The World Food Conference of November 1974 called for the establishment of an International Fund for Agricultural Development, in order to obtain the necessary great increase in external financial assistance for the agriculture of the developing countries. It also agreed on a wide range of other measures, particularly concerning the acceleration of the increase in food production in the developing countries, and a coordinated system of national stock policies embodied in an International Undertaking on World Food Security. If the follow-up to the World Food Conference lives up to professions of intent, a beginning will have been made in the establishment of a world food policy.

## Football, American and Canadian

Football is a game with a variety of forms played between two teams that try to advance an inflated ball by carrying, kicking, or throwing it, until it has been forced into, across, or over goal markers to effect a score.

There are three main varieties of football, each with distinctive rules, regulations, and procedures. In the order of their invention they are: association football (soccer); rugby football; and football, as it evolved in the United States and, with minor differences, in Canada. Soccer, which is played the world over, is fundamentally a game of the foot. Running with the ball and passing it by hand are violations. Rugby and United States football have much more in common. Both permit carrying and throwing the ball, as well as kicking it, though in rugby the ball may never be thrown forward, as it is in the American game. Also, the principle of possession of the ball—the most fundamental departure in the evolution of the United States game—is lacking in rugby (and soccer), in which the ball may and most often does change hands in a matter of seconds; and there is less opportunity to develop a planned scheme of attack.

This article will be devoted primarily to United States football, as played in the colleges and universities, and to its principal variations. It is divided into the following sections:

- I. History
  - Early history
  - Genesis of American football
  - Emergence of the modern game
- II. Play of the game
  - The field and equipment
  - Principles of play
- III. Other principal games
  - U.S. professional football
  - Canadian football

The article is intended for the general reader who may have no knowledge of the sports described and is designed at most to help a spectator understand a game he may be watching. For information on specific rules or on how to play, the reader should consult works listed in the bibliography. For U.S. and Canadian football records, see *SPORTING RECORD* in the *Ready Reference and Index*. For information on other major varieties of football, see the text articles ASSOCIATION FOOTBALL (SOCCER); and RUGBY.

## I. History

### EARLY HISTORY

The beginnings of games or contests in which two teams, or sides, vied with each other in attempting to push, kick, or otherwise move a ball, or ball-like object, in opposite directions have been traced to ancient Egyptian fertility rites, as have other athletic pastimes. An ancient Chinese writer wrote that a football game was played in China as early as 300 BC, and by AD 500 round footballs stuffed with hair were in use. In ancient Greece a game with elements of football was called *harpaston*. It was much the same game that, as *harpastum*, became popular with Romans after they conquered Greece in the 2nd century BC. Play began with a ball being thrown into the air between two bands of players, each of which endeavoured to advance it beyond what would today be called the opponent's goal line. It was marked by much pushing backward and forward. In all likelihood, Roman legions introduced *harpastum* to the natives of Britain during their occupation, although one historian reports that the Irish had been kicking a stuffed ball in play 50 years earlier.

Whether or not the Romans introduced the game to the British, there were *mêlées*, or mellays, in ancient and medieval Britain in which a ball, usually an inflated animal bladder, was advanced by kicking, punching, or carrying. Royal edicts were issued against the pastime as interfering with the practice of military skills such as archery, but it flourished. In William Fitzstephen's *Description of the City of London*, published late in the 12th century, there is a reference to a football game played on Shrove Tuesday. In later years Shrove Tuesday was to become a great football day in England, a holiday on which business was suspended and the citizenry gathered for a game that officially began with the mayor making the kickoff.

Chester, a town founded by the Romans, was famed for its Shrove Tuesday football game. It was said that the game had been played for centuries in commemoration of the great day in AD 217 when a mighty flying wedge was organized to drive the Roman legions out of Chester. Elsewhere, town played town or parish opposed parish in Shrove Tuesday festival games, often involving several hundred men who played for hours until the ball had been kicked into the domain of one side or the other. These medieval mellays took place also at Derby, Corfe Castle, Alnwick, and Bromford in England and at the Cross of Scone and Midlothian in Scotland.

Football was also associated with the holiday of Candlemas Day. King Edward III prohibited the playing of football in 1365 for military reasons; and similar edicts were also issued by Richard II, Henry IV, Henry VIII, and Elizabeth I, but they had no effect. The festival matches increased in popularity. Joseph Strutt, historian of English sport, in 1801 wrote the following description:

... an equal number of competitors take the field and stand between two goals placed at a distance of 80 or 100 yards the one from the other. The goal is usually made with two sticks driven into the ground about two or three feet apart. The ball, which is commonly made of a blown bladder and cased

An early British match

with leather, is delivered in the midst of the ground, and the object of each party is to drive it through the goal of their antagonists, which being achieved the game is won. . . . When the exercise becomes exceedingly violent the players kick each others' shins without the least ceremony and some of them are overthrown at the hazard of their limbs.

Football was taken up in a less violent form in the 17th century. Youths from wealthy and aristocratic families played the game in British secondary schools, though the authorities regarded it as too rowdy for young gentlemen. Rules differed at the various schools, but all in common allowed no running with the ball or passing it forward by hand.

It was not until early in the 19th century that the restriction against running with the ball was disregarded. According to legend, this came in 1823 at Rugby School, Rugby, Warwickshire, when a schoolboy caught a kicked ball and, instead of heeling the ball or taking a free kick, tucked it under his arm and, to the amazement and consternation of the other players and onlookers, sped on to the opponents' goal. This gross violation was at first severely censured. In time, however, the idea of running with the ball won favour, and today a tablet placed in a wall at Rugby School reads:

This stone commemorates the exploit of William Webb Ellis, who, with a fine disregard for the rules of football, as played in his time, first took the ball in his arms and ran with it, thus originating the distinctive feature of the rugby game. AD 1823.

Running with the ball was at first permitted only if the player received it by fair catch. Later, it was also allowed if the ball was caught on the first bound. Finally, all restrictions were removed. In time, other schools also accepted the new procedure.

There were no unified rules for rugby or soccer until finally, in 1863, the London Football Association was formed by clubs playing the kicking game. Rules were drafted, and carrying the ball was forbidden. Then, in 1871, rugby players from 17 clubs and three schools organized the Rugby Football Union and appointed a committee to draw up a code based on that in use at Rugby School. A year later Oxford and Cambridge met at rugby for the first time.

Both of these football games were taken up in America. Soccer was the one known in the United States before rugby was introduced in the 1870s with the cooperation of McGill University of Montreal, Canada, and immediately replaced the kicking game in favour at colleges and universities. It was rugby from which the United States style of football evolved.

#### GENESIS OF AMERICAN FOOTBALL

Football in its crudest form was known in America virtually from the time British colonists established their first settlements. There is evidence that as early as 1609 teams or groups of men were kicking around an air-filled bladder, as they had in their mother country. More than two centuries were to pass, however, before the game took root in the colleges.

**The first college games.** Students at Princeton University in 1820 played a game known as "ballown," in which a ball was batted with the fist. By 1840 an organization had been formed to schedule games and choose sides. At Harvard University a football game was played between the freshman and sophomore classes in 1827 and became an established custom, scheduled annually for the first Monday of the new college year. Because the play was so rough, the day became known as "Bloody Monday," and the faculty put an end to it in 1860. The same kind of roughhouse play was also going on at Yale University. By 1840 it was organized and known as the annual rush, and in 1851 the freshmen and sophomores started an annual contest. In 1858 the New Haven authorities halted play by denying students the use of the city green. Amherst College in Massachusetts and Brown University in Providence, Rhode Island, were other schools where the game was being played.

There were no established rules at any of the colleges, and sides might be of any number agreed upon. Follow-

ing the introduction of a round, rubber ball in the 1850s, considerable skill was developed in kicking the ball a long distance and in dribbling it with the toe in short advances and sending it on to a teammate, eluding an interceptor. These were the skills of modern association football (soccer).

The Civil War (1861-65) put an end to, or severely curtailed, sports activity on college campuses; but football was played in secondary schools in New England during the hiatus. Starting in 1860, nine years before the first intercollegiate game was played between Princeton and Rutgers, secondary schools in the Boston area were meeting each other on the Common. The first formal football organization in the United States was established in 1862 by Gerritt Smith Miller, a 17-year-old student. He organized a group of Boston players into the Oneida Football Club of Boston some months prior to the formation of the London Football Association and was its president and team captain. From 1862 to 1865 the Oneida Club played all comers and never was beaten or scored upon. On November 21, 1925, the seven surviving members from the original group of 17 unveiled a marble monument in commemoration of the club at the entrance to the Common.

Following the end of the Civil War in 1865, football activity was renewed on the college campuses. In 1866 Beadle and Company of New York City published a book on cricket and football, in which Henry Chadwick, a sports authority, enumerated the rules for both varieties of football—the kicking game of soccer, or association football, and the carrying style of rugby, which was virtually unknown at the time in the United States. In 1867 so-called Princeton Rules were drawn up for the soccer style of football. They called for 25 players to a side, and a team of that number played an intramural game with the Princeton Theological Seminary. Late in the year one H.A. Alden of Matteawan, New York, patented the first football covering, a canvas layer protecting a rubber bladder. Rutgers College, New Brunswick, New Jersey, not far north of Princeton, also drew up rules in 1867, and in November 1869 the two met in the first intercollegiate game of football in the United States at New Brunswick. Some exception has been taken to so labelling the game because the game played was the soccer style of football. The distinction has also been bestowed on the first Harvard-Yale game in 1875, which was part rugby and part soccer, or on a second game between them (1876), which was rugby.

The rules drawn up for the first game between Princeton and Rutgers by the team captains were largely Rutgers' rules, since Princeton's were to be in force for a second game at Princeton a week later. These were a modification of those of the London Football Association. There was a maximum of 25 players to a side. The team first scoring six goals was the winner. The grounds were 360 feet (110 metres) long and 225 feet (70 metres) wide and the goals 24 feet (seven metres) wide. The round, inflated rubber ball that was used could be kicked or batted with the hand or fist, although no running with it or throwing it was allowed, nor any tripping or holding of a player. Rutgers won the game, 6 goals to 4. The second game, at Princeton, was won by Princeton, 8 goals to 0. A third game had been scheduled but was barred by the faculties of the two colleges.

Columbia, Cornell University of Ithaca, New York, and Yale were among the schools that took up football in the early 1870s, all adopting the kicking game. Harvard, where football had been banned, revived the game in 1871 and played what was known as the "Boston Game," essentially a kicking game with elements of rugby. The ball could be picked up, and the holder, if pursued, could run with it. This difference was of historic importance. Harvard formed its football association in 1872 with competition limited to games between the classes.

Representatives from Princeton, Yale, Columbia, and Rutgers met in New York City in 1873 and formulated the first intercollegiate rules in the United States with the code of the London Football Association as their model. The number of players on a side was set at 20. The field

collegiate  
rules

dimensions were 400 feet by 250 feet (120 by 75 metres). The distance between the goal posts was 25 feet (eight metres). Six goals were necessary to win, and to score a goal the ball had to pass between the goal posts. No player could throw or carry the ball.

In 1873 Yale lost to Princeton, 3 goals to 0, in the inaugural meeting of what is today intercollegiate football's oldest, continuous rivalry. Yale then met a team from England known as the Eton Players in the first international match in the United States and won, 2 goals to 1. It has been said that rugby football was played in this game, but evidence indicates that it was soccer. The Eton Players, not all of whom had gone to the famous English school, were accustomed to using only 11 men on a side, and Yale was persuaded to limit its team in this game. Yale was won over to 11-man football and thereafter fought for the principle until it was adopted generally in 1880.

Harvard, because it played a different game, had declined to participate in the 1873 rules convention and looked elsewhere for competition. It found a rival in the football club of McGill University in Montreal, Quebec. The teams met twice in the spring of 1874 at Cambridge, Massachusetts. McGill played football under the code of the Rugby Football Union of England. Harvard's football was largely soccer, but a player could run with the ball if pursued, as noted above. The first of the two games was played under Harvard's rules, with goals the only scoring medium, and Harvard won, 3 goals to 0. The next day the teams met under McGill's rules, using an egg-shaped ball, in the first intercollegiate rugby match in the United States. Canadian rugby differed from the English game in allowing tries (*i.e.*, running with the ball across the goal line, called touchdowns in the U.S.) as well as goals (kicking the ball between the goal posts) to count in the scoring. They played for an hour and a half in three periods and neither side scored. A third game was played on McGill's grounds in Montreal, again under English rules, and Harvard won by 3 tries to 0.

Harvard was won over completely to rugby as a result of its matches with McGill. Then came an event that contributed greatly to the shape of the game as it developed in the United States. Harvard challenged Yale to a game under "Concessionary Rules" and thus inaugurated one of the most celebrated of all U.S. football rivalries. The game was played in November 1875 at New Haven and was part rugby and part soccer. According to the account of the game in the Harvard *Crimson*, neither side fully understood the "Concessionary Rules." Yale men said that they differed more from their own rules than from Harvard's. They played with 15 men on a side instead of 11 as Yale would have preferred, and Harvard won by 4 goals and 4 tries, or touchdowns, to none. Despite its decisive defeat, Yale was so taken with rugby that it became a convert and adopted the rules. Observers from Princeton who saw the game also were won over to rugby, and in 1876 representatives of Princeton, Harvard, Yale, and Columbia organized the Intercollegiate Football Association. They adopted the code of the Rugby Football Union with a change in the scoring rule—instead of a match being decided by a majority of goals alone, it was decided by a majority of touchdowns. A goal was equal to four touchdowns, but in the case of a tie, a goal kicked from a touchdown took precedence over four touchdowns. The size of the field was set at 140 yards by 70 yards (130 by 60 metres), the number of players at 15 to a side, and the time of a game at two 45-minute halves. The egg-shaped leather ball replaced the round rubber ball of soccer. Yale attached such importance to limiting the teams to 11 men that it declined to become a member of the new Intercollegiate Football Association, though it was represented unofficially at its meetings and played against the other members.

Rugby thus became the American college football game just as other schools were entering the intercollegiate lists. Stevens Institute in New Jersey had played against Columbia in 1872 and Wesleyan University, Middletown, Connecticut, against Yale in 1875. Pennsylvania began,

in 1876, against Princeton. The first game in the South was played between club teams from Virginia Military Institute and Washington and Lee, both in Lexington, Virginia, on the grounds of VMI in 1873. All of these newcomers played the soccer game with varying numbers of players until the switch to rugby began in 1876.

At the United States Naval Academy in Annapolis, Maryland, midshipmen were playing football in 1882, but it was not until 1888 that they began to play a representative schedule. In 1890 they challenged the United States Military Academy at West Point, and the famous service rivalry started.

The first game in the Middle West was played in 1879 between the University of Michigan, Ann Arbor, and Racine College of Wisconsin. Though Michigan had organized a team as early as 1873, it had been unable to find an opponent until the Racine game. In 1881 Michigan inaugurated intersectional competition by sending its team east to play Yale, Harvard, and Princeton, losing to all three in the space of five days. In 1887 the University of Notre Dame from South Bend, Indiana, made its bow against Michigan and lost 8-0 at South Bend. Also taking up the game in the 1880s were the University of Minnesota, Minneapolis; Northwestern University, Evanston, Illinois; Indiana University, Bloomington; Purdue University, Lafayette, Indiana; the University of Iowa, Iowa City; and Michigan State University, East Lansing; all of which, with Michigan and several others, were to form the Western Conference (Big Ten).

On the Pacific coast, football was being played between classes at the University of California, Berkeley, as early as 1881, but it was not until the 1890s that football took hold seriously.

Seven years after VMI and Washington and Lee met in 1873, football matches began to be played elsewhere in the South. Centre College, in Danville, Kentucky, whose team would later make a kind of history by defeating Harvard, played a scoreless tie in 1880 with the University of Kentucky in Lexington. It was another eight years before the game caught on in earnest at Trinity College, Durham, North Carolina (later Duke University); at the University of North Carolina, Chapel Hill, in 1888; and at Wake Forest University, Winston-Salem, North Carolina, in 1889. Vanderbilt University, Nashville, Tennessee, played its first game in 1890; the University of Tennessee, Knoxville, and West Virginia University, Morgantown, started in 1891; and Alabama University, University, Alabama; Auburn University, Auburn, Alabama; Georgia Institute of Technology, Atlanta; the University of Georgia, Athens; and the University of Kentucky, Lexington, started in 1892. A year later Louisiana State University and Agricultural and Mechanical College, Baton Rouge; Tulane University of Louisiana, New Orleans; and the University of Mississippi, University, Mississippi, joined in, and the Southern Intercollegiate Association was organized. All of these schools with the exception of West Virginia were to be members of the powerful Southeastern Conference.

The Southwest was a late starter, but in no part of the country did the game become more of a craze. The University of Texas, Austin, was the first to organize, in 1893. Texas Agriculture and Mines (Texas A. & M.), College Station, and the University of Arkansas, Fayetteville, followed in 1894, and Texas Christian University, Fort Worth, in 1897. Baylor University of Waco, Texas, was next, in 1901, followed by Rice University of Houston, Texas, in 1912, and Southern Methodist University, Dallas, in 1915. At the start of the 1970s, all of these teams were competing in the Southwest Conference.

**Evolution of American football.** In its early years, the American game was purely a test of brawn, with dull pileups and entanglements of bodies in marked contrast with rugby's speed and wide-open action over the breadth and length of the field. The man who conceived and designed most of the basic changes and departures from rugby and brought about their acceptance in the conventions and rules committee meetings was Walter Camp, now rightly known as the "Father of American Football."

Inter-sectional competition

Rugby—  
Harvard  
versus  
Yale, 1875

Walter  
Camp,  
"Father of  
American  
Football"

In 1880 Camp effected the first of the changes in the evolution of the American game. This was the substitution of scrimmage for the scrummage, or scrum, of rugby. In scrummage the ball was put between two opposing interlocked packs of rushers, or forwards, who endeavoured to heel the ball backward to their own backs. In the new scrimmage, the ball was given into the orderly possession of one team, which then put it in play without interference until the ball was "snapped." Camp defined the scrimmage procedure as follows:

A scrimmage takes place when the holder of the ball, being in the field of play, puts it down on the ground in front of him and puts it in play while on side, first, by kicking the ball; second by snapping it back with his foot. The man who first receives the ball from the snap-back shall be called the quarter-back, and shall not then rush forward with the ball under penalty of foul.

Thus Camp also initiated the role of the quarterback, which was to become the most glamorous position in football. In the same year, he finally succeeded in his efforts to have the number of players reduced from the 15 of rugby to the 11 of modern U.S. football. Camp, too, was the one who came up with the standard alignment for 11 men—seven forwards in the line, a quarter-back, two halfbacks, and a fullback.

Downs  
and yards  
to gain

In 1882 Camp's next far-reaching change was the introduction of a system of downs and yardage to be gained. This followed as a result of the tactics used at the time to keep indefinite possession of the ball. Rules makers had assumed that a team given possession of the ball would inevitably surrender it in the then customary procedure of kicking the ball almost every other play. No means had been devised for forcing surrender of the ball, and a team that was unable to score but chose not to let its opponent have the chance to score was able to maintain possession indefinitely. There was no penalty for a safety (tackling a ball carrier behind his own goal line), and a team could touch the ball down behind its goal, bring it out to the 25-yard line, and do this over and over. Princeton and Yale played their 1880 game in this way, Princeton having the ball for the first half and Yale for the second, without a score and with 17 safeties being registered. There was great public dissatisfaction with such tactics, which were repeated in their 1881 game.

Camp recommended that

If on three consecutive fails [attempts to move the ball forward] and downs a team shall not have advanced the ball five yards or lost ten, they must give up the ball to the other side at the spot where the fourth down was made.

The rule was adopted and started the practice of marking the field with horizontal lines five yards apart, giving it the appearance of a gridiron. The requirement was changed to ten yards in 1906, and in 1912 a fourth down was allowed. The rule was the heart of American football. It encouraged development of a planned running attack and abandonment of kicking as the predominant element in offensive play.

The following year Camp introduced a scoring system to end disputes over the outcome of games. Point values were given to the various scoring methods—safety, 1 point (against team in possession of the ball); touchdown, 2 points; goal after touchdown, 4; and field goal, 5. Over the years the point values changed several times; and at the start of the 1970s the safety was 2 points, the field goal 3, the touchdown 6, and the conversion after touchdown was 1 point if kicked and 2 points if the ball was run across the goal line or brought into the end zone by a completed pass.

In 1888 came another change that was to transform the pattern of the game. Tackling up to this time had been permitted only from the waist up—the rule of rugby. An 1888 rule now permitted tackling as low as the knees, and along with this there came a prohibition against linemen blocking with extended arms, requiring them to keep their arms at their sides. The forward line of players, which had been extended across the field, was therefore forced to contract. The players in the backfield behind the forward line, who also had spread wide for the lateral passing of the ball, as in rugby, also moved

close together behind their forwards for protection.

In the positions in which they were now stationed, the backs formed the close-order alignment of the T—which became the original, standard arrangement of American football.

It was in the momentous 1906 football rules committee meeting that the last fundamental change in football was made—the introduction of the forward pass. Camp was far from being solely responsible for it, but his leadership in bringing together diverse groups helped bring about the legalization of the pass and the adoption of other steps taken to eliminate the brutality of football.

**Mass formations.** In 1890 the first of many mass formations that were to make the game so hazardous had been unveiled. The man who originated it was Amos Alonzo Stagg, famous as a player at Yale from 1885 to 1889 and far more renowned for his 63 years of coaching college teams, 41 of them at the University of Chicago. Stagg devised the "ends back" formation in his first year of coaching at the International YMCA Training School in Springfield, Massachusetts. He moved the ends from their regular positions at each end of the line to positions behind the line, where, along with the backs, they became interferers, pushers, and pullers, helping the ball carrier to advance. The resulting impact on the defense was much more forceful than anything previously known.

Earlier teams had given assistance to the ball carrier by stationing a player on each side of him to fend off tacklers. If the players conveying the ball carrier preceded him, it was a violation of the so-called off-side rule. In 1884 Princeton boldly sent its blockers in advance of the carrier—a violation—but there was no resulting penalty, and the practice became general by sufferance before any change in the rule.

Stagg's ends-back formation provided interference of a more formidable character in that the linemen were stationed in the backfield and were able to pick up more speed before contact with the opponents. In 1891 Stagg presented a second mass formation known as the "turtle-back," a massing of the team into a solid oval directed against the opposing tackle. Harvard used this in 1893 and was credited by some with being the originator.

In 1892 the most devastating of the mass plays was introduced—the "flying wedge," a kickoff tactic invented at Harvard. The flying wedge was an extension of the so-called V trick, credited to both Princeton and Lehigh University, Bethlehem, Pennsylvania, in which the kicker, instead of kicking off to start the half, nudged the ball with his toe and then picked it up and ran with it as his teammates formed a V-shaped mass around him. The V was taken up by other teams and became the accepted procedure for the kickoff. In 1892 Harvard added momentum to the mass by starting the wedge in motion before the ball was put in play. This flying wedge was used against Yale at the start of the second half of their 1892 game, after Yale had employed the standard V to open the game. Instead of the customary standing start in the middle of the field (the 55-yard line), Harvard deployed its men in two files of five, 15 to 25 yards behind the captain, who stood on the 55-yard line with the ball. The two files, slanting inward from the sidelines, converged at the signal on their captain. As the flying mass reached him at top speed, he put the ball in play, flipped it to a player in the wedge, and joined in as an interferer. The ball carrier went to Yale's 25-yard line before he was stopped. So sensational was the device that it was taken up immediately and in 1893 it was in general use. It added greatly to the roughness of the game and by the end of the season, football was under heavy attack for its violence. The army and navy departments cancelled the game between the service academies in 1894, and the Intercollegiate Football Association began to break up. Only Yale and Princeton remained as members.

Flying  
wedge

In 1894 the University Athletic Club of New York invited Yale, Princeton, Harvard, and Pennsylvania to send representatives to a meeting to form a new rules committee. In a dramatic revision of the rules by this group, the V trick and the flying wedge were banned by a re-

quirement that the kickoff travel at least ten yards to be in play unless touched by a member of the receiving side. It was also prohibited for more than three men to group more than five yards in back of the line of scrimmage to project a mass play. Also, a player was prohibited from laying hands on an opponent unless he had the ball. A linesman was added as a third official (in addition to the referee and umpire), and playing time was cut from 90 to 70 minutes, divided into halves of 35 minutes.

But the violence of mass plays continued. In 1894 Stagg, then at the University of Chicago, introduced a "tackles back" formation and at Pennsylvania, the coach, George Woodruff, originated a "guards back" arrangement that was widely imitated. Pennsylvania, which was challenging the Big Three (Yale, Princeton, and Harvard) for supremacy as it went through a perfect season in 1894, was unwilling to abandon its guards-back formation, and Harvard declined to give up its flying wedge. Yale and Harvard broke relations after a rough 1894 game. In 1895 Yale and Princeton adopted a separate code, inviting Navy to come in with them. To curb mass play they ruled that the team on offense must have seven men on the line of scrimmage and that only one back might be in forward motion before the snap of the ball. The groups differed not only on the use of mass plays but also on permitting graduate students to play. Harvard and Pennsylvania, with large numbers of graduate students, refused to disqualify them.

Also in 1895, colleges in the Middle West, dissatisfied with the divided leadership of the East, asserted their independence. The presidents of Chicago, Illinois, Michigan, Minnesota, Northwestern, Purdue, and Wisconsin universities met and took steps toward organizing what was to become the Western Conference (Big Ten). At a second meeting in 1896 they adopted a rule barring freshmen from varsity teams and set a limit of three years on varsity eligibility. Later, they were to establish faculty control of all athletics.

In the summer of 1896 the two groups in the East met in an effort to resolve their differences. They set up a permanent rules committee and put a curb on momentum in mass plays by ruling that "no player on the side in possession of the ball shall take more than one step toward his opponent's goal before the ball is in play without coming to a full stop." The matter of "coming to a full stop" was to be argued for years before momentum was to be eliminated entirely. In 1910 the rules committee required seven men on the line, to put an end to mass plays.

#### EMERGENCE OF THE MODERN GAME

The season of 1905 was one of the ugliest, if not the most critical, football has gone through in the United States. According to tabulations of the *Chicago Tribune*, there were 18 deaths and 159 other injuries of consequence resulting from college games. There was a mounting uproar of protest as the season progressed. Pres. Theodore Roosevelt summoned representatives of Harvard, Yale, and Princeton to the White House and requested them to take steps to save the game, observing, "Brutality and foul play should receive the same summary punishment given to a man who cheats at cards."

At a meeting in New York City late in 1905, representatives of about 60 colleges and universities appointed a football rules committee of seven members and organized the Intercollegiate Athletic Association of the United States with Capt. Palmer E. Pierce of West Point as its first president. In 1910 the association changed its name to the National Collegiate Athletic Association (NCAA) and later became the governing body of intercollegiate athletics in the United States. Under the leadership of Captain Pierce and Walter Camp of the American Football Rules Committee, the two groups met in joint session in 1906 in New York City and adopted changes that were to save the game. A member of the rules committee reported that the fundamental objectives of the 1906 meeting were

- (1) to make the game both safe and more interesting for the player, (2) to make the game a distinctly more open game, (3) to remove the premium on mere weight and to develop

greater opportunity for speed, agility and brains, (4) to produce a game affording broader strategic possibilities, thereby giving the lighter teams and the teams of the smaller colleges a real chance and preventing the probable outcome of so many games from being a foregone conclusion, (5) to improve the standards of sportsmanship of the game and, by developing better officiating, to remove the continual temptation to violate the rules.

One of the committee's changes was the legalization of the forward pass.

**The forward pass.** One of the men most instrumental in the introduction of the forward pass was John Heisman, for whom college football's most prized individual trophy was later named. In 1895 he had seen a pass thrown in a game between North Carolina and Georgia, 11 years before it was legal to throw the ball forward. The North Carolina player who caught it ran 70 yards for a touchdown. The Georgia coach protested the pass as illegal, but the referee stated that he had not seen it and allowed the touchdown.

In 1903, when football was under heavy attack for its brutality, it occurred to Heisman that the pass he had seen thrown eight years before could be the salvation of the game, loosening up the strangling mass play. He wrote to Camp suggesting that the forward pass be incorporated into the game, and in 1904 he did so again. Others joined as advocates of the pass, and it was finally approved in 1906.

In addition to legalizing the forward pass, rules changes put through in 1906 were: (1) reduction of the length of the game from 70 to 60 minutes, divided into 30-minute halves; (2) establishment of a neutral zone, separating the forward line of teams by the length of the ball; (3) increasing the distance required to be gained in three downs from five to ten yards; (4) banning of hurdling (jumping over opposing players); (5) prohibiting centres, guards, and tackles from dropping behind the line of scrimmage on offense unless they fell back five yards; (6) stipulation that punts striking the ground put all members of the kicking team on side (behind the ball) except the kicker; (7) marking of the field with lengthwise stripes five yards apart, changing it from a gridiron to a checkerboard; (8) addition of a second umpire; (9) requirement that substitutes report to the referee. A central board of officials, which Camp had advocated in 1905, was established.

Despite these changes, football remained a dangerously rough game. Interlocked interference was still used, with only six men required on the offensive line. Defensive halfbacks, who formerly had supported the tackles against the running game, had to fall back to guard against the new forward pass, and the tackles took brutal punishment. In 1906 six suffered fatal injuries.

In 1910 the rules committee acted and took the final step to end mass plays. Seven men of the offensive team were required on the forward line, and interlocked interference and aiding the runner by pushing or pulling were outlawed. The effect of these changes was so pronounced that the balance of power switched from the offense to the defense. There was a falling off in scoring, and numerous games ended in scoreless ties. To correct the imbalance, the rules committee in 1912 increased the number of downs from three to four. The length of the playing field was reduced from 110 to 100 yards (90 metres) and end zones ten yards (nine metres) deep were established behind the goal lines, within which forward passes could be completed for touchdowns. The kickoff, formerly made from the centre of the field, was moved back to the kicking side's 40-yard line.

Gradually, early restrictions on the forward pass, which discouraged its use, were removed. Following the ending of a 15-yard penalty for an incomplete pass in 1907, a requirement that the pass cross the line five yards to either side of where the ball had been put in play was done away with in 1910. This made it no longer necessary to put chalk lines down the length of the field. In 1912 the limitation of 20 yards on the distance the ball could be thrown beyond the line of scrimmage was removed. The restrictions remaining were that the pass had to be thrown from five yards behind the line and only

meeting

Notre  
Dame  
and the  
forward  
pass

one pass could be thrown on each scrimmage. The first of these was also eventually discarded.

The awakening to the immense possibilities of the forward pass came primarily as a result of a sensational exhibition by Notre Dame in defeating Army in the inaugural game of their rivalry in 1913 at West Point. Arranged to fill a vacant spot in Army's schedule, the game was looked upon as an easy, pleasant afternoon of sport for the home team. Notre Dame's name in football meant nothing to the East at the time. With quarterback Gus Dorais throwing to end Knute Rockne (later the most famous coach in football history) and to back Joe Pliska, Notre Dame caught Army completely unprepared and scored an astonishing 35-13 victory over the cadets and their old-style, battering-ram running game. Later that same season Army used the forward pass against Navy and won 22-9.

Actually, Notre Dame was not the trailblazer its performance made it appear to be. Numerous teams had used the pass since its inception in 1906. Probably the most successful of all in that year was a St. Louis University (Missouri) team that won every game in its season and used the pass from the very first. Stagg said that in 1906 he had 64 pass patterns. Illinois, Michigan, and Carlisle Indian School, Pennsylvania, were also experimenting, and as early as 1908 the pass was introduced in the Southwest. In 1913, the same year that Notre Dame beat Army, Texas defeated the University of Oklahoma, Norman, with the pass, and in 1915 Oklahoma averaged 30 to 35 passes a game and won all of its ten contests.

Impetus was given to the forward pass, too, in other regions of the country in the 1920s. In 1925 it carried Alabama to California's prestigious Rose Bowl game. Andrew ("Swede") Oberlander's passes carried Dartmouth College, Hanover, New Hampshire, to its first national championship. At Michigan, Benny Friedman, one of football's most famous quarterbacks, was pitching aerial strikes to Bennie Oosterbaan, equally renowned end, on the 1925 Michigan team.

**Spread of the game.** Whatever the style of football played in the early years, Yale almost invariably had the best team. From 1876 to 1879 it lost only one game (to Princeton) and was tied in only four. From 1880 it lost one game, to Princeton in 1885 by 6-5, and was tied four times (by Princeton) through 1887. In 1888, when the pattern of the game changed, as tackling below the waist was permitted and the offensive team took the close-order formation of the T, Yale continued supreme and that year had the most famous of its teams to the turn of the century. With Camp serving as Yale's first coach, the team scored 698 points to none for its 13 opponents. Yale continued to overwhelm its opponents to the end of the century, with infrequent defeat, usually by Princeton or Harvard, which, with Yale, formed the Big Three of early football.

Yale and  
the Big  
Three

In the 1890s, teams in other regions began to establish themselves as football powers. Purdue won all of its eight games in 1892, and Minnesota; Oberlin College, Oberlin, Ohio; Butler University, Indianapolis, Indiana; Centre College; Trinity (Duke); the University of Kansas, Lawrence; Colgate University, Hamilton, New York; and Johns Hopkins University, Baltimore, also had strong teams. Oberlin won all of its seven games under Heisman, who was starting an illustrious 36-year coaching career. Cornell defeated ten opponents, including Michigan, and lost only to Harvard. In 1893 Princeton had one of the strongest teams in its history. Princeton beat Yale 6-0 in what was called "the greatest sports spectacle New York or America has ever witnessed." Yale had won 37 games in a row. Stanford University, Stanford, California; Minnesota; Colgate; Grinnell College, Grinnell, Iowa; and Pennsylvania had good seasons in 1893, and the Stanford-California classic of the West Coast started.

Pennsylvania challenged the Big Three in 1894 as it set out on a four-year rampage that was to establish it as one of the new Big Four. In 1891 John Adams of Pennsylvania had been the first player from a team other than one of the Big Three to be named an All-American.

When Pennsylvania introduced its "guards back" formation in 1894, it won every game. The formation was to be irresistible for 34 successive games in 1894, 1895, and 1896, until Pennsylvania lost 6-4 to Lafayette College of Easton, Pennsylvania, in 1896. It then swept through 31 more games before losing to Harvard in 1898, after which it added Carlisle and Cornell to its victims. In the five years it scored 1,957 points and gave up only 120. One of its most outstanding players, a guard, Truxton Hare, was four times an All-America selection.

The Southern Intercollegiate Association, the first formal athletic conference, was formed in 1894 "for the development, regulation and purification of college athletics in the South." Vanderbilt's William L. Dudley was the leader. Georgia, Alabama, Georgia Tech, Sewanee (The University of the South at Sewanee, Tennessee), and North Carolina were charter members with Vanderbilt. The next year saw the organization of the Western Intercollegiate League, which was to become the Western Conference, or Big Ten, traditionally one of the strongest football conferences in the nation.

Lafayette challenged Penn for top honours in 1896, ending Penn's winning streak and beating every opponent, except for a scoreless tie with Princeton. It was the first small college to beat one of the Big Four.

The Sewanee team of 1899 was the first in the South to win wide renown. Coached by Herman Suter of Princeton, it won all of its 12 games, from North Carolina to Texas, holding 11 opponents scoreless. Five of the games were played in the space of six days on a 3,000-mile trip. Sewanee began its spectacular rise in 1898, when it won its four games with the loss of only four points. Also in 1898, Carlisle went to the West Coast to play California in the start of East-Far West competition.

The year 1901 was particularly notable. Fielding Yost began his long career as coach at the University of Michigan and his "point-a-minute" teams of 1901 to 1905 achieved one of the most remarkable records in history. In five years they scored 2,821 points to 42 for their opponents, winning 55 games, losing one and tying one. Two of their players, Willie Heston and Adolph Schulz, are ranked among the greatest of all time. At the end of the 1901 season Yost took his team west to play Stanford. On January 1, 1902, in the first Rose Bowl game at Pasadena, California, Michigan won 49-0.

Michigan's  
"point-a-  
minute"  
teams

In 1905 Michigan finally met defeat for the first time in 57 games, losing to the University of Chicago, coached by Stagg. The score was 2-0, on a safety, the only points Michigan gave up all season. Walter Eckersall, three times All-America and ranked for years as the best quarterback of all time as well as one of the best drop-kickers in history, piloted the winning team to the national championship. Chicago was then to go on to compile a record comparable to that of the point-a-minute teams in losing only two games from 1905 to 1909.

In 1905 Yale repeated its perfect record of 1900, giving up only four points, to Princeton. The legendary Tom Shelvin was captain and All-America for the third time. Tad Jones, a Yale idol as both player and coach, was quarterback, and his brother, Howard, later one of football's most successful coaches, was also on the team. They played, too, on the 1906 and 1907 teams, which also were unbeaten, though tied by Princeton in 1906 and by Army in 1907. Tad was an All-America quarterback in 1906 and 1907.

The rise of the Carlisle Indian School to fame began in the 1907 season. Football had been introduced at Carlisle in 1894. In 1899 the Indians, whose teams never had averaged over 170 pounds, quickly mastered the game, some of them becoming remarkable kickers in both punting and dropkicking. Deception and trick plays were their forte. One of these was a so-called hunchback play, in which the ball was placed under the back of a Carlisle player's jersey, completely confounding Harvard for a touchdown in 1903.

In 1907, 1911, and 1912 Carlisle was one of the strongest teams in the country and gave the football

# The Carlisle Indians and Jim Thorpe

world the player who is often ranked as the greatest of all time—Jim Thorpe. In 1907, with Thorpe making his first appearance as a substitute, the team defeated Pennsylvania, Harvard, Minnesota, and Chicago, suffering only one setback—against Princeton. This was the second year of the forward pass and the Indians took to it quickly with their skill of hand and lightness and speed of foot.

In 1911 and 1912, with Thorpe, the Indians were nearly, but not entirely, invincible. In 1911, with Thorpe kicking four field goals, one of 48 yards, they defeated a powerful Harvard team. The Indians also beat the University of Pittsburgh, Lafayette, and all others, only to lose to Syracuse University, Syracuse, New York. In 1912 they crushed Syracuse 33–0, routed Pitt 45–8, and beat the University of Toronto, Lehigh, Army, and Brown—all by wide margins—only to succumb to Pennsylvania 34–26. During the 1912 season Thorpe scored the remarkable total of 25 touchdowns and 198 points.

Jim Thorpe, a Sac and Fox Indian, was picked by Camp for his All-America teams in 1911 and 1912. In 1950 he was chosen as the greatest athlete of the 20th century, and the greatest football player of all time in polls of sportswriters and sportscasters.

Two of football's most famous coaching dynasties were started in 1908—by Percy Haughton at Harvard and Gilmour Dobie at the University of Washington, Seattle. Under Haughton, an aristocrat and an iron disciplinarian who was a master of strategy and attached far more importance than the vast majority of coaches to kicking, Harvard enjoyed its “golden age.” Never before nor since has it known such success as it did from 1908 to 1915. It went through 33 games in a row without defeat in 1911–15. In the eight years Harvard won 64 games, lost four, and tied five. Gilmour Dobie established an intercollegiate record of 39 successive victories at Washington from 1908 to 1914. It was not broken until 1957. Not once in his nine years at Washington did Dobie's teams lose, while winning 58 games and tying three.

**New strategies.** Until 1913 football had remained a relatively dull game and the coach had received little recognition or remuneration for his services. The game was in a transitional stage from the mass brutality outlawed by the rules changes of 1906, 1910, and 1912, but it had remained almost exclusively a running and kicking game for most teams. The removal of restrictions on the forward pass and the creation of end zones, in which the pass might be caught for a touchdown, provided the impetus to make more use of the new weapon.

With the opening up of the game, the coach became more important, as a deviser of plays, pass patterns, and defensive arrangements. Only a few coaches had achieved renown.

Knute Rockne of Notre Dame achieved a celebrity that surpassed that of any other coach in history, with the possible exception of Stagg. Rockne created little, but he was the most magnetic of all coaches, one of the smartest and wittiest. Becoming head coach at Notre Dame in 1918, he saw his team (which included George Gipp, who Rockne later said was the greatest back Notre Dame ever had) win every game in 1919 and again in 1920. His fame became nationwide when his team of 1924 won the national championship. Sportswriter Grantland Rice began his account of that year's Notre Dame–Army game with these words:

Outlined against the blue-gray October sky, the Four Horsemen rode again. In dramatic lore they were known as famine, pestilence, destruction and death. These are only aliases. Their real names are Stuhldreher, Miller, Crowley and Layden.

Rice's phrase became imperishable, as did the fame of the team and its coach. Harry Stuhldreher was quarterback, Elmer Layden, fullback, and Don Miller and Jim Crowley, halfbacks. The men in the line became known as the “Seven Mules.” The team played north, south, east, and west and won every game, including a Rose Bowl victory over Stanford. Rockne had undefeated and untied teams also in 1929 and 1930. No one knew better than Rockne how to make the most of all the devices,

Ball carrier for Notre Dame plunges through the Stanford line during the Rose Bowl game, January 1, 1925.

Brown Brothers

including the shift (see below), with which he was so successful that football legislators finally required players in motion to come to a definite one-second stop before the snap of the ball.

**The shift.** Rockne credited Stagg as the originator of the shift installed at Notre Dame in 1914, in which the backs moved just before the snap of the ball from their T formation into a box alignment behind the left or right side of the line. A year later the ends also shifted out from the line. Stagg said that at the beginning of the century he started shifting linemen quickly from one side to another in the first deviation away from a balanced line and the start of the shift. In 1904 he used a backfield shift synchronously, and in 1910, a backfield shift in which the ball was snapped instantly without delay.

In addition to the Stagg-Notre Dame shift, also famous were the Minnesota (the “greatest shift ever invented”), created by Harry Williams, and the Heisman shifts. The Minnesota began with tackles back, shifting both of them to either side of an unbalanced line while simultaneously rearranging the backfield. Minnesota first used the shift about 1903 or 1904. Coach John Heisman unveiled his complex shift at Georgia Tech in 1910. It involved moving most of the line as well as the backfield just prior to the snap of the ball. In 1917 he achieved his greatest success with it when Georgia Tech defeated every opponent, crushing a strong Pennsylvania team 41–0.

The Notre Dame shift lost its effectiveness with successive decrees of the rules committee to eliminate its momentum. In 1924 it was ruled that the team must come to an absolute stop and remain stationary “momentarily.” In 1927 a pause of one second was imposed. In 1931 the pause had to be “at least one second.” The vogue of the shift had been waning, and after Rockne's death in 1931 it lost most of its remaining followers.

**Wingback formations.** Contributing to the decline of the Notre Dame system was the rise in popularity of the wingback formations originated by Glenn (Pop) Warner. One of the most creative minds in football and one of the most successful of all coaches in 44 years at Georgia, Cornell, Carlisle, Pittsburgh, Stanford, and Temple University (Philadelphia), Warner devised first a single wingback formation and then a double wingback (see Figure 2). In the single wing, the backs were in Z alignment, a halfback to the flank and just to the rear of his end on the strong side of an unbalanced line, in which the tackles were side by side. In the double wing, the other halfback moved up from his single-wing station, five yards behind centre, to the flank of his short-side end. The fullback was positioned four yards behind centre and the quarterback was a yard behind the right guard. Power, deception, and speed were emphasized in Warner single- and double-wing football. Big, hard-running quarterbacks and fullbacks were required. Warner invented the single wing in 1912, and his Carlisle team used it against Army. The double-wing formation in all probability was worked out and perfected while he was at Pittsburgh, but it was not until 1928 that it won nationwide acclaim when his Stan-

Knute Rockne and Notre Dame

Pop Warner

ford team overwhelmed Army in New York City. Both formations eventually lost favour because their complex, delayed manoeuvres required such precise timing as well as a quarterback of a type not commonly available. The double wing became almost extinct and the single wing a rarity after the modern T formation won favour in the 1940s.

**T formation.** The modern T—employing principles that Stagg had worked out over the years, including the stand-up position of the quarterback behind centre (1894), quarterback fakes and “keeper” plays in which the quarterback pretends to hand the ball to one back and then gives it to another or keeps it himself (1905), and the man in motion (1927)—was the creation in the 1930s of George Halas and his Chicago Bears coaching staff of the professional National Football League and Clark Shaughnessy, University of Chicago coach. The Bears’ 73–0 defeat of the Washington Redskins in the NFL championship game of 1940 and the overwhelming success of Stanford University with it the same year started the trend toward reviving the formation. The addition of men-in-motion, flanking backs, wide receivers, and brush-blocking (the blocker only bumps his opponent to interrupt his rush and then runs on as a potential pass receiver or downfield blocker) techniques produced a fast-hitting, quick-opening attack and put a tremendous burden upon the defense. When coach Frank Leahy used the T in developing what was regarded as the greatest of Notre Dame teams in 1943, and Earl (“Red”) Blaik produced three unbeaten Army teams with it in 1944, 1945, and 1946, the Rockne and Warner styles of football went into discard.

The T has not been displaced since then, although many variations have been introduced. In 1941 Don Faurot at the University of Missouri revealed the split T, with wider line spacing (splits) and a sliding, ball-carrying quarterback rather than a spinning ball feeder, with options of keeping, pitching out, and passing. Others to use the split T included Charles (“Bud”) Wilkinson, whose Oklahoma teams won the national championship in 1950, 1955, and 1956, and Jim Tatum, whose Maryland teams won the championship in 1953 and beat every opponent in 1951 and 1955.

Another variation was a so-called wing T, a combination of the T and the single wing. Among its exponents was coach Lou Little of Columbia, who had devised a particularly clever single-wing attack, putting his fullback and tailback on a line to spin and fake to one another, as well as to the wingback circling around. It was this formation that produced Columbia’s winning touchdown against Stanford in the 1934 Rose Bowl game. The double wing T worked out by Clarence (“Biggie”) Munn at Michigan State was another variation, and there have also been the slot, double slot, highly publicized “lonely end” T of Blaik’s at Army, and, in more recent years, I and wishbone T varieties and formations with split ends, wide receivers, flankers, double flankers, and other types of spreads, popular with professional teams.

**Coaches, teams, and players.** Football had become a national mania and large-scale business enterprise in the United States by the 1920s. Highly publicized football heroes such as the Four Horsemen of Notre Dame and Harold (“Red”) Grange of Illinois won new football followers the country over. Attendance mounted: Notre Dame played to 500,000 spectators a season, Army and Navy drew 110,000 to their 1926 game in Chicago; and crowds of 90,000 in California, 80,000 in the Middle West, and 75,000 in the East became commonplace. New and larger stadiums went up across the land. The most famous coaches drew salaries of \$15,000 to \$20,000, far in excess of what they had been paid before World War I. The rewards of success were such that more and more colleges sought to share in them by building an arena, hiring a winning coach, and recruiting players for him to develop into an attraction that would fill the arena. As money poured in and more and more colleges assumed heavy obligations in expanding their athletic plants, the need for success became greater and greater. Winning teams were needed to attract customers and so provide

the income necessary to meet mounting budgets as football was burdened with supporting the entire structure of intercollegiate athletics.

The scramble to obtain the best high-school and preparatory-school talent led to unscrupulous recruiting practices. Financial inducements were offered to players by college coaches or athletic-department officials or by alumni, in violation of amateur regulations and ethical standards. Educational requirements were let down or waived to get good players into college and keep them there for four years. A variety of dishonest recruiting practices became widespread. Athletic scholarships were given wholesale, and large pools of funds were subscribed by alumni to bring prize athletes to their alma mater.

The college football world was rocked in 1929 when a *Carnegie Foundation Bulletin* exposed the extent of unethical practices and named some of the most prestigious universities. Respectable colleges took corrective measures, and for a while the reaction was so strong that it seemed football might be limited to intramural competition. But the intercollegiate game had too strong a hold on the public and was too strong a bond between alumni and alma mater to be downgraded more than temporarily. Also, many colleges had extensive commitments that depended upon receipts from football for their continuance.

The rising calibre of the football played in all areas of the country immediately following World War I was evidenced by Walter Camp’s praise of his 1919 All-America selections as representing “the most powerful aggregation of players that has been on the gridiron for a long time.” Two of Camp’s first-team choices were from little Centre College in Danville, Kentucky, which came into prominence when it beat all opponents, including West Virginia, which had itself crushed powerful Princeton. Two years later Centre College scored one of the notable victories of all time in inflicting Harvard’s first defeat in three years, 6–0.

The South was beginning to establish itself as a football force. In 1917 Georgia Tech, under John Heisman, had a strong claim to the national championship, and both Vanderbilt, under coach Dan McGugin, and Centre College teams won acclaim across the nation. In 1923 Wallace Wade was installed as coach at the University of Alabama and there, and later at Duke, he was to establish himself as one of the most successful coaches in history. Alabama in 1925 won every game and defeated Washington in the Rose Bowl in the first appearance there of a team from the deep South.

Bob Neyland went to Tennessee in 1926 and began one of football’s great coaching dynasties. In his second year his team was unbeaten, after losing only one game in 1926. In nine years they won 76 games, lost six and were tied five times. After a year’s leave of absence in 1935, Neyland returned to Tennessee, and in 1938, 1939, and 1940 his teams won every game, a total of 30, and, in 1939, shut out every opponent. Neyland’s teams used the single-wing formation with a balanced line and displayed exceptional defensive strength. They won 173 games in all, lost 31, and were tied 12 times. Very few coaches have had a winning percentage equal to this.

In 1928 Georgia Tech, under coach William Alexander, defeated every opponent and then beat California in the Rose Bowl after one of the most bizarre happenings in all the history of football, in which Roy Riegels, the California centre, grabbed a ball that dropped from the hands of a Georgia back, and, losing his bearings, reversed his field and sped almost 60 yards toward his own goal before a teammate overhauled him at the three-yard line. At that instant the Georgia pursuers also caught up with him and as he turned to head back, he was tackled on the one-yard line. An attempted kick out of the end zone was blocked and resulted in a safety that provided the margin of Georgia’s 8–7 victory.

Bernie Bierman was another coach who contributed to the rising prestige of Southern football, although his name is most usually associated with Minnesota, where he played and later developed a succession of national champions. His earlier 1929 and 1931 Tulane teams won

Unethical  
recruiting  
practices

“Wrong  
way”  
Riegels

every game, and the 1930 eleven lost only to Northwestern.

Football on the Pacific coast was also on the rise in the 1920s because of an influx of coaching talent. Glenn Warner went to Stanford in 1924 after great success at Pittsburgh, Carlisle, and Cornell. In 1925 Howard Jones, who had turned out champion teams at Yale and Iowa, was appointed at Southern California. By 1928 Jones was challenging the supremacy Warner had taken from California, and his teams were recognized as national champions.

The six leading colleges in the Missouri Valley Conference withdrew in 1928 and organized the Missouri Valley Intercollegiate Athletic Association, known as the Big Six: Nebraska, Missouri, Oklahoma, Kansas, Kansas State, and Iowa State. Colorado joined in 1948 to make it the Big Seven, and in 1957 it became the Big Eight with the entry of Oklahoma State. Remaining in the Missouri Valley Conference were Tulsa, Cincinnati, Louisville, North Texas State, Wichita State, and Memphis State.

In the Rocky Mountain area few intersectional games were scheduled and little recognition was given to the teams. Colorado University at Boulder; Colorado State (known then as Colorado A. & M.) at Fort Collins; the University of Denver; the University of Utah, at Salt Lake City; Utah State at Logan; the University of Wyoming, Laramie; and Brigham Young University, Provo, Utah, withdrew from the Rocky Mountain Conference in 1938 and formed the Mountain States (Skyline) Conference.

Matty Bell started a long coaching tenure at Southern Methodist University in 1935 and in his inaugural year brought the Southwest its first national championship. Stanford invited his team to play in the Rose Bowl, marking the first appearance there of a team from the Southwest. Homer Norton, who went to Texas A. & M. when Bell left for SMU, had a national champion in 1939. The year before, Leo ("Dutch") Meyer had piloted Texas Christian to the championship.

The 1930s were ushered in not only by Notre Dame's championship team, Rockne's last, but by another of the best of all time—Wallace Wade's last Alabama eleven, which defeated Washington State in the Rose Bowl 24–0. In all, Wade took five Alabama and Duke teams to the Rose Bowl. His record for 24 years included 171 victories, 49 losses, and ten ties.

Notre Dame continued strong after Rockne's death, and other powerful teams were Michigan, Colgate, and Princeton.

Minnesota was one of the strongest teams of the 1930s, going through three years of success in 1934, 1935, and 1936, losing only one game—to Northwestern in 1936. The 1934 team, which has been rated as the best of Bierman's regime and among the greatest in football history, beat Michigan 34–0. Wisconsin was beaten by the same score. Bierman's teams were recognized as national champions in 1934, 1936, 1940, and 1941.

Along with Minnesota, the 1934 season brought forth another team now ranked among the great—Alabama. Under Frank Thomas, successor to Wade and the first to carry the Notre Dame style of football to the South, Alabama defeated every opponent, including Stanford in the Rose Bowl. In 1935 the first award of the Heisman Trophy to the outstanding college player of the year was made to Jay Berwanger of the University of Chicago.

**A new style.** The 1940s saw a new style of football. As the youth of the country went off to World War II and many coaches entered the armed forces, it seemed at first that intercollegiate football might have to be abandoned. Numerous colleges dropped out in 1943—among them, Stanford, Alabama, Fordham, Syracuse, Tennessee, Florida, Mississippi, Mississippi State, Oregon, Oregon State, Santa Clara, and Washington State. Others carried on only informally—as Harvard, Boston College, and Vanderbilt. But the game was kept going at most schools. Navy flying-cadet trainees in various colleges were permitted to participate in varsity sports. Freshmen also were made eligible. War restrictions, including dimout regulations, rationing of gasoline and rubber, and cur-

tailment of travel, had their effect. The Rose Bowl game of New Year's Day, 1942, was transferred east from Pasadena to the campus of Duke University in Durham because of the possibility of an enemy attack on the West Coast. Though the quality of football fell off sharply and the immediate future of the game seemed uncertain, the public attended games in increasing numbers.

In 1945 the picture changed. With the end of the war in Europe, former college stars and coaches returned to campus and veterans' benefit programs enabled many servicemen to get a higher education. The influx of veterans reached a crest in 1946—football's most prosperous season to that time, when there were so many players on campus that numerous former varsity-letter winners were unable to regain their places on their teams.

It was a changing game to which the players and coaches came back. The change to T-formation football had begun before most of them had gone to war in 1942 and 1943. This was the modern T, with man in motion, flanking backs, and other features experimented with in the distant past and developed in professional football in the 1930s. This formation, striking swiftly and deceptively through quick openings in the line, with the ball handed quickly to a darting back by a quarterback, and blockers merely brushing opponents off balance and continuing on for secondary targets, was to replace both the old wingback system of Glenn Warner, with its emphasis on power, deception, and complex manoeuvres, and the shift attack employed so successfully by Knute Rockne's Notre Dame teams and much imitated.

Among the outstanding teams of the decade was coach Clark Shaughnessy's Stanford University team of 1940, which achieved a perfect record and gave the T formation a spectacular send-off. This was in Shaughnessy's first year at Stanford, which had not won a single conference game in 1939. He was voted the coach of the year.

Army dominated the scene in 1944 and 1945 and then was challenged by Notre Dame in 1946. Coach Earl ("Red") Blaik had the finest pair of running backs in Army history at his command for the three years—Felix ("Doc") Blanchard and Glenn Davis. In 1944 Army, for the first time since 1931, defeated Notre Dame 59–0 and scored 504 points for the season, an academy record. In 1946 a game between Army and coach Frank Leahy's Notre Dame team resulted in a 0–0 stalemate, and in the most dramatic game of the season Army beat Navy 21–18, to complete a three-year record of 27 victories and one tie.

On the same day Notre Dame beat Southern California, to complete a record that, like Army's, showed all victories except for their scoreless tie. In the final ranking poll, it finished on top, and Army dropped to second place. Blaik was voted the coach of the year, in reward, partly, for the three years of 1944, 1945, and 1946—the greatest in West Point history. Glenn Davis received the Heisman Trophy, which had gone to Blanchard in 1945 and would go to Notre Dame's quarterback John Lujack in 1947.

In 1945 coach Fritz Crisler at Michigan originated what was to become famous as platoon football. Because of the shortcomings of wartime players, he formed separate units for offense and defense. At first only his line specialized while backs played both offense and defense. In 1947, however, Crisler began to substitute entire teams drilled in offense or defense. In 1953 platoon football was temporarily abandoned following a change in the substitution rule.

Another of the strongest postwar teams was, again, Notre Dame, which, under Leahy, won 36 games and tied two from 1946 thru 1949, with no losses, and ranked first in the nation in 1946, 1947, and 1949. In 1953 the team was again undefeated, although tied once, and ranked second to Maryland. That was the last year of Leahy's successful regime. He collapsed in the dressing room during the intermission in the Georgia Tech game, and on his doctor's advice resigned as Notre Dame's coach early in 1954. In his 11 years at Notre Dame, Leahy's teams won 87 games, lost 11, and tied nine. His

The Big  
Eight

Wartime  
restrictions

Platoon  
football

earlier Boston College teams in 1939 and 1940 had won 20 and lost two.

One of the most remarkable coaching records football has known began in 1948 when coach Charles ("Bud") Wilkinson started Oklahoma on a record that was to win him a place among the most successful coaches of all time. Beginning with the second game, Oklahoma, using a split T formation, won 31 games in a row before losing to Kentucky in a 1951 postseason game. From 1953 to 1957 Oklahoma compiled the longest winning streak in the history of intercollegiate football, defeating 47 opponents in succession before they lost 7-0 in the eighth game of 1957 to Notre Dame. In 1949, 1950, 1954, 1955, and 1956 Oklahoma won every game of the season. It was the national champion in 1950, 1955, and 1956, and champion of its conference from 1948 to 1959. The 1955 team created a sensation with its speed, particularly in a 20-6 victory in the Orange Bowl over a Maryland team that had been unbeaten and untied and had the most powerful defense against rushing in the country. In his 17 years at Oklahoma—from 1947 through 1963—Wilkinson had compiled a remarkable record of 145 games won, 29 lost, and four tied when he resigned to run for Congress. He was voted coach of the year in 1949. In 1958, when the substitution rule was liberalized so that it again became possible to use platoons, Coach Paul Dietzel of Louisiana State University devised a format calling for a team that played both offense and defense and separate offensive and defensive units; LSU finished an undefeated season ranked as first in the country, and Dietzel was coach of the year.

In his last year before retiring as Army coach, Earl Blaik in 1958 trained a team that was unbeaten for the first time in nine years and was ranked third. Blaik originated what became known as the "lonely end" formation, in which an end was stationed 18 to 20 yards to the side of the line. He did not join his teammates in the huddle, and it was a mystery as to how he got the signal for each play. It was not until the season was over that Blaik explained that the position of the quarterback's feet furnished the cue. Army passed from this formation more than did any other Blaik team.

The year 1958 was notable for the fact that there was a scoring change for the first time since 1912. For the score after a touchdown, 2 points were awarded if it was made on a run or forward pass into the end zone; 1 point if it was made on a placement or drop kick over the crossbar between the goal posts. The ball was put on the three-yard line, instead of the two-yard line, for the conversion. The distance between the goal posts was widened the next year from 18 feet six inches, to 23 feet four inches (7.1 metres), and from then on far more field goals were to be attempted and far more were to be successful.

College football attendance increased in the 1950s, and during the decade from 1959 to 1969 it rose roughly 35 percent, from about 20,000,000 to more than 27,000,000. In 1970, attendance had the biggest rise ever in a single year—over 1,800,000—for a total of about 29,500,000. Permitting colleges to schedule an extra game accounted in part for the increase.

In the 1940s the Middle West had dominated football except for the three years Army was invincible—1944, 1945, and 1946. Notre Dame, with four national champions, Minnesota, Ohio State, and Michigan were the great powers. In the 1950s Oklahoma had gone to the top, and the deep South had great teams in Tennessee, Auburn, and LSU. The East, in Syracuse and Maryland, had its first national champions since the 1930s, other than Army. In the 1960s, however, there was a wide distribution of strength, with every section represented except the northeast. Southern California, under coach John McKay, brought the West Coast back into the mainstream for the first time since the early 1930s, with the University of California at Los Angeles (UCLA) a challenger. The University of Texas returned to a football prominence it had not had since the 1930s, and the University of Arkansas furnished the chief conference competition. Alabama returned to the height, and Ohio State, Michigan State, and Minnesota kept the Big Ten in the

fore. Notre Dame consistently produced some of the best teams in the nation from 1964 on, and Nebraska started its climb to the very top, which they attained in 1970 and 1971.

