint committee of players and owners. It was also determined that 60 percent of the World Series and All-Star Game television and radio income as well as 60 percent of the gate receipts from the All-Star Game would go to the pension fund. That formula assured the players of larger pension money as the cost of television and radio rights soared.

Lewis remained as the players' attorney for six years. Frank Scott, a former travelling secretary of the New York Yankees and later a business agent for most of the star players, was then chosen by the players as their general administrator and representative. In December 1959, the players appointed a new legal adviser, Judge Robert C. Cannon of Milwaukee, the son of Raymond Cannon, who had been unsuccessful in organizing the previous generation of players. He established rapport with both players and owners and was often mentioned as a potential successor to Ford Frick, who had followed Chandler as commissioner and was approaching retirement. Some of the veteran players, however, particularly those closely involved with association affairs, began expressing dissatisfaction with Judge Cannon, maintaining that association gains were small, sometimes insignificant. Nonetheless, in 1965 and in early 1966, after it was determined the association would hire a full-time counsel and negotiator, Judge Cannon was the favoured candidate and he was offered a $50,000 contract. But the judge soon disqualified himself. He rejected, accepted, and then a second time balked, requesting certain fringe benefits not previously included.

The players, many of them now financially sophisticated, formed a committee to find a successor and sought the advice of the chairman of the economics department of the Wharton School of Finance and Commerce of the University of Pennsylvania. Marvin J. Miller, then the assistant to the president of the United Steelworkers of America, was recommended. He had a thorough background in labour relations and had been appointed to the National Labor–Management Panel by Pres. John F. Kennedy in 1963 and reappointed the following year by Pres. Lyndon B. Johnson. Miller was the choice of the players' nominating committee and immediately toured the 20 major-league spring-training camps, speaking at hastily arranged clubhouse meetings. The players ratified Miller's nomination by a vote of 489–136, and he assumed office as the executive director of the Major League Baseball Players Association on July 1, 1966. Richard M. Moss, like Miller previously associated with the Steelworkers' Union, was appointed the association's chief counsel in January 1967. The owners retained their own negotiator, John J. Gaherin of New York City, previously a management representative for the Publishers Association of New York City and a negotiator for trucking and bus companies and railroads. Under Miller, the association established a bona fide collective-bargaining relationship with the owners. Rights and benefits of the players were set forth contractually, and grievance procedures, with unprecedented impartial arbitration, were established.

Establishment of collective bargaining

The minimum salary was raised 100 percent, to $10,000 in 1968, the first genuine across-the-board minimum increase in 20 years, and increased again to $12,000 in 1970, and to $12,750 in 1971. First-class travel and a liberal meal allowance, $16 daily in 1970, were assured. The players' financial gains, in salaries and benefits, were estimated at more than $11,000,000 during the first five years of Miller's tenure. On February 3, 1969, an estimated 125 players, including most of the top stars, met in New York City. It was believed to be the biggest mass player meeting in history and was a show of strength in a dispute with the owners over pension grants. The players threatened to boycott spring training and twice rejected owner proposals, first by a vote of 491 to seven, and then 461 to six. The owners subsequently increased their offer, and a compromise was reached several days before spring training was to open. The median player salary in 1969 was $20,000. On March 31, 1972, the Players Association, by a vote of 633 to 10, with two abstentions, voted to go on strike, also over a pension dispute. It was baseball's first general players' strike and lasted 13 days. The last few exhibition games of spring training were eliminated, along with the first 10 days of the championship season. The strike was settled when the owners agreed to release $500,000 of an estimated $1,000,000 surplus in the pension fund, for the purpose of widening player benefits eroded by a cost of living rise; and with the agreement there would be no attempt to re-schedule the 86 regular season games cancelled by the strike. The players also agreed to an approximate 5 percent salary loss because of these cancellations. The result was a shortened and imbalanced schedule for the 1972 season, with some teams playing several more games than others.

The umpires also began organizing. At a secret meeting in Chicago on September 19, 1963, the Association of National League Umpires was formed. John Reynolds, a Chicago attorney, was hired as counsel and administrator and won immediate financial gains. The American League umpires joined five years later, merging into the Major League Umpires Association. Two umpires, William Valentine and Anthony Salerno, were fired by American League president Joe Cronin, who announced they were dismissed for incompetency. Valentine and Salerno insisted they were fired for their union activities. The National Labor Relations Board, by a four to one vote, agreed to a hearing, an unprecedented action interpreted by some observers as an indication that baseball was no longer immune from the antitrust laws. The board, on November 19, 1970, dismissed the Salerno–Valentine charges, ruling insufficient evidence.

COMPETITION

The schedule. The regular major-league season usually opens the second Monday in April and closes on the last Thursday in September or the first in October. Divisional play-offs (best three of five games) begin the next Saturday and the World Series (best four of seven) a Saturday later. Minor-league seasons are shorter, usually ending on Labor Day (first Monday in September) or the Sunday following. Rookie leagues operate in July and August only, whereas Mexican leagues hold postseason series. Some split their loop into two divisions, winners playing off for the league championship. Others hold a Shaughnessy play-off series. In this, the top four clubs

The baseball season

in the final standing play a knockout tourney for a trophy, nominally a "governors' cup."

During the winter months there are league operations in Puerto Rico, Venezuela, the Dominican Republic, and frequently in Panama. These clubs are staffed with players on loan from the majors and minors as well as with native players. A Caribbean Series in February, to which the winter leagues send their championship teams, climaxes the winter season.

Preceding the opening of the championship season, each club has a period of spring training that lasts for a month or more, during which time its men are conditioned for playing almost every day over a period of months (5½ in the majors). It is during this training season that new candidates are tried out. The manager and his coaches extend their efforts to select and train the strongest lineup possible from their squad. Practice games are played between teams picked from the squad, and there are usually 30 to 35 exhibition games played against teams representing other organized baseball cities.

In 1904 the major leagues fixed on 154 games. With expansion of the major leagues to ten teams in 1961 (American) and 1962 (National), the figure was revised to 162. When games end in ties, the statistics of such games go into the records of the individual players, although subsequent dates for play-offs of the deadlocked contests are arranged. Postponements because of inclement weather, especially late in the pennant campaigns, often cause a reduction in the allotted number of encounters for the clubs involved because travel schedules of the teams might prevent the opportunity for a play-off before the scheduled closing day of the season.

In common practice, the play-off of ties and postponed games takes the form of the doubleheader, in which two games are played on the same date, with a 20-minute period intervening. The popularity of this bargain billing with the public has resulted in doubleheaders being placed in the schedule in its original draft before the season's start, usually on holidays and Sundays.

The games are arranged to take in 25 weekends and the three nationally celebrated holidays: Memorial Day, Independence Day, and Labor Day.

Starting in the 1930s, additional big days appeared in league schedules in the form of night games. Experiments in playing games under artificial lighting were reported in 1880 (Nantasket Beach, Massachusetts), but, because of the large area necessary to be illuminated, it was not tried in league games until 1930.

Baseball games at night

On April 28, 1930 (Muskogee at Independence, Kansas, Western League), the first night game that counted toward a league pennant was played. Since to most patrons of professional baseball weekdays are workdays, the opportunity to see a game on a weekday evening instead of waiting until Saturday or Sunday came as a boon. Night baseball became popular.

By 1935 engineers had solved the problem of lighting the extensive areas of large stadiums, and in May of that year the first major-league night game was played in Cincinnati (versus Philadelphia). By the 1960s most teams were playing approximately half of their games at night, and in 1971 a World Series game was played at night for the first time. All but one of the major-league parks were equipped to play games at night. The Chicago Cubs of the National League continued to play all their home games at Wrigley Field during the daylight hours. In 1965 the first indoor games were played, in Houston's air-conditioned Astrodome stadium.

Records and statistics. Each league maintains a bureau in which are filed the statistics of all its contests. After each game the official scorer, appointed by the league, drafts a record of the game, with its detailed columns showing each player's hits, runs, errors, etc. At the end of each season, the official averages for the entire campaign are compiled. With expansion of the major leagues in 1961–62, all previous averages and statistics, based on a 154-game season, became obsolete, and comparison between old and new records became a matter of controversy.

The biggest controversy occurred in 1961 when Roger Maris of the New York Yankees hit a total of 61 home runs in one season, one more than Babe Ruth's historic 60 in 1927, the most cherished of all baseball records. When it became apparent that Maris might surpass Ruth's record, Commissioner Ford Frick ruled that Maris would have to break the record within the confines of the Yankees' first 154 games to replace Ruth in the record books. This would not give Maris the benefit of the eight additional games created by the expanded schedule. Maris' last two homers were hit in the extra eight games, the 60th in the Yankees' 158th game and the 61st in the 162nd. Ruth also had the advantage of one extra game because of the replay of a tie. Both the Maris and Ruth marks are listed in the record books. Other records have toppled because of the longer schedule but have not caused concern.

The two home run records

Also affecting the records, though in a more subtle manner, were the new artificial playing surfaces. When it was apparent that grass would not grow in the Astrodome, Houston's indoor stadium, a synthetic grass, called Astroturf, was introduced in 1966. Three years later, the Chicago White Sox installed a similar artificial turf infield, setting a precedent for an outdoor stadium. By 1972 artificial grass had been installed at seven major-league parks. The ersatz grass has, in the main, helped the hitters. A ground ball skips through these infields with greater speed. For modern records, see under SPORTING RECORD in the *Ready Reference and Index*.

The championships. All scheduled games must have a winner. Games ending in a tie or unplayed because of inclement weather are scheduled for replay as soon as possible before the season closes. Games that remain unplayed at the close of the season, because of travel limitations or other cause, are cancelled, unless a club would lose a chance to become the divisional winner as a consequence. In such rare instances, these unplayed games are rescheduled after the close of the season.

Arranged in order of games-won-and-lost percentage, from the highest to the lowest, the list of clubs in a major-league division on any given day is called the club standing. The team at the top of the list (in first place) at the close of the season becomes the divisional winner and the final standing becomes the record for the regular season. When two clubs are tied for first place, a single postseason game is played between the two to decide the divisional winner. Divisional winners then meet in a best-of-five-games series for the league championship. The first two games are played on the home field of one club and the remaining game or games on the home field of the other.

The play-off winners become the league champions for the year, each winning the right to fly from a flagpole in its home field a banner or pennant, combining the red, white and blue of the U.S. flag in a design of its own selection, with lettering and numerals proclaiming the team as champion of its league for that year. This pennant is customarily raised at the champion's opening game at home the ensuing season and flown from the masthead throughout the new campaign. The pennant winners in each major league then meet in the World Series, a postseason competition in which about half of the total cash receipts of the first four games forms a players' pool.

The World Series. In the fall of 1903 the pennant winners of the two leagues met in a postseason series, won by the Boston Red Sox of the American League from the Pittsburgh Pirates, National League champions, five games to three. This postseason series was no new idea. In seven successive years, starting with 1884, postseason games had been played between the pennant winners of the National League and the American Association.

For the 1903 World Series, as in the World Series of the 1880s, the teams arranged matters between themselves, scheduling games and dividing the proceeds by mutual agreement. In 1904 the Boston Red Sox, who had won the 1903 world championship, won the American League pennant and issued a challenge to the National pennant winners, the New York Giants. The Giants refused, on the ground that there should be formal rules and central

supervision of a contest in which the prestige of the rival leagues was involved. Boston claimed the 1904 world championship by default. New York president John T. Brush offered a code of rules that was adopted starting in 1905. These rules were amended at various times but the main features remained unchanged. From 1919–21 the number of victories required to win the series was raised to five, but it reverted to four in 1922.

Schedule of World Series games

The scheduling of games originally involved choosing by lot or by tossing a coin. The major leagues now alternate in opening the series. In the even-numbered years, the series opens in the park of the National League pennant winner. In the odd-numbered years, the American League champion plays its first World Series games at home. Instead of 3–3–1, the distribution of the games is 2–3–2. After the first two games in the series-opening park, the team shifts to the park of the rival league's champions for three games. If neither has won four games after five games have been played, the scene shifts back to the field on which its first game was played and remains there for as many more games as are necessary to decide the winner.

During World War II, starting with 1943, transportation emergencies changed this order. Again, the system became three games in the series-opening park, then the shift to the other team's field, with the difference from the original Brush plan that regardless of how many games should become necessary, there would be no return trip to the first city. After the war the 2–3–2 system was again adopted. For World Series results, see under SPORTING RECORD in the *Ready Reference and Index*.

The All-Star Game. Starting with 1933, the major leagues have played an annual All-Star Game in July, one game between teams of players chosen from all the teams of both leagues. They oppose each other as league against league. No championship is involved; the players do not receive any part of the gate receipts, which are donated to the players' pension fund and to charitable purposes. The first All-Star Game, held in conjunction with the Century of Progress Exposition in Chicago, was played in Comiskey Park, home field of the Chicago White Sox (American League). In subsequent years the leagues have alternated as "home" teams. From 1959 to 1962 the major leagues played two All-Star Games each season.

The Hall of Fame. A National Baseball Hall of Fame and Museum is at Cooperstown, New York, where Abner Doubleday supposedly laid out the first baseball field. It contains relics, pictures, and documents, and its central chamber is the Baseball Hall of Fame, in which players and personalities who have made major contributions to baseball are memorialized. The first five players selected for membership in the Hall of Fame in 1936 were Ty Cobb, Babe Ruth, Walter Johnson, John P. ("Honus") Wagner, and Christy Mathewson. Additions to the roll of immortals are made from time to time by election in polls conducted by the Baseball Writers' Association of America and by the Hall of Fame Committee appointed by the commissioner of baseball. A special committee was formed in 1971 for the purpose of selecting one player each year from the Negro leagues, now extinct. The first Negro player to win election from this committee was Leroy ("Satchel") Paige, who pitched in the major leagues for five years when he was in the twilight of his career. For members of the Hall of Fame, see under SPORTING RECORD in the *Ready Reference and Index*.

AMATEUR BASEBALL

According to legend, in the United States almost every boy plays baseball or its variant, softball, during his school years. In the lower grades it is often played by both boys and girls during school hours, in the brief periods set aside for outdoor recreation. Records of competition between high schools date to 1886. Though the popularity of baseball in the rural and town areas has declined, it has grown at the high school level, from 150,000 participants in 1947 to more than 400,000 in the 1970s, with 13,000 high schools having at least one baseball team. In the warm-weather states, such as Arizona, Florida, and California, some of the high schools play a 50-game schedule, opening their season in January and finishing in June.

The largest organization offering a continuous amateur program without regard to age limit is the American Amateur Baseball Congress (AABC), founded in 1935. Originally designed for adults (unlimited age division), this program has grown to five divisions: Stan Musial Division (19 and older); Connie Mack (18 and under); Mickey Mantle (16 and under); Sandy Koufax (14 and under); and Pee Wee Reese (12 and under). By 1970, the AABC had approximately 3,000 sanctioned teams with an estimated 60,000 participants. National champions are crowned in each age division.

Organized ball for boys. The Little League, originally for the eight to 12 age group, is the best known of the boys' baseball programs. It started in 1939 with three teams in Williamsport, Pennsylvania, and had a phenomenal growth. By 1970 in the United States alone there were more than 60,000 Little League teams and 1,000,000 participants at the age 12 and under level. Subsequently, two older age groups were added—senior division for boys 13–15, and big leagues 16–18.

Little and junior leagues

Little League, which is now international, was granted a federal charter in 1964 by act of the U.S. Congress. The Little-Bigger League, for boys 13–15, was organized on a national basis in 1952 and at the end of the 1953 season changed its name to the Babe Ruth League. Competition supervised by the Police Athletic leagues in various cities and Boys' Baseball (formerly, PONY [Protect Our Nation's Youth] League) has been arranged for promotion of the game among boys.

The first national baseball program for boys was the American Legion Junior League, which was formed in 1926 for boys up to 17 years of age. In 1960 it was changed to include 18 year olds as well. There are American Legion teams in all 50 states and the Panama Canal Zone and Puerto Rico. In 1971 there were 3,200 teams. More than 60 percent of all the major league players participated in the Legion program as boys. When the Baltimore Orioles met the Pittsburgh Pirates in the 1971 World Series, 30 of the 50 eligible players for the series were graduates of the American Legion program.

College and international competition. Baseball is also widely played in colleges and universities. In 1967, the last time the National Collegiate Athletic Association (NCAA) surveyed its members, it was learned that more than 500 colleges fielded varsity teams, involving some 17,000 players. The NCAA, in 1963, provided the thrust in the formation of the United States Baseball Federation, which, in effect, is a collection of all the amateur groups. The federation sponsors clinics, is vigorous in promoting baseball, and, equally important, gives the United States a link with the International Federation, making American teams eligible for international competition such as the Pan-American Games and the World Amateur Tournament. The U.S. Federation usually selects all-star teams for international play, choosing the best players from the major and junior colleges and from the armed forces; in 1972 the federation announced an agreement with the Japanese Amateur Baseball Association to conduct a Collegiate World Series between the United States and Japan, beginning in July 1972.

Baseball tournaments are played on U.S. Army posts the world over. The game is a minor sport in many European countries (*e.g.*, The Netherlands, Italy, Belgium, England, Spain), as well as in Australia and Tunisia.

(Je.Ho.)

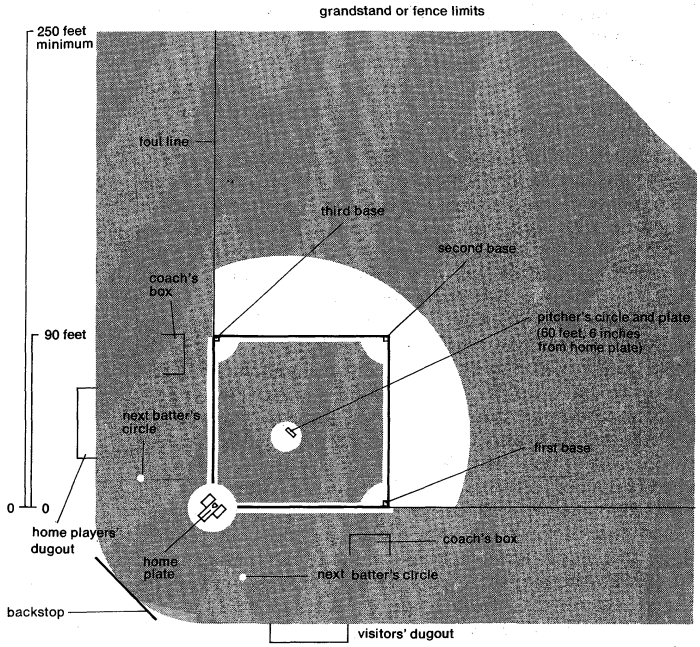
II. Play of the game

GROUNDS AND EQUIPMENT

The field of play. The baseball field, usually called the diamond, is a large, level area, most of which is covered with natural or artificial grass. Though the field may cover about two acres (one hectare), the actual dimensions vary from field to field.

The layout of the field is based on the layout of the bases, which form a square, also known as the diamond or infield, with the home base, or home plate, as the

point of orientation (see diagram). The sides of the square, and thus the distance between the bases which form its corners, are 90 feet (27.4 metres). White lines marked on the ground along two sides of the square



Layout of a representative baseball field.

The baseball diamond

(from home to first base and home to third) extend beyond first and third to the nearest fence, stand, or other obstruction. These are foul lines marking the left and right limits of the field of play; the outer limits are formed by a fence or the walls of stands. The distance along the foul lines from home plate to the limits of the field must be 250 feet (75 metres) or more; in ball fields built after 1958, it must be at least 325 feet (100 metres) and the distance to the centre-field fence at least 400 feet (120 metres). The entire area between the foul lines and extending roughly from the square to the outer limits of the field is known as the outfield.

The playing field is covered with natural or artificial turf except for a circular area around the pitcher's plate (see below), which is bare; traditionally, the paths between the bases and an area extending beyond the base lines from first to third (the size and shape of the area being determined by each club for its own ball field) also are left bare, as is the area around home plate. With the introduction of artificial turf, the tendency has been to cover the entire field except the areas around the pitcher's plate, home plate, and immediately around the bases. Although the infield is defined as the square delineated by the four bases, in common usage it also includes the area beyond the second- and third-base lines. There is no actual dividing line between the infield and the outfield.

First, second, and third bases are marked by white canvas bags filled with a soft material (such as kapok) and securely attached to the ground by means of a metal peg or stake. Home base or, more generally, home plate, is a pentagonal white slab of rubber embedded in the ground at the intersection of the first- and third-base lines, its front edge facing the pitcher.

In the middle of the infield is the pitcher's mound, a circular area kept free of grass and rising in a gentle slope only slightly above the level of the base lines. On its summit, which is flat, the pitcher's plate, a slab of rubber that the pitcher must step on when delivering the ball, is embedded in the ground 60 feet six inches (18.5 metres) from home plate. The pitcher's mound and plate are sometimes referred to collectively by the term pitcher's box, a holdover from the 19th century when an oblong area was marked out on the ground for the pitcher to occupy in the act of throwing the ball.

Behind home plate is the catcher's box, the rectangular area within which the catcher must remain until the pitcher delivers the ball. On either side of the plate are marked batter's boxes, one for right-hand and one for left-hand hitters. The official rules recommend that the distance behind home base and the backstop screen and from the first and third base lines to the grandstand or fence limits be at least 60 feet (18 metres). Within this area, known as foul territory, and 15 feet (5 metres) off of first and third base are the coaches' boxes, rectangles, for the two men for each team assigned to guide base runners and communicate signals. Also in this territory and about 40 feet (12 metres) from each of the batter's boxes are two "on deck" circles—areas in which the next person to bat waits his turn.

Uniforms. The uniform consists of a cap, blouse, pants, stockings, and shoes. Traditionally, the home team wore white blouses and pants, the visiting team gray; in the 1960s and 1970s, however, some teams began to wear coloured uniforms. An identification number is worn by each player.

The blouse is collarless and without sleeves or with short sleeves usually ending halfway from shoulder and elbow. The pants cover the player's knee, the elastic at the bottom pinching in just below the knee joint. Most players wear thigh pads under the pants and suspended from the waist for protection from abrasions when sliding along the ground into a base and in unintentional tumbles.

Players wear white cotton stockings underneath coloured stockings.

The shoes are oxford-style, light in weight, with flexible soles and heels. Each shoe has three prongs (spikes) on the sole and three more on the heel. The spikes, whether attached to the shoe individually or to triangular metal

spike plates, give the player a good grip on both the turf and the grassless dirt surface of the base lines. The pitcher also wears on his pitching foot (right foot for a right-handed pitcher; left foot for a left-handed pitcher) an additional pitcher's plate, a metal reinforcement at the inside of the toe to give him a better foothold in the act of pivoting to deliver the ball. Umpires wear shoes similar to those of the players. On artificial turf, some players wear a shoe that has up to three dozen small cleats, usually made of a synthetic and similar to the type worn by football players on synthetic grass.

The bat and ball. The bat is a smooth, rounded stick, made either of a single piece of hardwood or of laminated construction; the maximum length allowed is 42 inches (107 centimetres) and the maximum thickness is 2¾ inches (7 centimetres), decreasing in diameter at its handle end. There is no restriction of the bat's weight, except that no metal or any other reinforcement may be used in its construction. The gripping surface may have a covering of tape or other abrasive agent to give a firm hold for the batter's hands.

The ball is restricted to a weight of between five and 5¼ ounces (142 and 149 grams) and a circumference of from nine to 9¼ inches (23 to 23½ centimetres). It has a cork and rubber core, is wound tightly with woolen yarn, and is covered with two pieces of white leather shaped to fit together tightly when the two pieces are sewn together.

Gloves. In preleague baseball, the game was played bare-handed. One by one, starting with the catcher and first baseman, players began to wear gloves to protect whichever hand bore the brunt of the ball's impact. Every player now wears a glove when in the field.

Types of gloves

The gloves are leather, with some reinforcement (padding). The catcher's glove is the largest and heaviest, thickly padded at all points except the middle of the palm, in which the pitched ball embeds itself. It is all one piece, except for a cleft between the thumb and the index finger. The size of this glove is limited to 38 inches (97 centimetres) in circumference and cannot be more than 15½ inches (39 centimetres) from top to bottom. The first-baseman's glove, thinner and much more flexible than the catching mitt, is a solid expanse of leather for the four fingers. The thumb, however, is separate, with a webbing connecting it with the index-finger edge of the rest of the glove. Gloves worn by pitchers, infielders, and outfielders are finger gloves, usually with a separate compartment for each finger and for the thumb. Two or more leather straps connect the thumb with the index finger, enabling the player to get a tight hold on a swiftly moving ball.

Protective equipment. Except for the catcher, the player in the field is considered adequately armoured when he wears his regulation uniform and glove. The catcher wears a mask, chest protector, and shin guards as well. The mask, a padded metal frame with solid bars across its open front, fits the front half of his head, so that the catcher has full visibility but is protected from being hit in the face or about the head, ears, and throat by the ball. The chest protector is a solid, padded framework extending up over both shoulders and down between the legs, folding at about the waistline to allow stooping. The catcher's shin guards are of light metal over the shins, with padded leather extensions that fit over the knees, and at the bottom are shaped to the shoes so that a catcher blocking home plate has reasonable protection from the spikes of a player sliding feet first.

Protection for the catcher

At bat, a player wears a lightweight batting helmet in addition to his regulation uniform.

The umpire, likewise, wears mask, chest protector, and shin guards when on duty behind home plate. The mask is similar to the catcher's.

CONDUCT OF THE GAME

The umpires. Play is under supervision and control of one or more umpires, acting as judges and announcing decisions on whether pitched balls pass over the plate within or outside the strike zone, whether batted balls are fair or foul, and whether a base runner has been put out by a throw or by tagging or is safe (*i.e.*, entitled to hold the base he has reached by running).

Four umpires are on duty in major-league games, one stationed behind the catcher and the other three covering the plays that occur at first, second, and third bases. The home-plate umpire starts the game by calling play for the first inning. The ball goes into play when the pitcher pitches it to the catcher. It remains in play except when an umpire calls "time," which is done on all foul balls except those that are flies (*i.e.*, caught before touching the ground) and also upon the request of either team at a time when the ball is being held by a player of the fielding team and no base runner is attempting to advance. The request for time most frequently is made by a batter when he wishes to step out of the batter's box between pitches. Time is also called on the rare occasions when a batted ball strikes a base runner, and in other circumstances as the umpire's discretion dictates.

Managers and coaches. In professional baseball, the manager is the man who runs the team. He selects the players who will play in each position in each game and the order in which each will bat; he formulates plays; and he determines offensive and defensive strategy and tactics, and how and when they will be used or altered during the game. He decides, for example, when to change pitchers or use a pinch (substitute) batter.

The manager is assisted by a staff of coaches, usually accomplished players who have passed their playing days; they act as all-around assistants to the manager and work with the players, especially the younger players, to help them develop their pitching, batting, fielding, and other skills of the game.

Another coaching function, which may be performed not only by a member of the coaching staff but also by any other member of the team, including the manager, is to give instructions (by voice or by means of signals) to base runners and batters of his team. When a team is at bat, one coach may stand within the coach's box off first base and one within the coach's box off third. The coaches, in turn, receive instructions from the manager, usually through signals, as to what strategy should be employed in a given situation.

Coaching functions

PRINCIPLES OF PLAY

The bases are called first, second, and third base and home base or plate. All batting is done at home plate. Base running proceeds from home plate along the base lines (the boundaries of the square). A run is scored when a player, having successively touched first, second, and third, reaches home plate.

Seven of the nine players on the fielding team take their stations, prepared to capture (field) the ball as soon as possible after it is hit by the batter. The other two, the pitcher and the catcher, form the battery. The catcher stands behind and within stepping distance of home plate but not close enough to impede the batter's activities.

The pitcher stands near the centre of the infield. He puts the ball in play by throwing it to the catcher. The batter, standing on one side of home plate, gets a chance to hit the ball as it passes him on its way to the catcher. He stands facing the plate, swinging the bat with both hands, and putting the full force of his shoulders and arms into his swing at the ball.

The pitcher is the central figure in the game, which is a succession of "plays." Each play begins when the pitcher delivers the ball to the batter and lasts until the pitcher holds the ball again, standing with his foot against the pitcher's plate, or rubber, ready to toss the next pitch.

If the ball travels past the batter to the catcher and is then tossed directly back to the pitcher, it is a complete play in itself. If the ball is batted, the play goes on until the ball has been fielded, all base running has come to a stop, and the ball returned to the pitcher.

Players are termed right-handed batters or left-handed batters, according to whether they swing the bat from their right side or their left.

When the batter hits the ball inside fair territory (the area of the playing field between the foul lines), he is entitled to start running round the bases. Since it is only

a fair ball that entitles the batter to run, the fielding team's defensive arrangement places its seven movable men within the fair territory. Four of them (the infielders) patrol the ground between first and second and between second and third. The other three (the outfielders) play the outfield, the wide sweep of the field from foul line to foul line beyond the two base lines.

The fielders' playing positions

The outfielders are called right fielder, centre fielder, and left fielder with relation to a man standing on home plate and facing toward second base, but there are no visible boundaries separating the three fields. With the exception of the pitcher and catcher (and in their case only at the moment of putting the ball in play), there is no restriction on the movements of the members of the fielding team. The four infielders are named first baseman, second baseman, shortstop, and third baseman, stationed in that order from first base around the rim of the infield to third. Their fields of operation are nearly as flexible as those of the outfielders. The arrangement of the fielding team, at any given point in a game, is changed to meet the needs of the existing situation.

Offense. The objective of the offense is to score runs. The main offensive force at work in a baseball game, at any given point, is the batting team's ability to hit fair balls out of the reach of the defending fielders. Along with this batting goes the running speed of the batting team in its efforts to traverse the bases. Each team strives to advance its players around the bases to score as many runs as possible before the third out ends its half of the inning at bat. Each inning is a new game in the sense that it starts with the bases empty. The first man in the batting order is the first batter in his team's first inning. In subsequent innings, the first batter up is the man in the batting order after the last batter in the previous inning to complete his turn at bat.

Hitting the ball. The acme of successful batting is to drive a pitched ball inside the foul lines and beyond the confines of the playing field (usually into the stands among the spectators or completely out of the park). A ball so driven is called a home run. It has passed beyond the reach of any fielder and entitles the batter to run at any speed around the bases to score a run at home plate. Any and all runners who are on base when the home run is hit likewise make their way to the plate, in the order in which they reached base, and register a run each.

Hits and errors

Failing such a hit, the batter aims to drive the ball so that it cannot be caught either before touching the ground in fair territory or soon enough after touching ground to be thrown to first or any other base before the batter or any other runner gets there. If he succeeds in getting on base before the ball gets there, he has made a hit. If he reaches first base and no farther, it is called a one-base hit. If he drives it far enough so that he can reach second base safely, it is a two-base hit. A hit long enough for the batter to reach third base is a three-base hit. A similar hit by a batter that enables him to touch all bases and score a run is known as an "inside-the-park" home run—a rarity.

With the ball thus hit by the batter into fair territory, any members of his team who are already occupying bases advance as far as possible toward home plate before the ball is returned to the infield. They must reach their objectives without being tagged out; thus, their judgment of how far they can go when the ball is hit safely is a major element in successful attack.

A batter may hit the ball inside fair ground and reach base safely because of a fielding lapse (*i.e.*, failure to catch the ball or inaccurate throwing). This is recorded as an error committed by the fielder. Failure to tag a runner with the ball when the fielder has a chance to make a putout in this way also counts as an error.

Base on balls. A batter may also reach first base without having hit the ball. This is nearly always the result of inaccuracy by the pitcher in his efforts to make the batter hit a bad ball (*i.e.*, a ball passing the batter at a point at which the batter cannot hit the ball with his full power). Whenever the batter does not swing at a pitched ball, and the ball does not cross the plate inside the strike zone, the umpire standing behind the catcher announces, "one ball." If four balls are thus declared in a single turn at bat—that is, before the pitcher has thrown three strikes—the batter is entitled to go to first base without a play being made on him, the recipient of a base on balls, also known as a walk. A game without a base on balls for any batter of either side is unusual.

Getting on base without a hit

Wide World Photos

Hit by pitched ball. The batter reaches first base, without hitting the ball, if a pitched ball at which he does not swing strikes any part of his person. The umpire then awards him the right to go to first base.

Interference. The batter also reaches first base if the catcher interferes with him by touching any part of his body or interferes with the swing of his bat as the pitched ball is on its way to home plate. The catcher in such a case is charged with an error.

When a batter is awarded a base on balls, for being hit by a pitched ball or for interference by the catcher, teammates on consecutive bases from first on advance one base; if all three bases are occupied (loaded), all advance one base, thus scoring a run for the batter's side.

Missed third strike. If, with two out or with first base unoccupied regardless of how many are out, the batter swings and misses the ball for his third strike and the catcher does not catch the pitched ball before it touches the ground, the batter is entitled to run for first just as if he had hit the ball along the ground in fair territory. The batter is also entitled to run to first base if the catcher misses a third strike that the batter does not swing at. The catcher must then get the ball and throw to first ahead of the batter in order to put him out. If such a pitched ball rebounds off the catcher out into the infield, the pitcher or any infielder may make the pickup and throw to first, just as if it were an infield grounder. This right to try for first base does not exist when first is occupied and there are fewer than two out because, if it did, the catcher might drop the ball directly in front of him and thereby create the opportunity for a double play, throwing to second to force out the man on first.

followed by a throw from second to first before the batter arrived at first. Missed or dropped third strikes are uncommon in the professional leagues.

The infield fly rule. Similar protection is afforded the batting side by the infield fly rule. This rule applies only if both first and second or first, second, and third bases are occupied, there are fewer than two out, and the batter hits a high fly that in the judgment of the umpire can readily be caught by an infielder or the pitcher or catcher inside fair territory. In such circumstances, the umpire immediately declares the batter out, whether or not the ball is actually caught. This law was enacted in 1895 because clever infield players would pretend to catch the fly but at the last moment would let it strike the ground, thus setting up a force play (see below) at both third base and second base, which could be made a double play by quick and accurate throwing. An attempt to bunt (a light tap of the ball rather than a full swing at it; see below) under the conditions noted above, which results in a fair fly, is not regarded as an infield fly.

Stolen bases. The base runner can wait on a base until a teammate drives the ball out of reach of fielders, enabling him to advance toward home plate to score a run. The rules do not, however, compel him to wait for the ball to be batted. He may advance on the bases at any time the ball is in play, his only restraint being the threat of being tagged out; that is, of being touched with the ball in the hand of a member of the fielding team when he is not on a base. Obviously, a dash for the next base when the ball is being held by the pitcher, the catcher, or an infielder makes the runner almost a certain out. When the pitcher delivers the ball to the batter, however, the runner can match his speed with the strength and accuracy of the catcher's arm. If the runner makes such an attempt and succeeds in reaching the next base without being tagged out, he is said to have stolen a base.

Stolen-base records

Major league stolen-base totals rose significantly in the 1950s and 1960s; there were 650 successful steals in 1950, 923 in 1960, and 1,908 in 1970, when 12 players, six in each of the two major leagues, stole 30 or more bases. Maury Wills, who was instrumental in the return of the stolen base, in 1962 set a modern (20th-century) major league record by stealing 104 bases, bettering the record of 96 set by the famous Ty Cobb in 1915.

The hit-and-run. Many attempts at stealing bases in modern baseball take the form of the hit-and-run play, in which the batter cooperates with the runner. The setup almost always calls for a runner on first, but on no other base. The runner starts for second as the pitcher begins his pitch. If the second baseman shifts to be in position to receive a throw from the catcher, the batter tries to drive the ball along the ground through the area ordinarily guarded by the second baseman. If it is the shortstop who has thus covered second, the batter tries to drive the ball through the shortstop's vacated sector.