Michigan State blockers delay onrushing linemen, as quarterback Steve Juday (23) passes to halfback Clinton Jones (26) on a rollout pattern from the T-formation against Illinois, 1965.

In 1964 the substitution rule was liberalized to permit any number of players to be sent in whenever the clock was stopped and two players when it was running. This opened the way for a partial return to platoon football. Also in 1964, Oregon and Oregon State rejoined California, Stanford, Southern California, the University of California at Los Angeles, Washington, and Washington State, in this way forming an eight-team Pacific Conference.

Few football games have generated as much interest all over the country as the Notre Dame-Michigan State game of 1966. Both unbeaten and untied, with some of the most publicized players of the season, they met before a record 80,000 in Michigan State's stadium and a television audience estimated at 33,000,000. The game ended in a 10-10 tie, as Notre Dame cautiously ran out the clock in the final minute without risking a pass in its own territory. Notre Dame was ranked first for the year and Michigan State second.

Other highlights of the decade included the performances of Southern California's halfback O.J. Simpson in 1967-68 and of the Ohio State teams of 1968-70. Simpson, a transfer student from a junior college, won All-America honours and nearly won the Heisman Trophy in his first season of major college football. With great balance, speed, and durability, he executed break-away touchdown runs and often carried the ball 30 or 40 times to gain more than 100 yards in a single game. He led the nation in rushing in 1967 and 1968 and won the Heisman Trophy in 1968. Ohio State, with a team comprised mostly of sophomores, was national champion that year, undefeated and winner over Southern California and Simpson in the Rose Bowl. Ohio was also considered the best team in the nation through most of the 1969 and 1970 seasons but lost crucial games at the end of both years. In 1969 Ohio was bested by Michigan 24-12 in the last game of the regular season. The next year it was upset 27-17 in the Rose Bowl by Stanford.

Texas was sensational in 1969, defeating Arkansas and then Notre Dame in the Cotton Bowl, to be crowned national champion. They remained invincible through 1970 until their 30-game winning streak was ended by Notre Dame in their repeat Cotton Bowl meeting, January 1, 1971.

**Speed and defense.** Speed has been a key ingredient of football increasingly since the modern T formation and its variations became the major vehicle of attack. Athletes are faster, particularly the running backs and pass receivers, and so must be the pass defenders. With the

Oklahoma—the longest winning streak

The 1960s—distribution of strength

Higher  
scores

use of specialists in platoons, passers and receivers are more skilled and more rested than in the days when they played both offense and defense.

The number of points scored in a game averaged more than 42 in 1969, and the number of plays a game that year increased by 17 over 1967. This was attributable in part to the fact that the playing time had been lengthened by the change in starting the clock on the snap of the ball instead of when it is ready for play. The widening of the distance between the goal posts in 1959 also contributed to higher scoring. Whereas there were 163 field goals kicked that year, the number had risen to 555 a decade later. But the high scoring may be explained most of all by the increasing burden placed on the defense by the speed and variety of the T-formation attack.

Defense in football is far more complex than it was in the early years. Before the introduction of the forward pass, the problems of the defense were simple, though the punishment was brutal. The concentration was entirely on stopping a running attack. Linesmen stood erect or crouched and used their fists in fighting to get at the ball carrier. Backs played in close behind what amounted to a nine-man line, with the fullback just behind the line and the safety farther back. When the forward pass was adopted, the defensive halfbacks, who had been supporting their tackles, were forced to drop back to guard against the new weapon, and a roughly diamond-shaped (7-1-2-1) defense came into being. The practice of dropping the centre out of the line led to a 6-2-2-1 defense, with the centre supporting the fullback in backing up the line.

The introduction of the pass led to continually changing defenses to cope with it over the years, particularly after the modern T formation came into vogue with a never-ending variation of formations. The six-man defensive line became a five-man line in a 5-4-2 arrangement in the 1930s. Various line adaptations were used to confuse the blocking assignments. A four-man line has been a development of recent years, particularly favoured by the professionals (see Figure 2).

**All-America teams.** In 1889 an all-star college football team was picked, and it has been an annual custom since. Walter Camp's All-America teams appeared annually in *Collier's Weekly* for many years, but researchers have established that it was Caspar Whitney who picked the first team, probably in consultation with Camp.

The first team of 1889 was published under Whitney's by-line in his periodical, *The Week's Sport*, as was the team of 1890. In 1891 Whitney became associated with *Harper's Weekly*, and in the issue of December 12 he printed his selections of 1889 and 1890 and picked his 1891 team. His selections were published in *Harper's* through 1899, except for 1897, when he was on a world tour, and from 1901 through 1907 in *Outing Magazine*, of which he had become editor.

The first All-America team that Camp picked was in 1897. He selected first, second, and third teams and his findings were published in *Harper's Weekly* of December 11. Camp's selections for 1898 were published in *Collier's* of January 7, 1899. Thereafter Camp's teams appeared annually in *Collier's*, except for 1917 through 1924. Camp died in 1925, and from that year through 1947 Grantland Rice, one of the country's most prominent sportswriters, picked the teams for *Collier's*. An article by Camp in *Collier's* in 1899 credited Whitney as the team selector from 1889 to 1896. In all likelihood, Whitney consulted with Camp in picking teams that appeared under Camp's name in the *Spalding Football Guide* from 1891 to 1896.

As football spread around the country and more and more teams took up the game, the task of picking an All-America team became more difficult. In 1948 a board from the American Football Coaches Association was set up by *Collier's*, with Rice as chairman until his death in 1954. In 1924 a rival All-America Board of football coaches had been established by the Christy Walsh syndicate to pick a team. The next year the Associated Press started selecting a team, and the other two big news-gathering agencies, the United Press and the International

News Service (which merged in 1958), came out with teams. The Football Writers Association of America annually picked a team for *Look* magazine until 1970. *Time* magazine, in 1958, started selecting a team based on the reports of scouts for the professional teams. Other magazines and newspapers have printed their own selections over the years. None has been looked upon as official to the degree that Camp's and Rice's were.

**Postseason games.** The postseason or "bowl game" idea was launched at Pasadena, California, on January 1, 1902, when the Tournament of Roses Committee of that city arranged the first Rose Bowl tournament game between Michigan's "point-a-minute" team, whose record gave it a strong claim to the national championship, and Stanford. Michigan won 49-0. The next game was not played until New Year's Day, 1916, when Washington State defeated Brown University 14-0. Since then, the game has been played annually between college teams, except that the 1918 and 1919 contestants were World War I service elevens. The 1942 wartime game was transferred from Pasadena to the campus of Duke University in Durham, North Carolina.

In 1925 the East-West Shrine games for charity were started at San Francisco. This was the first of several all-star games, in which outstanding players from all over the country were invited to compete. Other post-season contests between outstanding college teams include the Orange Bowl, inaugurated in 1933 at Miami; the Sugar Bowl at New Orleans in 1935; the Sun Bowl at El Paso, Texas, in 1936; the Cotton Bowl at Dallas, Texas, in 1937; and the Gator Bowl at Jacksonville, Florida, in 1946. New Year's Day is the date of most of the major bowl contests.

Rose Bowl

## II. Play of the game

## THE FIELD AND EQUIPMENT

U.S. football is played on a field of grass (natural or synthetic), measuring 100 yards (91 metres) in length from goal line to goal line, with an end zone ten yards (nine metres) in depth behind each goal line, and 160 feet (49 metres) in width (Figure 1). Goal posts 23 feet four inches (7.1 metres) apart are erected on each end line, the limit of the end zone. Parallel lines the width of the field are marked five yards (4.5 metres) apart between goal lines. An inbounds line the length of the field is marked 53 feet four inches (16.25 metres) inside each side line.

Figure 1: U.S. college football field.

The ball is oval in shape. A leather case covers a rubber bladder inflated to the pressure of 12½ to 13½ pounds (5.5 to six kilograms). Its long axis measures 11 to 11¼ inches (28 to 28.5 centimetres); its short axis measures 6.73 to 6.85 inches (17.09 to 17.40 centimetres) and its weight is from 14 to 15 ounces (400 to 425 grams). A rubber-covered ball may be used by mutual agreement.

Teams are composed of 11 players. Their uniforms consist of jerseys, snugly fitting pants to the knee, protective pads and underequipment, helmets with face masks, fitted mouth protectors, cleated shoes, and stockings.

Of the 11 members of the team, four are backs and seven are linemen. The backs are known as quarterback, left and right halfback, and fullback. They may also be called tailback, wingback, or flanker in certain offensive forma-

tions and cornerback or safety in some defensive alignments. The linemen are left end, left tackle, left guard, centre, right guard, right tackle, and right end. Since platoon football was introduced, there have actually been 22 members to a team, 11 on offense and 11 on defense, though only 11 may be on the field at a time. The players are required to wear numbers—tackles, guards, and centres being numbered from 50 to 79, ends from 80 through 99, and backs from 1 through 49.

#### PRINCIPLES OF PLAY

Players line up in various formations for offense and defense. When a scrimmage begins (with the snap of the ball) players must be "on side" (*i.e.*, on the proper side of the ball) and the team in possession of the ball (on offense) must have at least seven men on the line of scrimmage. One player of the offensive side may be in motion, laterally or backward. Movement of defensive players is not restricted, as long as they remain on side.

**Objective and procedures.** Each team's objective is to score more points than its opponent; the team having the more points at the end of the game being the winner. Points are usually scored by moving the ball by running or passing or both across the opponent's goal line for a touchdown (six points); or by kicking the ball from scrimmage by placement kick or dropkick above the crossbar and between the uprights of the goal for a field goal (three points). With each touchdown goes the privilege of trying for extra points on the conversion. The ball is put in play on the opponent's three-yard line with a scrimmage. If it is carried across the goal line by a run or a pass, two points are scored. If a conversion is kicked by placement kick or dropkick, one point is scored. Points are also scored on a safety, which is made when a play ends with the defenders of a goal in possession of the ball behind their own goal line, the impetus that caused the ball to cross the goal line having been given by the defenders themselves. The safety is scored as two points for the opponents. A touchdown may also be scored by recovering a free ball in the opponent's end zone. A forfeited game is scored as 1-0.

The playing time of a game is 60 minutes, divided into quarters of 15 minutes each. After the second quarter there is an intermission of 15 minutes (half time). Time out may be taken for various reasons during the game and the elapsed time for a game may be over two hours. After the first and third quarters there is a one-minute interval when the teams exchange goals and the ball is re-located.

Before the start of the game the referee tosses a coin in the presence of the opposing captains and asks one to call. The winner of the toss has the choice of goals or of kicking or receiving the first kickoff. The loser of the toss gets the same choice at the start of the second half.

Each half starts with a kickoff—a place-kick or dropkick from the kicking team's 40-yard line, with the receiving team behind a line ten yards distant. A member of the receiving side attempts to catch the ball or pick it up if it is rolling and run it back toward the kicking team's goal as far as possible before he is tackled or brought to a halt; except that if the kickoff carries beyond the goal line, the receiving team may let it go without touching it, and play will begin on the 20-yard line. A tackle is made by grasping the runner's body with the arms and throwing him to the ground, knocking him down with a body block, pushing him out of bounds, or by stopping his forward progress.

Following the kickoff and runback, the team in possession of the ball gets a series of four scrimmage downs during which it must either advance the ball a minimum of ten yards or forfeit possession to the defenders. Each down starts with the ball resting on the ground and with the teams separated by a neutral zone the width of the ball's length. The centre snaps or passes the ball back between his legs to a back who may run with it himself or hand it or pass it to a teammate who runs with it. Opponents try to stop any advance toward their goal by tackling the runner or by batting down or intercepting passes in flight. Each down ends when the ball becomes dead—

as when the ball carrier is stopped or tackled, when a forward pass is missed or dropped, or when the ball is thrown or carried out of bounds. At the end of any down, if the attacking team has advanced the ball ten yards from where the series started it gets a new series of four downs with a new line to gain. At the end of the fourth down, if the attacking team has not advanced the ball beyond its line to gain, the ball is given to the defenders and they become the attacking team. Scrimmage downs, in successive series for one team or the other, continue until a series ends in a score. Then comes another free kick and the same pattern (free kick—runback—scrimmage—score) is repeated until playing time for the current half expires. After a touchdown (and the try for extra points), or after a field goal, the former defenders receive an ensuing kickoff. After a safety, the defenders make a free kick from their own 20-yard line.

During any scrimmage down, usually the fourth and last, the attacking team may surrender the ball to the defenders by kicking it (punting). When that is done the kicking team may not interfere with a defender's opportunity to catch the ball. A defender may gain added protection by signalling (arm aloft) for a fair catch. If he does so, he must stand fast after a catch and the kicking team is prohibited from tackling him. The traditional privilege of making a free kick after a fair catch was abolished in 1950.

Three methods of kicking the ball are permitted: a dropkick, now rarely used, made by dropping the ball from the hands and kicking it as it touches or is rising from the ground; a place-kick, made by kicking the ball while it is resting on the ground or a tee—the ball may be steadied by another member of the team; and a punt, made by dropping the ball from the hands and kicking it before it strikes the ground.

**Systems of play.** In the T formation (Figure 2), three of the backs (the left halfback, the fullback, and the right halfback) line up from four to five yards behind the centre and parallel to the line, just as they did in the early days of the game. The quarterback, now as then, plays close to and directly behind the centre. In the older game, the quarterback was required by rule to handle the ball before it could be touched by any other back except on a punt. In the modern T, he always handles it so as to prevent defenders from knowing just which back has received it, a deception less likely to succeed on a direct pass.

Rockne's Notre Dame system, which enjoyed a vogue in the 1920s and 1930s but was employed by few teams after World War II, also operated behind a balanced line (Figure 2), but the backs were deployed differently, and the ball was always passed to them by direct pass from centre. The backs in the Notre Dame system first lined up in a T and then, at a given signal, jumped into a box formation to the right (see Figure 2) or left side. The two forward backs were slightly more than one yard behind the line; the two rear backs were about four and one-half yards behind it.

Warner, or single- or double-wing football, both used less often after World War II, calls for an unbalanced line (see Figure 2) and a widely deployed backfield. The line usually is unbalanced by shifting a tackle, but some coaches choose to shift a guard instead. In the single wing the forward halfback (wingback) stands one yard behind the line and up to one yard outside the end. The quarterback (blocking back) is placed about one-half yard to the rear of the wingback and about two yards inside the wingback position. The fullback (plunging back) is one and one-half yards behind and one yard inside the quarterback. The left halfback (carrying back, or tailback) is one and one-half yards to the rear and one yard inside the fullback. In single wing, teams may shift to the left as well as to the right, depending on the needs of the moment or the position on the field.

In the double wing (Figure 2), each of the halfbacks (wingbacks) stands one yard behind the line and one yard outside his end. The quarterback (blocking back) stands about two yards behind the strong side guard. The fullback (plunging back) is from three and one-half to four

Scoring

wing  
formations

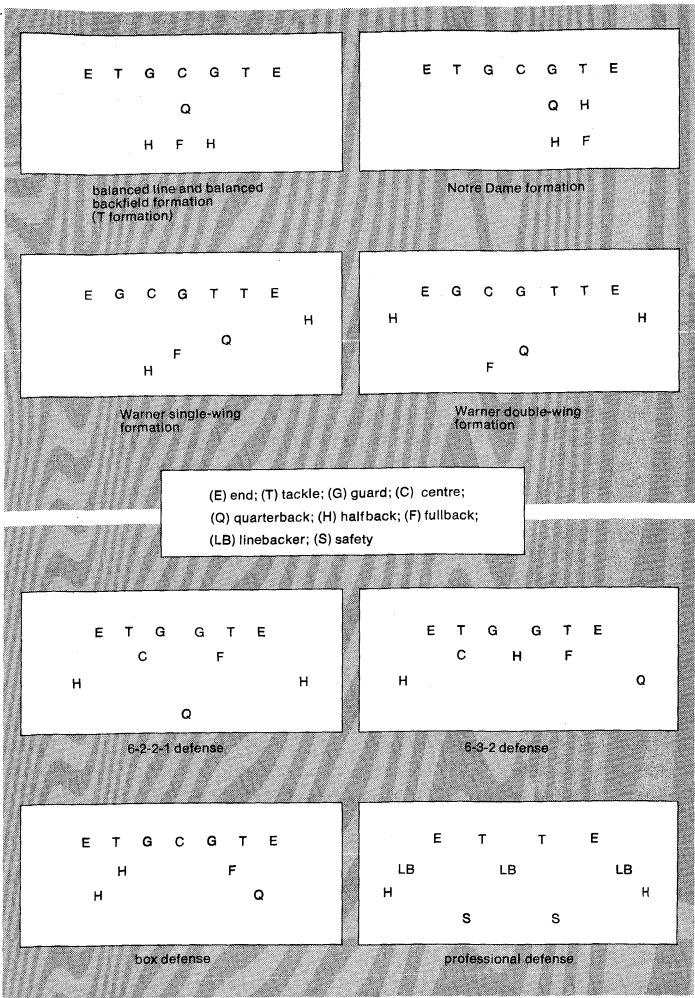

Figure 2: Offensive and defensive formations.

and one-half yards behind the centre, depending on what play has been called. The fullback is more than a plunger in the double wing. He handles the ball first on most of the plays and is a key man in starting the delicately measured reverses.

**Defense.** Defensive formations vary with the coaching systems and with the position of the ball on the field. A defense naturally must be much tighter when the attacking team has the ball near the defensive team's goal line than it would be near midfield.

The objectives of the defense are (1) to recover the ball if an opponent fumbles it; (2) to throw the runner for a loss or limit him to as short a gain as possible; (3) to bat down or intercept any forward pass; (4) to block and try to recover any punt; or (5) to catch a punt and run it back toward the opposing goal line.

To accomplish these ends, coaches employ various defenses. The commonest all-purpose defense is the 6-2-2-1 or 6-3-2 alignment (Figure 2). The offense must have, as noted, seven men on the line of scrimmage. The defense is free to get along with as few as it dares to leave there. In all defenses where only six men are left on the defensive scrimmage line, the centre, invariably a sturdy player, is the man withdrawn. Defenses calling for fewer than six men on the scrimmage line are used less often, but five- and even four-man lines still are commonplace.

The line on defense is spread more widely than it is on attack and is shifted to meet offensive shifts. The players who protect the zone immediately back of the line, called "linebackers," stand about one yard back of the line, usually behind the defensive tackles.

From four to ten yards behind the linebackers are the defensive halfbacks. Their lateral spacing varies with different coaches. If they are too widely spaced, a forward

pass may easily be completed between them. If they are too close together, offensive backs may more easily run outside them or passes may be completed in the "flat zones," just forward and to the right or left of the line. On an average, the defensive halfbacks stand no more than one yard outside their own ends. Back of the four forward defenders in this secondary defense stand the safety men. They are about 20 yards behind the scrimmage line on ordinary plays, but, if the attacking team is likely to kick, they may stand from 30 to 40 yards back. In the 6-3-2 alignment there is no safety man, but there are three linebackers.

The box defense (Figure 2) calls for a seven-man line, two linebackers and two men in the secondary defense. The diamond defense, now used only rarely, also calls for a seven-man line with one backer up, two defensive halfbacks, and a safety man.

Defenses calling for the five-man line are used in part to confuse the offensive players on their blocking assignments. An offensive blocker cannot block a man who is not there to be blocked. The five-man defense invariably calls for three linebackers—each a potential line defender if he is agile enough to plunge one yard forward to the threatened area of the forward wall.

To stop modern attacks, coaches deploy their forces in ever-changing patterns. The rules favour the defense in that it is not required to have any set number of men on the line of scrimmage, nor do the players on defense have to come to a pause in their forward movement before the ball is put in play.

The old standard defenses had difficulty in adjusting to the split T line spacing, creating gaps. It became necessary to put more men close to the line of scrimmage. Five-man lines are now commonplace and four-man lines have ceased to be a novelty. The 4-5, 4-4, tight 5, angling 5, and the Oklahoma 5 or corner defense (which does away with the old type of end play by bringing the ends in so close that they are no longer a force for containment) are among the arrangements used. They amount to eight- or nine-man lines, leaving two or three players in the secondary. The goal is to create chaos by getting more men into the offensive backfield. Five- and four-man lines may also be used to put more men in the backfield to defend against the forward pass (Figure 2). Defensive backs may alternate methods of coverage from zone (each back defends a certain area of the field) to man-to-man (each back defends against a certain opponent). Sometimes two or three defensive backs will cover a single potential pass receiver.

**Officials.** The playing of a game is supervised by a referee, an umpire, a linesman, a field judge, and sometimes a back judge. The referee positions the ball, orders play started and stopped according to rule, inflicts all penalties, declares all scores, and is in overall charge. The umpire inspects and rules on equipment and the conduct of players. The linesman locates the line to gain and keeps count of the downs for each series, notes whether players are on side when each play starts, and marks the distance gained or lost by each play. The field judge keeps time, using a stopwatch or a scoreboard clock operated by an assistant, and supervises downfield play that has passed his fellow officials. The back judge assists the field judge in supervising downfield play.

**Fouls and penalties.** In addition to their primary duties, all officials have a joint responsibility for calling fouls; i.e., infractions of the rules. Each one carries a marker, which he tosses or drops when he calls a foul. At the end of the play he reports his ruling to the referee, who inflicts the prescribed penalty. Loss of yardage and loss of a down are the penalties frequently inflicted. No team, however, may be penalized more than half the distance between the enforcement spot and its own goal line. The most common fouls, with the penalty for each, are: off side (prematurely charging across a restraining line), five yards; illegal use of hand or arm (holding an opponent), 15 yards; ineligible pass receiver (in legal formation, any offensive lineman between the ends when a scrimmage starts) first touching a forward pass beyond the neutral zone, 15 yards plus loss of a down; unsports-

The five-man line

Common penalties

manlike conduct (sideline coaching, invalid fair-catch signal, illegal return of disqualified player to the game, rule violation during intermission), 15 yards; illegal position or procedure (less than seven men on the offensive scrimmage line at the snap, wingback less than one yard behind the scrimmage line at the snap, false start, illegal substitution), five yards; illegal motion (by back or lineman at the snap), five yards; delay of the game (taking more than 25 seconds to put the ball into play, excessive time-out), five yards (15 yards for delaying the start of a half); personal foul (piling on, hurdling, tripping, kicking an opponent, late tackling, etc.), 15 yards, possible ejection of the offender from the game; clipping (blocking from behind), 15 yards; roughing the kicker or place-kick holder, 15 yards; intentional grounding of a forward pass (throwing a pass into the ground to avoid a loss), five yards, loss of a down; interference with pass receiver, pass declared completed and offended team given first down on the spot of the foul; interference with pass defender, 15 yards, loss of a down; batting or kicking a free ball or illegally touching a free kick, offended team's ball at the spot of the foul. Although an incompleting forward pass does not call for a penalty as such, it does result in the loss of a down.

Penalty  
declined

Any penalty may be declined by the offended team, but a player who is declared ineligible because of a personal foul must leave the game. A team will decline a penalty if the play, as completed, has given it a greater advantage than would accrue to it by accepting the penalty. An example would be a team's declining a penalty on a play that ended in its scoring a touchdown.

On the same play, fouls by both teams offset each other and the resultant penalties cancel each other.

If, on a single play, a team commits two fouls, the offended team may accept either penalty or decline both.

### III. Other principal games

#### U.S. PROFESSIONAL FOOTBALL

**Early history, 1895-1920.** The first professional football game to be officially recognized as such was played in the township of Latrobe, Pennsylvania, on August 31, 1895, when a team from Latrobe beat one from Jeannette, ten miles away, by the score of 12-0. For the next ten years, Latrobe fielded a powerful team that played whenever and wherever it could for whatever returns it could earn.

One John Brallier, who later became a dentist in Latrobe, was recorded as the first "confessed" professional after he left the University of West Virginia team to play for Latrobe. Other college athletes, however, were earning expenses in scattered games of the time. Fielding Yost, later to become an outspoken opponent of professional football, played with the Greensburg, Pennsylvania, team. Walter Okeson of Lehigh, Walter Howard of Cornell, and Thomas Trenchard of Princeton were heroes of many off-the-record contests. In 1897 the entire backfield of Lafayette College in Easton, Pennsylvania, also played for Greensburg.

During the next few years other professional teams appeared. In Pittsburgh, Pennsylvania, the Allegheny Athletic Club was created, and its rosters bore the names of the most famous college players of the day. Upper New York state followed Pennsylvania into professional football soon after the start at Latrobe. There were teams in Buffalo, Syracuse, Watertown, Auburn, Corinth, Clayton, Oswego, Alexandria Bay, and Ogdensburg. On December 28, 1902, Syracuse, with Glenn ("Pop") Warner and his brother in the lineup, along with other college stars, defeated the Philadelphia Nationals, 6-0, in the first indoor football game at Madison Square Garden, New York City. Thirty years later the Chicago Bears beat the Portsmouth Spartans, 9-0, in the Chicago Stadium. These two contests were the only major-league games held indoors until the advent of domed stadiums in the 1960s.

In 1902, Connie Mack of baseball fame organized a football team that he named the Philadelphia Athletics. In the lineup was George ("Rube") Waddell, the famous

pitcher of Mack's baseball team. Mack claimed the "championship of the world" after his club vanquished a squad representing Pittsburgh, which had Christy Mathewson, another great baseball pitcher, as its full-back. Mathewson had been a star during his college days at Bucknell. Bemus and Hawley Pierce, brothers and itinerant professionals from the Carlisle Indian School, played for Philadelphia.

College stars of the time did not enter the professional game as eagerly as they did in the more prosperous years after World War II, but early squads included such players as Willie Heston of Michigan, D.O. ("Tuss") McLaughry of Dartmouth, Charles Brickley of Harvard, Herbert ("Fido") Kempton of Yale, Fritz Pollard of Brown, John ("Jock") Sutherland, Earle ("Greasy") Neale, Lou Little of Pennsylvania, Arnold and Ralph Horween of Harvard, and many others.

One of the most unusual teams of history represented Columbus, Ohio, in 1906 and for several years thereafter. Sponsored by the Pennsylvania Railroad and calling itself the Panhandles, this team had six brothers, John, Ted, Frank, Phil, Fred, and Al Nesser, who were railroad workers, in its lineup. These rugged men practiced in their leisure hours after full days of railroad work. All were besieged with contracts from colleges and other professional teams, but they preferred to stay on the job at home and play the bruising game "just for fun." Only Al accepted outside offers, playing with teams in Akron and Cleveland and with the New York Giants championship team of 1927. He completed 25 years of professional football in 1931.

The  
Columbus  
Pan-  
handles

The combination of World War I, a chance remark by Robert Zuppke, veteran coach of the University of Illinois, and the enthusiasm of George Halas in Chicago for football combined in 1918 to spark the beginning of the modern major league game.

Zuppke, at the postseason banquet of his 1917 Illinois team (on which Halas had been an outstanding end), said that it was unfortunate that football players at the time when they were just beginning to learn something about the game were graduated from college and played it no more. A few weeks later, reporting for training at Great Lakes Naval Training Station in Illinois, Halas found several former college stars eager to continue playing. On New Year's Day in 1919, a Rose Bowl championship match was held, in which Great Lakes upset a powerful Mare Island Marines team.

Knute Rockne, who became one of the immortals of football as a coach at Notre Dame, was one of the busiest and hardest-to-trace professional players of the 1914-20 period. He played as often as he could for whatever team was offering the best salary. One team claimed he played against them in six successive games in six different uniforms. He was one of the trickiest and hardest ends to stop.

Wide World Photos

**The growing years, 1920–45.** As the early days ended with the organization of the American Professional Football Association in 1920, hundreds of unrecorded warriors of the gridiron faded from the scene. Scant records had been kept and the bruising battles of pickup games were lost forever. Even the glory of the individual stars dimmed, leaving only Jim Thorpe to live a few more years in sports pages. Unpadded, often unpaid, the pioneers played a vicious and smashing game of football, often for the full 60 minutes of each encounter unless crippled beyond the possibility of completing the game. A “big” squad of those days might have contained 15 players; the modern teams of 40 players, specialists, and platoons were unknown.

Jim Thorpe was a superlative back, but his approach to the game was lighthearted and erratic. Despite contempt for ordinary training rules, however, Thorpe could run in the open, crash the line, and shatter the attack of his opponents. He ran like a later star, Harold (“Red”) Grange, with swiveling hips, change of pace, and extreme confidence. Defensively, he broke up opponents with a lethal and illegal special shoulder pad with an outer covering of sheet metal, which he was ordered not to wear when the league was formed. It was said by those who had played with and against Jim Thorpe that he was one of the greatest football players of all time. Thorpe, who died in 1953, also excelled in other sports. In his honour, the towns of Mauch Chunk and East Mauch Chunk, Pennsylvania, were joined and renamed Jim Thorpe in 1954.

Eleven league franchises at \$100 each were sold when the American Professional Football Association was officially formed on September 17, 1920. Jim Thorpe was elected president and George Halas purchased a franchise for the Staley Starch Company of Decatur, Illinois, which had recently made him athletic director. The first 11 teams in the league were the Canton Bulldogs (Thorpe’s team); Cleveland Indians; Dayton Triangles; Akron Professionals; Massillon Tigers; Rochester, New York; Rock Island, Illinois; Muncie, Indiana; Hammond, Indiana; the Chicago Cardinals; and the Decatur (Illinois) Staleys, who became the Chicago Bears in 1922.

The league had a perilous beginning that fall. Few games were played, and there seemed little chance that the league would survive. However, in April 1921 the league elected Joe Carr, an experienced promoter, as its new president. Carr created an immediate realignment of teams. Massillon, Muncie, and Hammond dropped out; Green Bay, Wisconsin; Buffalo, New York; Detroit; Columbus; and Cincinnati came in, and a full schedule was completed with the Chicago Bears winning more games than any other team. The name was changed to National Football League in 1922, with Carr continuing as president until his death in 1939. In 1933 the NFL played in two divisions, with an annual championship game. For more than a decade the National Football League survived with little support from the fans and even less from newspapers. Some franchises moved to other cities; new teams joined; some dropped out. More than 45 cities were at various times the homes of NFL teams.

The first trend toward prosperity began in 1925 when Harold “Red” Grange left the University of Illinois to play with the Chicago Bears. Grange was the biggest name in the sports world at that time, and he was the spark that professional football needed. His debut against the Chicago Cardinals drew an audience of 36,000. Seven days later 68,000 jammed New York’s Polo Grounds to see him play against the Giants. Grange and the Bears then went on a coast-to-coast tour that sowed the seeds of interest in the sport. Grange established himself as one of the all-time stars of the NFL before he retired from the game in 1935.

**The modern era.** In 1945 a rival league, the All America Football Conference, was formed and began play in 1946 with eight clubs representing Brooklyn, Buffalo, Chicago, Cleveland, Los Angeles, Miami, New York City, and San Francisco. Dan Topping, owner of the former Brooklyn NFL team, transferred his entire squad to the AAFC. In 1947 Miami forfeited its franchise and was

Jim Bakken (right) of the St. Louis Cardinals attempts a place-kick with Larry Wilson holding, 1964.  
Jack Zehrt—FPG

replaced by Baltimore. There was considerable opposition among the NFL owners against the new league, and four years of competition for support followed. When it ended before the 1950 season, professional football in general had come of age, and the fans from coast to coast were aware of its existence. Under an agreement between the leagues, Baltimore, San Francisco, and Cleveland moved their teams into the NFL, and the balance of the AAFC players were pooled and drafted by the 13 clubs in the NFL. After one season the NFL was reorganized into 12 clubs: the New York Yanks, Chicago Bears, Chicago Cardinals, Cleveland Browns, Detroit Lions, Green Bay Packers, Los Angeles Rams, New York Giants, Philadelphia Eagles, Pittsburgh Steelers, San Francisco 49ers, and Washington Redskins. In 1952 the Yanks franchise moved to Dallas for one year, after which the Baltimore Colts, whose franchise was dropped in 1951, were allowed to pick it up and transfer it to Baltimore.

Attendance records started to climb rapidly as the new era opened. Bert Bell, veteran player, coach, and owner, was commissioner of the league from 1946 until his death in 1959. Pete Rozelle, general manager of the Los Angeles Rams, was named as Bell’s successor in 1960. In 1960 the Cardinals moved to St. Louis, and a new team, the Dallas Cowboys, was added to the league. The Minnesota Vikings (Minneapolis-St. Paul) were added to the league in 1961, the Atlanta Falcons in 1966, and the New Orleans Saints in 1967.

In 1959 another rival, the American Football League, was organized with Texas millionaire Lamar Hunt the first president and Joe Foss, World War II air hero and former governor of South Dakota, serving as its first commissioner. Initially, in 1960, the teams were the Boston Patriots, Buffalo Bills, Denver Broncos, Houston Oilers, New York Jets, Oakland Raiders, Dallas, and Los Angeles; the Los Angeles franchise was transferred to the San Diego Chargers in 1961 and the Dallas franchise to the Kansas City Chiefs in 1963. The Miami Dolphins were added to the league in 1966.

A merger of the two leagues was announced in 1966, effective in 1970. By the start of the 1968 season, the two leagues had begun interleague play and a total of 26 cities from coast to coast was represented. In January 1970 the new National Football League began and consisted of two conferences—the National Conference and the American Conference, each with three divisions. Rozelle remained as commissioner.

The teams were aligned as follows:

*National Conference, Eastern Division:* Dallas, New York Giants, Philadelphia, St. Louis, Washington. *Central Division:* Chicago, Detroit, Green Bay, Minnesota. *Western Division:* Atlanta, Los Angeles, New Orleans, San Francisco.

*American Conference, Eastern Division:* Baltimore, Boston (changed to New England), Buffalo, Miami, New York Jets. *Central Division:* Cincinnati, Cleveland, Houston, Pittsburgh. *Western Division:* Oakland, Kansas City, San Diego, Denver.

First professional leagues

Expansion and reorganization

The Super  
Bowl

**The boom period.** Interest in the new, merged leagues became apparent almost immediately. The first meeting between the champions of each of the leagues, named the Super Bowl, brought together the Green Bay Packers, NFL champions, and the Kansas City Chiefs, AFL champions.

The Packers won easily, 35–10, in Los Angeles in January 1967 before 63,036 fans. Each of the players on the winning team received \$15,000 and the losers, \$7,500—a far cry from the \$210.34 and \$140.22 the players received in the first professional play-off in 1933 between the Chicago Bears and the New York Giants. Television networks paid \$2,000,000 for the telecast.

There was a new play-off system when the merger of the two leagues was completely effected in 1970. The Dallas Cowboys and the Baltimore Colts emerged as champions in their respective National and American Conferences. The Cowboys, playing in a title game for the fifth year in a row, had defeated the San Francisco 49ers 17–10 and so finally qualified for the Super Bowl. Baltimore, in the American Conference, defeated the Oakland Raiders 27–17. In the world championship game in Miami, Baltimore defeated Dallas 16–13 after trailing for more than three periods, Jim O'Brien kicking a 32-yard field goal with five seconds left.

Football became America's no. 1 professional sports attraction despite the claim of professional baseball that baseball was the "national game."

As money poured into the treasuries of the owners, there were demands from the players for a share. While the NFL and the AFL were in competition for players—before they agreed on a common draft in 1967—the bidding reached new heights. The New York Jets of the AFL were reported to have signed Joe Namath, University of Alabama quarterback, for \$400,000, presumably for four years. The merger brought more conservative bidding for players. Before the 1968 season the NFL faced the serious possibility of a player strike, but an agreement increased pension benefits, insurance, and other fringe benefits, and established a \$12,000 annual minimum salary for second-year players and \$13,000 for players of three or more years. In 1970, in another dispute over pension benefits, veteran players boycotted the training camps. It was not until five days before the start of the exhibition season that a settlement was agreed upon.

**Rules.** The rules for professional football permit a more wide-open, high-scoring game than that played by the colleges, despite the fact that in the NFL only one point can be scored after touchdown, on a kick. Because the professional goals are on the goal line (the posts may be offset six feet) rather than at the back of the ten-yard end zone as in the college game, the professionals attempt and make more field goals than college teams.

In professional ball a member of the defensive team can run with a recovered fumble; the colleges call the ball dead at recovery. A professional ball carrier can rise and run if he falls to the ground unless he has gone down as the result of contact with an opponent; the collegian is down even if he simply slips and falls. The professionals have added a sixth official, the line judge, to the five who are standard in the college game. Substitutions are unrestricted.

In professional football, divisional play-offs or championship games cannot end in a tie. If the score is tied after the regulation 60 minutes, additional periods of 15 minutes each are played. The first team to score a touchdown, field goal, or safety is declared the winner, and the game ends immediately. This "sudden death" system allowed Baltimore to win the NFL championship 23–17 over New York in 1958. (A.D.)

#### CANADIAN FOOTBALL

**History.** Football in the form of rugby was brought to Canada by British immigrants not long after William Webb Ellis' historic run with a soccer ball in 1823 on the playing fields of Rugby School. By 1862 British regiments in Montreal were playing the game on an informal basis, and the formation of the Montreal Football Club in 1868 gave the sport an official Canadian birthdate.

In the United States at that time the schools were still playing according to the Princeton Rules, a game that more closely resembled soccer. Soccer might even have become the great American game if Harvard had not broken away and started playing rugby under Boston Rules, for which offense they were ostracized by their Ivy League brethren at Yale, Columbia, Princeton, and Rutgers. Harvard's search for opponents brought them into competition with Montreal's McGill University.

The schools first met in Cambridge, Massachusetts, on May 14 and 15, 1874, for two games that had a profound effect on the development of football on both sides of the border. Because McGill only brought 11 of their usual 15 players, Harvard players decided that they preferred this innovation, and 11 eventually became the standard number of a U.S. football team. The Canadians, however, returned home and reverted to the English-style game with 15 players on a side. Today, a Canadian team has 12 men on a side, a move suggested as early as 1900 by captain Thrift Burnside at the University of Toronto but not widely used until 1912.

The colleges did not set the early pace in Canadian football as they did in the United States. Instead it was the clubs, such as the Toronto Argonaut Rowing Club, the Hamilton Amateur Athletic Association, and other groups in Guelph, Stratford, London, and Port Hope, that banded together to form the first league. The colleges continued to play under the English Rugby Union rules and scorned the brawling "city" teams and their roughhouse style of play.

Inevitably, however, as Canadian schools continued to play exhibitions with college teams in the U.S., the games drew closer and closer together. Since play was relatively informal in those days, changes were readily adopted. The scrum form of scrimmage soon gave way to the set backfield, although the first centres still kicked the ball back to their backfielders with their heels.

In 1882 the Ontario Rugby Football Union was formed, immediately followed by the Quebec Rugby Football Union. These groups and others combined in a loose confederation under the name of the Canadian Rugby Football Union, later shortened to Canadian Rugby Union. The colleges formed the Intercollegiate Rugby Football Union in 1898. In its formative years Canadian football was a player's game with no stadiums, admission charges, or other forms of commercialization. By 1900 railroads were opening the west and the game was played over most of Canada's 3,000-mile expanse. Still, when Governor General Lord Earl Grey offered a cup for the amateur football championship of Canada in 1909, Ontario and Quebec were playing the best football by far, with teams in other regions more or less overlooked.

Competition for the Grey Cup, as Lord Grey's trophy came to be known, was intended to be open to every association in the country on a challenge basis. Lord Grey's advisers thought that this would help unify the country. As recently as 1954, the amateur Ontario Rugby Football Union issued a challenge and forced an additional play-off game, but in 1956 the professionals finally took full command of the cup competition and discontinued the challenge procedure. The Grey Cup game was not a prominent sports event for many years, as it seemed only to provide an endless stream of eastern champions with an opportunity to humiliate an undermanned western challenger.

As with many Canadian institutions, the game of football felt a strong U.S. influence. One of the earliest and most prominent came in the person of Frank ("Shag") Shaughnessy, a former Notre Dame player and coach who in 1912 took over as football coach at McGill. Shaughnessy was a superb athlete, a magnificent coach, and one of the great sports innovators of all time. He brought motion into the backfield, created the idea of a secondary on defense, and generally kept one step ahead of those who copied his moves. Within ten years he had completely transformed the Canadian game. Shaughnessy also had some success with other sports: although he knew nothing about hockey, he once became a coaching adviser to the Ottawa Senators and helped them to a

Origins in  
rugby

The Grey  
Cup

Stanley Cup; later he turned to baseball and became a czar of the minor leagues.

In the 1930s several U.S. college stars came north in search of jobs in cities like Winnipeg, Regina, Calgary, and Edmonton. Among them was Fritz Hanson, a running back from North Dakota State University, who in 1935 teamed with seven other Americans to lead Winnipeg through an undefeated season in the west. Winnipeg fans contributed a then unheard-of \$7,500 to send the club east, where they beat a powerful Hamilton team 18–12 and brought the west its first Grey Cup. The eastern teams responded with a rule that only Americans living in town on January 1 could play during that year. When the Regina (now Saskatchewan) Roughriders won the western championship in 1936 without adhering to the rule, they were ruled ineligible for Grey Cup play. Sarnia beat Ottawa 26–20 for the cup that year amid howls of western protest. This was only one of many disputes over the years between the various unions and associations that made up the CRU.

Rise of  
profes-  
sionals

After the 1936 controversy, the colleges withdrew from Grey Cup competition altogether. By the 1950s it was obvious that the days of amateur–professional play were numbered, as the professional teams of the Eastern Big Four (Toronto, Hamilton, Ottawa, Montreal) and the Western Interprovincial Football Union (Winnipeg, Saskatchewan, Calgary, Edmonton, Vancouver) dominated competition. In 1956 the two groups joined the Canadian Football Council (later the Canadian Football League) and the amateurs were ruled out of Grey Cup play.

A major impetus in the turn to professionalism was the 1948 Calgary team, a powerhouse built around coach Les Lear, quarterback Keith Spaith, and receivers Woody Strode and Sugarfoot Anderson, all from the U.S. After the team won in the west, a large proportion of the population of the city packed its Calgary Stampede paraphernalia aboard special trains for Toronto, where the fans staged a wild, two-day celebration and the team won the Grey Cup, beating Ottawa 12–7. After this, every city in the country felt it had to put on a better show than Calgary and hire American players to compete on the football field. The league limit on Americans per team was gradually increased from six to the present level of 15 Americans and 17 Canadians.

Canadian teams found themselves competing with U.S. professional teams for top U.S. college players. At one point, in 1953 and 1954, Harry Sonshine of the Toronto Argonauts decided to try raiding the U.S. National Football League rosters as well, regardless of contracts.

In the early 1950s outstanding U.S. players such as Heisman Trophy winner Billy Vessels, Sam Etcheverry, Tobin Rote, Indian Jack Jacobs, Bud Grant, Glenn Dobbs, Alex Webster, Tex Coulter, Frank Filchock, and dozens more came to play in the Canadian league, which at the time offered higher salaries than the NFL. With the new players came a mercurial rise in status for the Grey Cup competition, which became a week-long festival and the premier sporting event in the country.

The 1960s were sobering years, as rivalry between the National Football League and the American Football League priced the Canadians out of the top talent market. Merger of the two U.S. leagues in 1970 restored a degree of normalcy, but the Canadians continued to worry over the threat of NFL franchises moving into Toronto, Montreal, and Vancouver.

**Play of the game.** Although Canadian football stems from English rugby, modern rules changes have brought it closer and closer to United States football. The playing field is larger, being 110 yards (100 metres) long and 65 yards (60 metres) wide. The end zones are 25 yards (23 metres) deep. The wide field encourages lateral passing and the deep end zones, forward passing for touchdowns. There are 12 men on a team. The extra man is invariably used in the backfield or as a wide receiver on offense and as a back on defense. The other positions are the same as those in United States football and have the same names. Formerly they were different, but the many players imported from the U.S. after World War II influenced a shift to U.S. nomenclature.

There are only three downs in the Canadian game. Teams must try for the big gain, which makes the play more open than in United States football. To offset the lack of a down, defensive linemen must be one yard away from the ball when they take their stance. Also, all offensive backs may be in motion before the ball is snapped. Blocking is unlimited on rushing plays, but only eligible receivers can block downfield on passing plays after a forward pass has been completed. Blocking is not allowed on punt returns, and the punt return man may not signal for a fair catch; tacklers, however, cannot come within five yards of the safety back fielding the punt until he has touched the ball. A single point is scored if the team in possession kicks the ball over the defending team's dead line, 25 yards beyond the goal line, or if the defending team's safety back is tackled or run out of bounds in his own end zone after receiving a kick.

Other scoring is exactly the same as that of the U.S. professional game. Offensive and defensive formations are also similar to those in U.S. football. (D.Gi.)

## Ford, Henry

Automobile manufacturer Henry Ford revolutionized United States industry with his assembly line method of production, first employed in 1913 with his Model T automobile. The savings in time and money realized by mass production techniques enabled him to sell the vehicle at a price the public could afford, thus popularizing the automobile as a means of transportation for the average American.

Henry Ford was born on a farm in Wayne County, (near Dearborn), Michigan, on July 30, 1863, the son of Mary and William Ford, who had emigrated from Ireland in 1847. Henry attended rural schools only to the age of 15, when he found employment as a machinist's apprentice in Detroit. In his spare time he repaired watches and clocks to improve his knowledge of mechanical things, an interest that never waned. Even after he had become the master of an industrial empire, he delighted in disassembling the watches of his friends or joining the mechanics in his plant in a greasy repair job.

Intermittently during his youth, he returned to his father's farm where he built a small machine shop and sawmill. In 1888 he married Clara J. Bryant of Greenfield, Michigan; their only child was Edsel Bryant. Ford was

The Ford  
Motor  
Company

then chief engineer of the Edison Company in Detroit, a position that he left in 1899 to organize with a number of associates the Detroit Automobile Company, a firm that built custom cars. He later left the company in order to build racing cars; his cars not only set records but brought Ford enough publicity to attract partners who joined in launching the Ford Motor Company in 1903. By 1908 his famous Model T had appeared; by 1913, mass production enabled Ford to sell it for \$500.

Ford's industrial philosophy was simple: reduce the price of the product, increase the volume of sales, improve production efficiency, increase output to sell at still lower prices, and so repeat the cycle indefinitely. His contemporaries, viewing the automobile as a luxury item or rich man's plaything to be custom-produced for a restricted market, regarded Ford's policies as heretical. Thus in the company's formative years, his ideas were pushed into practice against the resistance of his associates and stockholders, but the workability of those ideas was demonstrated vividly by the phenomenal growth of the Ford Motor Company. From a firm nominally capitalized at \$100,000 in 1903, it became an industrial giant with a surplus balance alone of nearly \$700,000,000 in 1927, when the last of the more than 15,000,000 Model T's built from 1908 to 1927 rolled off the assembly line.

During the 40-odd years that Ford ran the company, other technical advances and new ways of planning, organizing, and controlling production were developed that came to bear the "Ford label," and these advances could be attributed as much to the man as to the firm. Willingness to depart from previous practice—as by standardizing processes and products, integrating supplying industries, building assembly plants at dispersed locations, and organizing manufacturing around continuous line-to-line flow of product components—was a significant factor in the company's success.

Minimum  
wage and  
profit  
sharing

There was a curious mixture of 19th and 20th century in Henry Ford, and his was a strong and contradictory personality. Though he rejected many of the doctrines of the business and economics of his day, on some subjects he clung to anachronistic ideas. In 1914, when workers in United States manufacturing industries were making about \$11 a week on the average, he announced that every Ford worker would start receiving a minimum wage of \$5 a day, a sum about 15 percent higher than salaries paid elsewhere for the same types of work. Ford workers would also participate in a profit-sharing plan. The impact of the move, both damned and praised in the press, earned for Ford his reputation as a trailblazer. Yet at the same time, Ford tightened his paternalistic labour policy, establishing sobriety and thrift on the part of the workers as conditions for sharing in the distribution of profits.

Ford always displayed concern for the welfare of workers and believed firmly in the dignity of work. But

he resisted unionization for his employees, apparently thinking that unionism would pass away or that agitators were misleading his men. The company police in his plants for years waged a repressive campaign against union membership, and the company remained nonunion for several years after his competitors had concluded agreements with unions. After he had lost a union-recognition election conducted by the National Labor Relations Board in 1941, however, he signed the first union shop and dues checkoff contract in the automotive industry with the United Auto Workers.

Ford was a prophet of the new industrial order, yet he was reluctant to use new devices to achieve it. He had a profound distrust of bankers and of Wall Street; he preferred to finance expansion from earnings rather than by selling stock and borrowed only when it was unavoidable. In 1917 stockholders filed suit against the Ford Motor Company in order to force a distribution of most of the company's accumulated surplus, to compel future distribution of earnings, and to enjoin the company from expanding its plant. The outcome was that a special dividend had to be paid, but the right of the company to use its capital for expansion remained unimpaired. As he was able, Ford bought out the other stockholders and eventually attained complete control. He thereafter operated to suit himself, and his company ultimately became the only one of comparable size that was individually owned—a personal empire worth billions.

Though Henry Ford showed great vision and "put America on wheels" with the Model T, the first car designed for a mass market, he later failed to appreciate the dynamic character of that market. Against the advice of his management, he held out for the planetary transmission against the conventional gearshift; the mechanical against the hydraulic brake; the four-cylinder against the six- or eight-cylinder engine; and a single colour, black, against the colour variety offered by other manufacturers. When, however, he was finally convinced in 1927 that the Model T had seen its day, he completely retooled and produced an entirely new car in the Model A. (Ford had produced a different Model A in 1903.) In 1932 he brought the V-8 engine on the market. Nonetheless, his adjustment to consumer demand for comfort, style, and convenience was too tardy to prevent losing first position in the industry to General Motors.

Diet faddist, foot racer, folk-dance enthusiast, collector of early Americana, philanthropist, practical joker—Ford was all of these. Consistency meant little to him. He endowed a modern hospital but subsidized a newspaper that specialized in anti-Jewish articles. During World War I he chartered a ship and sailed with an oddly as-

sorted list of pacifist passengers to appeal to heads of state to "get the boys out of the trenches by Christmas," but during both World Wars I and II his company was a major producer of war materials. He ran for the Senate and lost but thought about running for president. He ruthlessly played his executives off against each other but banned smoking in his plants. Most important, he was a man who could make an auto in his barn with his own hands but could also make the principles of mass production work on a scale unparalleled before his time. He died on April 7, 1947, at Dearborn.

**BIBLIOGRAPHY.** No definitive biography exists. Much information may be found in *My Life and Work* (1922) and *Today and Tomorrow* (1926), written by HENRY FORD in collaboration with SAMUEL CROWTHER; SAMUEL S. ## Foreign Aid Programs

Foreign aid consists of international transfers of capital, goods, or services for the benefit of other nations and their citizens. This article does not discuss two ancient and enduring forms of foreign aid: tribute paid by the weak to the strong and indemnity paid by those responsible for another nation's losses. For example, modern-day reparations payments, such as those paid by Germany after World Wars I and II, are indemnity from the victors' viewpoint and tribute from the losers'.

Two other forms of capital transfers from rich to poor countries are largely excluded from the scope of this article: the normal flow of private capital investment and the assistance offered by private voluntary organizations and individuals. When government policies are designed to subsidize or encourage these flows, through such devices as tax credits or guarantee of investment risks, such policies are an aspect of foreign aid policy and are discussed as such below.

**Kinds of aid.** Official foreign aid is offered in two major forms: (1) capital transfers, in cash or kind, either as grants or loans, and (2) technical assistance and training, usually as grants in the form of men and technical equipment. Technical assistance is most important at early stages of economic development, when industry and agriculture, technology, public administration, education, public health, and transportation are at a fairly primitive level. As the knowledge of modern techniques increases, the nation will be increasingly able to absorb large amounts of foreign capital. Development assistance in the form of loans or grants of capital then assume the dominant role. In countries that are very poor with little industrial development, this assistance commonly takes the form of grants or low-interest-bearing loans (as in U.S. aid to Laos or French aid to African states). As the country's income, trade, and debt-servicing capacity grow, aid may be extended largely in the form of regular loans. The rationale of economic aid assumes that when a country reaches a stage of sustained economic growth foreign aid can be reduced and cut off. The United States has stopped providing economic aid to several countries on such a premise, including Iran, Greece, and Taiwan.

Military assistance—in the form of either equipment or training advisers—has been an extremely important part of aid, both East and West. Sometimes such aid is supplemented by grants of funds for "budgetary support" to poor countries where the donor country has substantial military and political interests (as the United States has had in Taiwan, South Korea, and South Vietnam). Disaster relief is another form of foreign aid; for the United States it has become a method of reducing agricultural surpluses by distributing them to famine-stricken countries such as India.

**The principal beneficiaries.** The distribution of aid among recipient countries reflects varying interests and priorities. The principal beneficiaries of U.S. aid during the 1960s were India, Pakistan, South Korea, Vietnam, Turkey, Chile, Colombia, Taiwan, Brazil, U.A.R., and Israel—reflecting U.S. interests in Asia, Latin America, and the Middle East. French and British aid in that period was heavily concentrated in former colonies (particularly Algeria, overseas territories, Morocco, Senegal, and Tunisia for France; and India, Pakistan, Nigeria, Kenya, Tanzania, and Malaysia for the United Kingdom). Japanese aid focused on Asian countries—India, Indonesia, Pakistan, South Korea, the Philippines, and Taiwan—while West Germany, without any tradition in this respect, gave aid to the larger developing countries such as India, Pakistan, Brazil, Turkey, and Indonesia, and also to countries of special political or economic interest, such as Greece, the U.A.R., Israel, Chile, and Liberia. The aid of Communist countries was directed mainly to Communist-developing countries, but the Soviet Union also offered substantial aid to India, Afghanistan, Indonesia, Pakistan, the U.A.R., Syria, Iran, and African countries, notably Ghana and Algeria.

The distribution of aid among recipients was consequently the result of many different priorities. Countries near China and the Soviet Union received priority, particularly in times of armed conflict. Countries undergoing sharp political change also received substantial aid (Cuba, Ghana, Guinea, Indonesia). Although large countries—India, Indonesia, Pakistan, Brazil—received correspondingly large quantities of aid, small countries tended to receive more in relation to their population: the leading recipients of aid per capita for the period 1966-68 were Malta, Liberia, Israel, Senegal, South Vietnam, Gabon, and Jordan—all but two with populations of less than 3,000,000.

Table 1 shows how Western countries belonging to the Organization for Economic Co-operation and Development (18 European countries, the United States, and Canada) have distributed economic aid among major recipients—that is, among those receiving upward of \$100,000,000 annually.

**Table 1: Flow of Economic Aid to Major Recipients from OECD Countries and Multilateral Agencies, 1960-64 and 1966-68**

recipient	aid receipts (\$000,000)		percent of total aid receipts 1966-68	per capita aid 1966-68 (\$)

## HISTORY OF CHANGING CONCEPTIONS OF FOREIGN AID

Foreign aid as an instrument of national policy goes back to the 18th century, when Frederick the Great subsidized certain allies in order to assure their military support and effectiveness. This practice continued intermittently in Europe during the 19th century.

In World War I the United States made substantial loans to its European allies that became, in effect, grants when the allies defaulted on their repayments at the out-

Aid as an instrument of national policy

set of the Great Depression. Because of this experience, U.S. aid during World War II, amounting to \$47,000,000,000, was offered in the form of "lend-lease": the United States provided its allies with essential equipment and supplies, and in return the allies equipped and supplied United States troops stationed abroad. After the war, outstanding lend-lease balances were settled largely as gifts.

The establishment of the United Nations Relief and Rehabilitation Administration (UNRRA), which operated from 1943 to 1946, marked an important, although largely unwitting, transition from the older conception of aid as a subsidy to a new conception of foreign aid as an institutional element of policy. UNRRA demonstrated that rich nations, notably the United States, which supplied most of the funds, were coming to view official international aid as an essential element of postwar reconstruction.

**After World War II.** In 1946 the United Nations set up the International Bank for Reconstruction and Development (IBRD) to make long-term loans at market rates of interest, financing its operations largely by borrowing in private capital markets. A sister agency, the International Monetary Fund, was designed to smooth out international payments difficulties. These devices, however, proved insufficient for the times. By early 1947 it was clear that a far broader and more vigorous reconstruction effort was needed for Europe. The economic and humanitarian motives for promoting large-scale reconstruction were catalyzed by political considerations—the West's fear of Soviet expansion into western Europe. The first foreign-aid response was Pres. Harry Truman's decision in March 1947 to provide military and economic aid to Greece and Turkey, which were faced by military aggression from Communist forces based in Yugoslavia. In June 1947 U.S. Secretary of State George Marshall proposed a European Recovery Program of aid to western Europe with a much heavier emphasis on economic reconstruction. The program was approved by Congress in 1948; a planning agency, the Organization for European Economic Cooperation (OEEC), was created with its seat in Paris; and, during the four-year life of the "Marshall Plan," western Europe was provided with more than \$17,000,000,000 in U.S. government aid. The Marshall Plan is generally considered to have achieved its twin goals of promoting European reconstruction and preventing the westward spread of Soviet power.

In the Marshall Plan a major power had for the first time explicitly linked aid for economic reconstruction to the promotion of its political and military interests. During the period of the late 1940s and early 1950s, security motives indeed shaped the flow of aid in both the West and the Communist world directing it increasingly to underdeveloped countries. From 1950 on, for instance, the successful revolution in China and the outbreak of the Korean conflict led the United States to offer major aid to Taiwan and South Korea. During the same period, Soviet aid went exclusively to developing Communist countries—North Korea, Mongolia, China. France and the United Kingdom were still too crippled by the after-effects of war to offer much aid; their modest aid in the first post-war decade was directed toward maintaining economic and political interests in selected colonies. Other nations offered virtually no aid before 1956.

**Aid for development.** During the 1950s it became apparent in both the United States and the Soviet Union that direct conflict between the two powers was unlikely and that there would be a struggle for the allegiance of underdeveloped countries of the "Third World." At the same time, the emergence of China as an independent world power and the de facto withdrawal of Great Britain and Japan from major military influence in Asia led to a heavy focus of Soviet and U.S. interest in Asia. As early as January 1949 President Truman had listed as Point IV of his inaugural address a plan to make assistance available from the United States to underdeveloped countries. The Point Four program initially focused on technical assistance, largely in the fields of agriculture, public

health, and education. Some technical assistance was furnished through specialized UN agencies, including the World Health Organization (WHO), the Food and Agriculture Organization (FAO), and the United Nations Educational, Scientific, and Cultural Organization (UNESCO). Most, however, was provided initially mainly by the United States and on a bilateral basis. Private capital, domestic and foreign, was expected to provide the resources needed for industrial growth.

It soon became clear that the formula of technical assistance plus private investment was inadequate to meet the goals for Asia. During the 1950s, in consequence, the U.S. steadily increased its official grants and loans for development purposes, mainly to India, Pakistan, Taiwan, and South Korea.

Although initially both military and economic aid to underdeveloped countries were heavily concentrated on supporting U.S. security objectives in Asia, security-oriented aid was not enough to meet all the objectives of U.S. foreign policy. India, Pakistan, Brazil, Indonesia, and other developing countries were considered important to the United States but did not face external military pressures or organized insurrection. The scope of U.S. economic aid accordingly was broadened. The conception that emerged during the 1950s rejected the direct security approach, and its rationale could be expressed in the form of a syllogism: (1) economic development promotes societies that are economically strong, politically stable and able to resist Communist political and military subversion, thereby favouring U.S. national interests; (2) economic aid stimulates economic development; (3) therefore, the United States should offer aid to developing countries.

Other rich nations began to extend aid on a substantial scale in the late 1950s. The major donors were France, Germany, the United Kingdom, Japan, and Italy. Other industrialized nations that were members of the Development Assistance Committee (DAC) of the Organization for Economic Co-operation and Development (OECD) gave aid in lesser amounts. For these nations, security motives play a lesser role in their conception of aid than for the United States. For the former colonial powers—France, the United Kingdom, and Belgium—the maintenance of prior political commitments was more prominent. Japan and Germany sought to rebuild links with those underdeveloped countries that could be of political or economic importance to them. For all these countries, aid also represented an investment in trade and economic expansion. For some of the smaller donors—the Netherlands, the Scandinavian countries, Canada—the main motives have been charitable; much of their aid has been channelled through multilateral agencies such as the United Nations.

The Soviet Union, various eastern European countries, and China have also offered aid to poor nations. Their aid was not, as a rule, in the form of grants but consisted of low-interest-bearing loans or credits in barter deals. Soviet loans presented a dilemma for the Western powers. Theoretically, if a recipient country's economic needs were being met by the Soviet Union, its assistance from the West could be reduced. But this was considered politically undesirable. And the competition for favours was on. The receipt of Soviet aid usually enabled a country to get more, not less, aid from the West.