If the batter succeeds in his effort, the ball goes to the outfield as a hit and the runner reaches third base easily. There are lesser degrees of success. The batter may hit the ball along the ground but not through the open sector. This usually results in an out at first base on the batter, with the runner reaching second safely, a moderately advantageous outcome because it has placed the runner on second, in position to score on an ordinary one-base hit to the outfield by a subsequent batter, and has removed the double-play menace that always exists when a runner is on first base with fewer than two out.

If the batter hits a fly, the runner must quickly retrace his path and regain first base; this is usually done easily. If the batter misses the ball entirely, the most he has accomplished is to offer a visual hazard to the catcher's throw to second base. The play in this instance takes the pattern of a plain attempt to steal second. In every major league season a large percentage of the stolen bases credited to players are the result of hit-and-run plays in which the batter fails to hit the ball.

The bunt. Nearly every time a batter tries to hit a ball he takes a full swing, aiming to drive it as fast and as far as he can. There are times, however, when he tries to bunt the ball—that is, tries to tap it lightly with the bat—to make it roll slowly along the ground in fair territory but off to one side or the other of a straight line from catcher to pitcher. In bunting, the batter usually relaxes his grip on the bat and, instead of swinging, merely holds out his bat so that the ball strikes it and drops to the ground with only enough force to send it out at a point in the infield. The batter tries to conceal his intent as long as possible so that neither the pitcher and catcher nor the infielders can get the jump on the play. The bunt is usually intended to be a sacrifice; that is, the batter expects to be thrown out at first base. His purpose is to enable one or more runners to proceed to their next base while the play is being made on his bunt, retiring him at first base. He thus sacrifices himself in the interests of advancing a potential run or two.

The squeeze play. The bunt is also used to sacrifice a runner home from third base, but the technique is somewhat different. On a prearranged signal, as the pitcher starts delivering his pitch, the man on third starts running toward home plate. This is an all-or-nothing play and was the original squeeze play. It is now known as the suicide squeeze because, if the batter misses entirely, the catcher, by catching the ball, has the runner trapped between third and home, a certain out, unless the runner resorts to dodging back and forth and some error of throwing or catching allows him to escape. If the batter does bunt the ball into fair territory, it means a certain run scoring for his side because of the runner's flying start. At best, the defensive side can only throw out the batter at first base.

Bunting to bring in a run

The suicide squeeze is the most spectacular and dangerous sacrifice bunt and was the forerunner of the safety squeeze, a similar manoeuvre but without as much risk. On the safety squeeze the runner at third holds until the hitter has bunted the ball on the ground. This delay makes it easier for the defense to adjust, but the play will succeed with a fast runner at third and a better than average bunter capable of pushing the ball about 20 feet (six metres) down either the first- or third-base line, but not much farther. If the bunt is shorter, the catcher can run it down and throw the ball to the pitcher who has rushed to cover the plate.

The batting order. Each of the nine players on a team must take his turn at bat. The strongest hitters are grouped conventionally in a certain order that has no relation to the positions they may play in the field. The first two positions, leadoff and number two, are assigned usually to players with keen eyes and brains, those fast afoot, and usually not so powerful in driving the ball for distance as batter number three and the cleanup man, number four.

The best leadoff is one who can judge whether the pitch will be a strike or a ball if he lets it pass him without swinging. By waiting out the pitcher, letting the bad ones pass, he draws many a base on balls. In his strategic position, first batter up in the first inning, and following the weak-hitting pitcher in the other innings in which he bats, a base on balls for him is usually just as advantageous to his team as making a one-base hit. Getting on base is the leadoff's main offensive function. Over a stretch of games his run-driving opportunities are relatively few.

For batter number two the manager selects his best hit-and-run man, the batter who is most skilled in driving the ball toward the right side of the field. When there is a runner on first, the first baseman must stay on or close to first, thus opening a wider sector through which the ball may safely be driven along the ground into right field. The ability to hit the ball in this direction is important, especially on a hit-and-run play with the runner rushing for second as the pitcher pitches. The number two man must also be a capable bunter.

Number three is usually the best all-around offensive player on the team, having running speed combined with batting power and skill. The greatest hitters of all time have been, in the main, number three in their team's batting order—Ty Cobb, Babe Ruth, Rogers Hornsby, Eddie Collins, George Sisler, Joe DiMaggio, Ted Williams, Stan Musial, Willie Mays, and Roberto Clemente.

The number-three hitter

Not all of those players hit third every season; sometimes they batted fourth, usually when their teams were without another outstanding home-run hitter.

Numbers four and five are the long-distance hitters, not likely to hit the ball safely as often as number three, but often with greater distance. The remaining positions in the batting order scale downward, and it is there the highly skilled defensive stars, players whose value to the team is their mastery of their fielding position, may be found. Number nine is almost invariably the pitcher, the most specialized of all players, whose hitting ability is usually negligible. Because a pitcher is called on for duty only about once in four or five days, even pitchers who can hit well do not have the chance to remain tuned up. Their batting ability is rarely considered; in every other position a man's worth always represents his combined batting and fielding skills.

In the positions requiring less skills, fielding ability is a less important factor. Batting ability overshadows fielding considerations in positions such as right field or left field, third base, and even first base; in the other positions the manager will weigh very carefully the fielding merits of the aspirants in making his selections. He usually wants for his shortstop the best possible fielder he can find, regardless of batting, and whatever such a star fielder can furnish in hitting power is sheer profit. His left and right fielders and first and third basemen, however, must be hitters, and their ability to run faster, to judge a fly ball, or to throw a ball straighter is secondary.

Substitutions. Substitutions may be made at any point in the game when time has been called by the umpire. A player taken out of the lineup cannot return in the same game. When the manager makes two or more substitutions at one time, he must specify them one at a time to the umpire, so that each substitute's place in the batting order is immediately established. Such substitutions may be made regardless of the positions played by the players involved. For instance, the manager may take out of his lineup his pitcher and second baseman, substituting a second baseman to bat in the pitcher's place in the batting order, the new pitcher batting where the second baseman formerly batted. He may send in as many substitutions at one time as he wishes, up to the limit of his nine names, but each substitute takes a fixed position in the batting order at the moment the change is made. Without making any substitution, the manager may at any time in the game shift his players from one fielding position to another. He may shift all nine positions in fielding, but he cannot change a man from one place to another in his batting order.

The use of a substitute as an offensive tactic most commonly involves sending in a pinch hitter; that is, taking a weaker hitter out of the lineup and substituting another player whose likelihood for driving the ball for a hit or a fly to the deep outfield is greater than that of the player next up in the batting order. Such a pinch hitter must be a player not already in the lineup nor in the batting order at any previous time in the game.

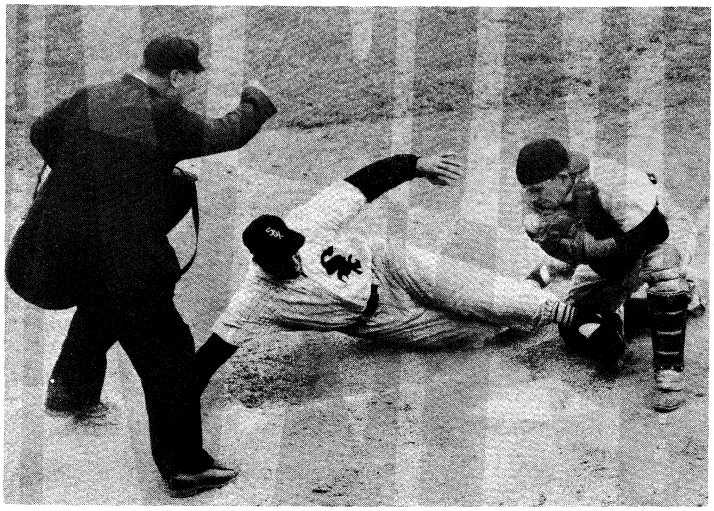
In 1973 the American League adopted experimentally the designated pinch hitter rule. The rule allows a pinch hitter, designated before the game, to bat for the pitcher without forcing the pitcher from the game. The pitcher may take his normal turn at bat, however, in which case the designated pinch hitter is taken out of the lineup and regular rules prevail. During a game the designated pinch hitter can replace a defensive man on the field. If this happens he continues to bat in the pitcher's spot, and the pitcher then bats in the spot vacated by the defensive player forced from the game.

Defense. To meet the offensive force of the team at bat, the rules provide the fielding team with ways of making putouts. A putout removes the player from further offensive play until his next turn at bat. The batting team's inning continues until three putouts are made; then the team goes into the field and the rival team comes in for its turn at bat.

Putouts. Most putouts are made by (1) striking out the batter; (2) catching a fly; (3) throwing him out; or (4) tagging out a base runner. The batter is struck out when the pitcher succeeds in preventing him from hitting the ball into fair territory within the limit of three strikes. Strikes are counted on the batter whenever he swings at a pitched ball and misses or when he does not swing at a pitched ball that passed him inside the strike zone.

The strike zone is an imaginary rectangular plane in front of the batter. Its top and bottom are in line with his armpits and knees, respectively. Its long sides are imaginary perpendiculars extending upward from both ends of the front rim of home plate (see diagram). The strike zone is thus a rectangle 17 inches wide, facing toward the pitcher, the length of its vertical sides depending on the height of the batter. When the ball passes through this rectangle at any point and the batter does not swing, it is called a strike, as if he had swung and missed.

UPI Compix



Sliding into home plate to score. Base runner Jim Rivera (Chicago White Sox), who knocks the ball from catcher Yogi Berra (New York Yankees), July 28, 1954.

A strike also is counted when the batter fouls the ball to the ground or out of the field of play. Fouling the ball means striking it with the bat but not driving it inside fair territory. This foul strike is not counted if the batter has two strikes against him, provided he swings at the ball in fouling it. If, with two strikes, he fouls in an attempt to bunt—that is, merely blocks the ball with his bat—his foul counts as a third strike and he is out.

Foul balls and force outs

A batter is put out if a member of the fielding team catches and holds a batted ball before it touches the ground, whether it is a fair ball or foul. There is the exception that a foul tip, a pitched ball that the batter merely flicks slightly with his bat, counts as a strike even if it is caught and held by the catcher. It does not count as a putout unless it occurs on the third strike.

A member of the offensive team is tagged out if, when running the bases and not in contact with a base, he is touched by the ball in the hand of a member of the fielding team. A member of the batting team is thrown, or forced, out if he bats a ball that touches the ground before being caught (usually by an infielder or the pitcher) and thrown to the first baseman, who touches first base, while holding the ball securely, before the batter can reach first base.

Only one runner may have title to a base at any given moment. It is therefore possible for a runner to be thrown out at second base, third, or even at home plate without being tagged. The batter becomes a runner entitled to try to reach first base safely the instant he hits a fair ball that strikes the ground. At that same instant, if there was a teammate on first when the ball was hit, that base runner is no longer entitled to first base and must run to second. If runners are on both first and second or runners are on all three bases, they are all forced to run when the batter hits a fair ball that strikes the ground. Any base runner thus forced to run can be put out, or retired, without tagging, by the throw of the ball to a

fielder who can touch the base before the runner reaches it.

The force play

This method of retiring base runners is called the force play. With first base occupied and the ball driven along the ground to the pitcher or an infielder, the ball can often be first thrown to second base for a force out of the man from first base, then relayed to the first baseman to retire the batter—two outs on one play. This is the usual form of the double play in baseball, one of the most effective and spectacular defensive tactics.

A runner can also be thrown out without being tagged if he has left his base before the ball was hit in a fly that is caught. With the catching of the fly, the runner must return to the base he just left before being eligible to advance. If the catcher of the fly throws the ball to that base before the runner returns and touches it, it counts as an out, retiring the runner as well as the batter by a double play of a different type than the force play, "double up," described above.

In very rare cases a runner can be tagged out while standing on a base if, through confusion of mind or misjudgment of the play in progress, he remains standing on a base to which he is no longer entitled. In almost all situations of baseball, however, the bases form anchoring posts (isles of safety) for the players of the side at bat in their progress toward scoring runs.

Intentional pass. Frequently (sometimes as many as three or four times in a single game), a base on balls is given not because of the pitcher's inaccuracy (see above *Base on balls*) but for tactical reasons. If, for instance, the team at bat has a runner in scoring position (*i.e.*, on second or third base, or both) but none on first, and especially if the man at bat is more likely to make a safe hit than the man who will follow him in the batting order, it is considered sound tactics to give the batter an intentional pass, or base on balls, to first base. The catcher moves from behind the plate to one side after the pitcher delivers the ball, and the pitcher delivers four pitches that the batter cannot reach while standing in the batter's box. The batter thus receives a base on balls and must go to first base, thus setting up a possible force play if the next batter can be induced to hit a ground ball into the infield.

Defensive positions and strategies. In the scale of defensive skills, pitcher is number one, shortstop is number two, and second baseman is number three, followed by catcher, centre fielder, first baseman, and third baseman, and, finally, the two flanking outfielders, whose relative importance is usually determined by the contour of their home playing field's outfield boundaries.

This scale of skills is the basis of the baseball expert's argument in rating one team defensively superior to another because it is stronger "down the middle." An outstanding team usually has a star player at each middle position—catcher; "the keystone combination," meaning the second baseman and shortstop; and centre fielder.

Outfielders. The three outfielders collectively require less special skill than in any of the other six positions. All the catching of thrown balls, all tagging of base runners, and all plays on ground balls to retire runners at bases take place in the infield and the immediately adjacent terrain. The outfielders are stationed in order to be able to catch batted balls driven reasonably high in the air beyond the infield. They must be able to judge the trajectory of such flies and have enough speed to run to the point where the ball will come down.

Batted or thrown balls that pass beyond the infielders along the ground must be run to earth and picked up by the outfielders. Strong throwing arms are essential, as is accuracy in throwing the ball to the right point in the infield. An alert outfielder can also add to his value by moving in as a backup of the infield when the ball has been batted to some point other than his own area and is being thrown about by his teammates in an effort to retire runners. On rare occasions an outfielder aids in a double play, when a base runner misjudges the fielder's ability to catch a well-hit fly ball, which then is returned to a base before the runner can return to it as the rule requires, or when a runner tries to advance after the catch and has misjudged either his own speed or the fielder's ability to throw.

Role of the centre fielder

Because of his central position in the outfield, the centre fielder must possess great speed and expert judgment of a batted ball's trajectory. The accomplished centre fielder makes a study of all the important batters of rival teams. He keeps a mental chart of each batter's power (*i.e.*, toward which point in the rim of the outfield the batter's longest drives usually are directed). The centre fielder will not only station himself at a strategic point to meet each threat but will also direct the playing positions of his outfield teammates on either side. Such a strategic shift of position often makes the difference between a three-base hit and a putout. Almost invariably the great defensive outfielders of baseball history have been centre fielders (Tris Speaker, Max Carey, Terry Moore, Joe DiMaggio, and Willie Mays, to name a few).

Infielders. The outfielders form the outer ring of defense against the batting of the opposing team; the infielders form an inner ring, four strong, their function to field the ball at close range. They sometimes capture line drives on the fly, but mainly they pick up grounders skipping along the ground toward the outfield or shooting swiftly across the grass on one or more bounces. The fielding of a grounder is the most characteristic play in baseball, setting it apart from most other sports. When a batted ball strikes the ground, the game becomes a race between the batter's speed in running to first and an infielder's agility in gaining control of the ball and throwing it.

The four infielders shift positions to guard against each batter's individual power, as do the outfielders. They have the additional responsibility of guarding the bases when occupied. When a ball is batted along the ground, only one of them is called upon to gain control of it, but at least one of the others almost always covers a base to take the throw; sometimes two bases must be covered for a possible throw, and sometimes all three. If an attempted bunt is anticipated, the first and third basemen move in from their accustomed positions toward home

plate, ready, as are the pitcher and catcher, to rush toward the bunted ball and to throw it to second, third, or home for the force play or to first to retire the runner.

Infield strategy

In many situations arising in the course of one game, the infielders must adjust themselves correctly, rapidly, and in cooperation. The fielding of grounders—pickup and throw—is the common skill of all four infielders. Each position has its special fielding requirements.

The throw from shortstop is the longest and most difficult. The batted ball may be a swift one shooting toward the outfield to his right or left or straight at him, or it may be a tantalizing slow "hopper," for which he must rush toward the plate in order to field quickly enough to retire the batter.

The second baseman's function on grounders is the same, except that his shorter distance from first gives his throw an extra instant of time. In contrast to the shortstop, however, who always faces first base except when a ball is off to his right, the second baseman on most of his grounders must turn and throw "around the corner."

On a force play at second, whether or not a part of a double play, either the second baseman or the shortstop must cover second to catch the throw, with his foot touching the base, just as the first baseman does on an out at first. The force play is always a potential double play. The second baseman, coming to the base to take the throw, must turn to his left for the throw to first base to complete the double play. Thus, skill in pivoting is important in a second baseman.

The third baseman, playing nearer the batter than the shortstop or second baseman, is not called on to cover as wide a zone. The grounder aimed his way reaches him or is past him into the outfield sooner than at second or short. On his most difficult play, the fielding of a bunt or a dribbling roller halfway between home plate and his position, the third baseman has a throw to first that is shorter than those the second baseman and shortstop ordinarily make, and he often has more time in which to make it.

The first baseman's fielding of grounders is made easier because of his position near the base that the batter is running toward. Often the first baseman is able to touch base with his foot, with ample time to spare, after picking up the grounder. When there is no time for that, his throw may be a mere underhand toss to the player (often the pitcher) who moves over to cover first.

The battery. The pitcher and catcher together are known as the battery or as batterymen. The pitcher may function as an emergency first baseman when the first baseman fields a grounder too far from first to reach the base before the batter. This is not a difficult fielding play for the pitcher, provided he starts running promptly. The distance from the pitcher's box to first is roughly two-thirds as far as the batter must run. The pitcher then catches the ball tossed to him by the first baseman and touches first base with his foot. This is a fairly common play.

Fielding functions of the pitcher and catcher

The pitcher's other fielding functions consist of trying to field any ball batted in his direction. On bunts the pitcher functions as an infielder, covering his share of the zone between the foul lines and between the pitcher's box and home plate. Fielding skill is an important asset to a pitcher.

The catcher, as a fielder, is mainly a catcher of high flies, a thrower, and a guard at home plate. The flies usually soar almost straight upward from the bat and come down in foul territory someplace between the base lines and the grandstand or directly in front of home plate. Ability to perceive the angle at which the ball leaves the bat is necessary to get a quick start in the right direction from home plate.

The "good hands" essential to every player are especially important for the catcher. Throughout the game he must catch the pitched balls not hit by the batter and sometimes pitches that strike the ground near the plate. Sometimes he must jump for high ones or wide ones. The bat swinging directly in his visual line as he reaches for the pitch is no hazard to him. From long experience he has become accustomed to it. It is when the bat flicks the ball slightly in passing that the catcher's good hands are needed most. If the batter has two strikes, the ability of the catcher to catch such a tipped ball and hold it results in a strikeout, ending the batter's turn at bat with a putout; eluding the catcher's grasp, it becomes a mere foul ball, granting the batter one more chance to hit safely.

The catcher sometimes fields a bunt or a half-hit ball just in front of the plate. Agility in pouncing upon the ball and accuracy in throwing to the proper base are then required. The catcher's throwing arm is a valuable element in his team's defense. Base runners will be cautious of straying too far from their bases when the catcher has a quick and strong arm ready to shoot the ball to the baseman for a tag-out before the runner can scramble to safety. When a runner attempts to steal a base, the attempt usually begins at the start of the pitch. Unless the batter hits the ball, the play then becomes a match between the catcher's throwing arm and the runner's speed.

The catcher as counselor

Important as is his fielding, the catcher functions even more importantly as the counselor of the pitcher, as well as the rest of the team. As the only player in the defensive lineup who has the whole game in front of him at all times, the catcher is best placed for advising teammates when necessary.

In general, the catcher directs the pitching strategy. Veteran pitchers, learned in the ways of batters in general and with their own special systems of pitching to each, need little assistance from the catcher. For most pitchers, however, and particularly for those with less experience, the catcher, squatting behind the plate with his hands together between his knees, signals with the fingers of his bare hand what the next pitch should be. His knowledge of the pitcher's and the batter's abilities and peculiarities guides him. The catcher keeps his partner under constant study, alert to signs of weakening, even in a veteran pitcher. Occasionally, the catcher consults with the manager to replace one pitcher with another.

Pitching as the basis of defense. Until a batter hits the ball, the game is a duel between the pitcher (and catcher) and the batter, which is repeated as each batter comes to bat. Each batter that a pitcher strikes out or forces to hit a pop-up (an easily caught fly) or easily fielded grounder is a gain for the defense, preventing runs and bringing the team closer to its turn at bat and a chance to score.

In 19th-century U.S. baseball, up until about 1870, the pitcher was merely a player assigned to put the ball in play by pitching it to the batter to hit. One man generally did nearly all the pitching for a club all season, with a change pitcher to relieve him of some of the load at times. This change pitcher was usually an outfielder. The two would often merely exchange fielding positions without leaving the game. With the start of league baseball in the 1870s, the pitcher became a stronger factor in defensive play. His use of speed and curves became a deciding element in championship contests.

A major league club normally has 25 players on its roster; usually ten are pitchers. A team's infield and outfield lineup may remain intact for weeks on end, barring injuries and illnesses. Its regular catcher occupies that position in more than two-thirds of the season's games.

Starting and relief pitchers

In a staff of ten pitchers, the manager usually earmarks his best four or five at any given time as starting pitchers. These are the rotation starters. They take their turn every four or five days, resting in between. During rest days they do light exercise, run about the outfield during practice, and keep their pitching arms moderately exerted each day, but in general merely keep in shape until their next turn to pitch.

The remainder of the staff constitutes the bullpen squad or the relief pitchers. When the manager or pitching coach detects signs of weakening on the part of the pitcher in the game, these bullpen pitchers begin warming up. Near their bench, regulation-size home plates are embedded in the ground. At the correct distance from each of these plates is a pitcher's plate, or rubber. They warm up by throwing practice pitches to substitute catchers. The bench, together with the practice ground, is known as the bullpen. An effective relief pitcher is one

who can depend upon his ability to control the placement of his pitches, because he often enters the game at a stage in which the offensive team poses a scoring threat with one or more base runners and a dangerous hitter at bat.

Throughout the 1940s, usually one relief pitcher (sometimes two) was used regularly as the bullpen pitcher. The rotation starters, whether they were winning or losing, were accustomed to pitching a complete game; *i.e.*, the full nine innings. In the early 1950s, however, relief pitching began to grow in importance, and it became extremely difficult for a team to win a championship without a strong bullpen.

Control. Pitching demands more exact coordination of mental and muscular faculties and more continuous physical exertion than any other activity in the game. On each pitch the pitcher is aiming at the strike zone or a small part of it (*e.g.*, the lower right-hand corner), 60 feet 6 inches from the plate on which his foot pivots in the act of pitching the ball. His ability to throw the ball where he aims it is known as his control. Lapses of control become apparent to the catcher with a slowing up of fast pitches and a dulling in the break of the curve. To the spectators, they are seen in increasing bases on balls and safe hits. Less often, as a pitcher begins to tire, his loss of control may result in hit batsmen and wild pitches. Each base on balls puts a potential run on first base, as does each batter hit with a pitched ball.

The balk. A balk is a departure from the restrictions imposed upon the pitcher by the rules; it can only be committed with a runner or runners on base. A balk may occur under three circumstances: (1) in pitching the ball to the batter if the pitcher does not have his pivoting foot in contact with the pitching plate; (2) if the pitcher does not hold the ball in both hands in front of him at chest level before starting his delivery, or, once started, does not continue his motion so that the ball is delivered to home plate; and (3) if he starts to make a throw to first base when a runner is occupying that base but does not go through with the throw. When a balk is called by the umpire all runners on base advance one base each. With a runner on third, a balk thus results in one run for the team at bat. Under the old regulations the ball was declared dead as soon as a balk was called. The runners, if there were any at the time, automatically moved ahead one base each as a penalty for the infraction, but the batter was not involved and anything he might have done on the pitch was nullified by the balk. Under a clarification of the balk rule in 1953 the batter became involved. If he hit a balk pitch for a home run or for a shorter base hit, if he drove the ball through a fielder's position for an error, or was thrown a fourth ball or a wild pitch, his team could accept either the play or the penalty, whichever result was more favourable to its interest. Thus, the balk is declined in most cases in which the runners advance more than one base or the batter reaches base safely.

Clarification of the balk rule

The pitching repertoire. A pitcher's speed is usually the index of his general ability. Although the curve was developed in the late 1860s and other variations from the straight line of fast ball pitching developed in succeeding epochs, the fast ball continues to be the basis of pitching skill.

The fundamental or regulation curve is a swerving pitch that breaks away from the straight line downward and across home plate, in the direction of the catcher's left knee if the pitcher throws left-handed.

Some pitchers employ a curving ball that breaks in the opposite way from the regulation curve, a pitch known variously as the fadeaway (Christy Mathewson) or the screwball (Carl Hubbell), or some other name applied by the pitcher himself. The effect is to endow the pitcher with a reverse curve; thus Mathewson, a right-handed pitcher, used the conventional curve to break the ball away from right-handed batters, and his fadeaway to break it away from left-handed hitters. Hubbell, a left-hander, used his screwball to slant the pitched ball out and beyond the reach of right-handed hitters, using the regulation curve when facing a left-handed hitter. In the case of both curves and reverse curves, the ball reaches the batter at a slower rate of speed than the fast ball, and the deception is almost as much a result of the slower ball's falling away from the bat as to its swerving from the straight trajectory from the pitcher's hand to catcher's glove.

Kinds of pitches

A comparatively new pitch, called the slider, was introduced in the 1920s by George Blaeholder, who otherwise had an undistinguished major league career. The slider is a cross between the fast ball and the curve and includes the best features of both. It is thrown with the speed and the motion of the fast ball but, instead of the wide sweep of the conventional curve, has a short and mostly lateral break; in effect, it slides away from the hitter. The break, which is not easily discernible by spectators, is short and quick. The slider is perhaps the most difficult of all breaking pitches to hit and is widely used.

Relatively few pitchers use the knuckle ball, the power of which lies in its lack of axial rotation as it sails toward home plate, making it subject to air currents. The ball is wobbly as it approaches the batter, and so is harder to hit solidly than a spinning ball sailing along "on the beam." The knuckle ball is also difficult to catch; it can be dangerous to use with a runner at third base, from which he could easily score on a passed ball (one that gets past the catcher). The knuckler is thrown with an easy, almost lob, motion and requires not much more effort than a ball thrown when playing "catch." Because of the minimal arm strain, knuckle-ball pitchers have remarkable longevity and can pitch almost every day, if necessary. The most celebrated knuckle-ball pitcher was Hoyt Wilhelm, who, in 1972, at the age of 49, was in his 21st major-league season; he had appeared in more than 1,000 major-league games—a record.

When a player comes to bat, the pitcher and catcher operate against him as a unit. The pitcher is equipped with a strong arm, able to fire the ball across home plate so rapidly as to offer the batter only an instant to decide whether or not to swing at it.

Besides sheer speed, the pitcher has curves, sliders, or other ways of throwing the ball to divert from the usual line of a fast ball. This causes the batter to go off his stride, to swing too early or too late, to strike it merely a glancing blow, or to miss it entirely.

Most batters get their greatest power into a drive when the ball comes to them a little above waist level. A minority are low-ball hitters, preferring a pitch between the belt line and the knees. The batter usually prefers the ball to be either inside or outside; that is, near the edge of the plate that is closer to him or farther from him. Most younger batters can more readily hit a fast ball—that is, a straight one—than a curve or any of the breaking balls. Some batters, usually veterans, have more success when the ball breaks; the breaking ball is always less swift in its course than the fast one. (G.P.L.)

BIBLIOGRAPHY. The *Official Baseball Guide*, containing records and a narrative review of the previous season, is published annually by *The Sporting News*. The standard reference work covering the records of professional players since 1871 is HY TURKIN and S.C. THOMPSON, *The Official Encyclopedia of Baseball*, 5th ed., rev. by SUZANNE TREAT (1970). A good general survey of the modern game is LEONARD KOPPETT, *A Thinking Man's Guide to Baseball* (1967). Early history is covered in HAROLD SEYMOUR, *Baseball: The Early Years* (1960) and *The Golden Age* (1971); and LAWRENCE S. RITTER, *The Glory of Their Times* (1966). For a history of Negro players and teams, see ROBERT W. PETERSON, *Only the Ball Was White* (1970). The life of the professional player is well depicted in JIM BROSNAN'S autobiographical journal, *The Long Season* (1960); JIM BOUTON, *Ball Four* (1970); and GIL HODGES, *The Game of Baseball* (1969). The inside business and politics of the game are covered in BILL VEECK'S autobiographical *Veeck–As in Wreck* (1962) and *The Hustler's Handbook* (1965). Baseball serves as a medium for philosophical concepts in novels by BERNARD MALAMUD, *The Natural* (1952); and ROBERT COOVER, *The Universal Baseball Association, Inc., J. Henry Waugh, Prop.* (1968). A successful baseball fantasy is DOUGLASS WALLOP, *The Year the Yankees Lost the Pennant* (1954), later a hit musical comedy and motion picture, *Damn Yankees*. See also Wallop's *Baseball: An Informal History* (1969), an anecdotal account from 1869.

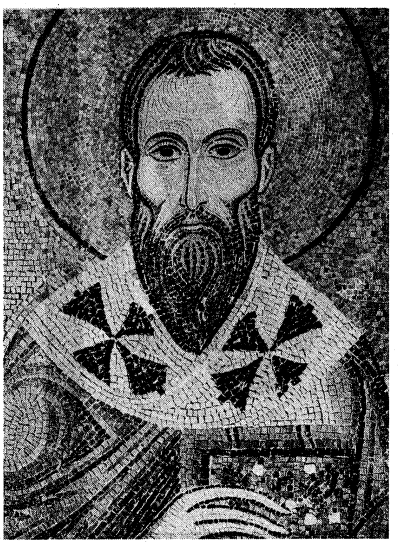
Basil the Great, Saint

Basil the Great, as one of the three Cappadocian Fathers —along with his brother Gregory of Nyssa and their friend Gregory of Nazianzus—helped to consolidate Greek Orthodox thought between AD 360 and 390. Along with the two Gregories, he played an important part in securing the final victory of the orthodox supporters of the Nicene faith (defined at the Council of Nicaea in 325) over the heretical Arians, who denied the divinity of Christ. The piety, devotion, and learning of these three theologians won for them a place among the saints and doctors (teachers) of the church. Basil was the leader and inspirer of the group, even though his life's work was unfinished at his death.

Alinari



Saint Basil, detail of a mosaic, 12th century. In the Palatine Chapel, Palermo.

Early life and ecclesiastical career

Basil was born about AD 329, coming from a distinguished family of Caesarea, the capital of Cappadocia, which was a province of Asia Minor of special importance in the 4th century due to its position on the military road between Constantinople and Antioch. The family had been Christian since the days of the persecutions of Christians, which ended early in the 4th century. One of Basil's uncles was a bishop, as later were two of his brothers (Gregory and Peter of Sebaste). He received a literary education, however, which would have fitted him to follow in his father's footsteps as lawyer and orator. He studied at Caesarea and Constantinople and, finally (*c.* 351–356), at Athens, where he developed his friendship with Gregory of Nazianzus. On returning home he began a secular career, but the influence of his pious sister Macrina, later a nun and abbess, confirmed his earlier inclination to the ascetic life. With a group of friends, he established a monastic settlement on the family estate at Annesi in Pontus. In 357 he made an extensive tour of the monasteries of Egypt, and in 360 he assisted the Cappadocian bishops at a synod at Constantinople. He had been distressed by the general acceptance of the Arian Creed of the Council of Ariminum the previous year and especially by the fact that his own bishop, Dianius of Caesarea, had supported it. Shortly before the death of Dianius (362), Basil was reconciled to him and later was ordained presbyter (priest) to assist Dianius' successor, the new convert Eusebius. Basil's abilities and prestige, as well as Eusebius' dislike of asceticism, led to tension between them, and Basil withdrew to Annesi. In 365 he was called back to Caesarea, when the church was threatened by the Arian emperor Valens. His theological and ecclesiastical policy thereafter aimed to unite against Arianism the former semi-Arians and the supporters of Nicaea under the formula "three persons (*hypostases*) in one substance (*ousia*)," thus preserving both unity and the necessary distinctions in the theological concept of the godhead. On Eusebius' death in 370, Basil became his successor, although he was opposed by some of the other bishops in the province.

Anti-Arian activities

As bishop of Caesarea, Basil was metropolitan (ecclesiastical primate of a province) of Cappadocia, and his own diocese covered the great estates of eastern Cappadocia, where he was assisted by a number of "country bishops" (*chorepiscopi*). He also founded charitable institutions to aid the poor, the ill, and travellers. When Valens passed through Caesarea in 371, Basil dramatically defied his demand for submission. But in 372 Valens divided the province, and Basil considered this a personal attack, since Anthimus of Tyana thus became metropolitan for the cities of western Cappadocia. Basil countered by installing supporters in some of the border towns—Gregory of Nazianzus at Sasima and his own brother Gregory at Nyssa. This tactic was only partially successful, but Basil escaped the attacks that Valens launched on orthodox bishops elsewhere. Meanwhile, Basil tried to secure general support for the former semi-Arian Meletius as bishop of Antioch (one of the five major patriarchates of the early church), against Paulinus, the leader of the strict Nicene minority, since he feared that the extreme Nicenes at this point were lapsing into Sabellianism, a heresy exaggerating the oneness of God. During Basil's lifetime, however, this was prevented by the recognition of Paulinus by the bishops of Alexandria and —in spite of a series of negotiations—after 375 by Pope Damasus of Rome.

Basil's numerous and influential writings stemmed from his practical concerns as monk, pastor, and church leader. The *Longer Rules* and *Shorter Rules* (for monasteries) and other ascetic writings distill the experience that began at Annesi and continued in his supervision of the monasteries of Cappadocia: they were to exert strong influence on the monastic life of Eastern Christianity. A notable feature is Basil's strong preference for the monastic life, in which brotherly love can be practiced, as opposed to that of the hermit. Basil's preserved sermons deal mainly with ethical and social problems. One of the best known, the *Address to Young Men*, defends the study of pagan literature by Christians (Basil himself made considerable critical use of Greek philosophical thought). In the *Hexaëmeron* ("Six Days"), nine Lenten sermons on the days of creation, Basil speaks of the varied beauty of the world as reflecting the splendour of God. *Against Eunomius* defends the deity of the Son against an extreme Arian thinker, and *On the Holy Spirit* expounds the deity of the spirit implied in the church's tradition, though not previously formally defined. Basil is most characteristically revealed in his letters, of which over 300 are preserved. Many deal with daily activities; others are, in effect, short treatises on theology or ethics; several of his *Canonical Epistles*, decisions on points of discipline, have become part of the canon law of the Eastern Orthodox Church. The extent of Basil's actual contribution to the magnificent series of eucharistic prayers known as the *Liturgy of St. Basil* is uncertain. But at least the central prayer of consecration (setting apart the bread and wine) reflects his spirit and was probably in use at Caesarea in his own lifetime.

Basil's health was poor, perhaps because of the rigours of his ascetic life. He died on January 1, 379, soon after Valens' death in the Battle of Adrianople had opened the way for the victory of Basil's cause. Vigorous and firm and sure of his own position, in his own time he seems to have been admired rather than loved, even by his intimates. But he was widely mourned and was soon numbered among the saints. In the Greek Church January 1 is still observed as St. Basil's Day and is marked by the use of the Basilian Liturgy.