#### THE DONORS OF AID

**U.S. aid.** The United States has been by far the largest aid donor. From July 1945 to December 1970 it gave military and economic aid totalling nearly \$125,000,000,000. The economic component of U.S. aid rose during the late 1950s and early 1960s, stabilizing at an annual level of about \$3,500,000,000. Military aid to underdeveloped countries declined steadily from 1953 on and averaged less than a billion annually by the late 1960s. By 1970 both military and economic aid were losing favour with Congress and the public. In its appropriations for 1970–71, Congress voted less than \$2,000,000,000 for aid programs. By 1968 the category of grants consisted

The widening concept of assistance

largely of technical assistance, including funds for the Peace Corps, contributions of food for relief purposes, and aid to Vietnam. Balance-of-payments considerations contributed to the decline of local-currency repayment provisions, both for loans in cash and for transfer of agricultural products. By 1970 all but a tiny fraction of U.S. lending was repayable in dollars. U.S. contributions to multilateral agencies rose steadily during the period and by 1970 reached an annual rate of more than \$400,000,000. As official bilateral aid declined, the government increased its efforts to encourage private investment through various investment guarantee and insurance schemes. In 1970 a new government organization, the Overseas Private Investment Corporation, was established to take over and expand the private investment incentive program. U.S. net private investment in poor countries rose from an average of \$1,000,000,000 annually in the early 1960s to \$2,000,000,000 annually at the end of the decade.

**Other Western donors.** The increasing part played by other countries in the extension of foreign aid is shown in Table 2, which gives data for 1956, 1962, and 1968 for the major Western countries and Japan and compares each donor's 1968 aid effort with its gross national product. By this latter criterion the U.S. ranked ninth in the relative magnitude of its foreign aid burden, behind such major donors as France, Japan, Germany, and the United Kingdom, as well as smaller nations.

**Table 2: Net Annual Flow of Official Aid by Donor Country, 1956-68**  
(\$000,000)

country	1956	1962	1968	aid in 1968 as percent of Gross National Product
Australia	34	74	157	0.56
Austria	—	14	28	0.24

The varieties of aid

The former colonial powers—France, United Kingdom, Belgium, Netherlands—not only advance relatively large amounts of aid but also offer it on generous terms, as grants or low-interest, long-term loans. In recent years Germany and Japan have substantially increased their aid levels and somewhat eased the terms of aid.

Among the smaller donors, Portugal ranked high because of its aid to its African colonies. Several small donors, including Australia, Canada, and the Scandinavian nations give much of their aid in grants, both bilateral and multilateral. France, Switzerland, Germany, and Japan give relatively little through multilateral channels. Italy, beset by poverty in underdeveloped areas at home, offers most of its modest aid in the form of loans at relatively high rates of interest. Austria, Germany, Japan, and Portugal also stress loans rather than grants and lend at somewhat higher than average interest rates, which nevertheless remain substantially below commercial terms and conditions.

By 1970 the accumulation of repayment obligations on loans extended by the donor countries had begun to create major debt service problems for the recipients: in 1970 their annual debt service payments exceeded \$5,-

000,000,000. This was accentuated by the increase in private investment directed to underdeveloped countries, since the payment of dividends and interest adds to the foreign exchange burden. This meant that if foreign aid was to continue on a large scale, more of it would have to take the form of grants.

**Communist aid donors.** The Soviet Union, eastern Europe, and China offer substantial amounts of aid. Much of it consists of aid to other Communist countries—e.g., from the Soviet Union to Bulgaria or from China to Albania. It is difficult to separate aid elements from trade flows in economic relations between Communist countries, hence estimates of aid magnitudes are highly uncertain. In 1968 the level of aid flows from the Soviet Union, eastern Europe, and China to Communist underdeveloped countries (Cuba, North Vietnam, North Korea and Mongolia) was estimated at \$1,200,000,000 and the cumulative total in the period 1947-1968 at \$10,000,000,000, of which about 70 percent was provided by the Soviet Union. Most of this aid is given in the form of loans repayable at 2 or 3 percent interest or in locally produced goods. As in the case of Western aid, the donor normally requires the recipient to buy the donor's products. This "tied" aid creates special problems for recipients because the prices of donors' goods may be higher than world market prices; in effect, this imposes hidden interest charges on the borrower.

Communist countries also offer aid to non-Communist countries, particularly in strategic areas such as the Middle East. It has been estimated that from the inception of such aid in 1954 through the year 1968, the total amount offered was \$10,000,000,000; only about \$3,500,000,000, however, or one-third of the commitment, had actually been disbursed. In 1968, the aid offered by Communist countries to non-Communist countries totalled about \$725,000,000: Soviet Union, \$307,000,000; eastern Europe, \$361,000,000; and China, \$56,000,000.

**Multilateral aid.** Multilateral programs have grown steadily. The major agency is the International Bank for Reconstruction and Development, often called the World Bank, which began operations in 1946 as an independent specialized agency of the United Nations. The World Bank has two financing affiliates: the International Development Association (IDA), founded in 1960, which makes virtually interest-free long-term loans financed by members' contributions and by a subsidy from the World Bank, and the International Finance Corporation (IFC), founded in 1956, which promotes private investment in underdeveloped countries.

There are also three regional development banks, each lending funds to underdeveloped countries in its region. The oldest and largest is the Inter-American Development Bank, founded in 1959, which lends to Latin American countries partly at market rates of interest and partly at subsidized rates based on a combination of market financing and U.S. government subsidy. The African Development Bank, founded in 1964, has had little success in attracting capital. The Asian Development Bank, founded in 1965, has been more successful. It has obtained both market financing and government subscriptions, notably from the United States and Japan, and is now lending at market rates of interest to a number of Asian nations.

European countries have established two institutions for multilateral aid—the Economic Development Fund and the European Investment Bank. Both are organs of the European Economic Community (Common Market), which through them extends loans and grants to overseas countries associated with the Common Market as well as to Greece and Turkey.

The United Nations finances through grants a number of economic aid programs, both directly—through the United Nations technical assistance programs and the U.N. Special Fund—and through specialized agencies, notably UNESCO, the World Health Organization, and the Food and Agriculture Organization.

Table 3 shows the rapid growth of multilateral aid during the 1960s. The table distinguishes between commit-

ments (formal offers of funds) and disbursements (actual expenditures). Total commitments in 1968 exceeded \$2,000,000,000 annually, of which about two-fifths on the average was provided by the World Bank. Most of the aid took the form of loans for agreed projects, which accounts for the characteristic lag between commitments and disbursements. Despite the steady growth of multilateral aid, net multilateral disbursements at the end of the 1960s represented only about one-eighth of OECD members' total economic aid and only about one-tenth of the aid given by all donors including the Communist countries.

**Table 3: Commitments and Disbursements by Multilateral Agencies to Less Developed Countries, 1960-68**  
(\$000,000)

	1960	1962	1964	1966	1968

#### PROBLEMS OF FOREIGN AID

**Early misconceptions.** The success of some programs such as the Marshall Plan led to overoptimistic notions of what could be achieved when the aid was extended to underdeveloped countries. These misconceptions applied not only to economic aid but to military aid as well.

The aid programs of the years 1945-55 had been directed toward the rebuilding of a pre-existing economic structure (in the case of Europe) or at strengthening an existing military capability (as with the aid given by the U.S. to Greece and Turkey). Military aid, when applied to the underdeveloped countries of Asia, Africa, and Latin America, proved to be of little value to the donor countries except in time of outright warfare (Korea, Malaya, Vietnam). The work of economic development was discovered to be far more difficult than the rebuilding of Europe because it required the transformation of entire societies and not simply their reconstruction. This task, it is now recognized, will be the work of generations; it will require massive commitments of resources and major efforts at mutual understanding and cooperation.

From the standpoint of the donor countries, foreign aid has often been politically unrewarding. The governments of new nations, with their colonial heritage, are naturally suspicious of the motives of industrial nations and concerned with demonstrating their independence. Even when the donor has the full support of the government receiving aid, as the U.S. had with Taiwan and the Soviet Union with Cuba, the political results are likely to be mixed: the donor government may find itself tied to the fortunes of its client, often at considerable financial, military, and political cost. Aid-receiving nations naturally attempt to pursue what they perceive to be their own interests, which may conflict with the interests of the donor countries. Some have accepted aid from capitalist and Communist countries alike while forswearing allegiance to either; in the cases of India, Algeria, and the U.A.R., the fact that there were competing donors has sometimes enabled the recipient country to get more aid than it might otherwise have. But since foreign aid is an element of foreign policy, governments will naturally be reluctant to spend funds for no tangible political gain.

The failure of foreign aid to stimulate rapid economic development in poor countries led to considerable skepticism in parliaments and among the populations of the donor countries as to the economic merits of foreign aid. Economic aid is manifestly only one element in the complex of factors required to bring about economic development. There is no way short of absolute tyranny to bring about rapid modernization in countries where the social and political institutions are based on traditional agriculture and where political power is effectively in the hands of landowners and small, moneyed commercial-

industrial groups whose interests are well served by existing social and economic structures. Economic aid has been most successful in promoting the development of countries that were at least partially modernized (Spain, Israel, Greece, Yugoslavia) or where the aid has been massive and sustained (South Korea, Taiwan, Jordan) or where modernization has proceeded under draconian measures of nationalization, forced investment, and restricted consumption (China, North Korea, North Vietnam). Rapid growth in underdeveloped countries also has been closely associated with government policies that encourage exports, even where foreign aid levels are modest (Thailand, Mexico, Pakistan, Central American countries), while slow growth has often been associated with government policies that encourage inflation and high-cost industrialization (Argentina, Uruguay, Indonesia, Chile, Algeria).

**Alternatives.** Most Western governments, wishing to reduce aid costs, have turned increasingly to the encouragement of private investment through guarantee schemes and tax concessions. During the period 1965-68, while government aid remained stable, donor countries' private investment rose from \$4,000,000,000 to \$5,800,000,000. Policies to encourage private investment offer both advantages and disadvantages. Private investment results in a transfer of capital that puts no pressure on government budgets. It is usually accompanied by managerial skills and by access to an international marketing organization and may include technical assistance. Private investors naturally require higher rates of return than official lenders. New nations, furthermore, are sensitive to the threat of foreign domination; consequently private investment may create tensions between rich and poor countries, particularly if rich countries feel obligated to intercede when foreign governments take actions that affect the interests of their nationals.

Private investment is only one of several alternatives to government foreign aid that have been suggested. The others include (1) revising the tariffs of developed countries to give preference to the manufactured exports of underdeveloped countries; (2) guaranteeing bond issues of underdeveloped countries in the international capital markets; (3) devoting some share of the proceeds from exploiting ocean resources to economic development; (4) establishing international machinery to support the prices of commodities exported by underdeveloped countries; and (5) using Special Drawing Rights (the "new money" created by the International Monetary Fund in 1969 to supplement members' international reserves of gold and foreign currency) as a source of development finance for poor nations. These alternatives to foreign aid have been taken up by spokesmen for the poor nations, who have used the United Nations Conference on Trade and Development as a platform for their views.

As the political disadvantages of country to country aid became increasingly apparent to donors, and the dimensions of the economic task more evident, interest grew in the use of multilateral channels as a vehicle for foreign aid, particularly after 1965.

The growth of the regional development banks, the expansion of World Bank lending, the refinancing of IDA (the "soft loan" affiliate of the World Bank), and the expansion of United Nations programs were elements in the new approach.

Multilateral agencies offer several advantages as agents of economic development. They are less likely to be instruments of purely national policy and at the same time less likely to fund unpromising programs under political pressure. Several of them, notably the World Bank, have earned high reputations for the effectiveness of their programs and their ability to exert benign influence on their borrowers' economic policies. Regional development banks offer their member countries a chance to plan together. To the extent that multilateral agencies finance their operations by borrowing on the financial markets, they are less subject to the pressures of national budget processes.

On the other hand, certain multilateral agencies, notably

Indifferent results of bilateral government aid

The advantages of multilateral aid

the United Nations and the African Development Bank, have been criticized as being controlled by the aid recipients. Not all multilateral agencies have equalled the World Bank's reputation for efficiency. As multilateral agencies become increasingly important, moreover, the political pressures on them are likely to increase.

There is obviously no easy solution to the problems of designing effective foreign aid programs. The programs will continue, however, as long as poverty remains an international concern.

**BIBLIOGRAPHY.** Current statistics for aid given by Western countries may be found in the ORGANIZATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT, *Development Assistance* (annual reviews). ## Forestry

Forestry is the science of managing woodlands, along with associated wastelands and waters, for the benefit of mankind. Its chief object is usually the raising and harvesting of successive crops of timber, but professional foresters increasingly have become involved in activities related to the conservation of soil, water, and wildlife resources, and in recreation.

**History.** Early communities of hunters and fishermen regarded the natural forests in which they lived as a form of property, either private or communal, and were ready to fight intruders to defend their assumed rights. As civilization and agriculture developed, private ownership of tracts of woodland became established in most countries, often taking the form of communal and feudal systems of forest exploitation. The typical pattern of forest management in medieval Europe, for example, was the ownership of large tracts of woodland by kings and barons. But many forests were subject to the rights of the peasants, in well-organized communes, to gather fuel, timber, and litter for use on their own properties, and to pasture defined numbers of sheep, goats, and cattle on the forest wastes. Hunting rights were vested solely in the feudal lord, who also held the sole right to fell and export timber, often to distant cities. Regulations, or forest laws, were essential to the orderly working of this system, and these were first aimed at protecting game and defining rights and responsibilities. Penalties for infringements were severe, and peasants who slew deer illegally faced the death sentence. Laws of this kind were introduced to England by William the Conqueror after 1066 and were

bitterly resented by the Anglo-Saxons for generations thereafter.

Timber gradually assumed economic importance as commerce developed and forests diminished through overfelling, overgrazing by livestock, and clearance for agriculture. In England, King Edward IV promulgated a law for ensuring the regeneration of cutover woodland by the exclusion of cattle as early as 1482. But systematic management really began in the German states during the 16th century. It was prompted by the need of the landowners to maintain a steady personal income from timber exports, while ensuring the provision of firewood and timber for local use by their feudal tenants. The classic solution was the working plan, under which each forest property was divided into sections for timber felling and regeneration, so as to sustain a steady annual yield of produce—and therefore a regular annual income—for all foreseeable time. This called for accurate maps and assessments of the timber volume of standing timber crops, together with their expected rates of growth. Professional foresters had to be knowledgeable in geology, soil science, and meteorology, as well as in botany, economics, and technical aspects of timber marketing, and their calling attracted able men with university training.

During the 19th century the reputation of German foresters stood so high that they were employed in most continental European countries, and also by the British in their vast Indian and colonial forests. Early American foresters, including the great conservation pioneer Gifford Pinchot, gained their training at European centres. But the doctrine of responsible control had to fight a hard battle against timber merchants who sought quick profits in the exploitation of natural forests without regard to their renewal. The 20th century has seen the steady growth of national forest laws and policies designed to protect woodlands as enduring assets. The character of these reflect national political philosophies. In Communist countries all forests are owned by the state. In the U.S. both the federal and the state governments have deemed it prudent to hold substantial areas of natural forest, while allowing commercial companies and private individuals to own other areas outright. Similar patterns of ownership are found over most of Asia, western Europe, and in the British Commonwealth. In Japan the extensive forests are largely state owned. Tribal ownership is found in many African countries and proves a serious obstacle to effective modern management. Private owners are nowhere wholly free from government control, which operates in various ways, including taxation of profits, licensing permits for timber fellings, and requirements to restock cutover land. The value of timber as an industrial raw material, and of the forests themselves for soil and water conservation, makes some form of centralized control imperative. Every developed country has therefore established a forestry department, research stations, and training centres for professional foresters. International cooperation is effected by the Forestry and Forest Products Division of the United Nations' Food and Agriculture Organization, with headquarters in Rome.

Trees have been raised from seed or cuttings since Biblical times, but the earliest record of a planned forest nursery is that of William Blair, cellarer to the Abbey of Coupar Angus in Scotland, who raised trees to grow in the Highland Forest of Ferter as early as 1460. After the dissolution of the monasteries, many newly rich landowners in Scotland and England found a profitable long-term investment in artificial plantations established on poor land. John Evelyn, a courtier in the reign of Charles II, published his classic textbook *Sylva* in 1664, exhorting them to do so, and today virtually the whole of Britain's 4,500,000 acres of woodland consists of artificial plantations. Other countries had husbanded their natural forests better and had little need, until recent times, to afforest bare land. The 20th century, however, has seen a tremendous expansion of artificial plantations in all the continents, planned to meet the ever-growing needs for wood and paper as essential materials in modern civilization.

The first forest nursery

## PURPOSES OF FOREST MANAGEMENT

**Multiple-use concept.** Multiple-use land management has become the guiding principle for enlightened forest authorities today. It contrasts with the single-use concepts of the past, which, if continued, could only lead to growing conflicts among the interests concerned. No country has an unlimited extent of forest land, and the reservation of any considerable area for one exclusive purpose creates economic and social stresses. Multiple-use calls for exceptional skill by forest managers who must operate under imaginative forest laws attuned to local circumstances.

**Forest products.** The raising of lumber and other marketable forest products usually takes the lead as the first object of management, producing the highest economic returns. Timber stands must be felled (Figure 1) and re-

By courtesy of the U.S. Forest Service; photograph, Freeman Heim

Figure 1: Loading tree-length logs onto a truck in New York.

generated in an orderly sequence to meet continuing industrial demands. This need has run counter to some public preferences. Lovers of wilderness conditions would prefer to see all trees age and die naturally. The harvesting of timber by huge modern machinery causes a major, though infrequent, disturbance of the forest's tranquility. On the other hand, the high-grade roads that must be built to carry the heavy loads of modern trucks open up for public enjoyment woods that would otherwise remain inaccessible.

**Recreation and wildlife protection.** Recreation in forests assumes ever-growing importance with the development of cities whose inhabitants need a change of scene, fresh air, and freedom to wander, as a relief to the stresses of industrial and commercial life. Imaginative planning is essential to ensure that people actually find what they are seeking without damaging the forest environment or conflicting with the pleasures of others.

Hunting, shooting, and some forms of fishing require close control because the number of people seeking sport commonly exceeds the stock of animals that can provide it. Other activities, such as camping, rambling, horseback riding, and the form of cross-country footracing known as orienteering, can be enjoyed by far larger numbers of people at one time, though sites and routes must be planned to avoid disturbance of game. Popular motor roads and trails must be sited so that they do not hinder lumber working, though it is often possible to effect a separation by time, using routes for trucks during the working week, and for private cars on weekends. Facilities and supervision cost money, which can sometimes, though not always, be recouped through camping and car-parking fees.

**Legislation** Protection of wildlife is a further main objective. It is effected both by forest laws and by the general national and state or provincial legislation of the region concerned. Forests comprise major natural habitats and refuges for a wide range of mammals, from the elks, wolves, lynxes, and bears of northern coniferous forests to the antelopes, giraffes, elephants, lions, and tigers of tropical

savannahs and jungles. Certain birds, such as pheasants and wood grouse, have high sporting values, while others are cherished for attractive song, appearance, or rarity. Plants include rare species, such as tropical orchids, that can only exist in the humid shades of the jungles.

Forest managers have to deal with several interrelated, and sometimes directly opposed, wildlife interests, those of sportsmen, conservationists, and farmers. The needs of the forest itself require the numbers of grazing and browsing animals to be kept down to a tolerable level; otherwise renewal of tree crops becomes impossible. Reconciliation of these varying interests requires a thorough scientific understanding of each creature's life history and feeding habits, in a practical application of animal ecology. The natural annual increase of a herd of deer may be estimated, and shooting permits issued to remove the surplus stock through planned culling of the correct proportion by age and sex.

**Watershed and erosion protection.** In mountainous territory the value of forests for watershed and erosion protection commonly exceeds their values as sources of lumber or recreation. The classic example is found in Switzerland and the neighbouring Alpine regions where the existence of pastoral settlements in the valleys is wholly dependent on the maintenance of continuous forest cover on the foothills of the great peaks. This is combined skillfully with limited lumbering and widespread recreational use by tourists.

Every thriving forest forms a natural protective covering over the earth's soil and bedrock, effective in several ways at different levels. The impact of the large raindrops and hailstones of summer storms, which could damage bare soil, is broken by the trees' leafy canopy. Though much moisture is evaporated, and more is taken up by tree roots and later transpired (given off) by living leaves, a great deal is held by the leaf litter of the forest floor. This is slowly released through soil kept porous through the trees' root action, to feed streams, at a steady rate over a long period, with pure silt-free rainwater. By contrast, storms striking bare slopes result in rapid runoff, causing soil erosion and carrying off silt in sudden flows, leading to choked riverbeds and silted-up reservoirs downstream. Forest cover is also the ideal protection against avalanches, because winter snowfall is trapped on the forest floor, and only gradually released in the form of water during the following spring, since the forest shade delays snowmelt.

**Sustained yield.** Forest management originated in the desire of the large central European landowners to secure dependable income to maintain their castles and retinues of servants. Today forest management is still primarily economic in essence, because modern forest industries, mainly sawmilling and paper manufacture, can be efficient only on a continuous-operation basis.

Foresters think in long time scales, in line with the long life of their renewable crop. Their guiding concept is rotation, used in the special sense of the economic age to which each crop can be grown before it is succeeded by the next one. Examples of short rotation periods, both being for pulpwood in the subtropics, are 10 years for eucalyptus and 20 years for pines. Here a sustained yield could be obtained, in theory, simply by felling one-tenth or one-twentieth of the forest in turn and replanting it. Rotation periods for pulpwood in northern Europe and North America extend to 50 years. Softwood sawlogs often need 100 years to reach an economic size, while rotation periods for broadleaved trees, such as oak and beech, in central Europe, may extend to two centuries. Over so long a growing spell only part of the lumber yield is obtained by the clear cutting of a small fraction of the forest each year. The rest is secured by systematically thinning out the whole forest, each section or compartment being so treated every few years. For example, on a 100-year rotation, 1 percent of the forest would be clear cut, and a further 20 percent thinned out each year, with the whole forest completely thinned every five years. The whole forest thus contributes to the sustained yield.

Over the long periods of time involved, circumstances

The rotation concept

Figure 2: Logs floating down a Canadian stream that winds through a coniferous forest to a pulp mill at Marathon, Ont.

inevitably upset original schemes. Storms may blow down woods not yet ripe for felling, fire or insect plagues may destroy plantations, or changes in end-use may call for new sizes of logs. Management for sustained yield must therefore be flexible, with plans revised at intervals.

Sustained yield principles are likewise applied to minor forest produce. Turpentine and pitch, also known as naval stores, are obtained by the systematic tapping of the lower trunk of subtropical pines, by making successive cuts, every few days, during a succession of summers, using a chisel-like tool. This eventually kills the trees, though their lumber can be salvaged. To ensure continued yields, crops of young pines are raised rotationally to replace those felled. A similar system is followed for Para rubber, *Hevea brasiliensis*, grown in plantations, though in this case the valuable latex exudes from the bast (phloem), not from the true wood (xylem).

Cork is stripped as outer bark from the evergreen cork oak, *Quercus suber*, found in Portugal, Spain, and North Africa. This tree grows a fresh crop over an average span of 20 years. The cork groves themselves—though they endure for centuries—must eventually be renewed to maintain supplies. Coppice or sprout crops of hazel, sweet chestnut, and similar broadleaved trees, cultivated in Europe to yield small poles, likewise repeat their rotational crops at intervals of several years; but here too the stumps or stools must eventually be replaced.

Maple syrup, obtained by tapping the wood of the sugar maple, *Acer saccharum*, in New England and eastern Canada during the spring sap flow, gives a perpetual harvest, available seasonally as long as the trees thrive. Nuts come from many species of trees as perpetual autumn crops, though yields vary from year to year. For both of these products, replacement of individual trees eventually becomes essential to keep up yields.

#### CLASSIFICATION OF FORESTS

Botanically, nearly all forest trees fall into three main groups, conifers, monocots, and broadleaves, one of

which normally takes the lead in determining the character of any natural forest.

**Conifers.** The earliest in the evolutionary scale, with the simplest form of wood structure, are the conifers or coniferous trees, which are also called gymnosperms or naked-seeded trees because their seeds lie exposed on the cone scales. Because the wood of most conifers is relatively soft, they are also called softwoods; another name, needle-leaved trees, arises from the shape of their leaves. Nearly all are evergreen, the larches of the genus *Larix* being the only common exceptions.

The narrow, needle-shaped leaf and evergreen habit of the conifers helps them to thrive under difficult climates. Because they can restrict transpiration of water, and make use of sunlight over most of the year, they can grow in the short seasons of the far north and high up the mountains of temperate zones. They also tolerate semi-arid climates in the subtropics. Conifers as a group grow faster, and on poorer soils, than do broadleaved trees.

The northern coniferous forest (Figure 2), or taiga, extends across North America from the Pacific to the Atlantic, on across northern Europe through Scandinavia and the U.S.S.R., and thence across Asia through Siberia to Mongolia, northern China, and northern Japan. It has outliers along all the temperate mountain ranges, including the Rockies, the Appalachians, the Alps, the Urals, and the Himalayas. Its principal trees are spruces (of the genus *Picea*), northern Pines (*Pinus*), silver firs (*Abies*), Douglas firs (*Pseudotsuga*), hemlocks (*Tsuga*), and larches (*Larix*). Together these northern softwood forests form a world resource of tremendous importance, yielding the bulk of the lumber and pulpwood handled commercially. The relatively simple structure of coniferous lumber fits it well for everyday use in building and packaging trades, while its long fibres are ideal for papermaking. Northern conifers from many lands are extensively planted in Europe, including the British Isles.

The southern coniferous forest has a discontinuous spread through the southern part of the Northern Hemi-

The northern softwood forests

sphere, including California, the southeastern states of the U.S., the Mediterranean lands of southern Europe, North Africa, Asia Minor, parts of the Asian mainland, and southern Japan. Pines are the principal trees, along with cypresses (*Cupressus* and *Chamaecyparis*), cedars (*Cedrus*), and redwoods and mammoth trees (*Sequoia* and *Sequoiadendron*). Certain southern pines such as the Californian Monterey pine (*Pinus radiata*) grow exceptionally fast, yielding sound lumber and pulpwood, and have been widely planted in subtropical Europe, Africa, and Australasia.

In addition, small areas of coniferous forest are found in the Southern Hemisphere, notably the Chile pine, *Araucaria araucana*, in the Andes, hoop pine or bunyabunya, *Araucaria bidwillii*, in Australia, and kauri pine, *Agathis australis*, in New Zealand.

**Monocots.** The second group is called the monocots, or monocotyledons, a botanical classification based on the fact that these trees have one instead of two cotyledons, or seed leaves. They include principally the palms and bamboos. Palm trees form extensive savannahs in certain tropical and subtropical zones but are more usually seen along watersides or in plantations. Their lumber has no commercial value but is used locally. Palm trees have no annual rings, being made up of spirally arranged bundles of fibres, giving a light, spongy wood. Palms are valuable, however, for their various fruits (coconuts, dates, and palm-kernel oil) and leaf products (carnauba wax, raffia, and thatching and walling materials for houses and huts in the tropics).

Bamboo

Another form of tropical monocotyledonous forest is the bamboo thicket, common in Asia, composed of giant woody grasses springing from stout rootstocks. One of the most versatile plants in the world, bamboo is valuable as a construction material, as well as for hundreds of other applications, notably in high-grade paper products. Young shoots are widely eaten as vegetables and are a valuable source of certain enzymes and other substances.

**Broadleaves.** Finally, a more highly evolved group of forest trees is the broadleaves, also called hardwoods because the wood of most, though not all, is harder than that of coniferous softwoods. Their wood structure is complex, and each sort of broad-leaved lumber has characteristic properties that fit it for particular uses. There are three major climatic groups, forming three characteristic types of forest.

Temperate deciduous broad-leaved forests are made up of the summer-green trees of North America, northern Europe, and the temperate regions of Asia and South America. Characteristic trees are oaks (*Quercus* species), beeches (*Fagus* and *Nothofagus*), ash trees (*Fraxinus*), birches (*Betula*), elms (*Ulmus*), alders (*Alnus*), and sweet chestnuts (*Castanea*). All alike stand leafless in winter, when the climate is too cold for active life. The typical soft leaf blade of a temperate broad-leaved tree transpires water so rapidly that if it were held on the tree in winter, when low temperatures restrict sap flow, the tree would die of drought. Therefore the temperate broadleaves expand their foliage in spring, grow rapidly in summer, and shed all their leaves each fall.

Subtropical evergreen broad-leaved forests grow largely in countries with the Mediterranean type of climate, having hot, dry summers and cool, moist winters. Their trees have characteristic thick hard-surfaced leathery-textured leaves, with waxy coatings that enable them to resist water loss during summer droughts. Their evergreen habit enables them to make use of moist winters. Typical trees are the evergreen oaks, species of *Quercus*, and the madrone or *Arbutus*, while in Australia most evergreen broadleaves are species of *Eucalyptus*. Few evergreen broadleaves have high timber value, and many are little more than scrub, highly inflammable during hot, dry summers. Their world distribution embraces California; the southeastern states of the U.S.; Mexico; parts of Chile and Argentina; the Mediterranean shores of Europe, Asia, and North Africa; South Africa; and most of Australia.

Tropical evergreen broad-leaved forests grow in the hot,

humid belt of high rainfall that follows the Equator around the globe. They occur in West and Central Africa, south Asia, the northern zone of Australia, and in Central and South America. Where they extend into regions of seasonal rainfall, such as monsoon zones, they become less truly evergreen, holding many trees that stand leafless during the short dry seasons. Tropical rain forests, as they are also called, hold a great variety of tree species. A few of the timbers, such as teak, *Tectona grandis*, in India, and mahogany, *Swietenia macrophylla*, in Central America, have uniquely useful properties, or ornamental appearance, and hence a high commercial value. Balsa, *Ochroma pyramidale*, from Central America, is the lightest timber known; it is used for rafts, aircraft construction, and insulation against noise, heat, or cold. As a rule these desirable kinds grow scattered amid a far larger number of poorer timbers, which are only used locally for fuel or building. These forests carry many lianas, or climbing vines, while ferns and orchids grow on the bark of tall trees, high up and out of all contact with the ground.

#### TECHNIQUES OF FOREST MANAGEMENT

**Silviculture.** The branch of forestry concerned with tending growing tree crops is called silviculture. Its successful application demands an appreciation of the ways in which trees grow both singly and in forest communities. Growth in turn depends on local soils and climate, competition from other forms of plant life, and interrelations with animals, insect pests, and the organisms that cause disease.

Silvicultural systems are divided into those employing natural regeneration, whereby tree crops are renewed by natural seeding, or occasionally sprout regrowth, and those involving artificial regeneration, whereby trees are raised from seed or cuttings. Natural regeneration is easier but may be slow and irregular; it can only renew existing forests with the same sorts of tree that grew before. Artificial regeneration needs more effort yet can prove quicker, more even, and in the long run more economical. It permits the introduction of new sorts of trees, or better strains of the pre-existing ones. While both methods have a place in reforestation, afforestation of bare lands must be done by artificial methods.

**Natural regeneration.** In established forests the selective cutting of marketable timber, taking one tree at a time and leaving gaps in which replacements can grow up from natural seedlings, can prove economical and also ensure the best possible use of available soil, light, and growing space. The best examples of single-tree-selection forests are found in Switzerland, on slopes where any clear felling could lead quickly to soil erosion and avalanches.

In mixed forests, especially in the tropics, selective removal of valuable marketable species carries the risk that the gaps will be filled by worthless though fast-growing "weed" trees, having no commercial value. The whole forest will therefore deteriorate as the proportion of trees worth harvesting drops. A desirable balance can be maintained by weeding, mechanically or chemically, but this may be costly.

Alternative methods of natural regeneration deal with areas of land as units, rather than with single trees. One highly effective example is employed in the Douglas fir forests along the Pacific slope of Canada and the western U.S. Logging by powerful yarding machines, using overhead cables, creates wedge-shaped gaps of cleared ground. The surrounding forest is left standing for many years in order to provide shelter and seed. Abundant seed is carried by wind on to the cleared land and gives rise, in a few years, to a full crop of seedling firs. After these have reached seed-bearing age, the areas previously left standing may be removed in their turn.

Similar systems using a pattern of strips cut across the forest, or circular plots gradually extended until they meet and coalesce, are employed in France and Germany. All demand high skill and patience by the forester, who must be able to assess the exact degrees of light and soil

Tropical  
evergreen  
broad-  
leaved  
forests

conditions that favour regrowth of crop trees, rather than invasion by weeds.

Regeneration from sprouts or coppice shoots, arising from the stumps of felled broad-leaved trees, was formerly a widespread practice in Europe but is diminishing today. It yields vast numbers of small poles well suited for fuel or fencing, but the timber stems that can be grown by singling these out are of low quality.

**Artificial regeneration.** Artificial regeneration for the reforestation of clearings or the afforestation of bare land usually begins with seed. A few trees, such as poplars (*Populus* species) and willows (*Salix* species) can be more effectively increased by cuttings. Each tree has its own pattern and season of seed bearing, and annual crops vary in quantity or may fail altogether. Softwoods bear small winged seeds firmly lodged in hard cones. These cones are collected, as they ripen between autumn and early spring, either from freshly felled trees or by men who climb into the crowns of selected parent trees. At the seed-extraction station the cones are heated until they expand, then tumbled in a revolving drum sieve until the seed falls free. Another machine removes the wings, and the seed is then ready for sowing. Most kinds can be safely stored, sealed from fresh air in refrigerators, at temperatures close to freezing point, for several years.

The seeds of broad-leaved trees vary widely in character, from small hard grains to large nuts, and many are set in fleshy pulp, awkward to handle. Each kind needs its own techniques for harvesting and extraction, and few can be stored for more than a few months. Seed of all kinds is usually tested in a laboratory prior to sowing.

The direct sowing of harvested seed in the forest is rare because of forest seed eaters (mice, squirrels, birds) and the problem of weed growth. Trees are therefore raised in forest nurseries, where effective protection is possible. Raised seedbeds are prepared, sometimes by hand but usually by tractor-drawn tools, on well-tilled and fertilized soil. Seed is spread, by hand or by seed drills, at carefully judged densities. It is then covered over with sand or earth to a precise depth. Selective weed killers, mainly petroleum-based, are usually applied after sowing to lessen the need and cost of hand weeding. Lath screens may be needed against hot sunshine or sudden frost, and spray irrigation is frequently applied. Early growth of most kinds of forest trees is slow, and diligent weeding is needed to safeguard them from smothering by faster growing plants. After one or two years in the seedbeds they are big enough to be transplanted (Figure 3).

By courtesy of the Japanese Forestry Agency

Figure 3: Year-old larch seedlings growing in a Japanese nursery being dug for transplanting in a reforestation area.

Direct planting of seedlings in the forest only succeeds with certain kinds in favourable circumstances. Most species need a further stage in the nursery to promote the bushy root system essential for sure and speedy early growth on forest land. Nursery transplanting can be done by hand but is much speedier when mechanized. Trans-

planting machines, powered by their own engines, move slowly across the prepared nursery beds carrying squads of workers who feed the seedlings, one at a time, into grips, on rotating wheels. These transfer them to grooves cut in the soil by miniature plows, which are followed by earth-restoring blades and rollers that firm the soil. Machines can only operate on easily worked soil, and during limited spells in spring when the soil has thawed but tree growth has not yet become fully active. Highly efficient, they enable each team member to transplant around 8,000 trees each working day.

Weeds are controlled during the transplant stage by chemical herbicides that inhibit seed germination, or by mechanical harrows travelling between the rows. During their year or two of growth in the transplant beds, the trees become very sturdy and develop bushy roots. These factors enable them to thrive when transplanted to the forest. During moving they are protected against loss of moisture by means such as packing in polythene bags kept in the shade. Planting is restricted to favourable seasons, usually late spring in temperate climates.

On level ground, particularly on the American prairies and the Russian steppes, planting machines, which are simply larger and sturdier versions of those used in nurseries, operate efficiently. They put in several thousand trees each day, spaced an appropriate distance apart. Elsewhere, on slopes, broken or rocky ground, or amid tree stumps, planting is done by hand. The planter uses a spade or mattock to cut a notch, or dig a pit, into which he inserts the tree's roots. Earth is then replaced and stamped firmly round the tree's base.

During the following summer, and possibly for two or three summers thereafter, weed growth that would otherwise smother the small newly planted trees must be kept in check. Usually this is done with a sharp tool such as a curved sickle, a reaping hook or a billhook. Alternatively, crushing or cutting machinery may be driven between the rows of trees. Herbicides are also effective, but risky to use unless each tree is carefully shielded from contact with the weed killing chemicals. During the crop's earliest years trees that appear stunted are replaced. In some regions the lower branches of conifers are pruned away as they die through overshadowing, largely to improve access. Otherwise the artificially established plantation needs, and receives, no more attention than does a naturally regenerated crop.

Until the present century foresters usually accepted the land much as they found it. Their reaction to infertile soil was to plant less exacting kinds of trees and accept lower returns. Development of modern machines and a growing understanding of plant nutrition and soil chemistry now enable them to improve sites much as a farmer does, and to increase output substantially. Mechanical draining, using tractor-drawn plows to create deep open drains and so aerate the soil, is now usual on the peaty swamps of Europe, especially in Finland. On the hard heathlands of Great Britain, 300,000 acres of new afforestation land have been broken up, during the past 30 years, with sturdy plows designed to turn over firmly compacted soil layers. Plowing facilitates penetration of air, water, and tree roots, checks weed growth, and lessens fire hazard. So far it has usually been confined to strips for each row of trees, but full plowing as done on a farm promises further advantages. Forest crops are rarely irrigated as returns are too slow for the high capital cost involved.

Fertilizer trials have been concentrated on the use of nitrogen, potassium, and phosphorus, the three elements found most beneficial in agriculture. As a rule, additions of phosphorus have given greatest benefits at least cost. Only moderate amounts, around five tons of ground mineral calcium phosphate per acre, are needed. This can be spread around individual trees as two ounces per tree at planting time, or distributed evenly over the whole area at a later stage of growth, by spraying from a helicopter or light aircraft. The phosphorus is gradually taken up by the roots and carried to the leaves, where it acts as a catalyst to promote better photosynthesis and therefore

faster growth. As the leaves fall, the phosphorus is returned to the soil and recycled. Small additions therefore give perpetual benefits to the forest land. Fertilizers also are applied to maturing timber crops on nutrient-deficient soils, to gain greater volume growth over the years preceding final felling.

In theory, the quality of timber can be greatly improved by pruning away dead side branches as each overshadowed limb dies. Wood formed outside the pruned zone holds no knots and fetches higher prices as "clear" lumber for specialized uses. But high labour costs, for a long-delayed price improvement, make this trimming doubtfully economic. Most clear lumber comes from the overshadowed lower trunks of giant trees in natural forests and has incurred no pruning charges.

**Fire prevention and control.** Forest fires seldom occur in tropical rain forests or in the deciduous broad-leaved forests of the temperate zones. But all coniferous forests, and the evergreen broadleaves of hot, dry zones, frequently develop conditions ideally suited to the spread of fire through standing trees. For this, both the air and the fuel must be dry, and the fuel must form an open matrix through which air, smoke, and the gases arising from combustion can quickly pass. Hot, sunny days with low air humidity and steady or strong breezes favour rapid fire spread. In conifer woods the resinous needles, both living and dead, and fallen branchwood make an ideal fuel bed. The leaves of evergreen broadleaves, such as hollies, madrone, evergreen oaks, and eucalyptus trees, are coated in inflammable wax and blaze fiercely even when green. Once started, fire may travel at speeds of up to ten miles per hour downwind, spreading slowly outward in other directions, until the weather changes or the fuel runs out.

Effective fire control begins with a field survey and map to identify the areas at risk, delineate them, and define and improve the barriers or firebreaks that may limit fire spread. Natural barriers include rivers, lakes, ridge tops, and tracts of bare land. Artificial barriers can be roads, railways, canals, and power-line tracks, but usually extra firebreaks must be cut to link these and provide wider gaps that fire cannot readily jump. Belts of land from 30 to 60 feet wide are cut clear of trees or left unplanted when a new forest is formed. Sometimes the soil is left bare and cultivated only at intervals to check invasion by weeds. Usually it is sown with an even crop of low perennial grasses or clovers, kept short by mowing or grazing. This checks soil erosion, provides an evergreen fireproof surface, and allows access on foot, by car, or in an emergency by fire-fighting trucks. Surfaced roads, serving also for lumber haulage and access for recreation, are of critical importance in fire fighting. Signposts are needed to guide fire crews unfamiliar with the woods, and to mark water supplies and rendezvous points.

Fire watching is essential through seasons of high risk.

Wooden or steel fire towers are set on hilltops where the fire watcher, or ranger, equipped with binoculars, maps, and a direction scale that enables him to ascertain the compass direction of smoke, is linked by telephone and radio with the fire-control base. If a fire can be seen from two or more towers its precise position is quickly pinpointed by mapping the intersection of cross bearings. An alternative method of fire watching, widely used in Canada, is to fly observers in light aircraft continuously over the forest, providing both an incomparable range of view and the ability quickly to approach outbreaks, for close inspection and first-hand radio report.

Once an outbreak of fire is sighted, the critical next step is to rush trained men to the spot to suppress it, which in effect means restricting its spread. Small brush fires—the great majority of all forest fires—are attacked by beating their edges with spades, beaters consisting of flaps of noncombustible material fixed on long handles, or simply the newly cut green branches of trees. Small amounts of water can be carried on backpacks and applied forcefully by hand pumps; to give this limited amount of water maximum effect a chemical derived from plant algae is added, which makes the water adhere to smouldering foliage. Mattocks or spades are used to scrape litter aside, forming barriers of bare earth, while other firebreaks are created by felling belts of trees with axes or power saws. Trained fire crews with such hand equipment can be carried quickly to the fire by truck, or even dropped by parachute.

Motorized fire pumps prove very effective provided they can approach the fire by hard roads and can get access to ample water supplies. The volume of water that can be carried by a fire truck rarely exceeds 2,000 gallons (about 7,600 litres), only enough to quell minor outbreaks. Bulldozers, where available, can rapidly scrape away inflammable litter and build up banks of fireproof bare earth (Figure 4). Aircraft can quickly carry in water bombs consisting of waterproof cardboard containers that burst on impact, but weights are limited and skilled pilotage is needed to land the bombs at effective spots. An alternative developed on Canadian lakes is to fill the floats of a seaplane with water, which is done automatically as it skims the lake on takeoff and to discharge this through escape valves over the fire.

In combatting large fires, an almost military strategy is required. A senior forest officer must coordinate team work, usually by short-wave radio, much as a general in battle. Acting on the basis of aerial observation, he directs operations by phone and radio to all available sources of aid, including associated forests, public fire services, and the armed forces. Big blazes may last for days; plans must be made for reliefs as well as reinforcements, and for food-and-drink supplies, overnight camps, and first aid. Under such planning and control serious casualties are infrequent.

## Causes of fires

Modern organization lessens the risk of the great holocausts of the past, when whole townships went up in smoke with high loss of life. Timber losses also have been held down to a small percentage of the crops at risk, which nevertheless represents a substantial loss. Since nearly all forest fires are man-made, the only significant exceptions being those caused by lightning strikes, a major preventive measure is the education of the public. Main sources of wildfires are smokers, picnic fires, and graziers who light fires to improve spring grazing.

**Insect and disease protection and control.** When protecting his crops against insect pests and fungal diseases, the forester faces a formidable task. Trees are individually so large that chemical or physical treatments, which might be practicable for smaller plants in gardens, farms, or orchards, become both technically difficult and prohibitively expensive. Trees also grow larger each year, and a treatment applied today fails to reach and save next year's fresh shoots and leaves. With life spans averaging 100 years, for long-delayed harvests of lumber, the cost of annual applications, though acceptable for fruit trees, becomes altogether too high for a crop of forest trees to carry.

Foresters therefore aim, in the long-term, to avoid serious trouble by using only trees known to resist existing insect pests in the regions where they are grown. Strict quarantine measures are applied along many international frontiers to exclude foreign pests and diseases. Typically disasters have arisen where quarantine has failed or has been imposed too late. The American chestnut, *Castanea dentata*, has been virtually wiped out by the chestnut blight fungus, *Endothia parasitica*, which does little harm to related trees in its native China. Elms have suffered severely, both in Europe and in the U.S., from the elm disease fungus, *Ceratocystis ulmi*, which was first detected in the Netherlands and is carried from tree to tree by flying beetles. Minute aphids, probably introduced on living plants from Asia, now make it impossible to raise commercial crops of two conifers once valued in Britain, namely, the white pine, *Pinus strobus*, from New England, and the European silver fir, *Abies alba*, native to Switzerland. Once a quarantine barrier has been crossed, eradication is virtually impossible in the vast, irregular structure of the forest.

Short-term measures to check a sudden plague of insects, or outbreak of fungal disease, are now technically possible through the development of aircraft and insecticidal or fungicidal sprays. They demand exacting advance studies by skilled botanists, entomologists, plant pathologists, and meteorologists to determine the precise stage in each organism's life cycle and the correct weather conditions for spraying to be effective at acceptable cost. Action has most frequently been taken against exceptional outbreaks of defoliating caterpillars, including those of the gypsy moth in the U.S., the nun moth in Central Europe, and the pine looper moth in England. At the time of year when feeding caterpillars are most vulnerable, light aircraft fly across the forest on carefully planned courses, distributing a strong insecticide.

A disadvantage of these blanket treatments by strong chemicals is that they also eliminate parasitic and predatory insects that serve as natural controls on the pest's numbers; they may also adversely affect bird life. It has been maintained that natural control through insectivorous organisms, combined with physical factors like cold winters, provides adequate checks. Occasional drastic interference by man may possibly prove harmful by disrupting the so-called natural balance. In practice, large-scale chemical treatments of forests are infrequent and are restricted to a small proportion of the areas at risk.

Less spectacular preventive measures are commonly taken as routine steps in practical forestry to lessen anticipated losses. Nursery stock, easily reached and handled, may be sprayed with a specific fungicide in the seedbeds, or be dipped in an insecticide prior to planting in the forest. Certain harmful beetles breed below the bark of felled trees; prompt removal of the bark makes this impossible. Alternatively, the early removal of the logs

from the forest to distant sawmills transfers emerging beetles to places where they can do no harm. Stumps of freshly felled conifers can be easily and cheaply treated by brushing on a fungicide to check the white root-rot fungus, *Fomes annosus*. This is a serious agent of decay that spreads from root to root, underground, after gaining entry to the first tree it attacks via the exposed surface of a felled stump.

Every part of a growing tree—root, trunk, bark, leaf, flowers, and seed—is potentially subject to attack by some harmful insect or fungus. Continuing research by entomologists and plant pathologists facilitates effective action in emergencies.

**Watershed management.** The control of tree cover to safeguard watersheds plays a growing part in forest management, as greater heed is given to the conservation of soil and pure water. Forests provide a permanent and self-perpetuating cover in depth, at low cost. A watershed from which all tree cover is removed has its soil exposed to severe climatic damage.

The guiding principle of management where erosion threatens is therefore the maintenance of continual cover. Ideally, this is achieved by single-stem harvesting. Only one tree is felled at any one point, and the small gap so created is soon closed by the outward growth of its neighbours. This is effective where desirable crop species are available to fill in the gap, by natural regrowth, but it does not permit artificial planting or a change to a more profitable kind of tree. In many protection forests therefore, clear cuttings must be made, but these are kept small and are aligned along hill contours to limit downward movement of soil.

The concept of water balance sets the factors that increase water supply in the woods against those that diminish it. Water arrives as rain, snow, hail, or condensing fog. That which is intercepted by foliage is called interception loss; the remainder is called the throughfall. To this must be added stemflow, the water that is intercepted by the tree canopy and runs down the tree trunks. Evaporation takes place from both foliage and soil and is augmented, and even exceeded, by transpiration of the sap water that roots draw from the soil to support the life of the foliage above.

Water falling on a saturated soil, or conversely on a very dry one, gives immediate runoff to feed streams, which are otherwise fed by percolation through a moist, though unsaturated, soil. Deep forest soils have a high water-storage capacity. Unless they are very porous and freely draining they have a water table or level below which the subsoil is saturated. The depth of this varies seasonally with the water balance. Roots, which need air, cannot exploit soil below the water table. The drainage of land having a high water table usually increases the productivity of the forest and its seasonal water storage capacity, though the amount of water held permanently captive in the soil becomes less.

Despite this uncertain balance of water gain and loss, forests are accepted everywhere by water-supply undertakings as desirable cover. Water release from forested land is gradual and reliable, with the deep porous soil giving storage capacity additional to that of reservoirs. More important, it carries hardly any silt, whereas water running more rapidly off bare land carries sand, clay, and gravel that can silt up reservoirs. Water from forest springs is exceptionally clear and pure, requiring minimum filtration or chemical treatment. Since few people work on the watershed, risks of pollution are low, and the dangers of contamination by agricultural residues, such as dung, chemical fertilizers, and weed killers are far lower than on farm land.

Experiments to compare the water yield of two similar watersheds, one forested and the other unforested, have proved difficult in practice. It is hard to find any two areas that receive identical rainfall, either before or during the course of the experiment, which must extend over many years to cover annual and seasonal variations.

It is generally agreed, however, that unforested land sheds water swiftly, causing sudden rises in the rivers

Single-stem harvesting

## Control of defoliating caterpillars

Local  
weather  
effects

below. In contrast, the outflow from forests, though less in total, is gradual, has lower peaks, and is sustained over longer periods. Over a large river system, such as that of the Mississippi, this has definite advantages since it lessens the risk of floods. It also provides conditions more favourable to fishing and navigation than does the less regular outflow from bare land.

The long-standing belief that forests everywhere increase rainfall has not been substantiated by scientific enquiry. Local effects can, however, prove substantial, particularly in semiarid regions where every inch of rain counts. The air above a forest, as contrasted with grassland, remains relatively cool and humid on hot days, so showers are more frequent. Fog belts, such as those found along the Pacific seaboard of North America and around the peaks of the Canary Islands, give significant water yields through the interception of water vapour by tree foliage. The vapour condenses and falls as solid water, in a process described as fog drip.

**Recreation and wildlife management.** From the earliest times man has looked to the forests for recreation. An old Malayan proverb asserts: "The Almighty does not count, in the reckoning of a man's years, those days that he spends in hunting." Today, when millions of workers are tied to their factory bench or office desk for most of the year, there is great need for the spiritual refreshment and physical exercise that forests can provide.

Animal life of all kinds, from elephants, giraffes, and deer to eagles, pheasants, and birds of paradise, along with rare plants such as jungle lilies, form a main attraction of the woods and oblige the forest manager to deal firmly yet diplomatically with three competing groups of people.

Those who only seek to preserve wild life—the conservationists, biologists, and nature lovers—have grown so numerous that their visits to the haunts of the rarer creatures must sometimes be controlled, lest their sheer numbers drive away the very beast or bird they come to seek. As an extreme instance, in 1962 a special law was passed in Scotland to keep thousands of photographers at a tolerable distance from the nest of a single pair of ospreys, or fish-eating hawks, unique in that country.

A second group comprises neighbouring farmers who want the numbers of animals allowed to remain in the forest restricted to levels that result in little or no damage to their crops and livestock, and in some regions, their lives. Forest-based marauders include deer that devour grain crops, wolves that take sheep, and, in Africa, lions.

The third group consists of the hunters and sportsmen who look to the woods as the resort of game birds and animals.

Obviously the same animal can present a different aspect to each group. A Bengal tiger, for example, provides a biologist with a classic example of a carnivorous beast living in harmony with a jungle environment and restraining its main prey, deer, from undue increase in numbers. But to a village peasant it is a menace to his cows and goats, and a threat to the safety of himself and his family, while a sportsman regards it as a magnificent quarry demanding all his skill.

Protection  
of wildlife

In virtually every country the sporting aspect of woodland wildlife management is controlled, to some degree, by general game laws, which also apply outside the forests. These prescribe licenses for firearms, and the taking of specified birds and beasts; they usually lay down closed seasons during which certain game may not be shot, and also set limits to the sportsman's bag of particularly rare species. In the U.S. a peculiar situation exists whereby the game legislation of the separate states applies unchanged over most publicly owned forests. In other countries the forest managers are in a stronger position, since local game laws are adjusted to their particular requirements.

Within the concept of multiple use, which requires that forests yield timber and water besides protecting soil and providing recreation, enlightened forest managers aim to develop maximum acceptable public usage. Conflict-

ing forms of enjoyment can usually be separated by space, and also by time of day or time of year. Skillful siting of roads, picnic points, car parks, campgrounds, and restaurants ensures that the great majority of visitors congregate in relatively small portions of a large forest. The tourist season falls around midsummer, but the main season for shooting deer or pheasants comes in the fall.

A general practice is to estimate the numbers of people likely to use recreational facilities, both the year round and at peak periods, such as national holidays falling in summer. Such estimates allow for the probability that improvements in facilities will be followed by increased public use. Restrictions to numbers below the possible demand are sometimes inevitable, but never popular, and often both difficult and costly to enforce.

In the U.S. an effective means of controlling entry, and obtaining some revenue to meet upkeep and administration costs, has been found in road tolls and parking charges. The public has become accustomed to these on freeways and in urban surroundings and regards them as reasonable in relation to the numbers of passengers that can be carried in each car. Nevertheless, these charges presuppose a high level of highway upkeep and wages for staff to collect them. In other countries, where there are long traditions, amounting in places to legal rights, of free public access to national and communally owned forests, threaded by minor roads and rights-of-way, this method is not generally applicable. Local by-laws often facilitate control but are not easily enforced over widespread woodlands.

Camping is a form of woodland recreation that increases in popularity as better equipment, carried or towed by automobiles, is developed. Forests provide ideal campsites, in which large numbers of cars, tents, and caravans can be sheltered, concealed from view, and isolated from each other. The trees and their associated lakes, streams, and hills provide opportunities for walking, fishing, swimming, and nature studies.

Organization is essential, since sites must be allocated, roads and hard standings built, water supplied, and sanitary facilities installed. Fortunately funds for these developments are readily available from camping fees levied on a "pay-as-you-stay" basis.

The interpretation of what visitors see in the forests has become a growing activity of most forest services. Town dwellers often have no immediate appreciation of forest trees, plants, birds and beasts, or of geological and scenic features. Nature trails, guidebooks, signposts, forest-centre museums, and information stations assist visitors who come to learn as well as to enjoy.

Forests as  
campsites

#### WORLDWIDE STATISTICS ON FORESTRY

Detailed statistics on the world's forest wealth are compiled every five years by the Food and Agriculture Organization of the United Nations. They relate to areas of land under forest, volumes of standing timber, annual increases in timber volume, and amounts of timber harvested for use. They also bring out the areas of forest, and the volumes of timber, relative to the number of people living in each country, which may have great significance for human economy.

**Areas of forest.** Out of the world land area of 13,333,000,000 hectares, some 4,126,000,000 hectares, or 32%, are classed as forest land. (One hectare is about 2½ acres.) Details are given in Table 1.

Except for Asia and the Pacific, most regions have at least one-quarter of their land surface under forest. South America, North America, and the U.S.S.R. each have over one-third.

When forest areas are related to population, great differences become apparent. The world average of 1.1 hectares per head hides two extremes. Asia and Europe, with teeming peoples on limited land, show only one-third of a hectare per head. North America has 3.4 hectares, but this is exceeded by the U.S.S.R. with 3.8, and South America with no less than 4.9.

**Timber volumes.** The world as a whole possesses 238,000,000,000 cubic metres of standing timber, made

Table 1: Areas of Forest

area	land area (000,000 hectares)	forest land (000,000 hectares)	percentage of land under forest	forest area per head (hectares)
North America	1,875	750	40	3.4
Central America	272	76	28	0.87
South America	1,760	890	51	4.9
Africa	2,970	710	24	2.1
Europe	471	144	31	0.32
U.S.S.R.	2,144	910	42	3.8
Asia	2,700	550	20	0.27
Pacific Area, including Australia	842	96	11	5.2
Total	13,033	4,126	32	1.1

up of 114,000,000,000 cubic metres of conifers or softwoods, and 124,000,000,000 cubic metres of nonconifers, mainly broad-leaved trees or hardwoods (one cubic metre is about 1.3 cubic yards).

The annual timber harvest (averaged from 1960 to 1962) comprises some 2,090,000,000 cubic metres (including bark). It therefore amounts to only 1 percent of the standing volume. No reliable world figures are available for annual overall increase in volume, but general experience suggests that it balances losses due to timber harvesting, plus an inevitable "drain" due to fires, diseases, windfalls, and insect attacks.

Details, by regions, after adjusting volumes for bark, are given in Table 2.

Table 2: Annual Timber Harvest

area	standing volume of timber (000,000 cubic metres)	annual timber harvest (000,000 cubic metres)	harvest as percentage of standing volume	harvest per head (cubic metres)
North America	44,000	434	1.00	1.90
Central America	800	47	5.20	0.65
South America	78,000	199	0.25	1.30
Africa	3,800	216	5.00	0.65
Europe	12,000	353	3.00	0.74
U.S.S.R.	79,000	395	0.50	1.60
Asia	17,000	419	2.60	0.21
Pacific area, including Australia	3,800	27	7.00	1.60
total	238,000	2,090	0.90 (average)	0.65

When annual harvests are related to standing volumes, wide regional differences appear. In Europe, where most forests are accessible and all felled timber is used, 3 percent of the growing stock is cut each year. This is made good by annual regrowth, and the forests do not diminish. In North America, South America, and the U.S.S.R., the annual cut does not exceed 1 percent of the standing volume. The remoteness from markets of great expanses of conifer forests in Canada and Siberia, and of tropical jungles in the Amazon basin, explains such low proportions. In these inaccessible forests, far more wood is still lost by fire, decay, and insect attack than is cut by man for his own use.

Despite the development of coal, oil, gas, and electric power, nearly half the wood felled in the world is used as fuel. World fuel wood consumption, mainly in the less industrialized countries, amounts to 990,000,000 cubic metres annually, while industrial uses require 1,100,000,000 cubic metres, giving a total of 2,090,000,000.

The harvest of timber per head of the population is highest in North America, at 1.9 cubic metres per person annually, or three times the world average. The comparable figure for the U.S.S.R. is 1.6 cubic metres, but the European average is only 0.74 cubic metre. In Asia only 0.21 cubic metre of timber is harvested each year, for each inhabitant. Though these differences are adjusted to some degree by international trade, it is true to say that the forest-rich countries maintain a higher living standard than those poor in timber resources. The systematic harvesting of well-stocked forests ensures ample fuel, sawmill timber, pulpwood for the paper and

packaging industries, and raw material for many manufacturing industries.

**BIBLIOGRAPHY.** Forestry textbooks usually deal with one specialized aspect of the science, often in one geographic region; tree species and their native habitats vary widely. A. REHDER, *Manual of Cultivated Trees and Shrubs, Hardy in North America*, 2nd rev. ed. (1940), is a thorough regional botanical survey treating both cultivated and wild species. W. DALLIMORE and A.B. JACKSON, *A Handbook of Coniferae and Ginkgoaceae*, 4th ed. rev. (1966), gives world-wide botanical details for these major natural orders. P.W. RICHARDS, *The Tropical Rain Forest* (1952), describes the make-up of natural tree and plant associations, comprised of many species that thrive together.

The theory and practice of raising and tending tree crops are treated in such silviculture manuals as J.W. TOUMEY and F.S. KORSTIAN, *Foundations of Silviculture*, 2nd ed. rev. (1947, reprinted 1962); and F.S. BAKER, *Principles of Silviculture* (1950), discussing temperate-zone forests. Details of handling seed and young stock are comprehensively treated in J.W. TOUMEY and F.S. KORSTIAN, *Seeding and Planting in the Practice of Forestry*, 3rd ed. (1942, reprinted 1960); and in the UNITED STATES DEPARTMENT OF AGRICULTURE, *Woody-Plant Seed Manual* (1948). The care of tree crops in tropical jungles of both hemispheres is outlined in the FOOD AND AGRICULTURE ORGANIZATION, *Tropical Silviculture* (1958). A wide range of Asiatic conditions are discussed in H.G. CHAMPION and A.L. GRIFFITH, *Manual of General Silviculture for India* rev. ed. (1948); and R.S. TROUP, *Silviculture of Indian Trees* (1921), an exceptionally thorough and well-illustrated work.

Forest protection is treated in specialized textbooks discussing specific hazards. K.P. DAVIS, *Forest Fire: Control and Use* (1959), outlines fire perils, precautions, and combat. J.S. BOYCE, *Forest Pathology*, 3rd ed. (1961); and T.R. PEACE, *Pathology of Trees and Shrubs* (1962), give specific details of fungal diseases, climatic dangers, and airborne fume and salt damage. Insect pests of North American trees are described by R.F. ANDERSON, *Forest and Shade Tree Entomology* (1960); and those native to Europe by R.N. CHRYSTAL, *Insects of the British Woodlands* (1937).