BIBLIOGRAPHY. The Benedictine edition of Basil's works is reprinted in J.P. MIGNE (ed.), *Patrologia Graeca*, vol. 29–32 (1857). Basil I the Macedonian

The Byzantine emperor Basil I, who reigned from 867 to 886, was the founder of the Macedonian dynasty that lasted until 1056. He also inaugurated a much-needed legal reform, heralded during his own reign by two small handbooks, the *Procheiron* and the *Epanagoge*, and completed under his son and successor, Leo VI, with the appearance of the Greek code known as the Basilica.

Basil I, coin, 9th century. In the British Museum.

Basil's rise to power

Basil came of a peasant family that had settled in Macedonia, perhaps of Armenian origin. He was a handsome and physically powerful man who gained employment in influential official circles in Constantinople and was fortunate enough to attract the imperial eye of the reigning emperor, Michael III. After rapid promotion he became chief equerry, then chamberlain, and finally, in 866, co-emperor with Michael. Quick to sense opposition, he forestalled the Emperor's uncle, the powerful Caesar Bardas, by murdering him (866) and followed this by killing his patron, Michael, who had begun to show signs of withdrawing his favour (867).

From the mid-9th century onward, the Byzantines had taken the offensive in the agelong struggle between Christian and Muslim on the eastern borders of Asia Minor. Basil continued the attacks made during Michael III's reign against the Arabs and their allies, the Paulicians, and had some success. Raids across the eastern frontier into the Euphrates region continued, though Basil did not manage to take the key city of Melitene. But the dangerous heretical Paulicians on the borders of the Armenian province in Asia Minor were crushed by 872, largely owing to the efforts of Basil's son-in-law Christopher. In Cilicia, in southeast Asia Minor, the advance against the emir of Tarsus succeeded under the gifted general Nicephorus Phocas the Elder. Though Constantinople had lost much of its former naval supremacy in the Mediterranean, it still had an effective fleet. Cyprus appears to have been regained for several years.

Basil's plans for Italy involved him in negotiations with the Frankish emperor Louis II, the great-grandson of Charlemagne. The Byzantine position in southern Italy was strengthened with the help of the Lombard duchy of Benevento, and the campaigns of Nicephorus Phocas the Elder did much to consolidate this. The region was organized into the provinces of Calabria and Langobardia. But key cities in Sicily, such as Syracuse in 878, still continued to fall into Muslim hands, an indication of the strength of Arab forces in the Mediterranean.

Relations with Rome

Another arm of Byzantine policy was the attempt to establish some measure of control over the Slavs in the Balkans. Closely allied to this was the delicate question of ecclesiastical relations between Constantinople and Rome. During Basil I's reign, the young Bulgar state accepted the ecclesiastical jurisdiction of Constantinople (870). This had significant results both for the Balkan principalities and for the Orthodox Church, as well as greatly strengthening Byzantine influence in the south Slav world. Basil had succeeded to a quarrel between Photius and Ignatius as to which was to be patriarch of Constantinople. This had international implications, since appeals had been made to Rome. Immediately on his accession, Basil attempted to win support at home and to conciliate Rome by reinstating the deposed patriarch Ignatius and excommunicating Photius. Eventually, Photius was restored by Basil on the death of Ignatius (877) and recognized by Rome in 879. Contrary to the belief that used to be held, no "second schism" occurred. Basil successfully resolved the tension between liberal and strict Byzantine churchmen and managed to maintain a show of peace between East and West despite Rome's displeasure at the marked extension of imperial influence in the new Balkan principalities.

Toward the end of his life, Basil seemed to suffer fits of derangement, and he was cruelly biassed against his son Leo. He died on the hunting field in 886. The 11th-century historian Psellus wrote of his dynasty as "more blessed by God than any other family known to me, though rooted in murder and bloodshed." But Macedonian historians were understandably biassed in favour of the existing dynasty, to the detriment of the rulers it had supplanted. Recent historical research has raised the stature of Basil's predecessor, Michael III, and his regents. It is now generally agreed that the "new age" in Byzantine history began with Michael III in 842 and not with the Macedonian dynasty in 867. Basil's policies were largely determined, both at home and abroad, by factors not of his own making.

BIBLIOGRAPHY. A good short outline of Bzyantine history is G. OSTROGORSKY, *Geschichte des byzantinischen Staates*, 3rd ed. (1963; Eng. trans., *History of the Byzantine State*, 2nd ed., 1968). Recent views on Basil I, particularly in relation to his predecessor Michael III, are presented in H. GREGORIE, "The Amorians and Macedonians 842–1025," *Cambridge Medieval History*, new ed., 4:105–192 (1966). A lively account of ecclesiastical problems and Byzantine relations with the Slavs is G. EVERY, *The Byzantine Patriarchate 451–1204*, 2nd ed. rev. (1962).

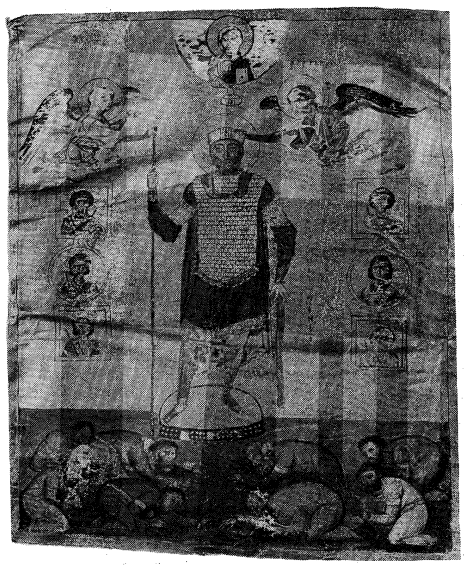
Basil II Bulgaroctonus

The reign of Basil II, widely acknowledged to be one of the outstanding Byzantine emperors, admirably illustrates both the strength and the weakness of the Byzantine system of government. His indomitable and forceful personality and his shrewd statesmanship enabled him to expand imperial territory in the Balkans and in the regions of Mesopotamia, Georgia, and Armenia. At home he increased imperial authority by ruthlessly attacking the powerful landed interests, both of the military aristocrats and of the church. Under him the Byzantine Empire reached its peak, but his reign demonstrates the inherent weakness of an imperial autocracy that depended so much on the character of the ruler.

Basil II (*c.* 958–1025), son of Romanus II and Theophano, was crowned co-emperor with his brother Constantine in 960, but as minors both he and his brother remained in the background. After their father's death in 963, the government was effectively undertaken by the senior military emperors, first by Nicephorus II Phocas, their stepfather, and then by John I Tzimisces. On the latter's death (976) the powerful great-uncle of Basil II, the eunuch Basil the chamberlain, took control. His authority—and that of Basil II—was challenged by two generals who coveted the position of senior emperor. Both related to emperors, they belonged to powerful landed families and commanded outside support from Georgia and from the Caliph in Baghdad. After a pro-



Basil II, illumination from the frontispiece of his psalter; showing Bulgars prostrate before the Emperor. In the Biblioteca Nazionale Marciana, Venice (MS. Gr. 217).

longed struggle both were defeated by 989, though only with the help of Russians under Vladimir of Kiev, who was rewarded by the hand of Basil's sister Anna on condition that the Kievan state adopted Christianity. Certain Russian soldiers remained in Basil's service, forming the famous imperial Varangian guard. Eventually, Basil asserted his claim to sole authority by ruthlessly eliminating the dominating grand chamberlain, who was exiled in 985.

Consolidation of imperial authority

Basil aimed solely at the extension and consolidation of imperial authority at home and abroad. The main fields of external conflict were in Syria, Armenia, and Georgia on the eastern front, in the Balkans, and in south Italy. He maintained the Byzantine position in Syria against aggression stirred up by the Fāṭimid dynasty in Egypt and on occasion made forced marches from Constantinople across Asia Minor to relieve Antioch. By aggression and by diplomacy he secured land from Georgia and from Armenia, with the promise of more to come on the death of the Armenian ruler. He is, however, best known for his persistent and ultimately successful campaigns against a revived Bulgarian kingdom under its tsar Samuel. This ruler centred his activities in Macedonia and established his hegemony in the west Balkans. From 986 until 1014 there was warfare between Byzantium and Bulgaria, interrupted from time to time by Basil's intermittent expeditions to settle crises on the eastern front. Basil enlisted Venetian help in protecting the Dalmatian coast and Adriatic waters from Bulgarian aggression. Year by year he slowly penetrated into Samuel's territory, campaigning in winter as well as summer. Finally, holding northern and central Bulgaria, he advanced towards Samuel's capital, Ochrida, and won the crushing victory that gave him his nickname, "Slayer of the Bulgars" (Bulgaroctonus). It was then that he blinded the whole Bulgarian army, leaving one eye to each 100th man, so that the soldiers might be led back to their tsar (who died of shock shortly after seeing this terrible spectacle). Thus the revived Bulgarian kingdom was incorporated into the Byzantine Empire. Basil then looked further west and planned to strengthen Byzantine control in south Italy and to regain Sicily from the Arabs. He attempted to establish a Greek pope in Rome and to unite in marriage the German (though by birth half Byzantine) ruler Otto III with his favourite niece Zoe. Both schemes failed, but he was more successful in south Italy, where order was restored, and at his death preparations were being made for the reconquest of Sicily.

The ruthlessness and tenacity that served Basil in his military and diplomatic activities were displayed in his domestic policy as well. Its keynote was the strengthening of imperial authority by striking at his overpowerful subjects, particularly the military families who ruled like princes in Asia Minor. The by-product of this policy was the imperial protection of the small farmers, some of whom owed military service to the crown and paid taxes to the central exchequer. Title to land was rigorously inspected, and vast estates were arbitrarily confiscated. Thus, in spite of his costly wars, Basil left a full treasury, some of it stored in special underground chambers.

Domestic policy

Both in near-contemporary history and in manuscript illustrations, Basil is pictured as a short, well-proportioned figure, with brilliant light-blue eyes, a round face, and full, bushy whiskers, which he would twirl in his fingers when angry or while giving an audience. He dressed plainly and even when wearing the purple chose only a dark hue. An abrupt speaker, he scorned rhetoric yet was capable of wit. He has been described as mean, austere, and irascible, spending most of his time as though he were a soldier on guard. He knew only too well the danger of any relaxation. He showed no obvious interest in learning, but he did apparently commission works of religious art, and he had churches and monasteries rebuilt or completed in Boeotia and in Athens, though this may be accounted for by conventional piety. He seems never to have married or had children. On his death there was no able military aristocrat or other leader to take the situation in hand, and thus Basil II's work was rapidly undone.

Basin and Range Province

The unique topography, climate, and drainage of a great natural region of the western United States combine to make the area one of the most distinctive surface features of the entire North American continent and of considerable interest to a variety of natural scientists. The term Basin and Range Province is used by geographers and geologists to describe this 190,000 square mile (492,000 square kilometre) expanse, stretching from the Sierra Nevada Range on the west to the fringes of the Rocky Mountains—specifically the Wasatch Mountains of central Utah—on the east, and tapering to the Mojave Desert of California in the south. The term Great Basin, also in use, is probably more common among the people who inhabit the region (for related information see ROCKY MOUNTAINS; NORTH AMERICA; NORTH AMERICAN DESERT).

Environmental characteristics. The ranges of the region have been likened, in an old survey report, to a group of caterpillars, all crawling irregularly northward. Each range generally has a linear character and is separated from adjacent ranges, east and west, by wide valleys. The ranges are from 60 to 120 miles in length, and from three to 15 miles in width. The valleys are usually somewhat wider than the ranges and are for the most part deserts, with floors 1,000 to 6,000 feet (300 to 1,800 metres) above sea level. The ranges have peaks commonly reaching 9,000 or more feet above sea level, and where this occurs they catch a moderate amount of precipitation and support conifer stands. Some of the higher ranges have small permanent streams, but most of these disappear underground when they reach the basin. The Sierra Nevada Range otherwise blocks rain-bearing winds from the Pacific, forming a "rain shadow" over the entire region, which has an annual rainfall of 10 inches (254 millimetres) or less, and supports little more than a sparse desert or semidesert vegetation.

The Great Basin is particularly noted for its internal drainage system, whereby rain falling on the surface

leads eventually to closed valleys and does not reach the sea. The Humboldt River of northern Nevada, for example, rises in ranges in the northeast of the state, drains a number of small valleys on its way westward, and ends in a closed basin called Humboldt Sink. The Great Salt Lake (*q.v.*) lies in the final and lowest catchment basin of western Utah and gathers much of the drainage of the region that has not evaporated or seeped underground en route. Some of the smaller closed basins may be draining underground to adjacent, lower, basins, and thus may contain temporary lakes, which hold water only during the spring run-off from the ranges, or after flash-flood storms. The Colorado River (*q.v.*) cuts across the Great Basin in southwestern Utah, southern Nevada, western Arizona, and southeastern California, and, since it is deeply incised, drains the tributary valleys on either side, forming an exception to the internal drainage pattern.

Salt Lake drainage catchment

The Great Basin is recognized as extending to the Sonoran Desert area of southern Arizona and to north-central Mexico, although there the ranges are subdued and more circular than linear, with the intervening valleys very wide and the surface drainage better developed than it is further north. The Gila River drains most of the region into the Colorado River.

Exploration. The arid Great Basin for a long time thwarted cross-country travel to California, and hence impeded significantly the development of the American nation. Jedediah Smith (1798–1831), a great explorer of the West, made the first journey across the Basin in 1824, but did not document his travels. He was followed by John C. Frémont, who surveyed an eastern swathe of the Great Basin in 1846, but did not cross it. In the summer and fall of 1846 the ill-fated Donner Party crossed the Basin from what became Salt Lake City to the Sierra Nevada, following the Humboldt River, but most members lost their lives the following winter in the dreadful snows of the Sierras. The California Gold Rush brought thousands westward in 1848 and 1849, many of them reaching Salt Lake City and then attempting alternate routes across the Great Basin. Most of them proceeded northward into southern Idaho, around the Great Salt Lake Desert, entering the Humboldt River route in northwestern Nevada.

A survey made in 1867–78 produced the first federally-sponsored scientific account of the climate, travel conditions, and resources of the Utah-Nevada region. With the subsequent discovery of many mineral deposits in western Utah, Nevada, and southern Arizona, the U.S. Geological Survey made many studies of the specific mining districts and published a variety of reports. In the 1950s a flurry of interest in oil resources resulted in a number of valuable regional geological studies, adding to the work produced by the appropriate state geological surveys.

Geological background. Many scientists have characterized the ranges and valleys of the Great Basin as huge blocks of the earth's crust, which have been uplifted, dropped, and tilted. Enormous cracks, or faults, bound the blocks, and the uplifted parts have been eroded, over geologic time, with the debris accumulating over the depressed parts. Several such blocks are to be found in both western Utah and western Nevada. The blocks are 15–30 miles across and follow an approximate north-south direction. There are about 30 major fault-bounded blocks between the Wasatch Range and the Sierra Nevada. The movement in the faults—a response to stresses in the earth's crust—has been in an up and down direction, 1,000 to 15,000 feet in extent, although toward the western edge of the province some horizontal movement has been observed.

In many places volcanic rocks have been cut and displaced by the block faults, and since the volcanic rocks are about 30,000,000 years old, the faulting is obviously younger than that. Since the faulting occurs in small steps of a few feet each, and since most of the faults have total displacements of several thousand feet, it is believed that, in general, the process took an enormous period of time. Furthermore, many of the faults exhibit fresh surfaces, indicating recent movement, while there are historical records of earthquakes and constant contemporary micro-earthquakes, indicating that faulting has continued to the present day.

The Great Basin is nevertheless geologically youthful, and it is quite likely that it obscures older mountain systems that were, respectively, eastward extensions of the Sierra Nevada and westward extentions of the developing Rocky Mountains.

Resources. Minerals have proved to be the greatest resource of the Great Basin. There are large copper mines at Bingham, Utah, and Ely, Nevada, and a number of major copper mines in Arizona make it the nation's leading copper producing state, with a good share of the nation's molybdenum (a rare metal) produced as a by-product, along with gold. Silver, gold, lead, zinc, and copper have been found in many of the widely scattered mining districts of the region and result from the widespread penetration of sedimentary rocks by hot, mineralizing solutions associated with former volcanic activity. Many valuable nonmetallic minerals, such as limestone, dolomite, gypsum, and pumice, are also widely quarried.

Most of the population in Utah is located along the west base of the Wasatch Mountains focussing on Salt Lake City, with sustaining water supplies coming from streams in the mountains and also from wells tapping the great underground water reservoir trapped beneath the adjacent valley.

Similarly, on the other side of the Great Basin, a good part of the population of western Nevada, centering on Reno, is found along the east front of the Sierra Nevada, which supplies most of the water. To the south, in the Las Vegas, Tucson, and Phoenix areas of Nevada and Arizona, water comes largely from wells. In the large Las Vegas Valley the water table has not yet been lowered noticeably, but in the Tucson and Phoenix population centres the water table has been drawn down hundreds of feet, and by the 1970s the problem of future water supply had become a serious consideration.

Development. The Mormons settled the eastern part of the Great Basin beginning in 1847, and now about 1,000,000 people live there. The early prospectors were transient inhabitants from elsewhere in the Great Basin, but from their early towns and supply points a number of lasting communities have evolved. These are sustained by livestock raising, mining, and railroading. The dry, warm climate has attracted many people to Arizona and southern Nevada. The cities there have had a rapid expansion rate, especially in the last 30 years. The desert floors of south central Nevada have been used for testing of nuclear devices since 1945.

Basketball

The only major sport strictly of U.S. origin, basketball was invented by James Naismith (1861–1939) on or about Dec. 1, 1891, at the International Young Men's Christian Association Training School (now Springfield College), Springfield, Massachusetts, where Naismith was an instructor in physical education. His invention of the game was motivated by a desire to relieve the boredom of students in gymnasium classes, where marching, calisthenics, and apparatus work were the usual activities.

After considerable trial and error and much meditation, Naismith, borrowing, modifying, and sometimes inserting ideas from football, soccer, hockey, and other outdoor games, prepared a set of 13 simple rules embodying five principles that still govern today's game:

1. There must be a ball—large, light, and handled with the hands. 2. There shall be no running with the ball. 3. No mem-

Principles of the game

ber of either team shall be restricted from getting the ball at any time it is in play. 4. Both teams are to occupy the same area, yet there is to be no personal contact. 5. The goal shall be horizontal and elevated.

Originally, Naismith planned to nail square boxes as targets at opposite ends of the overhead gymnasium board track, but as boxes were not immediately available he used instead two half-bushel peach baskets, which gave the sport its name.

In making his first test of the game, Naismith explained the rules to a class of 18, asked two of them, Frank Mahan and Duncan Patton, to choose sides of 9 men each, and the game was underway. To everyone's amazement, the students became enthusiastic. After much running and shooting, William R. Chase chanced to connect on a midcourt shot and that historic contest ended in a 1–0 score.

In marked contrast to their former attitude, the Springfield students awaited their daily gym classes with immense interest. When all 18 went home for the Christmas vacation, they told their friends and the local YMCA people about the newly invented game. Numerous associations wrote Naismith for a copy of the rules, which were published in the Jan. 15, 1892, issue of the *Triangle*, the campus paper.

THE EARLY YEARS OF BASKETBALL

In the early years, the number of players on a team varied according to the number in the class and the size of the playing surface. At Cornell University in 1892, Ed Hitchcock, Jr., the physical director, divided his class of 100, but the results were dismal since everyone converged upon the ball. In 1894 teams started to experiment with five on a side when the playing surface was less than 1,800 sq ft (167.2 sq m); the number rose to seven when the gymnasium measured 3,600 sq ft, and back to nine when the playing areas exceeded that. In 1895 the number was occasionally set at five by mutual consent and, two years later, the rules stipulated five, and this number has remained.

Since five of the original players were Canadians, it is not surprising that Canada was the first country outside the U.S. to play the game. It was introduced in France in 1893, in Australia, China, and India soon thereafter, in Japan in 1900, and in Iran in 1901. A missionary is said to have tested the game in São Paulo, Brazil, in 1896. The game was demonstrated in London in June 1894 on the 50th anniversary of the founding of the YMCA.

While basketball helped swell the membership of YMCA's because of the availability of their gyms, within five years the game was outlawed by various associations because the outcome of the contests created ill-feeling among the members; where the gyms formerly were occupied by classes of 50 or 60 members, the areas were now monopolized by only 10 to 18 players—thus inactivating the others. Since the physical directors were largely judged by the size of their classes, they sensed their positions were in jeopardy. The banishment of the game induced many members to terminate their YMCA membership and to hire halls to play the game, thus paving the way to the professionalization of the sport (see below *Professional Basketball*).

Early uniforms and equipment

Originally, players had the choice of three styles of uniforms: knee-length football trousers; jersey tights, as commonly worn by wrestlers; and short padded pants, forerunners of today's uniforms, plus knee guards. The courts often were of irregular shapes with occasional obstructions such as pillars, stairways, or offices that interfered with play. In 1903 it was ruled that all boundary lines must be straight.

In 1892 Lew Allen, of Hartford, Connecticut, conceived the idea of fashioning a cylindrical basket of heavy woven wire to replace the peach baskets, and the following year the Narragansett Machinery Co., of Providence, Rhode Island, marketed a hoop of iron with a hammock style of basket. Originally, a ladder was used to remove the ball from the net after each successful throw. Later, a pole was used to retrieve the ball, then a chain fastened to the bottom of the net with a cord that extended within reach of the official. Nets open at the bottom, thus permitting the ball to drop through, were adopted in 1912–13. In 1895–96 the points for making a basket (field goal) were reduced from three to two, and for making a free throw from three to one.

In the first years, spectators delighted in occupying positions behind the basket so that they could lean over the railings and deflect the ball to favour one side or hinder the other, and in 1895 teams were urged to provide a 4 × 6 ft screen to eliminate such unsportsmanlike interference. Soon after, wooden backboards proved more suitable. Glass backboards were legalized by the professionals in 1908–09 and by colleges in 1909–10. Fan-shaped backboards were made legal in 1940–41, and transparent backboards, although commonly used in public auditoriums since the mid-1930s, were finally authorized in 1946–47. In 1920–21 the backboards were moved two feet, and in 1939–40 four feet, from the end lines to reduce frequent stepping out-of-bounds.

The soccer ball was used for the first two years. In 1894, the Overman Wheel Co., bicycle manufacturers of Chicopee Falls, Massachusetts, marketed the first basketball, laced, close to 32 in. or about 4 in. larger than the soccer ball in circumference and weighing less than 20 oz. By 1948–49 when the laceless molded ball was made official, the size had been set at 30 inches (76 centimetres). The weight of the ball is 20 to 22 oz. (565–625 g).

Introduction to colleges

The distinction of becoming the first college to play the game belongs to either Geneva College (Beaver Falls, Pennsylvania) or the University of Iowa in 1892. At the former institution, C.O. Bemis chanced to return to Springfield, heard about the new sport and tried it out with his students. At Iowa, H.F. Kallenberg, who attended Springfield in 1890, wrote Naismith for a copy of the rules and similarly presented the game to his undergraduates.

A friendship that had developed in 1890–91 at Springfield between Kallenberg and Amos Alonzo Stagg, who became athletic director at the new University of Chicago the following fall, led to the playing of the first college basketball game with five on a side, at Iowa City, Iowa, on Jan. 18, 1896. The University of Chicago won, 15–12, with neither team using a substitute. Kallenberg refereed that game, a common practice in that era—and some of the spectators, although attending their first game, took exception to some of his calls.

The first official rules committee had been formed in 1896. The colleges formed their own rules committee in 1905. In 1913 there were as many as five sets of rules: the collegiate, YMCA–Amateur Athletic Union, state militia groups, and two varieties of professional rules, and often teams agreed to play under a different set for each half. To establish some measure of uniformity, the colleges, AAU, and YMCA formed a Joint Rules Committee in 1915, in 1933 renamed the National Basketball Committee (NBC) of the United States and Canada. It meets each March to formulate rules for the Canadian Intercollegiate Union, the Canadian Amateur Basketball Association, the National Collegiate Athletic Association, the National Federation of State High School Athletic Associations, National Junior College Athletic Association, and the YMCA. Rules for women and professional and international rules vary slightly from those of the NBC.

Moves toward uniform rules

GROWTH OF THE GAME

In the 20th century, and especially since World War II, basketball has grown into a major sport, not only in the country of its origin but also in international competition including the Olympic Games. The history of that growth is discussed below as it relates to the game's four major branches: U.S. school and college basketball, women's basketball, international basketball, and professional basketball.

For listings of U.S. college tournament, international (world men's and world women's), and professional champions, see RELATED ENTRIES under SPORTING RECORD in the *Ready Reference and Index*.

years is reflected in the rules changes made by the NBC and its predecessors. Intended to improve, refine, and equalize competition, many of them were designed to simplify procedures and speed up the game.

In the early years of the game scores were usually low (winning scores of less than 30 points were not unusual) and action, at least from the spectators' viewpoint, was slow. A team with a small lead usually would protect it by stalling—retaining possession of the ball indefinitely by dribbling and passing it back and forth. To reduce opportunities for this manoeuvre a rule change in 1932–33 required that a team must advance the ball beyond midcourt within 10 sec or lose possession of the ball, and no player could stand within the foul lane with the ball for more than 3 sec. Another step to speed the game was the elimination, in 1937–38, of the centre jump after a field goal or foul shot, the ball being put in play from out-of-bounds on the end line where the score was made. In line with these efforts, Frank W. Keaney, coach at Rhode Island University for 28 years, is credited with introducing the now-popular "racehorse," or fast breaking, high scoring style of play. Another 1930s innovation was the one-hand shot, popularized by Stanford University's Angelo (Hank) Luisetti who scored as many as 50 points a game.

Other rule changes over the years have attempted to offset some of the advantages enjoyed by a team with one or more extremely tall players. Joe Lapchick at 6 ft 5 in. was regarded as a big man when he played for the Original Celtics in the 1920s, and young men much over that height generally were thought to be too clumsy and fragile to be really good players. But some did manage to get on teams, and in 1936–37 the 3-sec foul lane rule was changed to limit their effectiveness under the basket by requiring that no member of the team having the ball could stand within the foul lane more than 3 sec—with or without the ball. And in 1937–38 defensive players were prohibited from interfering with the ball or the basket while the ball was on or above the basket—a rule obviously directed against those who were able to reach that high. Later, in 1944–45, goal tending (*i.e.*, interfering with a ball above the level of the hoop on its downward flight) became illegal.

Meanwhile the tall men began to make their mark, led by George Mikan, 6 ft 10 in. who in the 1940s scored over 550 points in each of his last two years at De Paul University, and more than 11,000 points in nine seasons as a professional. Ed Macauley, 6 ft 8 in., of St. Louis University was ranked college player of the year in 1948 and in ten professional years was named to all-pro honours three times. Coaches began to recruit and develop tall boys—from grade school up—and to build their teams around the tallest. An indication of the prominent role of tall men in the game may be seen in the 20-year All America team named by the Associated Press in 1967: Bill Bradley, 6 ft 5 in., Princeton; Ed Macauley, 6 ft 8 in., St. Louis; Bill Russell, 6 ft 10 in., San Francisco; Wilt Chamberlain, 7 ft 1$\frac{1}{16}$ in., Kansas; and Oscar Robertson, 6 ft 4 in., Cincinnati. That same year, when 7 ft 1$\frac{3}{8}$ in. Lew Alcindor (later Kareem Abdul Jabbar) began to play at UCLA, the colleges banned the dunk shot, in which a man who can reach higher than the basket stuffs the ball through the hoop.

The big men did not completely take over the game. Bob Cousy, 6 ft 1 in., for example, was generally regarded as one of the greatest playmakers and best ball handlers of all time and, with Bill Russell in the 1950s and 1960s, led the Boston Celtics to six world professional titles in seven seasons. Some developments over the years have helped players whatever their size. Thus the slightly smaller and more perfect basketball, coupled with the incessant practice of youngsters to better themselves, have led to remarkable performances, such as that of Pete Maravich, 6 ft 5 in., of Louisiana State University who in 1970 set an all-time college scoring record with successive yearly totals of 741, 1,138, 1,148, and 1,381 points, the latter representing a 31-game average of 44.5 points per game.

Basketball's growing popularity has been largely due to new strategy, shooting excellence, larger playing arenas, the desire of youngsters to secure college scholarships on the strength of their playing abilities, and the salaries paid outstanding players by the professional teams. Because of the nationwide appeal of the game, an increasing number of colleges, especially smaller institutions, have either abolished or de-emphasized football and have relied upon basketball to gain national athletic prominence. Between December and March, seldom does a week go by when some relatively small or lightly regarded college does not upset a larger or formidable foe. Coast-to-coast scheduling and an increasing number of national or sectional televising of games permits the average fan to see and evaluate the best teams and players.

Intersectional basketball contests

Intersectional college contests were a rarity before Dec. 29, 1934, when arrangements were made for two out-of-state teams to play two local teams at Madison Square Garden arena in New York City. On that date, the University of Notre Dame (Indiana) lost to New York University 25–18 and St. John's lost to Westminster College (Pennsylvania) 37–33 before an audience of 16,000. The success of that season's program induced principal cities to follow suit as the growth of air travel permitted teams to play anywhere in the country with a minimum of classes missed by the student players.

Such intersectional contests brought about a more uniform interpretation of officiating, helped introduce new playing styles and offensive and defensive strategies, and focussed greater public attention upon the more successful teams and finer players. Following World War II, many colleges built larger indoor field houses to accommodate their undergraduates and alumni, and many municipalities put up new and larger auditoriums, thus enabling college teams to make long trips with intermittent stops for games. This not only enriched their athletic as-

sociation coffers but also brought them greater national athletic fame.

By 1970 at least 30 colleges travelled more than 10,000 miles in a season or played before more than 200,000 spectators. During the 1968–69 campaign, the national champion UCLA covered 22,523 miles and appeared before 393,390 fans. College basketball as a whole drew 22,000,000 spectators.

Basketball tournaments

The first national tournament was staged by the AAU in 1897 and was won by the 23rd-Street YMCA, of New York City, which subsequently became a professional travelling team, the New York Wanderers. With most of the best collegians turning professional upon graduation, the AAU tournament today is at its lowest ebb. Although the YMCA was prominently identified with the game in its early years, it did not hold its first national tournament until 1923, and it was discontinued after 1962.

Naismith was of considerable help to Emil S. Liston in organizing the first national college tournament in 1937, conducted by the National Association of Intercollegiate Athletics, in Kansas City, Missouri. This group now numbers 550, largely small colleges. This colourful tournament consumes an entire week of eliminations from a field of 32 teams, each determined via district play-offs.

In 1938 New York City basketball writers organized the first National Invitational Tournament (NIT); the local colleges took it over the following year, and all games are played at Madison Square Garden. Today, the field consists of 16 teams, largely independents and runners-up in conference play.

In 1939 the NCAA started its tournament, now called the University Division. The field consists of the champions of the nations' principal conferences (*e.g.*, the Eastern College Athletic Conference, Western [Big Ten] Conference, Pacific Coast Intercollegiate Athletic Conference), plus the teams without conference affiliations that have the best competitive records each year. There are sectional eliminations, and the survivors of four area playoffs qualify for the finals, the winner being acclaimed as the national champion. To accommodate its minor college members, the NCAA inaugurated the College Division tournament in 1957, with the winners of the four-team play-of district championships providing an eight-team field for the finals, which are played in Evansville, Indiana, each March. Since 1945, the National Junior College Tournament has been held at Hutchinson, Kansas. In addition to the above, there are about 200 preconference tournaments usually during the Christmas recess, other national small college tournaments, and two women's national tourneys.

High school basketball

More than 20,000 high schools in the United States had basketball teams in the 1970s. Forty-eight of the 50 states annually conduct statewide tournaments in one or as many as five divisions. The other two states, New York and California, which formerly conducted state tournaments, now have district or area championships. Ten states—Arkansas, Georgia, Louisiana, Iowa, Oklahoma, Pa., Rhode Island, South Carolina, Tennessee, and Texas—conduct annual tournaments for girls. Between 1917 and 1930, the University of Chicago, under Stagg, sponsored a national schoolboy tournament that helped disseminate the finer points of various systems of play and standardize scholastic eligibility rules, but the National Federation of State High School Athletic Associations, founded in 1920, opposed its continuance. The Federation consists of all 50 state high school athletic and/or activities associations, the District of Columbia, and similar groups from Guam, the Philippines, Virgin Islands, and seven Canadian provinces.

The most famous high school team of all time was the Passaic, New Jersey, "Wonder Team" between 1919 and 1925, which won 159 consecutive games, until defeated by Hackensack, Feb. 6, 1925, by 39–35. Another colourful team was Carr Creek, Kentucky, of 1927–28, consisting of eight players, all related, who owned no uniforms, lost the state tourney finals in four overtime periods, to Ashland High (13–11), then won three contests in the national tournament in Chicago before losing to Vienna, Georgia, the national champions.

The first high schools to play basketball are believed to be Holyoke, Massachusetts, and Central High School, of Philadelphia, occasional victors over local college and town teams.

By 1970 the seasonal interscholastic basketball attendance, was approximately 125,000,000. In some communities, especially in Indiana, where the state's 580 schools draw 13,000,000 in any season and 1,500,000 to the state tournament eliminations, some communities have high school gymnasiums that seat more than the total population of the town.

Schoolboy basketball

While basketball is largely regarded as a winter sport, it is played on a 12-month basis—upon summer playgrounds, in church, municipal and industrial halls, schoolyards, family driveways, in summer camps—often on an informal basis between two or more contestants. Youngsters often fashion their own games with an undersized ball and hoops below the regulation height nailed to the side of a building or utility pole. Many grade, or grammar, schools, youth groups, municipal recreation programs, churches, and other organizations conduct basketball programs for youngsters of less than high school age. Jay Archer, of Scranton, Pennsylvania, introduced "biddy" basketball in 1950 for boys and girls under 12 years of age. The ball is smaller (28 in. in circumference) than the official ball and the baskets are lower, 8½ ft instead of 10 ft above the court, which measures 60 × 40 ft, foul line 12 ft from backboard, and there are 6-min quarters. An international tournament has been held since 1952, and the success of this program has encouraged many European countries to foster "mini" basketball in hopes of improving the quality of their games when the young future players and fans grow up. Some junior high schools and grammar schools encourage intercity and intracity games and tournaments.

Women's basketball (U.S.). Clara Baer, who introduced basketball at The H. Sophie Newcomb College for Women in New Orleans, Louisiana, had a hand in fashioning the women's style of play with her set of women's rules, published in 1895. On receiving a diagram of the court from Naismith, Miss Baer mistook dotted lines, indicating the areas wherein the players might best execute team play, to be restraining lines, with the result the forwards, centres, and guards confined their activity to specified areas. This seemed appropriate because many felt that the men's game was too strenuous for women. Women's rules over the years frequently have been modified; there are six players on a team and the court is so divided that the three forwards play in the forecourt and do all the scoring, while the three guards cover the backcourt. Senda Berenson staged the first women's college basketball game in 1893 when her freshmen and sophomore Smith College girls played against one another. In April 1895 the girls of the University of California (Berkeley) played Stanford University.

Basketball is included in many high school and college girls' athletic programs as an intramural sport. More women's colleges participate on an intercollegiate basis than ever before.

Most high school girls' interscholastic games are played preliminary to the boys' varsity games. In some states such contests are prohibited or discouraged. In Iowa the girls' tournament frequently outdraws the boys' tournament in attendance, the girls drawing 450,000 for sectional, district, and final rounds.