Basic principles of tree felling and timber haulage are covered in N.C. BROWN, *Logging* (1949); and A.E. WACKERMAN *et al.*, *Harvesting Timber Crops*, 2nd ed. (1966). Methods and machines evolve so rapidly that recent issues of a trade periodical, such as *World Wood* (monthly), should be consulted for current practice and equipment.

Principles of forest management, worldwide in application, are systematically outlined by D.R. JOHNSTON, A.J. GRAYSON, and R.T. BRADLEY, *Forest Planning* (1967). The requisite basis of factual survey is detailed by S.H. SPURR, *Forest Inventory* (1952); and B. HUSCH, *Forest Mensuration and Statistics* (1963). Financial implications for a particular region are given in A.C. WORRELL, *Economics of American Forestry* (1959). The leading international source of forest area and timber output statistics is the FOOD AND AGRICULTURE ORGANIZATION, *World Forest Inventory* (1963). Fundamental studies of physical bases of forest distribution and yield include: S. HADEN-GUEST (ed.), *A World Geography of Forest Resources* (1956); and S.S. PATERSON, *The Forest Area of the World and its Potential Productivity* (1956).

(H.L.E.)

## Forests

The forest is a complex ecological system dominated by trees, which form a buffer for the earth against the full impact of the sun, wind, and precipitation. Whatever the type of forest—whether evergreen or deciduous, temperate or tropical—the trees that constitute it provide special environments, which in turn affect the kinds of plants and animals that can live within the forest.

### THE ENVIRONMENTAL SETTING

**Climate.** Forests can develop wherever there is an average temperature greater than 10° C (50° F) in the warmest months and an annual rainfall in excess of 200 millimetres (about eight inches). Above these limits there exists an infinite variety of tree species grouped into a number of stable forest types determined by the particular conditions of the environment. Boundaries between these types are difficult to determine precisely, but the major forest communities can be linked to broad latitudinal zones (see Figure 1).

The forests of the high latitude subpolar regions constitute the taiga and are dominated by stands of such coniferous

fers as pines (*Pinus*), spruces (*Picea*), and larches (*Larix*). Taiga forests are found only in the Northern Hemisphere, where winters are long, with six months of the year showing an average maximum temperature of less than  $0^{\circ}\text{C}$  ( $32^{\circ}\text{F}$ ), there is a growing season of one to three months, and precipitation varies between 250 millimetres (about ten inches) and 500 millimetres (20 inches), evenly distributed throughout the year. Broad-leaved trees predominate in the middle latitudes, where there are six months with an average maximum temperature above  $10^{\circ}\text{C}$  ( $50^{\circ}\text{F}$ ), precipitation in excess of 400 millimetres (about 16 inches), and a growing season of between 100 and 200 days. Broad-leaved deciduous forests occupy the cooler regions and are dominated by associations of several species including oaks (*Quercus*), beeches (*Fagus*), birches (*Betula*), aspens (*Populus*), elms (*Ulmus*), and maples (*Acer*).

Mixed forests form a transition between the coniferous taiga and the deciduous broad-leaved forest. Further south, as frost becomes infrequent, the composition again changes, and a temperate rain forest of evergreen broad-leaved species develops. In the Southern Hemisphere the forest type contains conifers similar to the true pines: Kauri pine (*Agathis*), Chile pine (*Araucaria*), and white

pine (*Podocarpus*). As rainfall becomes more seasonally distributed a scrublike forest of stunted trees develops, typical of the Mediterranean maquis, the Californian chaparral, and the Australian mallee. The natural vegetation of the lowland tropical latitudes is the tropical rain forest, dominated by a rich variety of broad-leaved evergreens adapted to hot and humid conditions. Outside the humid tropical zone, where temperatures remain high but rainfall becomes more seasonal, the broad-leaved forest becomes less varied and more deciduous as it yields to the parklike savanna and then to dry thorn forest.

Precipitation and temperature play important roles in the determination of forest type. The combined effect controls the amount of soil water available for tree growth. Water is lost from the forest by evaporation from the tree crowns and by transpiration from the leaves, both processes in large measure controlled by air temperature. In the middle latitudes an annual precipitation of between 200 and 500 millimetres (eight to 20 inches) concentrated in the summer months, when the evaporation power of the air is high, supports a scrublike drought-resistant forest formation; the same precipitation, evenly distributed throughout the year, can support a rich broad-leaved deciduous forest.

Determination of forest type

The principal influence of sunlight is on the air temperature. At high latitudes the sun's rays strike the earth at a larger angle and therefore give less heat than at low latitudes. More solar energy is available in the tropics, where solar rays strike the earth more directly; as a consequence, tropical forests can be expected to be more productive than temperate forests. The difference is, however, not so great as might be anticipated because of the higher rate of respiration in the tropical environment. Another influence of solar radiation is through the day length (photoperiodism), which varies according to the season and affects flowering, bud opening, and a range of other physiological activities.

**Topography and soil.** Topography is also an important influence on forest vegetation; an increase of 300 metres (1,000 feet) in altitude is equivalent to a movement of 480 kilometres (300 miles) closer to the pole at sea level, so that a broad correlation can be drawn between montane forests and those at higher latitudes. Exact duplication of forest type is not expected, however, since the montane environment differs in important respects from that at an equivalent lowland station; notably, it has a shorter day length, greater precipitation, and higher maximum temperatures. The altitude at which the lowland forest passes into an Alpine type depends chiefly on the length of the growing season and the frequency of frosts. The zonation of forest types with increasing altitude is seen in the sub-Alpine forest formations of the middle latitudes and the montane forests of the tropics. In the middle latitudes the sub-Alpine forest is dominated by the more tolerant conifers (pines and larches), with poorly formed deciduous broad-leaved species (beeches, birches, and willows) occupying the tree line, the upper limit. In the tropics altitudinal zonation rises from the rain forest through a transition zone to a mossy forest of reduced stature, but featuring a profuse development of air plants (epiphytes), lichens, and mosses. The final stage is the development of a broad-leaved elfin forest, so called because the trees are stunted, high on tropical mountains.

Another important physical influence on forest type is the soil. The most important feature is soil depth, because this not only determines the capacity of the tree roots to reach for water and nutrients but also determines the stability of the trees. Forest soil shows considerable variability, but common features are depth, relative infertility, an undisturbed condition, a large quantity of woody perennial roots and characteristic plant and animal life. Quick-draining, highly stratified, sandy soils (podzols) are characteristic of the taiga. Brown forest soils, which are richer in nutrients, less porous, and less stratified than podzols, are characteristic of deciduous broad-leaved forests. Tropical rain forests and savanna woodlands have deep, intensely weathered clayey soils, rich in aluminum or iron, which gives them their reddish or yellowish colour. Variation in soil type may be considerable even in small areas, as for example in regions subject to past glaciation; this variation is often reflected in species preference. In the mixed broad-leaved-conifer forests of the middle latitudes, the conifers are usually found in poorer sandy soils of low alkalinity, whereas the broad-leaved trees are found on richer clayey soils.

**Wind and fire.** Wind plays a primary role in the creation of the forest, by assisting in pollination and seed dispersal, but has only a secondary role in its maintenance. Air movement affects transpiration and may be a significant ecological factor in determining some forest types; e.g., in West Africa the dry harmattan wind reduces humidity to a very small value for short periods and is believed thereby to affect species distribution. Violent winds destroy forests either by uprooting or breaking stems; prevailing winds affect tree growth by producing eccentric stems and deformed crowns. Prominent among the physical destructive agents in the forest is fire, which usually results from man's encroachment. Infrequent natural fires arising from lightning may be responsible for the development of stable fire forest types, such as Douglas fir (*Pseudotsuga menziesii*) stands in North America and the savannas of Africa.

#### THE BIOTIC COMPONENT

Forests are distinguished from each other primarily by their composition. The number and variety of species present in the forest community depends upon the age and density of the tree cover, the type of climate and soil, and the geological history of the region. The richest forests in terms of total species composition are those having older and more open stands of trees, situated in favourable climates, and on fertile soils that have been relatively undisturbed in recent geological time. Thus within a given forest community there exists a complex interaction between the vegetation and the environment, which leads to the development of micro-environments with a wide variety of physical properties.

**Plant stratification and its influence on the forest environment.** The forest community shows an extensive vertical stratification, from the tops of the tallest trees to the tips of the deepest roots. The effect on the stratification above ground is to moderate climatic extremes progressively downward from the treetops to the soil surface.

The pattern of vertical stratification varies with forest type (see Figure 2). The conifer-dominated forest has the

Figure 2: Vertical stratification in different forest types (tree size not to scale).

simplest structure: the tree layer is continuous up to 30 metres (98 feet) high, the shrub layer is absent or spotty, the field layer of herbaceous plants is best developed in more southerly forests, and the ground layer of liverworts, mosses, and lichens is almost uniform, particularly in the northerly forests. In the deciduous broad-leaved forests stratification becomes more complex. The continuous canopy of trees is between ten and 30 metres (33–98 feet) tall but is subdivided into distinct upper and lower stories, in addition to the shrub field and ground layers. In the tropical rain forest stratification is even more complex, with at least three canopy layers—a discontinuous uneven top layer, a level midlayer of continuous canopy (30–40 metres), and a spotty layer of shorter trees (15–20 metres) with narrow crowns. The field layer is rich in ferns that approach treelike proportions but also contains islands of herbaceous plants, which form an insignificant proportion of the total number of individuals.

Considerable lateral variability exists within each layer, or stratum, resulting from local differences in environmental conditions. Forests thus provide a great range of habitats for both other plants and animals. The most important physical factors influenced by forest structure are air temperature, precipitation, and soil characteristics; of secondary importance are sunlight and wind.

The forest environment exercises a moderating influence on air temperature, which is especially marked at the extremes of the temperature range. The forest is cooler in summer and warmer in winter, when compared with surrounding areas.

Richness of habitats in forests

The effect is most marked where seasonal temperature variation is greatest; *i.e.*, the further removed from the Equator the greater the effect. In the tropics, seasonal climatic variation is conditioned more by rainfall than by temperature, and, although the forest environment reduces average maximum temperatures in the wet season more than in the dry season, there is little effect on minimum temperatures.

The ameliorating effect of the forest on air temperature results from the vertical stratification of the forest vegetation. Seasonal influences are less marked as the canopy cover decreases; thus winter temperatures are little influenced in the leafless deciduous forest, although in the summer the same forest, in full leaf, shows not only differences in temperature compared with outside conditions but also a temperature gradient within the various strata of the forest. Daily fluctuations of temperature within the forest also depend upon the nature of the vertical stratification. In the single-storied temperate conifer forest, temperatures are highest nearest the tree crowns. At night, heat is radiated from the crowns and the surrounding air is cooled, increases in density, and sinks to the ground. Subcanopy temperatures are therefore lower than canopy temperatures. During the day the temperature gradient is broadened; the crowns of the tree are warmed by the sun, but at the same time shade the subcanopy region. As the canopy structure becomes more complex, more than one form of daily fluctuation in temperature can exist. In the tropics the luxuriant development of the lower tree strata may impede air movement so that at night the upper canopy may lose heat faster than the cooled night air falls. In such conditions the subcanopy at night may be warmer than the upper canopy, whereas during the day the temperature gradient is reversed. Forest vegetation also has a marked effect on soil temperature. Forest soils are cooler in the day and warmer at night and show less seasonal fluctuation than similar soils outside the forest.

Forest soils

As precipitation falls on the forest, its movement is greatly influenced by the forest cover. The dense tree layer initially intercepts precipitation, some of which is immediately evaporated back to the atmosphere. Conifers tend to hold more water than broad-leaved trees (there is, of course, little or no interception from dormant leafless trees). Water penetrates to the soil from the canopy either through stem flow down the main trunks and thence into the soil along the root channels, or by direct absorption in the litter of the forest floor. In either case the velocity of the fall is reduced, there is little soil compaction or surface runoff and consequently a reduced risk of soil erosion. Compared with stations outside the forest, the moisture content of forest soil, particularly at the surface, tends to be high. Water is lost through surface evaporation, which is low in the forest because of the ameliorating effect of the tree cover, and by transpiration, which is high and may be a limiting factor in tree growth. The water budget for the forest will vary greatly with type and situation, but the ability of the forest cover to reduce erosion and to even out the yearly fluctuations of stream flow are recognized advantages to water catchment areas. Although there is no evidence that forest conditions affect the amount of precipitation, the forest atmosphere is always more humid than surrounding areas.

Types of organic matter

The forest floor consists of a layer of organic matter overlying mineral soil. In the temperate regions two major types of organic matter predominate, the mull and the mor. The mull is associated with broad-leaved deciduous forests, especially those growing on relatively rich soils. It is less acid than the mor type, of a granular structure, and contains a considerable admixture of mineral soil. There is an indistinct boundary with the upper horizons, due to the activity of earthworms moving freely between the decomposed layer of litter and the mineral soil. Mor humus, on the other hand, is strongly acidic and of a matted structure (attributed to the network of fine roots). There is a distinct boundary between mor humus and mineral soil, with little evidence of the activity of mixing agents. The earthworm population is smaller, although fungal activity may be greater, than in mull. Mor is char-

acteristic of the northern coniferous zone and is especially evident under pines growing on mineral-poor soil, although some broad-leaved species, especially oaks (*Quercus*) and beeches (*Fagus*) produce a mor humus when growing on similar soils. The differences between mull and mor are generally attributed to differences in the chemical composition of the plant material from which they are derived and the nature of the mineral soil, rather than to the rate of decomposition. Tropical soils, however, are affected by the rate of decomposition. Persistently high temperatures and humid conditions accelerate decomposition of organic matter, releasing minerals rapidly. Occasionally in swampy conditions where acidic groundwater percolates laterally, and in conditions of heavy, regular rainfall, a thick peat, made up almost entirely of woody plant debris, may build up.

The forest structure produces less spectacular, though equally important changes in wind speed and solar radiation. Dense multistoried forests are most effective in reducing overall wind velocity in the subcanopy layers. The filtering of the various tree strata also affects solar radiation. A tropical rain forest typically allows not more than 1 percent of visible light to reach the forest floor, a conifer forest 10 percent, and a deciduous forest about 5 percent when in leaf but between 50 and 90 percent when leafless. Forests in full canopy approach the maximum possible efficiency in their utilization of solar energy: 60–90 percent is absorbed, and the remainder is reradiated and used up by evaporation and transpiration. In qualitative terms the light values within the forest vary since the canopy vegetation absorbs more red than blue light. Blue light is, however, utilized at subcanopy and low-canopy levels and is said to reduce the tendency toward side branching, a possible explanation for the observation that understory trees are generally pyramidal but adopt a rounded crown when they achieve upper story height. In their youth some trees, such as oak and pine, require much sunlight, whereas others, spruce, fir, beech, and many tropical hardwoods, almost demand shade.

As indicated earlier, stratification within the forest supplies a wide variety of habitats for both plants and animals and provides the opportunity for considerable interaction between organisms.

**The role of decomposer organisms.** The fungi of the litter and mineral soil layers play an important role in the chain of litter decomposition and the release of nutrients in the soil. Some species live in a mutually beneficial partnership (mycorrhiza) with active tree roots, thus improving the efficiency of nutrient uptake by the trees. On the other hand, some species are parasitic and may cause devastation; *e.g.*, the chestnut blight, which has decimated the population of native chestnut in North America, and the blister rust, which is a serious pest of white pine (*Pinus strobus*). The fungus *Fomes annosus* attacks a number of conifer species; it is transmitted from tree to tree not only by spore infection via cut wood surfaces but also by root contact. Some higher plants are also parasitic; *e.g.*, the European mistletoe, and its North American counterpart, cause stem and crown deformation. Among the animals, the insects are the most mobile in the forest. They are also the most numerous and the most highly adapted as to feeding habits. Insects are an important link in the food chain between vegetation and higher animals, particularly birds. Many tree species have flowers adapted to insect pollination, the range is wide from simple nectar-rich flowers to highly structured pollination mechanisms. Insects are often highly specialized in their feeding habitats; of 20 species known to occur on white pine, five are leaf feeders, three are bud feeders, three are twig borers, two are wood borers, and two are root borers. Species preference is also noticeable; of 43 species of British weevils whose larvae feed on scots pine, oaks, and birches, all except one attacks only one species of tree. Insect damage to forests reaches disaster proportions only when populations break through the natural control barriers; *e.g.*, the periodic defoliation of balsam fir by the spruce budworm is triggered by several summers of clear, dry weather, which favours a rapid increase in the insect population. Insects also are known carriers of the viral,

Quality of light absorbed

Serious insect damage

bacterial, and fungal diseases of trees. As a proportion of the total insect population, however, the serious forest pests are small in number and localized in their influence.

**Forest animals and their adaptations.** Larger forest animals are likewise especially adapted to their environment. Sharpness of sight and smell are apparently not as useful as a sense of hearing in the forest habitat, and most gregarious animals, including birds and monkeys, are noisy in contrast to the animals of open country. The value of flying and running is also reduced, and true forest birds are poor flyers but good climbers. Movement on the ground is restricted; but elephants and the larger swines, massive in proportion to their height, can push their way through vegetation; and deer and antelope, slender and lithe, can thread their way through the forest. Specialist adaptations include those that enable the animal to move through the dense canopy layers; sharp claws (as on woodpeckers, squirrels, martens); gripping feet or prehensile tails (as on South American monkeys, porcupines, anteaters, marsupials); and parachute-like skin extensions (as on flying lizards, flying squirrels and *Rhacophorus* frogs). The tree frogs of the tropics have become so adapted to the tree crown as to have abandoned ground life almost completely. Some animals, such as birds of prey, wolves, foxes, and stags, use the forest only for shelter. Although the forest is a sheltered and ameliorated environment, food is scarce and populations are relatively low.

Each forest type has its distinctive animal life. In the deciduous broad-leaved forests snails and slugs are more numerous than in the conifer forest, a reflection of the difference in the quality and quantity of the herb layer. In temperate zones forest birds distribute seeds and insects pollinate. In the tropical rain forest, fruit bats assist in both pollination and seed dispersal.

Animal damage rarely reaches catastrophic proportions in the forest, but local damage from grazing and browsing can result in bark stripping of young trees.

#### SEASONAL CHANGE

The forest community changes with the seasons. Superimposed on these changes are the daily rhythms of daylight and darkness; of these effects, the length of daylight, or photoperiod, is an important component of seasonal change, or aspection. The stimulus of these changes is environmental and as a consequence is most marked in regions where temperature, precipitation, and day length are seasonally variable. The responses of organisms to periodic changes in the environment have evolved over a long period of time to parallel the external environmental conditions (see PERIODICITY, BIOLOGICAL).

Aspection is also influenced by latitude, altitude, and rainfall distribution. At high latitudes the winters are prolonged, snow and frost occurring for as long as six to eight months continuously; the spring and autumn periods are very short, and the growing season may be as short as three months. (Seasonal changes in the Southern Hemisphere are the reverse of those in the Northern Hemisphere.) Longer, cooler periods are associated with increasing altitude and are reflected in the forest composition even within the tropics. The seasonal changes in forest communities at high elevation are similar to those closely related communities at lower elevation but higher latitudes. Finally, aspection is affected by moisture availability; thus at the margins of the tropical forest belt and in Mediterranean climates, the resting period for many plants, presaged by leaf fall in deciduous species, results from a seasonal lack of moisture rather than from decreasing air temperature and decreasing day length.

In the middle latitudes of the temperate zone, characterized by the deciduous broad-leaved forest belt, six phases of the seasonal cycle are recognized. In this region aspection is most strongly evident, and the phases correlate climatic conditions with the outward appearance of the tree cover. In the early spring, or prevernal period, the hardy species and the lower storied trees bud and bloom as air temperatures and day length increase. In the upper stories, bud break is delayed, but the sap rises from the roots to the crown. The late spring, or vernal period, sees

soil temperatures rise with air temperatures and day length reach its maximum value. As the leaves expand, shoot growth accelerates; the transpiration rate becomes more rapid as the leaves mature and as moisture in the soil becomes more readily available. At this period the vegetation is most vulnerable to frost damage. The next two periods, aestival (estival) and serotinal periods, cover early summer and midsummer, when conditions for growth are optimal. Air and soil temperatures reach their maximum, the full-storied structure of the forest is operative, and the metabolic rate is at its highest. During this period, moisture availability becomes the critical, or limiting, factor to growth; high temperatures combined with extremely dry conditions may induce a lowering of the metabolism of the tree, characterized by premature aging of leaves and a slowing down of plant activity. The autumnal period is characterized by falling air temperatures, decreasing day length, and the advent of frosts. These changes induce a gradual reduction of metabolic activity and defoliation of deciduous vegetation. Finally, the winter, or hiemal period, is characterized by low daily maximum temperatures, heavy frosts, precipitation in the form of snow, and short day lengths. During this season the trees enter a dormant stage in which metabolic activity is diminished to the minimum level necessary for survival.

Seasonal change is least marked in the higher latitudes of the temperate zone, characterized by the coniferous belt of forests. Here the species mixture is limited and simple in physiognomy, and although the conifers are evergreen, water loss through transpiration is considerably reduced as water becomes less available from the freezing soil. The evergreen habit does enable the maximum use to be made of the short growing season and conifers are particularly well adapted to a wide range of rigorous environments. The understory plants, mosses, ferns, lichens, and grasses show no spectacular seasonal changes, and the trees themselves change little in appearance with the passage of the seasons, except for the deciduous species such as the larches. Even in the species-rich coniferous zones of western North America and in Asia, aspection is not well marked in the tree cover, although breaks in the canopy reveal herb and shrub layers that show the same periodic changes that are seen typically in the broad-leaved forest.

One common feature of the extratropical forest regions is the periodic activity of the tree growth. The growing tips (meristems) in the buds, which are responsible for height growth and crown development, are most active in the spring. The lateral, or cambial, meristem, which is responsible for increase in the diameter of the tree trunk, also is most active in the spring, slowing down in the autumn and ceasing activity in the winter. All temperate trees show an annual ring structure, roughly indicative of age, resulting from the episodic nature of this cambial activity.

The essential difference in periodicity between the forest of the tropics and that of other climates is the behaviour of the different species, different individuals of the same species, and, in some cases, different parts of the same plant. Periodicity often is apparently unrelated to environmental conditions and is certainly very much less synchronized; within the tropical zone, however, the more seasonal the climate, particularly the rainfall distribution, the greater becomes the synchronization with the periodicity of the climate. Where marked dry periods occur in the wet evergreen forest, there is a marked tendency to produce new foliage at the beginning of the wet season, whereas flowering tends to occur in the dry period. Elsewhere new foliage is not always produced in response to an external stimulus, and in nearly all species leaves are produced in periodic flushes so that several generations of leaves may be found on the same tree at any given time. Meristematic activity is, however, episodic, although not annual. As in the trees of other regions, growth of the shoots is accompanied by the expansion of the buds. Well-marked growth rings often occur in the timber of the tropical rain forest trees, and in the truly deciduous species they coincide with a definite

Seasonal  
flowering

interruption of the cambial activity. As with the production of foliage, there is considerable variation both between and within species, which results in considerable diversity in the structure of the wood. Seasonal flowering is more strongly in evidence in the upper stories of the forest, probably due to the influence of slight changes in average temperature rather than in light periods. Of special interest in the tropical rain forest are those plants that cluster together and flower at the same time, the best known being species of bamboo that flower at long intervals and die after the ripening of the fruit. This habit of flowering is attributed to the necessity of particular weather conditions operating on fully developed but unopened buds.

#### COMMUNITY DEVELOPMENT

Forest communities represent the terminal aggregation of species in a series of associations that may have begun from primary succession—i.e., colonization of bare mineral soil, exposed rock surfaces, volcanic ash, or sand dunes—or from secondary succession, in which the substrate had first been occupied by a community that, because of a catastrophic event (e.g., wind devastation, fire, or man's intervention), has since been destroyed. Although successional changes may vary considerably between these two major avenues of development, the time span in each case is quite long, and the biological interactions between the various plant and animal components are rather complex. Each recognizable stage in the development of a stable, or climax, community is known as a sere. Climax forest communities, because they usually represent the terminal point of seral development, are grouped together in more or less climatically controlled geographic groupings identified as forest biomes (see Figure 3).

**Coniferous forests.** *Taiga.* The circumpolar high-latitude forests of the Northern Hemisphere are dominated by pines (*Pinus*), spruces (*Picea*), firs (*Abies*), and larches (*Larix*). The Eurasian and North American formations are very similar in structure, and in both the species composition changes from east to west of the formation. Important eastern formations in Europe are the native stands of Siberian pine (*Pinus sibirica*), Siberian fir (*Abies sibirica*), and Siberian and Dahurian larches (*Larix russica* and *L. gmelini*); in North America white spruce (*Picea glauca*) and balsam fir (*Abies balsamea*) are the eastern dominants. In western Europe Scots pine (*Pinus sylvestris*) and Norway spruce (*Picea abies*) ab-

solutely predominate; in western North America lodgepole pine (*Pinus contorta* var. *murrayana*) and Alpine fir (*Abies lasiocarpa*) are among the important species in the area.

The taiga forests, especially in the almost pure strands, have been exploited on a very large scale from the mid-19th century on. On cleared areas, on catastrophic burns, or whenever adequate precautions to ensure conifer regeneration are not taken, secondary succession begins. Dominated initially by herbaceous cover, the succession soon contains deciduous broad-leaved trees, especially birches (*Betula*) and aspens (*Populus*), prolific seed bearers, whose seeds are wind dispersed and of a high germination capacity. Willows (*Salix*) and alders (*Alnus*) are also early arrivals in the hardwood stage of succession. Scots pine in Europe and jack pine (*Pinus banksiana*) in North America produce the advanced succession stage. Final reversion to the climax forest is achieved after a considerable time interval through the ability of the conifer species to regenerate and grow under the shade of the canopy. In addition, conifers tend to grow taller than the broad-leaved species when in direct competition and eventually shade them out. Broad-leaved species occur in the taiga in locally induced biotic climax, and are common on the latitudinal and altitudinal margins of the biome.

**Moist-temperate conifer forest.** Forests of this distinctive type occur along the western seaboard of North America from Alaska to California and inland to the Rocky Mountains. Here conditions are very humid and a high proportion of the precipitation occurs as mist. Species domination shifts from Sitka spruce (*Picea sitchensis*) in Alaska through the western red cedar (*Thuja plicata*)—western hemlock (*Tsuga heterophylla*) association in British Columbia to Douglas fir (*Pseudotsuga menziesii*) and finally the coast redwood (*Sequoia sempervirens*). Because of the high humidity a rich understory development, especially of mosses and other moisture-loving plants, is a feature of this forest formation. The trees are massive, and they constitute the richest commercial forest in the world. As in the taiga, secondary succession features the pioneer broad-leaved species, especially the alders (*Alnus*), and in the south, maples (*Acer*). Where the humid conditions are maintained only under continuous conifer cover, oaks (*Quercus*) infiltrate late in the succession from the neighbouring transition to the Californian chaparral. Primary succession from the coast tends to be dominated by pioneer pine species,

Exploitation and  
recovery of  
the taiga

especially lodgepole pine, before the climax is rapidly formed.

**Middle-latitude forests.** *Deciduous broad-leaved forests.* This biome, which occurs in Europe and North America, is floristically richest in the New World. Associations of beeches (*Fagus*) and maples occur in the north, maples and basswoods (*Tilia*) in the centre, oaks and hickories (*Carya*) in the west and south, and oaks and chestnuts (*Castanea*) in the Appalachian Mountains. Native species of oaks, beeches, and birches form the associations in the northern European formation, limes (basswoods), chestnuts, and elms (*Ulmus*) appearing in the south. Community development in this region again arises from forest clearances; in North America, where population pressure is not so great as in Europe, abandoned agricultural land is a common starting point. The grassland community is first invaded by broad-leaved shrubby trees and a mixed-species thicket stage develops. Later successional changes feature the invasion of jack pines for reasons analogous to those operating in the conifer biome. The richer soils and better growing conditions of the deciduous broad-leaved biome allow a more rapid growth of broad-leaved species, some of which are shade tolerant. The pioneer pines soon become mixed with broad-leaved species, which in the course of time dominate the community as the climax forest develops. It is not uncommon for the succession to be deflected to a conifer climax by either regular burning or grazing. The pine barrens of southeastern North America, dominated by several pine species, are an example of such a climax.

*Evergreen broad-leaved forests.* This formation occurs both north and south of the Equator on the eastern seaboard of continental land masses. The cooler temperate formation is found in the Southern Hemisphere; in New Zealand, southern so-called false beeches (*Nothofagus*) dominate. Although evergreen, the formation has much in common with the deciduous broad-leaved forest of the north. In the warm temperate forests of the Southern Hemisphere, the beeches are joined by the southern conifers: Kauri pine (*Agathis australis*) and *Podocarpus* species in New Zealand, and *Araucaria* species in Chile. Particularly in the warmer regions secondary succession is complex and very slow. Pure strands of southern beeches develop especially on the more exposed hillsides. The southern conifers are very slow growing and are susceptible to grazing damage; once removed they are unlikely to regain their place in the community. *Nothofagus* species are very susceptible to grazing damage; recovery is difficult, and often the forest reverts to a thick grassy turf.

**Tropical forest.** The variety within the forest community reaches its zenith in the tropical rain forests, which occupy low-altitude areas near the Equator. Rainfall exceeds 2,000 millimetres (about 79 inches) a year and is evenly distributed with either one or two short, dry seasons of rainfall 150 millimetres (six inches) or less per month. The largest continuous rain forests occur in the Amazon and Orinoco river basins of South America. Less extensive are the rain forests on the Central American isthmus, in the Congo, Niger, and Zambezi basins of Africa, in Madagascar, and in the East Indies. The variation in temperature between winter and summer is less than that between night and day, and the suddenness and force of rain showers are unknown in other biomes. Although vegetative composition varies between geographical regions, the forest presents a remarkably uniform appearance. The trees are tall, evergreen, often shallow rooted and significantly buttressed at the base. There is a profusion of climbing plants, especially woody vines, or lianes, and air plants, or epiphytes. The profusion of vegetation within the canopy zones obscures this highly structured biome. There is perhaps a greater variety of trees in a few acres of tropical rain forest than in the entire vegetation of Europe. This richness of species is matched in the animal life as well; e.g., in a six-square-mile area of the Panama Canal Zone, 20,000 insect species have been recorded. For a more complete description of this biome see JUNGLES AND RAIN FORESTS.

Within the rain forest the most important community changes are associated with secondary succession leading toward the climatic climax. Fire, grazing, and soil deterioration may deflect the succession and lead to the stabilization of a biotic climax. Secondary succession normally arises from forest clearings used for cultivation; when these are abandoned succession begins with a short-lived (less than one year) weed domination followed by shrubs, but dominance quickly passes to trees, usually by a massive invasion. The young secondary forest consists of species with efficient seed-dispersal mechanisms. Characteristically the trees are quick-growing light demanders, as opposed to the shade-tolerant slow-growing climax species, and they often produce soft and light wood. They include such commercially desirable species as balsa (*Ochroma species*), common in the South American formation; obeche (*Triplochiton scleroxylon*); iroko (*Chlorophora exsela*); okoume (*Aucoumea klaineana*) and afara (*Terminalia superba*), present in the African formation. The secondary forest tends to be smaller, very rich in lianes, and dominated by fewer and different species in comparison to the climax. Secondary succession species often fail to reproduce themselves, shading out their own regeneration, and as the succession ages, more representatives of the climax become established.

**Forest ecotones.** At the edge of forests are transitional woodland formations called forest ecotones; four types have been chosen for description. In tropical latitudes the savanna and thorn forest ecotones are intermediate formations between the rain forest and semi-arid desert. In the middle latitudes the sclerophyllous forest ecotone is a prominent formation. The final example, the mangrove swamp forest, is an ecotone between an aquatic biome and the forest.

*Savannas.* Savannas lie between the tropical rain forest and semidesert vegetation in a broad latitudinal zone between 5° and 20° N and S of the Equator. The dominant vegetation is an open parklike tree cover over dense, tufted and often tall grass. The climate is tropical and semihumid, with summer rain and a long dry season. Precipitation varies between 600 millimetres (about 23 inches) and 1,500 millimetres (about 59 inches); at the lower range of rainfall the savanna passes into thorn scrub, whereas at the upper limit the savanna grades into semi-evergreen or mixed deciduous forest. The savanna occurs extensively in Africa, both north and south of the Equator, covering most of the East African highlands. In South America the savannas of Venezuela and Brazil are separated by the Amazon forests. In Australia savannas are found between the forests of the wet coastal regions and the deserts of the interior. In all localities the savanna offers a unique environment for large animals, many of which, such as the zebras and giraffes of Africa, are particularly adapted to the open woodland and some, like the carnivores, to sparse woodland conditions. The environment is especially prone to fire, and it is probable that large areas of savanna are stabilized by fire. Annual burning is a common practice in Africa, and the savanna vegetation is subject to severe selection; only species resistant to periodic fires can maintain themselves. If burning is abandoned, increase in woody plant development takes place.

The dominant tree species of the savanna are typically deciduous, shedding their leaves during the dry season; they have a gnarled, Y-shaped form, branching a few feet above the ground and spreading out to an umbrella-shaped crown. In Africa, outside the influence of the savanna-closed forest margins, the *miombo* (*Brachystegia-Isobertia*) woodland grades into an *Acacia* formation as drought conditions increase. This formation includes also elephant grass (*Pennisetum species*) mixed with other tussock grasses of the genera *Imperata*, *Andropogon*, and *Hyparrhenia*. At their most luxuriant they are often more than 3.6 metres (12 feet) tall at the end of the growing season; their stature diminishes as conditions become drier, until, under the *Acacia* species at the border of the semi-arid desert and thorn forest, they give way to species of *Aristida*.

**Thorn forests.** The thorn forest is stabilized by the climate over most of its area, although occasionally it is maintained by grazing or burning. It is found on the equatorial margins of subtropical and tropical semi-deserts, where rainfall in a two to four month summer season rarely exceeds 700 millimetres (about 27 inches). The forest resembles the savanna woodland but is somewhat shorter in stature; the ground layer is confined to sparse arid-adapted grasses but is richer than its savanna neighbour in understory woody species. The vegetation is markedly adapted to dry conditions, the trees being deciduous or if evergreen, with leaves protected against drying; the branches often bear thorns as protection against grazing animals. Cacti and other spiny succulents appear in the ground layers and understory. The common dominant trees are native species of *Acacia*, which appear in the South American, African, and Australasian formations, in the last case displacing the *Eucalyptus* species of the savanna. In the Asian formation, *Acacia catechu* is associated with *Tectona hamiltoniana*, a deciduous nonthorny species. Like the tree species of the savanna, the thorn forest dominants are very deep rooted, competing most successfully on soils where water penetrates deeply and quickly.

**Sclerophyllous woodlands.** This formation, with trees rarely exceeding four metres (about 13 feet), occurs in the middle latitudes of summer drought and winter rainfall. It is typified by a warm, dry climate, as in parts of the Mediterranean, southwestern U.S., Australia, South Africa, and Chile. Characteristically the formation is dominated by evergreen broad-leaved species; but occasionally, as in the Mediterranean formation, there is an admixture of coniferous species. Oaks are dominant in the Northern Hemisphere; in the southern counterpart, *Eucalyptus* species dominate in Australia, and elsewhere a range of uniquely characteristic genera are drawn from many families. Arid tolerant, woody, and often fire-resistant evergreen species are present in the understory. Herbaceous vegetation is normally restricted to grasses. Probably this formation is stable only where the annual rainfall is less than 300 millimetres; it is, however, maintained elsewhere in areas of higher rainfall by grazing and by burning particularly. The sclerophyllous woodlands finally fade into arid or desert conditions in all but the Mediterranean formation.

**Mangrove swamp forests.** Coastal mud flats throughout the tropics carry a vegetation of mangrove swamp and are particularly luxuriant in the wet tropics, where the rain forest is the stable formation. Mangroves are evergreen trees and shrubs that share similar habitat preferences and a similar appearance. Their common features include a tolerance of brackish water, the development of "breathing roots," and a marked tendency to germinate their seeds on the tree. These features enable the mangroves to pioneer the water environment and to dominate the subsequent secondary succession.

The pioneer species develops from seedlings that float out to sea and become established on shoals and sandbanks. Tiers of prop roots develop and, as groups of seedlings become established, sedimentation and the accumulation of debris builds up the soil level. A mature community develops in which the mangrove pioneer, up

to nine metres (about 30 feet) tall, is dominant. Other salt-tolerant species gradually become established, especially in associations subject to periodic flooding. The soil level continues to be raised by the accumulation of litter until it is no longer washed by water and the climax vegetation species begin to be established. In the Florida formation, *Rhizophora mangle* is the pioneer behind which develops an association in which *Avicennia nitida* is dominant. Next, the *Conocarpus* transition association of semimangrove species forms, and finally the climax rain forest develops. More complex successions are found in the Malaysian succession. Other variants include the stagnation of the succession at a mature mangrove association stage, or the development of a freshwater swamp forest rather than a climax rain forest.

#### PRODUCTIVITY OF FORESTS

Quantitative estimates for the productivity of forest communities are scarce and unreliable. Among the reasons for these conditions are the complexity of the forest community, the longevity of tree species, and the lack of historical records of routine weight data. Moreover, there are three levels of production that might be measured. Gross, or primary, productivity is the quantity of organic matter created by photosynthesis. From this value the energy used in respiration is subtracted to give the net production, which is measured as the dry matter, or dry weight of the total community. A third measure is the merchantable production, which is the dry weight of the usable tree stems only and is calculated by multiplying the stem volume by the basic density of the wood. Although volume figures are available for most of the species under regular forest management, this measure cannot be regarded as an estimate of total production; even for a single tree it represents less than 70 percent of the total dry weight, the unmerchantable stem (1-6 percent), stump (10-18 percent), green branches and foliage (10-20 percent) making up the remainder. For a complete evaluation of forest productivity, both the vegetation and the animal life need to be measured, a task that is overwhelming in magnitude. The difficulties of measuring even the dry weight of the total plant community present extreme sampling difficulties. Much of the data available are concerned with the plant biomass (net production), and often only for the tree component. The magnitude of the loss of gross production through respiration is illustrated in Table 1, although direct comparisons are dubious since the age and stand composition is not specified.

Forests are the most efficient of all terrestrial communities in the production and storage of organic matter. A very high proportion of the sunlight that falls on the forest is absorbed; the canopy provides a large area of chlorophyll-bearing tissue dispersed through a considerable volume of air for the absorption of carbon dioxide, and tree roots exploit a considerable volume of soil for water and nutrients. The three essential prerequisites for efficient photosynthesis are, therefore, effectively fulfilled, and as a consequence the forest system capitalizes on the production of organic matter. Additionally, the forest community operates efficiently through time, although forests of evergreen conifers are more efficient

Dominance of broad-leaved species

Interpretation of data from reforestation

than deciduous broad-leaved forests in total as well as tree biomass production. Systematic studies of the changes in the rate of organic matter production through the life of the forest are lacking, but the data available from reforestation programs indicate that the tree component increases slowly as the canopy closes, maximizing at the point of greatest competition between trees, and thereafter falling as trees are removed or die. The contribution of the ground layer is most marked at the youngest and oldest ages of the crop—i.e., when the canopy is open. Complementary data on the dry weight of foliage confirms this pattern, and it is probable that the number of stems per unit area (stand density) is as important as geographical location for both the weight of foliage and the total biomass produced. Within a given geographic region there are considerable differences between tree species in their rate of organic matter accumulation. Various estimates of timber production indicate that conifer stands usually are more productive than deciduous tree stands. Despite the lack of comprehensive data, the biomass production from the forest community is impressive (Table 2).

## Form and Function, Biological

There is a tendency in modern biology to explain the behaviour of living things directly in terms of physics and chemistry, suggesting that biological form and function can finally be understood wholly in the interaction of atoms and molecules. Living structure, however, presents peculiar problems, for even at its lowest level it is both like and unlike nonliving constructs. Although both begin with the same atomic building blocks, and many of the interchanges of atomic particles in chemical reactions are identical, the stuff of life differs fundamentally from lifeless matter. Nonliving structure is marked by regular repetition of its atomic disposition,

which is a highly probable state. Living matter is remarkable in the irregularity of arrangement of its atoms, for example, in the genetic complex, and in the repetition of this arrangement in successive generations, a highly improbable condition. Hence biostructure tends at almost the lowest level to escape the statistical structure of physics. Living structure is distinctly nonrandom, whereas nonliving structure is wholly random. It is this intriguing uniqueness of the biological device that must be examined first, before probing it with the instruments of physics. An important concept in biology is thus the endurance of order, as distinct from the universe, where entropy and reduction to randomness prevail. The overall trend of evolution has been toward an increase in this peculiar kind of orderliness. The first goal of biology, however, is to understand the living organism. In the view of life presented here, the living entity is a homeostat, a seeker of regularity, distinct from its environment but peculiarly coupled with it. The goals that this homeostatic device seeks in the environment make up its behaviour, which persistently keeps the organism hovering about the peak of the orderly state. The crux of the evolutionary process is that the living order has a way to keep building into itself unique devices that ensure ever more probable persistence of order. This view of evolution indicates, in part, the peculiar coupling noted above. Nonrandom replication of genetic structure, random mutation and recombination, and nonrandom natural selection together yield adaptation, which makes each kind of organism able to persist in a particular kind of environment. It is at the level of adaptation that the mechanics of biological form and function become most clearly meaningful.

Structure may be defined as the observable organization that is explicit in the course of a flow of energy. Structure and behaviour are but moieties of an entity, the total adaptation of the organism to its environment. Although biomechanics tends to stress the movable parts that perform overt behaviour, in higher (more orderly) organisms the inseparable structure that makes movements meaningful is the nervous system. This is the selector that decides, on the basis of instinct and remembered learning, the course by which the most effective return to the steady state can be made.

From this total adaptation the permeating influence of form-function emerges in the continuum from atom to organism. The information immanent in the structure of the gene serves evolution, which is long-term homeostasis; that of the nervous system serves the organism, which is short-term homeostasis. In its interactions with the environment, the organism must obey the laws of physics through all aspects of its structure. Biomechanics, the study of biological form from the functional viewpoint, is an examination of the principles of engineering design as implemented in living organisms.

### BASIC MECHANICS

The structure of any working device must embody two mechanical features. It must, first, be able to maintain

its own structural integrity when outside forces act upon it, and, second, it must perform its specific functional movements. The structural properties that enable it to meet these two requirements are dictated by several types of mechanical forces.

**Newton's laws of motion.** Because living constructs are well within the intermediate zone in size—neither atomic nor astronomic—the laws of classical mechanics are entirely applicable to their motion. Certain of these, especially the laws of motion established by Isaac Newton, are fundamental to the understanding of biomechanics. Newton's first law states that an object at rest will remain at rest, and an object in motion will maintain that motion, unless acted upon by some force. The second law states that, when a constant force is applied, the object will accelerate at a rate proportional to the force divided by the object's mass. The energy imparted by the force causes the object to accelerate in the direction of the applied force. Newton's third law, perhaps the most central to the structure of living organisms and non-living machines, states that, when one body exerts a force upon another, it receives an equal and opposite force.

**Static forces.** Even a stable or nonmoving structure may be subject to forces. For the purposes of analysis, three basic types of force may be recognized in terms of their effect on a mass: compression, tension, and shearing. Each of these is really a pair of forces. A single force may be defined in terms of magnitude and direction, together called the vector of force. If the mass is stationary, the sum of force vectors acting upon it must be zero. Simple compression consists of a pair of forces, acting in opposite directions along the same line and directed toward each other, tending to squeeze or shorten the object on which they act. Tension is the opposite; the forces are directed away from the object and tend to lengthen it. Shearing forces are opposite and parallel but in different planes, tending to slide one portion of the object along the adjacent portion, tearing it.

When force is applied to a body, two phenomena may be noted: stress and strain. Stress is the resistance among the molecules of the body to the distorting effect of the outside force. If a weight is suspended by a wire, there is tension along the wire, parallel to the axis, and the tensile stress is the resistance of the molecules measured on either side of an arbitrary cross section. Strain is the change in linear dimension (*i.e.*, the distortion) of the object as the forces act on it. The tension upon the wire supporting the weight will cause the wire to elongate while under tension; the strain is the ratio between the change in length and the original length, usually expressed as a percentage. The property of elasticity causes an object to return to its original dimension when the force is removed.

**Simple machines.** Basic machines, which transmit and modify forces, are common to both living and nonliving systems and are usually considered to include the lever, the inclined plane, the wedge, the screw, the wheel, and the pulley. The six may be reduced to two basic devices: the lever and the inclined plane. The wheel is simply a rigidly linked, continuous set of levers pivoting around a single terminal fulcrum (the axle) and the pulley merely a modified wheel. The wedge is a double inclined plane and the screw an inclined plane wrapped around a rod.

The lever

Of these devices, the most important in biological systems is the lever. The wheel, of course, is impossible, since complete rotation of a part would tear the connections with the rest of the organism, destroying its organic unity. Although the principles of the lever are well-known, its biological implications are often overlooked. Every organism attached to, resting on, or moving on a surface and every projecting part of an organism, particularly a rigid extension, such as a leg or a branch, is subject to forces that act upon it as they would upon a simple lever. In its simplest form a lever consists of a straight bar with a fixed pivot point, the fulcrum, and two forces, one of which is usually considered applied; the other is the load. The magnitudes of the two forces are inversely related to their respective distances

from the fulcrum, and their effective directions are at right angles to the lever. Because of the inequality of the two forces, the difference between them in magnitude and direction must be borne by the fulcrum. In dynamic terms, the work (force multiplied by the displacement of the point of application) of the lever system must also balance. The distances through which the applied force and load move are directly proportional to their distances from the fulcrum.

The human forearm, when bent at a right angle, provides an excellent example of a relatively simple lever system, if the weight of the arm itself is ignored and the biceps muscle (*musculus biceps brachii*) is considered the sole muscle bending the arm. The elbow joint is the fulcrum. The upward force of the biceps is applied about one-sixth of the way from the elbow to the palm, which bears the load. A ten-kilogram weight held in the hand thus requires six times that force, or 60 kilograms of tensile force, by the biceps. If the arm is stationary, the elbow must provide 50 kilograms of downward force to balance the upward forces applied to the forearm. The 60 kilograms of tension in the muscle and the 50 kilograms of compression in the upper arm are transmitted to the shoulder, the difference of ten kilograms (downward) being passed to the body and thence to the ground as extra weight of the individual.

As applied in living or nonliving systems, the principles of leverage are never as simple as described above. The lever must have thickness and mass (weight) and must be attached to a firm base. The thickness of the bar may be viewed as a second lever, lying at a right angle to the first and pivoting about the same point. A force applied at right angles to the bar is transmitted to this secondary lever by the molecular adhesion of the material and lies at right angles to the short lever, taking the form of tension or compression along the bar. If the bar is horizontal and cantilevered (anchored at one end to a vertical surface) and the force a downward one (assuming for simplicity that the bar is weightless) applied at the tip, the tension in the top of the bar at any point along its

By courtesy of E. Lloyd DuBrul

Figure 1: Internal strutting in the head of the human femur (thighbone).

length is directly proportional to the distance of the point from the tip. The lower surface of the bar will be subject to compression, in the same relationship to the applied force as the tension on the upper surface.

The application of force to the bar results in the famil-

lar form of distortion known as bending; the bending stress is greatest at the point of attachment. Failure of a structural member usually occurs at the point where the particular force (tension, compression, or shearing) exceeds the breaking point of the material. A cantilevered bar under downward force often fails initially at the base of the upper surface, the location where the tension is greatest.

The bending limits of a bar may be increased by strengthening the region under greatest stress, by adding structural material, or by using material with greater tensile strength. This is usually achieved by lightening the centre of the beam, where the stress is less. In the pelican and the New World vulture the upper and lower walls of tubular wing bones are thicker than the lateral walls, and internal compressive stresses are borne by a series of struts, like those of many man-made girders. Human leg bones (Figure 1) also have internal struts.

The tree trunk as a lever

The trunks of trees, particularly tall, straight ones, demonstrate several aspects of lever dynamics. The wind resistance of the leaves and small branches provides an enormous horizontal force, applied at a distance from the effective fulcrum, the base of the root system. Each cross section of the trunk must transmit downward the bending forces applied above it; the forces increase progressively toward the ground. The thicker base of the tapering trunk provides additional strength where needed, resulting in controlled bending. The bending of the trunk and deflection of the leaves result in reducing the applied force of the wind. The roots, extending downward and outward from the base of the trunk, provide moment arms that distribute the force to the soil. The weakest point in the system—i.e., the junction of stem and roots—is sometimes strengthened by high, thin buttresses that provide both tension and compression braces (Figure 2).

Bipedal organisms, such as man and birds, must use the toes as levers to maintain stability on level surfaces. Without adhesion to the surface, toes can transmit only compressive forces and provide no resistance to a force tipping the animal backward. In both cases, stability is improved by rearward extensions—the hind toes of birds and the heel of man.

An important adaptation to bending forces is the evolution of tubular rather than solid structures in circumstances in which economy of material or lightness is of greater importance than compactness. Because the stress-bearing material is located further from the axis of the lever, a tube is substantially stronger than a rod of the same weight. A possible disadvantage is that the tube must always be of greater diameter than a rod of the same strength, but this disadvantage is often outweighed by the advantages of the tube as a conductor of liquids (e.g., in vascular plants) or as a form of armour to protect vulnerable soft parts (as in arthropods, such as insects and crustaceans). The advantages have led to the evolution of tubular limb bones in terrestrial mammals and, especially, in birds.

#### LIMITS ON BODY SIZE

**The upper limit.** A structural system works dependably only within a limited range of size. The upper and lower limits of body size are often imposed by requirements determined by the ratio of body mass to area. If the proportions and composition of the organism remain constant, the mass (essentially, the weight), which is governed by the volume, varies with the cube of linear dimension. A twofold increase in linear size results in an eightfold increase in volume; a threefold increase in linear dimension results in a 27-fold increase in volume. The surface and cross-sectional areas of the organism, however, vary with the square of the linear dimension. Stresses are usually expressed in terms of force per unit of area, but the force itself is expressed in units of mass (i.e., weight). The strength of a structural material is expressed in terms of the force required for breaking under tension, compression, or shearing, expressed in terms of force per unit area.

The ratio of surface (or cross section) to volume has a profound effect upon the supportive structures of plants

Figure 2: (Top) The silk-cotton tree (*Ceiba pentandra*), the expansive buttress roots of which function as lateral supports for its massive canopy. (Bottom) Close-up of the roots.

Walter H. Hodge

and animals. A sphere hanging by a wire exerts a tension on the wire that may be given as the mass of the sphere (in grams or pounds) divided by the cross-sectional area of the wire (in square millimetres or square inches). If the linear dimensions of sphere and wire are increased by the same multiples, the volume of the sphere, growing with the cube of linear change, will soon outstrip the cross section of the wire and exceed its breaking point. Thus, as the diameter of the sphere increases, that of the wire must increase at a proportionately greater rate to give effective support.

The evolutionary response to the area-volume problem is never quite as simple as a mere increase in the diameter of the supporting member, for the latter is subject to more complex forces than simple tension and compression, and the body dimensions seldom have evolved through simple proportional increases. There are, however, groups of animals, exhibiting the same basic body

plan but differing sizes, in which the effects of the area-volume ratio may be seen. The legs of mammals, for example, are subject to compression stresses; those of a small antelope are extremely slender, those of a horse proportionately thicker, and those of a rhinoceros or an elephant enormously thicker. If the size of the animal were increased further, the supporting pillars (especially the long bones of the legs) would have to become so broad that they would ultimately touch, and the animal would be immobilized. In fact, practical immobility would be reached long before that point because of the limitations imposed by other factors, such as the need for increased muscle volumes, heat dissipation, and nutrition. Clearly, the modern elephants approach the upper limits for land size. Whales, supported by buoyancy, which distributes the compressive force over a broad area, attain considerably larger size, but the huge extinct reptiles, such as the dinosaurs *Brontosaurus* and *Diplodocus*, relied on the increased area of support provided by their massive tails.

#### Size limitations of flying animals

The problem of surface-to-volume ratios also imposes an upper limit on the size of flying animals. In such forms, as in fixed-wing aircraft, a critical factor in merely remaining aloft is wing loading, the ratio of total weight to wing area, usually expressed in terms of grams per square centimetre ( $\text{gm}/\text{cm}^2$ ; one gram per square centimetre equals 2.05 pounds per square foot). The allowable wing loading is dependent upon airfoil shape, wing shape, and airspeed, but the body plan of birds is limited by their genetic heritage. In general, large birds have sacrificed the propulsive power of the wing to attain airfoils and wing shapes capable of higher loadings. Despite appearances, the ruby-throated hummingbird (*Archilochus colubris*), with relatively short, narrow wings, has a much lower wing loading (0.15 gram per square centimetre) than the golden eagle (*Aquila chrysaetos*) whose long, broad wings are able to provide it with a loading no lower than about 0.9 gram per square centimetre. To be able to obtain functional wing loadings at all, birds have had to undergo great evolutionary changes from the ancestral reptile. The total skeleton has been altered, especially by the fusion of parts, and lightened through the use of an elaborate series of air sacs, extensions of those in the body. The bones are mostly thin-walled tubes, sometimes delicately strutted within. The pectoral and pelvic girdles, providing structural bases for the wings and legs, respectively, are arranged to provide maximum strength with economy of bone. The air sacs of the body allow it to be relatively large, so that the massive flight muscles can be long enough to operate at an efficient percentage of contraction. The feathers, which provide a light covering for the body and strong supportive surfaces for the wings, are hollow structures composed of the protein keratin.

In the lower range of size, the efficiency of the wing is less critical, some organisms managing to fly passively on updrafts of air without any real organs of flight. Newly hatched spiders can travel notable distances in wind, supported by wisps of web spun for that purpose.

Numerous plants achieve wind-borne dispersal merely by slowing the descent of their seeds to the ground, thus providing time for the wind to carry them considerable distances. The seeds may be provided with numerous fine hairs that catch the wind (for example, the seeds of thistles, *Cirsium*, and milkweeds, *Asclepias*), or they may have wings. Among the most striking of the latter type are the seeds of maples (*Acer*), which may be called airscrew flyers. The seed is carried in a streamlined spheroidal capsule that extends laterally into a single, eccentric wing in the form of a wide blade with a blunt leading edge, thinning to a fine trailing edge. Rigidity is achieved by a series of closely packed struts that lie parallel and close to the leading edge and turn toward the trailing edge at regular intervals, providing reinforcement in two directions. In falling from the tree, the seed rotates around the centre of the capsule because of the eccentricity of the vane, and the rotation provides lift, slowing the fall. This device does not carry as far as the downy seeds of the thistles, but it carries a larger seed.

Figure 3: Adaptation of maple seed for flight. (Top) Maple seed (*Acer*). (Bottom) Paths of seed pod and wing tip in descending seed.

Aeronautical engineers have determined experimentally that, considering the weight, vane area, and speed of fall, this form of airscrew functions about 1.2 times as efficiently as the best designed windmill.

**The lower limit.** The lower limit of effective size of organisms can never approach the realm of atomic sizes. An analogy may be made to a torsion balance, which measures minute forces. The essential parts of this balance consist of two spheres attached to the ends of a slim, horizontal rod, which is suspended at its centre by a fine wire. A horizontal force, applied to either sphere, causes the rod to rotate around the axis of the wire, twisting the wire slightly. The magnitude of movement provides a measurement of the applied force. In order to measure progressively smaller forces, the size of the instrument must be decreased. At a certain point, however, the spheres and wire begin to move in the absence of any outside forces; the machine's components have become so small that the random movements of their own molecules have emerged. At this point the system has become too small to operate with mechanical reliability.

Like the torsion balance, the retina of the eye is an instrument that measures minute forces, in this case the energies of certain light waves. The retina is composed of small receptor cells, called rods and cones, that transduce (convert to neural signals), then transmit the information contained in light energy. The smallest object that can be seen with the best light microscope contains millions of molecules, indicating that the photoreceptor cells seen microscopically are comparatively large, containing countless clumps of atoms. This quantity is so great that the random movements of the individual atoms cancel one another, thereby yielding a smooth

The lower limit for light receptors

mean neural signal. If this were not so, and the photo-receptor cells were small enough to record signals of individual atoms, the brain would be forever filled with flashes and the person would see nothing.

Surface-to-volume ratios may also impose a lower limit of size for some organisms or limit the distribution of small organisms. Warm-blooded animals (mammals and birds) lose heat at a rate determined by the surface area of the body, modified, of course, by the insulation of the body covering. Heat is produced largely by metabolism, the amount being dependent on body volume. As size decreases, the ratio of surface to volume increases until a point is reached at which the animal is unable to produce heat fast enough to keep up with the loss through the skin. This phenomenon apparently imposes a northern limit on the ranges of some small birds, such as hummingbirds.

#### THE INCORPORATION OF SIMPLE MECHANISMS INTO COMPLEX SYSTEMS

Complex machines and living organisms transform certain types of energy into other types (*e.g.*, heat, chemical, or kinetic), some of which may be stored. To do so involves the close coupling of two major systems—one to manage the processing of energy, the second to control the activities of the first—in order to yield a stable, coordinated, effective output. The energy-management system may be considered to include three basic components which reflect its operational requirements. First, an input device must receive energy from various external sources by various collecting and transporting structures and direct it to the internal processing complex. In green plants the means of collecting energy is simple; the photosynthetic pigment chlorophyll absorbs solar energy of the needed wavelengths. Animals, of course, possess more elaborate means of absorbing energy (food), which they can take in only as energy stored in plant or animal tissues. The internal processing complex contains selective devices that distribute the energy, in the appropriate form and amount, to each of various output devices. Both plants and animals handle energy internally in the form of chemical energy in organic molecules. These are physically transported within the organism by some form of directed vascular system. The various output devices utilize the energy provided them for the performance of their individual functions. In plants the output functions include primary tissue growth (of the type appropriate to the part of the plant and to the season), some movements, and reproduction. The output functions of animals include all forms of observable behaviour, tissue growth and repair, physiological activity, and reproduction. In both groups of organisms, some output functions serve to ensure energy input; others serve to channel residues or waste to the exterior of the organism.

The control system serves to monitor continuously the operation of the energy-management system. Cybernetics is the science of control systems. Its principles are as valid in the behaviour of man himself as in that of his machines. It is based on two major propositions: energy changes contain information, and this information is continually recycled within the system. These cycles or reflected loops introduce the concept of feedback, which is the central feature of control. Two kinds of feedback are possible, negative or positive. Negative feedback counteracts deviation in output. Hence, for a device to perform a predetermined pattern of motion, any difference between pattern and performance is fed back as a new input of corrective information to bring the movement toward coincidence with the pattern. The value of positive feedback is less obvious. It is the reverse of the previous process; that is, it is deviation-reinforcing rather than homeokinetic. It is seen in the "fight or flight" behaviour of an animal faced with a serious survival situation. Positive feedback is also involved in evolutionary processes and apparently has been operating strongly in the later phases of human evolution, thus speeding up the process.

The feeding mechanism of woodpeckers provides a good example of the close relationship between the control system and output devices. The typical woodpecker

feeds by flaking off bark and drilling in dead wood to expose insect tunnels, from which the bird removes insects with its tongue. The tongue is a slender, spearlike organ supported within by a shaft of bone (the urohyal) in front and driven from behind by force transmitted through a pair of slender bones, the hyoid horns, which extend under the skull and around to the top of the head. The horns slide in muscular tubes which, on contraction, extend the tongue a distance greater than the length of the beak. The tip of the tongue, a hard spearhead with bristles pointing rearward, is attached to the urohyal by tiny fibres of the protein collagen. As the tongue probes a tunnel or crevice, the impact of the spearhead on any object jams the head back along the shaft. Proprioceptive nerve endings are precisely located in the fluid-filled spaces between the collagen fibres. They provide the brain with information about the type of material contacted; thus, the bird knows whether it has impaled an insect or hit the hard wood of a tree.

Control of feeding in the woodpecker

#### EVOLUTIONARY CHANGE IN FORM AND FUNCTION

**Preadaptation.** The continuity of evolution, coupled with the close dependence of the development of the organism upon its genetic endowment, means that each life-form can contain only adaptations of structures present in its ancestors. Structure and function, however, may change with evolution; a structure that evolves from one function to another is often considered to have been "preadapted" for the second function. The term preadaptation is rejected by many modern biologists as tainted with Aristotelian teleology—the implication that the earlier form of the structure was somehow determined by its ultimate function. The term does indicate, however, the potential of a structure to serve the organism in a role for which the structure was not originally evolved.