Outstanding teams and records

Baskin (Louisiana) High School won 218 successive games between 1947 and 1953. The famous girls high school coach, Bertha Frank Teague, of Byng High, Ada, Oklahoma, retired after the 1968–69 season with a 43-year record of 1,152 wins and 115 losses. Over one period, her teams won 96 games in a row. Her teams won eight state titles, were runners-up seven times and qualified for the state tourney on 22 occasions.

The Hanes Hosiery (North Carolina) team streak of 102 victories was terminated in 1953–54, the Wayland (Texas) Flyers rolled up a series of 131 victories in 1957–58, and Nashville Business College won the national AAU women's title in 1969 for the eighth successive year, but—after sponsoring a team for 30 years—did not

have a team the following season. An earlier famous women's club was the Edmonton Grads of Alberta, Canada, former students at the McDougall Commercial School of that city who, between 1915 and 1940, won 502 of 522 games—78 successively.

The U.S. six-player, divided forecourt and backcourt game has come to be known as the "rover" game. New five-player rules as used in the men's game and in women's international competition were adopted experimentally by the AAU in the late 1960s (see also below *International Basketball*).

International basketball. Basketball's popularity has increased manyfold since World War II through clinics sponsored by the U.S. Department of State and international exchange of teams, coaches, etc. Also, U.S. servicemen stationed abroad have aided materially.

Greatest credit for the success of the game in other lands goes to Forrest C. Allen, coach emeritus at the University of Kansas, a Naismith disciple who, as a committee of one, struggled for six years to place the game on the Olympic program. Allen was rebuffed by the U.S. Olympic Committee in his efforts to have the game demonstrated at the 1932 Olympics in Los Angeles. Undaunted, he attended the games where his efforts were encouraged by Sohaku Ri, of Waseda University, Tokyo, who raved about the success of basketball at the Far Eastern Olympics, and by Count Soyejima, president of the Japanese Basketball Association. On Oct. 19, 1933, the Berlin Organization Committee voted to have basketball introduced at the games of the XI Olympiad, scheduled for Berlin in 1936. A total of 21 nations competed in the 1936 Olympics and, most appropriately, U.S. college coaches raised sufficient funds to permit Naismith to attend the games and to toss up the first ball. Basketball has been one of the official sports in every subsequent Olympics. Prominent contenders in the Olympics have included the U.S. (undefeated from 1936 through 1968), Canada, Mexico, Poland, France, Brazil, U.S.S.R., Uruguay, Argentina, Italy, Spain, and Puerto Rico (see further ATHLETIC GAMES AND CONTESTS: *Olympic record*). Basketball has also been a fixture of the quadrennial Pan-American Games since their inauguration in 1951.

Basketball in the Olympics

The popularity of basketball upon the Olympic schedule has had a profound effect upon the growth of the game. In most nations, it ranks third in numbers both of fans and participants, behind only soccer and cycling. The international game is governed by the Fédération Internationale de Basketball Amateur (more commonly called FIBA) representing 129 nations, 31 of which are European.

In 1932 a lack of uniformity in rules caused Czechoslovakia, Portugal, and Switzerland to call a meeting at Geneva, and seven other nations—Latvia, Italy, Argentina, Greece, Hungary, Bulgaria, and Rumania—sent representatives. The body adopted the U.S. college rules of that time but since has amended them. Under international rules the court differs in that there is no front or back court, and the free-throw lanes form a modified wedge shape. There are some differences in rules governing substitutions, technical and personal fouls and free throws, intermissions and time-outs, and out-of-bounds throw-ins; a team must try for a goal within 30 sec; and dunking is legal.

Since 1935, European men's and women's championships have been held periodically (except for war years). In 1969 Czechoslovakia met Greece in the Olympic outdoor stadium in Athens before 65,000 fans. In 1953, in Moscow, the European men's championships drew 50,000 spectators. It is conservatively estimated that more than 5,000,000 men and women play basketball in Europe, at all levels. In all countries except the U.S., women play under the same rules as men.

European and World championships

In western Europe, the top division teams are sponsored by industrial firms or sports-social clubs, while in the Communist nations the game is state operated, although since 1963 government finances have been gradually decreased. Spain, Italy, France, and Belgium have a rule that permits any top division team to import one player who usually is a fine rebounder—and an American. In each nation the leagues consist of a dozen teams each, as a rule, and, at the conclusion of every season, the two lowest in standing drop into the next division, and are replaced by the top teams of the lower division. The basketball season starts in mid-October and extends into April, when the National Cup Tournament is held, with each national winner then competing in the "Cup of Cups" championship.

In the VI World championships held in Ljubljana in May 1970, the host nation Yugoslavia won, with the others finishing as follows: Brazil, U.S.S.R., Italy, United States, Czechoslovakia, Uruguay, Cuba, Panama, Canada, South Korea, Australia, United Arab Republic. Three games were played each day, each with separate admissions, and over 150,000 attended the seven-day program. Marshal Tito, watching his first basketball, inaugurated the tournament, which was televised to nine nations with an estimated audience of 50,000,000.

European nations and several members of FIBA are going more energetically into mini basketball, especially Italy, France, and Spain, with a view of encouraging the game among youngsters for future development. Such a program not only will create more and superior players, but also more fans, an advantage the United States has long enjoyed.

Professional basketball. Professional basketball appeared a few years after the game was introduced in 1891. After the YMCA's banned the sport in the mid-1890s, the various teams sought out halls they could hire and charged admission. A Trenton, New Jersey, team became the first professional club when in 1898 it hired the auditorium of the local Masonic order for $25 and was amazed to learn that there was a profit.

The play-for-pay game prospered largely in the Middle Atlantic and New England states. Trenton and the New York Wanderers were the first great professional clubs, followed by the Buffalo Germans, who started out in 1895 as 14-year-old members of the Buffalo (New York) YMCA and, with occasional new members, continued for 44 years, winning 792 out of 878 games.

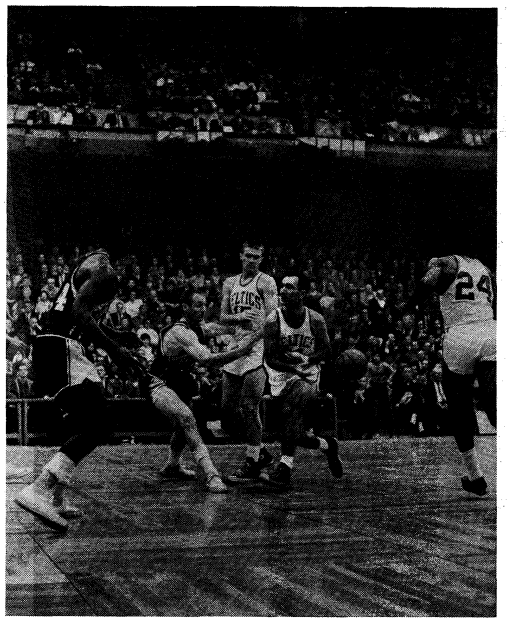
Early stylists

A group of basketball stylists who never received the acclaim they deserved because they wore the colours of three different towns in their heyday consisted of Edward and Lew Wachter, Jimmy Williamson, Jack Inglis (a behind-the-back dribbler), and Bill Hardman. They introduced the bounce pass and long pass as offensive weapons and championed the rule that made each player, when fouled, shoot his own free throw. Performing as Co. E of Schenectady, New York, they defeated the Kansas City Blue Diamonds in three straight games in 1905 in what was billed as the "world championship." While playing for Co. G, of Gloversville, New York, in 1907–08, this same contingent trounced the Buffalo Germans twice on the same day, and, in 1915, when they proved too strong for the Hudson River League, they engineered the first transcontinental tour in the history of the game, meeting all comers, under any set of rules, going as far west as Montana and winning all 29 games played. Upon their return, they won 10 more.

The Original Celtics, Rens, and others

Before World War II, the most widely heralded professional team was the Original Celtics, which started out in 1915 as a group of youngsters from New York City, kept adding better players in the early 1920s, and became so invincible that the team disbanded in 1928, only to regroup in the early 1930s as the "New York Celtics." They finally retired in 1936. The Celtics played every night of the week, twice on Sundays, and largely on the road. During the 1922–23 season, they won 204 of 215 games.

Another formidable aggregation was the New York Renaissance (the "Rens") organized by Robert Douglas in 1923, and regarded as the strongest all-Negro team of all time. During the 1925–26 campaign, they split a six-game series with the Original Celtics. During the 1932–33 season, the Rens won 88 consecutive games. In 1939 they trimmed the Harlem Globe-trotters and the Oshkosh All Stars for the world championship pro tournament in Chicago. On Feb. 16, 1935 in Kansas City, the Rens defeated the New York Celtics by one point by controlling the ball for the last six minutes.



Bob Cousy passes ball to teammate on his left as he continues to drive toward the opposition.
Sports Illustrated/Rich Clarkson © Time Inc.

The Celtics were elected to the Naismith Hall of Fame in 1959, and the Rens in 1964.

The two most successful professional coaches of all time were the Rens' Douglas, who won 2,318 games and lost 381 over a 22-year period; and Hall of Famer Frank Morgenweck, who coached for 32 years with the same team, operating in two or three different cities within the same season.

Among some of the great professional clubs were the New York Nationals; Fond du Lac, Wisconsin; East Liverpool, Ohio; the Paterson New Jersey Crescents; and the South Philadelphia Hebrew All Stars—better known as the Sphas.

The pro leagues

The first professional league was the National Basketball League (NBL) formed in 1898 to protect the players against unscrupulous promoters and to save the sport from extinction because of rough play. Their game differed from the college rules in that a netting usually separated the players from the spectators and the players bounced off the ropes like prizefighters in a ring; the ball could not go out of bounds; and the players were permitted to resume dribbling after halting. Because of the inequality of the teams or inability of the weaker clubs to meet their expenses, leagues did not survive for more than three or four seasons and invariably new circuits came into existence. As a rule, the same players performed in all these leagues, some playing for several cities or clubs within the same seasons, the better players often being teammates one night and opponents the next day.

The Depression of the 1930s hurt professional basketball and a new NBL was organized in 1938 in and around the upper Midwest. The play-for-pay ranks started to assume major league status with the organization of the new Basketball Association of America, on June 6, 1946, under the guidance of Walter A. Brown, president of the Boston Garden. Brown's contention was that professional basketball would succeed only if there was sufficient financial support to nurse the league over the early lean years; the game was conducted upon a high standard; and all players were restricted to exclusive contracts such as used in baseball, with a reserve rule protecting each team from raiding another club. Following a costly two-year war, the BAA and the NBL combined on Aug. 11, 1949, to form a 17-team National Basketball Association (NBA), which thereafter continued to attract the leading college players.

To help equalize the strength of the teams, the NBA established an annual college draft permitting each club to select a college senior in inverse order to the final standings in the previous year's competition, thus enabling the lower standing clubs to select the more talented collegians.

The game was saved from public apathy through three radical rules changes written in for the 1954–55 season: (1) a team must shoot for a basket within 24 sec after acquiring possession of the ball; (2) a bonus free throw is awarded a player anytime the opposing team commits more than six (later five, now four) personal fouls in a quarter or more than two personal fouls in an overtime period; and (3) two free throws are granted for any backcourt foul.

The leading teams in each division participate in a postseason play-off series with the eventual winner declared the world champion.

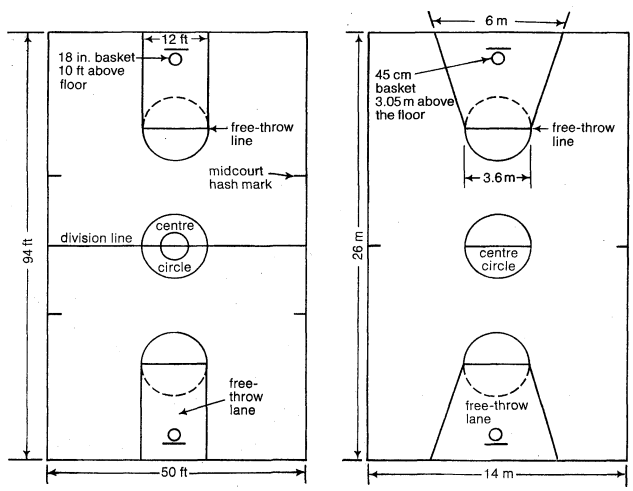
A rival 11-team American Basketball Association, with George Mikan as commissioner, was launched in the 1967–68 season and a bitter feud developed between these circuits for the top collegian talent each season.

PLAYING THE GAME

Synopsis of rules. The rules governing play of the game are based on Naismith's five principles (cited under *History* above) requiring a large, light ball, handled with the hands; no running with the ball; no player restricted from getting the ball when it is in play; no personal contact; and a horizontal, elevated goal. The rules are spelled out in specific detail by the governing bodies of the several branches of the sport and cover the playing court and equipment, officials, players, scoring and timing, fouls, violations, and other matters.

Equipment, officials, players, and scoring

The general dimensions and plans of the U.S. college court (which are essentially the same as those of U.S. high school and professional basketball courts) and the international court are shown in the accompanying diagram.



Basketball Courts.
(Left) U.S. college and high school court. (Right) International court.

The officials include a referee, an umpire, two timers, and two scorers. The International Association of Approved Basketball Officials, founded 1921, trains and certifies officials.

One player on each team acts as captain and speaks for his team on all matters involving the officials, as, for example, interpretation of rules. Specific rules cover such details as the numbering of players, the sizes of the numbers the players must wear on their jerseys, and colour of uniforms (white or light for home teams, dark for visitors). Other rules cover eligibility and related matters.

Since 1895–96 a field goal has scored 2 points, a free throw 1 point. Changes have been proposed from time to time: since 1967–68 the ABA awarded 3 points for a field goal scored from 25 ft or more from the basket.

Basketball is a noncontact game. A player may pass or

Fouls and violations

bounce (dribble) the ball to secure a position whereby he or a teammate may make a try for a basket from the floor. A foul is committed whenever a player makes such contact with an opponent so as to put him at a distinct disadvantage. It provides the offended player with a free throw, an unhindered throw for a goal from behind the foul line. Under National Basketball Committee (NBC) rules, if the offended player was fouled while in the act of shooting, if his toss was successful the basket counts and he is awarded one free throw; if he missed his shot, he is awarded two free throws. Unsportsmanlike conduct by a player or coach incurs a technical foul and possible banishment.

Under NBC rules violation occurs when a player (with the ball) takes an excessive number of steps, or slides; causes the ball to go out-of-bounds; steps over the foul line while tossing for a free throw; steps over the end line or sideline while tossing the ball in to a teammate, or fails to pass the ball in within 5 sec; runs with, kicks, or strikes the ball with his fist; dribbles a second time after having once concluded his dribble; remains more than 3 sec in his free-throw lane while he or his team has the ball; causes the ball to go into the backcourt or retains the ball in the backcourt more than 10 sec. Penalty is loss of the ball—opponents throw in the ball from the side.

Basketball terms and definitions. *Blocking.* Any illegal personal contact that impedes the progress of an opponent who does not have the ball.

Dribble. Ball movement by a player who taps the ball in the air or on the floor and then touches (bounces) it one or more times. A dribble ends when a player touches the ball with both hands simultaneously or loses contact with it.

Held ball. Called when two opponents have one or two hands so firmly upon the ball that neither can gain possession without undue roughness. It also is called when a player in the front court is so closely guarded that he cannot pass or try for a goal or is obviously withholding the ball from play.

Jump ball. A method of putting the ball into play. The referee tosses it up between two opponents who try to tap it to a teammate.

Pass. Throwing, batting, or rolling the ball to another player. The main types are: (1) the chest pass—ball is released from a position in front of the chest; (2) the bounce pass—the ball is bounced on the floor to get it past a defensive opponent; (3) the roll pass on the floor; (4) the hook pass (side or overhead); and (5) the baseball pass—the ball is thrown a longer distance with one hand in a manner similar to a baseball throw.

Pick. See *Screen.*

Pivot. A movement in which a player with the ball steps once or more in any direction with the same foot while the other foot (pivot foot) is kept at its point of contact with the floor.

Rebounding. Both teams attempting to gain possession of the ball after any try for a basket is unsuccessful but the ball does not go out-of-bounds and remains in play.

Screen. Legal action of a player who, without causing contact, delays or prevents an opponent from reaching his desired position. A pick.

Shots from the field. The main field shots are: the lay-up (the shooter, close to the basket, jumps and lays the ball against the backboard so it will rebound into the basket) and the over-the-rim shot (the player jumps and shoots or lays the ball over the rim). From a distance of up to 24 ft from the basket many players use a one-hand push shot from a stride, jump, or standing position, and a hook shot, which is overhead. From longer range, so-called set shots may be the two-hand shot starting from a chest position or the one-hand shot.

Travelling (running with the ball). Progressing in any direction in excess of the prescribed limits while holding the ball.

Turnover. Loss of possession of the ball by a team before any member has been able to try for a basket.

Principles of play. Each team of five players consists of two forwards, two guards, and a centre, usually the tallest man on the team. At the beginning of each period the ball is put into play by a jump ball at centre court; *i.e.*, the referee tosses the ball up between the opposing centres, higher than either can jump, and when it descends each tries to tap it to one of his teammates, who must remain outside the centre circle until the ball is tapped. Jump balls are also held when opposing players share possession of the ball (held ball), or cause it to go out-of-bounds at the same time. After each successful basket (goal or field goal) the ball is put back in play by the team that is scored on by one player passing the ball in from behind the end line where the score was made. The ball is put in play in the same manner after a successful free throw; if two have been awarded, after the second if it is successful. After violations (see above) the ball is awarded to the opposing team to be passed in from out-of-bounds from a point designated by an official.

A player in possession of the ball must pass or shoot before taking two steps or must start dribbling before taking his second step. The dribble stops if the player permits the ball to come to rest or when he touches it with both hands at once, when he must stop or pass the ball. The ball may be tapped or batted with the hands, passed, bounced, or rolled in any direction.

Systems of offense

As basketball progressed, various coaches and players devised intricate plays and offensive manoeuvres. Some systems emphasize speed, deft ball handling, and high scores; others stress ball control, slower patterned movement, and low scores. A strategy based on speed is called fast break. When fast-break players recover possession of the ball in their backcourt, as by getting the rebound from an opponent's missed shot, they race to beat the defense to its backcourt by a combination of speed and passing and try to make a field goal before the opponents have time to set up a defense. The fast break and its many variants are sometimes described as the racehorse style of play.

Some teams, following an overall game plan or when they do not have the opportunity for a fast break, employ a more deliberate style of offense. The guards bring the ball down the court toward the basket carefully and maintain possession of the ball in the front court, passing, dribbling, and screening opponents in an effort to set up a play that will free a player for an open shot. Generally, set patterns of offense use one or two pivot men who play near the free-throw area at the low post positions (between the free-throw line and the end line) or at high post positions (between the free-throw line and the basket). The pivot, or post, men are usually the taller men on the team and are in position to receive passes, pass to teammates, shoot, screen for teammates, and tip-in or rebound (recover) missed shots. All of the players are constantly on the move executing the patterns designed to give one player a favourable shot—and at the same time place one or more teammates in good position to tip-in or rebound if he misses.

Systems of defense

Systems of defense also have developed over the years. One of the major strategies is known as man-to-man, or man-for-man. Each player has a specific opponent whom he guards whenever he moves, except when he "switches" with a teammate when he is screened, or in order to guard another player in a more threatening scoring position. Another major strategy is the zone or five-man defense. In this system each player has a specific area to guard irrespective of which opponent plays in that area. The zone is designed to keep the offense from driving in to the basket and force them to take long shots, while preventing tip-ins and controlling rebounds from the backboard. A great many variations and combinations have been devised to employ various aspects of both man-to-man or zone defense strategies. The press, which can be man-to-man or zone, exists when a team guards an opponent so thoroughly that it forces the opposition to hurry its movements, especially to commit errors. Well-coached teams can modify both their offensive and defensive strategies according to the shifting circumstances of the game and in response to their opponents' particular strengths and weaknesses and styles of play.

(W.G.M.)

Basketry

Though it would appear that basketry might best be defined as the art or craft of making baskets, the fact is that the term is one of those the limits of which seem increasingly imprecise the more one tries to grasp it. The category basket may include receptacles made of interwoven, rather rigid material, but it may also include pliant sacks made of a mesh indistinguishable from netting—or garments or pieces of furniture made of the same materials and using the same processes as classical basketmaking. In fact, neither function nor appearance nor material nor mode of construction are of themselves sufficient to delimit the field of what common sense nevertheless recognizes as basketry.

In this article the term will be taken to mean a handmade assemblage of vegetable fibers that are relatively large and rigid, so as to make a continuous surface, usually (but not exclusively) a receptacle. The consistency of the materials used distinguishes basketry, which is handmade, from weaving, in which the flexibility of the threads requires the use of an apparatus to put tension on the warp, the lengthwise threads. What basketry has in common with weaving is that both are means of assembling separate fibres by twisting them together in various ways.

MATERIALS

There is no region in the world, except in the northernmost and southernmost parts, where man does not have at his disposal materials, such as twigs, roots, canes, and grasses, that lend themselves to basketry.

The variety and quality of materials available in a particular region has a bearing on the relative importance of basketry in a culture and on the types of basketry produced. Rainy, tropical zones, for example, have palms and large leaves that require plaiting techniques different from those required for the grass stalks that predominate in the dry, subtropical savanna regions or for the roots and stalks found in cold temperate zones. The interrelationship between materials and methods of construction might in part explain why the principal types of basketry are distributed in large areas that perhaps correspond to climatic zones as much as to cultural groups: the predominance of sewed coiling, for example, in the African savannas, in the arid zones of southern Eurasia and of North America; of spiral coiling and twining in temperate regions; and of various forms of plaiting in hot regions. There is also a connection between the materials used and the function of the basket, which determines whether rigid or soft materials—either as found in nature or specially prepared—are used. In the Far East, for example, twined basketry made of thin, narrow strips (laths) of bamboo is effective for such objects as cages and fish traps that require solid partitions with openings at regular intervals. Often soft and rigid fibres are used together: rigid to provide the shape of the object and soft to act as a binder to hold the shape.

Aesthetic goals and choice of material

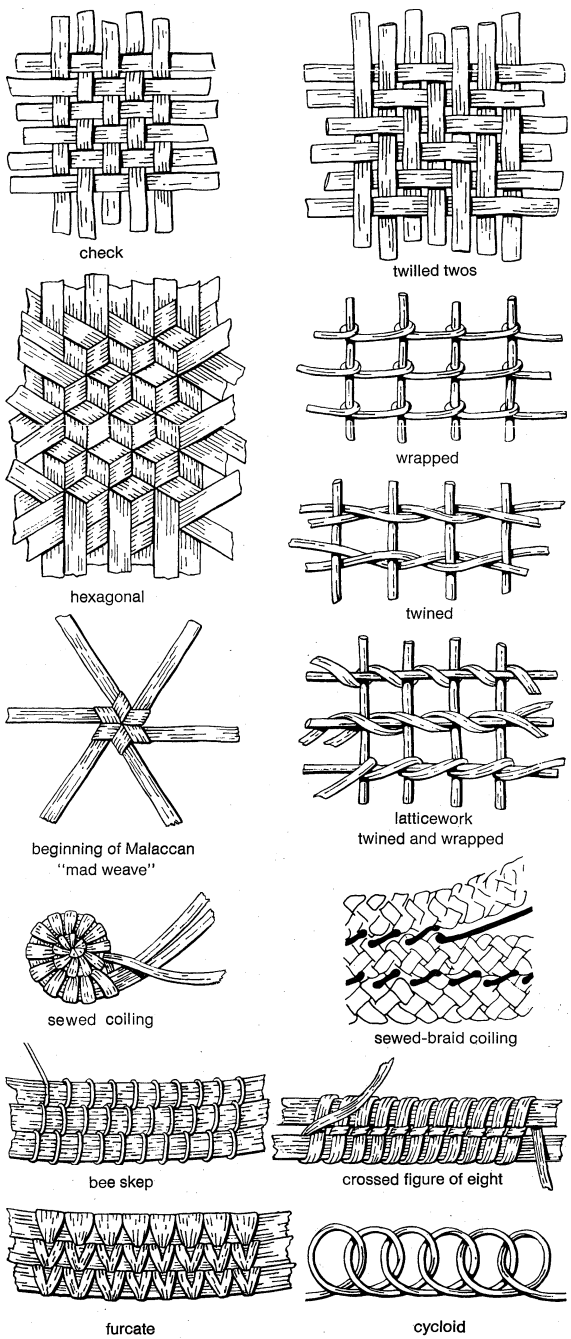
Finally, materials are chosen with a view toward achieving certain aesthetic goals; conversely, aesthetic goals are limited by the materials available. The effects most commonly sought are delicacy and regularity of the

threads; a smooth, glossy surface or a dull, rough surface; and colour, whether natural or dyed. Striking effects can be achieved from the contrast between threads that are light and dark, broad and narrow, dull and shiny —contrasts that complement either the regularity or the decorative motifs obtained by the intricate work of plaiting.

TECHNIQUES

Despite an appearance of almost infinite variety, the techniques of basketry can be grouped into several general types according to how the elements making up the foundation (the standards, which are analogous to the warp of cloth) are arranged and how the moving element (the thread) holds the standards by intertwining among them.

Coiled construction. The distinctive feature of this type is its foundation, which is made up of a single element, or standard, wound in a spiral around itself. The coils are kept in place by the thread, the work being done stitch by stitch and coil by coil. Variations within this type are defined by the method of sewing, as well as by the nature of the coil, which largely determines the type of stitch.



Varieties of plaited and coiled work used in basketry.

Spiral coiling. The most common form is spiral coiling, in which the nature of the standard introduces two main subvariations: when it is solid, made up of a single whole stem, the thread must squeeze the two coils together binding each to the preceding one (giving a diagonal, or twilled, effect); with a double or triple standard the thread catches in each stitch one of the standards of the preceding coil. Many other variations of spiral coiling are possible. Distribution of this type of basketry construction extends in a band across northern Eurasia and into northwest North America; it is also found in the southern Pacific region (China and Melanesia) and, infrequently, in Africa (Rhodesia).

Sewed coiling. Sewed coiling has a foundation of multiple elements—a bundle of fine fibres. Sewing is done with a needle or an awl, which binds each coil to the preceding one by piercing it through with the thread. The appearance varies according to whether the thread conceals the foundation or not (bee-skep variety) or goes through the centre of the corresponding stitch on the preceding coil (split stitch, or furcate). This sewed type of coiled ware has a very wide distribution: it is almost the exclusive form in many regions of North and West Africa; it existed in ancient Egypt and occurs today in Arabia and throughout the Mediterranean basin as far as western Europe; it also occurs in North America, in India, and sporadically in the Asiatic Pacific. A variety of sewed coiling, made from a long braid sewed in a spiral, has been found throughout North Africa since ancient Egyptian times.

Distribution of sewed coiling

Half-hitch and knotted coiling. In half-hitch coiling, the thread forms half hitches (simple knots) holding the coils in place, the standard serving only as a support. There is a relationship between half-hitch coiling and the half-hitch net (without a foundation), the distribution of which is much more extensive. The half-hitch type of basketry appears to be limited to Australia, Tasmania, Tierra del Fuego in South America, and Pygmy territory in Africa. In knotted coiling, the thread forms knots around two successive rows of standards; many varieties can be noted in the Congo, in Indonesia, and among the Basket Makers, an ancient culture of the plateau area of southwestern United States, centred in parts of Arizona, New Mexico, Colorado, and Utah.

The half-hitch and knotted-coiling types of basketry each have a single element variety in which there is no foundation, the thread forming a spiral by itself analogous to the movement of the foundation in the usual type. An openwork variety of the single element half hitch (called cycloid coiling) comes from the Malay area; and knotted single-element basketry, from Tierra del Fuego and New Guinea.

Noncoiled construction. Compared to the coiled techniques, all other types of basketry have a certain unity of construction: the standards form a foundation that is set up when the work is begun and that predetermines the shape and dimensions of the finished article. Nevertheless, if one considers the part played by the standards and the threads, respectively, most noncoiled basketry can be divided into three main groups.

Wattle construction. A single layer of rigid, passive, parallel standards is held together by flexible threads in one of three ways, each representing a different subtype. (1) The bound, or wrapped, type, which is not very elaborate, has a widespread distribution, being used for burden baskets in the Andaman Islands in the Bay of Bengal, for poultry cages in different parts of Africa and the Near East, and for small crude baskets in Tierra del Fuego. (2) In the twined type, the threads are twisted in two or threes, two or three strands twining around the standards and enclosing them. The twining may be close or openwork or may combine tight standards and spaced threads. Close twining mainly occurs in three zones: Central Africa, Australia, and western North America, where there are a number of variations such as twilled and braided twining and zigzag or honeycomb twining. The openwork subtype is found almost universally because it provides a perfect solution to the problem of maintaining rigid standards with even spacing for fish traps and hurdles (portable panels used for enclosing land or livestock). Using spaced threads, this subtype is also used for flexible basketry among the Ainu of northern Japan and the Kuril Islands and sporadically throughout the northern Pacific. (3) The woven type, sometimes termed wickerwork, is made of stiff standards interwoven with flexible threads. It is the type most commonly found in European and African basketry and is found sporadically in North and South America and in Near and Far Eastern Asia.

Lattice construction. In lattice construction a frame made of two or three layers of passive standards is bound together by wrapping the intersections with a thread. The ways of intertwining hardly vary at all and the commonest is also the simplest: the threads are wrapped in a spiral around two layers of standards. This method is widely used throughout the world in making strong, fairly rigid objects for daily use: partitions for dwellings, baskets to be carried on the back, cages, and fish traps (with a Mediterranean variety composed of three layers of standards and a knotted thread). The same method, moreover, can be adapted for decorative purposes, with threads—often of different colours—to form a variety of motifs similar to embroidery. This kind of lattice construction appears mainly among the Makah Indians of the U.S. Pacific Northwest and in Central and East Africa.

Uses of lattice construction

Matting or plaited construction. Standards and threads are indistinguishable in matting or plaited construction; they are either parallel and perpendicular to the edge (straight basketry) or oblique (diagonal basketry). Such basketry is closest to textile weaving. The materials used are almost always woven, using the whole gamut of weaving techniques (check, twill, satin, and innumerable decorative combinations). Depending on the material and on the technique used, this type of construction lends itself to a wide variety of forms, in particular to the finest tiny boxes and to the most artistic large plane surfaces. It is widely distributed but seems particularly well adapted to the natural resources and to the kind of life found in intertropical areas. The regions where it is most common are different from, and complementary with, those specializing in coiled and twined ware; that is, eastern and southeastern Asia (from Japan to Malaysia and Indonesia), tropical America, and the island of Madagascar off the east coast of Africa.

One variety of matting or plaited work consists of three or four layers of elements, which are in some cases completely woven and in others form an intermediate stage between woven and lattice basketry. The intermediate type (with two layered elements, one woven) is known as hexagonal openwork and is the technique most common in openwork basketry using flat elements. It has a very wide distribution: from Europe to Japan, southern Asia, Central Africa, and the tropical Americas. A closely woven fabric in three layers, forming a six-pointed star design, is found on a small scale in Indonesia and Malaysia.

Decorative devices. Clearly, a variety of decorative possibilities arise from the actual work of constructing basketry. These, combined with the possible contrasts of colour and texture, would seem to provide extensive decorative possibilities. Each particular type of basketry, however, imposes certain limitations, which may lead to convergent effects: hexagonal openwork, for example, forms the same pattern the world over, just as twilled weaving forms the same chevrons (vertical or horizontal). Each type, also, allows a certain range of freedom in the decoration within the basic restrictions imposed by the rigidity of the interlaced threads, which tends to impose geometric designs or at least to geometrize the motifs. In general, the two main types of basketry—plaited and coiled—lend themselves to two different kinds of decoration. Coiled basketry lends itself to radiating designs, generally star- or flower-shaped compositions or whirling designs sweeping from the centre to the outer edge. Typical coiled and plaited basketry decorations

lends itself to over-all compositions of horizontal stripes and, in the detail, to intertwined shapes that result from the way two series of threads, usually in contrasting colours, appear alternately on the surface of the basket.

Other art forms have been influenced ornamentally by basketry's plaited shapes and characteristic motifs. Because of their intrinsic decorative value—and not because the medium dictates it—these shapes and motifs have been reproduced in such materials as wood, metal, and clay. Some notable examples are the interlacing decorations carved on wood in the Central African Congo; basketry motifs engraved into metalwork and set off with inlayed silver by Frankish artisans in the Merovingian period (6th to 8th centuries); and osier patterns (molded basketwork designs) developed in 18th-century Europe to decorate porcelain.

SYMBOLISM

The Babylonian god Marduk "plaited a wicker hurdle on the surface of the waters. He created dust and spread it on the hurdle." Thus ancient Mesopotamian myth describes the creation of the earth using a reed mat. Many other creation myths place basketry among the first of the arts given to man. The Dogon of West Africa tell how their first ancestor received a square-bottomed basket with a round mouth like those still used there in the 20th century. This basket, upended, served him as a model on which to erect a world system with a circular base representing the sun and a square terrace representing the sky.

Like the decorative motifs of any other art form, the geometric, stylized shapes may represent natural or supernatural objects, such as the snakes and pigeon eyes of Borneo, and the kachina (deified ancestral spirit), clouds, and rainbows of the Hopi Indians of Arizona. However, the fact that these motifs are given a name does not always mean they have symbolic significance or express religious ideas.

Sometimes symbolism is associated with the basket itself. Among the Guayaki Indians of eastern Paraguay, for example, it is identified with the female: the men are hunters, the women are bearers as they wander through the forest; when a woman dies, her last burden basket is ritually burned and thus dies with her.

USES

As domestic utensils. Household basketry objects consist primarily of receptacles for preparing and serving food and vary widely in dimension, shape, and watertightness. Baskets are used the world over for serving dry food, such as fruit and bread, and they are also used as plates and bowls. Sometimes—if made waterproof by a special coating or by particularly close plaiting—they are used as containers for liquids. Such receptacles are found in various parts of Europe and Africa (Chad, Rwanda, Ethiopia) and among several groups of North American Indians. By dropping hot stones into the liquid, the Hupa Indians of northwestern California even boil water or food in baskets.

Waterproofing

Openwork, which is permeable and can be made with mesh of various sizes, is used for such utensils as sieves, strainers, and filters. Such basketry objects are used in the most primitive cultures as well as in the most modern (the tea strainers used in Japan, for example). The flexibility of work done on the diagonal is put to particularly ingenious use by the Africans in beer making and, above all, by Amazonian Indians in extracting the toxic juices from manioc pulp (a long basketwork cylinder is pulled down at the bottom by ballasting and, as it gets longer, compresses the pulp with which it had previously been filled).

Finally, basketry plays an important part as storage containers. For personal possessions, there are baskets, boxes, and cases of all kinds—nested boxes from Madagascar, for example, which are made in a graduated

series so that they fit snugly one within another, or caskets with multiple compartments from Indonesia. For provisions, there are baskets in various sizes that can be hung up out of the reach of predators, and there are baskets so large that they are used as granaries. In The Sudan in Africa, as in southern Europe, these are usually raised off the ground on a platform and sheltered by a large roof or stored in the house, particularly in Mediterranean regions; for preserving cereals they are sometimes caulked with clay.