An example of the adaptive potential of feeding structures is found in the skulls of many swift predatory fishes. Such fishes are faced with the problem of seizing and swallowing prey while swimming in a dense, resistant medium. A large mouth, opening like a scoop, would slow the predator drastically, and the prey would escape. In a number of unrelated fishes, the skull has been modified from a rigid to a kinetic one through the loosening and elongation of the multiple bones that make up the mouth. The result is that, instead of having a simple hinged jaw like that of many fishes, these predators have a complex apparatus that shoots the whole mouth for-

From W.K. Gregory, *Fish Skulls*; Transactions of the American Philosophical Society

Figure 4: Protrusion of the jaw in the wrasse *Epibulus*.

ward at the last moment (using the mass of the body to absorb recoil energy) and envelops the prey like a sleeve. At the same time, the pharyngeal region is spread, caus-

The control of energy-management systems

ing a negative pressure that sucks the prey into the mouth.

An excellent example of the opportunities open to pre-adapted structures is found in the evolution of the mammalian auditory ossicles, a chain of three tiny bones that transmit sound through the middle ear. One ossicle, the stapes, was present (as the columella) in the reptilian ancestors of the mammals; the other two, the malleus and incus, were derived from the articular and quadrate bones, respectively, which formed the hinge joint between the jaw and the skull in reptiles. Among the many innovations that are identified with mammals is a change in jaw articulation. The dentary bone, one of many in the reptile jaw, expanded at the expense of the other bones and formed a new articulation with the braincase, in front of and outside the quadrate-articular joint. The quadrate and articular became less functional and much reduced in size, were incorporated into the ear, the quadrate becoming the incus; the articular, the malleus. Another bone of the reptilian jaw, the angular, evolved into the curved mammalian tympanic bone, which now forms the rim of the eardrum.

By virtue of their fortuitous position close to the eardrum, the quadrate and articular were ideally preadapted to serve in sound conduction. Many paleontologists believe that these bones were already aiding in sound conduction while still part of the jaw assembly. As the contribution of the bones to jaw articulation became less important, their function in sound conduction became more so, and they gradually became incorporated into the ear.

**Levels of orderliness and complexity.** Many of the broad concepts of biomechanics are most easily demonstrated in large or at least visible organisms. A large organism, however, is an integrated complex of substructures, some of which may be called organ systems, others merely tissues. These in turn are made up of interacting cells, each of which has certain functioning organelles. The latter are made up of molecules. Each of these levels in a large organism has parallels that exist as independent life forms. A virus, the smallest unit of matter that may be called living, is a relatively simple structure; some of the smaller viruses contain only nucleic acids and proteins. A single-celled organism, such as a protozoan or an alga, has a far more complex self-regulating apparatus, visible, in part, in the structure and variety of its components. The evolution of higher organisms may be viewed as increasing specialization, in part to balance the advantages of larger size. With specialization comes a greater necessity for effective interaction between the parts of the organism and for a master control system to coordinate the substructures and keep the organism in tune with the environment.

The process of natural selection acts on every aspect of the organism that has been genetically determined, from cell components to the configuration of the whole organism. The biomechanical principles that determine the form and function of a given component will vary, depending in part on its level in the hierarchy of complexity and in part on its role in the total system. These principles both limit and shape the ways in which the organism adapts to its environment.

## Forster, E.M.

Well-known initially as a novelist, E.M. Forster was also widely read in English-speaking countries during his later years as a critic of social, political, and moral attitudes. His lack of a systematic philosophy was deliberate, harmonizing with a liberal humanist attitude that sought especially to stress the importance of the particular human being and of personal relationships.

Radio Times Hulton Picture Library

Forster.

Edward Morgan Forster was born in London on January 1, 1879. His father, an architect, died when he was a baby, and he was brought up by his mother and paternal aunts. The difference between the two families, his father's being strongly evangelical with a high sense of moral responsibility, his mother's more feckless and generous-minded, gave him an enduring insight into the nature of domestic tensions, while his education as a day-boy (day student) at Tonbridge School, Kent, was responsible for many of his later criticisms of the English public school (private) system. At King's College, Cambridge, he enjoyed a sense of liberation. For the first time he was free to follow his own intellectual inclinations; and he gained a sense of the uniqueness of the individual, of the healthiness of moderate skepticism, and of the importance of Mediterranean civilization as a counterbalance to the more straitlaced attitudes of north European countries.

On leaving Cambridge, Forster decided to devote his life to writing. His first novels and short stories were redolent of an age that was shaking off the shackles of Victorianism. While adopting certain themes (the importance of women in their own right, for example) from earlier English novelists such as George Meredith, he broke with the elaborations and intricacies favoured in the late 19th century and wrote in a freer, more colloquial style. From the first his novels included a strong strain of social comment, based on acute observation of middle class life. There was also a deeper concern, however, a belief, associated with Forster's interest in Mediterranean "paganism," that if men and women were to achieve a satisfactory life, they needed to keep contact with the earth and to cultivate their imaginations. In an early novel, *The Longest Journey* (1907), he suggested that cultivation of either in isolation is not enough, reliance on the earth alone leading to a genial brutishness and exaggerated development of imagination undermining the individual's sense of reality.

The same theme runs through *Howards End* (1910), a more ambitious novel that brought Forster his first major success. The novel is conceived in terms of an alliance between the Schlegel sisters, Margaret and Helen, who embody the liberal imagination at its best, and Mrs. Ruth

First  
major  
success

Wilcox, the owner of the house *Howards End*, which has remained close to the earth for generations; spiritually they recognize a kinship against the values of Henry Wilcox and his children, who conceive life mainly in terms of commerce. In a symbolic ending, Margaret Schlegel marries Henry Wilcox and brings him back, a broken man, to *Howards End*, re-establishing there a link (however heavily threatened by the forces of progress around it) between the imagination and the earth.

The resolution is a precarious one, and World War I was to undermine it still further. Forster spent three wartime years in Alexandria, Egypt, doing civilian war work, and visited India twice, in 1912–13 and 1921. When he returned to former themes in his postwar novel *A Passage to India* (1924), they presented themselves in a negative form: against the vaster scale of India, in which the earth itself seems alien, a resolution between it and the imagination could appear as almost impossible to achieve. Only Adela Quested, the young girl who is most open to experience, can glimpse their possible concord, and then only momentarily, in the courtroom during the trial at which she is the central witness. Much of the novel is devoted to less spectacular values: those of seriousness and truthfulness (represented here by the administrator Fielding) and of an outgoing and benevolent sensibility (embodied in the English visitor Mrs. Moore). Neither Fielding nor Mrs. Moore is totally successful; neither totally fails. The novel ends in an uneasy equilibrium. Immediate reconciliation between Indians and British is ruled out, but the further possibilities inherent in Adela's experience, along with the surrounding uncertainties, are echoed in the ritual birth of the God of Love amid scenes of confusion at a Hindu festival.

The values of truthfulness and kindness dominate Forster's later thinking. A reconciliation of humanity to the earth and its own imagination may be the ultimate ideal, but Forster sees it receding in a civilization devoting itself more and more to technological progress. The values of common sense, goodwill, and regard for the individual, on the other hand, can still be cultivated, and these underlie Forster's later pleas for more liberal attitudes. During World War II he acquired a position of particular respect as a man who had never been seduced by totalitarianisms of any kind and whose belief in personal relationships and the simple decencies seemed to embody some of the common values behind the fight against Nazism and Fascism. In 1946, his old college gave him an honorary fellowship, which enabled him to make his home in Cambridge and to keep in communication with both old and young, until his death at Coventry, England, on June 7, 1970.

Although the later Forster is an important figure in mid-20th-century culture, his emphasis on a kindly, uncommitted, and understated morality being congenial to many of his contemporaries, it is by his novels that he is more likely to be remembered, and these are best seen in the context of the preceding Romantic tradition. The novels sustain the cult of the heart's affections that was central to that tradition, but they also share with the first Romantics a concern for the status of man in nature and for his imaginative life, a concern that remains important to an age that has turned against other aspects of Romanticism.

In addition to essays, short stories, and novels, Forster wrote a biography of his great-aunt, *Marianne Thornton* (1956); a documentary account of his Indian experiences, *The Hill of Devi* (1953); and *Alexandria: A History and a Guide* (1922; new ed., 1961). *Maurice*, a novel with a homosexual theme, was published posthumously in 1971 but written many years earlier; some short stories remain in manuscript.

#### MAJOR WORKS

NOVELS: *Where Angels Fear to Tread* (1905); *The Longest Journey* (1907); *A Room with a View* (1908); *Howards End* (1910); *A Passage to India* (1924); and *Maurice* (posthumously, 1971).

OTHER WORKS: *Aspects of the Novel* (1927), criticism; *The Collected Tales of E.M. Forster* (1947), *Abinger Harvest* (1936), and *Two Cheers for Democracy* (1951), essays; and

*Billy Budd* (1951), libretto collaboration with E. Crozier for an opera by Benjamin Britten.

**BIBLIOGRAPHY.** B.J. KIRKPATRICK, *A Bibliography of E.M. Forster*, 2nd ed. (1968), is a recent listing of additional source material. Most manuscripts and papers are held by the Library of King's College, Cambridge; others are in the University of Texas Library. The authorized biography is being written by P.N. FURBANK. Critical works include: ROSE MACAULAY, *The Writings of E.M. Forster* (1968), a view of Forster by a late Edwardian; LIONEL TRILLING, *E.M. Forster: A Study*, 2nd rev. ed. (1965), an account of Forster as liberal humanist; F.C. CREWS, *E.M. Forster: The Perils of Humanism* (1962), a further contribution to this discussion; J.B. BEER, *The Achievement of E.M. Forster* (1962), dwelling on Forster's visionary and pagan themes; and WILFRED STONE, *The Cave and the Mountain* (1966), the most complete discussion to date of Forster's work.

## Fortifications

Fortifications are military positions that have been strengthened against attack. Fortification is the military art or science of strengthening such positions. Permanent fortifications include elaborate forts and troop shelters; they are usually constructed of masonry and are most often erected in times of peace or upon threat of war. Field fortifications are constructed when in contact with an enemy or when contact is imminent. They consist of entrenched positions for personnel and crew-served weapons; cleared fields of fire; and obstacles such as explosive mines, barbed-wire entanglements, felled trees, and anti-tank ditches. Both field and permanent fortifications often take advantage of natural obstacles, such as canals and rivers, and they are usually camouflaged or otherwise concealed.

Both field and permanent fortifications assist the defender to obtain the greatest advantage from his own strength and weapons while preventing the enemy from using his resources to best advantage. When supported by covering fire, for example, fortifications may force the enemy to deploy prematurely into open and less controllable formations. Fortifications may also be used to deny easier invasion routes and channel enemy operations into less advantageous paths.

Before the advent of the most modern weapons, almost all important cities and trade centres were defended by permanent fortifications, either a high wall encircling the city, a series of forts on the periphery, a walled and moated citadel within the heart of the city, or a combination or variations of the three. Fortifications also might be established at strategic points along likely routes of invasion. Throughout history coastal fortifications have been constructed to guard seaports against naval attack or to counter amphibious assault.

Some fortifications may be considered semipermanent, such as the extensive trench systems employed in World War I or the forts and base camps used in more recent times in Southeast Asia, Korea, and the Middle East. These were usually entrenched fighting positions and troop shelters reinforced by log or timber revetments and earth-filled burlap or plastic bags.

Neither fortifications nor the obstacles contributing to them are of optimum value unless actively defended by troops and guns. Antitank obstacles, for example, may be covered over by bulldozers or destroyed by demolition charges. Since no fortifications, however stoutly constructed, can be considered impregnable, an integral part of the defense is the sally or sortie, whereby troops rush out from the fortifications to engage the enemy in close combat, or the counterattack, whereby reserve forces seek to destroy or eject any troops who may have penetrated the defenses.

Before the invention of gunpowder led to the creation of artillery firing powerful explosive projectiles, permanent fortifications might hold up an attacker for months and even years. Sometimes starvation or the threat of starvation was all that finally induced defenders to surrender.

The effect of even fairly primitive artillery was dramatically demonstrated at Constantinople in AD 1453 when a

Importance of adequate defense

Later thinking and attitudes

besieging Turkish force in 55 days breached defenses that had earlier withstood sieges as long as five years. Improvements in design and construction retained considerable advantage for fortifications through ensuing years, despite improved artillery. In the two world wars, some permanent fortifications held up well against the most powerful bombardment.

Yet, in no case have fortifications proven impervious to modern weapons, and against atomic weapons permanent fortifications as known throughout history may well be a thing of the past. Although all types of fortifications have continued even in recent years to be of some value, certainly in part because nuclear weapons have not been employed, most fortifications designed to counteract the vast new explosive power of the nuclear age are constructed deep underground, not as conventional fighting positions but as protection for headquarters staffs, command and control systems, and antiballistic missiles.

## Early forms

### ANCIENT FORTIFICATIONS

Both field and permanent fortifications played an important role in warfare in the ancient world, but permanent fortifications were particularly effective against the limited power of ancient offensive weapons. Even the lengthy siege aimed at starving the defenders was not always effective, for the defenders were often able to supply themselves better than the besieging army could live off a hostile land. Sometimes a ruse or subterfuge, as in the legend of the Trojan Horse, was more effective than any weapon.

Early civilized tribes of Africa fought from behind a parapet filled with alternate layers of stone, earth, and logs. Sometime later came walls made of mud, sun-dried brick, or masonry and towers constructed at intervals along the wall to serve as sentry posts or as defensive bastions from which archers could cover the approaches between towers.

**The first fortresses.** As early as 7000 BC the city of Jericho was protected by a wall 21 feet high encompassing an area of ten acres and by an outer moat 15 feet wide and nine feet deep ( $7 \times 5 \times 3$  metres) hewn through solid rock. In ancient Egypt and Assyria walls as thick as 30 feet (nine metres) and as high as 120 feet (37 metres) were constructed, frequently with a ditch in front to keep attackers at a distance. To counter such defenses, attacking forces developed devices such as scaling ladders, battering rams, torsion-activated catapults for throwing heavy missiles, tension-activated ballistae for shooting large spears, and movable towers from which to overlook the walls and rain incendiary arrows into the fortress. The defenders reinforced their bastions with similar engines of war, firing them from atop or behind the walls. The attackers sometimes resorted to mining, digging tunnels beneath the defenses, then setting fire to the timber that shored up the tunnels, causing the earth above to collapse.

One of the most renowned of the ancient fortresses was the city of Tyre, built on an island half a mile from shore. Only after a seven-month siege did one of history's great captains, Alexander the Great, succeed in breaching the defenses. The Tyrians defeated Alexander's first efforts to build a mole 200 feet wide from the mainland to the walls, but after gaining mastery of the sea around the fortress, Alexander built a fleet of barges armed with war engines and anchored them at strategic points along the defensive works. From the barges he mounted his successful assault.

Another famous siege was the unsuccessful Macedonian attack on the city of Rhodes, undertaken some years after Alexander's death. So large was one of the towers used in the attack that 3,400 men were required to move it up to the walls. Another 1,000 men were needed to wield a battering ram 180 feet long. Despite such impressive efforts by the attackers, Rhodes held out for six years until finally relieved by allied forces that drove off the Macedonians.

The fortresses and towers and assault devices of early Greece and Rome remain a wonder to modern engineers

accustomed to steam-, hydraulic-, and diesel-operated machinery. The Romans, for example, constructed huge siege towers, one of which Caesar mentions as being 150 feet (46 metres) high. The lower stories housed the battering ram, which had either a pointed head for breaching or a ramlike head for battering. Archers in the upper stories shot arrows to drive the defenders from their ramparts. From the top of the tower, a hinged bridge might be lowered to serve a storming party. To guard the attackers against enemy missiles, the Romans used mantelets, which were great wicker or wooden shields, sometimes mounted on wheels. In some cases the attackers might approach the fortress under the protection of wooden galleries.

**Protective walls.** Massive, elongated walls were also a feature of early permanent fortifications. The Great Wall of China, built by the emperor Shih Huang Ti in the 3rd century BC to discourage incursions by nomadic tribes, was 1,600 miles (2575 kilometres) long, generally 25 feet (eight metres) wide at the base and 17 feet (five metres) at the top, with an average height of more than 20 feet (six metres). When the frontiers of the Roman Empire rested in northwestern Europe and Africa, the Romans built a number of continuous walls, including the Limes Germanicus, some 250 to 300 miles long (402 to 483 kilometres) from the Rhine near Neuwied to the Danube near Ratisbon, and Hadrian's Wall in Britain, 73 miles long (117 kilometres) from the Solway Firth to a point on the North Sea coast just north of Newcastle-on-Tyne. The Limes was for half its length an earthen mound with a ditch and for the other half a rough stone wall four feet (1.2 metres) thick. Hadrian's Wall was originally built of earth but later strengthened by a masonry wall eight feet (2.4 metres) thick and 16 feet (4.8 metres) high. None of the walls was defended along its entire length. Sentry posts, watchtowers, or roving patrols gave notice of enemy incursions, whereupon reserves operating from camps spaced at intervals either along the wall or several miles behind it moved to eliminate them. Remarkably preserved vestiges of these walls, including the Great Wall of China, remain to this day.

**Early field fortifications.** The main purpose of early field fortifications, particularly among the Greeks, was to secure an advantage by standing on higher ground so that the enemy was forced to attack uphill. The solid mass formation of the Macedonian phalanx was particularly effective on the defense when supplemented by natural or man-made obstacles. The Romans were especially adept at field fortifications, preparing fortified camps at the close of each day's march. Roman camps normally were square or rectangular, though they could vary with the details of terrain. The troops usually required three to four hours to dig a ditch around the periphery, erect a rampart of palisade from timbers carried by each man, lay out streets, and pitch tents. In hostile territory as much as half of each legion might mount guard or engage the enemy while the remainder worked. During extended campaigns the Romans strengthened the camps with towers and outlying redoubts, or small forts, and used the camps as a base for offensive forays into the surrounding territory.

In the campaign in Gaul against the insurgent Arverni chieftain, Vercingetorix, the Romans under Julius Caesar performed a formidable engineering feat in surrounding a large number of Gauls in the fortified town of Alesia near the present French city of Dijon. With about 55,000 men, Caesar built two separate walls of "contravallation"—facing the town—and "circumvallation"—facing outward, the latter 14 miles (23 kilometres) in circumference. While holding Vercingetorix at bay with these fortifications, Caesar defeated three attempts by a Gallic relief army to break through to the besieged force. Facing starvation, Vercingetorix at last surrendered.

Among the Teutonic barbarians, the Goths developed their own version of the fortified camp. When travelling, the Goths moved in a large convoy of wagons, which they assembled at night in a circle, or laager, providing an effective fort both for defense and as a base for forage and plunder. The methods later used by the wagon trains

Roman  
fortified  
camps

Siege of  
Rhodes

of American pioneers against the Indians of the western plains were similar, as were procedures adopted by armoured divisions in World War II.

#### THE MIDDLE AGES

With the decline of the Roman Empire and the rise of feudalism, the importance of field fortifications diminished. The mounted knight depended for protection in the field on his heavy armour, while the art of permanent fortifications centred on the medieval castle. The castle built of heavy stone on high ground came early to the mainland of Europe (11th century) but was slower to develop in Britain, where simple ditches and wooden palisades continued longer. William the Conqueror used wooden forts to consolidate his conquest of England.

Motte-and-bailey castles

**The medieval castle.** The continental castles were typified by the Normans' motte-and-bailey castles. The motte was a mound surrounded by a ditch and surmounted by a wall and a single large tower, the keep or donjon. The bailey was a forecourt protected by another ditch and wall, its purpose originally being to protect the domestic animals. Entrance to the castle was by way of a retractable drawbridge. The concept of the castle was one of almost totally passive defense, for however difficult it was for the attacker to reach and assault the defenses, located as they were on virtually inaccessible terrain, it was almost as difficult for the defender to debouch rapidly to harass the attacker. Although a new weapon was introduced, the trebuchet, or mangonel, a missile-hurling machine propelled by counterweight rather than tension or torsion, starvation continued to constitute the principal offensive weapon in sieges.

As a result of the Crusades (AD 1095–1291), fortifications in western Europe underwent something of a revolution. The crusaders' encounter with powerful walled Byzantine cities and fortresses with double or triple concentric lines of turreted walls led to a strengthening of castle and city defense. The most impressive single example was the Chateau Gaillard, built by Richard the Lionhearted in Normandy, which actually improved on the eastern prototypes, although the castle's siege and capture by Philip II (1203–04) proved that an attacker willing to devote sufficient resources and time to the effort might overcome even the most powerful defenses. Yet long campaigns in this era were the exception, since feudal levies could be called to service for only a few weeks each year and mercenary armies were too expensive to maintain indefinitely.

Castles continued to be built well into the 14th century and, growing increasingly elaborate, constituted some of the most efficient fortifications of any age. The later versions were protected by a series of concentric powerful curtain walls fronted by a moat, often a lake. Gate houses were three or four stories tall, surmounted by twin towers. Machicolations (overhanging parapets), portcullises, and loopholes strengthened the defenses. Sometimes the central bailey was large enough to include a town. An example of the later castles is the Bastille in Paris (1370–83).

**Mongol field fortifications.** Both the art of siegecraft and that of field fortifications were rejuvenated by the Asian Mongols in both their eastern and western conquests (1190–1400). The Mongols employed mammoth siege trains with missile engines and other equipment carried on wagons and pack animals. The main body of Mongol warriors often went on to further conquest while

leaving reduction of the fortress to a subordinate force. In field operations the Mongols consistently followed a tactic of defending their centre by entrenchment, employing the troops thus released for strengthening flank operations on the wings of the defended position.

#### THE AGE OF FIREARMS

Although gunpowder weapons appeared at least as early as the mid-14th century, they were at first inaccurate and generally ineffective cannon consisting of small metal pots or tubes. Only after the opening of the 15th century did most European armies and the Turks possess artillery weapons that posed a genuine threat to the existing medieval fortifications. When Henry V's cannon in 1415 began the second half of the Hundred Years' War by battering down the walls of Harfleur, the era of impregnable fortifications can be said to have passed.

**Siege warfare.** The early gunpowder weapons, tubes of cast or wrought iron, were used almost exclusively for siege operations. Known as bombards, they were moved about on ox-drawn sledges and had to be emplaced on mounds of earth or log platforms. Projectiles were either iron or stone and had no explosive content. They were nevertheless effective, as in the siege of Constantinople in 1453 when Turkish bombards battered down walls that had stood for centuries. The Turkish cannon included 70 heavy pieces, one a 19-ton behemoth firing stone balls up to 1,500 pounds in weight for a distance in excess of a mile.

By the mid-15th century so effective was the artillery of Charles VII of France—the best on the Continent—that the French were able to reduce all of the castles of Normandy in one year. Partly because artillery was not yet adaptable to emplacement atop or within fortifications to provide counterbattery fire, but mainly because of the increased power of the cannon, artillery by the close of the century had rendered medieval fortifications obsolete. The use of gunpowder in mining further increased the vulnerability of the castles.

Effect of artillery

Not until the closing decade of the 15th century, when the French introduced a relatively light cast-bronze cannon on two-wheeled carriages pulled by horses, was artillery to figure prominently in field operations and thus to become an important element in field fortifications. Nevertheless, as early as the Hussite Wars (1419–36) in Bohemia, the Hussite leader, John Ziska, in creating a defense called the *wagenburg*, an adaptation of the laager tactic of the Goths, effectively employed bombards in the intervals between his wagons.

Yet despite these developments, field fortifications were seldom used during the early years of the age of gunpowder. Since cannons were still relatively inaccurate and firearms cumbersome and of short range, most armies in the field relied on the strength of men en masse to repel attack. Important in the defense were bodies of disciplined, heavily armoured pikemen who stood in a variety of close formations, their pikes planted firmly on the ground and slanted toward the attacker. Pikemen of the Swiss army gained a reputation for solid defense unequalled since the days of the Macedonian phalanx.

**The strengthening of permanent fortifications.** By the 16th century the revolution in permanent fortifications occasioned by gunpowder was in full swing, as even the most massive medieval fortifications had become vulnerable to heavy siege guns. Some of the greatest figures of the Renaissance contributed to new developments in

Figure 1: Cross-section of the main wall of a fortress.

permanent defenses: Leonardo da Vinci, Michelangelo, and Niccolo Machiavelli, among others. The German artist, Albrecht Dürer, wrote extensively on the theory of fortification.

As new fortifications were constructed, the walls tended to be broad and low, sometimes even sunk below ground level, in order to keep the portion exposed to artillery fire to a minimum. Triangular bastions extended outward from the walls so that defending artillery might sweep all approaches. The usual fort had five or six bastions, leading to the name of star fortress. The main wall was known as the enceinte; the top of it, the parapet; the area behind the parapet, the terreplein. An escarp or forward face of the wall led down to a wide ditch, beyond which stood the counterscarp, a low outwork defended by light artillery and small arms. Earth excavated from the ditch was spread in front of the counterscarp to create a gradually sloping terrace, or glacis, which added to the strength of the counterscarp and absorbed many of the projectiles fired from artillery pieces of limited range and elevation (see Figure 1).

As military engineers continued to search for increased defensive strength, the star fortress was replaced by the tenaille trace (see Figure 2A) in which the flanks of the bastions were placed back-to-back between the faces. Yet a certain amount of the ditch still could not be reached by fire from the bastions. This led to development of the bastioned trace (see Figure 2B), its flanks directly opposite each other and linked by curtain walls. In succeeding decades, fortifications employed varied geometric patterns with a wealth of gates, sally ports, redans, coverings and other refinements. Each part of the fortification

Improved  
fortress  
designs

Figure 2: (A) Tenaille trace and (B) bastioned trace.

became a separate fort that could be self-sustaining with its own garrison while providing mutual support to the remainder of the units in the system.

These fortresses were constructed either as outposts or citadels in the defense of cities or as barriers along strategic routes. Border towns such as Metz and Verdun in France and Liège, Namur, and Charleroi in Belgium became critically important. Nations sought to control the approaches to their territory while retaining a base or springboard from which to counterattack or to launch a retaliatory invasion. Since the more powerful cannon now became a part of naval armament, port cities had to be protected with fortifications guarding against assault from the sea.

**Modification of siege operations.** The new methods of fortification having outstripped gunnery developments, long, difficult sieges again ensued. Such old devices as mantelets, galleries, and siege towers were of no use in the face of gunpowder, and even mining was of limited use because the range of artillery dictated that tunnels had to be so long that fresh air could not reach the diggers. The besiegers resorted to digging approach entrenchments. Covered by artillery fire, troops dug trenches in the direction of the fortification's outer works, then threw up earthen walls as protection for their own artillery. The guns were brought up under cover of darkness, and the process was repeated until the attackers were close enough to overwhelm the counterscarp defenders. The process again had to be repeated against the main walls.

Sieges grew longer and more costly. In 1522 the Ottoman Turks besieged Rhodes, the eastern Mediterranean stronghold of the Knights Hospitalers of St. John (a military order formed during the Crusades). Rhodes was one of the earliest of the new bastion fortresses. Although the defenders were greatly outnumbered and cut off from resupply and although the Turks at one point penetrated into the city, so appalled was the Turkish commander at

his losses that he withdrew and offered honourable terms for a treaty.

The difficulty of siege operations against the new permanent fortifications and the increased effectiveness of small arms rejuvenated the art of field fortifications. The first to combine the new power of small arms with field works was Gonzalo de Córdoba of Spain. He discerned that a few arquebusiers might utilize entrenchments to cover extensive frontages, thus enabling smaller forces to contain and then outmanoeuvre larger forces. Alexander of Parma (16th-century Spanish commander in the Low Countries) fought on several occasions against Henry IV of France from field fortifications that his veterans erected overnight. The Spaniards subsequently met their engineering match in Maurice of Nassau, commanding Dutch forces, who made skillful use of natural obstacles to swiftly construct field fortifications capable of resisting any assault.

## Modern fortifications

### THE ADVENT OF MODERN WARFARE

With the beginning of modern warfare in the 17th century, field fortifications continued to exercise an important influence, particularly as practiced by Gustavus Adolphus, the father of modern tactics and army organization. Gustavus and his Swedish troops constructed outposts defended by redoubts and protected their forts with palisades and entanglements. In the manner of the Romans, the Swedes dug in each night and built a wall around their camp. On the banks of the Elbe, Gustavus' troops, fighting from field fortifications backed by cannons firing at point-blank range, twice repulsed assaults by the army of the Holy Roman Empire under Johann Tserclaes, Graf von Tilly. On the other hand, field fortifications of his enemy led to one of Gustavus' more serious defeats: at Nuremberg Gustavus grew impatient for battle and ordered his forces from their entrenchments to attack the imperial army, now commanded by Count Albrecht von Wallenstein; the Swedes suffered a sharp repulse.

**The influence of Vauban.** Late in the 17th century, the art of permanent fortifications, already highly developed, became an even more critical element of warfare as the result of the genius of a French engineer, Sébastien de Vauban. Vauban retained the traditional plan for a fortress—inner enclosure, rampart, moat, and outer rampart—but he extended the outworks as far as possible in order to compel the enemy to begin his siege operations at a distance. He also insured that every defensive face was flanked and supported by the works behind and beside it, in the process creating a vast polygon replete with great bastions at every angle interspersed with smaller ones in between, each of which was close enough to the next to provide supporting small-arms fire.

Vauban also was a master of siegecraft. Before his time, the usual method was to approach the walls with zigzag trenches, then, with artillery brought forward, to assault from the head of the trench. Since the defenders could concentrate their fire against the head of the trench, this was a costly process. Vauban instead instituted a system of parallel trenches (see Figure 3). Some 600 yards from the fortress—the approximate maximum range of contemporary artillery—his engineers dug a trench parallel to the periphery of the fortress to serve as protection for the infantry while a preliminary artillery duel raged. Thereupon the engineers dug a series of zigzag trenches (called saps), culminating in a second parallel about halfway to the wall and within musket range; this served as forward cover for infantry and artillery. The engineers—who gradually acquired the name sappers after the name of the trenches—then dug slowly ahead under cover of wheeled shields called gabions. They dug a final third parallel near the glacis. From that point, with breaching batteries brought forward, the infantry could assault at a number of points simultaneously. Vauban's methods of fortification and siege remained standard until the later 19th century, although such 18th-century commanders as the Duke of Marlborough and Frederick the Great of Prussia came to deplore siege warfare and to circumvent

Vauban's  
new siege  
technique

Figure 3: Attack upon a fortress using the Vauban system.

it by disciplined marches designed to manoeuvre the enemy away from the permanent forts and by expert battlefield tactics.

In North America, in the meantime, the frontier fort surrounded by a log palisade had been an integral part of warfare as Europeans pushed their settlements westward. In North America, too, in the Revolutionary War, American soldiers demonstrated again the value of field fortifications: the hasty entrenchment, the waist-high parapet, the cover of a tree or stone hedge. Within a generation American troops under Andrew Jackson at the Battle of New Orleans made effective use of cotton bales to defend their position against advancing British troops.

In the Napoleonic period the outstanding example of field fortifications was the Torres Vedras line, erected by the Duke of Wellington 25 miles north of Lisbon (1810): three lines of mutually supporting batteries and redoubts running for 30 miles through a range of low hills between the Tagus River and the sea. The rapid movements of the Napoleonic Wars generally discouraged elaborate defensive works, though Russian field fortifications played a central role in the bitterly fought battle of Borodino (1812).

**Increased use of entrenchment.** In the American Civil War, field fortifications emerged as an essential of warfare with both armies employing entrenchments to an extent never before seen. Troops learned to fortify newly won positions immediately, employing spades and axes carried in their packs, first digging rifle pits, then expanding them into trenches. Early in the war, Gen. Robert E. Lee adopted the frontier rifleman's breastwork composed of two logs on the parapet of the entrenchment, and many of Lee's victories were the result of his ability to use hasty entrenchments as a base for aggressive employment of fire and manoeuvre. In two notable sieges, that of Vicksburg, Miss., in the west, and Petersburg, Va., in the east, trench warfare was the accepted method of siege. In the Vicksburg siege, which lasted for almost a year, Union troops tunnelled under the defenses and placed a powder charge timed to explode after they had pulled back. In the Cold Harbor, Va., campaign, when Gen. Ulysses S. Grant sent his troops against Confederate earthworks, he lost 14,000 men in 13 days. Field mines and booby traps were used extensively, and trench mortars were developed to lob shells into opposing trenches.

At the start of the war, the United States had few permanent fortifications except on the coast, such as Fort Sumter in Charleston harbour where the first shot was fired, but the Confederate threat to Washington prompted early construction of a defense system around the capital. It included 68 separate forts, a number of blockhouses, and 20 miles of connecting trenches. Although never put to a test, the fortifications had a considerable indirect influence on the campaigns in nearby

Virginia; in the summer of 1864 they contained Confederate General Jubal Early's threat to Washington.

#### WORLD WAR I (1914-18)

The lesson learned in the American Civil War was for a time lost on European commanders. Even the bitter experiences of appalling losses in the Crimean, Franco-German, and Boer wars failed to lessen an ardour for the theory of the offensive that was so fervent as to leave little concern for defensive tactics in the field. Few took notice of the immense casualties the Turks inflicted from behind field fortifications in the Russo-Turkish War of 1877-78, and even though the Russo-Japanese War soon after the turn of the century underscored the lethal power of the machine gun and breech-loading rifled artillery, most European commanders saw the increased firepower as more a boon to the offensive than to the defensive.

**The permanent fort.** Most defensive thinking was reserved for the permanent fort, which was designed to canalize enemy advance and to afford time for national mobilization. The leading fortification engineer of the time was Henri Brialmont, who was considered a Belgian Vauban. He placed his forts, built of concrete, at an average distance of four miles from a city, as with 12 forts at Liège, and at intervals of approximately 2½ miles. At Antwerp his defense system was even more dense. He protected the big guns of his forts with turrets of steel and developed disappearing cupolas. Some forts were pentagonal, others triangular, with much of the construction underground. In building defenses along the frontier facing Germany, French engineers emulated Brialmont, with particularly strong clusters of fortresses at Verdun and Belfort. So monstrous were the forts of the time that they were known as "land battleships."

By marching through Belgium with a strong right wing (the Schlieffen plan), the Germans circumvented the powerful French fortresses. Passing between the forts at Liège, which Brialmont had intended to be connected with trenches, they took Liège in only three days, then systematically reduced the forts. Namur, also heavily fortified, resisted the powerful German guns for only four days. The concrete of the Belgian fortifications crumbled under the pounding, but the French forts at Verdun, of more recent and sturdier construction, later absorbed tremendous punishment and served as focal points for some of the war's bloodiest fighting.

**The trench systems.** Despite German success against the Belgian forts, the fallacy of the belief that the new firepower favoured the offensive was soon convincingly demonstrated. Once the French had checked the German right wing at the Marne River, the fighting degenerated into what was in effect a massive siege. For 600 miles, from Switzerland to the North Sea, the landscape was soon scarred with opposing systems of zigzag, timber-

revetted, sandbag-reinforced trenches, fronted by tangles of barbed wire sometimes more than 150 feet deep and featured here and there by covered dugouts providing shelter for troops and horses and by observation posts in log bunkers or concrete turrets. The trench systems consisted of several lines in depth, so that if the first line was penetrated, the assailants were little better off. Rail and motor transport could rush fresh reserves forward to seal off a gap faster than the attackers could continue forward. Out beyond the trenches and the barbed wire was a muddy, virtually impassable desert called no-man's-land, where artillery fire soon eliminated habitation and vegetation alike. The fighting involved masses of men, masses of artillery, and masses of casualties. Toxic gases—asphyxiating, lachrymatory and vesicant—were introduced in a vain effort to break the dominance of the defense, which was so overpowering that for more than two years the opposing lines varied less than ten miles in either direction.

The  
Hinden-  
burg Line

During the winter of 1916–17, the Germans prepared a reserve trench system, the Hindenburg Line, containing deep dugouts where the men could take cover against artillery fire and machine guns emplaced in concrete shelters called pillboxes. Approximately two miles behind the forward line was a second position, almost as strong. The Hindenburg Line resisted all allied assaults in 1917, including a vast British mining operation under the Messines Ridge in Belgium that literally blew up the ridge, inflicting 17,000 casualties at one blow; the advance failed to carry beyond the ridge.

In northern Italy the fighting assumed much the same complexion. Only on the eastern front did the vast distances dictate a more open form of warfare but one equally expensive in casualties.

#### WORLD WAR II (1939–45)

**Permanent fortifications.** *The Maginot Line and the West Wall.* In the interval between world wars, several European countries built elaborate permanent fortifications. The largest was the French Maginot Line, named after a minister of defense, a system of mammoth, self-contained forts stretching from Switzerland to the vicinity of the Belgian frontier near Montmédy. The reinforced concrete of the forts was thicker than any heretofore used, the disappearing guns bigger and more heavily armoured. Ditches, embedded steel beams, and minefields guarded against tank attack. A large part of the works were completely underground. Outposts were connected to the main forts by concrete tunnels. But since French and British military leaders were convinced that if war came again with Germany, the Allies would fight in Belgium, the French failed to extend the line to the sea, relying instead on an outmoded system of unconnected fortresses left over from before World War I. It was this weakness that the Germans subsequently exploited in executing a modified version of the Schlieffen plan, cutting in behind the permanent defenses and defeating France without having to come to grips with the Maginot Line.

The Germans confronted that portion of the Maginot Line facing the Saar River with fortifications of their own, the West Wall. Later extended northward to the Dutch frontier and southward along the Rhine to Switzerland, the West Wall was not a thin line of big forts but a deep band, a mile to five miles thick, of more than 3,000 small, mutually supporting pillboxes, observation posts, and troop shelters. For passive antitank defense the line depended upon natural obstacles, such as rivers and lakes, and upon “dragon’s teeth,” five rows of pyramid-shaped reinforced concrete projections.

The Germans did not rely on the West Wall to halt an attack but merely to delay it until counterattacks by mobile reserves could eliminate any penetration. The value of their concept remains undetermined; the line was not attacked until late 1944, after the German armies had incurred severe defeats and lacked adequate reserves. The West Wall nevertheless forced Allied troops into costly attacks to eliminate it.

**Other fort series.** Elsewhere in World War II many fortifications similar to these two basic types were built.

The Italians constructed a series of new fortifications and modernized existing World War I defenses along the country’s mountainous northern and northeastern frontiers; the Finns maintained a World War I defense facing the Soviet Union: the Mannerheim Line (named after a Finnish marshal and statesman); the Soviets built the Stalin Line facing Poland; the Czechoslovaks constructed what became known as the Little Maginot Line to oppose Germany; the Greeks built the Metaxas Line facing Bulgaria; and the Belgians erected a series of elaborate forts along the Albert Canal. German capture of the most elaborate and allegedly impregnable of the Belgian forts, Eben Emael, in a matter of hours in the first two days of the campaign against France and the Low Countries in 1940 startled the world. Arriving silently by night in gliders, troops landed atop the fort and began systematically to destroy turrets and casemates. Soon after daylight they were joined by 300 men arriving by parachute. Around noon of May 11 the 1,000-man garrison surrendered.

The  
capture  
of Eben  
Emael

Despite at least comparable surprise and the same so-called blitzkrieg methods, the Germans required more time to penetrate the more dispersed forts of the Stalin Line in the U.S.S.R. The delay gained two months of invaluable time for the Soviet troops, without which they might well have been unable to stop the Germans at the gates of Moscow.

The other notable Soviet use of permanent fortifications was at Leningrad, where, with a combination of old Baltic forts, field fortifications, water barriers, and ruined buildings, they held out for 900 days—from September 1941 until January 1944—when they finally were relieved. The ordeal of Leningrad constituted one of history’s more notable sieges, a defense sustained by incredible fortitude and such exigent methods as a seasonal supply line across the frozen surface of Lake Ladoga. In the historic defense of another city, Stalingrad, the Soviet army made notable use of a new material for field fortifications: rubble of a city’s buildings.

In Asia and the Pacific, the most renowned permanent defenses, those of the British at Singapore, revealed an unexpected weakness. Singapore’s guns faced the sea, while the Japanese approached the city from the landward side, crossed the narrow channel separating Singapore island from the mainland, and forced a British capitulation. Another famed Far East fortification, the American bastion of Corregidor in Manila Bay, held out for less than a month.

**German channel defenses.** The Germans employed Fritz Todt, the engineer who had designed the West Wall, and thousands of impressed labourers to construct permanent fortifications along the Belgian and French coasts facing the English Channel: the Atlantic Wall. The line consisted primarily of pillboxes and gun emplacements embedded in cliffsides or placed on the waterfronts of seaside resorts and ports. Included were massive blockhouses with disappearing guns, newsreels of which the Germans sent out through neutral sources in an effort to awe their adversaries, but the numbers of big blockhouses actually were few. Behind the line, in likely landing spots for gliders and parachutists, the Germans emplaced slanted poles, which the troops called *Rommelspargel* (Rommel’s asparagus), after their commander Field Marshal Erwin Rommel. Embedded in the sand of the beaches below the high-tide mark were numerous obstacles, varying in shape and depth, some topped with mines. Barbed wire and antitank and antipersonnel mines interlaced the whole. On the French southwestern and southern coasts similar, through less formidable, defenses were erected.

The Allies first tested the German fortifications in August of 1942 at the resort town of Dieppe in a raid by a 6,100-man force, primarily Canadians. The result was nearly catastrophic: all but 1,650 of the 5,000 who got ashore were lost.

Despite the example of Dieppe, when the Allies landed in force on the Cotentin Peninsula of Normandy on D-Day—June 6, 1944—they found the defenses far less formidable than they had anticipated. This was attributable

Beach  
defenses in  
Normandy

to a number of reasons. The Germans had constructed the strongest defenses in the Pas-de-Calais region facing the narrowest part of the English Channel and had stationed their most battleworthy troops there; demands of other fighting fronts had siphoned many of the best German troops from France; the Germans lacked air and naval support; Allied airpower was so strong that movement of German reserves was seriously impeded; landings of Allied airborne troops behind the beaches spread confusion in German ranks; and the Germans were deluded into believing the invasion was a diversion, that a second and larger invasion was to follow in the Pas-de-Calais. Only at one of the two American beaches, given the code name Omaha, was the success of the landing ever in doubt, partly because of rough seas, partly because of the chance presence of an elite German division, and partly because of the presence of high bluffs. Paradoxically, the Allies had less difficulty with the highly publicized beach defenses than they had later with field fortifications based on the Norman hedgerows, earthen embankments several feet thick and five feet high that local farmers through the centuries have erected around thousands of irregularly shaped little fields to fence their cattle and protect their crops from strong ocean winds.

**Field fortifications.** Field fortifications were even more extensively employed in World War II than in either the American Civil War or World War I, but they were in general less of the semipermanent trench type than of the individual or two-man position, called a slit trench, rifle pit, or foxhole. There were exceptions: great masses of humanity poured from the threatened cities of the Soviet Union, such as Leningrad, Moscow, and Stalingrad, to dig miles of zig-zag trenches not unlike those on the western front in World War I. In beleaguered footholds, such as the Bataan Peninsula and the Allied beachhead at Anzio in Italy, foxholes and other positions often were connected by communications trenches. The German Todt organization built a series of formidable field positions in the craggy mountainous terrain of Italy, oftentimes hewing them with explosives from solid rock. From the Gustav Line (so named from the symbol for *G* in the German military's phonetic alphabet) behind the Garigliano and Rapido rivers, anchored on the forbidding slopes of Monte Cassino, the Germans held the Allies at bay throughout the entire winter of 1943–44. Some of the defensive positions consisted of prefabricated steel turrets or cupolas placed over excavations. Through the winter of 1944–45 the Germans in northern Italy held a similar position called the Gothic Line, located in the precipitous northern Apennines below Florence.

**Japanese defenses in the Pacific.** On the Pacific islands the Japanese proved to be pertinacious masters of defense from field fortifications. Rapidly growing jungle foliage afforded ideal concealment for natural caves and log emplacements, so that Allied troops often incurred severe losses even in locating the Japanese positions. Artillery, mortars, and naval gunfire were helpful in reducing them, but more often than not final reduction was the province of little groups of infantrymen fighting with individual weapons and portable flame throwers. When the Japanese elected to defend the invasion beaches, as on Tarawa, casualties among both attackers and defenders were enormous; indeed, Tarawa was one of the bloodiest division-sized actions of the war. Even when the Japanese chose to forego beach defense, as on Okinawa, they subsequently employed field fortifications and natural obstacles with tremendous skill to prolong the campaign. The final battle, and one of the largest of the war in the Pacific, the conquest of Okinawa, required almost three months of intensive fighting. The last defenders resisted from caves on a coral promontory at the southern end of the island, their defense culminating in a mass suicide that included the commanders. More than 100,000 Japanese died on Okinawa. Another of the more tenacious Japanese defenses was conducted amid the volcanic ash and coral caves of the tiny island of Iwo Jima, later used as a way station for big American planes bombing the Japanese home islands.

The  
defense of  
Okinawa

**North African and European theatres.** As caves were readily adaptable by the Japanese for defense on Pacific Islands, so towns and cities of masonry construction in North Africa and Europe in many cases provided steadfast fighting positions. If cities were defended, the fighting almost always was slow and costly, as in Stalingrad on the eastern front and Aachen in the west. Even when bombing and shelling demolished many of the buildings, the defenders often fought even more tenaciously from the rubble. When some Allied commanders proposed bombing the historic Benedictine abbey atop Monte Cassino in Italy on the theory that the Germans were using it for observation and for troop shelter, others objected not only for cultural considerations but in the belief that the Germans could fight better from rubble than from the intact edifice. It was an anomaly that some earlier permanent fortifications, such as the forts around Metz dating from the mid-19th century and the medieval citadel of Juelich on the Roer River required prolonged and costly attacks to subdue them, for all the power of 20th-century weapons.

Except where sturdy buildings were available—or following a breakthrough resulting in pursuit operations in which enemy riposte was unlikely—combat troops of any army seldom paused for even brief periods without digging hasty field fortifications, either slit trenches or foxholes; and if the possibility of aerial bombardment existed, even troops performing rear-echelon duties had to have some form of protection at hand. In a hasty defensive position, a line of outposts or listening posts was usually established several hundred yards forward of the main line of resistance, while telephone or radio provided ready support from mortars and artillery to the rear. For more prolonged pauses, mines, booby traps, and trip flares were emplaced; barbed wire was strung; foxholes were covered with logs; and trees were felled to blockade roads. In forests, such as the jungles of the Pacific and Southeast Asia or the evergreen forests of northwestern Europe, overhead cover for foxholes was essential to guard against tree bursts of artillery shells, which rained deadly fragments upon the forest floor. A convenient, readily emplaced form of barbed wire was the “concertina,” a coil of wire three feet in diameter, which could be stretched out in the manner of a concertina to create an effective delaying obstacle.

**The foxhole.** The foxhole, or variation thereof, constituted the basic field fortification of World War II. It was dug usually with an entrenching tool carried by the individual soldier and was two to five feet in diameter, depending upon whether it was to be occupied by one man, two, or three, and at least four feet deep. Sometimes it had a firing step and a drainage pit. If concealment was vital, the earth taken from the hole was carted away or dispersed beneath foliage; otherwise it might be used to create a small parapet. Holes for crew-served weapons, such as machine guns and mortars, were appreciably larger. In severe winter weather the troops might use small explosive charges to break through the frozen top crust of earth and enable them to dig. The foxhole—particularly if covered—afforded effective protection against almost any shelling except a direct hit and if dug in firm ground, was effective against the grinding action of tank treads.

#### THE NUCLEAR AGE

At the close of World War II most military theorists considered that permanent fortifications of the type previously employed were economically impracticable in view of their vulnerability to the incredible power of nuclear explosives and the methods, such as vertical envelopment from the air, that might be employed to reduce them. Field fortifications were another matter, since these are less costly and impose at least some delay on an enemy advance. The foxhole was expected to continue to be the mainstay of field fortifications but with even greater dispersion, both laterally and in depth, than in World War II.

As events developed through and past mid-century, neither strategic nor tactical nuclear weapons were em-

ployed, although the threat of their use was often present. Consequently, field fortifications not unlike those of World War II, but with local adjustments, were used.

**The Korean War.** Fought with weapons and methods little changed from World War II, the Korean War (1950–53) produced little new in fortifications. There were few permanent fortifications on the Korean peninsula, and the foxhole, barbed wire, mines, and other familiar devices comprised the field fortifications. The Chinese Communists often elected to defend the reverse slope of a hill or mountain, keeping only outposts on the forward slope and thus achieving a measure of protection for the bulk of the defenders from direct fire. In later stages of the war, as the fighting sometimes evolved into position warfare in some ways similar to that of World War I, both sides constructed extensive field fortifications across the entire breadth of the peninsula. Aside from sandbag-reinforced and covered foxholes, these included squad huts or bunkers made of heavy timber and covered with earth or sandbags, timber-revetted firing positions for crew-served weapons, and extensive communications trenches. During the long period of truce negotiations, the lines were constantly improved, and in the years of uneasy truce following the armistice, they took on many of the characteristics of permanent fortifications. A special feature was a tall wire fence across the peninsula running through the so-called demilitarized zone and protected by minefields. Constant roving patrols of each side watched for infiltrators.

**The war in Vietnam.** In the guerrilla warfare waged in Southeast Asia during the French Indochina War (1945–54) and the Vietnam War, a number of unusual types of field fortifications were employed, yet their origins could be traced to other eras. The *agroville*, for example, a consolidated and fortified hamlet designed to protect the population from guerrilla incursions, in many ways resembled the fortified towns of ancient or medieval times. Similar methods were used by the British in defeating an insurgency in Malaya and by the Filipinos in countering the Huk rebellion in the Philippines. Triangular-shaped forts with walls of dried mud, usually occupied by local militia, and camps in remote regions manned by tribesmen with the help of U.S. Army Special Forces advisers looked much like the primitive forts of ancient times. Both U.S. and South Vietnamese forces constructed fortified base camps with exterior walls of earth topped by occasional sentry towers, in some ways resembling the semipermanent camps set up by Roman legions. The French defensive position at Dien Bien Phu, capture of which precipitated the end of the French Indochina War, had many of the characteristics of field fortifications in other eras: sandbagged and timber-revetted bunkers and firing positions, communications trenches, triangular-shaped bastions, outposts, and redoubts.

Both U.S. and South Vietnamese forces made extensive use of fire support bases, which were semipermanent entrenchments and bunkers protecting artillery batteries. Along the demilitarized zone separating North and South Vietnam, some bases had concrete emplacements and bunkers. Some of the bases served both for defense against enemy attack and as bases for patrols. The North Vietnamese and the Viet Cong insurgents established base camps in remote areas protected by log bunkers covered with earth and cleverly camouflaged. A good number of the facilities were housed in labyrinthian underground tunnels or in natural caves. The Viet Cong laced the countryside with countless booby traps of various types.

To provide a measure of protection for helicopters and other aircraft from random mortar and rocket attacks, the Americans built earth or concrete revetments several feet thick and four to five feet high on aircraft parking aprons alongside runways. Chemical defoliants were used to clear fields of fire around bases, destroy food crops in Viet Cong controlled areas, and eliminate concealed ambush positions along roads and waterways. To prevent the enemy from reoccupying base camps in jungle areas, special bulldozers called "Rome plows" leveled hundreds of acres of forest.

**Other modern fortifications.** Meanwhile, in the Arab-Israeli confrontations, semipermanent forts similar to the French position at Dien Bien Phu were built along the frontiers. Often Israeli farms and settlements had to be protected with field fortifications against incursions by Palestinian guerrillas.

An unusual fortification was the Berlin Wall constructed by the Communist East German government through the heart of Berlin, not to keep intruders out but to prevent citizens from fleeing to West Germany. Long lines of barbed wire protected by minefields and sentry posts ran along the western boundaries of East Germany, Czechoslovakia, and Hungary for the same purpose.

No nation has in recent years constructed permanent linear fortifications such as those used in World War II. The pillboxes of the West Wall have been demolished or abandoned, and though most of the elaborate forts of the Maginot Line still exist, their utility in future conflicts is problematical, though they might provide some protection to troops and supplies against nuclear explosions.

Most permanent fortifications of the nuclear age have been designed as headquarters sites or command and control installations or are in some way related to anti-aircraft and antimissile defense. A joint U.S.-Canadian project, the North American Air Defense Command (NORAD), includes a series of radar posts across northern Canada and Alaska to provide early warning of the approach of hostile bombers or missiles. The system and the aircraft and missiles supporting it are controlled from a vast underground complex embedded in rock of Cheyenne Mountain near Colorado Springs, Colo. Giant Spartan and Minuteman missiles are housed underground in "silos" with thick concrete walls. Soviet SS-9 ballistic missiles presumably are similarly protected.

**BIBLIOGRAPHY.** R.E. and T.N. DUPUY, *The Encyclopedia of Military History: From 3500 B.C. to the Present* (1970), is the most recent work to provide considerable material on the subject, and is amply indexed. Other works by distinguished historians on fortifications from ancient times to the present include: MONTGOMERY, VISCOUNT OF ALAMEIN, *A History of Warfare* (1968); C.B. FALLS, *The Art of War: From the Age of Napoleon to the Present Day* (1961); LYNN MONTROSS, *War Through the Ages*, 3rd rev. and enl. ed. (1960); THEODORE ROPP, *War in the Modern World* (1959); and J.F.C. FULLER, *A Military History of the Western World*, 3 vol. (1954–56). Less recent but nevertheless commendable works also covering fortifications are: U.S. MILITARY ACADEMY, DEPT. OF MILITARY ART AND ENGINEERING, *Notes on Permanent Land Fortifications* (1944); QUINCY WRIGHT, *A Study of War*, 2 vol. (1942); O.L. SPAULDING, H. NICKERSON, and J.W. WRIGHT, *Warfare: A Study of Military Methods from the Earliest Times* (1925); W.A. MITCHELL, *Outlines of the World's Military History* (1931); B.H. LIDDELL HART, *The Decisive Wars of History* (1929); R.G. ALBION, *Introduction to Military History* (1929); and E.M. LLOYD, *Review of the History of Infantry* (1908). Another work particularly helpful for the period covered is C.B. FALLS, *A Hundred Years of War, 1850–1950* (1962). Greater detail on fortifications in World War II may be found in the official history series, U.S. DEPT. OF THE ARMY, OFFICE OF MILITARY HISTORY, *United States Army in World War II* (1947– ); *Australia in the War of 1939–1945* (1952– ); and most notably in the campaign volumes of J.R.M. BUTLER (ed.), *United Kingdom Military Series* (1952– ) in *History of the Second World War* (1949– ). For a treatment of Korean fortifications, see R.E. APPLEMAN, *South to the Nak-tong, North to the Yalu* (1961). Literature on the French Indochina War and the American experience in Vietnam is extensive; but see in particular, B.B. FALL, *Hell in a Very Small Place: The Siege of Dien Bien Phu* (1966). For the Israeli experience, see S.L.A. MARSHALL et al., *Swift Sword: The Historical Record of Israel's Victory, June 1967* (1967).

(W.H.B./C.B.MacD.)

## Fossil Record

Fossils are the remains or imprints of organisms in rocks that document the history of life. Traces of various activities of organisms, such as trails, tracks, and borings, also are considered as fossils. The study of fossil animals and plants has permitted some reconstruction of the life forms and environments in remote times.

It has been estimated that the weight of all organisms that have lived on the earth since the Cambrian Period (q.v.) would equal the total mass of the earth. Most of

The  
agroville

The Berlin  
Wall

the organic material ultimately is transmitted from the dead organisms to the living ones (see BIOSPHERE), but even so only an exceedingly small fraction of ancient organisms are preserved as fossils. Only organisms that have a solid and resistant skeleton can readily be preserved. Most major groups of invertebrate animals have a calcareous skeleton or shell (e.g., corals, mollusks, brachiopods, bryozoans). Other forms have shells of calcium phosphate, which also occurs in vertebrate bones, or silicon dioxide. Arthropod skeletons are composed of a hard substance termed "chitin," which may be impregnated by mineral salts (see ELEMENTS, PHYSIOLOGICAL CONCENTRATION OF).

The hard parts of organisms that do become buried in sediment are subject to changes during the conversion of that sediment to solid rock. Solutions may fill the pores of the shell or bone with mineral salts and thus fossilize the remains. The structures preserved, however, may be partly destroyed by later recrystallization. In other cases, circulating acid solutions may dissolve the original shell and leave an open cavity that corresponds to the original shell. In the formation of shales (q.v.), such open cavities may be compressed, leaving only a fossil impression. Circulating calcareous or siliceous solutions may deposit a new matrix in the cavities, however, and by this pseudomorphosis a "new" shell is formed.

Soft parts of animals or plants are very rarely preserved. Famous cases are the Cambrian Burgess Shale fossils (Canada) and the Tertiary lignite fossils of Geiselthal (Germany). The embedding of insects in amber is another example of extraordinary fossil preservation.

The great majority of fossils are preserved in a water environment because land remains are more easily destroyed. Anaerobic conditions at the bottom are favourable for preserving fine details; no bottom faunas are present (except anaerobic bacteria) to destroy the remains. Study of fossil preservation assists in reconstruction of fossil communities, providing the basis for paleoecology, paleogeography (q.v.), and evidence of climatic change (q.v.).

Fossils were known in antiquity, but their meaning was not understood. Herodotus thought that the large foraminiferans preserved in the limestone of the Egyptian Pyramids were petrified lentils that served as a food supply for the pyramid workers. During the Middle Ages, fossils were looked upon as *vis plastica*, half-made material left over from the trial and error of creation, or merely as *lusus naturae*, a play of nature. Leonardo da Vinci was one of the first to understand the true nature of fossils, but it was not until the beginning of the 19th century that paleontology, the study of fossils, became one of the well-established earth sciences (q.v.). Today more than 200,000 fossil animals have been described; however, this is but a mere fraction of the millions of animals and plants that lived at various times on the earth during at least 3,000,000,000 years.

The study of fossils is primarily a biological study because knowledge of the morphology and anatomy of extinct animals and plants is fundamental to a general understanding of the living forms (see CLASSIFICATION, BIOLOGICAL; PHYLOGENY). Through fossils, it is possible to study changes of life over long time periods. Evolution (q.v.) may be interpreted from field and laboratory studies, but fossils provide another dimension, one that permits a following of the trends in evolution and the branching off of new groups through time.

Fossils have an important use in dating events in earth history (see DATING, RELATIVE AND ABSOLUTE). Each period of the geological time scale (q.v.) has its characteristic faunas and floras. Similar assemblages of fossils that occur in widely separated deposits may therefore be correlated in time and determine stratigraphic boundaries (q.v.). In addition to the utility of fossils in deciphering the geological history of the earth in general, fossils are useful in the exploration for minerals and mineral fuels. They serve to determine the stratigraphic position of coal seams, and in recent years the subsurface stratigraphy of petroleum (q.v.) and gas deposits have been studied by

means of microfossils that occur in cores of deep borings. Micropaleontology and stratigraphic paleontology have become important branches of the geological sciences (q.v.). This article is divided into the following sections:

# I. The Precambrian fossil record

## II. The Phanerozoic fossil record

- The Protista
- The sponges
- The Coelenterata
- The Mollusca
- The Conodonta
- The Bryozoa

- The Arthropoda
- The Echinodermata
- The Graptolithina
- The fishes
- The Amphibia
- The Reptilia
- The birds
- The mammals
- Plants

## III. Summary of the geological range of fossil groups through time

### I. The Precambrian fossil record

The apparent lack or scarcity of fossils in the Precambrian record has been a puzzle to scientists for a long time. Stromatolites occur in Precambrian sediments, particularly limestone and dolomites, and these laminated dome- or finger-shaped structures are widely distributed. The earliest ones are more than 2,000,000,000 years old, and it is probable that the thin laminae were deposited by blue-green algae.

In recent years, knowledge of Precambrian life has been greatly extended, not only because of new finds of well-preserved organisms but by the study of organic compounds that represent degradation products of dead organisms. These are termed chemicofossils, and among the more important are isoprenoid alkanes, which have been interpreted as breakdown products of chlorophyll. Samples from the Soudan Iron Formation, Minnesota, have a minimum age of 2,800,000,000 years. These isoprenoids may also be formed by inorganic processes however, though the scarcity of such carbon isotopes as carbon-18 and carbon-17 suggests degradation rather than synthesis. Isoprenoid compounds also have been traced in meteorites.

The Gunflint Chert of Ontario, Canada, contains the oldest undoubted fossils of the Precambrian. These microfossils, discovered by S.A. Tyler and E.S. Barghoorn in 1954, occur in a dark chert partly coating stromatolites in the Gunflint Iron Formation. The age of the beds is 1,900,000,000 years. The well-preserved fossils are interpreted as lower thallophytes, thread bacteria, and blue-green algae.