In house and furniture construction. Some of these granaries are not far from being houses. Basketry used in house construction, however, usually consists of separately made elements that are later assembled; partitions of varying degrees of rigidity used as walls or to fence in an enclosure; roofs made of great basketry cones (in Chad, for example); and, above all, mats, which have numerous uses in the actual construction as well as in the equipping of a house. Probably the oldest evidence of basketry is the mud impressions of woven mats that covered the floors of houses in the Neolithic (*c.* 7000 BC) village of Jarmo in northern Iraq. Mats were used in ancient Egypt to cover floors and walls and were also rolled up and unrolled in front of doorways, as is shown by stone replicas decorating the doorways of tombs dating from the Old Kingdom, *c.* 2686–2160 BC. It is known from paintings that they were made of palm leaves and were decorated with polychrome (multicoloured) stripes, much like the mats found in Africa and the Near East. Two notable examples of modern mats are the pliant ones, made of pandanus leaves, found in southern Asia and Oceania and the tatami, which provide the unit of measurement of the surface area of Japanese dwellings.

Woven mats

Just as basketry has been used for making containers and mats, so from ancient times to modern it has been used for making such pieces of furniture as cradles, beds, tables, and various kinds of seats and cabinets.

In dress and ornament. In addition to the use of basketry for skirts and loincloths (particularly common in Oceania), supple diagonal plaiting has even been used to make dresses (Madagascar). Plaited raincoats exist throughout eastern Asia as well as Portugal. Basketry most frequently is used for shoes (particularly sandals, some of which come close to covering the foot and are plaited in various materials), and, of course, for hats—the conical hat particularly common in eastern Asia, for example, and the skullcaps and brimmed hats found in Africa, the Americas, and much of Europe.

To protect head and body against weapons, thick, strong basketry has been used in the form of helmets (Africa, the Assam region in India, and Hawaii); armour (for example, armour of coconut palm fibre for protection against weapons made of sharks' teeth by the Micronesia inhabitants of the Gilbert Islands); and shields, for which basketry is eminently suitable because of its lightness.

In addition to clothes themselves, there are numerous basketry accessories: small purses, combs, headdresses, necklaces, bracelets, and anklets. In West Africa there are even chains made of fine links and pendants plaited in a beautiful, bright yellow straw in imitation of gold jewelry. Many objects are plaited just for decoration or amusement such as ornaments like those used for Christmas trees or for harvest festivals and scale models and little animal or human figurines that sometimes serve as children's toys.

As ritual objects. There is often no very clear distinction between accessories and ritual ornaments, as in the ephemeral headdresses made for initiation rites by the young Masa people in the Cameroon; dance accessories; ornaments for masks, such as the leaf masks that the Bobo of Upper Volta make with materials from the bush.

More clearly ritual in nature are the palms (woven into elaborate geometric shapes and liturgical symbols) carried in processions on Palm Sunday by Christians in various Mediterranean regions; some, like those from Elche in Spain, are over six feet (nearly two metres) high and take days to make. In Bali an infinite variety of plaiting techniques are involved in the preparation of ritual offerings, which is a permanent occupation for the women, a hundred of whom may work for a month or two preparing for certain great festivals.

In hunting and fishing. Baskets are used throughout the world as snares and fish traps, which allow the catch to enter but not to leave. They are often used in conjunction with a corral (on land) or a weir (an enclosure set in the water), which are themselves made either of pliable nets or panels of basketry. In Africa as well as in eastern Asia a basketry object is used for fishing in shallow water; open at top and bottom, this object is deposited sharply on the bottom of shallow rivers or ponds, and, when a fish is trapped, it is retrieved by putting a hand in through the opening at the top.

Baskets as snares

In harvesting. Basketry is also used in harvesting foodstuffs; for example, in the form of winnowing trays (from whose French name, *van*, the French word for basketry, *vannerie*, is derived). A curious basket, found in the Sahel region south of the Sahara, is swung among wild grasses and in knocking against the stalks collects the grain.

As a means of transport. Baskets are used as transport receptacles; they are made easier to carry by the addition of one or two handles or straps depending on whether the basket is carried by hand, on a yoke, or on the back. The supple two-handled palm-leaf basket, common in North Africa and the Near East, existed long ago in ancient Mesopotamia; in Europe and eastern Asia, the one-handled basket, which comes in a variety of shapes, sizes, and types of plaiting, is common; in Africa, however, where burdens are generally carried on the head, there is no difference between baskets used for transporting goods and those used for storing or preserving.

Burden baskets are large, deep baskets in which heavy loads can be carried on the back; they are provided either with a headband that goes across the forehead (especially American Indian, southern Asia), or with two straps that go over the shoulders (especially in Southeast Asia and Indonesia).

There are three fairly spectacular types of small basketry craft found in regions as far apart as Peru, Ireland, and Mesopotamia: the balsa (boats) of Lake Titicaca, made of reeds and sometimes fitted out with a sail also made of matting; the British coracle, the basketry framework of which is covered with a skin sewn onto the edge; and the gufa of the Tigris, which is round like the coracle and made of plaited reeds caulked with bitumen.

ORIGINS AND CENTRES OF DEVELOPMENT

Prehistoric basketry. Something about the prehistoric origins of basketry can be assumed from archaeological evidence. The evidence that does exist from Neolithic times onward has been preserved because of conditions of extreme dryness (Egypt, Peru, southern Spain) or extreme humidity (peat bogs in northern Europe, lake dwellings in Switzerland); because it had been buried in volcanic ash (Oregon); or because, like the mats at Jarmo, it left impressions in the mud or on a pottery base that had originally been molded onto a basketry foundation. More recently, when written and pictorial documentation is available, an activity as humble and banal as basketry is not systematically described but appears only by chance in narratives, inventories, or pictures in which basketry objects figure as accessories.

On the evidence available, researchers have concluded that the salient characteristics of basketry are the same today as they were before the 3rd millenium BC. Then, as now, there was a wide variety of types (and a wide distribution of most types): coiled basketry either spiral or sewed, including furcate and sewed braid (mainly in Europe and the Near East as far as the Indus valley); wattlework with twined threads (America, Europe, Egypt) and with woven threads (Jarmo, Peru, Egypt); and plaited construction with twilled weaving (Palestine, Europe).

To list the centres of production would almost be to list all human cultural groups. Some regions, however, stand out for the emphasis their inhabitants place on basketry or for the excellence of workmanship there.

American Indian basketry. In western North America the art of basketry has attained one of its highest peaks of

perfection and has occupied a pre-eminent place in the equipment of all the groups who practice it. The American Indians are particularly noted for their twined and coiled work. The Chilkat and the Tlingit of the Pacific Northwest are known for the extreme delicacy of their twined basketry; the California Indians, for the excellence of their work with both types; and the Apache, Moki, and other Pueblo Indians of the southwestern interior of the U.S., for coiled basketry remarkable for the bold composition of its decoration and for the delicacy with which it is carried out.

Central and South American basketry is similar in materials and plaiting processes. The notable difference lies in the finishes used, and here the Guyana Indians of northeastern South America excel, being among the best basketry makers in the world and using a technique of fine plaiting with a twill pattern.

Importance of basketry in Oceania

Oceanic basketry. Various plaiting processes have been highly developed in Oceania, not just for making utilitarian articles but also for ceremonial and prestige items, such as very finely twined cloaks in New Zealand, statues in Polynesia, masks in New Guinea, and decorated shields in the Solomon Islands. In Oceania, as in southern Asia, one can speak of a vegetal civilization, in which basketry predominates over such arts as metalwork and pottery. Particular mention should be made of the Sakai of the Malay Peninsula and of the Australian aborigines, whose meagre equipment includes very delicate basketry done by the women. The Sakai use various plaiting techniques and the Australians tight twining.

Basketry mask, from the Sepik region of New Guinea. In the Musée de l'Homme, Paris.

African basketry. Africa presents an almost infinite variety of basket types and uses. In such regions as Chad and the Cameroon basketry is everywhere in evidence—edging the roads, roofing the houses, decorating the people, and providing the greater part of domestic equipment. The very delicate twill plaited baskets of Congo are notable for their clever patterning. In the central and eastern Sudanese zone the rich decorative effect of the sewed coiled baskets is derived from the interplay of colours. The Great Rift Valley lake area produces coiled and twined basketry the elegance of which results from restrained decoration and careful finishing.

East Asian basketry. The temperate zone of East Asia produces a variety of work. Bamboo occupies a particularly important place both in ordinary basketry equipment and in objects with a primarily aesthetic function (Japanese flower baskets, for example). The production of decorative objects is one feature that distinguishes East Asian basketry from Near Eastern and African, which is primarily utilitarian. Southeast Asia must be mentioned, together with Indonesia and Madagascar, as among the first places for fine decorative plaiting techniques.

European basketry. In Europe almost the whole range of basketry techniques is used, chiefly in making utilitarian objects (receptacles for domestic and carrying purposes and household furniture) but also in making objects primarily for decorative use.

Modern basketry. Even in the modern hyperindustrial world, there seems to be a future for basketry in two directions. Because of its flexibility, lightness, permeability and solidity, it will probably remain unsurpassed for some utilitarian ends; such articles, however, because they are entirely handmade, will gradually become luxury items. As a folk art, on the other hand, it has the advantage of needing no investment, since the essential requirements have been available to anyone for at least 50,000 years: a simple awl, nimble fingers, and patience.

Basque Language

Basque, the only remnant of the languages spoken in southwestern Europe before the region was romanized, is currently used in a narrow area of approximately 10,000 square kilometres (3,900 square miles) in Spain and France. The number of Basque-speaking people outside of that territory, in Europe and in the Americas, however, is far from insignificant. In Spain the Basque-speaking region comprises the province of Guipúzcoa, parts of Biscay and Navarra, and a corner of Álava, and in France the western region of the *département* of Pyrénées Altantiques. Although no statistics are available, the number of speakers, who are largely bilingual, might be judiciously estimated at something over 500,000. Most of them live in the highly industrialized Spanish part of the Basque country. The Basques have derived their name, Euskaldunak, from Euskara, the native word for their language. According to the classification of the philologist Prince Louis-Lucien Bonaparte (1813–91), there are eight modern dialects of Basque. Dialectal division is not strong enough to mask the common origin or to preclude mutual understanding. Basque attained official status only for a short period (1936–37) during the Spanish Civil War, under the Basque autonomous government.

Origins and classification. Basque remains an isolated language with no known linguistic relatives. The hypothesis of the German philologist Hugo Schuchardt (1842–

1927), which once had wide currency, posited an intimate genetic connection between Basque and Iberian (see below) and the Hamito-Semitic (Afro-Asiatic) language group. This theory was superseded by attempts to establish a more or less close link between Basque and Caucasian, the language group indigenous to the Caucasus region. A lack of common linguistic characteristics between the Basque and Hamito-Semitic languages makes Schuchardt's hypothesis extremely dubious. There are, however, some common features that favour the relationship between Basque and Caucasian. Still, proof of a genetic relationship beyond reasonable doubt appears remote. Perhaps the most promising theory current in the 1970s involves the comparison of Basque with the long-extinct Iberian, the language of the ancient inscriptions of eastern Spain and of the Mediterranean coast of France. But, despite amazing phonological coincidences, Basque has so far contributed next to nothing to the understanding of the now-readable Iberian texts. Therefore, it is possible that the similarity may have resulted from close contact between Basques and Iberians and not from a genetic linguistic relationship.

Link between Basque and Iberian

History of the language. At the beginning of the Christian Era, dialects of Euskarian (Basque) stock were probably spoken north and south of the Pyrenees and as far east as the Valle de Arán in northeastern Spain. It is likely that only the disruption of Roman administration in these regions saved the Basque dialects from being completely overcome by Latín. It is also likely that the Basque tongue, which had a firm foothold in the country that then began to be called Vasconia, experienced a substantial expansion toward the southwest, which carried it to the Rioja Alta (High Rioja) region in Old Castile and near Burgos. The more eastern Basque dialects, separated from the main area by Romance-speaking populations, were doomed. During the Middle Ages, Basque, the language of a population more peasant than urban, could not possibly hold the field as a written language against Latin and its successors, Navarrese Romance and, to a certain extent, Occitan (the *langue d'Oc*, also called Provençal) in the kingdom of Navarre. Since the 10th century, Basque has slowly but steadily lost ground to Castilian Spanish; in the north, however, where French is a more modern rival, the Basque-speaking area is practically the same as it was in the 16th century. In the last two centuries, above all in industrial centres, Basque has had to fight for survival in the heart of the Basque-speaking country, as well as on the frontier of the Basque-speaking area.

Basque records and writing

Latin inscriptions from the Roman period, found mostly in southwestern France, record a handful of proper names of unmistakable Basque etymology. From AD 1000 on, records consisting chiefly of proper names but also of Basque phrases and sentences grew more numerous and reliable. The first printed Basque book, dating from 1545, began an uninterrupted written tradition. Scholarly Basque literature, with its prevailing religious interests, has been neither abundant nor varied until recent times. Intense efforts are now being made to introduce Basque as a vehicle of private primary education. In addition, a model of a unified, standard written language also seems to be gaining increasing acceptance.

Phonology. The sound pattern of Basque is, on the whole, similar to that of Spanish. The number of distinctive sounds is relatively low compared with other languages. Combinations of sound (*e.g.*, consonant clusters) are subject to severe constraints. It can confidently be asserted that certain types of consonant clusters, such as *tr*, *pl*, *dr*, and *bl*, were all but unknown about two millennia ago. The common sound system underlying the systems of the present Basque dialects has five (pure) vowels and two series of stopped consonants—one voiced (without complete stoppage in many contexts), represented by *b*, *d*, *g*, and the other voiceless, represented by *p*, *t*, *k*. Nasal sounds include *m*, *n*, and palatal *ñ*, similar to the sound indicated by *ny* in "canyon." In this respect, as in others, Basque orthography coincides with the Spanish norm. There are two varieties of *l*, the common lateral *l* and a palatal variety, *ll*, as in Spanish, that sounds similar to the *lli* in "million" (as *l* + *y*). The Basque *r*, made by a single tap of the tongue against the roof of the mouth, contrasts with a rolled or trilled *r*, written *rr*. Two phonological features are worthy of special attention. Sibilants (both fricatives and affricates) made with the area of the tongue directly before the dorsum (the back of the tongue) are distinct from the apical sibilants, produced with the tip of the tongue. The letter *z* in Basque symbolizes the predorsal fricative, and *tz*, the predorsal affricate sound; *s* and *ts* represent the apical fricative (similar to Castillian Spanish *s*) and affricate, respectively. (A fricative is a sound, such as English *f* or *s*, produced with friction and, hence, without complete stoppage in the vocal tract; an affricate is a sound, such as *ch* in "church" or *j* in "jam," that begins as a stop and ends as a fricative, with incomplete stoppage.) In addition to these hissing sibilants, Basque also includes the hushing ones, written as *x* and *tx*; they are like the English *sh* and *ch*. The *x* and *tx* sounds, along with the palatal sounds written as *ll* and *ñ*, often have an expressive value (diminutive, endearing) in comparison with their non-palatal counterparts; *e.g.*, *hezur* means "bone" and *hexur* "little bone" (fish bone, for example); *sagu* is "mouse" and *xagu* "little mouse."

Varieties of sibilants

The phonology of some Basque dialects may be more complex than that presented in the preceding paragraph. In the easternmost Souletin region, for example, the dialect has acquired, by internal development or by contact with other languages, a sixth oral vowel—rounded *e* or *i*—and nasal vowels, voiced sibilants, and voiceless aspirated stops. The aspiration accompanying stop consonants consists of a small puff of air. There is also, word-initially and between vowels, an aspirated *h*, once common but now peculiar to the northern dialects. It has also been retained in the proposed standard form of Basque.

Grammar. The mention of two features is unavoidable in describing Basque syntax. Basque is, in the first place, a language of the so-called ergative type. That is, it has a case denoting the agent of an action. Hence, what in English would stand for the subject of a transitive verb is expressed in Basque by means of a suffix *-k*; for example, in the sentence "the foot serves the hand, and the hand serves the foot," *oinak zerbitzatzen du eskua, eta eskuak oina*, the first word, meaning "the foot," is composed of three elements, *oin* "foot," *-a*, "the," and *-k*, which marks the Basque equivalent of the subject of the verb. The fourth word, meaning "the hand," does not have the *-k* ending. In the second clause, *eta eskuak oina*, the word for hand, *eskuak*, now has the ergative *-k* ending to indicate that the hand is the agent of the clause "the hand serves the foot." The subject of an intransitive verb, which is not distinguished from the object of a transitive verb, has no overt mark—*e.g.*, in "if the belly does not eat, the belly itself will fail," *sabelak jaten ez ba du, sabela bera ihartuko da*, the first term, *sabelak* "the belly," has the *-k* marker because it is the agent of a transitive verb "eat"; but, in the second clause, *sabela* is the subject of the intransitive verb "fail" and, therefore, has no overt grammatical mark.

The second characteristic feature of Basque concerns the finite verb, which acts as a summary of all the noun phrases in the sentence. It has markers for all three persons—the 1st, 2nd, and 3rd—and may contain as many as three personal references (for subject, direct object, and indirect object). *Da*, for example, means "is," *du* means "he has it," and *dio* means "he has it for him" in the sentence *oinari ez dio eskuak kolperik emaiten* "the hand does not give a blow [*kolpe*] to the foot [*oin-a-ri*]." In certain situations the interlocutor can also be referred to within the verb. Further, most Basque verbs have only a compound conjugation; *e.g.*, *erori da* "he has fallen," literally, "he is fallen," and *jaten du* "he eats [is eating] it."

Although some ancient prefixes are still apparent in modern Basque, they are no longer productive, so that Basque can be characterized as an over-all suffixing language; that is, it appends suffixes to the ends of words. There is one declension with suffixes or postpositions to indicate number and case; *e.g.*, *etxe-a* "the house," but

etxe berri-a "the new house," and *etxe berri-a-ri* "to [for] the new house." Suffixes, under certain restrictions, may be heaped upon one another. Theoretically, genitival endings indicating possession may be added to one another without limit. This is similar to the case in English of "the button of the coat of the son of the Major of York"; in Basque, however, the phrase "of the" is indicated by an ending, *-(r)en*, added to the noun. Noun suffixes can also be attached to verb forms in order to express subordination of the clauses in which the verb forms appear; *e.g.*, *da* "is," *den* "which is," *dena* "that (*-a*) which is," *denean* "when there is," literally, "in that which is." Prefixes are also used for that purpose; *e.g.*, *ez du jaten* "he does not eat" with the particle *ba* "if" becomes "if [the belly] does not eat," *jaten ez ba du.*

Vocabulary. Basque has preserved a peculiar and distinctive appearance, despite the overwhelming pressure it has been subjected to during at least 2,000 years. Nevertheless, its borrowings from the neighbouring languages, especially words and idioms, can hardly be underrated. Loanwords from the Romance languages are numerous. Some of them bear the stamp of their archaic Latin ancestry; *e.g.*, *bake* "peace" from Latin *pax, pacis*, *bike* "pitch" from Latin *pix, picis*, and *errege* "king" from Latin *rex, regis*. Contrary to a widely held opinion, Indo-European loanwords of non-Latin origin are extremely scarce. Derivation, the formation of new words by the use of suffixes, is accomplished partly through the use of borrowed suffixes. This practice, as well as the compounding of nouns to form new words, as in *bizkar-hezur* "backbone," has been very much alive throughout the history of the language. Basque itself has contributed but little to the Spanish, Occitan, French, and English languages. But family and place names of Basque coinage are frequent in Spain and in Latin America, where they can be found in such proper names as Aramburu, Bolívar, Echeverría, and Guevara.

Latin loanwords

Batteries and Fuel Cells

In strict usage, the term battery designates an assembly of two or more cells that convert chemical energy directly to electrical energy. The term, however, has long been applied equally to a single cell. In a voltaic cell, for example, chemical reactions take place so that electrons are released on one part (the anode, or negative electrode) of the cell and caused to flow through an external circuit to the other part (the cathode, or positive electrode). The process continues until the circuit is interrupted or one of the reactants is exhausted (see Figure 1).

At rest, a cell exhibits a potential difference, or voltage, between the two electrodes, which is determined by the amount of chemical energy available when an electron is transferred from one electrode to the other and is therefore subject to the chemical nature of the materials

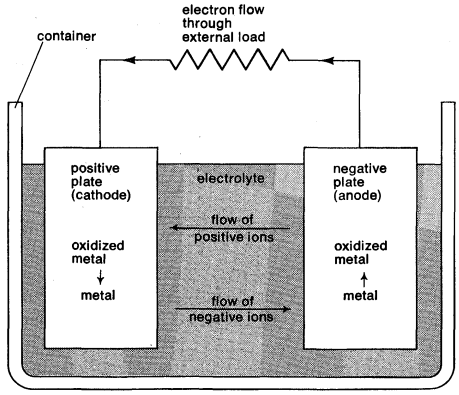

Figure 1: Basic components of an electrochemical cell.
From G. Vinal, *Primary Batteries* (©1950); John Wiley & Sons, Inc.

used in the electrode rather than the size of the cell. The current which flows from a cell is determined by the resistance of the total circuit, including that of the cell itself. If very large currents are required, a low-resistance cell is needed. This can be achieved by the use of electrodes with large areas. The maximum current that can be drawn from a cell is, thus, determined by the area of the electrodes. When a current flows, the cell voltage decreases because of the internal resistance of the cell and the slowness of the chemical processes at the electrodes. The drop in voltage, called polarization, is recovered when the current is stopped.

The cell has a limited energy content, called its "capacity," usually given in ampere-hours, and determined by the quantity of electrons that can be released at the anode and accepted at the cathode. When all of the chemical energy of the cell has been used up—usually because one electrode has become completely exhausted—the voltage falls to zero and will not recover. The capacity of the cell is determined by the amount of active material in the electrode, or, in other words, by the electrode volume (or the thickness for an electrode of a given area).

In a fuel cell, electricity is produced directly by the reaction of a gas or liquid fuel supplied to one electrode, and oxygen or air supplied to the other. To be continuously useful, the electrodes and the electrolyte between them should be unchanged by the reaction. Cells and batteries that do not depend upon a chemical reaction have been developed to convert solar and nuclear energy directly to electrical energy. These are commonly called solar batteries, thermal batteries, and nuclear batteries.

Fuel cells

Battery applications include such things as flashlights and radios, starting systems for internal-combustion engines, the propulsion of special-purpose vehicles, submarines, standby power sources for telephone systems, emergency lighting, and communications devices.

HISTORY

In 1791 Luigi Galvani, an Italian professor of anatomy at the University of Bologna, accidentally discovered that it was possible to cause a direct or continuous flow of current along an electrical conductor by bringing two dissimilar metals into contact with a moist substance. About 1800, acting upon Galvani's discovery, Alessandro Volta, professor of natural philosophy at the neighbouring University of Pavia, created the first battery, the epoch-making "voltaic pile" (see Figure 2). Volta assembled a series of silver and zinc disks in pairs, separating each pair with a sheet of pasteboard soaked in a conducting liquid (salt water). When the top disk of silver was connected by an external wire to the bottom disk of zinc, a current was produced. Volta believed that the current was generated by the contact of silver with zinc, whereas it was actually developed across the salt-soaked pasteboard, which was an electrolyte. Volta constructed piles with as many as 60 pairs of disks, but in use the pile always dried out and ceased to operate, forcing him finally to make a modification that he called a crown of cups. This device consisted of a series of cups filled with a salt solution, each cup

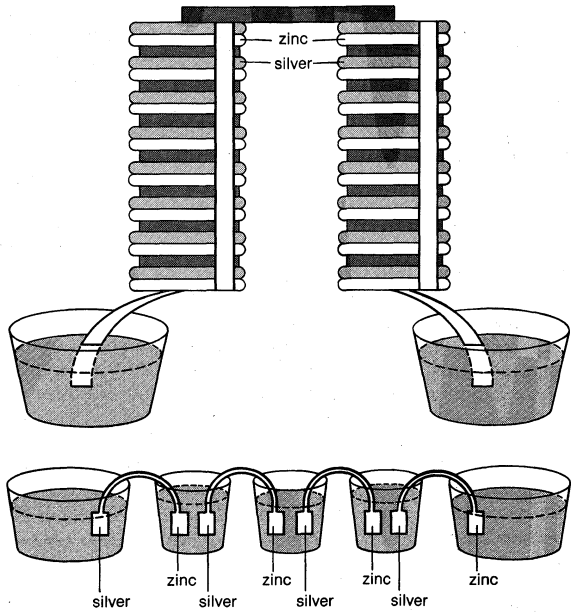

Figure 2: Alessandro Volta's (top) pile and (bottom) crown of cups.

containing a piece of zinc and silver. The zinc in each cup was connected electrically to the silver of an adjacent cup or cell and the cups arranged in a circle. He measured the strength of his battery simply by placing his fingers across the end terminals.

In 1836 a professor of chemistry in London developed the classic form of the primary cell; that is, a battery that is nonchargeable, and once used up cannot be used again. In this cell, known as the Daniell cell, the positive electrode, or anode, was a rod of pure zinc, immersed in sulfuric acid (the electrolyte). A coating of mercury protected the zinc from attack by the acid. The negative electrode, or cathode, consisted of a copper canister, containing sulfuric acid saturated with copper sulfate (see Figure 3).

From G. Vinal, *Primary Batteries* (©1950); John Wiley & Sons, Inc.

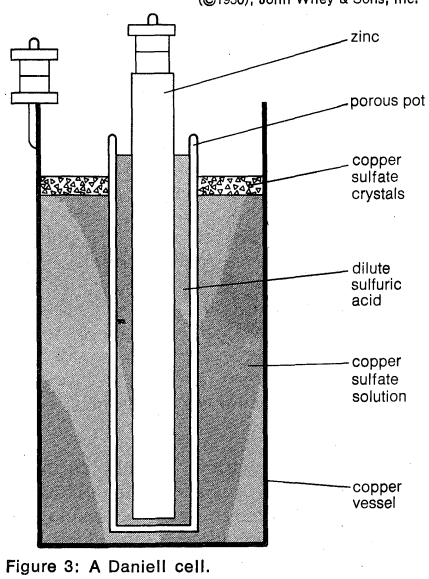

Figure 3: A Daniell cell.

Three years later, in 1839, Sir William Grove, a British jurist who made notable contributions to science, published a description of a battery of cells using platinum electrodes housed in inverted test tubes in a bath of sulfuric acid and water. When an electric current was passed through this battery, hydrogen and oxygen collected in the tubes because of the decomposition of the water. From this "charged" battery, an appreciable current could be drawn. It was the first fuel cell in which the reactants, hydrogen and oxygen, were not included in the electrodes themselves, and it was also the first secondary or storage battery, so-called because the action can be reversed by a direct current so that the cell is made to appear to "store" electricity.

The lead-acid cell, the first practical storage battery and probably the most widely used battery today, was invented by Gaston Planté, a French physicist, in 1859. Planté's cell consisted of two sheets of lead, separated by strips of rubber and rolled into a spiral. When immersed in a 10 percent solution of sulfuric acid and charged, the cell was capable of storing electrical energy. Though Planté's cell could deliver its stored energy very rapidly (that is, it could produce a large current) it remained a laboratory curiosity for 20 years.

The first "dry" cell was invented about 1865 by Georges Leclanché, a French chemist, and remains one of the most widely used primary cells. In its original form (see Figure 4), it consisted of a glass jar filled with the elec-

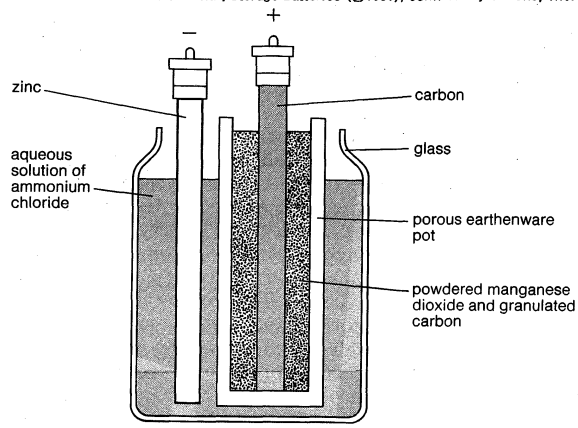

Figure 4: Georges Leclanché's cell.

trolyte, an ammonium chloride solution. The anode was a zinc rod, protected from corrosion by mercury. When a current flowed, zinc ions were formed and passed into solution. In the centre of the jar was a porous pot, filled with a mixture of manganese dioxide and carbon powder that served as an electrical conductor to connect the manganese dioxide powder particles with the cathode, a carbon rod in the centre of the cell. When a current flowed, manganese dioxide was reduced to manganous oxide.

PRIMARY OR VOLTAIC BATTERIES

Dry cells. Primary batteries or cells are those that, once discharged, are discarded. Early primary cells used liquid electrolytes and were not very portable. Today, most primary cells use electrolytes in jelly form, absorbed in a sheet of a porous material, and are known as dry cells.

Acidic dry cells. The modern acidic dry cell is simply an improved version of the 1865 cell described above, one in which the electrolyte is made into a jelly, the porous pot is replaced with a muslin bag, and the glass jar is replaced by a thin zinc cylinder that is the anode. To inhibit leakage, more zinc than necessary is used, and some modern cells also have a steel outer jacket. Dry cells

One version of this cell, which has been turned "inside out," uses a central zinc rod, a fabric separator, and annular rings of a manganese dioxide and carbon mixture packed inside a steel cylinder. Dry cells are almost universally used today in flashlights, portable radios, and toys.

Alkaline dry cells. Another improved version of the Leclanché cell is the manganese-alkali cell, in which the ammonium chloride has been replaced by potassium hydroxide. This electrolyte has a lower resistance, allowing larger currents to be drawn from it. Constructed on the The manganese alkali cell

"inside-out" principle, with a porous zinc anode in the centre, the cell provides higher capacity than that obtainable in a conventional Leclanché cell of the same size. Manganese-alkali cells are used in portable devices, which require large amounts of current (have high current drain), such as devices containing motors, rather than with electronic equipment. Battery-operated razors, cameras, and tape recorders are in this category.

Another modern alkaline dry cell is the mercury cell, using mercuric oxide (mixed with graphite) instead of manganese dioxide at the cathode, and an alkaline electrolyte (potassium hydroxide). This alternative cathode is capable of sustaining far higher currents than manganese dioxide, thus providing a greater capacity for a given battery weight and size. Mercury batteries are expensive, however, compared to other dry-cell types. They are limited to devices that require high current pulses or extremely long service. Photographic flashguns and hearing aids are typical uses.

Other dry cells. The "air–depolarized" cell or "metal–air" cell uses an air electrode from a fuel cell as the cathode and a conventional metal anode, usually zinc. Since an air electrode uses atmospheric oxygen as its active material, it has an infinite capacity and is light in weight. In recently developed zinc-air cells, the space that is normally occupied by the manganese dioxide is filled instead with extra zinc. Ten times more capacity can thus be obtained. In another form of zinc-air cell, the spent zinc anodes can be removed and replaced with new anodes. This mechanically rechargeable battery is useful for portable communications devices. Less successful, but significant, attempts have been made to develop magnesium-air, aluminum-air, and iron-air battery systems.

Wet cells. Another potentially important class of primary cell is the so-called reserve battery. It was found in the early 1970s that such high-energy compounds as magnesium, silver chloride, and cuprous chloride, could be used to obtain a high amount of energy from small or light batteries for special applications, primarily military. Since these materials are attacked by electrolytes, the battery is assembled with the electrolyte stored in a separate container. The electrolyte is inserted into the battery immediately before it is required for use, and the battery consequently enjoys a short but active life. In one form, seawater is the electrolyte; in another, liquid ammonia.

Standard cell. Since the voltage of a cell is determined solely by the chemical nature of the electrodes and electrolyte, a carefully made cell can be used as a standard reference voltage source. Identical cells, constructed from the same materials anywhere in the world and operated under the same conditions, will always produce the same voltage.

Weston cadmium cell

The best known standard cell is the Weston cadmium cell (see Figure 5), which consists of a glass tube in the form of the letter H. A pool of mercury at the bottom of each limb makes contact with a metal electrode inserted through the glass. At the anode, the mercury is amalgamated with 10 percent cadmium, in contact with crystals of cadmium sulfate. At the cathode, the mercury pool is in contact with a layer of mercurous sulfate, in turn covered with cadmium sulfate crystals. The electrolyte is a saturated solution of cadmium sulfate. If the materials of this cell are prepared in a carefully controlled and specified way, the voltage is 1.01864 volts at 20° C, with a well-defined temperature coefficient (that is, a close and regular relationship exists between changes in temperature and changes in voltage). Used as a definition standard for the volt, it forms one of the basic standards for all other electrical units. Many modern electrical devices use a Weston cadmium cell in their circuitry as a standard reference voltage, but the construction is miniaturized and somewhat modified from the classical laboratory cell described. One commercial Weston cell is in the form of a cylinder, four centimetres long and one centimetre in diameter, which can operate in any orientation.

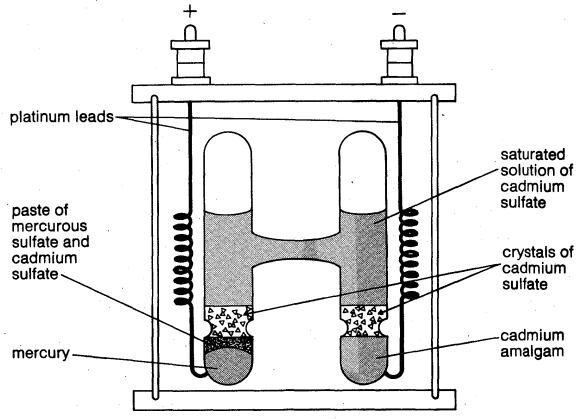

Figure 5: Weston normal or saturated standard cell.

SECONDARY OR STORAGE BATTERIES

Some cells can be recharged by passing a current through them in the reverse direction. The chemical processes that occurred at the electrodes during discharge are then reversed, and the cell recovers its original state, except that some energy is lost during the charge-discharge cycle.

Lead acid. When dynamogenerators became common, Planté's cell was studied more intently and is now widely used in vehicles of all kinds. This cell produced active lead oxide and spongy lead deposits on the surfaces of lead sheets, however, and, thus, had shortcomings. It was clear that better performance could be obtained if these materials were plastered into an open mesh or grid, made of lead. The electrodes of modern lead-acid batteries employ this form of construction (see Figure 6), using grids

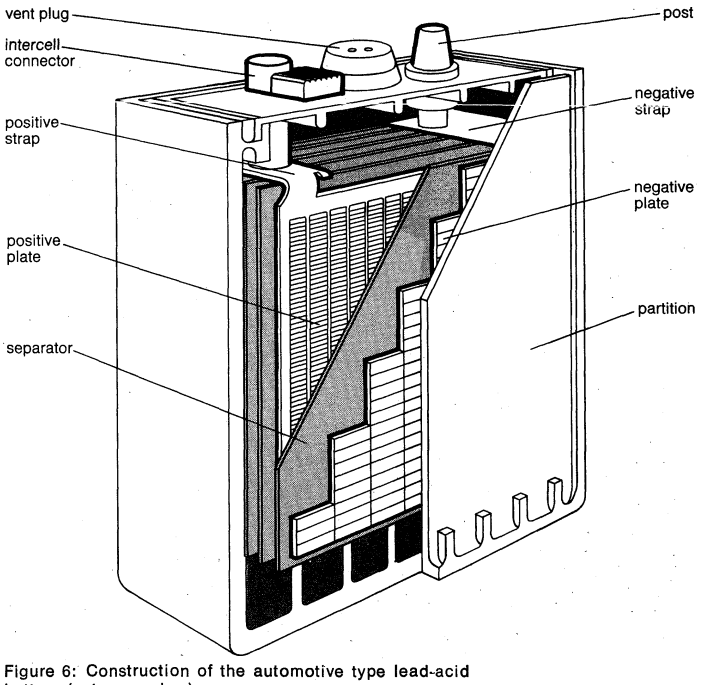

Figure 6: Construction of the automotive type lead-acid battery (cut-away view).

made from an alloy of lead with 5 percent antimony added to improve mechanical qualities. The plates are plastered with a mixture of litharge (lead monoxide) and dilute sulfuric acid. Some red lead is often added. The negative plate also contains small amounts of lampblack, barium sulfate, and organic extracts of wood to act as "expanders" to improve the performance. The plates are cured or dried in air, and then processed to provide positive and negative electrodes. The negative electrode is reduced to spongy lead, while the positive electrode is oxidized to lead dioxide. The plates, separated from each other by a porous insulating separator that may be wood, rubber, plastic, or glass fibre, are immersed in an elec-

trolyte of dilute sulfuric acid contained in a glass or rubber composition tank.