Silicified stromatolites from Queensland, Australia, that are 1,600,000,000 years in age contain fossil microorganisms with a characteristic pattern resembling closely living myxophycean algae. This is a primitive group on the borderline between the plant and animal kingdoms.

The 1,200,000,000–1,400,000,000-year-old Beck Spring Dolomite from California has yielded blue-green and green algae, which evidently means that cells with a nucleus had evolved by that time. And nuclei are clearly demonstrated in cells from the Bitter Springs Formation of central Australia, which is 1,000,000,000 years old. These microfossils, even better preserved than those in the Gunflint Chert, also occur within chert stromatolites. More than 30 species, representing bacteria, blue-green algae, green algae, and fungus-like organisms, have been described.

Less certain fossil remains have been found in the South African Fig Tree series and Onverwacht formations, which are 3,100,000,000 and 3,200,000,000 years old, respectively. The presumed fossils appear as small spheroid and rod-shaped, bacteria-like bodies. Carbon isotope studies of the Fig Tree series chert suggests that the spheroids may be algae.

Study of  
fossils

The oldest  
fossils

The Ediacaran fauna from the Pound Quartzite of South Australia was discovered in 1947 and has been studied in detail in recent years. The age of the beds is either very late Precambrian or very early Cambrian. Most important, however, is the Precambrian character of the fauna. The fossils, which occur as imprints on the surface of the flaggy quartzite beds, are well preserved and represent groups of Metazoa different from those of the Lower Cambrian above and elsewhere. The fossils have been interpreted as hydrozoans (*Ediacaria*), sea pens (*Rangia*), segmented worms, or primitive arthropods (*Spriggina*); others have been difficult to place in known groups. That more or less identical "sea pens" (*Charnia* and *Rangia*) occur in Precambrian beds in England and Siberia confirms the Precambrian aspect of the Ediacaran fauna.

Atmospheric implications

The Precambrian fossils so far known agree with the theory of a primarily anoxybiotic atmosphere that became gradually oxygenic toward Paleozoic time. In the beginning, a synthesis of organic compounds was followed by the development of primitive organisms. About 3,000,000,000 years ago some of these attained the ability of photosynthesis. Because of the strong, shortwave ultraviolet radiation, the early organisms had to live in protected places, either in the water or in porous, unconsolidated sediments. Certain organisms like the stromatolites may have been protected by the calcareous mats or laminae produced during their growth.

Bacteria and blue-green algae evidently flourished during the Middle Precambrian (from 1,500,000,000 to 2,500,000,000 years ago, approximately). Cells with nuclei, possibly appearing at the end of this time, heralded a new time in biological evolution and prepared the path for the creation of higher plants and animals. At this time the atmosphere probably contained not much more than 1 percent of  $O_2$ . At the end of the Precambrian still less than 5 percent of  $O_2$  was probably present. It has been generally assumed that because of the relatively rich and diverse life known to have existed in Cambrian time, many-celled animals, or metazoans, originated early in the Precambrian. But the fossil record and probable low content of  $O_2$  in the atmosphere may indicate that the more advanced metazoans, needing sufficient oxygen for their respiration, developed late in the Precambrian, perhaps less than 1,000,000,000 years ago (see ATMOSPHERE, DEVELOPMENT OF; PRECAMBRIAN TIME; LIFE).

## II. The Phanerozoic fossil record

### THE PROTISTA

In recent years, various groups of protists including microfossils of minute planktonic forms (nanoplankton), have been subjected to comprehensive studies utilizing electron microscopy. Because of their distinct vertical and regional distribution, these forms have proved very valuable in the search for petroleum and other mineral deposits. Fossil remains are limited to the hard parts, and it often is difficult to determine taxonomic identities or even to decide whether they are plants or animals. Definitely known unicellular plants are described later. Among protozoans (*q.v.*), only the Sarcodina are of particular fossil importance. Many members of this group have skeletons or tests composed of tectin, calcite, aragonite, or silica or were formed by the agglutination of foreign particles.

Radiolaria and Foraminiferida

The Radiolaria, a subclass of the Sarcodina, are well known from the radiolarian ooze of modern marine sediments. These exclusively marine forms, which are 0.05 to a few millimetres in diameter, have a silicified skeleton consisting of an intricate latticework with or without spines. Members of the group appeared in the Middle Ordovician or possibly in the Cambrian, flourished in the Carboniferous and Tertiary, and continued into Recent time. The Foraminiferida, another Sarcodina group, abound in strata from Cambrian to Recent age. Nearly 30,000 species are known, of which almost 90 percent are fossil forms.

**Form and structure of the foraminifera.** The foraminiferans, or "forams," are mostly marine forms of both benthonic and planktonic types. The size varies from a

fraction of a millimetre to several centimetres. The animal usually secretes a support or test that may form a single chamber (primitive forms) with one or more apertures. In most species, however, new chambers are successively added to the primary one (the proloculus) with the apertures (*foramina*, hence the name) maintained through the separating walls, or septa. The chambers are arranged in characteristic patterns, either in a single row, alternating rows, in spirals where the whorls may be visible (evolute), or hidden by later whorls (involute). Their reproduction involves an alternation of asexual and sexual generations with two corresponding types of individuals. The shell wall varies considerably in structure; it may be perforate or imperforate and may be composed of organic material (freshwater forms), calcite or aragonite, or built up by agglutinated material. The calcareous shells, which may be lamellar, are either microgranular, porcellaneous imperforate, or hyaline perforate. The major taxonomic divisions are based on these shell structures. Studies of recent forms suggest that right coiling (dextral) in trochospirally coiled shells (those chambers arranged along a spiral line that does not lie in a plane) indicate populations from warm water, whereas left-

Figure 1: Representative protists and their geological range.

(Left) Occurrence of Foraminifera and Radiolaria in the geological record. Width of the stippled zone indicates relative abundance. (1-9) Foraminifera, (10) Radiolaria.

From (1,3,4,7) H. Wienberg Rasmussen, *Paleontologi, Fossile Invertebrater*; (6) V. Potkory, *Grundzüge der zoologischen Mikropaläontologie*; (8,10) Terrier and Terrier, *Paleontologie Stratigraphique*, copyright 1960, Masson & Cie, Paris; (9) L. Stormer, *Jordens og livets historie*

coiled (sinistral) ones characterize residents of colder waters.

The earliest representatives of the Foraminiferida occur in Cambrian and Ordovician rocks. They are simple forms with a single chamber and a pseudochitinous (suborder Allogromiina) or agglutinated (suborder Textulariina) shells. In the Silurian, the first enrolled tubular textularians appeared. Microgranular calcareous genera also appear in the Silurian and become very abundant in the Upper Paleozoic. Particularly important are members of the suborder Fusulinina, including, among others, the small Endothyridae and the large Fusulinaceae. The Endothyridae with their mainly planispiral shells (those with chambers arranged in a spiral fashion but within the same plane) dominated the Lower Carboniferous (Mississippian) and were partly rock building. Characteristic of the Upper Carboniferous (Pennsylvanian) are the larger (up to several centimetres long) members of the Fusulinaceae. They are good index fossils, and about 72 genera and more than 1,000 species have been described. *Fusulina* has a spindle-shaped shell with a lamellar outer wall.

The low chambers are coiled around the longest axis, each coil totally covering the earlier ones (involute). *Schwagerina* with fusiform to spheroid shells were mainly characteristic of the Permian.

The Triassic-Jurassic foraminiferid faunas of the Mesozoic Era (*q.v.*) were dominated by members of the suborder Nodosaridacea with hyaline perforate and lamellar shells of calcite or aragonite. *Nodosaria* has several chambers in a single row. Suborder Miliolina is also characteristic of the Mesozoic. These have porcellaneous (imperforate) shells of calcite, and the few chambers are coiled in a spiral round the longest axis. Only the distal parts of the earlier chambers are covered by the later ones (*Quinqueloculina*, *Triloculina*).

**Cretaceous and Tertiary evolutionary trends.** Foraminiferans were very abundant in the Cretaceous, and some limestone formations have been named for them. Among imperforate calcareous forms, representatives of the Miliolina were characteristic in the earliest Cretaceous, whereas Alveolinidae appeared in the Late Cretaceous. A great expansion of coiled hyaline calcareous foraminiferans took place in the last part of the Mesozoic (*Bulminella*, *Bolivina*), and the first Rotaliacea with shells of calcite with radial structures appeared (*Rotalia* with lens-shaped trochoid shell). The first important planktonic forms belonging to the Globigerinacea were also present (*Heterohelix*, *Globotruncana*). The Orbitoidacea have a similar shell structure, but only benthonic forms, usually with spiral-shaped, planoconvex shells (*Cibicides*), are included in the group. Typical of the rich Cretaceous faunas are also the coarsely perforate Anomaliniidae.

Paleocene  
transition  
fauna

A considerable change in the foraminiferid faunas took place at the beginning of the Tertiary. In the Paleocene, a transition fauna consisting of many small forms similar to those in the Cretaceous occurs with several new ones, particularly planktonic genera such as *Globigerina*, larger *Orbitolina* (porcellaneous), and the earliest *Nummulites*. In the Eocene, nummulitic, alveolinid, and miliolinid limestones occur, the terms indicating the abundance of these foraminiferans. The nummulites were characteristic of the tropic Tethys Sea. *Nummulites* has a flat to lens-shaped (lenticuline) shell with up to 40 close-set coils in a spiral round the shortest axis. The short chambers, more or less V-shaped in cross section, are often involute in the inner and evolute in the outer coils. The large, coin-shaped nummulites were characteristic of the Eocene. In Egypt the giant *N. gizehensis*, measuring several centimetres in diameter, is abundant in the limestone used for building the Pyramids. The alveolinid genus *Fasciulites* was also characteristic of this time. The large Alveolinidae resemble the fusulinids with respect to the general shape of the shell, but the latter had a microgranular calcite shell, whereas the former has a porcellaneous imperforate shell. There are no genetic relationships between the two groups; the Alveolinidae are to some extent related to the Miliolidae. The numerous chambers in the shell of the alveolinids are divided by secondary septula into tubular chamberlets. Large foraminiferans characteristic of the Middle Tertiary (transition Paleogene-Neogene) belong to the family Miogypsiniidae, a group related to the Nummulitidae. Numerous smaller foraminiferans remain and appear during Tertiary and Pleistocene times. The ecology of the later planktonic forms is known through a comparison with living species. A few genera serve as important paleotemperature indicators. The fossil record of the Foraminiferida has shown that this group has played and continues to play an important part in aquatic ecosystems (*q.v.*).

#### THE SPONGES

Fossil sponges have been recorded from Lower Cambrian to Recent time. Certain remains from the Precambrian have been interpreted as belonging to the Porifera (*q.v.*), but neither the structure nor the age of the fossils are sufficiently well known to warrant a determination. Among the more than 10,000 Recent species of sponges, only a limited number have hard parts capable of being preserved. Assuming similar conditions in the past, the com-

prehensive material of fossil sponges gives but a faint picture of the development of the whole group.

**Structures and fossil remains.** The Recent Porifera are mainly sessile, marine forms that inhabit shallow waters, but they also occur at depth in the oceans. The shapes of the sponges vary from thin covering to free bodies of very different shape. Anatomically they form a primitive group with a zoological position somewhere between unicellular flagellate protozoans and the multicellular metazoans. Characteristic of the body is a system of pores and channels through which passes a water current produced by whiplike collared flagellate cells; an interior wall faces a central cavity. Spicules, which are composed of calcite or silica, form the hard parts of sponges, and these are preserved as fossils. The spicules may be slender rods (monaxon), may form a unit of three to four axes (triaxon, tetraaxon), or may be composed of rays (polyaxon). The spicules arranged with distinct angles between the axes may unite, forming solid skeleton.

The  
Recent  
Porifera

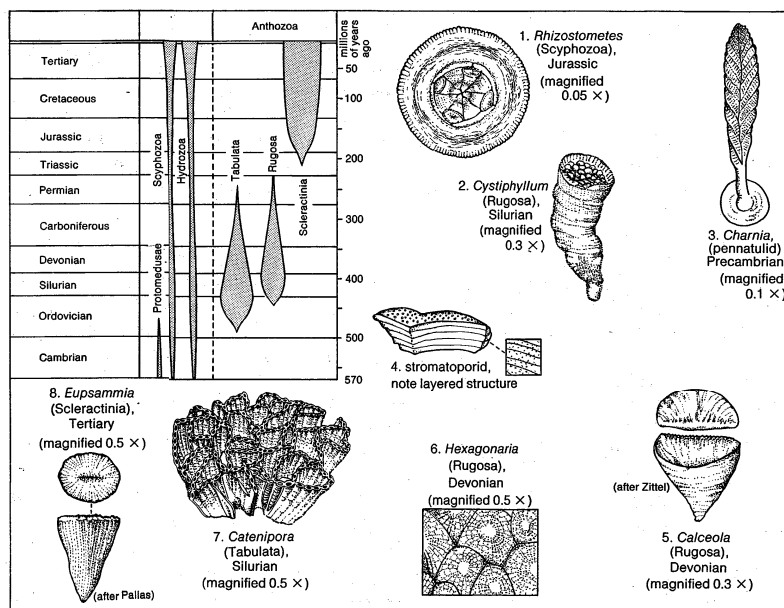

Figure 2: Representative Porifera and Archaeocyathida and their geological range. (Left) Occurrence of Porifera and Archaeocyathida in the geological record. Width of stippled zone indicates relative abundance. (1-6) Porifera, (7) Archaeocyathida.

From (1,3,5,7) H. Wienberg Rasmussen, *Paleontologi, Fossile Invertebrater*; (4) Termier and Termier, *Paleontologie Stratigraphique*, copyright 1960, Mason & Cie, Paris

The first fossil remains of the Porifera date from the Lower Cambrian. In the Upper Cambrian, simple monaxon desmosponges (skeleton composed of horny fibres or siliceous spicules) appear; and at the beginning of the Ordovician, lithistid forms (with solid skeleton) develop. These desmosponges form, together with bryozoans, corals, and stromatoporids, distinct reefs in the Middle Ordovician. The heteractinids are fairly evenly distributed throughout the Paleozoic, the last representatives recorded from the Permian. In the Paleozoic, the hexactinellids dominate the Late Devonian and Early Carboniferous faunas.

At the end of the Paleozoic several important groups became extinct, among others the class Heteractinida, and certain hexactinellids and lithistids of the desmosponges. Most of the groups that dominated the Mesozoic faunas, however, appeared in the Carboniferous and Permian. This was the case with the Calcarea, of which the first known representatives occur in the Carboniferous. Representatives of this group became prominent in the Permian and Triassic and were reef builders at the time when the Paleozoic corals declined and the later scleractinous corals (stony corals) were ready to start their strong development. The Calcarea became extinct at the end of the Cretaceous.

**Figure 3: Representative Coelenterata (Cnidaria) and their geological range.** (Left) Occurrence of the classes Protomedusae, Scyphozoa, Hydrozoa, and Anthozoa in the geological record. Anthozoa are shown in terms of the subclasses Tabulata, Rugosa, and Scleractinia. Width of stippled zone indicates relative abundance. (1-8) Fossil coelenterates as designated.

Stormer, *Jordens og livets historie*; (6) Hill, *Treatise on Invertebrate Paleontology*, courtesy of The Geological Society of America and The University of Kansas Press; (8) Termier and Termier, *Paleontologie Stratigraphique*, copyright 1960, Masson & Cie, Paris

#### Archaeocyathids

The Porifera had a strong development in the Cretaceous. A great number of genera have been described from different countries. The flint of the chalk beds may have received its silica from hexactinellid sponges. During the Cenozoic, the Porifera apparently played about the same role in the marine faunas as they do today.

**Relation of sponges and archaeocyathids.** The Archaeocyathida are an ancient and apparently short-lived group, once considered to be among the Porifera. More recent studies, however, have shown that they represent a separate phylum with no close affinities to the sponges or other known groups, except that certain authors have suggested that Carboniferous sponges of the Calcareum may have evolved from the archaeocyathids.

The Archaeocyathida had fragile calcite skeletons. A three- to ten-centimetre-high cup was attached to the hard bottom by rootlike extensions. The cup consists of two cones, one within the other, held apart by radial plates reaching from the inner wall of the outer cone to the outer wall of the inner. Both cones are perforated by many pores; these are very fine in the outer cone and coarser in the inner. Pores also are on the radial plates.

The archaeocyathids had a strong development in the Lower Cambrian but probably became extinct in the earlier part of the Middle Cambrian. Several classes and orders and 92 genera have been established for members of this phylum, which had a worldwide distribution. The reefs or "gardens" of archaeocyathids along ancient Cambrian shores in Australia are quite famous.

#### THE COELENTERATA

The Coelenterata (Cnidaria) are characterized by the presence of stinging capsules or nematocysts, and the phylum includes the hydras, siphonophores, jellyfish, sea anemones, and corals, comprising about 9,000 species, almost all of them marine (see CNIDARIA; CORAL ISLANDS, CORAL REEFS, and ATOLLS).

The fossil record of the coelenterates is chiefly based on specimens with a calcareous skeleton. Impressions of softer parts, such as the outer surface of jellyfishes and the sedimentary filling of their gastrovascular cavities, provide important information on their structure, however. The fossil coelenterates belong to the classes Protomedusae, Scyphozoa, Hydrozoa, and Anthozoa.

The class Protomedusae is represented by jellyfish-like

molds and impressions from the Precambrian and Early Ordovician, particularly in North America and Europe. The precise classification of these forms is uncertain; *Brooksella* had a subellipsoidal body with 4 to 15 radial lobes and four oral arms. A fourfold symmetry, characteristic of scyphozoans, is most abundant, but five or seven lobes are also common. *Hallidaya* and *Skinneria* from the transitional Precambrian-Cambrian in Australia show a threefold radial symmetry, possibly an offshoot of the general trend of development.

Representatives of the class Scyphozoa have been recorded from all systems, from Late Precambrian upwards to Recent time. It is difficult to be sure that the jellyfish-like imprints are scyphozoans and not medusae of hydrozoans. Paleozoic forms have been included in the Recent order Coronatida, while the well-preserved *Rhizostomites* from the Jurassic of Solnhofen in Germany has been referred to a separate order, Lithorhizostomatida.

Among the class Hydrozoa, the Recent orders Trachylina, Hydroida, Milleporina, Stylasterina, and Siphonophorida have been recorded as fossils as well as the extinct Stromatoporida. Trachylinids occur in the Jurassic, and possibly *Etiacaria* from the Late Precambrian belongs to the order. Middle Cambrian and Upper Carboniferous medusae are known, and a few Ordovician-Devonian impressions of pneumatophores and velae have been referred to as siphonophores. The Milleporina and Stylasterina (often united as the order Hydrocorallina) are known from Early Tertiary to Recent time. More important geologically were the Stromatoporida, which are known from the Cambrian to the Lower Tertiary. The colonial stromatoporids secreted a calcareous skeleton, usually forming irregular rounded masses up to one metre thick. The stromatoporids were common in the Ordovician-Devonian when they formed reefs of considerable thickness.

**Occurrence and evolution of corals.** The class Anthozoa, or corals, comprises five subclasses, the Alcyonaria (or Octocoralla), Tabulata, Rugosa, Heterocorallia, and Scleractinia (the three last often included in subclass Zoantharia). The colonial Octocoralla have eight pinnate tentacles and a calcareous spicular or horny skeleton with no septa. Scattered fossil representatives are known from the Mesozoic onward. The Pennatulacea, or sea pens, have been recorded (with doubt) from the Silurian, and

#### Hydrozoans

the Precambrian *Rangia* and *Charnia* show a superficial resemblance to the pennatulids.

The subclass Tabulata, or tetracorals, played an important part in the Paleozoic faunas. During their range, from the Cambrian to the close of the Permian, they formed important reefs in many parts of the world. Characteristic of the tabulates are the exclusively colonial mode of growth and the slender tubes or corallites with distinct partitions or tabulae and faint development, or absence, of longitudinal partitions or septa. The first representatives of the group were certain auloporids in the Middle Cambrian. A great development took place in the Middle Ordovician, when 14 new families appeared. Characteristic genera of the Ordovician and Silurian were *Favosites* (with perforate walls), *Halysites*, *Syringopora* (with connecting tubules between corallites), and *Heliolites* (with coenenchyme). The Ordovician *Tetradium* is a guide fossil for American Arctic faunas. Favositidae were common in the Devonian, Auloporidae and Chaetidae in the Carboniferous. The Tabulata apparently became extinct abruptly (seven families) at the end of the Permian.

Rugose  
corals

The subclass Rugosa, with more than 600 genera, is another important group of Paleozoic corals. Members of the group were contemporaneous with the Tabulata, appearing in the Ordovician and becoming extinct at the end of the Permian. The fairly large rugose corals were either solitary or had a colonial manner of growth. The solitary types were cone shaped or curved (horn corals) and might be attached to the substrate by rootlike appendages. Numerous minute transverse ribs and furrows on the surface of the cups probably indicate daily and seasonal growth and have been used to determine the length of the year in ancient times (see DATING, RELATIVE AND ABSOLUTE). The colonial forms were dendroid or densely packed, forming massive colonies with prismatic corallites. Characteristic of the Rugosa are the prominent and numerous septa sometimes meeting centrally to form a columella. The septa are radially arranged, but a four-part symmetry is also present (in Tetracoralla). Of the three orders of rugose corals, two (Streptelasmata and Columnariida) and possibly a third (Ceptiphyllida) appeared in the Middle Ordovician. A rapid and strong development with reef building took place in the Middle Silurian and Lower Devonian, and later in the Devonian a great wealth of new forms appeared. A new evolution took place in the Carboniferous, and, in the Permian, members of the Cyathaxonicae might have given rise to the Scleractinia, which replaced the Rugosa in the Mesozoic. During the Paleozoic, rugose corals without dissepiments, supporting structures of horizontal plates (*Lamoeophyllum* and *Columnaria*), were characteristic of the Ordovician. Dissepiments developed in early Silurian Streptelasmata and Columnarina and particularly in the Cystiphyllida. In the Devonian, the Digonophyllidae and the Goniophyllidae (with an operculum) were common; and in the Carboniferous, forms with axial structures, such as the Lithostrotionidae and Lonsdaleiidae, prevailed. In the Carboniferous, a small group that has been distinguished as a separate subclass (Heterocoralla), characterized mainly by the unique manner of insertion of the septa in the corallite, occurs.

**Reef-building corals.** The subclass Scleractinia, or hexacorals, includes practically all solitary and colonial modern corals. Characteristic of the group is the essentially radial symmetry (no bilateral symmetry, such as in the Rugosa), and the ontogeny of the septa is also different. The Scleractinia are related to sea anemones, which, however, have no hard parts. The possible derivation of the Scleractinia from the Rugosa is uncertain. The oldest known representatives are from the Middle Triassic (five families); the first ones did not form reefs, but in Late Triassic time, reefs became common. Great evolution and expansion of the group occurred in the Middle Jurassic and Lower Cretaceous, with worldwide reef building.

Depth of  
coral reefs

The reefs have been subject to comprehensive studies, largely because they have proved to be important pockets of oil. Most recent reefs occur in tropical areas where the temperature of the water varies largely between 23°–

29° C and where the depth is less than 50 metres. Other corals may be found at greater depth, however, chiefly from 20 to 500 metres, where certain dendroid forms may form comprehensive "copsewood." When the large reefs are confined to shallow depths, it is chiefly due to the presence of certain dinoflagellates (Zooxanthellae) in the coral endoderm cells. These algae need light for photosynthesis, which produces oxygen useful to corals.

#### THE MOLLUSCA

Members of this large group are perhaps the most common macrofossils to be found in aquatic sediments. This is particularly the case with the gastropods, bivalves, and cephalopods, which occur in great numbers of genera and species (about 70,000) throughout the Phanerozoic. The shell-bearing mollusks that occur as fossils include the following classes: Polyplacophora, Monoplacophora, Gastropoda, Scaphopoda, and Bivalvia (Pelecypoda).

In general, the mollusks (see MOLLUSCA) vary considerably both in morphology and size, but in spite of these differences the general plan of construction is the same in all groups of the phylum. The soft body, primarily segmented with a bilateral symmetry, has a mouth in front and an anus in the posterior end. On the ventral side, a powerful foot is developed; and on the dorsal side, lateral outgrowths from the mantle cover the mantle cavity with gills. This general pattern may be strongly modified by a considerable twisting or torsion of the body in gastropods and a strong bending of the body in cephalopods. The fossil remains of the mollusks are usually limited to the calcium carbonate shells secreted by the mantle; muscle scars and other impressions of soft parts occasionally provide additional information.

The class Polyplacophora, or Amphineura, are represented today by the chitons. With their simple bilateral symmetry and a segmentation indicated by a single row of dorsal plates, these forms are primitive representatives of the Mollusca. They are known from the Upper Cambrian to Recent time.

Of particular interest is the class Monoplacophora, which until quite recently was known only from shells from the Lower Paleozoic. In 1952 the Danish Galathea Expedition discovered a living species in the Pacific, essentially an unexpected living fossil; *Neopilina* has a cap-like shell that covers a bilateral body with five pairs of gills. These primitive structures indicate that the monoplacophorans developed from annelid worms. Fossil representatives are known from the Lower Cambrian to the Upper Silurian (possibly Devonian).

**Gastropods and scaphopods.** The class Gastropoda (q.v.), or snails, includes about 85,000 species, of which one-third are fossil species. They are recorded from the Lower Cambrian onward and were more common in the Mesozoic and Cenozoic than in the Paleozoic. Most species are marine, but freshwater and terrestrial forms also occur, evidently derived from marine ancestors.

The earliest gastropods known are the Helcionellacea, which appeared in the Lower Cambrian and apparently became extinct by Upper Cambrian time. Members of the group had a worldwide distribution, but because only the shells are known, their gastropod nature is not definitely established. By Cambrian-Ordovician time, most of the major orders of gastropods were present, a fact that demonstrates the considerable age of the group. Silurian specimens of *Bellerophon* have imprints on the shell that indicate the presence of two identical gills, a feature that must be interpreted as primitive. During the Paleozoic and the Mesozoic, the gastropods flourished and displayed a great variation in shell morphology. In the Cretaceous, forms with a well-developed siphon appeared, and this group became very common in the Tertiary. The *Pteropoda*, pelagic forms in which the mantle is modified into "fins," appeared in the Carboniferous. Small tubelike forms from the Lower Cambrian also have been referred to this group, but they may belong to the worms. The terrestrial Pulmonata (*Helix*, *Planorbis*) are known from the Upper Jurassic onward.

The class Scaphopoda forms a small group of mollusks

Snails in  
the fossil  
record

Figure 4: Representative mollusks and their geological range. (Left) Occurrence of the classes Polyplacophora, Monoplacophora, Gastropoda, Scaphopoda, Pelecypoda, and Cephalopoda in the geological record. Cephalopoda are shown in terms of the subclasses Nautiloidea, Bactritoidea, Ammonoidea, and Coleoidea. Width of stippled zone indicates relative abundance. (1-12) Fossil mollusks as designated.

with slender cone-shaped, bilateral shells. Adapted to a burrowing habitat, the head is reduced to a conic projection. They show affinities to the bivalves because of their bilateral symmetry and resemble the gastropods in having a radula. Scaphopods are known with certainty from Devonian and later geological systems to recent time.

**Structure and evolution of pelecypods.** The class Bivalvia (Pelecypoda or Lamellibranchia of other authors; see BIVALVIA) occurs in abundance throughout the Phanerozoic. The soft body is laterally compressed between two shells, a right and left shell, each of which is a mirror image of the other except when a secondary modification has taken place. No head is present, and the two rows of gill blades in the mantle cavity serve as filters for catching micro-organisms. The mantle is fused along the margins of both sides and may be prolonged into a single or doubled siphon with channels for inflowing and outgoing water currents. The two protecting shells of aragonite or calcite are held together by muscles and open and close along with a hinge with a hinge plate provided with teeth and sockets. These structures and the development of the muscle scars are of major importance to the taxonomy.

The first bivalves are known from the Middle Cambrian (order Actonodontoidea). The Ribeiroidea from the Lower Cambrian have been referred by some authors to the Bivalvia, but their taxonomic position is doubtful. Some of the earliest bivalves have muscle scars (of six to eight pairs of pedal retractor muscles) directly comparable to those of *Neopilina*, a feature that indicates that both groups had common ancestors. By Ordovician time, a number of more advanced and still living orders (Nuculoida, Pteroida, Arcoida, Veneroida, Lucinoida, and Praecardioida) are represented. The bivalves were subject to considerable adaptive radiation in the Ordovician, but as faunal elements they became more important in the upper part of the Paleozoic. They flourished through the Mesozoic and Cenozoic; thin-shelled forms were characteristic of soft bottoms, and thick-shelled forms were characteristic of hard bottoms, particularly reefs subject to wave action. The reef forms display a strong specialization to this habit of life. Members of the Hippuritoidea, ranging from the Jurassic to the Cretaceous, were large thick-shelled forms in which the two shells were very differently developed. *Requienia* had the left shell whorled almost like a gastropod shell, whereas the right shell formed a small operculum only. In the peculiar rudists,

so characteristic of the tropical reef faunas of the Tethys, the right shell forms a large ribbed cone covered by a disklike left shell.

**Structure of cephalopods.** The class Cephalopoda (*q.v.*), which is represented in the present seas by the octopus, the squid, and nautilus, is of particular interest to the paleontologist. The fossil remains of cephalopods provide valuable information of the evolution and adaptive radiations of this peculiar group. Characteristic of the cephalopod body are the well-developed head surrounded by arms or tentacles, the ventrally situated mantle cavity with one or two pairs of gills, and the presence of a funnel formed by the fused lateral portions of the mantle. In the above mentioned groups of mollusks, the soft body was generally enclosed in a solid shell; in cephalopods this was true only of the nautiloids (represented today by *Nautilus*) and the ammonites (now extinct); in the coleoids, on the other hand, the shell became covered by the mantle and reduced, and in some it was even lost. The generally elongate cone-shaped or coiled shells were divided by transverse septa into numerous gas-filled compartments; a large one at the open end served as the living chamber for the animal. A fleshy stalk or siphuncle, often enclosed in septal necks, runs from the living chamber backward to the initial compartment. The line marking the junction between the septa and the inner wall of the shell is known as the suture line, a structure of considerable taxonomic importance. Calcite may have been deposited in the gas chambers to adjust the weight and the horizontal position of the body in the water.

The cephalopods are represented today by some 150 genera, but they had a far greater development in ancient times. In the Mesozoic in particular they were the champions of the seas and have served as some of the very best guide fossils.

The first true cephalopods, the Ellesmeroceratida, appeared rather suddenly in the Upper Cambrian (certain Lower Cambrian forms, *Salterella* and *Volborthella*, have been regarded as cephalopods but probably belong to other groups). The widespread ellesmeroceratids, characteristic of the Lower Ordovician, evidently formed a central group from which both the nautiloids and the bactritoids evolved. Related to the ellesmeroceratids were the Ordovician endoceratids that attained a length of nearly nine metres and had a large siphuncle partly filled

Ancestors  
of the  
octopus  
and squid

Bivalves

by an inner tube of calcite. The nautiloids were abundant during the Paleozoic; both the shell and the siphuncle were subject to great variation.

In the Silurian, representatives of the subclass Bactritoida appeared; these form a transition stage between the nautiloids and the ammonites. The bactritoids had the simple slender shells of the nautiloids and, at the same time, the bulbous initial chamber characteristic of the ammonites. Indication of undulated suture lines was also present.

**Ammonites in the fossil record.** The subclass Ammonoidea is of particular interest. Thousands of species have been described from all parts of the world, from Lower Devonian to Upper Cretaceous strata. Their importance as guide fossils is demonstrated by the fact that most of the Mesozoic stratigraphic stages (zones) are named after ammonites.

Coiling  
character-  
istics of  
ammonites

Characteristic of the ammonites are tightly coiled, bilaterally symmetrical shells. The aragonite shell has a long living chamber, septa with the convex surface directed forward, and complex suture lines. The initial chamber (protoconch) is bulbous, the siphuncle thin and mostly marginal, and the size ranges from one centimetre to 2.5 metres.

The first ammonites are known from the Lower Devonian. They evidently evolved from nautiloids, very possibly through the bactritoids, in three periods: the Upper Paleozoic, characterized by goniatites; the Triassic, characterized by ceratites; and the Jurassic-Cretaceous, characterized by the true ammonites. The earliest goniatites had one simple lobe in the suture line, and septa directed backward as in nautiloids; later representatives had several lobes and ammonoid septa. The earliest ceratids appeared in the Permian and had an "explosive" radiation in the Triassic. About 400 genera and subgenera are known. These are divided into 30 ammonite stages or zones, each of which lasted a little more than 1,000,000 years. The ceratites had simple lobes, but the saddles were serrate. In later Triassic forms (*Ptychites*), however, the suture lines became considerably more complex, almost of ammonite type.

For some unknown reason, practically all the ammonites died out at the end of the Permian. Only two families survived, and one (Otoceratacea) gave rise to the great number of ceratids in the Triassic. A second major extinction of ammonites took place at the close of the Triassic. In this case, all the ceratites left the scene, only one member of one family (Octocertacea) of the suborder Phylloceratina crossing the boundary to the Jurassic to give rise to still another explosive radiation in the Jurassic-Cretaceous. The phylloceratids, with their characteristic phylloid saddle endings, became a very stable group, remaining little changed from Triassic to Cretaceous time. From the Phylloceratina evolved the Lytoceratina (characterized by strongly divided lobes with mosslike endings), which were the main ancestors to the Ammonitina.

Aberrant  
ammonite  
forms

Of particular interest is the unusual development of the shell in some lytoceratid families. Uncoiled forms occur in the Jurassic, and in the Cretaceous various "aberrant" shell types became abundant and significant. Loosely coiled shells (*Critoceratites*), partly uncoiled shells (*Macroscaphites*), and straight ones (*Baculites*) occur together with helical forms (*Turrillites*) and forms forming an irregular tangle (*Nipponites*). These irregular ammonites have been looked upon as degenerate forms predicting the final extinction of the ammonites. It may be true to some extent for this particular group; however, "normal" ammonites lived side by side with the "aberrant" ones for 60,000,000–70,000,000 years. In the Upper Cretaceous ammonites with simple ceratites-like suture lines occur (*Tissotia*).

The suborder Ammonitina includes a great number of usually thick-shelled and strongly ornamented forms ranging from the Lower Jurassic to the Upper Cretaceous. Narrow disklike forms were probably good swimmers. Often the cover of the shell opening, the so-called aptychus composed of calcite (not aragonite), is the only

part preserved. More than 500 ammonite genera are known from the Cretaceous. At the end of this period a third, and final, extinction of the ammonites took place.

**Occurrence and evolution of coleoids.** The subclass Coleoidea leads to the living squids and octopuses. Representatives of the group are known from the Carboniferous (possibly even the Devonian), and they flourished in the Mesozoic. In contrast to the other cephalopods mentioned, the shell of the coleoids is covered by the mantle. This interior skeleton may be partly or completely reduced. Only one wall of the living chamber (pro-ostacum) is present. The cone-shaped camerate portion (phragmocone) has a bulbous initial chamber, and the distal portion of the shell may be enclosed in a solid torpedo-shaped rostrum composed of calcite. This is more readily preserved than the camerate portion of aragonite.

The coleoids probably also evolved from bactritoids. The Belemnitina were characteristic of the Jurassic and Cretaceous. The distribution of the isotopes oxygen-18 and oxygen-16 in the layered calcite of the prominent rostra of the belemnitids has registered the temperatures of the water in which the animal lived and grew. The Mesozoic Belemniteuthina, with their strongly reduced rostrum, form a transition to the Recent teuthids. The sepiids appeared in the Tertiary and the octopods in the Upper Cretaceous.

#### THE CONODONTA

These enigmatic microfossils ranging from the Ordovician to the Upper Triassic, possibly Cretaceous, form another group of important index fossils. To the stratigraphers, particularly those dealing with subsurface cores, these microfossils play about the same role in the Paleozoic as do the foraminiferans in the Mesozoic and the Cenozoic. Thousands of species, or form species, rather, have been described. See the article CONODONTA for information on the occurrence and evolution of this group.

#### THE BRYOZOA

The calcareous skeletons of these small colonial invertebrates are common fossils in Paleozoic and younger formations. Living species are, with a few exceptions, marine; they prefer clear, not turbid, water.

Marine bryozoans (*q.v.*) belong to the class Gymnolaemata. The class has been divided into five or six orders (a last order, Cystiporata, was recently established by G.G. Astrova in 1964). The different orders are characterized mainly by the shape of the colony (zoaria) and the individuals that comprise it. Of the six orders, three are confined to the Paleozoic: the Trepustomata, the Cystoporata, and the Cryptostomata. The three remaining orders, of which the Cyclostomata and the Ctenostomata start in the Ordovician and the Cheilostomata in the Cretaceous, all live on to Recent time.

Uncertain remains from the Upper Cambrian have been interpreted as possible bryozoans. The first true bryozoans are recorded from the Lower Ordovician, and a strong development of the group took place in Middle Ordovician time, when five orders and 20 families were represented. This marked unfolding of the bryozoans coincides with a similar rapid evolution of other large groups with well-developed calcareous shells: the corals, brachiopods, and crinoids. Characteristic of the Ordovician is the semisphaeric *Diplotrypa*, while *Hallopora*, among others, is common in the Silurian. Some families did not continue into the Devonian. Bryozoans also were common throughout the Upper Paleozoic, but at the end of the Permian several families became extinct. The Fenestellidae, the "lace bryozoans," are particularly characteristic of the Carboniferous and Permian. In the Mesozoic and Cenozoic, especially in the Cretaceous and Tertiary, the cheilostoms are the most common. They appear as thin crusts on stones and shells. A common genus is *Membranipora*. As guide fossils the bryozoans have become increasingly important because of their abundance and worldwide distribution.

#### THE BRACHIOPODA

The about 260 living species of brachiopods (*q.v.*) constitute only a fraction of the approximate 30,000 fossil species known. In the Paleozoic particularly, these "lamp shells" flourished and to a large extent dominated the shelly marine faunas.

Characteristic of the brachiopods are the lophophore, an appendage around the mouth (similar to that of the bryozoans), and the two bilaterally symmetrical shells or valves that are secreted by the mantle. The fossil remains left to the paleontologist are largely limited to the hard parts comprising the valves and the skeleton supporting the lophophore (if such a structure is present) and the various markings on the inside of the valves. The markings on the inner shell surface are mainly muscle scars and pallial markings made by a branched system of circulatory canals in the mantle. The muscles are placed behind the mantle cavity. In primitive brachiopods belonging to the class Inarticulata, the two valves are held together by two pairs of adductor muscles. In the class Articulata, the two valves articulate along a posterior hinge line, a structure that needs both adductor and diductor muscles.

The shell of most inarticulate brachiopods is composed of calcium phosphate and chitinous organic matter; some inarticulates and all articulates have shells of calcium carbonate. These shells are either impunctate (compact), punctate, or pseudopunctate. The punctate shells have fine pores, whereas the pseudopunctate ones have rodlike calcareous bodies that, when subject to weathering, may look like puncta.

Most brachiopods prefer a hard bottom, but soft bottom forms occur too. In the latter case the pedicle may be reduced to form a thin thread by which the animal was tied to the bottom. In some species the pedicle is lost, but in burrowing forms (*Lingula*) it is large and strong.

The taxonomy of the brachiopods is based on various characters such as the shell structure, the pedicle opening, and the development of the cardinalia (hinge structures). Of the 11 brachiopod orders, only four, the Lingulida, Acrotretida, Rhynchonellida, and Terebratulida, are still extant. The Inarticulata are confined chiefly to the Cambrian and Ordovician; the Articulata were common from the Ordovician onward.

In Lower Cambrian strata seven inarticulate families are found to appear, together with a few articulates belonging to the order Orthida. A great burst in the de-

velopment of the articulates took place at the beginning of the Middle Ordovician. This was particularly the case with the three superfamilies Orthacea, Plectambonitacea, and Strophomenacea. The Pentameracea were characteristic of the Silurian, together with the Rhynchonellida and the Atrypida, and the latter also were typical of Devonian strata. The large, and stratigraphically important, order Spiriferida had a strong development in the Upper Silurian, flourished throughout the Paleozoic, and then became extinct in the Jurassic. The Productacea, a superfamily of the Strophomenida, dominated the Carboniferous and Permian faunas (in the Lower Carboniferous 45 percent of the 142 known brachiopod genera were Productacea). Related to productids were the highly specialized Richthofeniacea, in which the ventral valve was long and cone shaped while the dorsal valve formed a small operculum within the cone. These forms were attached to the bottom by rootlike spines and lived on exposed coral reefs like the similar rugose corals and rudist bivalves. The Terebratulida occur in Mesozoic and Cenozoic deposits.

#### THE ARTHROPODA

Today the arthropods have a unique position among the animals inhabiting the earth. Because of the insects in particular, arthropods (*q.v.*) form about 75–80 percent of all species described, and no other metazoans have been able to adapt themselves to so many different environments. In ancient times, the arthropods were of primary import and were rather easily preserved as fossils because of their usually solid exoskeleton. Because of molting, one individual could actually be preserved many times, each molt providing a separate fossil. The arthropods have proved to be very important index fossils. Their geological appearance from the dawn of the Cambrian until today has shed light on the complex relationships and phylogeny of the phylum's members.

This large and heterogeneous phylum may have had a polyphyletic origin. A natural systematic division of the arthropods has proved difficult, in large part because of the many cases of adaptations leading to parallel development in less related forms. Obviously complex organs such as compound eyes, mandibles, and trachea have developed independently in remote groups. Six major groups (subphyla or superclasses) of arthropods may be separated: Onychophora, Trilobitomorpha, Chelicerata, Crustacea, Myriapoda, and Insecta. The second and third

Brachio-  
pods in  
the fossil  
record

Brachio-  
pod  
structures

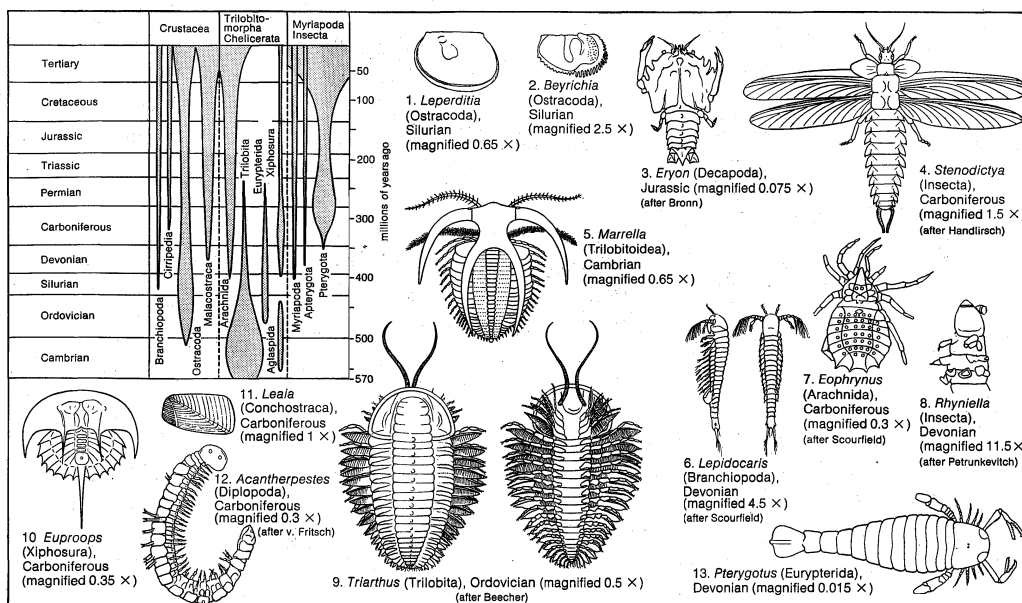

Figure 6: Representative arthropods and their geological range. (Left) Occurrence of the Crustacea, Trilobitomorpha, Chelicerata, and Myriapoda and Insecta groups in the geological record. Width of stippled zone indicates relative abundance. (1-13) Fossil arthropods as designated.

From (1,4,6,7,9,12) H. Wienberg Rasmussen, *Paleontologi, Fossile Invertebrater*; (2) Benson, *Treatise on Invertebrate Paleontology*, courtesy of the Geological Society of America and The University of Kansas Press; (3,11) Termier and Termier, *Paleontologie Stratigraphique*, copyright 1960, Masson & Cie, Paris; (8,10,13) L. Stormer, *Jordens og livets historie*

groups probably belong to one stock, and the same is true of the Myriapoda and Insecta.

**Structure of trilobites.** In the Cambrian about 60 percent of the fossils described are trilobites. Fifteen hundred genera and about 10,000 species are known from the earliest Cambrian to the end of the Permian. The numerous trilobites vary considerably in shape and size (from 0.5 millimetre to 700 millimetres), but it is interesting that, in spite of this diversity, the definite plan of construction seems to have remained unchanged.

The trilobite had a solid exoskeleton composed of calcite or calcium phosphate with a smooth, granulated, or spiny surface, the shell pierced by fine canals. The dorsal armour shows a double tripartition; a pair of longitudinal furrows separate a median axis from the lateral pleurae, and transverse joint lines separate the thorax from the head shield, or cephalon, and from the tail shield, or pygidium.

The head shield has a median axis (glabella) with transverse lobes indicating a metamer segmentation and a pair of lateral compound eyes that might have had several thousands facets. Lines of weakness in the shell ran across the cheeks along the eyes. They opened during the molting and facilitated the process. These so-called facial sutures divide the head shield into a median portion (cranidium) and lateral portions that represented the free cheeks (librigenae), often provided with horns or spines. The thorax is composed of 2-40 transverses, free segments articulated to each other and to the head shield and tail shield. The tail shield forms a solid plate composed of a variable number of segments.

On the ventral side of the flat trilobite body only the inflected marginal parts (doublure) and a large upper lip (hypostoma) ventral to the mouth were covered by an exoskeleton capable of being preserved under normal conditions. The rest of the ventral surface was covered by a thin chitinous integument. The axial portion contained the vital portion of the body; here the appendages were attached.

The delicate appendages are known in a limited but representative number of species ranging from the Cambrian to the Devonian. Of particular interest is the uniform development of the appendages. In front a pair of flexible antennae occurs, and beyond these all appendages are practically identical (with the exception of an anten-

na-like posterior appendage in one species). This primitive condition is unique among arthropods and is indicative of annelid ancestors. Four pairs of appendages behind the antennae belong to the head shield. Each appendage is biramous with a median walking leg (telopodite) and a lateral comblike appendage attached to the base, not the end of the strong coxa, as in crustaceans. The teeth of the "comb" on the lateral branch may have served as gills such as in the living horseshoe crabs. Because no jaws are developed and the upper lip completely covers the front of the mouth, the trilobites probably were mud eaters, the mud probably carried forward by water currents and filtered through the comblike structures. A satisfactory taxonomy has not yet been established. No single character (*e.g.*, the cephalic sutures) has proved adequate for a major classification.

**Occurrence and evolution of trilobites.** In the Lower Cambrian, 21 trilobite families were present, among them the primitive Olenellina and Redlichina, which have a distinctly segmented axis in the cephalon, a thorax of many segments, and a very small pygidium. More advanced forms with a larger pygidium also appeared in the Lower Cambrian. During the Upper Cambrian, members of the Olenida were practically the only fossils present in the black-mud seas of Europe. The olenids probably had large gill combs and were able to endure the stagnant waters of these shallow seas.

The adaptive radiation of the trilobites increased until the end of the Cambrian, and from then on a gradual decrease took place, slowly during the Ordovician and then more rapidly through the Silurian. Several new superfamilies appeared in the Lower Ordovician, among them the Trinucleina, Calymenina, Phacopina, and Lichida, which gradually replaced the Lower Ordovician asaphid faunas. The phacopina also were common in the Devonian, and the Proetacea lasted through the Carboniferous and Permian. The class Trilobitoidea comprises a small group chiefly confined to a number of excellently preserved arthropods from the Middle Cambrian Burgess Shale in British Columbia. The trilobitoids are mostly small arthropods with appendage of the characteristic trilobite type. Compared with the trilobites, the contemporaneous trilobitoids show a surprising degree of diversity, both in the development of the body and of the appendages. The trilobitoids were able to break the strong

Trilobites and trilobito-morphs

Trilobite appendages

frames of construction that prevented a further development and radiation of the trilobites, yet they were not successful in their further development.

**Merostomatans and arachnids.** Whereas the trilobitiforms evidently were marine forms only, members of the subphylum Chelicerata lived in saltwater and freshwater (merostomes) and adapted to both a terrestrial and parasitic mode of life (arachnids). The class Merostomata includes the Aglaspida, Xiphosura, and Eurypterida. The aglaspids, ranging from the Lower Cambrian to the Middle Ordovician, had an elongate body with a head shield, lateral eyes, a trunk or abdomen composed of 11 free segments, and a styliform terminal segment (telson). As far as is known, the appendages were simple.

The Xiphosura, including the living horseshoe crab (*Limulus*), have a long, interesting geological history. The earliest representatives in the Silurian had free segments in the abdomen. Most Silurian and Devonian forms had these free abdominal segments, but gradually they fused into a continuous abdominal shield, as is present in Recent members of the group. In the Triassic, some 200,000,000 years ago, the main traits of the present horseshoe crab were well established. More than most living archaic forms, the horseshoe crabs deserve to be called "living fossils."

The *Eurypterida*, or sea scorpions, have become famous both because of the excellently preserved specimens known and the giant size of certain species. The Devonian *Pterygotus* grew to more than 180 centimetres, longer than any other known arthropod. Most preserved chitinous exoskeletons may be shed exuviae from moltings.

The elongate body has a more or less semicircular head shield or prosoma, a 12-segmented abdomen, and a spine-like or finlike telson. Six pairs of appendages correspond to those in the Xiphosura, and the legs may be modified into swimming paddles. As in the xiphosurans, the abdomen had plate-shaped ventral appendages protecting the gills. The eurypterids appeared in the Ordovician and were common in nonmarine faunas in the Silurian and Devonian. Like the trilobites, the group became extinct at the end of the Permian.

The class Arachnida (*q.v.*) includes mostly terrestrial forms, but their ancestors probably were aquatic. In the arachnids, air-breathing structures replace gills.

The earliest scorpions (see SCORPIONIDA) occur in Silurian strata. They differ from Recent forms by their coarse legs and lack of slits or spiracles leading into the book lungs. The structures indicate that the early scorpions were aquatic. True terrestrial scorpions (with spiracles) have been recorded from the Carboniferous. Yet a few Devonian occurrences have shown that certain terrestrial arachnids existed in the Lower Devonian. Aquatic arachnids may have invaded the land at the end of the Silurian, a time when the first land plants began to flourish.

**Crustaceans in the fossil record.** Most crustaceans (*q.v.*) are marine, a few live in freshwater, some are parasitic, and some have become adapted to a terrestrial mode of life. The chitinous, mostly calcified exoskeleton of the crustaceans provides good opportunities for fossilization. Of the many existing groups, Branchiopoda, Ostracoda, Phyllocarida, and Decapoda are important as fossils.

Characteristic of the Crustacea are the appendages of the head, the two pairs of antennae, the mandibles, and the maxillae. The Branchiopoda (*q.v.*) are known from the Silurian (possibly Ordovician) onward. In the Conchostraca the carapace is folded round the laterally compressed body giving the impression of pelecypod valves. Such carapaces of conchostracs (" *Estheria*" and *Leaia*) are characteristic of freshwater and brackish water and possibly of the saline environments in the Late Paleozoic and Mesozoic. The branchiopods apparently form a stagnant group, the living tadpole shrimp (*Triopsapus*) being practically identical with a form found in the Triassic.

The Ostracoda, the mussel or seed shrimps, are the most common fossil crustaceans. About 900 genera are known, ranging from Cambrian to Recent time. The importance of these microfossils (from 0.2 millimetre to 5 millimetres in length) as index fossils is steadily increasing.

The ostracods have a body enclosed in two separate valves connected along a dorsal hinge line. In the Lower Cambrian, valves interpreted as ostracods have been found. A strong development of the group took place at the beginning of the Ordovician, and from then on new families gradually appeared. The order Palaeocopida were common throughout the Paleozoic, whereas the Podocopida dominated the Mesozoic and Cenozoic.

The Malacostraca, including the Phyllocarida, Decapoda (*q.v.*), and several other groups, have a more or less constant number of segments in the body. While the phyllocarids, with their large folded carapace, were rather common in the Silurian, the decapods flourished in Mesozoic and later times. The decapods appeared at the end of the Permian and had their first evolution in the Triassic. A major expansion took place in the Lower Jurassic and another in Middle Jurassic time. Crabs developed at the beginning of the Tertiary.

**Insects in the fossil record.** With few exceptions, insects are terrestrial forms. For this reason the fossil occurrences are relatively few, but despite this, about 12,000 species of fossil insects have been described. A related group, the Myriapoda, are little known as fossils. It is interesting to note, however, that fossil remains resembling diplopods have been described from the Upper Silurian and Lower Devonian. If these forms turn out to be true terrestrial centipedes then they are the first known land arthropods.

The class Insecta, with its more than 700,000 living species, has a unique position in the animal world (see INSECTA). Its enormous expansion may partly be due to the fact that the insects are the only arthropods that became fully adapted to a life in the air. Although the whole body is covered by chitinous integument, the wings have proved to be the most resistant parts, the part generally preserved as fossils.

The fossil record does not give any information on the origin of insects, but it indicates the succession of the major groups. In the Rhynie Chert, Scotland, probably of Lower Devonian age, the first insects appear. They are typical collembolids, showing that this wingless apterygote group was well established by that time. A pair of jaws have been interpreted as possibly belonging to a pterygote insect, but their nature is uncertain. The most ancient and at the same time most primitive insect wing has been found in the Upper Devonian (U.S.S.R.). The great burst in insect development occurred in the Upper Carboniferous. In the lower part (Namurian) appear members of the primitive hemimetabol Orthoptera—cockroaches, grasshoppers, and mantids are living relatives.

Slightly higher in the geological sequence there was an almost explosive radiation comprising about 15 new families of winged insects. Most characteristic are the primitive Palaeoptera, related to dragonflies and mayflies. They had wings that could be moved up and down but not backward into a resting position. Of interest are the lateral integumental folds on the first thoracic segment, structures that have been interpreted as primitive undeveloped wings. Among the Palaeoptera were giant forms with a wingspan of nearly 70 centimetres. Insects with wings that could be turned backward covering each other became more common through the Carboniferous. Cockroaches also were characteristic of the Permian. In the dry Permian climates the insects generally were smaller than in the humid Carboniferous environments. In the Permian the first insects with a complete (holometabol) metamorphosis occur, among them beetles with leathery forewings. From the Triassic onward, all the fossil forms belong to orders also present today.

#### THE ECHINODERMATA

This well-defined and at the same time highly diversified phylum of marine invertebrates (see ECHINODERMATA) includes the living starfishes (asteroids), brittle stars (ophiuroids), sea urchins (echinoids), sea cucumbers (holothuroids), and sea lilies (crinoids). The echinoderms, with strong calcite skeletons, occur in all Phanerozoic systems.

Occurrence of scorpions

From (2,5,7,10–12) W. Rasmussen, *Paleontologi, Fossile invertebrater*; (3,8,9) L. Stormer, *Jordens og livets historie*; and (6) *Treatise on Invertebrate Paleontology*, courtesy of The Geological Society of America and The University of Kansas

sometimes in such abundance that thick rock formations are completely composed of their remains.

**Symmetry and structures.** Echinoderms are marine invertebrates with a marked radial fivefold symmetry (although a bilateral symmetry probably was primary). Characteristic is the skeleton, which is of mesodermal origin and not formed by the ectoderm as in other invertebrates. In the skeleton, crystalline calcite forms single crystals, and the plates are therefore easy to identify among fossil remains. Another characteristic feature of the echinoderms is the development of the water-circulation system present in most forms. The radial furrows, or ambulacra, form central elements in the echinoderm skeletons. The mouth and anus are interradial, and their positions vary in different groups.

The phylum has been divided into more than 15 classes, some of which have but few fossil representatives. Forms that live attached to the bottom with the mouth region directed upward are often referred to as *Pelmatozoa*; those that are free living with the mouth region downward or forward have been termed *Eleutherozoa*. This division, however, is based more on function and morphology than on genetic affinities. More appropriate seems to be a division into four subphyla, the Homalozoa, Crinozoa, Asterozoa, and Echinozoa.

The subphylum Homalozoa includes the peculiar echinoderms usually known as carpoids. They are known from the Middle Cambrian to the Lower Devonian. The depressed body covered by plates may be completely asymmetric with a stalklike appendage, yet they were probably free-living forms. No radial symmetry is present and only one ambulacrum. The shell structure and water-circulation system show that the carpoids are echinoderms; a relationship to primitive vertebrates is hardly probable in spite of certain similarities. The Homalozoa comprise three mutually very different classes that may represent very ancient, preradial radiations of the Echinodermata.

**Cystoids, blastoids, and crinoids.** The subphylum Crinozoa includes nine classes, of which the Cystoidea, Blastoidea, and Crinoidea are the most common fossils. Members of these groups have a radial symmetry and a sacklike spheroid or cuplike body borne on a stem attached to the ground.

In the cystoids the body may be less symmetrical, with numerous, mostly irregularly arranged plates pierced by characteristic pore structures. Free food-gathering ap-

pendages called brachioles extend from the ambulacra. The cystoids appeared at the beginning of the Ordovician and had a great development in the Middle Ordovician just like several other calcite-shelled forms. The group became extinct in the Devonian.

The blastoids also were Paleozoic but ranged from the Silurian to the Permian and were most abundant in the Lower Carboniferous. The budlike cup, the so-called theca or calyx, has a marked radial symmetry, a uniform arrangement of plates, and numerous thin brachioles forming simple external processes of the theca.

Most important are the crinoids, of which more than 5,000 species are known from Lower Ordovician to Recent time. Crinoids are rock building in some formations and may be good index fossils. The sea lilies had a length as great as 18 metres. Characteristic of the group are the strongly developed and diversified arms that carry the food—grooves extending from the mouth at the summit of the body. The theca, enclosing most of the soft parts, has the plates arranged in several horizontal cycles.

True crinoids appeared in the Ordovician, particularly in the Middle Ordovician, and they had a strong and rapid radiation. It is interesting to note that these forms had all the essential features of later representatives. Of the four major groups of crinoids, two became extinct in the Permian and one in the Triassic; the remaining group (*Articulata*) originated in the Triassic and has been present since then.

The origin of the Crinozoa is unknown. A heterogeneous group, the Eocrinoidea, occurs in the Lower Cambrian, but the relation between this and the other members of the Crinozoa is remote.

**Echinoids, holothuroids, and edrioasteroids.** The echinoids, ranging from Ordovician to Recent time, have a globose to discoid body composed of a great number of plates that are radially arranged. A secondary, bilateral symmetry is demonstrated in more advanced forms, however. Characteristic of the echinoid shell is the presence of movable spines. Regular echinoids have a pronounced radial symmetry, the mouth has a ventral and central position, and the anus is at the summit of the body. The irregular echinoids have a secondary bilateral symmetry, the anus has moved backward to the posterior interradial, and the mouth, correspondingly, has moved forward.

The regular echinoids had their main development in Early Jurassic, when a number of new families appeared. The *Cidaridæ*, with large, often club-shaped, spines, are

Crinoids  
as index  
fossils

known from the Devonian and are common in the Mesozoic. Irregular echinoids, some of them adapted to a burrowing habit, are known before the Jurassic.

The holothuroids have skeletal elements consisting mostly of microscopic ossicles of calcite or iron phosphate; the skin contains numerous spicules. The holothuroids are rare as fossils, and the earliest representatives are known from the Devonian.

The discovery of a new class of echinoderms in the Lower Cambrian of California was reported in 1963. Its members, the Helicoplacoidea, had a fusiform, probably flexible body covered by spirally arranged plates. From one pole, probably from the mouth, extended a generally single ambulacrum, a structure reminiscent of the Homalozoa (carpoids). This early and peculiar group of Echinozoa, confined to the Lower Cambrian, had little in common with the other classes of echinoderms.

The Edrioasteroids were sessile, but this form may have been a secondary adaptation. They differed, however, from the Crinozoa by having a meridional pattern of symmetry. They lacked arms or brachioles, and the ambulacra probably had tube feet like those of the asteroids. For these reasons, these Lower Cambrian to Lower Carboniferous forms may be included in the Echinozoa. The usually circular edrioasteroids had a dorsal, centrally situated mouth and five curved ambulacra.

#### THE GRAPTOLITHINA

Like the ammonites, these Paleozoic marine invertebrates are excellent index, or zone, fossils. The Ordovician and Silurian chronozones are largely based on graptolite species that had a worldwide distribution and were restricted to distinct intervals in geological time.