Lead-acid batteries

Normally several cells, each with several plate pairs connected in parallel, each cell providing 2.05 volts, are connected in series to make 6- or 12-volt batteries. The electrolyte in each cell is housed separately in its own compartment.

During discharge each plate is converted to lead sulfate, and the sulfuric acid is used up, producing water. The amount of charge remaining in the cell can be determined by measuring the density of the electrolyte compared to water (specific gravity). The specific gravity of the electrolyte varies from about 1.28 (that is, the electrolyte is 1.28 times as dense as water) when fully charged, to 1.12 when discharged.

When a direct current is passed through the battery, the electrode reactions are reversed and the cell is recharged. If the cell is overcharged, electrolysis of water occurs, producing hydrogen and oxygen. Overcharging, thus, results in a loss of water that must be replaced. It is never necessary to add more sulfuric acid.

Nickel-cadmium. The nickel-cadmium cell consists of a nickel hydroxide cathode and a cadmium anode in an electrolyte that is a solution of potassium hydroxide. The plates are highly porous nickel sheets, impregnated with cadmium and nickel salts and chemically converted to the appropriate oxides. In the pasted-plate type, the plates are made from nickel-plated steel structures containing many pockets filled with active materials, cadmium oxide in one plate and nickel hydroxide in the other.

The plates are assembled in a steel container filled with a solution of potassium hydroxide. No porous separators are used, the electrodes being held in place by plastic or rubber moldings that prevent them from touching each other. The potassium hydroxide is not used up, so that the specific gravity of the electrolyte cannot be used to indicate the amount of charge remaining in the battery. Because it is lighter, it is more often used in portable equipment, such as radios. Modern developments include a sealed nickel-cadmium battery for use in cordless appliances.

Nickel-iron. Once important as a long-life, rugged storage device, the nickel-iron battery, sometimes called the Edison cell, is being displaced by the nickel-cadmium battery. In the nickel-iron battery, the positive plates are nickel-plated steel "pocket" units, packed with a mixture of nickel hydroxide and graphite, the latter added as an aid to conductivity. The negative plates are similar units, packed with a mixture of iron powder, ferrous oxide, and mercurous oxide. On discharge, the nickelous hydroxide is converted to nickelic hydroxide, as in the nickel-cadmium cell, while the iron is converted to ferrous oxide; on charge, the action is reversed. The electrolyte is potassium hydroxide, to which a small amount of lithium hydroxide is added to improve the cell's capacity.

Silver-zinc. Another type of storage battery, increasingly significant in recent years, is the silver-zinc battery, in which the electrolyte is a solution of potassium hydroxide saturated with zinc hydroxide. The negative electrode, a porous plate of pure zinc, to which some mercury is added to suppress the corrosion of zinc by the electrolyte, is formed around a silver mesh screen. The positive electrode is a silver screen, pasted with silver oxide, usually electrochemically oxidized to silver peroxide. The plates are prevented from touching each other by separators made from cellulose sheets. The cells have a high energy-to-weight ratio, and are useful in applications in which lightness is more important than cost. These batteries have a limited-cycle life. That is, the number of times they can be charged and discharged is limited by the stability of the separator, which ultimately allows short circuiting. Lives of from 30 to 300 cycles have been reported for different designs.

FUEL CELLS

Like any other electrochemical cell, a fuel cell consists of two separate electrodes and an electrolyte. It differs from others in that the chemicals supplying the electrode processes are stored separately, and are supplied to the electrodes on demand. The reactants can be any pair of materials that are oxidizing (combining with oxygen molecules) and reducing (removing oxygen molecules), but the simplest fuel cell to describe, construct, and understand is one that operates on hydrogen and oxygen. Hydrogen reacts on the surface of a conducting electrode to produce hydrogen ions and electrons. The ions are transmitted through the electrolyte to the other electrode, where they absorb electrons from the electrode and react with oxygen to produce water. The reaction proceeds for as long as there is a supply of reactants and an external circuit for electrons to flow to balance the reactions. In reverse, this process is the electrolysis of water to produce hydrogen and oxygen. The reactants usually are gaseous, and the electrode must therefore provide a stable interface (point of contact) between the gaseous reactant phase, the electrolyte phase (usually liquid), and the electronic-conducting phase (usually solid).

This so-called three-phase interface problem is the key to successful fuel-cell electrode design. Many different techniques have been tested to achieve it; they fall into three main categories—capillary electrodes, in which the gas-liquid interface is stabilized within the pores of a conductor by surface-tension effects; hydrophobic electrodes, in which the interface is stabilized within the pores by wet-proofing part of the structure; and redox electrodes, in which the reactants and electrolyte exist together in one phase, in contact with a solid electrical conductor.

Although the electrode-electrolyte combination is the focal point of the fuel cell, the cell must also be equipped with a means of supplying fuel and oxidant in a suitably pure form at an appropriate rate and pressure. This may involve generating hydrogen from liquid fuel and/or scrubbing or filtration or both to remove impurities. Waste heat and water from the chemical reaction must also be removed at a controlled rate. Such an association of components, known as a fuel-cell system, is a self-balancing and self-contained device.

Because the fuel cell is not a heat engine, but operates at a uniform temperature, it is not subject to thermodynamic losses of heat engines, whose efficiency is about 40 to 50 percent. Theoretically, fuel cells can operate at a thermodynamic efficiency close to 100 percent. Moreover, since they contain few or no moving parts, fuel-cell systems are more reliable, need less maintenance, and are inherently quieter than conventional dynamo electrical generators. They produce a less noxious exhaust because electrochemical reactions are clear and complete.

Fuel-cell applications

For these reasons, fuel cells have possible applications in space vehicles, where efficiency and reliability are important; in remote areas where fuel transport costs and maintenance are at a premium; in crowded cities, where their quietness and clean exhaust are desirable; and in domestic "local generating stations" where quietness, cleanliness, and low operating costs are attractive. In the early 1970s, however, the high initial cost of fuel cells severely restricted their use.

Aqueous-acidic electrolyte type. Conventional, low-cost fuels consist basically of hydrocarbon compounds such as coal and oil that, when oxidized, produce carbon dioxide and water. If such a fuel is used in a fuel cell, the electrolyte must be compatible with carbon dioxide, and must therefore be acidic. Since the carbon dioxide and water are removed by evaporation, the electrolyte itself must not be volatile. This restricts the choice of common acidic media to sulfuric acid and phosphoric acid, both of which have been extensively used in experimental fuel cells.

Since acids are notoriously corrosive, especially under the conditions that prevail at the oxygen or air electrode; the choice of conducting material, though somewhat limited, includes gold, platinum, titanium, and carbon. A slightly wider, though still restricted choice exists for the fuel electrode. Similar corrosion restrictions apply to the choice of catalysts (material that increase reaction rates without themselves taking part in the reaction); platinum metals have commonly been used.

Evidence has been obtained to show that hydrocarbons may be directly oxidized at temperatures of 100° C and above, but at rates and efficiencies that are disappointingly low. Alcohols, which are more reactive, may be dissolved in the electrolyte, and higher reaction rates have been achieved.

A special type of the aqueous-acidic electrolyte cell is provided by the use of an ion-exchange membrane as electrolyte. A sulfonated polystyrene-type membrane, equilibrated with hydrogen ions, can conduct H^+ ions very readily. Platinum-black catalyst is applied to each face of the membrane and current is picked up by a grooved- or corrugated-metal collector, in the manner of the capillary cell. These collectors are usually titanium or tantalum to resist corrosion.

It is necessary that water formed in the reaction not be allowed to dilute the electrolyte. It is, therefore, either evaporated, or picked up by a system of wicks and carried outside the cell. This type of cell operates at ambient temperature and pressure on hydrogen or impure hydrogen fuel, and oxygen or air. It is limited to an upper temperature of about 50° to 70° C (120°–160° F) by the thermal stability of the membrane in the presence of oxygen and platinum catalyst. In one system developed for space use, the cells were arranged to give two kilowatts when fed with pure hydrogen and oxygen.

A number of successful demonstrations have been made of acid-electrolyte cells that operate on a mixture of hydrogen and carbon dioxide, cheaply produced from natural gas and steam.

Aqueous-alkaline electrolyte type. Alkaline electrolytes in general are less corrosive than acids, permitting the use of a wider range of materials. For this reason, far more research and development have been carried out on alkaline than on acid fuel-cell systems. Unfortunately, alkaline electrolytes are attacked by carbon dioxide, forming carbonates. Carbon dioxide is a minor constituent of atmospheric air, the product of oxidation of hydrocarbons, and a common impurity in commercial hydrogen supplies, and must be completely removed from the feed to alkaline fuel cells.

Capillary cell

Two different types of aqueous-alkaline electrolyte fuel cells have been developed. One is known as the capillary cell, or trapped electrolyte cell, in which the electrolyte is contained within the pores of an insulating matrix—for example, a sheet of asbestos paper or glass-fibre filter paper. The other is the free electrolyte cell, in which the electrolyte is circulated through the gap between two electrodes.

In the capillary cell, the electrodes are formed by a mixture of a powdered catalyst, such as platinum, and a wetproofing agent, such as the organic compound polytetrafluoroethylene. This mixture is embedded in the pores of a woven metal screen, usually nickel, which acts as an electrical conductor and a structural member. The electrodes are clamped against opposite faces of the sheet of matrix material by means of conducting plates of nickel or nickel-plated steel. The plates are formed so as to leave grooves or passages for the gas supply to flow between the plate and the electrode, while the parts in contact allow the electrons to flow from the electrode, through the plate, and into the electrode of the adjacent cell of the series. The electrolyte is contained within the pores of the matrix, wetting the catalyst particles. The major part of the electrode structure is kept dry and accessible to gas by the waterproof nature of the polytetrafluoroethylene, which is in the form of small agglomerated particles in a porous mass. Water produced by the reaction of hydrogen and oxygen, for example, is carried from the cell by an excess of either hydrogen or oxygen. Water evaporates into this stream and is condensed outside the cell. Excess heat is removed from the cell either by a system of fins mounted on the edge of the nickel plates or by a coolant that flows through the hollow passages within the plates.

In free-electrolyte cells, the electrodes are a dual layer structure, with a fine-pore layer on the side facing the electrolyte. Gas is fed to the coarse face of the electrode, at a pressure insufficient to overcome surface-tension forces and expel the electrolyte from the fine pores. Stabilization of the interface is assisted in some cases by making part of the electrode structure wetproof with polytetrafluoroethylene or paraffin wax. Electrodes of nickel and of carbon have been used.

To obtain a reaction between hydrogen and oxygen at temperatures around 0° to 70° C (32° to 160° F), the normal regime for these cells, highly active catalysts are used. Most frequently, platinum group metals in finely divided form, known as blacks, have been employed. Silver and carbon also have been used as oxygen electrodes, while nickel and nickel boride have been used at the hydrogen electrode.

Although it requires pure gas supplies, this type of cell starts operating at room temperatures or below and has found use in specialized military and space applications. Though demonstrated in a number of commercial applications, it has not yet been produced in commercial quantities.

Fused-salt electrolyte type. To avoid the use of expensive catalysts, much work has been carried out on fuel cells operating at higher temperatures. Experimental work has been carried out at 200° C (390° F) using aqueous electrolytes pressurized to 600 pounds per square inch in which the precious metal catalysts were not used. A modification of such an experimental cell, using 85 percent potassium hydroxide electrolyte at 200° C, has been operated at ambient pressures. This system was developed between 1958 and 1967 and provided electrical power for several space-flights including the first manned moon landings.

Space flight power

An experimental cell that has been developed uses a mixture of sodium-potassium-lithium carbonates and operates at approximately 500° to 700° C (930°–1,290° F). The electrolyte is usually contained in the pores of a ceramic matrix, analogous to the capillary cell previously described. The electrodes are porous, metal layers applied to each face of the matrix, consisting of nickel at the fuel side and silver, copper oxide, or nickel oxide at the oxidant side.

A mixture of air and carbon dioxide is fed to the oxidant electrode, where it reacts to form carbonate ions. These ions are transmitted through the electrolyte to the fuel electrode, where they are discharged by reaction with the carbon monoxide or hydrogen fuel to form carbon dioxide (and water). This type of cell requires the addition of carbon dioxide to the air to allow it to operate, in contrast to the alkaline cell that requires all carbon dioxide to be eliminated. The addition is usually achieved by mixing some of the fuel exhaust with air, and feeding the mixture to the air electrode. All traces of unreacted fuel must first be removed.

At the high temperature of operation, a mixture of steam reacts on a nickel surface (*i.e.*, the fuel electrode) to form hydrogen and carbon monoxide, both of which can react electrochemically. Cells of this type have been operated on such hydrocarbon fuels as methane and kerosene.

Though this type of cell is inherently cheap to construct and simple to operate, problems of corrosion and instability have limited its development, and no commercial applications have yet been found. It is particularly suitable as a combined source of electricity, heat, and hot water for small-scale industrial and domestic units.

Redox type. Bringing together three phases—gas, liquid, and solid—at the electrodes is one of the major problems with the fuel cell. The redox (reduction-oxidation) cell eliminates the problem. In it, a solid catalytic metal electrode is placed in contact with an electrolyte containing a dissolved substance in two different states of oxidation; for example, a mixed solution of ferrous iron and ferric iron. Ferrous iron behaves as the "fuel" that is oxidized to ferric iron on the surface of the electrode. At the other electrode, another reduction-oxidation couple (redox couple), such as a mixture of bromine and bromide ions, acts as an oxidant. When a current is drawn, the two electrolytes become richer in the products of reaction. To avoid a direct chemical reaction between the reactants, a porous separator keeps the two electrolytes

apart, permitting the transfer of common ions but not the reactive ions themselves.

The electrolyte in the fuel compartment is circulated through a regenerator, in which it is reduced from the ferric to the ferrous form by means of conventional fuel, such as hydrogen or carbon monoxide. The other is regenerated by blowing air through the solution. Both of these processes occur on the surface of a catalyst, but no electrochemical process is involved.

This type of cell has been limited to academic interest because of the additional complexity of the system, the inefficiency due to leakage of reactants through the separator, and the relatively slow regeneration processes. Much progress has been made toward better "three phase" electrodes, of the types described previously.

Other fuel cells. Another type of electrolyte is a solid oxide such as zirconia, which conducts oxygen ions above approximately 900° C (1,650° F). Thin sheets or tubes of zirconia, stabilized in the "fluorite" crystal structure by the addition of calcium oxide or yttrium oxide, are faced on either side with porous metal electrodes of nickel or nickel oxide. At the high temperature of operation, hydrocarbon fuels are broken down or react with steam to form hydrogen, which reacts with the oxide ion to form water. Oxide ions are replaced in the electrolyte by the reaction of atmospheric oxygen at the other electrode. Problems of materials stability, particularly at the air electrode, have prevented this type of cell from finding applications that would have to be limited to relatively large units maintained at about 1,000° C (1,830° F).

A special type of alkaline cell uses a dissolved substance as fuel rather than a gas. Hydrazine, dissolved in a potassium-hydroxide electrolyte, is pumped through the pores of a nickel electrolyte. Nitrogen and water, the products, must be removed without the loss of excessive amounts of fuel. The air-electrode catalyst is silver, which is selective to oxygen and does not decompose hydrazine. Cells of this type have been developed and used for military purposes, in which the high cost and toxicity of the fuel can be tolerated. A similar system using methanol requires the replacement of the electrolyte each time the system is refuelled because the carbon dioxide product attacks the alkali. This has been used for remote area communications devices, but has not yet achieved commercial significance.

NUCLEAR AND SOLAR CELLS

There is at present no commercially practical device for converting the energy released in a nuclear-fission process directly into electricity. But the radiation emitted from some radioactive substances, such as strontium-90, can be caught on a collector that develops a negative charge, leaving the source positive. Such a nuclear cell can generate high voltages but only small currents.

The nuclear battery

Radiation from the sun can be converted directly into electrical energy by an array of photoelectric cells, or solar cells. When sunlight falls on these cells, a voltage is generated and small currents can be drawn. Little practical use has been made of such cells in terrestrial operation, owing to the relatively low amount of energy per unit area arriving through the atmosphere, the poor efficiency of the cells, and their high cost. They are widely employed, however, in artificial satellites and unmanned spacecraft. Because they produce a steady supply of electrical energy when illuminated, they are usually employed to maintain secondary batteries in a fully charged condition, thus providing for peak loads, as in the operation of transmitting equipment.

PRESENT PROBLEMS AND FUTURE TRENDS

Efficiency and cost considerations. Batteries and fuel cells convert chemical energy directly into electrical energy by an electrochemical process. Such a process is far more efficient than most other indirect routes for converting chemical to electrical energy, or other forms of energy conversion. The Table shows typical efficiencies possible from various types of processes.

Efficiency of Various Energy Conversion Devices

conversion device	efficiency
Electrochemical	90
Heat engine	40
Thermionic	8
Thermoelectric	7
Solar cell (photoelectric)	12
Nuclear (β + current)	1

The cost of electrical energy obtained from electrochemical processes is rather more expensive than that obtained from heat engines operating on cheap fossil fuel (coal and oil). For example, zinc, which costs about $300 per ton in bulk, even if converted from its raw state to electricity at 100 percent efficiency, would cost over 30 cents per kilowatt-hour. It is quite impossible to operate a primary zinc battery for less than this cost. In practice, the energy costs from practical primary batteries depend enormously on battery size and type, ranging from about $10 per kilowatt-hour and up. A large-scale power station, in contrast, generates electricity for as little as under one cent per kilowatt-hour. Because packaged electrical energy is convenient, users are prepared to pay this high price for energy in some applications.

A secondary battery stores electrical energy in a convenient and moderately portable form. Both the charging and discharging processes are accompanied by losses. Efficiency depends mainly on the type of battery and the rate at which it is charged and discharged, but rarely exceeds 80 percent. The capital costs of secondary batteries are far higher than those of primaries, but as they can be used many times over, this is often not a significant factor. Mass-produced lead-acid batteries for automobile use are designed to be sold at a relatively low price, and, consequently, are not as long-lived as they could be at a higher price. There is a far higher unit cost for the more reliable and rugged batteries of electric trucks or submarines.

Battery efficiency loss

Production. Since commercial fuel cells have not yet been produced in quantity, it is impossible to obtain a true estimate of their cost. Generally speaking, fuel cells employing expensive fuels, such as hydrazine, are cheaper to construct than are more complex systems that use cheap fossil fuels. There will be a trade-off between the capital cost of the cell and the cost of the electrical energy that it produces. It is recognized that the main factor that has thus far prevented a commercial fuel cell from becoming a reality is the very high cost of the cell itself.

The battery industry has had a period of rapid growth since 1960, partly due to the introduction of new systems, but mainly due to the proliferation of new uses and increased traditional applications for conventional batteries.

Several exploratory attempts have been made to introduce fuel cells into commercial use, but by 1970 none had been particularly successful. Fuel cells operating on methanol have been used in small numbers to power TV repeater stations, and navigation buoys and beacons. Hydrogen-oxygen fuel cells have been demonstrated propelling a tractor, forklift truck, and a delivery van. Hydrazine-air fuel cells are believed to have had limited military use for communication systems. Hydrogen-oxygen fuel cells have been successfully used as the primary electrical power supply for spacecraft.

Future developments. One of the common faults with early primary batteries was that they were not portable. The development of the dry cell eased this problem, but these cells were not really leakproof, especially after complete discharge, when the zinc can corrodes. The dry-type Leclanché cells are now being made more resistant to leakage, and the trend is expected to continue.

A new type of dry cell, still under development, uses magnesium rather than zinc in an alkaline–manganese dioxide cell configuration. Magnesium stores far more energy than zinc of similar weight, but suffers from corrosion problems and does not deliver large current pulses.

Miniaturization of electronic circuitry has led to tiny devices such as radios and hearing aids that are dwarfed

by the batteries that drive them. There is a trend toward miniaturizing batteries, especially multicell packs that produce about nine volts. As cells become smaller, more advanced types of cells become attractive in order to maintain a reasonable capacity. The development of cheaper manganese-alkali, mercury, and metal-air cells in these miniature sizes promises to continue.

The shelf life of primary batteries is constantly being improved, but is still limited by internal corrosion of the metal electrodes. Developments of advanced battery systems with solid electrolytes, or improvements in the storage characteristics of conventional batteries, will be directed toward this problem.

It is possible that cheaper reserve-type batteries will become available for one-shot emergency applications. Commercial standby power supplies tend to use trickle-charged secondary cells at present, but reserve-type batteries would require no maintenance and be cheaper in the long run. A reserve-type starter battery for an automobile for emergency use has been introduced.

The biggest use of secondary batteries is in automobiles. Trends in the industry are to reduce the selling cost and to prolong the guarantee period of the battery. Much research is going into the development of lightweight batteries for portable applications, and for the propulsion of electric vehicles. For portable use in cordless appliances, nickel-cadmium appears to be the best choice. Successful sealing of secondary cells, preventing gassing vents, has been accomplished. Further developments with lighter, sealed, lead-acid cells, cheaper nickel-cadmium cells, and longer-lived cells designed to withstand frequent complete discharge, will continue.

Nickel-cadmium battery applications

For vehicle propulsion, no conventional battery appears capable of supplying the right characteristics for passenger-car performance. Research will continue on such high-energy systems as sodium-sulfur, lithium-chlorine, and lithium-tellurium. For larger urban vehicles, lighter batteries also are required, but it is possible that nickel-zinc, nickel-cadmium, or even lead-acid can be successful with suitable development. For special vehicle and aircraft applications, where a higher cost can be justified, the silver-zinc cell appears promising, and development of this type of battery to make it capable of deep discharge and long cycle life is likely to continue.

Another secondary battery, still under development but worthy of mention, is the sodium-sulfur battery that uses liquid sodium as one electrode, a solid aluminum-oxide electrolyte, and a sulfur and sodium sulfide mixture on the opposite side. A carbon current collector completes the cell. Current is produced when liquid sodium forms ions that migrate through the aluminum oxide and react with sulfur. The cell is reversible and has a high-energy capacity for its weight. Although it operates only at temperatures of about 250° C (580° F), its lightweight characteristics make it a contender for the battery of an electric car of the future. There are other high-energy batteries of this type also under development, one of which uses lithium and chlorine as the reactants.

After the initial surge of interest in fuel cells in the early 1960s, the only real applications to emerge have been for powering manned spacecraft. For longer missions to more distant planets, solar or nuclear generators are more appropriate, but regenerable or reversible fuel cells may be developed to store energy produced by these devices. For earth-orbit missions, and for lunar laboratory applications, hydrogen-oxygen cells are likely to remain in use.

The earlier promise of the fuel cell as a power source for automobiles is now recognized as a long-term prospect, and although research will continue toward this, it is likely to be at a low level. Increasing interest is being shown in static electrical generation from natural gas and liquid petroleum fuels for relatively small, local power stations, and the development of these for small communities will continue.

Baudelaire, Charles

Prosecuted for obscenity and blasphemy, and long after his death still identified in the public mind with depravity and vice, Baudelaire has become above all others of his age the poet of modern civilization, seeming to speak directly to the 20th century. Rejecting the posing of the Romantics, he revealed himself in his often introspective poetry as a seeker of God without religious beliefs, searching in every manifestation of life—the colour of a flower, the frown of a prostitute—for the true significance. Both as poet and critic he appeals to man's condition in the modern world; and modern, too, are his refusal to admit restriction in the poet's choice of theme and his assertion of the poetic power of symbols.

Baudelaire, photograph by Étienne Carjat, 1863.

Early years

Charles-Pierre Baudelaire was born in Paris on April 9, 1821. His father, François Baudelaire, an elderly widower, in 1819 had married a young woman, without dowry, who had despaired of acquiring through marriage the luxury and security for which she longed. Baudelaire was their only child, and on him she lavished all the devotion of her ardent nature. His father, who had retired from his position in the civil service on a substantial pension, was a man of culture and an amateur painter of some merit. He taught his son, when only four or five, to appreciate the beauty of form and line, thus laying the foundation of the sureness of taste that was to make him one of the most interesting art critics of the 19th century.

François Baudelaire died in February 1827. In November 1828 his widow married Jacques Aupick, a soldier who already had risen in the ranks and was to become a general, an ambassador, and a senator. Anxious that his stepson should learn discipline, in 1832 he sent Charles as a boarder to the Collège Royal at Lyons. There, in spite of the strict military routine of the school, he seems to have been happy; and he won several prizes. He also began to show a feeling for language and to develop a literary style.

In 1836, when his stepfather was transferred to Paris, he was sent to the Lycée Louis-le-Grand. There, instead of fulfilling Aupick's claim that he would "bring honour to the establishment," he proved troublesome and undisciplined. To his masters he seemed an example of precocious depravity, adopting what they called "affectations unsuited to his age" and cultivating his gifts for outra-

geous paradox. He developed a tendency to moods of intense melancholy, and he also became aware that he was by nature solitary.

After passing his *baccalauréat* examinations in 1839, he rejected his stepfather's offer of a post in the diplomatic service and, to his mother's alarm, announced that he meant to live by writing. His chief wish was for freedom, leisure to read what he liked and to enjoy the student life of the Latin Quarter. Like many future writers, he enrolled as a law student, remaining at the École de Droit, nominally at least, until 1840. It was probably at this time that he became addicted to opium and hashish and contracted the venereal disease from which he was to die.

Visit to the East

In 1841, hoping to wean him from his friends in whose company he was leading a life of debauchery, his stepfather sent him on a voyage to India, intending him to stay there for at least two years. Baudelaire set sail on June 9 but, becoming bored, amused himself by scandalizing the other passengers by his unconventional behaviour, and at Mauritius, where the boat put in for repairs after a storm (in which Baudelaire had behaved with great courage), he declared that he would go no farther. Persuaded to go on to Réunion, he there insisted on taking the next boat home and arrived back in France in February 1842. The voyage, however, and his three weeks in Mauritius, had deepened and enriched his imagination and had given him a store of images on which he was to draw in his poetry. He never forgot this, his only experience of the East, but kept for it a nostalgic, mystical yearning that gives his poetry its characteristic quality. He had gone away a boy, still uncertain of himself and his future; he returned a man, his imagination on fire, determined as never before to become a poet.

On attaining his majority in April 1842, he gained control of the capital left him by his father and, leaving home, determined to satisfy his inherited taste for luxury. He spent his money recklessly on fine clothes and on rich furnishings for his apartment at the Hôtel Lauzun, in the Île Saint-Louis, and lived the life of a typical "dandy" of the period. Knowing nothing of business or finance, he regarded his inheritance as a fortune and soon fell prey to cheats and moneylenders, thus laying the foundation for the pile of debts that were to cripple him for the rest of his life. It was while living at the Hôtel Lauzun that his reputation for eccentricity, affectation, and immorality was confirmed; in his desire to shock he did not, however, differ from most of the poets and artists of the Paris of his time.

Jeanne Duval: the "Black Venus"

By 1844 Baudelaire had formed an association with the mulatto woman Jeanne Duval, who was to bring him much unhappiness. For a time he loved her passionately, and even at the end, when her cruelty, treachery, and stupidity had driven him to attempted suicide, he still felt in some ways attached to her. She inspired his first cycle of love poems, the "Black Venus"; and these are among the finest erotic poems in the French language.

During those early years of leisure and freedom from anxiety, Baudelaire was composing many—perhaps most—of the poems that were to form part of *Les Fleurs du mal,* his one collection, which comprised the Lesbian poems, the poems of revolt and decay, and the great erotic poems. At this time, too, he became acquainted with many artists, among them Delacroix and Courbet, and so acquired the knowledge of painting that was to give his art criticism much of its distinction and originality.

When within two years he had run through half his inheritance, his family early in 1844 obtained a decree by which the remainder of his capital was placed in trust, and he received the income in monthly installments. Baudelaire was wounded that his mother should have consented to a step that put an end to his freedom. In attempting to secure his future, his family had misguidedly prevented him from recovering his independence; still heavily in debt, he was unable, out of the £75 a year allowed him, to clear off his debts without borrowing.

This sudden change in Baudelaire's circumstances ended his life of luxury and carefree leisure; in the future he was to know only straitened means and eventually real poverty. He began to be uncertain of his own gifts, and his bitterness against his family was deepened by doubts whether they were perhaps right to try to prevent him from following a literary career. The melancholy he had known in adolescence returned, and what he called his mood of "spleen" became more frequent. It was at this time that the first of his great poems of spleen were written. Among his friends were many more unfortunate than himself, and he developed a sympathy for suffering humanity. Attracted by the revolutionary idealism of many of his friends, he took part in the February revolution of 1848 that resulted in the establishment of a republic.

The Salons of 1845 and 1846

Determined to prove that he could live by his pen, he had meanwhile become a professional writer. His first published work was a piece of art criticism, a review of the Salon of 1845 that reveals a perceptive and farsighted judgment and shows that he had already formulated a conception of what modern art should be. His "Salon de 1846" is a landmark in aesthetic criticism: no longer content to give an account of the exhibition, he puts forward independent and original theories and gives the first hint of his later concept of the *correspondances* between nature and art, claiming that painting, like music, has its own harmony, of light and shade, and that in nature, colour is melody. In 1845 and 1846 some of his poems were printed in avant-garde journals, to which he also contributed articles and reviews.

In 1847 he published his only novel, the autobiographical *La Fanfarlo.* Begun much earlier, it is of interest mainly for its analysis of his personality during the period when he was living in luxury at the Hôtel Lauzun.

What Baudelaire did between the June revolution of 1848, in which thousands of workmen were killed in Paris, and December 1849 is not known, nor is it certain why he was then in Dijon or how long he stayed there. By 1850 he was back in Paris, as destitute and unhappy as ever. His mother had refused to write to him until he showed signs of reformation; and although she intended to goad him into working regularly, his brief burst of activity had ended without conspicuous success, and he was further discouraged by her sternness. Many articles were planned but never written; many begun but never finished. But in these years of experience and suffering he had prepared himself for his great creative period. Spiritually, his nature had been enriched, and after Pres. Louis-Napoleon Bonaparte's coup d'etat of December 1851, which ended his active interest in politics, he was ready for the opening of his mature period.

Translation of Edgar Allan Poe

This began with his discovery early in 1852 of the writings of Edgar Allan Poe, and he set to work at once to translate them. His first article on Poe—the first in any foreign language—appeared in March and April in the *Revue de Paris* and was followed by several translations published in reviews, among them his only attempt at translating a poem, "The Raven." From 1852 to 1865 he was occupied in translating Poe and in writing critical articles on him. *Histoires extraordinaires* appeared in 1856; *Nouvelles Histoires extraordinaires* in 1857; *Aventures d'Arthur Gordon Pym* in 1858; *Eureka* in 1864; and *Histoires grotesques et sérieuses* in 1865. The first two had long critical introductions.

As translations these are, at their best, classics of French prose: Baudelaire's mother had been born in England the daughter of an émigré, and he had spoken English as a child. In Poe he found for the first time someone who belonged to his own spiritual family and who had already reached, independently, conclusions toward which he had been groping. Poe thus gave him confidence in his own aesthetic theories and ideals of poetry.

In April 1852 Baudelaire had left Jeanne Duval—though by no means, as it turned out, for good. He could not, however, live without the company of women; and seeking someone to love, he turned first to the actress Marie Daubrun, and when she rejected him, to Mme Apollonie-Aglaé Sabatier, a well-known beauty and former artist's model and friend of many artists and writers whom he had known for many years. She was the inspiration of his cycle of the "White Venus." In 1854 he renewed his association with Marie Daubrun, who in-

spired the cycle of the "Green-Eyed Venus." In many of the poems in these two cycles he reaches the highest peak of his art.

Baudelaire's growing reputation as Poe's translator and as art critic at last enabled him to publish some of his poems; and in June 1855 the *Revue des Deux Mondes*, the bastion of conservative Romanticism, ventured to print a selection of 18, submitted by Baudelaire as representative and chosen because they were original and startling in expression and themes. Their publication brought him notoriety, and he was widely accused of obscenity. In the spring of 1857, however, nine more poems appeared in *La Revue Française* and three in *L'Artiste;* and in June *Les Fleurs du mal* was published. But as a result, Baudelaire, the publisher, his friend Poulet-Malassis, and the printers were prosecuted; and in a famous trial for obscenity and blasphemy, they were found guilty of an offense against public morality and fined. Six poems were banned—a ban lifted only in 1949. Although a few readers understood and appreciated Baudelaire's intention and consummate artistry, for several generations *Les Fleurs du mal* remained a byword for depravity, morbidity, and obscenity. Baudelaire published a second edition in 1861, greatly enlarged and enhanced but omitting the banned poems, which were first republished in Belgium in 1866 in the collection *Les Épaves*. A third edition, further enlarged, was being prepared in 1866 when Baudelaire became paralyzed; it was published posthumously by his friend Charles Asselineau, although probably not as Baudelaire had planned it. It contains, however, six "Nouvelles Fleurs du mal," first published in 1866 in *Le Parnasse Contemporain*, as well as some poems that do not belong to the plan of the collection.

Publication of *Les Fleurs du mal*

The failure of *Les Fleurs du mal*, from which he had expected so much, was a bitter blow to Baudelaire, and the remaining years of his life were darkened by a growing sense of failure, disillusionment, and despair. His platonic relationship with Mme Sabatier had ended sadly, and Jeanne Duval, from whom he had finally parted in 1861, remained a constant burden and anxiety. Although some of his finest works were written in these years, few were published in book form. Some appeared in periodicals—his "Salon de 1859" in *La Revue Francaise*; "Richard Wagner et Tannhaüser à Paris" in *La Revue Européene* (1861); "Le Peintre de la vie moderne" (the draftsman Constantin Guys) in *Le Figaro* (1863); and his prose poems, intended to form part of the collection *Le Spleen de Paris*, in various papers. This last was a work of which Baudelaire was particularly fond and in which he had been engaged for many years—he was still working on it just before his final collapse. He had taken the idea from Aloysius Bertrand's *Gaspard de la nuit*, but the subject is that of his poems in verse of the same period, and in mood the work reflects the settled pessimism of the aging and deeply saddened Baudelaire. These poems in prose express even more poignantly than does *Les Fleurs du mal* his feeling for Paris, for the teeming modern city, and his compassion for the failures and outcasts in its streets.

In 1860 Poulet-Malassis published two studies of the effects of hashish and opium as *Les Paradis artificiels*, and in 1861, the second version of *Les Fleurs du mal*. In 1862 he was declared bankrupt; Baudelaire was involved in his publisher's failure and his financial difficulties became desperate. To escape his creditors, and in an attempt to dispose of the copyright of the works he had ready for publication, in 1864 he went on a lecture tour in Belgium. It proved a failure, and he was unsuccessful in negotiating a contract for his books. This was a bitter disappointment, for he had wished particularly to publish his critical works, in which he had defined his theory of aesthetics; he regarded his work as an organic whole and his critical prose therefore as important as his poetry. To appreciate his poetry fully it is necessary to understand his ideas of the nature of art. Each of his poems is a crystallization of his vision, and his criticism is a meditation on the nature of a work of art and on the principles that underlie it. Baudelaire believed that every great creative artist must in the end become also a critic; his criticism explains his poetry, and his poetry is an extension of his aesthetic theory.

Theories of art and poetry

In February 1866, while still in Belgium, at Namur, Baudelaire became seriously ill. Taken back to Paris, he died there in his mother's arms on August 31, 1867. Of the many invited to give orations at his funeral, only Asselineau and the poet Théodore de Banville accepted; but they were among his oldest friends.

Baudelaire died unrecognized, with many of his writings still unpublished and those that had been published out of print. Among poets, however, opinion soon began to change: the future leaders of the Symbolist movement who were at his funeral were already describing themselves as his followers. By the 20th century he had become widely recognized as one of the great French poets of the 19th century. His admirers even claimed that he revolutionized the sensibility and way of thinking and writing throughout western Europe, and that the formulation of his aesthetic theory marks a turning-point in the history of poetry and, indeed, in the history of art. For it was in this theory that the Symbolist movement found its source.

MAJOR WORKS

VERSE: *Les Fleurs du mal* (1857; 2nd enl. ed. 1861; definitive ed., 1868), notable among many translations are those by Roy Campbell, 1952; *Les Épaves* (1866), 23 poems, including six banned poems from *Les Fleurs du mal.*

PROSE: *La Fanfarlo* (1847), autobiographical *nouvelle*, published in the *Bulletin de la Société des Gens de Lettres*; *Les Paradis artificiels* (1860), essays, including a study of and translation from Thomas De Quincey's *Confessions of an English Opium-Eater; Petits Poèmes en prose* (1869), later entitled, as intended by Baudelaire, *Le Spleen de Paris;* among translations are those by Arthur Symons (1905), Michael Hamburger (1946), and Louise Varèse (1951); *Curiosités esthétiques and L'Art romantique* (1868), critical essays, including "Salon de 1845," "Salon de 1846," "Salon de 1859," "Richard Wagner et Tannhäuser à Paris," and "Eugène Delacroix," translations by Jonathan Mayne in *The Mirror of Art* (1955), and *The Painter of Modern Life, and Other Essays* (1964).

TRANSLATIONS (FROM EDGAR ALLAN POE): *Histoires extraordinaires* (1856); *Nouvelles Histoires extraordinaires* (1857); *Adventures d'Arthur Gordon Pym* (1858); *Eureka* (1864); *Histoires grotesques et sérieuses* (1865).

BIBLIOGRAPHY. The first edition of Baudelaire's *Oeuvres complètes*, 7 vol. (1868–70), was edited by C. ASSELINEAU, with a preface by THEOPHILE GAUTIER. It does not contain the *Journaux intimes*, other posthumous works, or the correspondence. Fragments of the *Journaux intimes* were published in *Le Livre* in September 1884, and the first complete edition in 1909. *Lettres 1841–1866* were published in 1905, *Lettres inédites à sa mère* in 1918, and *Dernières lettres inédites à sa mère* 1926. Some *Juvenilia* were published by JULES MOUQUET in 1932. A complete edition of his entire works, including *Juvenilia, Oeuvres posthumes* and *Correspondance générale*, was edited by JACQUES CREPET (1922–53); a revised version of this, under the editorship of GEORGES BLIN and CLAUDE PICHOIS, began appearing in 1968. The best one-volume edition is that by YVES LE DANTEC for the "Pléiade Series" (1950); a further volume contains translations from Poe. ROBERT KOPP'S 1969 edition of *Petits poèmes en prose* may be considered definitive. The best edition of *L'Art romantique* is by L.J. AUSTIN (1968). ASSELINEAU was the first to attempt a vindication of Baudelaire's character in *Charles Baudelaire, sa vie et son oeuvre* (1869); and in 1872 a group of friends published a collection entitled *Souvenirs, correspondances, bibliographie*, ed. by CHARLES COUSIN. The first complete biography was included in *Oeuvres posthumes et correspondances inédites*, which was published in 1887 and revised and enlarged in 1907 by EUGENE and JACQUES CREPET. For systematic studies of Baudelaire's vocabulary, see R.T. CARGO (ed.), *A Concordance to Baudelaire's "Les Fleurs du mal"* (1965); and *Concordances, index et relevés statistiques des "Fleurs du mal,"* issued by the Centre d'étude du vocabulaire français de la Faculté des Lettres de Besançon (1965). A short selection of the many works on Baudelaire and his writings follows: L.J. AUSTIN, *L'Univers poétique de Baudelaire* (1956), evaluates the significance of Baudelaire in the development of French poetry in the 19th century; the title of W.T. BANDY (comp.), *Baudelaire Judged by His Contemporaries (1845–1867)* (1933), is self-explanatory, as is that of *Baudelaire en 1848* (1946), which he wrote with JULES MOUQUET; GEORGES BLIN, *Le Sadisme de Baudelaire* (1948), is a collection of essays on several aspects of Baudelaire's

work, not just a study of sadism; LEON BOPP, *Psychologie des "Fleurs du mal,"* 4 vol. (1964–69), is an extremely detailed investigation, based upon close study of the texts of *Les Fleurs du mal,* of the workings of Baudelaire's mind; G.T. CLAPTON, *Baudelaire et De Quincey* (1931), considers Baudelaire in relation to an author who influenced him deeply; P. EMMANUEL, *Baudelaire* (1967), is a valuable study (in French) of Baudelaire's religious attitudes; ALISON FAIRLIE, *Baudelaire: les Fleurs du mal* (1960), is a short study intended for undergraduates: there is no better introduction to Baudelaire in English; ANDRE FERRAN, *L'Esthétique de Baudelaire* (1933), contains a comprehensive account of Baudelaire's philosophy of art; P. MANSELL JONES, *Baudelaire* (1952), is a sensitive and scholarly introductory work; F.W. LEAKEY, *Baudelaire and Nature* (1969), is an exhaustive study of an important aspect of Baudelaire, a work of synthesis as well as of analysis, with a full and up-to-date bibliography; C. MAURON, *Le Dernier Baudelaire* (1966), is a valuable contribution to the understanding of the *Petits poèmes en prose;* D.J. MOSSOP, *Baudelaire's Tragic Hero* (1964), is a study of the design of *Les Fleurs du mal* that is interpreted as a record of the inner struggles of the "poet-hero"; HENRI PEYRE, *Connaissance de Baudelaire* (1951), is a first-rate introduction to the problems of Baudelaire criticism; JEAN POMMIER, *La Mystique de Baudelaire* (1932), has become a standard general critical survey: his *Dans les chemins de Baudelaire* (1945) contains useful essays on Baudelaire's earlier works; FRANCOIS PORCHE, *Baudelaire, histoire d'une âme* (1945), adopts a biographical approach to Baudelaire's poetry; JEAN PREVOST, *Baudelaire* (1953), contains a fine account (in French) of the forces that influenced Baudelaire and discussions of themes and versification; PETER QUENNELL, *Baudelaire and the Symbolists,* 2nd rev. ed. (1954), is a study of Baudelaire and of his influence; MARCEL RUFF, *L'Esprit du mal et l'esthétique baudelairienne* (1955), is a wide-ranging study of all aspects of Baudelaire; JEAN-PAUL SARTRE, *Baudelaire,* (1947; Eng. trans., 1950), is a thought-provoking, though controversial, work of criticism that takes biography as its starting point; ENID STARKIE, *Baudelaire* (1957), is a critical biography that places Baudelaire's work in its cultural context (1957); MARTIN TURNELL, *Baudelaire* (1953), contains a sensitive and detailed commentary on *Les Fleurs du mal;* PAUL VALERY, *Situation de Baudelaire* (1924), is a penetrating essay on the originality of Baudelaire and of his influence on later 19th-century French poets; ROBERT VIVIER, *L'Originalité de Baudelaire,* 2nd ed. (1952), contains a comprehensive and systematic study of Baudelaire's style and poetic technique. Additional titles may be found in R.T. CARGO, *Baudelaire Criticism, 1950–1967: A Bibliography with Critical Commentary* (1968).

(En.S.)

Baybars I

Baybars I, ruler of Egypt and Syria from 1260 to 1277, was the most eminent of the Mamlūk, or "slave," sultans of Egypt and Syria. His enduring fame rests not only on the prowess he showed in his military campaigns, especially those against the crusaders and Mongols, but also on his internal administrative reforms, which stabilized the nascent Mamlūk state and allowed it to grow and flourish. He became a legend in his own lifetime, and an extensive folk literature, *Sīrat Baybars,* purporting to be his life story, is still popular in the Arabic-speaking world.

Al-Malik aẓ-Ẓāhir Rukn ad-Dīn Baybars was born probably in 1223 in the country of the Kipchak Turks on the northern shores of the Black Sea. After the Mongol invasion of their country about 1242, Baybars was one of a number of Kipchak Turks sold as slaves. Turkish-speaking slaves, who had become the military backbone of most Islāmic states, were highly prized, and eventually Baybars came into the possession of Sultan aṣ-Ṣāliḥ Najm ad-Dīn Ayyūb of the Ayyūbid dynasty of Egypt. Sent, like all the Sultan's newly acquired slaves, for military training to an island in the Nile, Baybars demonstrated outstanding military abilities. Upon his graduation and emancipation, he was appointed commander of a group of the Sultan's bodyguard.

Early military successes

Baybars gained his first major military victory as commander of the Ayyūbid army at the city of al-Manṣūrah in February 1250 against the crusaders' army led by Louis IX of France, who was captured and later released for a large ransom. Filled with a sense of their military strength and growing importance in Egypt, a group of Mamlūk officers, led by Baybars, in the same year murdered the new sultan, Tūrān Shāh. The death of the last Ayyūbid sultan was followed by a period of confusion that continued throughout the first years of the Mamlūk sultanate.

Having angered the first Mamlūk sultan, Aybak, Baybars fled with other Mamlūk leaders to Syria, and stayed there until 1260, when they were welcomed back to Egypt by the third sultan, al-Muẓaffar Sayf ad-Dīn Quṭuz. He restored them to their place in the army and conferred a village upon Baybars.

Within a few months of Baybars' arrival, in September 1260, the Mamlūk troops defeated a Mongol army near Nābulus in Palestine. Baybars distinguished himself as the leader of the vanguard, and many Mongol leaders were slain on the field.

For his military achievement, Baybars expected to be rewarded with the town of Aleppo; but Sultan Quṭuz disappointed him. On the way home through Syria, Baybars approached Quṭuz and asked him for the gift of a captive Mongol girl. The Sultan agreed, and Baybars kissed his hand. On this prearranged signal the Mamlūks fell upon Quṭuz, while Baybars stabbed him in the neck with a sword. Baybars seized the throne to become the fourth Mamlūk sultan.

Military career as sultan

Baybars' ambition was to emulate Saladin, the founder of the Ayyūbid dynasty, in the holy war against the crusaders in Syria. As soon as he was acknowledged as sultan, Baybars set about consolidating and strengthening his military position. He rebuilt all the Syrian citadels and fortresses that had been destroyed by the Mongols and built new arsenals, warships, and cargo vessels. To achieve unity of command against the crusaders, Baybars united Muslim Syria and Egypt into a single state. He seized three important towns from the Ayyūbid princes, thus ending their rule in Syria. From 1265 to 1271 Baybars conducted almost annual raids against the crusaders. In 1265 he received the surrender of Arsūf from the Knights Hospitallers. He occupied 'Atlit and Haifa, and in July 1266 he received the town of Safed from the Knights Templar garrison after a heavy siege. Two years later, Baybars turned toward Jaffa, which he captured without resistance. The most important town taken by Baybars was Antioch (May 1268), which was followed by a number of minor Frankish fortresses. His seizure of additional strongholds in 1271 sealed the crusaders' fate; they were never able to recover from their territorial losses. Baybars' campaigns made possible the final victories won by his successors during the next decades.

Baybars' permanent goal was to contain the continued Mongol attacks on Syria from both north and east that threatened the very heart of the Islāmic east. During the 17 years of his reign, he engaged the Mongols of Persia in nine battles. Within Syria, Baybars dealt with the Assassins, a fanatical Islāmic sect. After seizing their major strongholds between 1271 and 1273, he wiped out the Syrian members of the group.

Baybars also took the offensive against the Christian Armenians, who were allies of the Mongols, devastating their lands and plundering their major cities. In 1276, having defeated the Seljuq troops and their Mongol allies, he personally seized Caesarea (modern Kayseri in Turkey) in Cappadocia. To secure Egypt on the south and west, Baybars sent military expeditions into Nubia and Libya, taking personal command in 15 campaigns and often endangering his life.

Foreign relations

In the interest of good diplomatic relations with the Byzantine Empire, Baybars sent envoys to the court of Michael VIII Palaeologus in Constantinople. The Byzantine sovereign thereupon ordered the restoration of the ancient mosque and permitted the Egyptian merchants and ambassadors to sail through the Hellespont and Bosporus. One of Baybars' principal goals during his reign was to acquire more Turkish slaves to be used in the Mamlūk army; another was to contract an alliance with the Mongols of the Golden Horde in South Russia against the Mongols of Persia. In 1261 Baybars sent an ambassador to the Sicilian king Manfred. Other embassies to Italy followed, and in 1264 Charles of An-

jou, later king of Naples and Sicily, sent an embassy with letters and gifts to Cairo, a remarkable testimony to Baybars' strength and influence. Baybars was also able to sign commercial treaties with such distant sovereigns as James I of Aragon and Alfonso X of León and Castile.

In a brilliant political move Baybars invited a fugitive descendant of the ʿAbbāsid dynasty of Baghdad to Cairo and established him as caliph—head of the Muslim community—in 1261. Baybars wished to legitimize his sultanate and to give pre-eminence to his rule in the Muslim world. The ʿAbbāsid caliphs in Cairo had no practical power in the Mamlūk state, however.

Internal policy

Baybars was, moreover, more than a military leader or a diplomatic politician. He built canals, improved harbours, and established a regular and fast postal service between Cairo and Damascus, one that required only four days. He built the great mosque and the school bearing his name in Cairo. He was also the first ruler in Egypt to appoint chief justices representing the four main schools of Islāmic law.

A sportsman as well as a warrior, Baybars was fond of hunting, polo, jousting, and archery. He was also a strict Muslim, a generous almsgiver, and watchful of the morals of his subjects—he issued a prohibition against the use of wine in 1271.

He died in Damascus on July 1, 1277, after drinking a cup of poison intended for someone else, and was buried in Damascus under the dome of the present aẓ-Ẓāhirīyah Library, which he had established.

BIBLIOGRAPHY. Two important primary sources for the career of Baybars I are the biographies of MUHYI AL-DIN IBN ʿABD AL-ZAHIR (d. 1292) and MUHAMMAD IBN SHADDAD (d. 1285). Unfortunately neither of these is fully extant. Part of the life of Baybars by IBN ʿABD AL-ZAHIR has been published by S.F. SADEQUE, *Baybars I Of Egypt* (1956). See also E.M. QUATREMERE (trans. and annot.), *Histoire des sultans mamlouks de l'Égypte*, vol. 1 (1837); S. LANE-POOLE, *A History of Egypt in the Middle Ages*, pp. 242–275 (1901, reprinted 1968); and G. WIET, "Baybars I," in the *Encyclopaedia of Islam*, new ed., vol. 1 (1960).

(H.Ra.)

Bayern

Bayern (Bavaria in English conventional usage) is the largest *Land*, or state, of the Federal Republic of Germany, with an area of 27,238 square miles (70,547 square kilometres). While it ranks second to Nordrhein-Westfalen in population, with about 10,500,000 by the early 1970s, its density of 385 persons per square mile is rather low in comparison to the rest of Germany. Bayern comprises the eastern part of south Germany and is bounded on the west by the *Länder* of Baden-Württemberg and Hessen, on the north by the German Democratic Republic, on the east by Czechoslovakia, and on the south and southeast by Austria. Munich (München; *q.v.*) is the capital.

History. *The Celts and Romans.* The earliest known inhabitants in the area of present-day Bayern were the Celts. They developed a considerable culture, as evidenced in their aristocratic governing structure and their carefully laid-out cities. In the last decade before Christ's birth they were pressed between Teutonic tribes in the north and the Romans in the south. The Romans divided the southern part into Raetia and Noricum and built fortifications along the northern boundary to keep out the Teutons. Flourishing Roman colonies arose in the south—Augsburg, Kempten, Regensburg, and Passau—that retained much of their Roman character in later times.

German invasions

The Middle Ages. The Romans were overcome in the 5th century by repeated Germanic attacks. The lands were eventually settled by tribes from the Elbe area and from Bohemia, Moravia, and Hungary, who mixed with the remaining Celts and Romans. The tribe that gave the territory its name was the Baiuvarii (Bavarians), who settled in the south between AD 500 and 800. The southwest belonged to the Alemanni, while northern Bavaria was in the hands of the Franks and Thuringians.

In the 7th and 8th centuries Bavaria was Christianized by Irish and Scottish monks (St. Boniface, St. Korbinian, St. Emmeram, and St. Rupert). From about 555 to 758 the Bavarians were ruled by Frankish dukes of the Agilolfing family. The last of the family, Tassilo III, was deposed by Charlemagne, who finally incorporated Bavaria into the Carolingian Empire.

After the partitioning of the empire in 817, the Duchy of Bavaria became a central part of the territory of the East Franks, with its capital at Regensburg. At this time Bavaria experienced a cultural upsurge, stemming primarily from the monasteries. In 1180 the Holy Roman emperor Frederick I Barbarossa gave Bavaria to the count palatine Otto of Wittelsbach, whose family ruled it until 1918. At first the Wittelsbachs possessed only the southeastern part of present-day Bavaria, the rest being fragmented into numerous imperial cities, monastic holdings, and family domains. Territorial changes were frequent. In 1214 the Palatinate was added (which remained Bavarian until 1945). In the 14th and 15th centuries, the power of the dukes was notably weakened by political divisions, until finally Albert IV (1467–1508) reunited Bavaria, making Munich the capital. The first Bavarian university was founded in 1472 in Ingolstadt.

William IV to Bismarck. William IV (1508–50) opposed the Protestant Reformation; under his successor, Albert V (1550–79), Bavaria became a strictly Catholic country. Maximilian I (1597–1651) fought on the side of the Habsburgs in the Thirty Years' War (1618–48) and by his leadership increased Bavaria's prestige, gaining territorial accessions and attaining for himself the title of elector. Bavaria suffered greatly in the later phases of the war from the incursions of Swedish and French armies. Territorial conflict continued throughout the 18th century as Bavaria was ravaged by the wars of the Spanish Succession, the Austrian Succession, and the Bavarian Succession. Despite this, the era was a glorious one culturally.

French occupation

In 1800, French Revolutionary armies occupied Munich. In the following year Bavaria became an ally of France and was able to expand its territories at the expense of Austria, acquiring by 1806 approximately the boundaries it now has. In 1813, shortly before the Battle of Leipzig, Bavaria rejected Napoleon and in 1815 joined the Germanic Confederation against him. The reigns of kings Maximilian I and Louis I saw the consolidation of the country and the achievement of many reforms: the first constitution, a parliament, municipal autonomy, and tax reform. Munich became a flourishing centre of learning and the arts. In 1848, however, Louis was forced to abdicate.

His successor, Maximilian II (ruled 1848–64), proceeded with domestic reform programs while also promoting the arts and learning. Politically, he sought to avoid being dominated by Prussia in a Germany that excluded Austria; he favoured union of the many small German states in order to withstand the force of Prussia's demands. His successor, Louis II (ruled 1864–86), is remembered for his romantic castles and his enthusiasm for the music of Richard Wagner. He refused Bismarck's proposal to incorporate Bavaria into a German domain under Prussian leadership, siding with Austria in the Prussian–Austrian War of 1866. The quick victory of the Prussians and the moderation of their policies led Bavaria to join Prussia in the Franco-German War of 1870 and afterward to share in the establishment of a German empire under Wilhelm I, King of Prussia.

After 1871. In the German constitution of 1871 Bavaria retained a few elements of sovereignty in its diplomatic service, military administration, postal service, and railways but otherwise cast its lot with the German empire. At the end of World War I, King Louis III had to abdicate, and Bavaria became a republic. The five years thereafter were filled with constant unrest: 1919 saw the murder of Kurt Eisner, the Socialist leader, and the establishment of a short-lived soviet republic; in 1920 and 1921 there were right-wing coups; and in 1923 Adolf Hitler and Gen. Erich Ludendorff attempted their unsuccessful *Putsch* in Munich.

After World War II Bavaria became part of the American zone of occupation. The Palatinate was detached and joined to the new Rhineland-Palatinate state. Under the Basic Law of Germany of 1948, Bavaria became a *Land* (state) of the Federal Republic. It retains, however, a certain uniqueness based upon its size, its long history as an independent state, and its great culture.

Geography. Bayern is a country of high plateaus and medium-sized mountains. In the northwest are the wooded sandstone hills of the Spessart; in the north are basalt knolls and high plateaus. The northwest is drained by the Main River, which flows into the Rhine. Moving southeast, the topography varies from the stratified land formations of Swabia-Franconia to shell limestone and red marl, the hill country of the Franconian–Rednitz Basin, and the limestone mountains of the Franconian Jura along the Danube, which divides Bayern north and south. On the eastern edge of Bayern, adjoining Czechoslovakia, is the Böhmerwald (Bohemian Woods) and, in the north, the Frankenwald (Franconian Forest). South of the Danube is a plateau upon which lies the capital, Munich, and beyond it the Bavarian Alps. Bayern's share of the Alps consists of wooded heights of several thousand feet, behind which rise steep ridges and high plateaus (in the west, the Allgäuer Alps; in the east, the Alps of Berchtesgaden). They reach their highest peak in the 9,718-foot (2,962-metre) Zugspitze in Germany's Wettersteingebirge (Wetterstein Range).

Mountain peaks

Bayern's climate is determined by its southern position in Europe along with its relatively high altitude and its distance from the sea. These give it a continental climate that is harsh for middle Europe, although there are some exceptions, such as the Lower Main Valley. Average temperatures in January vary from around freezing in Würzburg and Nürnberg, to 28° F (−2° C) in Regensburg and Munich, and 12° F (−11° C) on the Zugspitze. The July averages are in the middle 60s F except on the Zugspitze, where temperatures are close to freezing.

Bayern's ethnic characteristics are a reflection of its traditions and political history. The southeast is inhabited by an old Bavarian stock, the southwest by people of Bavarian–Swabian descent, and the north by descendants of the Franks. Traditional differences are still visible in their villages. The Franks built large village clusters and laid out their farms in narrow strips. The houses are partly sandstone, partly half-timbered. Row houses with paved floors appear in some areas. In old Bayern and Swabia there are both village clusters and one-street villages; most of the houses have wooden floors. The cities show even more marked differences. In the Swabian and, particularly, the Frankish areas, religious and secular landholders established a large number of towns, most of which remained small and were referred to as dwarf towns. These medieval towns were built compactly within protective walls. The churches, public buildings, and homes were lavishly decorated; the examples that remain are a constant delight to the tourist, notably in Rothenburg, Nördlingen, Dinkelsbühl, and sections of Nürnberg and Regensburg.

Recent industrialization

Industrialization and urbanization, which came to Bayern later than to the rest of Germany, gradually obliterated most of these traditional elements. While nearly half of Bayern's inhabitants still live in places of less than 5,000 population, more than 20 percent live in towns of 100,000 or more. Munich, the largest city, had 1,350,000 inhabitants in 1970; greater Munich, with its suburbs, had 1,800,000. As the third largest city in Germany, Munich is not only the capital of Bayern but a focal point of industry and trade. Its industries include electronics, precision instruments, aircraft, and various kinds of machinery. It plays a leading role in banking, insurance, and gastronomy. It has the largest German university and is also an art centre with excellent museums and galleries. In 1972 the Olympic Games were held there.

Nürnberg is the second largest Bavarian city, with 480,000 inhabitants in 1970; together with its neighbouring cities of Fürth and Erlangen it constitutes a populous industrial complex in Middle Franconia of 800,000 inhabitants. The next three Bavarian cities of considerable size are Augsburg (255,000), Regensburg (130,000), and Würzburg (120,000). Other significant cities include Ingolstadt, Bamberg, Bayreuth, Schweinfurt, Aschaffenburg, Hof, and Landshut.

Population. Bayern's population in 1818 was about 3,000,000; in 1925, about 6,000,000; and, in 1970, about 10,500,000. The Bavarian people consisted originally of descendants of the three tribes already mentioned: Baiuvarii, Franks, and Alemanni. After World War II there was an influx of refugees from the Sudetenland and eastern Europe, where many Germans had lived for centuries. About 20 percent of Bayern's population in 1970 was composed of these refugees. Beginning in the 1960s the industrial areas received large numbers of migrant workers from southern Europe, totalling approximately 400,000 in 1970.

Great changes took place in the religious composition of the population after the war, with a heavy incursion of Protestants. In 1970 about 70 percent of the Bavarians were Roman Catholics, having bishoprics in Munich–Freising, Augsburg, Regensburg, Passau, Bamberg, Eichstätt, and Würzburg. About 25 percent were of Evangelical Lutheran faith, with centres in Munich, Augsburg, Regensburg, Nürnberg, Bayreuth, and Ansbach. The proportion of the population engaged in farming declined from 52 percent in 1882 to 42 percent in 1900, 28 percent in 1939, and 15 percent in 1970. About 45 percent work in industry and 40 percent in services.

The economy. More than half of the state's gross output in 1969 consisted of industrial and handicraft products. Trade, transportation, and services accounted for 40 percent, and agriculture and forestry for 5 percent.

Agriculture. Farms have grown larger and employ fewer hands. There has been a trend to specialization in crops and to production for specific markets. Most farms are family operated and run in size from 38 to 75 acres. Smaller units are also common, and there are a few large landholdings manned by foreign workers.

About 33 percent of Bayern is covered by forests—mainly spruce and pine—and efforts are being made to extend forest areas where the soil is poor. A little over half of Bayern's surface is cultivable, although a quarter of it is given over to gardens and meadows. Rye, wheat, and barley take up about 60 percent of the farmland; potatoes, sugar beet, and other vegetables use 20 percent; and the rest is given to hay, hops, and vineyards. The most important arable land is in Lower Bavaria (Dungau) and in the Frankish district. Meadows are found primarily in the Upper Bavarian–Swabian forelands of the Alps, where cattle are pastured. Allgäu is the centre of German butter and cheese production. Pigs and poultry are found scattered throughout Bayern.

Principal crops

Industry. The development of Bavarian industry was at first hampered by a lack of minerals and poor transportation. Locally there were only brown coal, porcelain clay, a small amount of iron ore in the Upper Palatinate, and a deposit of salt near Berchtesgaden. The mining of coal at the edge of the Alps was discontinued in 1971.

The natural disadvantages have been overcome by the development of hydroelectric power and more recently by the use of oil piped in from the Mediterranean ports of Marseilles, Genoa, and Trieste. Improved transportation has encouraged industries that manufacture and finish quality materials.

After World War II the government made great efforts to attract expanding industries, with the result that Bayern attained a higher rate of industrial growth than the rest of Germany. In 1969 the leading industries were electronics, machinery, chemicals, textiles, automobiles, clothing, and foodstuffs; the range of industrial effort was too broad to give any industry a unique predominance. A wide variety of industries are located in Munich, the Nürnberg area, and Augsburg; important but more specialized centres are Ingolstadt, Schweinfurt, and other smaller cities. The textile and ceramics industry is scattered through northeastern Franconia.

Leading industries

Service trades. Trade and commerce resemble that of the rest of Germany, with the exception of the tourist

trade, which has assumed particular importance in the Bavarian Alps. Bayern had about 400,000 hotel beds in 1969, and three-quarters of them were in the Alpine area.

Transportation. Begun in 1835, the Bavarian railroad system was heavily developed in the second half of the 19th century. All main lines are either electrified or use diesel engines. In 1969 there were 4,779 miles of track. There are first-class highways from Munich to Frankfurt, to Berlin, and to Salzburg. Several other highways were under construction in 1971 (Munich–Lindau and Nürnberg–Passau); others were in the planning stages.

The most important waterway is the Main River, which is navigable as far as Bamberg. The Danube carries vessels as far upstream as Kelheim. A canal linking the two rivers was under construction in the early 1970s. When completed it would carry 1,350-ton ships from the North Sea and the Rhine River to the Black Sea. Bayern has airports at Munich–Riem and Nürnberg.

Government. Under its constitution of 1946, Bayern is a free state with democratic parliamentary institutions. The voters are represented directly in a lower house, the Landtag, elected every four years. The Langtag chooses a minister-president and a Cabinet. There is also a Senate composed of representatives of economic, social, cultural, and religious organizations.

The Parliament

From 1957 onward Bayern was controlled by the Christian-Social Union (CSU), which in 1970 won 124 of the 204 seats in the Landtag. The Social Democratic Party and the Free Democratic Party comprised the opposition, the former with 70 seats in 1970 and the latter with 10.

Bayern is divided into seven administrative regions: Upper Bavaria; Lower Bavaria; Upper Palatinate; Upper, Middle, and Lower Franconia; and Swabia. Each consists of independent cities and districts, the latter being further divided into communities with mayors and councillors. Bayern no longer possesses troops, a diplomatic corps, or an independent postal system. It has its own school system, law courts, and health programs, but these are fully integrated into those of the Federal Republic. In all areas, the Bavarian constitution and laws are subordinate to those of the Federal Republic of Germany.

Cultural life. The educational system resembles that of the Federal Republic generally: elementary school for those from 6 to 10 years of age, followed by five-, six-, or nine-year secondary schools (the latter called *Gymnasia*). There were six universities in 1971: two in Munich and one each in Erlangen–Nürnberg, Würzburg, Regensburg, and Augsburg. Plans were under way for new ones in Bayreuth and Passau.

Bayern has a rich heritage in literature, music, and other arts, which have been tenderly nurtured by state, municipal, and private efforts. There are theatres in all the larger cities (including three state theatres in Munich alone), as well as numerous orchestras, museums, and art galleries. The libraries are excellent, particularly the Bavarian State Library in Munich. The Bavarian radio (broadcasting both radio and television programs) is a public state-controlled system with headquarters in Munich. Efforts are being made both locally and nationally to maintain and develop Bayern's strong cultural individuality, in the hope that Munich may become an important cultural centre for all of Germany.

BIBLIOGRAPHY. Statistical information on Bavaria is conveniently obtainable in the *Statistisches Jahrbuch für Bayern* (annual). Recent census material is contained in *Beiträge zur Statistik Bayerns* (1971). The most recent and comprehensive treatment of Bavarian history is MAX SPINDLER, *Handbuch der bayerischen Geschichte*, 4 vol. (1967–). An historical atlas is *Bayerischer Geschichtsatlas* (1969). A classic geographical work on Bavaria is ROBERT GRADMANN, *Süddeutschland*, 2 vol. (1931). Other sources for climate and topography include OSKAR KUHN, *Geologie von Bayern* (1954); K. ROCZNIK, *Wetter und Klima in Bayern* (1960); K. KNOCH (ed.), *Klima-Atlas von Bayern* (1952); and *Topographischer Atlas Bayern* (1968), which has maps of selected landscapes and towns with geographical essays. For the economy, see K. SCHREYER, *Bayern: Ein Industriestaat* (1969), on the postwar development of Bavarian industry.

Bayezid II

Bayezid II, Ottoman sultan from 1481 to 1512, extended and consolidated Ottoman rule in the Balkans, in Asia Minor, and in the eastern Mediterranean. He also had to meet the danger from the Ṣafavīd dynasty of Persia (Iran).

Bayezid II, miniature by an unknown Ottoman artist, c. 1580. In the Topkapi Museum, Istanbul.

Bayezid II was born, probably in 1447, the elder son of the sultan Mehmed II, the conqueror of Constantinople. On the death of his father in 1481, his brother Cem contested the succession. Bayezid, however, supported by a strong faction of court officials at Constantinople, succeeded in taking the throne. Cem eventually sought refuge with the Knights of Saint John at Rhodes and remained a captive in European hands until his death in 1495.

Under the new reign an immediate reaction set in against some of the policies of Mehmed II. Influenced by the *'ulamā'*, interpreters of the law of Islām, and by the great officials aligned with them, Bayezid restored the Muslim properties dedicated to religious and charitable purposes that Sultan Mehmed had taken over for the state. Bayezid also rejected his father's marked pro-European orientation by such acts as removing from the imperial palace the paintings that Italian artists had executed for Mehmed II.

Expansion of the empire

At the same time, Bayezid II continued the territorial consolidation his father had begun. Hercegovina, in the Balkans, was brought under direct Ottoman control in 1483. The occupation, in 1484, of two fortresses on the estuaries of the Danube and the Dniester strengthened the hold of the Ottomans over the land route to the Crimea, where the Khan of the Krim Tatars had been, in name at least, a vassal of the sultan since 1475. The war of 1499–1503 directed against the Venetian empire in the Levant and in the Balkans carried the process of consolidation still further. It resulted in the Ottoman conquest of Venetian strongholds in Morea (Peloponnesus) and on the Adriatic shore—a triumph amply justifying the program of naval construction that Bayezid had approved in the years before the beginning of the war.

With the expansion of his rule over much of Asia Minor, Bayezid had earlier come into conflict with the Mamlūk sultanate of Egypt and Syria, each side striving to dominate the ill-defined border zones dividing them and to maintain under effective control the small principalities established there. While a Turkish fleet had sufficed to dismantle a large part of Venice's empire, Bayezid, fear-

ing that an alliance of Christian powers using his brother Cem might be formed against him, committed only a modest force against the Mamlūks. The long, drawn-out land war ended in a stalemate.

Suppression of rebellion in Asia Minor

More formidable still was the situation that arose in the lands to the east of Asia Minor. In 1499 the adherents of the Ṣafavīds, a heretical order of Islām, had set out to establish in Persia a powerful regime under their master Esmāʿīl I. The religious teaching of the Ṣafavīds had met with great success among the nomadic Turkmen tribes of Asia Minor, whose warriors formed the main element in the armies of Shah Esmāʿīl (or Ismāʿīl). It was evident that the propaganda of the Ṣafavīds, if allowed to continue without hindrance, might well undermine Ottoman rule within the Asiatic lands. The danger was underlined in 1511, when the adherents of the Shah rose in rebellion against the Ottomans in Asia Minor.

At this same time a dispute over the succession broke out between Bayezid's sons. One of them, Selim, the governor of Trebizond, went to the Crimea in 1511, secured aid there from the Tatar khan, and then crossed the Danube into the Balkans. Defeated in battle against Bayezid, Selim fled to the Crimea. Meanwhile, the Ṣafavīd rebellion had been put down; and Ahmed, another son, who had shared in the victory, marched toward Constantinople. Failing to gain the support of the Janissaries (elite military guards), he turned back to bring most of Asia Minor under his control. Bayezid, fearing that Ahmed might seek assistance from Shah Esmāʿīl and unable to resist pressures from some of his advisers and from the corps of Janissaries, who favoured Selim, he recalled Selim from the Crimea and abdicated (April 1512) in his favour. He died the following month.

Assessment

Bayezid II, known to his people as Adlî ("the Just") was a pious Muslim, strict in his observance of the precepts of the Qur'ān and the Islāmic law. During his reign, much of the state revenue was devoted to the building of mosques, colleges, hospitals, and bridges. He also supported jurists, scholars, and poets, both within and outside the Ottoman Empire. In temperament "molto melancolico, superstizioso e ostinato" ("very melancholic, superstitious, and stubborn"), in the words (1503) of the Venetian ambassador, Bayezid was interested in philosophical and cosmographical studies. He was an affectionate father, kind and forgiving toward his sons as well as toward the men who served him.