**Structure and growth of graptolites.** Knowledge of the extinct graptolites is limited to the empty chitinous skeletons, which offer little information of the zoological position of the soft animals that inhabited the protecting covering case. More recent studies of the periderm of the skeleton, however, have demonstrated the presence of two layers, a thin external cortical layer and an internal fusellar layer with growth bands, and in a few cases a stolon has been observed below the cortical layer. These structures are closely similar to those present in certain pterobranchs belonging to the hemichordates. For this reason the graptolites are now generally looked upon as belonging to the phylum Chordata, rather than to the Hydrozoa, as previously assumed.

The skeleton of the graptolite colony (rhabdosome) has the tubiform "living chambers" or thecae arranged in single or double rows along the branches or stipes of the colony. The outer theca may be of two types, the autotheca and the bitheca, the latter mostly reduced. The thecae are connected by the so-called stolothecae, which form a continuous closed chain along the dorsal side of the stipe. The growth of the graptolite starts with a small, tubiform, initial theca, the sicula, which develops a thread (nema) and a lateral bud, from which the whole rhabdosome gradually develops. During the great radiation of the graptolites throughout the Ordovician and Silurian, the morphology of the rhabdosome, particularly the stipes and thecae, was subject to great variation. Characteristic trends of evolution were repeated in groups not closely related, complicating the taxonomy.

**Evolutionary trends.** The Middle and Upper Cambrian graptolites belong to the Dendrograptidae, which have been referred to a separate order Dendrograptoida. They have mostly cone-shaped or dendroid rhabdosomes with both autothecae and bithecae arranged in one row on the stipes. Members of the order Graptoloidea appear in the Lower Ordovician. Typical species had few stipes and only autothecae; however, some of the early branched species of the group had bithecae, a fact that shows that there is not a distinct boundary between the two orders. Dendrograptids evidently gave rise to the Lower Ordovician graptolitoidea that display gradual reduction of the stipes throughout the Lower Ordovician (dichograptid) fauna. This fauna was replaced in the Middle Ordovician by two-branched, mostly reclined (leptograptid)

Figure 8: Representative graptolites and their geological range.

(Left) Occurrence of the Dendroidea and Graptoloidea in the geological record. Width of stippled zone indicates relative abundance. (1-3) Dendroidea, (4-10) Graptoloidea.

From L. Stormer, *Jordens og livets historie*

forms and by one-branched, biserial (with two rows of thecae on the stipe) forms (diplograptid fauna). The latter lasted into the Lower Silurian, when it was replaced by one-branched, uniserial forms with specialized thecae (monograptid fauna). The Silurian graptolite faunas were dominated by the family Monograptidae, which became extinct in the Lower Devonian. While the Graptoloidea lasted to the Upper Silurian, some of the Dendroidea existed up to Middle Carboniferous time.

The worldwide distribution of many graptolites is evidently due to a planktonic mode of life; alternatively, the individuals may have been attached to floating bodies (epiplanktonic). Most graptolites occur in black shales (graptolite facies) and other fossils usually are not present. The black mud of the shale probably was deposited slowly under anaerobic conditions. No bottom fauna was present to destroy the graptolites, which sank from better ventilated water levels above. Graptolites also occur in limestone, from which excellently preserved specimens have been etched out by acids.

#### THE FISHES

Most vertebrates have a solid skeleton, either external or internal, which offers good opportunities for preservation. Fossil vertebrates are known from the Ordovician and all later systems. Fossils, however, give no information concerning the origin of the vertebrates. The Ordovician forms are well organized; the stratigraphic appearance of the various groups clearly demonstrates the gradual progressive development of the vertebrates through geological time. The speed of development varied considerably between groups and from one time interval to another: within one interval, one group might display rapid development and considerable radiation while related groups might remain practically unchanged.

The fishes (see FISH) form the central group of the vertebrates. The main step in the evolution of the vertebrates is the "invention" of the jaws, a device that completely changed the life of the early vertebrates; from being mud feeders they developed into omnivorous and carnivorous forms able to feed on larger plants and animals. For this reason the vertebrates might naturally be divided into two major groups: the Agnatha (q.v.), or jawless forms, and the Gnathostomata, or jawed forms.

**Agnatha: jawless fishes.** The class Agnatha includes the living cyclostomes, the hagfishes and lampreys, which

Graptolites

Armoured fish: the ostracoderms

are but faint reflections of the rich agnath faunas of the Late Silurian and Lower Devonian. In contrast to the soft-bodied Recent forms, the ancient ostracoderms were heavily armoured, and in addition to this exoskeleton some of them had internal ossifications with distinct impressions of internal structures such as brain and nerves. The internal structures show that the ostracoderms are closely related to the living agnaths. Both in extant and extinct forms, two separate groups may be distinguished: the Diplorhina, with two nasal pockets, and the Monorhina, with a single nasal pocket. The hagfishes (*Myxine* and *Bdellostoma*) and the fossil Heterostraci (pteraspids and thelodontids) belong to the first group, the lamprey (*Petromyzon*) and the fossil Osteostraci (cephalaspids and anaspids) to the other.

The tadpole-shaped pteraspids had the anterior portion of the body covered by a solid dorsal and ventral shield. In more advanced forms these shields were split into smaller plates. A further development is found in the thelodontids (coelolepids) where the body was covered by small scales, almost like shark scales. The cephalaspids had a rather flat head shield and centrally placed eyes and pineal and nasal openings. Plate-covered lateral and median areas are interpreted as parts of sensory organs. On the ventral side, the jawless mouth is placed near the frontal margin, and farther back a number of gill openings are arranged in a circle. The anaspids had a narrow body and a fanlike tail and were probably nektonic (swimming) forms.

The earliest ostracoderms are known from the Ordovician, but these forms (*Astraspis*) are already well organized, indicating a long time of evolution of the ostracoderms before the Ordovician. The mostly nonmarine ostracoderms lived together with euryterids and, like members of this group, flourished in the Late Silurian and Devonian.

**Jawed fishes.** The class Acanthodii, or "spiny sharks," are fishes with jaws. The jaws were formed by a modification of an anterior pair of gill bars. The acanthodians occur in the Silurian, perhaps in the lower part, and remain in the fossil record until the Lower Permian. The acanthodians were small sharklike fishes with a considerable number of paired fins. The body was covered by small, close-set, diamond-shaped scales with a microscopic structure similar to that of the ganoid scales of bony fishes.

The class Placodermi (*q.v.*) comprises the most charac-

teristic and most spectacular fishes of the Devonian. In contrast to the other groups, they are confined to this period, with the exception of a small group (the ptyctodonts) that just reached into the earliest Carboniferous. Like the ostracoderms, the placoderms were armoured, but the thick exoskeleton was limited to the head and trunk. An internal skeleton was developed to some extent. Pectoral and pelvic fins were present.

The placoderms are commonly divided into two separate groups: the Arthrodira and Antiarchi. In both groups the shape of the head and trunk, as well as the size, display a considerable variation throughout the Devonian. The largest forms known had a length of more than 8 metres (30 feet). Characteristic of placoderms is the presence of an articulation between the head shield and trunk shield. As a general rule the armour became gradually reduced throughout the Devonian. The Middle and Upper Devonian Antiarchi had a small head with more centrally placed eyes, and the pectoral fins were covered by bony plates and articulated to the trunk shield. These weird looking fishes apparently lived in freshwater.

The sharks (see SELACHII) and chimaeras, evidently related to the placoderms, are usually united in one group—the Chondrichthyes, or cartilaginous fishes. The shark-like fishes lack true bone, the denticles probably remnants of a more continuous exoskeleton in ancient forms. Because cartilage is rarely preserved, the fossil remains are generally confined to teeth and denticles only. The oldest sharks are known from the Middle Devonian, and Late Devonian forms (*Cladoseleache*) have primitive, flap-like pectoral fins. Most of the ancient sharks became extinct at the end of the Paleozoic. Characteristic freshwater sharks (pleurochantids) were abundant in the Carboniferous and Early Permian. The more advanced sharks characteristic of the present seas developed through the Mesozoic, and giant Tertiary forms may have had a jaw gap of six or seven feet. Skates and rays and also the chimaeras (ratfishes) appeared in the Jurassic.

**Higher bony fishes.** The class Osteichthyes or higher bony fishes appeared in the Devonian. Characteristic of the group is the operculum covering the gills, a structure also present in the acanthodians. The osteichthyes are divisible into two major groups: the Actinopterygii, or ray-finned fishes, and the Sarcopterygii (Choanichthyes), or fleshy-finned fishes. The former includes the great ma-

Sharks, skates, and rays

jority of extinct and extant fishes; the latter attained a maximum in the Paleozoic and today is represented by a few lungfishes and the famous *Latimeria*, or bluefish. In the actinopterygians, the paired fins consist chiefly of rays supporting a web of skin. In the sarcopterygians, on the other hand, the well-developed paired fins are composed of flesh with an internal skeleton.

The actinopterygian first appear in the Middle Devonian. The Paleozoic-Triassic forms and certain living relics (*Polypterus* and sturgeons) constitute a separate group, the Chondrostei (*q.v.*), which have a powerful external skeleton of solid ganoid scales and a less developed (or rather reduced) internal skeleton. The tail fin is heterocercal (sharklike). In the chiefly Mesozoic Holostei (*q.v.*) the internal skeleton is more ossified and ganoid scales may be absent. The Teleostei (see TELEOSTEI, and the many separate groups of the fishes) have a well-developed internal skeleton forming a strong and elastic backbone. The thin cycloid scales form a light exoskeleton that does not impede swift movements in the water. The teleosts appear in the Jurassic and had a great adaptive radiation at the beginning of the Tertiary.

Lungfish  
and crosso-  
pterygians

The Sarcopterygii deserve particular interest because they include the ancestors of the tetrapods. The two separate groups, the Dipnoi (*q.v.*) and the Crossopterygii (*q.v.*), have many structures in common and probably had common ancestors in pre-Devonian times. In addition to the lobe fins, both groups have characteristic cosmoid scales, and lungs are usually present. Lungs, originating as sacklike extensions from the gut, are evidently an ancient structure. They probably developed in freshwater fishes (like most known fishes in the Devonian) to protect them in the dry seasons. In all actinopterygians except *Polypterus* (which live like the Devonian forms), the lungs are reduced or modified into an air bladder. In the lungfishes and one group of the crossopterygians, the rhipidistians, the nostrils have internal openings (choana) that allow the air to be inhaled without opening the mouth, a structure that also is characteristic of the tetrapods.

The lungfishes, or Dipnoi, arose in the Middle Devonian and linger on to the present time. During this long time a reduction in ossification is noticeable, but otherwise this conservative group, a blind alley in vertebrate evolution, was subject to little change.

The crossopterygians differ from the dipnois in the pattern of the skull plates and in the dentition. The group appeared in the Lower Devonian and flourished throughout this system, and the important rhipidistians became extinct in the Permian. Another group, the coelacanthids, was common in the Triassic and is represented today by *Latimeria*.

#### THE AMPHIBIA

The class Amphibia (*q.v.*), which is represented today by the frogs (see ANURA), the salamanders and newts (see URODELA), and the rare gymnophions, played a great role in Carboniferous to Triassic times. The amphibians were the dominating larger animals of the coal swamps, and a considerable radiation took place during the development of the group from Late Devonian to the end of the Triassic. Only a smaller group, including the extant forms, lingered on to present time. Fossil amphibians are of particular interest because they throw light on the origin of the tetrapods from fishes and at the same time demonstrate how certain primitive vertebrates were able to adapt themselves to a terrestrial mode of life.

Amphibians  
as a link  
between  
fishes  
and  
tetrapods

The Late Devonian amphibian *Ichthyostega* from Greenland clearly demonstrates its close relationships to certain crossopterygian rhipidistian fishes. In both groups the pattern of bone elements in the skull is essentially the same, and the primitive amphibians even have fishlike rays in their tails. The bones of the limbs have a distinct basic pattern in all tetrapods, and it is possible to derive this from the arrangement of the bones of the fleshy-fins of the crossopterygians.

In the early amphibians, the roof of the rather flat skull was completely covered by dermal bones; the only open-

ings were for the eyes and nostrils, and posterior notches mark the position of the ears. The vertebral column was more ossified than in recent forms. The development of the bone elements of each vertebra vary in different forms, and this distinction is used as a basis for a classification of the amphibians. The extant forms and their immediate fossil relatives are commonly placed in one group, *Lissamphibia*, characterized by a strong reduction of the bone, particularly in the braincase and skull. The Paleozoic and Triassic forms are divided into two main groups, the Labyrinthodontia (Aspidospondyli), with "arch-vertebra," and the Lepospondyli, with "husk-" or "ring-vertebrae."

The labyrinthodonts, also called stegocephalians because of their completely roofed skulls, have the characteristic labyrinthodont teeth present also in the crossopterygians. The body of the early forms had a nearly cylindrical cross section with laterally placed limbs. Only some of the later labyrinthodonts were better adapted to a terrestrial gait, but at this time several forms had already returned permanently to aquatic life, and the hegemony was taken over by the reptiles. Small labyrinthodonts had the size of common salamanders, but the larger ones reached a length of more than 4 metres (15 feet). The group flourished throughout the Carboniferous and Permian and became extinct at the end of the Triassic. Among the labyrinthodonts, the anthracosaurians are of great importance because they evidently include the ancestors of the reptiles and hence of all advanced vertebrates. *Seymouria*, from the Permian of Texas, is more or less a "missing link" between amphibians and reptiles. The skeleton demonstrates characters of both groups. The lepospondyls were restricted to the Carboniferous and Permian; some of them were eellike with reduced limbs.

#### THE REPTILIA

The class Reptilia (*q.v.*) represents the next and decisive step in the conquest of land by the vertebrates. The fossil record demonstrates the enormous radiation of the group throughout the Mesozoic, "the Age of Reptiles," a time span amounting to more than 200,000,000 years if the time of the Late Paleozoic forms is included. Of this great display of reptiles only the turtles (Chelonina), lizards and snakes (Squamata), rhynchocephalians (*q.v.*), and the crocodiles and alligators (Crocodylia) survived the Mesozoic and are present today. Characteristic of the reptiles are the large shell-covered eggs laid on land, in contrast to the small and soft water-laid eggs of the amphibians. Whereas the amphibians were dependent on an aquatic environment for their young, reptiles, so to speak, carried this environment with them on land, well protected within the egg. Compared with the amphibians, the skull of the reptiles is higher and more narrow, and the completely heavy roofed skulls are gradually replaced by lighter forms with lateral openings. The number and position of these openings are used in the classification of the reptiles, a classification that to a large extent may be artificial.

The  
"Age of  
Reptiles"

**Characteristics of early reptiles.** The earliest reptiles form more or less a stem group, the Cotylosauria, from which the others radiated. They flourished in the Permian and had much in common with the amphibians. As already mentioned, the genus *Seymouria* stands almost exactly on the dividing line between amphibians and reptiles.

One of the first groups to branch off from the stem reptiles was, surprisingly enough, the group leading to the mammals. These reptiles occur in the Carboniferous. They are characterized by an opening in the lower part of the cheek region of the skull (synapsid type). In the Lower Permian, the bizarre looking dimetrodons appear. They have a dorsal "sail" supported by greatly prolonged neural spines and well-differentiated teeth adapted for their carnivorous habit of life. From such early forms developed the therapsids, which are regarded as the ancestors of the Mammalia. They were rather lightly built, with the limbs placed underneath the body, not outward

Figure 10: Evolution of reptiles and birds from the ancestral thecodonts.

From (anterior, Rhamphorhynchus, Archaeopteryx) A.S. Romer, *Vertebrate Paleontology* (© 1966), The University of Chicago Press, all rights reserved

as in the primitive, less active forms. Through the Late Permian and the Triassic, a trend of increasing size is noticeable, and gradually the therapsids became more and more mammal-like. The structures of the teeth into incisors, canines, and molars, fill the gap between the Triassic therapsids and the first mammals appearing in the mid-Jurassic.

The main radiation of the reptiles took place at the end of the Permian. Several of the Triassic reptiles were marine. This is not necessarily a secondary adaptation. It is not unlikely that early amphibious forms remained aquatic, although they preferred to lay their eggs on land.

Ichthyosaurs and plesiosaurs

The specialized and mostly aquatic turtles have remained little changed up to Recent times. Sea turtles up to 4 metres (12 feet) in length occurred in the Cretaceous.

The Ichthyosauria, or "fish reptiles," were highly adapted to an aquatic mode of life. The fusiform body had a dorsal fin (unsupported by bones) and a well-developed tail fin, the limbs reduced to short steering paddles. The strongly modified head had large eyes and a long beak with the nares at the base. The young ichthyosaurs probably were born alive. The group became extinct at the end of the Cretaceous.

The Plesiosaurs and the allied nothosaurs form a separate group, the Sauropterygia, which is characterized by skulls with the cheek opening at the top of the skull (europsid type). The marine plesiosaurs appeared at the end of the Triassic and were abundant during the rest of the Mesozoic. These fish-eating creatures usually have a long neck and a short trunk and tail. The strongly modified

limbs were used as "rowing" paddles rather than steering organs. Cretaceous plesiosaurs measured up to 12 metres (50 feet) in length.

The nothosaurs of the Triassic were small forms with limbs serving both as fins and feet. The amphibious forms were probably related to the ancestors of the plesiosaurs. The placodonts were also related; they had large flat teeth that were well adapted for crushing mollusks.

The lizards and snakes and their extinct relatives form a separate group, the Lepidosauria. Recent finds have shown that lizard-like forms occur in the Triassic. Like the "ruling reptiles," the lepidosaurs have two openings in the cheek region of the skull (diapsid type). The earliest representatives of the group (the eosuchians) appear in the Early Permian. The living *Sphenodon* is the only representative of the similar rhynchocephalians of the Triassic.

Spectacular representatives of the lepidosaurs were the marine fish-eating mosasaurs of the Cretaceous. They had a large head and a short neck, and with their long, slim body they looked like "sea serpents." The snakes did not appear until the Cretaceous.

**Dominant terrestrial forms.** The Archosauria, or "ruling reptiles," dominated the terrestrial faunas throughout the Mesozoic. The group includes the crocodiles, dinosaurs, flying reptiles, and related primitive forms. Like the lepidosaurs, the archosaurs have two temporal openings (diapsid type), but otherwise the two groups have few characters in common.

The Thecodontia form a central group of the Archosauria, a group from which all the ruling reptiles and the birds evolved. As expressed in the name, the teeth of the thecodonts and their descendants were firmly set in deep sockets. The early thecodonts were small bipedal forms (proterosuchians) with moderately reduced front legs. The group became extinct at the end of the Triassic, but before that they had given rise to the below-mentioned groups.

The Crocodilia are known from the Middle Triassic onward. The early forms were small, heavily armoured, and lizard-like. Later representatives resemble the recent ones and probably had a similar mode of life.

The Dinosauria, the most spectacular vertebrates of all time, had a worldwide distribution and lived and flourished from the Late Triassic to the end of the Cretaceous, a time span of some 150,000,000 years. During this long time interval the dinosaurs were subject to a great radiation both in shape and size; the smallest were the size of a cock, and the largest attained a length of almost 30 metres (90 feet) and a weight of up to 36–50 metric tons.

The dinosaurs

The term dinosaur is actually an artificial term that includes two distinctly different orders of the archosaurs, two orders that evidently are not more closely related than are the crocodiles, pterosaurs, and birds. The two groups of dinosaurs, the order Saurischia and the order Ornithischia, are distinguished mainly by their different pelvic structures; the former had a triradiate and the latter a tetra-radiate pelvis.

**Saurischians.** Members of the Saurischia were common in the Triassic. These early forms were bipedal with a well-developed tail, useful as a supporter or "balancer." The suborder Theropoda includes all the small and giant carnivorous bipeds of the Jurassic and Cretaceous. Typical of the small ones were the small head, long neck, and moderately reduced front limbs. The ostrichlike *Ornithomimus* from the Cretaceous was probably an egg robber. Both the small and large theropods have birdlike feet (fossil tracks were originally interpreted as due to large birds). The large theropods, very common in the Jurassic, have, in contrast to the small ones, a large head with a short neck; and the front limbs were strongly reduced, so much so that in the latest forms they may have been practically useless, not even able to reach the mouth. Toward the end of the Cretaceous the largest carnivores appeared. The giant flesh-eating *Tyrannosaurus* measured about 15 metres (47 feet) in length with a height of 6 metres (19 feet) in bipedal pose.

The suborder Sauropoda comprises Jurassic and Creta-

Figure 11: Representative reptiles and birds and their geological range. (Left) Occurrence of dinosaurs and birds in the geological record. Width of stippled zone indicates relative abundance. (1–10) Fossil reptiles and birds as designated.

From (1,2,4) Romer, *Invertebrate Paleontology*, copyright 1966, University of Chicago; (3, 6–10) L. Störmér, *Jordens og livets historie*; (5) Termier and Termier, *Paleontologie Stratigraphique*, copyright 1960, Masson & Cie, Paris

ceous saurischians, which were herbivorous and had acquired a quadrupedal gait. In this group, the largest four-footed animals that ever lived (*Diplodocus*, *Brontosaurus*, and *Brachiosaurus*) are found. Characteristic of these reptiles are a small head, a long neck, a short and stout trunk borne on strong "elephantine" legs, and a long tail. The skull has an exceptionally small brain. In certain forms, the nares are placed on the top of the skull, a position suggesting that the long neck served as a "snorkel" when the large sauropod walked in deeper water. *Diplodocus* had a very long tail with a length of 26.7 metres (87.5 feet), and the more short-tailed *Brachiosaurus* measured about 25 metres (80 feet) but was larger, with an estimated weight of 50 tons.

**Ornithischians.** The order Ornithischia was largely confined to the Jurassic and Cretaceous. These birdlike, herbivorous dinosaurs display an extraordinary radiation during their development. In addition to a tetrapodal pelvis, they usually had a horny beak with a corresponding reduction of teeth in the frontal portion of the mouth. Four main groups have been distinguished: the bipedal ornithomorphs, the quadrupedal stegosaurs, the heavily armoured ankylosaurs, and the horned ceratopsids.

The bipedal forms include the well-known *Iguanodon*, with its spikelike "thumb" serving as a weapon. Tracks referred to this genus occur as far north as Spitzbergen. Duckbill dinosaurs (trachodonts) also were common in the Cretaceous. These were probably amphibious forms; they had hundreds of leaflike teeth adapted for grinding tough plant material. Other ornithomorphs (hadrosaurs) had peculiar hollow crests on the head, possibly for air storage during diving.

The Jurassic stegosaurs, quadrupedal ornithischians, were peculiar looking, with a double row of large, vertically arranged plates along the back. The brain was very small and the hind legs much longer than the front ones.

The Cretaceous quadrupedal ankylosaurs, or "reptilian tanks," were strongly armoured, a necessary protection against the contemporaneous carnivorous theropods (they could not escape into the water as could the other amphibious dinosaurs).

The Upper Cretaceous horned ornithischians also include quadrupedal forms with a large head (making up to one-third of the total length of the body), which in *Triceratops* ranged from 5 to 6 metres (16 to 20 feet). Characteristic of the group were the prominent horns and the great frill of bones extending back over the neck, form-

ing a good protection for this vulnerable part of the body. Eggs and young individuals of the ceratopsids are known from Mongolia.

No dinosaurs survived the Cretaceous. Most groups disappeared rather suddenly at the end of this system. Many hypotheses have been put forth to explain this extinction, including climatic and environmental change and the rise of the mammals, among others. None seems wholly satisfactory, and their rather sudden extinction remains one of the great mysteries of natural history.

**Flying reptiles.** The order Pterosauria, or flying reptiles, are known from the Jurassic and Cretaceous. Both the pterosaurs and the birds developed from the thecodonts. Both represent the reptilian conquest of the air. The pterosaurs, however, were the less successful of the two and became extinct before the end of the Cretaceous. The skeleton of the flying reptiles was light with air-filled bones. The elongate wings were composed of a membrane of skin attached to and supported by the arm and a strongly prolonged single finger of the hand. The wing was probably highly vulnerable to rupture, much more so than the wings of bats and birds. The more primitive Jurassic forms (*Rhamphorhynchus*) had a long reptilian tail, which in late Cretaceous forms was reduced to a stub. At the same time a reduction of the teeth is noticeable. Among the latest pterosaurs were very large forms (pterodons) with a wingspread of 7 metres (25 feet) and a long crest extending backward from the head.

#### THE BIRDS

Representatives of the class Aves (see BIRD) occupy a unique position among the vertebrates because of the feathers that cover their warm-blooded bodies and form the essential parts of the wings. In all other basic characters, the birds are reptilian; their feathers are, in spite of their complex structures, comparable to the scales of reptiles. The structural correspondence between birds and reptiles is so far reaching that inclusion of the Aves in the Archosauria has been seriously considered.

Because of their mode of life, birds are rarely preserved as fossils; seabirds are the more common because they might be preserved in marine sediments. The lack of other fossil birds may give an erroneous impression of their appearance in the fossil record.

The classical finds of three specimens of *Archaeopteryx* in the Late Jurassic of Solnhofen in Germany demonstrate the primitive, really reptilian bird. In contrast to

Sudden extinction of dinosaurs

The primitive, reptilian bird

Figure 12: Representative mammals and their geological range. (Left) Occurrence of principal mammalian groups in the geological record. Width of stippled zone indicates relative abundance. (1-9) Fossil mammals as designated.

later forms, it had nonpneumatic bones, a reptilian skeleton of the wings and pelvis, and a long reptilian tail. Teeth were present in the jaws, a feature that, however, also was maintained in Cretaceous birds. Practically nothing is known of the evolution of birds in the Lower and Middle Cretaceous. Late Cretaceous forms, evidently seabirds (*Hesperornis*), were advanced in many characters but still possessed teeth in their beaks.

About 20,000 species of living birds are known. Although the number of fossil forms is small, the group evidently developed and radiated greatly during the Tertiary. Of particular interest is the development of large flightless forms like the present ostriches. Such forms had possibilities for development, particularly in places where carnivores were absent and where flight was not necessary as a means of escape. This was true in Madagascar and New Zealand, where the giant "elephant birds" (*Aepyornis*) and moas (*Dinornis*) lived up to historical times when they evidently were exterminated by man.

#### THE MAMMALS

The living, warm-blooded mammals, members of the class Mammalia, are usually divided into three groups: the egg-laying mammals, or Monotremata; the live-bearing pouched mammals, or Marsupialia; and the placental mammals, or Placentalia (see MAMMALIA; MONOTREMATA; and MARSUPIALIA); but with present comprehensive knowledge of the many extinct mammal groups, this classification has proved too narrow. The monotremes are placed in the subclass Prototheria, some Mesozoic forms in the subclass Allotheria, and the marsupials and placentals in the subclass Theria, the latter divided into the Mesozoic Trituberculata, the Metatheria (Marsupialia), and the Eutheria (Placentalia).

**Characteristics and early types.** Characteristic of the mammalian skeleton and teeth (only parts generally preserved) are a thorough ossification with a reduction of certain bones in the skull, a swelling of the braincase, and changes in the auditory region involving an inclusion of bones from the lower jaw.

The oldest mammals are known from the Late Triassic of China. Throughout the Mesozoic they played a modest role, the mice- to rat-sized forms unable to compete with the prominent carnivorous reptiles of the time. The Mesozoic material is scarce, and the single jaws and teeth are difficult to place zoologically. Characteristic were the triconodonts with three-cusped teeth and the Multituberculata with large flat teeth and several rows of cusps, probably herbivorous forms. Both groups differ from the therians by lacking the angular process of the lower jaw. The Multituberculata was the only successful group of the Allotheria, lingering on to the Eocene.

The Pantotheria, with three-cusped molars and with an angular jaw process, also occur in the Jurassic. This group may have been ancestral to both Metatheria (marsupials) and Eutheria (placentals), the latter appearing in the Cretaceous. Opposum-like marsupials were common

in South America and Australia during the Early Tertiary, at the time when these continents were separated from North America and Asia. The separation prevented the carnivores from entering, a situation that has lasted until the present time in Australia.

Among the Eutheria, or placentals, the less specialized Insectivora had a central position. The radiation of this and other placental groups evidently started in the Cretaceous (see INSECTIVORA; CHIROPTERA).

**Primates.** Like the mammalian reptiles, the Primates (*q.v.*) branched off early from the main stem of their class. Because the early Primates apparently were tree dwellers and lived in tropical regions, fossil material is rare. For climbing trees the hallux had become opposable. A bipedal gait was attained later when Primates became adapted to the life in open savannas. Characteristic of the Primates are the small, specialized extremities and teeth; the relatively large brain size; and stereoscopic sight (not present in the most primitive forms).

The Primates are divided into Prosimii, including lemurs; the Anthropoidea, comprising monkeys, apes and man; and Tarsioida. Early lemurs had a rather long snout and a lateral position of the eyes in the Eocene. Stereoscopic sight was introduced by Eocene tarsids, which may have been more closely related to the ancestors of higher Primates or Anthropoidea. This group appeared in the Oligocene or late Eocene. The monkeys (ceboids and cercopithecoids), characterized by a well-developed tail, are known from the Oligocene onward.

The Hominoidea, including apes and man, have a more strongly developed brain and a reduced tail. Certain remains from the Eocene of Egypt and Burma may represent generalized ancestors of apes. Among Miocene-Pliocene apes the *Proconsul*, possibly belonging to a common genus *Dryopithecus*, stood near the ancestors of both apes and men. This would mean that man and apes parted in their evolution some 30,000,000 years ago.

Characteristic of early man is the making of tools from stone. Such implements are known from the earliest Pleistocene. Human remains are very rare and scattered and the evolution of the group is difficult to ascertain. But four different stages, evidently not directly derived from each other, may be distinguished (see PRIMATES).

**Carnivores.** The carnivores (*q.v.*) are primarily characterized by their specialized cheek teeth called the carnassials. The dentition, however, was more unspecialized among the early representatives of the group. The Early Tertiary forms have generally been placed in a separate group, the Creodonta. Recent research indicates, however, that only two families (the Oxyaenidae and Hyenodontidae) of this archaic order are to be regarded as true carnivores; the rest are probably related to primitive ungulates. The carnivorous creodonts flourished during the Eocene, and a few (hyenodonts) lingered on to Late Tertiary time.

A marked radiation of the more advanced carnivores, those belonging to order Carnivora, took place in late

Lemurs,  
monkeys,  
apes, and  
man

Eocene and early Oligocene time. These forms developed chiefly from the insectivores through the Eocene Miacidae, small forms with carnassial teeth and relatively larger brain than the contemporaneous creodonts. Advanced carnivores comprise the mustellids and dogs appearing in the Oligocene, the bears in Miocene, the cat-like aeluroids in the Eocene, and true cats in the Oligocene. Highly specialized were the sabre-toothed cats with their enormous canines, a group that persisted into the Pleistocene. The aquatic pinnipeds, with uniform teeth, are known from the Miocene onward.

The highly specialized whales, Cetacea (see WHALE), represent a separate order, although the Early Tertiary forms, like the 17-metre (55-foot) long *Basilosaurus*, evidently were fish-eating carnivores.

**Hoofed mammals.** The ungulates, or hoofed mammals, comprise many different types of large, herbivorous, Cenozoic mammals. Adaptions are characteristic of these herbivores. The teeth, adapted for food grinding, become high crowned and long. In order to facilitate locomotion, the gait changed from plantigrade, in which the entire foot makes contact with the ground, to digitigrade, which involves lifting the foot so that only the tips of the digits (hoofs) touched the ground.

The living "Ungulata," a rather artificial group, chiefly comprise the Artiodactyla (*q.v.*), which are the even-toed ungulates; the Perissodactyla (*q.v.*), which are the odd-toed ungulates; and the "Subungulata," of which the Proboscidea is the more prominent group. Fossil materials have added a great number of extinct forms, which demonstrate the strong radiation of the group, particularly in the Early Tertiary; at the same time these materials complicate the classification that was based on the relatively few living forms.

The earliest ungulate representatives were rather unspecialized and might be considered to be stem groups from which the later forms evolved. Archaic ungulates with a small brain and little specialized dentition have been placed in a separate group, the "Protungulata," of which the Condylarthra form the central and most unspecialized group. *Phenacodus* from the Eocene is characteristic, but even more unspecialized are certain Paleocene forms (*Tetraclaenodon*), which might have been ancestral to at least several of the later and more advanced ungulates. Among the early off shoots of the ungulate stem might be mentioned the queer-looking, heavy-bodied amblypods (pantopods); *Uintatherium* attained the size of a present-day rhinoceros. These early forms did not survive the Eocene.

Fossil elephants

The Proboscidea (*q.v.*), including elephants and related forms, comprise another group that branched off from the primitive ungulates. The highly specialized trunk and teeth of living forms were indicated by the Eocene *Moeritherium*. Through the Tertiary it is possible to follow the gradual development of the second incisor into the great tusks and also the strong reduction in the number of premolars and molars. Some Miocene forms had tusks in both jaws (*Trilophodon*) or only the lower jaw (*Deinotherium*). The mastodons appeared in the Oligocene; the large forms in the Pleistocene had large tusks but still less specialized cheek teeth.

The imposing evolution of the order Perissodactyla, particularly in the Lower Tertiary, is well documented by fossil finds, chiefly from North America. It has been possible to demonstrate the evolution of horses from lower Eocene to Recent time. From *Hyracotherium* (or *Eohippus*), which was the size of a fox terrier with few specialized cheek teeth and four toes on the front legs, a number of equoids that generally mark a continuous trend toward *Equus*, the recent horse, developed successively. Evolutionary stages are marked by *Meshippus* (lower Oligocene), with three toes; *Parahippus* (Miocene), with more advanced teeth, indicating a change from forest-browsing to grass-feeding habits; and *Hipparion* (Pliocene), which was the size of a pony with one toe and rudiments of the lateral ones.

The spectacular tithanoteres, limited in time to the Eocene and Oligocene, developed from primitive horse-

Figure 13: Evolution of certain mammalian groups. The horses (Equidae) and the elephants (Proboscidea), as well as the Amblypoda and Titanotheriidae (which became extinct in the Lower Tertiary), developed from primitive forms like *Tetraclaenodon* in the earliest Tertiary.

From (hoofs, Titanotheriidae, Uintatherium) L. Stormer, *Jordens og livets historie*; and (others) A.S. Romer, *Vertebrate Paleontology* (©1966), The University of Chicago Press, all rights reserved

like forms. The late *Brontotherium* was a huge animal with hornlike processes in front of the skull.

Rhinoceroses were common during the Tertiary. Evidently derived from early tapirids, they developed parallel to the horses, showing, however, a much stronger radiation. The earliest (Eocene) forms were adapted for running, whereas the later ones became more bulky and large. Some had horns, which are composed of fused, hairlike material, not bone. The hornless *Baluchitherium* from the Oligocene of Mongolia is the largest land animal known; it attained a shoulder height of about 5.5 metres (18 feet).

The order Artiodactyla includes a great number of the larger living mammals. In the Eocene, the group developed rapidly; and, particularly in the later part of the Cenozoic, it became the dominating group, considerably more so than the perissodactyls, which had their acme of development in the earlier part of the Tertiary.

Characteristic of the group is the axis of the foot, which runs between the third and fourth toe instead of the middle (third) toes as in the perissodactyls. The double pulleyed astragalus bone is also diagnostic of the group. This type of bone has been found in certain early Eocene forms resembling primitive carnivores, a fact suggesting that the ancestors of the artiodactyls were primitive condylarths.

The artiodactyls may largely be divided into three major groups: the Suina, including pigs, peccaries, hippopotamuses, anthracotheres, and others; the Ruminantia (cud chewers), including most other forms, such as ca-

Artiodactyls

mels, deer, giraffes, and cattle, and many extinct forms; and finally, the Palaeodonta, comprising Early Tertiary forms. The suines generally have bunodont (low-cusped) teeth, whereas the ruminants have selenodont (more advanced grinding) teeth. The paleodonts had intermediate types of teeth.

Primitive suines appeared in the Eocene. The important anthracotheres flourished in the Middle Tertiary, some of them amphibious like the hippopotamuses, which probably are divided from anthracotheres.

Among the ruminants, the camels (and llamas) were common in the later part of the Tertiary. Early forms (traguloids) appeared in the Eocene, some of them (the palaeomerycids) related to the ancestors of giraffes and deer. Deer (cervids) appeared in the Pliocene; the Pleistocene "Irish elk" with its enormous antlers is quite famous. Among the successful ruminants were the bovids, which evidently developed from tragulids in the Oligocene and flourished in the latter part of the Cenozoic.

The order Edentata (*q.v.*), including the living tree sloths, armadillos, and anteaters, had a spectacular development in South America during the Cenozoic. Fossil finds have shown that they came from North America in the Early Tertiary, before it was separated from South America. The extinct glyptodonts, related to the living armadillos, had stout armour and looked like turtles. Other large forms were the ground sloths; *Megatherium*, a Pliocene form, was larger than an elephant (length six metres).

The order Rodentia (*q.v.*) includes the most common mammals of today. These small herbivorous and omnivorous forms, more than any other group, have been able to adapt themselves to present environments. They have a particular dentition that began with Paleocene forms. They probably were derived from insectivores in the Late Mesozoic. Mice date from the Oligocene. The hares and rabbits appeared in late Eocene and are now generally regarded as belonging to the separate order Lagomorpha.

#### THE PLANTS

The study of fossil plants, paleobotany, shows in a convincing way the gradual appearance of the various plant groups through geologic time. The general development of higher plants has been demonstrated, although the transition between several major groups is still unknown. The main types of plant fossils are (1) impressions and casts, which may show very distinctly the external morphology of the plant; (2) compressions, in which carbonaceous remains of the plant body are preserved and resistant parts like the cuticle may be present and show fine details; (3) petrifications of the plant body, which before decaying has been impregnated with silica (or other chemical substances), preserving the cell walls and other anatomical details.

**Bacteria and algae.** The oldest remains of what probably have been living organisms have been found in South Africa and Rhodesia, in Precambrian rocks estimated to be about 3,000,000,000 years old.

Bacteria-like structures have been recorded both in Precambrian and younger sediments; in certain cases they are present in plant and animal tissues. Common types such as coccoid, bacilloid, filamental, or spirillar forms have been recorded. Many species have been described from the Carboniferous, mostly classified in the genus *Micrococcus*. The physiological activity of fossil bacteria cannot be traced, but there are reasons to believe that iron and sulfur bacteria took part in the formation of such deposits.

Blue-green algae (Cyanophyceae) have been identified in Precambrian deposits. They are quite common in younger deposits. Laminated calcareous structures, stromatolites, are generally interpreted as deposited by blue-green algae. The shapes vary from simple domes to complicated columns.

Unicellular planktonic algae evidently played an important role in ancient seas. Except for the coccolithophorids, diatoms, and dinoflagellates, little is known of

these nanofossils, which have increasing stratigraphic importance. The Coccolithinae are flagellates with a complicated calcareous skeleton. First recorded from the Triassic (possibly also from the Early Paleozoic), they were very important in the Cretaceous when they were largely responsible for the formation of chalk deposits. In present seas they occur in great quantities. Diatoms occur in Jurassic and later systems. The dinoflagellates probably also include the little known hystrichospherids, which were common in the Early Paleozoic.

Lime-secreting green algae of the families Codiaceae and Dasycladaceae are known from the Ordovician to Recent times. The Dasycladaceae were particularly numerous in the Triassic-Jurassic, whereas today there are only a few genera and species in warm seas. Calcareous red algae (*Lithothamnion* and relatives) are widespread today and play an important role in coral reefs. They were common reef builders in the Tertiary and range from the Early Paleozoic.

The Fungi and Bryophyta are little known as fossils. Hyphae and spores of fungi occur in the Carboniferous. Among the bryophytes, members of the liverworts (Hepaticopsida) are known from the Devonian and mosses (Bryopsida) from the Permian.

**Development of land plants.** The evolution of land plants started at the end of the Silurian (*Cooksonia* from Bohemia). Four main stages may be distinguished in the development of the land plants: (1) the "psilophyte flora" of the Lower and Middle Devonian, (2) the Upper Devonian-Lower Permian "Carboniferous flora," (3) the Mesozoic "gymnosperm flora," and (4) the Upper Cretaceous-Recent "angiosperm flora."

At the close of the Silurian, members of the class Psilopsida (*q.v.*) appeared in the nonmarine sediments. The group includes primitive plants lacking roots and true leaves. The aerial stems were dichotomous (or pseudomonopodial), naked, or with thorns, covered by a cuticle and provided with simple stomata and an internal strand with tracheids. The isosporous sporangia were either terminal on the shoots (Rhyniaceae) or attached by short side branches to the smooth portions of the main stems (Zosterophyllaceae). The plants, which may have grown to a height of about 0.5 metre, inhabited the coastal swamps. A few species like *Taeniocrada* (Lower Devonian, Germany) were possibly aquatic. The famous Rhynie Chert of Scotland, which has yielded excellently preserved specimens of *Rhynia*, *Horneophyton*, and *Asteroxylon*, was previously regarded as Middle Devonian but is now assumed to be Lower Devonian (Emsian). In *Asteroxylon* the aerial stem was densely covered by small leaves, about five millimetres long, and had a lobed protostele. The genus shows affinities to the lycopsids (*q.v.*).

*Baragwanathia* from the Lower Devonian of Australia represents the oldest known member of the lycopsids. The dichotomous shoots up to 28 centimetres long have threadlike leaves, at the base of which are placed the sporangia. *Drepanophycus* and *Protolepidodendron* resemble the recent club moss *Lycopodium*.

The sphenopsids (*q.v.*) have been cited as present in Lower and Middle Devonian. The Middle Devonian *Hyenia* and the somewhat older *Protohyenia*, formerly regarded as primitive sphenopsids, are no longer so considered.

The pteropsids, or ferns (*q.v.*), probably had precursors in the Lower and Middle Devonian. *Dawsonites* and *Trimerophyton*, generally grouped with psilopsids, had structures in common with later ferns. The Upper Devonian *Archaeopteris* was long regarded as a kind of fern; however, the organization of the large leaves has been shown to differ from that of true ferns. Leaves were borne on stems with wood resembling that of conifers (*Callixylon*). At least some species were heterosporous. *Archaeopteris* is therefore now referred to a separate class, Progymnospermopsida, which points forward to the gymnosperms.

The Devonian floras thus contain the main pteridophyte, or seed-bearing, groups, and with the exception of the sphenopsids, all made their first appearance in the early

The Carboniferous flora: *Lepidodendron*, *Sigillaria*, *Calamites*, and the ferns

part of that period. The psilopsids were decidedly the most primitive and were probably similar to the starting members of the other groups. Beyond that, little is known of the phylogeny of the various classes. In the Middle Devonian arborescent types formed the first forests.

The Carboniferous floras were dominated by the Pteridophyta, particularly the lycopsids, sphenopsids, and the pteropsids. Gymnosperms (*q.v.*), particularly conifer-like members, were an important part of the flora. Most of the coals (*q.v.*) of the Carboniferous formed from the giant *Lepidodendron* and *Sigillaria* trees, which inhabited widely distributed coastal (paralic) swamps, of a type similar to the Everglades of Florida and the mangrove swamps bordering tropical seas. *Lepidodendron* reached a height of up to 30 metres with a maximum stem diameter of one metre. The stems had an underground part with rootlike appendages (*Stigmaria*), and at the top of the long stem, a crown formed by dichotomous branching. The narrow leaves present only in the upper part of the tree were of variable length. The stem had characteristic diamond-shaped, spirally arranged scars, which actually were cushions where the leaves were attached. Conelike strobili from a few centimetres to  $\frac{3}{4}$  metre in length contained a very large number of macrospores and microspores. *Sigillaria* resembled *Lepidodendron* but had a more pillar-shaped stem with a crown of grasslike leaves and leaf bases in vertical rows. After the Permian, the lycopsids became less important. Arborescent types apparently did not survive the Paleozoic.

The sphenopsids had characteristic articulated stems and leaf whorls and were also important members of the Carboniferous flora. The Upper Devonian and Lower Carboniferous *Asterocalamitaceae* had woody stems, and large *Calamites* attained heights of 15-20 metres, even up to 30 metres. Like the giant lycopsids, the sphenopsids practically vanished at the end of the Paleozoic.

Ferns (*q.v.*) and fernlike plants were very common in the Carboniferous and were well represented in later periods. Members of this group had true roots, stems, and leaves, the latter showing a great variation in the development of the fronds and pinnae. Unfortunately, most fossil imprints of leaves do not show the sporangia, which are necessary for taxonomic determinations. Most fernlike leaves have proved to belong to a separate group of seed ferns (Pteridospermae) of the division called gymnosperms (*q.v.*). Carboniferous true ferns belong to different orders continuing into later periods.

The seed ferns differ fundamentally from the true ferns. The fossil material does not show any distinct connection between the vascular cryptogams and the gymnosperms (the seedlike structures in *Lepidocarpon* do not form a bridge). The seed ferns, ranging from the Lower Carboniferous to the Jurassic, generally had large fernlike leaves. The seeds were enclosed in cupulas, which were attached to leaves or to modified leaf structures. The microsporangia were in sori on the lower sides of leaves or in differently arranged synangia. *Glossopteris* and *Gangamopteris*, so characteristic of the Upper Carboniferous-Permian Gondwanaland of the Southern Hemisphere, probably belong to the pteridosperms. They had tongue-shaped, elongate leaves and reproductive organs that have been variously interpreted by paleobotanists.

**Conifers and the occurrence of forests.** The conifers may be traced back with some certainty to the Devonian. From Carboniferous time onward they form a major part of the forests. The late Paleozoic *Cordaites* were large trees, up to 30 metres in height, with a slender stem and strongly branched crown with long (up to one metre), strap-shaped leaves. Typical conifers such as *Lebachia* (*Walchia*), occurring in the Upper Carboniferous and Lower Permian, have a habitual resemblance to the extant *Araucaria* (Norfolk pine). The ovule-bearing cones show similarities to *Cordaites*. The living *Araucariaceae*, *Taxodiaceae*, and *Pinaceae* date back to the Triassic, Jurassic, and Cretaceous, respectively. The taxodian genera *Sequoia* and *Metasequoia* had a wide distribution in Cretaceous and Tertiary times. *Sequoia* now is restricted to North America. *Metasequoia*, thought to be extinct until a species was discovered in China, has been revived in the United States as an ornamental nursery stock. The order Ginkgoales, with the extant *Ginkgo* (maiden hair tree), represents a relict order of gymnospermous plants. Their distinctive fanlike leaves are significant fossils in Mesozoic and Tertiary floras.

Most characteristic of the Mesozoic floras were the cycads, represented today by small palmlike, subtropical ornamentals. True cycads are known from Early Triassic time, and morphological characters of these early representatives indicate that they developed from seed ferns. The erect, sometimes branched stems were covered by leaf scars and bore a terminal crown of large leaves either pennate or entire (like banana leaves). The foliage had two distinct types of stomatal apparatus. This character and the structure of the reproductive organs divide

The Mesozoic flora: cycads

the cycads into two distinct orders, the extant Cycadales and the Benettiales (Cycadeoidales), which became extinct in the Early Cretaceous. Both orders appeared in the Early Triassic and had their acme in the Jurassic. In certain bennettites, the reproductive organs form conspicuous "flowers" that, however, are not related to the true flowers of the angiosperms.

The angiosperms (*q.v.*) had an explosive development in the middle of the Cretaceous and from then on completely dominated the land flora. Angiosperms are not known with complete certainty from the Lower Cretaceous or older strata. The Late Cretaceous angiosperms are extant groups such as magnolias, platans, and palms. In spite of the considerable fossil material present, the fossil record has not been able to provide an answer to the problem of the origin of the angiosperms.

### III. Summary of the geological range of fossil groups through time

The fossil record has served to demonstrate the history of most major groups of animals and plants. It also has been able to throw some light on the mutual relationships and trends of evolution of fossil and recent forms.

The geological ranges of the several groups have been previously treated. When illustrating the geological range and abundance of major groups it should be borne in mind that each group actually is composed of a number of separate groups, each of which has a separate development, abundance, and range. The composite curves thus do not show the actual evolutionary trends within the major groups, and the abundance of taxa in fossil groups at different times is influenced to a large extent by the variation in the completeness of the record. Fossiliferous sediments may be less common in certain periods and more common in others, for example, and abundance does not necessarily illustrate the importance of a group. The recent fauna *Homo sapiens*, for example, is hardly negligible, but this single taxon would not show up in the curve.

**Development of a group.** The development of a group may follow different patterns. In any of the curves an "onion-shaped" outline is common; this indicates a rapid increase in taxa shortly after the first appearance of the group. After the maximum is reached, a slow decline and a possible extinction follow. The trilobites, amphibians, and reptiles belong more or less to this group. In other cases, such as the mammals, the first step in the development of the group is insignificant and modest.

In cases of rapid unfolding, this may be due to the origin of a new successful type (a favourable plan of construction) or the conquest of a new, unoccupied biological niche. In cases of slow development, the new group may have had to compete for a considerable time with powerful existing groups before conditions for full development were present (in the case of the mammals, the reason may also have been that the successful placentals did not arrive until just before the great radiation of the mammals).

The first appearance of a group in the fossil record virtually means the first appearance of members that were capable of being preserved in the sediments. Little is known of Precambrian many-celled animals and plants; however, the metazoans may not have developed very long before Cambrian time. The very long delay may chiefly be due to the slow increase in atmospheric oxygen, which was necessary for active metazoans.

The apparently sudden appearance of shell-bearing metazoans just before, and at the beginning of, the Cambrian has been a problem to geologists for a long time. The find of the ediacaran fauna, however, and more details of the Early Cambrian faunas have shown that the appearance of the metazoans in the record was not as sudden as previously believed.

The various groups appeared at different times during the 30,000,000-year interval representing the Lower Cambrian. The first to appear were the enigmatic archaeocyatids, with their fragile calcareous shell. The trilobites and other groups came a little later (but were then already

well established, indicating some antecedent development).

The appearance of forms with rather well-developed chitinous and calcareous skeletons at the beginning of the Cambrian marks the beginning of a more comprehensive fossil record. The formation of calcareous skeletons evidently was dependent on the amount of  $\text{CaCO}_3$  and  $\text{CO}_2$  in the water. The skeleton served both as a place of attachment for muscles and for protection against enemies and possibly against radiation.

Because several of the major invertebrate groups were already well established in the Cambrian, the early history of these forms is not known. Well-established groups also appear without forerunners in later periods. It may be mentioned that in the Early Devonian most of the Pteridophyta and fishes appear abruptly; the same is true of the appearance of the angiosperms in the Cretaceous. More common, however, is the gradual transition from one group to another, as is demonstrated in the record by the transition from fishes to amphibia, to reptiles, and to mammals.

**Problem of extinction.** The extinction of fossil groups has been the subject of much discussion. When considering this problem, however, the incompleteness of the fossil record must be remembered. The discovery of the living coelacanth *Latimeria* and the monoplacophoran *Neopilina* confirms this. It cannot be denied, however, that the record indicates the occurrence of fairly sudden extinctions of certain groups at certain times. The rate of extinction may have been greater at certain times, at the end of the Permian and at the end of the Cretaceous, for example, but the difference appears to be quantitative rather than qualitative. A more drastic example of extinction is provided by the dinosaurs. All the major groups except the primitive palaeopods and the stegosaurs became extinct, more or less simultaneously, at the end of the Cretaceous. Only two of the many ammonites survived the Paleozoic, and after a radiation in the Triassic, a new extinction took place, with only one family surviving into the Jurassic. The final extinction occurred at the end of the Cretaceous. This last extinction is, however, foreshadowed by a gradual decrease in the number of families through the Upper Cretaceous (from 22 to 11). Within certain of the dying families, an increase in size and the presence of bizarre-looking forms may be noted. This is a common accompaniment of extinctions of many groups.

The causes of extinction have been much discussed, but no single cause has been suggested that can truly explain this phenomena. Factors that influence extinctions include the following: (1) extraterrestrial, (2) geological-climatic, and (3) biological. Extinctions related to increased radiation are not well supported by the facts. Although most of the ammonite families died out at certain times, for example, the related nautiloids were little affected at the same times. A certain increase of mutations might create new competing forms, but this seems to have been of minor importance. It is possible that surface plankton to some extent might have been influenced by radiation.

Among geological factors, orogenic movements can result in major changes in the environments. The drying up of rivers and swamps might have been fatal to amphibious dinosaurs and also to the carnivorous dinosaurs that fed on them; however, such changes could have less influence on marine faunas unless accompanied by a large regression of the sea, which would alter the shallow marine environments.

Climatic changes evidently affected the land plants and animals, although migration might have saved most groups from extinction. A glacial climate could have favoured extinction in two ways. The decrease in temperature might have been too much for some groups. Glaciation also involves accumulation of ice on land and a corresponding lowering of the sea level. A general drying up of epicontinental seas and continental shelves would have had strong influence on the benthonic, shallow water faunas in particular.

Significance of first appearance

Geological and climatic factors

Possible biological causes include the strong competition for existing biological niches. This "struggle for life" might result in extinction. A "racial senescence" has also been advocated as a reason for extinction. Although such a cause is difficult to prove, racial senescence might have been present in certain groups, such as the trilobites and eurypterids.

Thus the causes of extinction remain unclear, but several factors probably were acting at the same time.

## Fourier, Jean-Baptiste-Joseph, Baron

The French mathematician Joseph Fourier, known also as an Egyptologist and administrator, exerted strong influence on mathematical physics through his pioneer work, *Théorie analytique de la chaleur* (1822; Eng. trans., *The Analytical Theory of Heat*, 1878). He showed how the conduction of heat in solid bodies may be analyzed in terms of infinite mathematical series now called by his name, the Fourier series. Far transcending the particular subject of heat conduction, his work stimulated research in mathematical physics, which has since been often identified with the solution of boundary-value problems, encompassing many natural occurrences such as sunspots, tides, and the weather.

His work had a great influence on the theory of functions of a real variable, one of the main branches of modern mathematics. Moreover, he contributed substantially to the compilation and publication of the influential *Description de l'Égypte* (1808-25), summarizing in 21 volumes the cultural and scientific results of Napoleon's invasion of Egypt. The work drew attention to the ancient Egyptian civilization and marked Egyptology as a new and separate discipline.

Joseph Fourier, lithograph by Jules Boilly, 1823.  
In the Académie des Sciences, Paris.  
Giraudon

Fourier, born March 21, 1768, in Auxerre, the son of a tailor, first attended the local military school conducted by Benedictine monks. He showed such proficiency in mathematics in his early years that he later became a teacher in mathematics at the same school. The ideals of the French Revolution then swept him into politics, and more than once his life was in danger. When the École Normale was founded in 1794 in Paris, he was among its

first students, and, in 1795, he became a teacher there. The same year, after the École Polytechnique was opened, he joined its faculty and became a colleague of Gaspard Monge and other mathematicians.

In 1798, with Monge and others, Fourier accompanied Napoleon on his expedition to Egypt. Until 1801 he engaged in extensive research on Egyptian antiquities, gave advice on engineering and diplomatic undertakings, and served for three years as the secretary of the Institut d'Égypte, which Napoleon established in Cairo in 1798.

After his return to France, Fourier was charged with the publication of the enormous mass of Egyptian materials. This became the *Description de l'Égypte*, to which he also wrote a lengthy historical preface on the ancient civilization of Egypt. He was also appointed prefect (administrator for the national government and *département*) of the Isère *département*, a position he held from 1802 to 1814, with his headquarters at Grenoble. He showed great administrative ability, as in directing the drainage of swamps, while continuing his Egyptological and mathematical work. In 1809 Napoleon made him a baron. Following Napoleon's fall from power in 1815, Fourier was appointed director of the Statistical Bureau of the Seine, allowing him a period of quiet academic life in Paris. In 1817 he was elected to the Académie des Sciences, of which, in 1822, he became perpetual secretary. Because of his work in Egyptology he was elected in 1826 to the Académie Française and the Académie de Médecine.

Fourier began his work on the *Théorie analytique de la chaleur* in Grenoble in 1807 and completed it in Paris in 1822. His work enabled him to express the conduction of heat in two-dimensional objects (*i.e.*, very thin sheets of material) in terms of the differential equation

$$\frac{\partial u}{\partial t} = k \left[ \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right],$$

in which  $u$  is the temperature at any time  $t$  at a point  $(x, y)$  of the plane and  $k$  is a constant of proportionality called the diffusivity of the material. The problem is to find the temperature, for example, in a conducting plate, if at time  $t = 0$ , the temperature is given at the boundary and at the points of the plane. For the solution of such problems in one dimension, Fourier introduced series with sines and cosines as terms:

$$y = \frac{1}{2}a_0 + (a_1 \cos x + b_1 \sin x) + (a_2 \cos 2x + b_2 \sin 2x) + \dots$$

Such Fourier series, already occasionally used by Leonhard Euler and other 18th-century mathematicians, but somewhat distrusted, received through Fourier their important position in modern mathematics. He also extended this concept into the so-called Fourier integral. Doubts of the validity of the Fourier series, which led later mathematicians to a fundamental renewal of the concept of real function, were resolved by P.G.L. Dirichlet, Bernhard Riemann, Henri Lebesgue, and others.

Fourier worked on the theory almost his entire life. He was also interested in the determination of roots of algebraic equations (the so-called theorem of Fourier). He died in Paris on May 16, 1830.

Theory of heat

## Fox, Charles James

In late 18th-century British politics, Charles James Fox was a famous champion of liberty, a colossus whose career, on the face of it, was nevertheless one of almost unrelieved failure. He conducted against King George III a long and brilliant vendetta, sometimes wrongheaded but constitutionally significant; for this reason he was almost always in political opposition and, in fact, held high office for less than a year altogether. His leadership of the parliamentary opposition was marked by incredible blunders. He achieved only two important reforms, steering through Parliament a resolution pledging it to abolish the slave trade speedily, and, in the 1792 Libel Act, restoring to juries their right to decide not merely whether an allegedly libellous article had, in fact, been published but also what constituted libel in any given case and whether or not a defendant was guilty of it.

Charles James Fox, detail of an oil painting attributed to John Zoffany (c. 1734–1810). In the Henry E. Huntington Library and Art Gallery, San Marino, California.

**Early life.** Fox was born in London on January 24, 1749, the third son of Henry Fox, afterward 1st Baron Holland, by his wife, Lady Caroline Lennox, daughter of the 2nd duke of Richmond. Through his mother he was descended from Charles II of England and Henry IV of France. He was educated at Eton and at Hertford College, Oxford, where he acquired an extensive knowledge of the classics, to which he remained devoted for the rest of his life. His father brought him up without the least regard for morality and encouraged him, while still a schoolboy, to acquire extravagant and dissolute habits. He lost vast sums at gambling, and in 1774 his father, just before his death, paid the young man's gambling debts to the amount of £140,000. Almost 20 years later political friends not only freed him from debt but settled on him a comfortable income. He then showed his gratitude by abandoning forever both racing and gambling.

**Entry into politics.** Fox was procured a seat in Parliament by his father in 1768. Two years later he was appointed a junior lord of the Admiralty but gave up his office in February 1772 in order that he might be free to oppose a bill (eventually the Royal Marriage Act) designed to prevent marriages of members of the royal family unless authorized by the king or ratified by the Privy Council. He re-entered the government the following December as a junior lord of the Treasury, but the King, who already disliked him for his recent opposition,

accused him of insubordination and dismissed him in February 1774.

Already a friend of Edmund Burke, he naturally gravitated into the Whig group and before long was their accepted leader in the Commons. He went into opposition just when the controversy with the American colonies was becoming acute. Believing that the colonial policy of the prime minister Lord North was unjust and oppressive, he opposed it with unrestrained violence, but he later admitted that the American war was popular in England. The series of disasters sustained by the British troops in America, culminating in the capitulation of the army led by Lord Cornwallis at Yorktown (October 1781), eventually brought down North's government (March 1782). The King had to call in a Whig ministry, of which Lord Rockingham became prime minister, and Lord Shelburne (later marquess of Lansdowne) colonial secretary; Fox became the first foreign secretary in English history.

First  
foreign  
secretary

Fox believed, erroneously, that the negotiations for peace with the Americans came within the province of the foreign secretary, and he wished to recognize the independence of the former colonies immediately and unconditionally. Shelburne wanted to withhold this recognition until the peace treaties with the European countries with which Britain had also been at war were ready for signature; and he maintained that since the independence of America had not yet been formally recognized, he, as colonial secretary, had the right to conduct the negotiations. Fox, therefore, notified his intention to resign (June 30), but before he could implement it, Rockingham died (July 1).

When the King offered the premiership to Shelburne, Fox and his friends maintained that it was for them, not for the King, to choose Rockingham's successor. This was unconstitutional; the King had the undoubted right to choose the minister. Fox and some of his friends at once resigned, but others remained to support Shelburne. The historian Sir George Otto Trevelyan described Fox's refusal to serve under Shelburne as the fatal and irreparable mistake of his life. Though his suspicions of Shelburne were far from groundless, they were exaggerated; moreover, Shelburne was in some respects the most enlightened statesman of his time.