Beaches

Beaches are the sediments that accumulate along the sea or lake shores, the configuration and contours of which depend on the action of marine processes, the kinds of sediment involved, and the rate of delivery of this sediment. There are three different kinds of beaches. The first occurs as a sediment strip bordering a rocky or cliffy coast; the second is the outer margin of a plain of marine or fluvial accumulation (free beaches); and the third, of fairly peculiar character, consists of the narrow sediment barriers stretching for dozens or even hundreds of kilometres parallel to the general direction of the coast. These barriers separate lagoons (*q.v.*) from the open sea and generally are dissected by some tidal inlets. Certain sediment forelands, such as spits, points, and tombolos (connecting an island with a mainland), also are called beaches occasionally.

Beach characteristics. The upper limit of the active beach is the swash line reached by highest sea level during big storms. The lower beach margin is beneath the water surface and can be determined only if there is a definite border present between the sediment layer and the naked surface of the rocky bench. If the sediment cover extends into deep water, the lowest beach margin may be defined as the line where the strongest waves no longer sort and move the sand. It occurs approximately at a depth equal to one-third the wave length or ten times the wave height.

Another definition of the lower beach limit has been suggested by V.P. Zenkovich and V. Longuinov, namely, the transitional zone in which the biggest waves break completely and form the swash flow of reversed directions. It is the zone in which the bottom is briefly exposed prior to occurrence of the next breaker and in which sediment drifts both shoreward and seaward. This definition is more exact, but it is primarily applicable to tideless seas or lake shores.

Broad plains of marine accumulation form in many areas in response to shore aggradation. They are easily identified by the occurrence of a series of well-developed shore ridges termed berms. The maximum width of such a plain is about 30 kilometres (*e.g.*, the southwestern coast of Mexico). These plains are often termed beach plains because their surface was developed by the usual processes of beach formation. Because this surface was subsequently influenced by other relief-forming factors, however, it seems incorrect to call them beach plains.

The total width of exposed beaches varies from several metres along small seas or lake shores to 60 metres (for pebble beaches) or even several kilometres (for sand beaches). There are also the beaches of intermittent character: shingle (pebbles and cobbles) at the upper part and sand at the lower part.

The profile of an active beach varies greatly. Its form and dimensions depend on a number of factors, such as wave parameters, tide height, and sediment composition and distribution. The following, however, constitute some of the profile elements that commonly occur. At the upper part, above high sea level, a beach terrace is located, and there may be a series of beach ridges or berms created by the waves of a previous major storm. This terrace surface is inclined seaward. The next element is a steeper, frontal beach slope or face, and beneath it a low-tide terrace may be developed. If the tides are high enough (over two metres), the frontal slope may be more than one kilometre in width in regions with abundant sand and a shallow bottom. In some areas the low-tide terrace terminates with another inclined shoreface, if the nearshore sea zone is rather deep. Finally, one or several parallel, submarine, long-shore bars with intervening troughs (Figure 1) may exist along sandy shores; if present, these bars constitute the last profile element.

After Fig. 33 (p. 82), "Terminology Used in Describing Beaches," from *Submarine Geology* by Francis P. Shepard (Harper & Row, 1948)

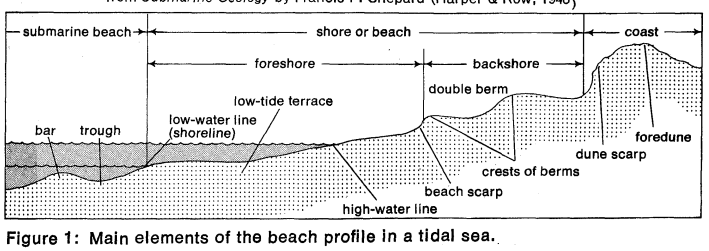

Figure 1: Main elements of the beach profile in a tidal sea.

Some minor relief forms are usually present on the surface of sand beaches. These include oscillation ripples, swash or rill furrows, and the well-known beach cusps (concave seaward) at the beach margin.

Given the established system of strong waves normal to the shoreline, submarine bars are sometimes dismembered and are converted into large crescent elements convex seaward. These relief forms reflect the existence of large water eddies with vertical axes, which form as a result of the ebb and flow of the water. Often, however,

the water outflow proceeds in the form of linear rip currents. These may be so strong that they cause erosion of deep channels in the submarine slopes and sometimes dissect the entire system of submarine bars.

Sediment transport. The declivity of beaches depends on sediment composition as well as on wave action. The coarser the sediment, the steeper and narrower the beach. This fact results from the permeability of the sediment. Part of the swash waters penetrate the sediment, thus decreasing the transporting power of the backwash. Other things being equal, however, wave size determines the height and width of a beach.

Bottom currents take sedimentary particles and move them to and fro in the wave direction; the particles also may shift up or down the slope. The speed and direction of this shifting depends on the hydraulic coarseness of the grains. Thus, sediment movement occurs on the exposed and submarine parts of the beach; it washes off some zones and accumulates elsewhere.

Effect of waves and wave parameters

The formation of the sloping beach partly exposed above sea level results from the unequal speeds and duration of the direct and reverse bottom currents under deformed waves (Cornaglia's principle). If these movements were identical, the beaches would not exist at all; all of the sediment would be carried out to the sea bottom. Measurements of this phenomenon were first carried out by V. Longuinov (1963) on the Black Sea shore.

The beach profile keenly reflects changes in wave parameters and changes in the character of transverse sediment drift. Considerable alteration may be observed in the course of a few hours, and the beach profile may be built anew. Moreover, there are general differences between summer and winter beach profiles. In winter, when there are strong storms, the exposed beach becomes narrower and in some places may completely disappear. In spring the beach begins to aggrade, and in summer it becomes maximally developed. Temporary beach changes may be as great as 3 metres in height and 50 metres in width.

In the opinion of most authorities, the accumulation of material and beach retreat both depend on wave steepness. Destructive waves of low steepness (for which the ratio of wave height to length, H/L, is less than 0.03) wash out the beach and transport part of the sediment to the sea bottom, whereas constructive waves of greater steepness (H/L greater than 0.03) throw the sediment back onto the beach, thus aggrading it.

This regularity, however, has not been corroborated in the case of relatively tideless seas, such as the Black and the Baltic. The main role in these areas is ascribed to wave energy and, consequently, to wave height because the expression for wave energy contains wave height raised to the second power and the length to the first power (see WATER WAVES).

There are some beaches that consist of sediments of marine origin—*e.g.*, oolite (small, rounded, calcium carbonate particle) beaches on the Bahamas and Yucatán, shell beaches along the Black and Caspian seas—and it is quite evident that beach sediment was always delivered to a given area by waves (if boulders and pebbles are present) or by waves and currents (if sand and gravel are present). With waves of equal power, a few hours are sufficient to stop the transverse shifting of beach sediment up or down the slope in the zone of effective action and to attain the equilibrium profile. This means that, for reciprocal wave oscillations, every particle or every unit volume of the beach will remain in a comparatively small zone until the wave parameters change. Then movement up or down the profile slope recommences, and a new equilibrium profile is constructed. This regularity has been repeatedly proved in experimental wave tanks with wave-reproducing machines. The beach profile will attain the same slope after the action of several thousands of waves, if equal parameters are involved. At the same time, submarine bars are formed beneath the water level.

In addition to transverse drifting, there is almost always a longshore sediment displacement in the zone where waves break (swash) and farther offshore. When the beach is formed by coarse sediment, longshore drifting may result from oblique wave approach. Oblique waves make the pebbles roll beachward in the direction of the wave ray and seaward along a line normal to the beach (Figure 2). This motion produces net transport parallel to

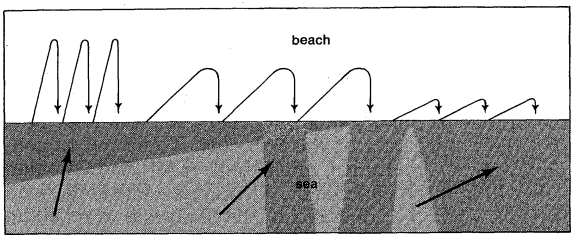

Figure 2: Beach sediment drifting under action of oblique wave incidence.

the shore. In longshore displacement of sand, the main factor is temporary currents that are caused by wave action and, most importantly, by winds that influence water flow. The speed of these currents near the bottom may attain two metres per second, sufficient to permit them to move sand independently. Usually, however, a complex mechanism is involved: waves (diving or spilling breakers) lift the sand grains, and the current carries them in suspension until the moment of settling is reached. The maximum rate of drift of boulders and pebbles occurs at the zone of breaking waves, whereas in the case of sand it occurs in the zone of primary wave surfing, sometimes far from the shoreline. If submarine bars are present, two or even three maximum drifting zones are created.

Wave action will produce excellent sorting of beach sediments. Small particles are washed away because they are in suspension longer than the duration of the wave period. Larger particles are segregated into several zones that accord with their hydraulic coarseness (size in relation to transportability of the currents). Usually coarser particles are located on the exposed part of a beach, close to its rear where the swash is still strong enough to move them. On broad beaches the sediment size decreases in both directions from the crest line. In the remote rear zones, only sand-sized particles will be transported by the weakened swash. Sediment size also decreases at the lower-beach margin. In every zone, however, the sorting is good.

Beach sands

Beach sands in temperate latitudes consist mainly of quartz, some feldspars, and a small percentage of heavy minerals. In the tropics, however, calcareous beaches composed of skeletal remnants of marine organisms and precipitated particles, such as oolites, are widespread.

Sometimes the basement layers of the beach are cemented by calcium carbonate, precipitated from the groundwater. This will commonly result if fresh water penetrates a beach from swamps behind it. If the beach undergoes erosion and thus retreats, the cemented strata become exposed; termed beach rock, they are widespread in the tropics and along the shores of the Mediterranean, Black, and Caspian seas.

Transverse and longshore sediment drift is a very complicated process and many aspects are not yet completely understood or studied. The depth to which sediment drifts has been measured by consecutive soundings (Figure 3). A number of soundings led U.S. scientists to conclude that this process does not occur at depths of more than 10 fathoms (18 metres). Some exact soundings and sediment tracing by Soviet scientists revealed, however, that sands in the Baltic Sea actively move at a depth of more than 20 metres and that pebbles in the Black Sea move at a depth of 30 metres along steep submarine slopes. Sediment movement must be of still greater importance in the nearshore zone of the open ocean. During storms in the Barents Sea, for example, sand is thrown onto the decks of fishing boats from depths of 50 metres.

The application of special indicators, or sediment tracers, has led to increased knowledge of these processes. There are two types of indicators: radioisotopes of a

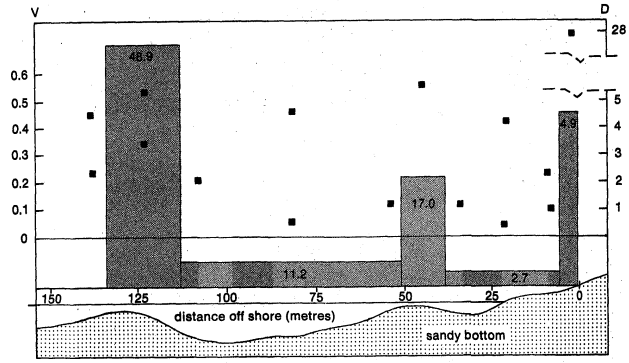

Figure 3: The sediment quantity transported in suspension by waves and currents along the sandy bottom with two bars.

number of metals and luminescent dyes. In using the first, artificial sand is activated in a nuclear reactor and then poured out onto the bottom. A Geiger counter is trailed across this zone at regular intervals. This fixes the frequency of the radioactive impulses at each spot and along the profile in general. The duration of the experiment depends on the half-life of the isotope used. The accuracy of the measurement also is determined by the natural background radioactivity of the bottom sand.

The use of luminescent dyes is more laborious, but there are a number of advantages. The indicator can be observed visually in bottom samples and on the exposed part of the beach. Dyes of different colours make it possible to study sand displacement from points or areas at various depths. By preparing dyed mixtures of various size fractions, it is possible to determine the speed and direction of transport of grains of different size. Highly successful experiments with luminescent tracers were carried out in the U.S.S.R. and in the U.S. before 1966. It was learned that individual sand grains can move at velocities as great as 2.8 kilometres per hour; the total mass of sediments, however, drifts more than ten times slower than this. Pebbles move along the beach at velocities sometimes as great as 260 metres per hour; this fact also was established by the studying of the movement of dyed specimens.

Waves normal to the shore commonly produce a series of beach cusps. The size and shape of these small bights depends on sediment coarseness and wave parameters. Cusp length varies from 2–3 metres to as much as 40–50 metres; cusp width is approximately two to three times less. The mechanism of their formation is not yet entirely clear, but cuspate shorelines are obviously related to potential wave energy and are thought to reflect equilibrium configurations.

Transverse and longshore sediment drifting produce beaches of quite different form. The former creates barrier beaches that consist of long sediment strips (usually sand, in some cases pebbles and shells) above sea level at a considerable distance offshore. This widespread beach type makes up 12–13 percent of the total world coastline. The majority of these beaches occur at the outer margins of alluvial plains, which received much sediment during the low stands of sea level associated with the Pleistocene glaciations. The main factor in the formation of barriers seems, in fact, to have been the late glacial rise of sea level (the rise associated with glacial melting), which ended about 3,000 years ago.

Longshore sediment drift

Longshore sediment drifting is variable; the drift direction changes according to the direction of wave approach. Thus, sediment may migrate in opposite directions, and if the shoreline consists of capes and concavities, the bulk of beach material may be divided into separate masses. Migration in opposite directions also occurs along straight shorelines; but when the prevailing waves tend to impinge along a path that is not perpendicular to the shore, net transport will take place, and this is termed longshore sediment flow. The capacity of the flow depends on the wave energy and frequency. The load and, consequently, the saturation depend on the stock of material on the beach. Sediment flows can transport up to 1,000,000 cubic metres of sand and 100,000 cubic metres of pebbles annually through a given section of shore. Sediment flows may be hundreds and thousands of kilometres in length. They have acted upon seashores during the whole of geological time.

The formation of a number of accumulative bodies (beaches) is connected with wave refraction, namely, the curving of a wave front when waves approach the shore at an acute angle. The wave front lengthens and the energy per unit length of wave is reduced. There is accordingly an optimal angle of wave approach to the shore at which the speed and volume of the transported sediment reach maximum values. Depending on the sediment size and the mean wave parameters, this angle lies between 40° and 50°.

If the shoreline is curved so that the capacity of a saturated sediment flow diminishes from one stretch to the next, part of the load is deposited. This material forms beach forelands, or spits. Another cause for such accumulations is the decrease of wave energy behind an obstacle (an island or a cape) or in a narrow bay. If the sediment flow retains some unused capacity, a more considerable energy drop is required to make the load precipitate and be deposited on submarine and exposed parts of a beach. If beaches are inside narrow bays, wave refraction serves to elaborate their arched outlines. The curved wave always approaches each spot of the beach at a right angle, and this produces much shifting of material offshore until a stable position is reached. Curved, semicircular beaches also occur in broad open bays. The waves approach these beaches from different sides and, consequently, cause permanent migration of sediments. Nevertheless, there exist certain stable outlines corresponding to the sum of all the forces imposed by the waves. The apex of the beach curve corresponds to the predominant wave system.

Beach destruction and preservation. When beach sediment is involved in permanent movement, it undergoes certain attrition. This is especially great for boulders and pebbles, and it reaches 5 percent of the weight as an annual average. Sand grains are only slightly abraded (the lower limit of perceptible abrasion corresponds to a diameter of 0.3 millimetre), but sand losses take place during intense storms if the near-shore sea is deep enough. On the California coast and along the eastern shore of the Black Sea, for example, much sand is carried away through submarine canyons. The beach is a dynamic self-regulating system that has its own input and expenditure balance. Beaches are sensitive to any distortion of this balance. For instance, they become smaller and may even disappear as a result of the intensive use of river waters for irrigation or hydroelectric power. In such cases the sediment discharge as well as the water discharge is reduced. Some construction projects (piers, jetties, breakwaters, etc.) will cause beach sediment accumulation where the longshore flow impinges, whereas erosion will occur along the shore on the opposite side. If there is no net transport, the sediment may be drawn up under the protection of the structure from both sides of the adjoining beaches. This is doubly harmful: protected areas and canals suffer silting, and the adjacent shore is eroded. For many years silting was prevented by means of artificial deepening of harbours and lengthening of inlet jetties. Recently, sediment bypassing to shift the flow

Use of groins and jetties

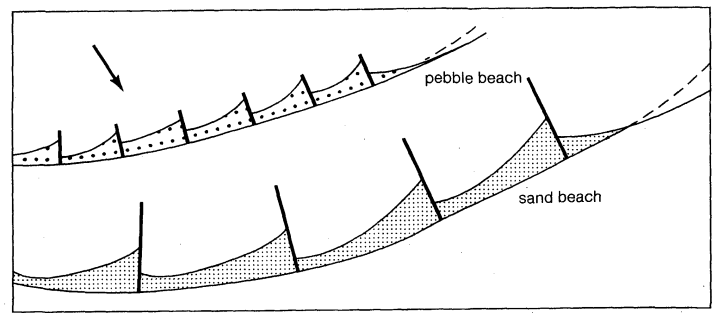

Figure 4: Comparative schemes of groins. Arrow indicates the general direction of incoming waves.

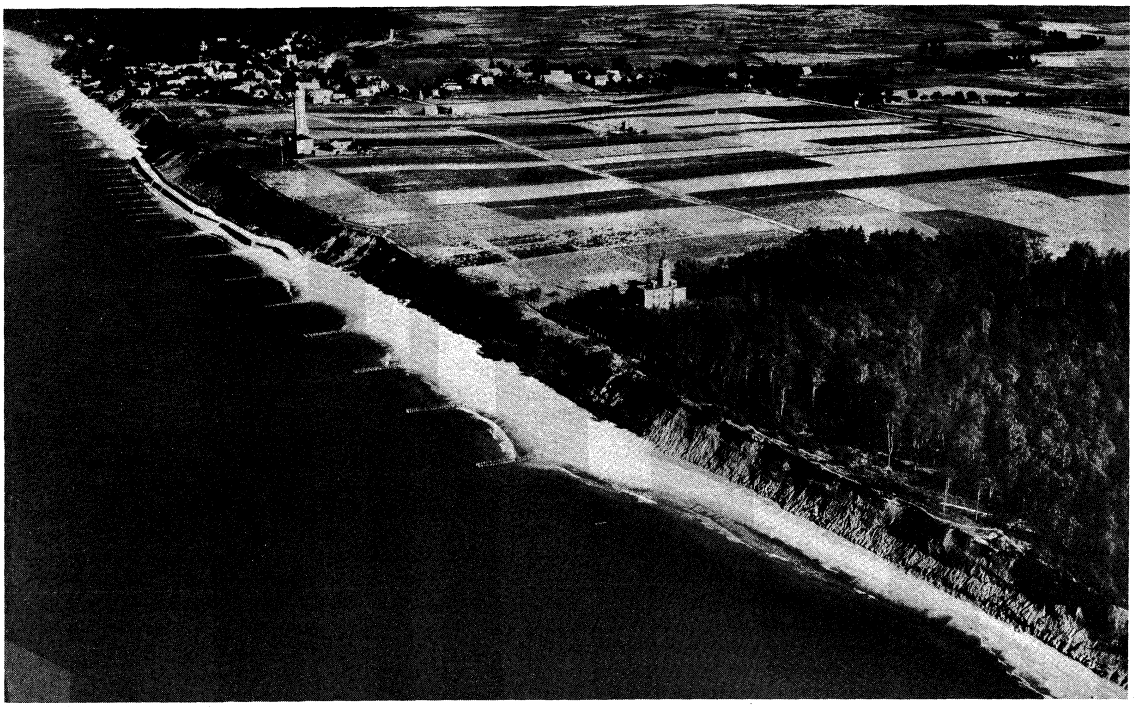

Figure 5: Baltic sand beach and jetties in front of a morainic cliff.
By courtesy of V.P. Zenkovich

from one side of the structure to the other has come into use; it is a most effective method.

Solid rock shores that lack beaches are easily destroyed by the sea. Consequently beaches provide protection for the shore. For this reason, among the several ways of protecting the shores from erosion is the use of groins—short piers that extend out into the sea at an adequate distance (30–40 metres for pebbles, 60–200 metres for sand). Usually there is a series of groins with the spacing interval depending on their length and on the angle of the resultant waves during the strongest storms (Figure 4). As a rule these intervals are equal to one to two groin lengths. The sediment flow deposits its load in the intervals until it takes a new route on the shallowed bottom in front of the groins' heads.

While a system of groins is being filled, no sediment is carried by the downflow, and so a certain part of the shore may undergo considerable erosion. If there is a deficiency of natural sediments, the intervals between the groins are filled up artificially. Gravel and pebbles will remain there for decades, but after that a supplement will be necessary. This kind of shore protection is widely used along the Caucasus and the Crimea coasts of the Black Sea (Figure 5).

Finally, within the last few years, artificial replenishment of the beaches with sand taken from the sea bottom or transported from adjoining dunes has been widely used. The best examples of the application of this method are on the Long Island, Virginia, and Florida beaches of the U.S. and those of the island of Norderney in the North Sea.

From E.C. F. Bird, *Coasts* (1968), p. 139; The Australian National University Press

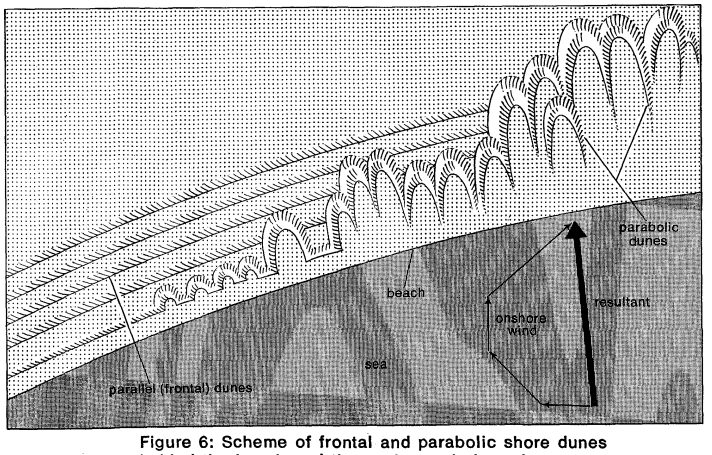

Figure 6: Scheme of frontal and parabolic shore dunes behind the beach and the onshore wind resultant.

In many countries the wind strongly affects the dynamics of the beach. The beach is exposed to the sea wind, and sand is usually blown off to the rear parts of the beach where it forms small hummocks. As these join together, foredunes are being built, and if the beach is well supplied with sand in the right area, several rows of dunes will be formed. When the sand is very abundant, dunes will shift to adjacent low-lying plains and may bury fertile soils, woods, and buildings (Figure 6).

If sand is no longer delivered to the region of developed dunes, gaps will form in the ridges parallel to the shore. In such zones parabolic dunes with their summits coastward are created. After long stabilization, the summits of the parabolas may be broken through by the wind, thus gradually forming a series of ridges parallel to the prevailing winds.

Dunes and vegetation

Vegetation is quite important in dune formation. Primary accumulation of foredunes is facilitated by the growth of marram grass, heather, and other plants. Vegetation may fix dunes that are some distance from the beach, covering them completely and thus protecting them from the winds. The formation of dunes in general will, however, reflect climatic conditions. For example, a humid tropical climate is not favourable for dune formation. Dunes are abundant along the California coast near the Sonora Desert. To the south, however, closer to Matzatlán, precipitation is more than 1,000 millimetres per year, and even embryonic dunes are completely overgrown with bushes. The same conditions pertain along the southwestern coast of the Gulf of Mexico.

Beaches bordered by dunes are widespread on all continents. There is much evidence that the bulk of the sand accumulated during the Holocene transgression. The ocean level was fairly low prior to this latest rise of sea level, and coasts were bordered by broad alluvial plains. In the course of the transgression, sand was transported by waves and wind onto the land in great masses.

The practical significance of beaches is not limited to their function as protectors of the coast or as recreation sites. The sorting mechanism of the offshore waves and

currents determines the accumulation of heavy-mineral (specific weight over 2.7) concentrates. On any sand beach there are thin layers of dark sand that can be seen. Some heavy minerals contain valuable metals, such as titanium, zirconium, germanium, tin, uranium, and gold. In many places the concentrations are so great that they are of industrial significance; placer deposits are worked in India, Brazil, Japan, Australia, the U.S.S.R., and Alaska. Heavy-mineral concentrates also are extracted from the submarine slopes by means of dredging ships.

In view of the public use of the beaches, a special service has been organized in many countries that must watch all the changes in the beaches and maintain them artificially in the best possible state. These are the functions of Nature Conservancy in England and a special Beach Erosion Board in the U.S., which formerly belonged to the U.S. Army Corps of Engineers. Almost every year scientific conferences on coastal engineering are organized by the U.S. Coastal Engineering Research Council.

(V.P.Z.)

Beaufort Sea

The Beaufort Sea is situated in the Arctic Ocean north of Canada and Alaska. It has no natural boundaries but has been defined by the International Hydrographic Bureau as extending from Point Barrow (Alaska) toward Lands End Point (on Prince Patrick Island, Canadian Arctic Archipelago), and from Banks Island in the east to the Chukchi Sea in the west. The sea owes its name to the British Rear Admiral Sir Francis Beaufort.

Its surface area is 184,000 square miles (476,000 square kilometres) and its volume 115,000 cubic miles. The average depth is 3,293 feet and the greatest depth 15,360 feet. The Beaufort Sea is under ice almost the year round; only in August and September does it break up and then only near the coasts. So far the sea has been most inadequately studied. Serious scientific investigations by icebreakers, drifting stations, atomic submarines, and aircraft began in the 1950s.

Physiography. The shelf of the sea is narrow, especially in the vicinity and east of Point Barrow; it widens somewhat north of the Mackenzie River mouth but nowhere exceeds 90 miles. The usual depth is less than 210 feet, although the continental slope is very steep in the sea's upper part, descending to 5,000 or 6,500 feet. Small gravel islands or shallows are often found on the shelf, the largest of them west of the Mackenzie River mouth. These are the islands of Herschel (seven square miles) and Barter (five square miles). A variety of very small islands and banks are found in the Mackenzie River Delta.

The continental slope of the sea is dissected by numerous submarine valleys. The largest of them begin from Point Barrow, from the Mackenzie River mouth, from 140 miles northeast of the Mackenzie River, and from the Amundsen Gulf, a submerged glacial trough. The Beaufort plateau, with depths from 6,500 to 10,000 feet, protrudes far into the sea west of Banks Island. The geological structure of the bottom is that of a massive platform, fringed with Mesozoic folds. The seismic data, however, negate the submergence hypotheses and indicate a similarity between the crust of the Canadian Basin and of the oceans.

Nature of the coastline

The sea coasts are low lying and covered with tundra over almost their entire extent. Only west of the Mackenzie River mouth do spurs of the Brooks Range approach the coastline. The Banks and Prince Patrick islands are also fairly low, maximum elevations being from about 900 to 2,450 feet. A northwestern passage begins in the eastern portion of the sea through the Amundsen Gulf. The southern coastal regions of the sea are navigable from middle August till late September. A permanent barrier of ice ten feet thick begins near the shores.

Hydrology. Four water masses may be distinguished: surface, subsurface Pacific, deep Atlantic, and bottom waters.

The surface water mass is nearly 330 feet thick and is the coldest of all. Temperature ranges from 29.5° F (−1.4° C) in late summer to 28.8° F (−1.8° C) in winter. Salinity is 28 to 32 parts per thousand.

The subsurface water mass is formed by the waters of the Pacific Ocean and the Bering Sea, which flow through the Bering Strait. This water mass is less noticeable in the northeastern and northern parts of the sea. The Pacific water is much warmer than the surface water and almost reaches the North Pole.

The deep Atlantic water is the warmest of all, its temperature ranging from 32° to 34° F (0° to 1° C) and its salinity from 34.9 to 35.5 parts per thousand. The warmest water is found at a depth of nearly 1,300 feet. The upper boundary of this mass lies at about 650 feet and the lower one at 2,600 to 3,000 feet.

The bottom water begins at depths of more than 3,000 feet. Negative temperature (−0.4° to −0.8° C, or 31.3° to 30.6° F) and almost constant salinity of 34.9 parts per thousand are typical.

Direction of currents

The direction of the surface and subsurface currents is closely related to the general current system of the Arctic Ocean. A clockwise water gyre flows north of the Beaufort Sea: the majority of the sea's currents are thus westward or southwestward. Only in the vicinity of the Mackenzie River mouth is an eastward current recorded. Current velocities in the open sea are not great, ranging from one to two miles per day. Current direction is also strongly affected by local winds.

Bottom sediments. Sedimentary material is supplied to the sea by rivers and is also brought in through the Bering Strait. Deposits from the Mackenzie River are particularly large: the annual liquid discharge of the river is nearly 440 million tons and the sedimentary one about 15 million tons. High concentrations of dolomite and calcium carbonate are distinguishing features of the Mackenzie's deposits, and these minerals are found at great distances from the river delta. Gravel, pebble, and sand deposits, sometimes mixed with mud, are widely distributed on the shelf. The deep-sea bottom is covered with fine clay muds. Dispersed gravel–pebble material carried by ice from the coastal zone into the open sea is a constant component of all types of sediments. Deep-sea muds are brown. Gray muds containing rare microfauna have been found on the continental slope and north of Banks Island. Sediments also contain significant proportions of hornblende and iron oxides.

Marine life. Phytoplankton in the Beaufort Sea is diversified, but its biomass is not large. Representatives of more than 70 phytoplankton species are found. The maximum development is recorded in August and September in the upper 160-foot layer of the open sea, in the open water between ice floes, and in lakelets on the ice floe surfaces. Nearly 80 zooplankton species have been found. The bottom fauna consists of nearly 700 species of polychaetes, bryozoans, crustaceans, and mollusks.

Fishing and sea hunting are for local supply only. The economic development of the coastal regions may in the future be stimulated by the search for marine oil and gas deposits.

Beaumont and Fletcher

Leading poetic dramatists of the early 17th century whose names are associated with a large body of plays, Francis Beaumont and John Fletcher furnish a remarkable example of collaboration in English literature. Their work is melodramatic, with tense situations and startling reversals; the characters are inconsistent and involved in peripheral situations. Although heroic ideals—friendship, honour, duty—are challenged, the issue is often left in balance; their plays often appear to demand a tragic resolution and yet manage to avoid one. The playwrights' talents fruitfully counterpointed each other, Beaumont providing tightness of organization and Fletcher, fertility of invention. The language of their plays is graceful and lucid, an idealized version of aristocratic speech.

Beaumont (left) and Fletcher (right), engravings by George Vertue, 1729.

Known biographical information

Beaumont and Fletcher lived during the reign of King James I (1603–25) and were younger contemporaries of William Shakespeare. They were of a social class somewhat higher than usual for Jacobean professional playwrights. Fletcher's father was an ecclesiastic and a favourite of Queen Elizabeth I, officiating at Mary Stuart's execution and finally becoming bishop of London; Beaumont was the youngest son of a justice of the common pleas of Grace-Dieu priory in Charnwood Forest, Leicestershire. Fletcher was baptized at Rye, in Sussex, on December 20, 1579; Beaumont was born in 1584, presumably at Grace-Dieu. Fletcher apparently entered Bene't (later Corpus Christi) College, Cambridge, in 1591; Beaumont entered Broadgates Hall (later Pembroke College), Oxford, in 1597 and afterward, being intended for a career at law, London's Inner Temple in 1600. Both young men found themselves in uncongenial situations, with insufficient private means.

By 1604 they were part of a circle surrounding Ben Jonson, the dominant figure in literary Bohemia, and they contributed prefatory verses to Jonson's play *Volpone*. Beaumont remains a shadowy figure; Fletcher appears to have been genial and carefree, perhaps as might be expected from the heroes in some of his plays. According to John Aubrey, a 17th-century memorialist, "They lived together on the Banke side, not far from the Play-house, both batchelors; lay together . . .; had one wench in the house between them . . .; the same cloathes and cloake, &c., betweene them" (*Brief Lives*). Their collaboration as playwrights began in about 1607 and was to last for some seven years: in 1613 Beaumont married an heiress, Ursula Isley of Sundridge in Kent, retired from the theatre, died on March 6, 1616, in London, and was buried in Westminster Abbey. Fletcher continued to write plays both alone and in collaboration with others; he may be the Fletcher whose marriage is recorded as taking place in St. Saviour's, Southwark, where he is said (by Sir Aston Cokayne in 1658) to have been buried on August 29, 1625. He had died of the plague in London, where he lingered to be measured for a suit of clothes instead of making his escape to the country. Little or nothing more is known about their lives and characters apart from what can be guessed at from the plays with which they are linked.

Professional career. *Their audience.* From the outset of Beaumont and Fletcher's careers, a change was apparent in the English theatre. The permanent playhouses that had been opened toward the end of Queen Elizabeth's reign had been public theatres, and side by side with them a number of private theatres began to emerge; in 1608 the King's Men, a theatre company for which Shakespeare had written and Beaumont and Fletcher were to write, took over one such private theatre at Blackfriars in London. The same company continued to maintain a public theatre (the Globe) in London, but Blackfriars became more and more their centre. Hitherto the sophisticated and the illiterate had together made up a London audience; Beaumont and Fletcher, however, spent their literary careers writing entirely for the private theatre and its smaller but educated audience, their work being performed on an enclosed, distant stage quite unlike the intimate thrust stage of, for example, the Globe. This ambience suited their adroit, self-conscious stagecraft and their love of casuistry in situation and argument—the last appealing particularly to the legal minds of the Inns of Court men who made up a majority of their audience.

The private theatre and its audience

Their plays. The canon of the Beaumont and Fletcher plays is largely represented by 52 plays contained in the folio *Fifty Comedies and Tragedies. Written by Francis Beaumont and John Fletcher, Gentlemen*, which appeared in 1679. It might properly be termed "The Works of Beaumont, Fletcher, and Company" for Fletcher collaborated with at least six other dramatists after Beaumont's retirement. Fifteen plays can be assigned with some certainty to Fletcher alone; Beaumont's notable sole offering is *The Knight of the Burning Pestle;* joint productions number ten in all, including *The Maides Tragedy*, *Phylaster*, and *A King and No King* (in which plays Beaumont's is assumed to have been the controlling hand, since they manifest a firmer structure than Fletcher's single or collaborative efforts). Three plays were the work of Beaumont, Fletcher, and Philip Massinger (who succeeded Fletcher as chief playwright for the King's Men); 12 plays were by Fletcher and Massinger together; 13 were by Fletcher working with other collaborators, including such outstanding dramatists as Shakespeare, Jonson, Thomas Middleton, John Webster, and George Chapman. One play contained in the 1679 folio is *The Coronation*, a comedy that has been fairly conclusively identified as the work of James Shirley: three plays not contained in this folio may be added to the Beaumont and Fletcher canon (*Henry VIII*, by Shakespeare with Fletcher; and *Sir John van Olden Barnavelt* by Fletcher and Massinger and probably *A very Woman*). Attributions of plays in which Fletcher is not the sole author are as relatively uncertain as defining the correct share of Beaumont and Fletcher.

Attempts to disentangle the various shares of Beaumont and Fletcher in any given work are complicated by the

fact that Beaumont sometimes revised scenes by Fletcher, and Fletcher edited some of Beaumont's work. Attribution is based chiefly on clues from internal stylistic evidence: metrical tests, for example, have shown that Fletcher's literary mannerisms included a fondness for feminine endings (*i.e.*, with the last syllable of a line left unstressed).