**The Fox-North coalition (1783).** Fox always had a liking for coalitions; on February 14, 1783, he joined with his old enemy North to eject the new government and accomplished his object ten days later. Defending an action that was undoubtedly unpopular and damaging to his reputation, Fox maintained that it was wise and candid to end the hostility between North and himself now that its sole cause, the American war, was over.

After trying desperately for five weeks to withstand "the most unprincipled coalition the annals of this or any other nation can equal," the King had to grant it office (April 2). The Duke of Portland, a nonentity, became the nominal prime minister; Fox and North, the two secretaries of state. Although the King withheld from the ministers various customary marks of royal confidence, they had no difficulty in retaining the vote of the independent country gentlemen in the House of Commons. The new ministers did not improve their position at court by proposing to give the Prince of Wales (later George IV) an income of £100,000 a year. By remaining the intimate friend of this dissolute young man, who was detested by his father and who ostentatiously supported the coalition, Fox further outraged the King's feelings.

Increasing  
unpopu-  
larity

The coalition fell because of its India bill. Fox and North had no wish to evade their responsibility for ending a system of misgovernment in India that had alarmed and disquieted English statesmen of all parties. Their bill proposed to change the whole constitution of the East India Company, which effectively controlled British India, by transferring control of the company's territories, revenues, and commerce to seven commissioners who were to be nominated by the British government and removable only upon a vote of either house of Parliament. But vested interests took alarm, and the House

of Lords rejected the bill on December 17 after the King had made it known that he would consider as an enemy anyone who voted for it. The coalition was dismissed next day, and the young politician William Pitt (the Younger) accepted an invitation to form a government.

Fox increased his unpopularity by attacking the sovereign's right to choose his ministers and to appeal to the electorate to confirm his choice. Fox's opponents could now plausibly maintain that he would not even submit his case to the judgment of the nation. Many of the coalition's supporters changed sides, and the dissolution of Parliament (March 1784) completed the discomfiture of the opposition, which found itself with only about 145 members in the new House of Commons. Fox himself, however, was re-elected for the great popular constituency of Westminster, defeating the ministerial candidate.

**Opposition to Pitt and Addington.** Had he been even a little accommodating, Fox could have joined William Pitt's government on honourable terms in 1784, to the great advantage of the cause of reform. But his attacks on Pitt's proposed commercial concessions to Ireland in 1785 and on a commercial treaty made with France in 1787 damaged his reputation. He blundered again in 1788–89, when the King was temporarily insane, by supporting the claim of the Prince of Wales to the regency as a right—whereas Pitt maintained that Parliament alone had the right and competence to appoint a regent. Party interests, of course, were deeply involved in the constitutional dispute; the Prince's first act of power would have been to dismiss Pitt and bring in the Whigs.

Regency  
crisis

Fox welcomed the outbreak of the French Revolution in 1789. War with Revolutionary France broke out in 1793, and a large part of the opposition, headed by Portland, went over to the government in 1794. The minority (50–60) adhering to Fox became one of the weakest oppositions ever known in England, and in about 1797 many opposition members even ceased to attend Parliament. Fox was dismissed from the Privy Council in 1798 for reaffirming in a public speech the doctrine of the sovereignty of the people; yet eight years later the King had to reinstate him without exacting any retraction of principle.

In 1795 Fox had secretly married Mrs. Elizabeth Armitstead, with whom he had been living for many years and to whom he always remained devoted; the marriage was revealed only in 1802. In their country house, St. Anne's Hill, near Chertsey in Surrey, he indulged his tastes for classical literature and a rural existence and found there ample compensation for all the disappointments and stresses of public life. Mrs. Fox, who bore him no children, died on July 8, 1842.

Fox approved of the peace negotiations that resulted in the treaty signed at Amiens (1802) but spoke of the "shameful surrender of all our conquests" to Napoleon. He was critical of the ministry (1801–04) of Henry Addington (afterward Viscount Sidmouth) for its failure either to preserve the peace or to put the country into an adequate state of defense to meet Napoleon's invasion threat, which followed the renewal of war in 1803. Though his motion, virtually one of censure (April 23, 1804), was defeated by 256 votes to 204, Addington's government resigned a few days later.

Pitt now wished to form a coalition government on a broad base but failed to persuade George III to waive his objections to Fox as a minister (he would have been foreign secretary), though the King was prepared to give him a foreign mission. Fox, with his usual generosity, acquiesced in this proscription, said that he was too old (at 55) to care about office, and advised his friends to join the coalition; but both they and the followers of Lord Grenville (with whom they had recently collaborated) rejected the suggestion and went into opposition.

**Last years.** When Grenville became prime minister after Pitt's death on January 23, 1806, the King's veto on Fox's appointment to office as foreign secretary disappeared without protest. During the earlier phase of the war against France, Fox had believed that the various European despots were fighting to destroy the newly won liberties of the French, and he had underestimated the

bellicose spirit of France and the danger to England of French conquests. But by 1806 he had come to realize that France, under Napoleon, threatened the independence of Great Britain and the whole Continent.

By this time Fox's health was breaking down. Suggestions were made that he should take some less laborious office, or even that he should take a peerage to save him from the more exacting task of leading the House of Commons. Fox made his last speech in Parliament on June 19, and he died on September 13, 1806, in the Duke of Devonshire's house at Chiswick. He was buried in Westminster Abbey by the side of Pitt.

**Assessment.** Fox had a genius for friendship, and the secret of his political influence was the uncalculating generosity of his mind. His charm could overcome the hostility of even the most inveterate of his foes. As a statesman he had great and manifest failings. He was often governed by prejudice, and he was not a profound political thinker. Above all, he hated anything that savoured of oppression, and his attitude on various colonial issues showed his passionate determination that the peoples of the empire were no longer to be exploited. His approval of the French Revolution shattered his friendship with the statesman and political writer Edmund Burke; although privately Fox showed himself far from insensible to the horrors perpetrated by the French Republicans, he gave these feelings no adequate public expression and opposed the war with republican France as a crusade against freedom in the interests of despotism. At home the excessive power of the crown was, in his view, the great source of all the country's ills, and to the destruction of that overweening power he dedicated his life. He put forward the view, afterward accepted, that the crown must choose the prime minister from the party that commanded a majority in the House of Commons, irrespective of the sovereign's personal inclinations. Yet he was no democrat, despising public opinion if he considered it prejudiced and intolerant. He would never have countenanced the notion that property, the security of which was one of the prime preoccupations of both Whig and Tory parties, would be safe in a democratic society in which the propertyless voters would obviously be in a majority. In his view property was the true foundation of aristocracy, and a country best prospered whose government was in such hands.

Hatred of  
oppression

Fox had a strong European sense and a deep feeling for the responsibilities of his own country as a member of a greater society with mutual obligations. It was because he held these large and generous views that his influence endured after his death, inspiring such measures as the Parliamentary Reform Act of 1832.

**BIBLIOGRAPHY.** For the general reader the best modern survey of the period covered by Fox's political career is JOHN STEVEN WATSON, *The Reign of George III, 1760–1815* (1960). IAN CHRISTIE, *The End of North's Ministry, 1780–82* (1958), is most useful, as also are RICHARD PARES, *King George III and the Politicians* (1953); and D.G. BARNES, *George III and William Pitt, 1783–1806* (1939, reprinted 1965). Older books that can still be read with profit are SIR GEORGE OTTO TREVELYAN, *The Early History of Charles James Fox*, new ed. (1908); and his *American Revolution*, new ed., 6 vol. (1905–16, reprinted 1964); LLOYD SANDERS, *The Holland House Circle* (1908); and G.S.H. FOX-STRANGWAYS, *The Home of the Hollands, 1605–1820* (1937). *The Memoirs of the Whig Party During My Time*, by Fox's nephew LORD HOLLAND, 2 vol. (1852–54), was almost a contemporary record. Students who wish to consult the manuscript sources for Fox's career should turn first to the *Memorials and Correspondence of Charles James Fox*, ed. (though not very accurately) by LORD JOHN RUSSELL, 2 vol. (1853). The new edition, by various editors, of Burke's correspondence, of which vol. 1 appeared in 1958, is in progress. A great deal of new correspondence and material bearing on Fox's career is in *The Later Correspondence of George III*, 5 vol. (1962–70), and *The Correspondence of George, Prince of Wales, 1770–1812*, 8 vol. (1963–71), both series edited by ARTHUR ASPINALL.

(A.As.)

## Fox, George

George Fox, the founder of the Society of Friends, also known as the Quakers, initiated a movement that has

Early life  
and  
activities

exerted a significant influence in the area of religious and political toleration for nearly 300 years.

He was born in July, 1624, the son of a weaver in the English village of Fenny Drayton (then Drayton-in-the-Clay), Leicestershire. Probably apprenticed for a while to a cobbler, he may also have tended sheep, but there is little evidence of any adult business occupation or of much formal education. He always seemed to have a modest amount of money. He read extensively and wrote legibly. At the age of 18 he left home in search of satisfying religious counsel or experience and later reported in his *Journal* various personal religious experiences or direct revelations, which he called "openings," that corrected, in his estimation, the traditional concepts of faith and practice in English religious life.

His religious background was apparently Puritan rather than strict Anglican, but he himself reacted even further than the Puritans from the formalism and traditionalism of the established church. He placed the God-given inward light (inspiration) above creeds and scripture and regarded personal experience as the true source of authority. In his *Journal* he wrote,

These things I did not see by the help of man, nor by the letter, though they are written in the letter, but I saw them in the light of the Lord Jesus Christ, and by his immediate Spirit and powers, as did the holy men of God, by whom the Holy Scriptures were written.

His negative attitude to ecclesiastical customs was matched by a similar attitude toward some political and economic conventions (e.g., oaths, titles, and military service).

He began preaching to individuals or groups as he travelled on foot, first in the Midland counties of England, then in the northern counties, where groups of Seekers (a 17th-century Puritan sect) welcomed him and his message. Local congregations were established, gathered both by Fox and by many other itinerant men and women preachers, who were called Publishers of Truth. Thus came into being in the last years of the British Commonwealth (1649–60) the Society of Friends, as it was much later called, though its members were early nicknamed "Quakers."

Fox had most success in winning adherents and fellow workers in the Lake District counties of Westmorland and Lancashire and later in Yorkshire, London, and other areas. He and his associates suffered public hostility and official constraint. They offended religious leaders both religiously and politically by their contradiction of the ministers in the churches (based on Fox's view that ministers "bred at Oxford or Cambridge" were not qualified to be spiritual leaders in the churches) and by their refusal to honour officials, to take oaths, or to pay tithes. Fox and his associates were often arrested and imprisoned. Fox, in fact, suffered eight imprisonments between 1649 and 1673.

The restoration of the monarchy in 1660 led to special legislation against the Quakers and a widespread action against them. To meet this and other needs, George Fox encouraged local Quaker groups to organize into regular monthly and quarterly business meetings, which, with some central national meetings, became a permanent pattern of their church government. The continuing pressure was only intermittently relieved until the Toleration Act of 1689, shortly before Fox's death, gave relief to the Quakers.

Missionary  
work in  
England  
and other  
countries

In 1669 Fox made a missionary visit to Ireland, and on his return he married one of his early converts, Margaret Fell, the widow of Judge Thomas Fell of Swarthmore Hall, Ulverston, Lancashire, where Fox spent parts of the following years. In the years 1671 to 1673 he paid an important visit to the British colonies in the Caribbean and the North American mainland, strengthening and organizing the existing Quaker communities, especially in Maryland and Rhode Island. Shorter journeys in 1677 and 1684 took him to Holland (The Netherlands) and a few other parts of northern Europe. About 1675 he dictated a running summary of his life that, with supplementary material, was posthumously edited and published as his *Journal*. For most of the last 15 years of his

life he lived as a boarder or visitor among friends in or about London, attending consultations and committees on practical questions, preaching at meetings for worship, and engaging in a wide correspondence with individual Friends or with congregations to whom he was known.

Throughout his life, Fox shared the contemporary practice of writing controversial pamphlets, scores of which were published. They dealt with social as well as theological questions but lacked stylistic attraction. Although he was quite familiar with the English Bible, he sometimes displayed a taste for subjects like history and grammar, in which he had little competence. He borrowed information occasionally from his learned friends.

He evidently was, as Thomas Carlyle (1795–1881) says, a man of enormous self-confidence, one who attracted rather than repelled. A magnetic personality, he was widely respected and admired by such men as William Penn, a man of culture and knowledge of the world, who left in writing an appreciation of Fox that is still the best summary of his character. His own *Journal* is naturally not entirely objective, but with its many details it forms the fullest account of the rise of Quakerism, as well as of Fox himself. It is partly due to Fox's own sense of the historic importance of the Quaker movement that much other early written material was recorded and preserved. He died January 13, 1691, in London and was buried in the Friends' burial ground near Bunhill Fields.

**BIBLIOGRAPHY.** *The Journal . . . of George Fox*, ed. by THOMAS ELLWOOD, with an illuminating and comprehensive introduction by WILLIAM PENN (1694), is the fundamental source. The most useful edition of the *Journal* is that ed. by JOHN L. NICKALLS (1952). It reduces the bulk of the many inserted papers and uses the manuscripts behind Ellwood's editing. Two other folio collections of his writings were issued after his death, *The Epistles of George Fox* (1698), and his doctrinal writings, *Gospel-Truth Demonstrated* (1706). All these were included in the *Works of George Fox*, 8 vol. (1831).

Modern biographies, useful because they include references to the historical setting, are VERNON NOBLE, *The Man in Leather Breeches* (1953), and HARRY EMERSON WILDES, *The Voice of the Lord* (1965). See also RUFUS M. JONES, *George Fox, Seeker and Friend* (1930), and A.N. BRAYSHAW, *The Personality of George Fox* (1933).

(H.J.C.)

## Fragonard, Jean-Honoré

Jean-Honoré Fragonard has been bracketed with Watteau as one of the two great poetic painters of the unpoetical 18th century in France. A prodigiously active artist, he produced over 550 paintings, several thousand drawings (although many hundreds are known to be lost), and 35 etchings. His style, based primarily on that of Rubens, was rapid, vigorous, and fluent, never tight or fussy like that of so many of his contemporaries. Although the greater part of his active life was passed during the Neoclassical period, he continued to paint in a Rococo idiom until shortly before the French Revolution. Only five paintings by Fragonard are dated, but the chronology of the rest can be fairly accurately established from engravings, documents, etc.

Fragonard was born at Grasse on April 5, 1732, the son of a haberdasher's assistant. The family moved to Paris around 1738, and in 1747 the boy was apprenticed to a lawyer, who, noticing his appetite for drawing, suggested that he be taught painting. Fragonard's mother first approached François Boucher, the most successful contemporary French painter, who refused to take an untrained youth into his studio but recommended him to Jean-Baptiste-Siméon Chardin, under whom he was soundly grounded in the technique of painting. Boucher thereupon accepted him as a pupil (c. 1748) and, in 1752, his elementary training completed, recommended that he compete for a Prix de Rome scholarship, which meant that he must first study for five years under the court painter to Louis XV, Carle Van Loo, at the École Royale des Élèves Protégés in Paris. On September 17, 1756, Fragonard set off with other scholarship winners for the French Academy at Rome, but not before enjoying suffi-

cient success to receive a handsome commission from his native town for a religious painting and a municipal grant toward his travelling expenses.

At the academy, Fragonard copied many paintings, chiefly by Roman Baroque artists, and, with his friend the French painter Hubert Robert, made numerous sketches of the Roman countryside. When his scholarship ended in July 1759, he was allowed to remain in residence until, in late November, he met a wealthy amateur artist, the Abbé de Saint-Non, who was to become one of his chief patrons. Early in 1760 Saint-Non took Fragonard and Robert on a prolonged tour of Italy, where the two artists studied Italian paintings and antiquities and made hundreds of sketches of local scenery. Some of these later developed into paintings, and others were used as backgrounds for *fêtes galantes* (aristocratic gatherings in a rural setting), while Saint-Non had still others engraved and published in his *Voyage Pittoresque . . . de Naples et de Sicile* (1781–86).

Four years after returning to Paris in 1761, Fragonard exhibited a few landscape paintings and the large "Coreus Sacrifices Himself to Save Callirhoe" at the salon where it was purchased for the King. Consequently, the artist was commissioned to paint a pendant, or companion piece, granted a studio in the Louvre Palace, and accepted as an Academician. Nevertheless, after 1767 he almost ceased to exhibit at the salons, concentrating on landscapes, often in the manner of the 17th-century Dutch painter Jacob van Ruisdael ("Return of the Herd," Worcester), portraits, and decorative, semi-erotic *fêtes galantes* in the style of Boucher ("The Swing") but more fluently painted. His admiration for Rembrandt, Rubens, Hals, and a Venetian contemporary, G.B. Tiepolo, emerges in a large series of loosely and vigorously executed heads of old men, painted c. 1760–67 ("Head of an Old Man"), followed by a series of portraits (c. 1765–72) in a similar style and in which the sitters were real persons, but their fantastic costumes were emphasized rather than facial expressions ("Abbé de Saint-Non in Spanish Costume").

In 1769 he married Marie-Anne Gérard from Grasse and shortly afterward received the accolade of fashion, when in 1770 he was commissioned by Mme du Barry to decorate her newly built Pavillon de Louveciennes, with four large paintings ("Progress of Love," Frick Collection), and in 1772 received a somewhat similar

commission from the notorious actress Mlle Guimard. Neither was a success, the Louveciennes paintings probably being rejected as too Rococo for a totally Neoclassical setting.

A journey to the Low Countries perhaps in 1772–73 increased his admiration for Rembrandt and Hals and was reflected in his later portraits. A second visit to Italy followed in 1773–74. As before, he concentrated on drawing picturesque Italian landscape subjects rather than on painting. The return journey was taken through Vienna, Prague, and Germany.

On his return to Paris, the family was joined by his wife's 14-year-old sister, Marguerite, with whom Fragonard fell passionately in love. This turned his interests toward a new type of subject matter: domestic scenes inspired by Rousseau's moral philosophy or romantic novels ("The Happy Family") or scenes concerned with children's upbringing, in which his son Évariste (born 1780) frequently figures ("The Schoolmistress").

In the last years preceding the French Revolution, Fragonard turned finally to Neoclassical subject matter and developed a less fluent Neoclassical style of painting ("The Fountain of Love"). This becomes increasingly evident in his latest works, the genre scenes executed in collaboration with Marguerite Gérard ("The Beloved Child").

Fragonard's art was too closely associated with the pre-Revolutionary period to make him acceptable during the Revolution, which also deprived him of private patrons. At first he retired to Grasse but returned to Paris in 1791, where the protection of the leading Neoclassical painter Jacques-Louis David obtained for him a post with the Museum Commission, but he was deprived of this in 1797. The rest of his life was spent in obscurity, painting little. Fragonard's death on August 22, 1806, passed almost unnoticed, and his work remained unfashionable until well after 1850, but he has since been increasingly esteemed.

#### MAJOR WORKS

"The Education of the Virgin" (c. 1748–52; California Palace of the Legion of Honor, San Francisco); "Girl with a Marmot" (c. 1748–52; Fogg Art Museum, Cambridge, Massachusetts); "Blind-Man's-Buff" (c. 1748–52; Toledo Museum of Art, Ohio); "The See-Saw" (c. 1750; Thyssen-Bornemisza Collection, Castagnola, Switzerland); "Winter," part of "The Seasons," overdoors for the Hôtel Matignon (c. 1751–61; Los Angeles County Museum of Art); "Landscape with Cowherd" (c. 1760–65; Detroit Institute of Arts); "Landscape and Greensward" (c. 1760–65; Musée National du Palais de Compiègne, France); "Head of an Old Man" (1760–67; Musée Jacquemart-André, Paris); "The Washerwoman" (c. 1761–65; Musée de Picardie, Amiens); "The Storm" (c. 1761–65; Louvre, Paris); "The Gardens of the Villa d'Este" (c. 1761–65; Wallace Collection, London); "The Lost Forfeit" or "Stolen Kiss" (c. 1761–65; Metropolitan Museum of Art, New York); "Landscape with Peasants and Animals" (c. 1761–65; Worcester Art Museum, Massachusetts); "The Dream of Love" (c. 1761–65; Louvre, Paris); "Coreus Sacrifices Himself to Save Callirhoe" (c. 1761–65; Louvre, Paris); "The Stable" (c. 1761; private collection); "Portrait of a Man" (c. 1763–65; André Meyer Collection, New York); "Rinaldo in the Gardens of Armida" (c. 1765; private collection, Paris); "Rinaldo in the Enchanted Forest" (c. 1765; private collection, Paris); "The Parents' Absence Turned to Account" (c. 1765; Hermitage, Leningrad); "The Stolen Shift" (c. 1765; Louvre, Paris); "All in a Blaze" (c. 1765; Louvre, Paris); "Women Bathing" (c. 1765; Louvre, Paris); "The Useless Resistance" (c. 1765–72; National Museum, Stockholm); "Abbé de Saint-Non in Spanish Costume" (c. 1765–72; Museo de Arte Moderno, Barcelona); "The Swing" (c. 1766; Wallace Collection, London); "Inspiration" (c. 1766; Louvre, Paris); "Music" (c. 1769; Louvre, Paris); "The Music Lesson" (c. 1770; Louvre, Paris); "Portrait of a Lady with a Dog" (c. 1770; Metropolitan Museum of Art, New York); "The Sleeping Bacchante" (c. 1770; Louvre, Paris); "The New Model" (c. 1770; Musée Jacquemart-André, Paris); "The Three Graces" (c. 1770; Louvre, Paris); "The Loves of Shepherds" or "The Ages of Life" (four paintings, c. 1771; Frick Collection, New York); "Love As Folly" and "Love As Conqueror" (c. 1771; National Gallery of Art, Washington, D.C.); "View of an Italian Villa" or "The Cascade" (c. 1773; Metropolitan Museum of Art, New York); "The Happy Family" (c. 1773–76; Metropolitan Museum of Art, New York, and National Gallery of Art,

Neo-  
classical  
period

Parisian  
success

Washington, D.C.); "Study Portrait of a Girl" (Wallace Collection, London); "The Washerwomen" (c. 1774; City Art Museum, St. Louis); "A Young Girl Reading" (c. 1775; National Gallery of Art, Washington, D.C.); "The Swing" (c. 1775; National Gallery of Art, Washington, D.C.); "Blind-Man's-Buff" (c. 1775; National Gallery of Art, Washington, D.C.); "The Fete at Saint-Cloud" (c. 1775; Banque de France); "Marie-Catherine Colombe As Victorious Venus" (c. 1775-76; Los Angeles County Museum of Art); "The Schoolmistress" (c. 1777-78; Wallace Collection, London); "The Fountain of Love" (c. 1780-81; private collection); "Portrait of Mme. Bergeret de Norinval" (c. 1785; Musée Cognacq-Jay, Paris); "The Stolen Kiss" (c. 1788; Hermitage, Leningrad); "Evariste Fragonard As Pierrot" (c. 1789-90; Wallace Collection, London); "The Beloved Child," painted with Marguerite Gérard (c. 1792; private collection, New York).

**BIBLIOGRAPHY.** The best work on Fragonard as a painter that supersedes all earlier publications and includes a catalogue raisonné is G. WILDENSTEIN, *The Paintings of Fragonard: Complete Edition* (1960). It includes a concise critical bibliography of the essential manuscript and printed sources. This is the only work of any significance in English apart from the essay of 1865 on the artist by the brothers JULES and EDMOND DE GONCOURT later reprinted in their *L'Art du dix-huitième siècle*, translated, together with certain other essays, by R. IRONSIDE in *French Eighteenth Century Painters* (1948), from the third and best edition (1881) of the Goncourts' work. The essay is important not only for its poetical interpretation of Fragonard's art but because the authors wrote just in time to interview the last surviving contacts of the artist himself. A catalogue raisonné of the drawings is being prepared by M. ALEXANDRE ANANOFF. Three volumes (out of four) covering 2,000 drawings, have so far been published (1961-68). It suffers, however, from faults of organization. The etchings have been exhaustively treated by G. WILDENSTEIN in *Fragonard aquafortiste* (1956).

## France

One of the oldest and historically and culturally most important nations of Europe and indeed of the whole Western world, France lies near the western end of the great Eurasian landmass, between latitudes 42° and 51° N, and covers a total area of 212,742 square miles (551,000 square kilometres). Hexagonal in outline, its territory is bordered on the north by Belgium, Luxembourg, and La Manche (the English Channel); on the west by the Atlantic Ocean and the Bay of Biscay; on the south by Spain and the Mediterranean Sea; and on the east by West Germany, Switzerland, and Italy. Its two mountain chains, the lofty Alps in the east and the Pyrenees in the southwest, form additional natural frontiers and thus leave only the northeast boundary—across which most of the great invasions afflicting the nation have been launched—open to any great extent. This geopolitical situation may well explain why the Rhine has sometimes been claimed as the natural boundary of the hexagon's sixth side, and it certainly helps to account for the relatively early achievement of national unity by the French people—a process initiated from Paris and the surrounding country, aptly named the Île de France. The climate is generally moderate, combining Atlantic, Mediterranean, and the more extreme continental influences. As a result of the strong recovery in the birth rate after World War II, the repatriation of more than 1,000,000 French citizens from its former colonies in North Africa, and the influx of foreign labour, the national territory thus circumscribed was the home of over 51,000,000 persons by the early 1970s.

Paris is both the head and the heart of France and, because of a constantly accelerating process of centralization, contains in its metropolitan area fully one-sixth of the total population, which is distributed in a very unequal manner between 38,000 *communes*, the smallest administrative units in the nation.

France has had 11 constitutions since 1791, when a constitutional monarchy was adopted. The constitution of the Third Republic, which took effect from 1875 and lasted until 1940, was in many ways the simplest and least formal of all. The present constitution, proclaimed on September 28, 1958, by Charles de Gaulle, consider-

ably strengthened the powers of the head of state. With de Gaulle's election to the presidency following the referendum of 1962, which was held on the issue of the election of the president by universal suffrage and not by a college of notables, the semipresidential character of the government appeared to be confirmed. De Gaulle was president of the Fifth Republic until 1969, and he envisaged, in a new pattern of government, not only the increase of his own "superstructural" presidential powers but also those of the infra-structure, or local authority, in matters that were not directly political, at the expense of the central government. One of his chief aims, therefore, was to decentralize the administration of France. When his bold plan to achieve this goal was rejected by the nation in a referendum held in April 1969, he immediately resigned from office. Regional reform remained a major problem of the 1970s. Decisions taken in Paris, the capital city, frequently frustrate local initiative.

Interregional commerce is also hindered by the pre-eminence of Paris among French cities and by matters such as the convergence of the railroads and major highways on Paris, by the insufficient number of navigable waterways, and by the natural obstacle of the Massif Central, an upland mass that hinders transverse communications between cities to the east, such as the ancient city of Lyon or the equally ancient Mediterranean port of Marseille, and those of the west, such as Bordeaux or Nantes. Finally, most of the great industrial concentrations lie east of a line running from Le Havre, in the north, to Marseille, in the south, while the western regions, which have remained more agricultural, are, generally less developed.

On the international scene, France launched, in 1950, the Communauté Européenne du Charbon et de l'Acier (European Coal and Steel Community, or ECSC)—the embryo, perhaps, of a future federation of European states—on the initiative of the statesman Jean Monnet and of the then prime minister, Robert Schuman. Although France rejected the Communauté Européenne de Défense (European Defense Community, or EDC) in 1954, it remains an active member of the Communauté Économique Européenne (European Economic Community [EEC], or Common Market), formed in 1957. The nation continues to participate in the Atlantic alliance, but it withdrew in 1966 from the pact's military organization (NATO) and thus regained full control over its own air, ground, and naval forces. As a permanent member of the United Nations Security Council—together with the United States, the Soviet Union, the United Kingdom, and the People's Republic of China—France enjoys the right to veto decisions presented before the council, a process reflecting the nation's continued international stature.

In the cultural world France has always held a high place. The dukedoms and provinces that came to be called France gave rise to Gothic architecture in the Middle Ages and to a broad Humanism in the Renaissance and the Enlightenment. The sciences have been expanded by French discoveries, and, in the arts, France has contributed richly, producing world figures in drama, poetry, the novel, and in music. In the 19th and early 20th centuries France unleashed a burst of creative energy in painting unequalled since the Italian Renaissance.

## I. The land

### TOPOGRAPHY

The three  
geological  
regions

The French landscape is typical of the diverse nature of continental Europe. Three main geological regions are distinguishable: the skeletal remains of ancient mountains that make up the principal massifs; the northern and western plains; and the narrow plains between the rugged younger mountains of the south and southeast.

**The ancient mountains.** The physical structure of France is dominated by a group of ancient mountains in the shape of a gigantic V, the sides of which form the two branches of Hercynian folding that took place between 345,000,000 and 225,000,000 years ago. The eastern branch is comprised of the Ardennes, the Vosges, and the eastern part of the Massif Central, while the Hercynian massifs to the west comprise the western part of the Massif Central and the hills of the Massif Armoricain.

**The eastern branch.** The Ardennes stretch into a large part of Belgium and extend into West Germany as the crystalline rocks of the Rhenish massif. Only its western extremity is located in France. An old mountain chain made of folded sedimentary rock, the Ardennes are cut by a wooded eroded plain and gashed by the deep and narrow gorges of the valleys of the Sambre and the Meuse rivers. Altogether, it is a dark and wooded area. The Vosges mountains separate the Paris Basin from the Rheinland to the east. A small asymmetric mountain chain rising gradually from the west, the Vosges fall rapidly to the east in a faulted escarpment that dominates the plain of Alsace. In the north it is completely covered by a shell of Triassic sandstone and a magnificent forest, which acts as a windshield on its slopes and summits. The southern part of the chain, which is higher, culminates in the rounded peak of crystalline rock of Ballon de Guebwiller (Mt. Guebwiller), 4,672 feet (1,424 metres) high. Although eroded by time, this small mountain is a distinctive landmark in eastern France.

**The western branch.** The largest geographical region in France, the plateau of the Massif Central, covers about 35,000 square miles (90,000 square kilometres), or one-sixth of the area of the country. It is an asymmetrical mountain region, sharp and high in the southeast but gradually merging with the plains of the Paris Basin and the Loire lowlands in the north and northwest. As with the Vosges, this asymmetry resulted from the Alpine folding of newer mountains upon the stumps of the old ones, which had been previously formed and severely eroded.

The Massif  
Central  
complex

The Massif Central complex is traditionally divided into four parts. In the northwest the province of Limousin is characterized by a series of stepped plateaus bounded in the east by a mountain approaching 3,300 feet (1,000 metres). A halo of peripheral plateaus about 1,100 to 1,300 feet (350 to 400 metres) high lies beneath a number of plateaus about 2,000 feet (600 metres) high. The plateaus are cut by many gorges, characterized by geological uplifting and fracturing, developments that occurred at the time of the rejuvenation due to the Alpine foldings. For the most part, the plateaus are composed of crystalline rocks, and these same rocks of the Limousin extend

into the central part of the massif, forming the high plateaus that reach 4,000 to 5,000 feet (1,200 to 1,500 metres) and that were greatly changed in the Tertiary Period (about 65,000,000 to 7,000,000 years ago). At that time gigantic faults fractured the massif, cutting both the long depressions of the Limagne plain where the Allier River flows, as well as the plains of the Loire and the Velay, the Forez, and the Roannes (Roanne) basins.

In the same epoch the great volcanic massifs of Cantal and Monts Dore rose in the central part of the region, the latter containing Puy de Sancy, which at 6,184 feet (1,885 metres) is the highest summit of the Massif Central. The Puy range dominates the western border of Limagne, and its best-known peak is Puy de Dôme (4,803 feet [1,464 metres]). Of these peaks—which are extinct volcanoes and are a dominant feature of the landscape—the most recent date back only about 10,000 years.

To the south lies the large limestone plateau known as the Causses. In a vast faulted depression, the seas of the secondary geological era deposited a 2,600-foot-thick layer of sediment on the underlying limestone. This region is marked by its aridity and its few rivers, which have cut deep canyons, the best known of which is the Tarn canyon. It is a generally dark and wooded area made up of the crystalline and volcanic rock that constitutes the rest of the massif.

The eastern border of the Massif Central snakes southward from Morvan, a small wooded massif in the north, to Montagnes Noires, a large, dark, and wooded plateau that dominates the gate of Carcassonne, a lowland area that provides a valley route between the Pyrenees and the Massif Central to the Atlantic Ocean and the Mediterranean. Between these two points lie a series of granite massifs, with pastures and forests on their western slopes and vineyards on their eastern sides, including the mountain slopes of Beaujolais, Lyonnais, Vivarais, and Cévennes. Between these massifs lie the northeast-southwest depressions of sedimentary rock, with coal deposits at Montceau-les-Mines and Saint-Étienne.

This enormous mountainous mass, which almost forms a complete barrier between the plains of the Saône and the Rhône, is an obstacle to communications in central France and has remained very isolated for a long time. It has also suffered from serious depopulation in recent times. It is the source of many rivers, which descend to the English Channel in the north, to the Atlantic in the west, and to the Mediterranean in the east, feeding numerous dams valuable for their hydroelectric power.

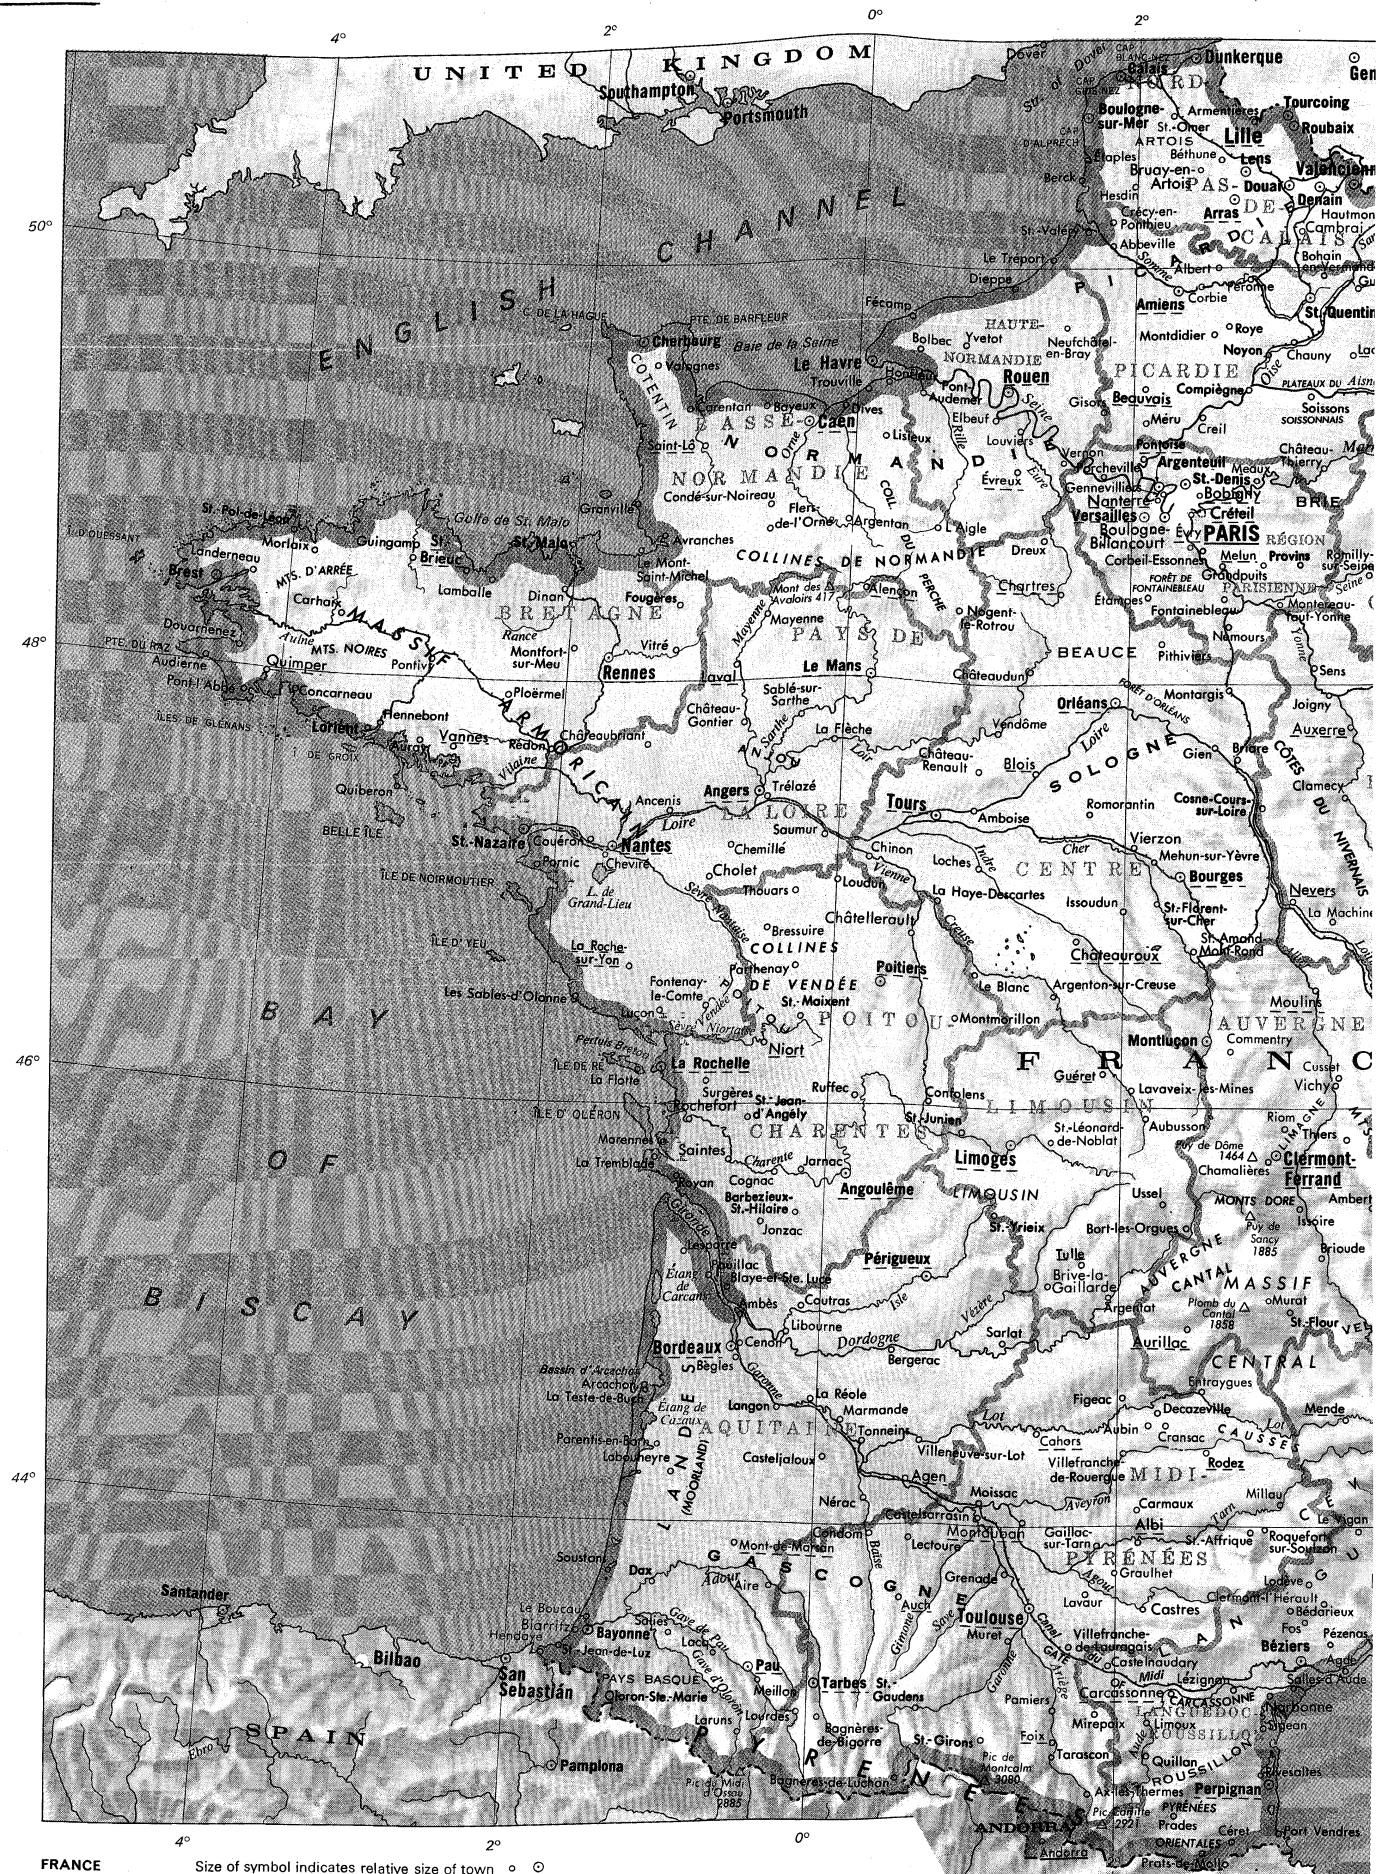

The Massif Armoricain, made of crystalline rocks and formed at the time of the Hercynian folding, extends in hilly ridges from the northwest, in Bretagne (Brittany), to the hills of Normandie (Normandy) in the east and on to the wooded upland country (known as *bo cage*) in the Vendée, to the southeast. It contains the highest point in the western plains of France, the Mont des Avaloirs (1,350 feet [417 metres] high) in the Collines des Perche (Perche Hills).

**The plains and the coasts.** *The northern plains.* To the east of these worn-down mountains, the plains form four different groups. The northern plain extends to the Ardennes in the southeast and to the Artois (a Hercynian ridge 682 feet [208 metres] high) in the northwest. It descends toward the North Sea and Belgium.

*The Paris Basin.* The Paris Basin contains the largest group of these plains. It consists of a number of plateaus and hills that slope down toward the central basin and the low-lying Paris-Orléans region. The surrounding hills are the Artois, the Ardennes, the Vosges, the Bourgogne (Burgundy) plateaus, the Morvan Massif, and the Collines de Normandie (Hills of Normandy). The Paris Basin is an accumulation of sedimentary beds of which the most recent belong to the Tertiary Period and in the central area are nearly horizontal. They make up the plateaus of Beauce, Brie, the Île de France, Vallois, and the Soissonnais, which are covered with the fertile wind-borne dust known as *limon*, or "loess," which dates from the glacial period. Toward the edge of the basin, the beds are older and dip down at an increasing angle. In the eastern and southeastern parts of the basin, the alterna-

tion of the hard and soft beds sloping toward the centre produces a distinctive kind of relief (known as "cuestas" in the southeast) that has been reflected in the great historical divisions of France. In the north the great chalk plains form eastern Normandie (Normandy), which is cut by the Seine Valley, and Picardie (Picardy), broken by the chalky ridge of Artois to the north. In western Normandie the Paris Basin joins the Massif Armoricain.

*The Loire plains.* Toward the southwest the basin opens on the third group of plains, which follow the Loire Valley. The hills of this region, such as the limestone plateaus of Touraine and the crystalline plateaus of Anjou and Vendée, are cut by the broad valleys of the Loire and its tributaries. The valley, which varies in width from one to four miles, is famous for its peaceful atmosphere and for its beauty and fertility.

*The Aquitaine Basin.* The Loire countryside adjoins the Aquitaine Basin through the gap known as the Gate of Poitou. The Aquitaine Basin is much smaller than the Paris Basin, and, while it is bounded in the south by the

Pyrenees, in the northeast it runs into the low foothills of the Massif Central. The slopes decline toward the central valley of the Garonne River. In the north there are limestone plateaus crossed by fertile valleys. In the centre, pointed hills were cut in the soft terrain during the Tertiary Period, while in the south, at the foot of the Pyrenees, there is a large sloping bank of hills composed of clastic rocks that has been cut into the shape of a fan by the rivers flowing down from the mountains. Finally, along the Atlantic coast, the Landes is a wasteland of sand dunes and marshes, much of which was reclaimed in the 19th century and transformed into pine forest.

*The coasts.* The coasts of the northern and western regions are as diverse as the countryside. The northern plain slopes down to the North Sea in great sandy dunes, while the hills of Artois near Belgium form the headlands of Cap Gris-Nez, Blanc-Nez, and Alprech. The chalky plateaus of Picardie and eastern Normandie face the English Channel with beautiful cliffs of white chalk that are bordered on the south by the deep estuary

of the Seine. West of the sandy beaches of central Normandie, the peninsulas of Cotentin and Bretagne, carved in the very hard and heterogeneous rocks of the Massif Armoricaire, are bounded by variegated and picturesque coasts that are cut by capes and reefs and penetrated by deep rias (drowned river valleys). In the south, the Loire Estuary penetrates about 40 miles inland. A deep and wide arm of the sea makes up the Gironde Estuary, farther south, and a sandy coast is bordered by islands with many rock promontories. To the south of the Gironde is the smooth unbroken coastline of the Landes.

**The younger mountains and adjacent plains.** *Pyrenees, Jura, and Alps.* The Pyrenees, the foothills of which shelter the picturesque Basque countryside, constitute the most ancient of the more recently formed mountains in France. They stretch for more than 280 miles (450 kilometres), making a natural barrier between France and Spain. Their formation, which began in the Mesozoic Era, continued in the Tertiary and perhaps even in the beginning of the Quaternary, about 2,500,000 years ago.

The central part is the highest, composed of a series of parallel chains with passes that are few and difficult to reach, falling sharply at each end (see PYRENEES RANGE).

The Jura Mountains (*q.v.*), near Switzerland, are composed of folded limestone. Their ridges extend parallel from the north-northeast to the south. The highest point is the Crêt-de-la-Neige, at 5,653 feet (1,723 metres).

The French Alps (see ALPS MOUNTAIN RANGES) are only a part of the great chain that extends throughout Europe, but they include the highest point, Mont Blanc (15,771 feet [4,807 metres] high). These majestic mountains were formed in a series of foldings that lasted from the beginning of the Tertiary to the Quaternary Period. They include the two greatest regions of permanent snow and glaciers in Europe, surmounted by the peaks of Mont Blanc and Mont Pelvoux, the latter exceeding 13,000 feet. The northern Alps, which are formed by four parallel segments (the folded chain of the Pre-Alps, the wide depression of the sub-Alpine hollow, the high central crystalline massifs, and the chains and peaks of the intra-

Divisions

Alpine zone), are easier to cross thanks to the great valleys created by the movement of glaciers. The relief of the southern Alps is much less orderly, and the valleys, which were not affected by glaciation, form narrow and winding gorges. Like the Pyrenees, the Alps form a natural barrier, dropping sharply down to the Po Plain in Italy.

**The southern plains.** Between these young mountains and the ancient Massif Central is a series of plains, including those of the Saône and the Rhône, which fan out to the Mediterranean in the great triangular delta of the Rhône and of Languedoc. In the south the Pyrenean foothills cut the basins and rocky coast of Roussillon. In the southeast the Alpine foothills adjoin the massifs of the Maures, the Estérel, and the Corsican mountains to form the coves, capes, and harbours that help to make the Mediterranean coast one of France's most beautiful.

#### CLIMATE AND VEGETATION

The location of France at the edge of the European continent makes it a crossroads subjected to three kinds of

climatic influences: oceanic, continental, and Mediterranean. It is largely exposed to winds from the Atlantic, which in temperate latitudes blow from the west to the east. About three-quarters of France is, for most of the year, under the influence of the great cyclonic depressions that come from the Atlantic. Their exact path is determined by the variations in the relative location of the polar and tropical masses of air. In winter, moreover, areas of high pressure frequently move over the eastern part of France, notably in the Alsatian plains and the Saône region. This, added to the proximity of the Mediterranean in the south, gives France an extremely varied but generally temperate climate, as well as sufficient rainfall.

**The oceanic region.** The pure oceanic climate prevails in the northwest, especially in Bretagne. It is characterized by its regularity (the average yearly temperature is 52° F [11° C] at Brest); by its extreme humidity (35 inches [900 millimetres] of rain falling in 200 days of the year, as well as cloudiness, haze, and high humidity);

by the frequency and sometimes the violence of the west winds that blow nearly constantly; and by large variations in the weather which can change several times a day. This climate is very favourable to the natural plains where grass grows the year round and to hills of broom, heather, and gorse moorlands, while, on sheltered slopes, forests of oak are abundant. This oceanic climate is modified toward the north, where the winters are cooler, and toward the south, where in the Aquitaine Basin, the winters are colder and the summers warmer. There is also less rainfall, although at Toulouse great summer storms caused by continental climatic conditions are quite frequent.

The French climate is generally very favourable for natural vegetation and cultivation. Snow lies permanently only above 9,000 feet in the Alps and 9,500 feet in the Pyrenees; and only in the drier areas of France, irrigation is sometimes necessary, as in the plains of the Lower Rhône and Languedoc.

The climate of the Paris Basin is somewhere between the oceanic and the continental. The average yearly temperature is 53° F (12° C) in Paris. In addition, the relatively light annual rainfall (24 inches [619 millimetres]) follows a pattern of moderately heavy rain in spring and especially autumn, as in the oceanic countries, but the maximum amount of rain occurs in summer, with storms of the continental type. Such a climate is very favourable to the cultivation of grain crops and especially to the growth of the great forests, which once covered the centre of the Paris Basin and still exist over wide areas, even close to Paris. This same type of climate is found on the western slopes of mountains, including those of the Ardennes, Vosges, Massif Central, and western Pyrenees. In the mountains the contrast between summer and winter becomes more marked and frost and snow last for several weeks in winter; the level of rainfall usually increases and can exceed 40 or even 80 inches (1,000 or 2,000 millimetres) on the primary slopes of the western Pyrenees, one of the most humid regions in France.

**The continental region.** The sheltered plains of the east are particularly affected by a continental climate. The city of Strasbourg has the greatest temperature range in France, with 33° F (6° C) in January and 66° F (19° C) in July. Winter is cold, with an average of 83 days of frost and with snow lying for several weeks, but the weather is often sunny. In the summer, storms cause maximum precipitation in June and July, although total rainfall is comparatively light. These regions are particularly suited for grain crops on the plains, vineyards on the favourably situated slopes, and beech forests on the highest slopes.

**The Mediterranean region.** In the southeast the Mediterranean climate extends over the plains to the coast and penetrates those of the Lower Rhône River as far as the Montélimar area. Its effects are felt in the southern Alps and in the Massif Central upon the southeast slopes of the Cévennes and the Montagne Noire and also on the eastern Pyrenees. The latitude and the proximity of the warm Mediterranean Sea means mild winters, with an average temperature of 47° F (8° C) in January at Nice and with only 3 days of frost. Precipitation is heavy (34 inches [862 millimetres] at Nice) and tends to fall in sudden downpours, especially in the autumn and spring, while summer is nearly completely dry for three to five months. The clear skies and the regularity of fine weather make it a unique area, where vegetation adapted to dryness abounds, including olive trees, box trees, thyme, rosemary, green-oak forests, cork trees, and thorny plants. In the mountainous zones there are two characteristic plant formations: the scrub formed of thorny plants and the moorland. These are found especially on the limestone soils. This region is the principal domain of the vineyard; but orange and lemon trees are also cultivated around Nice and Menton, and rice has been grown for 30 years in the Rhône Delta. Unfortunately, this area is also subject to the violent winds of the mistral, which blows from the north. The winds are caused by high-pressure areas from central France that move toward the low-pressure areas of the Gulf of Gen-

oa. Cypress hedges have been planted to protect cultivation from these winds in the Lower Rhône region. Other winds, such as the tramontana, which blows from the northeast from the Alps toward the coast, and the *marin*, which blows from the sea, also affect this area.

#### THE RIVER SYSTEMS

Flowing toward four seas, the English Channel, the Atlantic Ocean, the Mediterranean, and the North Sea, five great river systems drain the principle areas of France.

**The Rhine system.** In the east the Rhine, the second most important river in Europe after the Danube, barely touches French territory along the Alsace-Baden frontier for about 125 miles (200 kilometres). Its two great tributaries, however, the Moselle (German Mosel) and the Meuse, drain the eastern part of the Paris Basin, while the northern rivers, beyond the hills of Artois, flow into the North Sea through the Escaut (Flemish Schelde).

**The Seine system.** The Seine, the main river of the Paris Basin, is 485 miles (780 kilometres) long and has an outflow of 16,000 cubic feet (450 cubic metres) per second at its mouth. It flows slowly and regularly and is naturally navigable. It is the main axis of a river network that includes the Aube, the Marne, and the Oise, which flow from the eastern part of the basin, and also of short, left-bank tributaries, such as the Yonne, which has its source to the north of the Massif Central. The whole Seine network is very useful for navigation.

**The Loire system.** The Loire, the longest French river, flows for 634 miles (1,020 kilometres) and drains the widest area (44,400 square miles [115,000 square kilometres]). It is an extremely irregular river, with an outflow eight times greater in December and January than in August and September. Rising in the Massif Central on Mont Gerbier de Jonc, it flows for a long way over impervious terrain with steep slopes and has a system of irregular tributaries. Near its mouth it is joined by the calm waters of the Maine, a river formed by the confluence of the Mayenne, the Sarthe, and the Loir. Navigation is very limited, being confined to the Lower Loire and Maine.

**The Garonne system.** The Garonne, in the southwest, flows through the centre of the Aquitaine Basin. It is the shortest of the main French rivers (357 miles [575 kilometres] long), and it drains only 22,000 square miles (56,000 square kilometres). Its outflow is irregular, with high waters in winter (due to the oceanic rainfall) and in spring, when the snow melts, but with meagre flows in summer and autumn. Its source is in the centre of the Pyrenees in the valley of Aran (French Joyeuse), in Spain, and its main tributaries, the Tarn, the Lot, and the Dordogne, originate in the Massif Central. With the exception of the Gironde Estuary, which is formed by the confluence of the Garonne and the Dordogne and is fully penetrated by the sea, the whole network is useless for navigation and is filled with powerful, rapid, and dangerous currents.

**The Rhône system.** The Rhône, flowing from Lake Geneva to the Mediterranean, is the largest river in the southeast, but of its course of 500 miles (800 kilometres) only 324 are in France. It has the greatest flow and is the most industrially exploited river in France, discharging 777,000,000 cubic feet of water (22,000,000 cubic metres) per year into the delta. Its system is very different from that of the rivers of the west. It is fed by natural rainwater; by the Saône, which joins it at Lyon; and by the water from melted snow and glaciers, which is brought down from the mountains by the Isère, Drôme, and Durance rivers. The Rhône's flow, which is continuously ample, reaches a peak in spring and summer. It permits navigation, although it is often difficult travelling upstream, but large man-made projects have been completed to improve these conditions.

**Coastal rivers, lakes, and lagoons.** Besides these principal river systems, there are a certain number of coastal rivers, with sources near the sea, that flow directly into it. Among the most important are the calm oceanic rivers, such as the Somme, which crosses Picardie; the small

lakes and  
mountain  
lakes

rivers of Normandie; the Charente; and the streams, such as the Adour, which descend from mountains.

The French hydrographical system also includes a certain number of natural lakes of different origin. There are the lakes in depressions carved out by glaciation at the periphery of mountains, such as the lakes of Annecy and Bourget. Others occur at the centre of ancient massifs and include the lakes of the Vosges. There are the circular lakes in the mountains, such as those of the Pyrenees, and the lakes caused by structural faults and lodged in narrow valleys, such as the Jura lakes. There are also a certain number of lakes of volcanic origin, such as those in the Massif Central (the crater lakes and the barrier lakes), and regions scattered with lagoons or ponds, either created by coastal phenomena, as on the Landes and Languedoc coasts, or caused by impervious terrain and poor local drainage.

#### THE HUMAN IMPRINT

**The natural environment and man.** Men have found the natural conditions of France, with its varied physical landscape, to be exceptionally favourable. From the dawn of prehistory, the vast expanse of plains, the temperate climate with sufficient rainfall everywhere, and the existence of surface soils generally favourable to agriculture have attracted and stimulated human settlement. Further, a large labour force has made possible widespread and very dense cultivation of the land. Indeed, all of the cultivable land in France has been exploited by man, even if there is now a decline in the population of the most rugged mountain regions.

**The rural landscape.** There are four major kinds of human activity in rural France. In the northwest is the *bocage* ("woodland") country, dominated by fields surrounded with hedges and divided by groves of trees and forests. People there are scattered on farms or in hamlets, and stock breeding is the most widely practiced occupation. In the old massifs, such as central Bretagne, or in the Massif Central, hedges have often been replaced by small stone walls. On the other hand, the plains and the plateaus of the centre and the east of the Paris Basin are characterized by open fields without boundaries between the fields that are cultivated. There are few trees, except along the rivers and the roads, and the houses in the villages are pressed tightly against one another. The greatest part of this land is under cultivation. Explanations of this famous fundamental division between "open" and "closed" patterns of settlement have been sought in the nature of the soils, in the different climates, in the ethnic diversity of the first occupants, and in the differences between the times and types of settlement.

In the Mediterranean areas there is a different kind of countryside. Small, square fields bordered by stone walls occupy the plains, while slopes are terraced, allowing for cultivation without a disastrous erosion of the soil. Traditional villages are built high up for both defensive and sanitary reasons, while the modern population has settled widely in the plains and in the valleys. Finally, in the high mountains and especially in the Alps, there is the contrast between the *adrets*, the sunny and cultivated valley slopes, and the *ubacs*, cold and humid slopes covered with forests. The variety of vegetation on the great slopes is remarkable. Cultivated fields and grasslands are found in the depths of the valleys, orchards on the first sunny embankments, then forests, Alpine vegetation, bare rocks, and finally permanent snow. The coastal plains, however, often present the classical polder landscape that is associated with reclaimed land, such as the coastal plain of Vendée. Coastal land is also used for specialized cultivations, such as the ricefields of Camargue.

**The urban landscape.** The urban areas obviously occupy much less space than the rural regions. The most densely populated area in France is metropolitan Paris, which covers only 0.3 percent of French territory. The other great urban agglomerations are concentrated around Lyon, Marseille, the Lower Seine Valley, northern France, and, in a more dispersed manner, Alsace, the Lower Loire, and Gironde. Altogether, only 70 percent

of the French population lives in towns, but this proportion has increased considerably and regularly in recent times. The outlying areas are generally not very developed, but cities are frequently—and unhappily—extremely crowded.

**The major divisions of France.** This brief review of the most characteristic elements of the French landscape has delineated its most perceptible differences, but there are divisions of a different kind.

The great natural regions of the French landscape coincide with the various regions of climate and vegetation: the Nord (North), the Paris Basin, the Nord-Ouest (Northwest), the Loire country, the Massif Central, the Aquitaine Basin, the Pyrenees, the eastern plains, the Jura, the Alps, and the Mediterranean areas. Within these natural regions, history imposed divisions that were generally founded upon the power of a local family: the duchy of Burgundy, the earldom of Picardy, the duchy of Brittany, the earldom of Toulouse, the earldom of Provence, and others. In the course of the centuries, these historical divisions were absorbed little by little by the central power of the monarchy, but the provinces have nevertheless survived and retained a certain distinctiveness, as with Normandie, Bretagne, Champagne, and Auvergne, for example. At the time of the French Revolution, a uniformity of administrative divisions was brought about by the formation of *départements*. These divisions, however, have often not succeeded in erasing the persistent influences of the ancient provincial boundaries. In the last half century it has become obvious that the *départements* were units poorly adapted to the modern economy, and, in 1955, economic regions were created as heterogeneous in size as in population, though with little effective actual powers.

In the early 1970s, France was preparing to implement a policy of "regionalization," which would give a certain degree of autonomy to different regions in France, agreed jointly with the central government. Without giving the regions powers that were strictly political, the projected reform provided for the setting up of regional councils composed of both elected members and representatives of local bodies, as well as for a consultative assembly bringing together the principal branches of activity. With its own financial resources and credits granted to it by the state, each region would find itself in a position to launch and finance a plan covering several years for industry and development. The details of the proposed plan, however, remained to be worked out.

The policy  
of "region-  
alization"

## II. The people

#### THE DEVELOPMENT OF THE POPULATION

**Racial origins.** The French are, paradoxically, strongly conscious of belonging to a single race and a single nation, but they hardly constitute a unified racial group by any scientific gauge. Before the official discovery of the Americas at the end of the 15th century, France, located on the western extremity of the Old World, was regarded for centuries as the edge of the known world. Generations of different migrants travelling by way of the Mediterranean from the Middle East and Africa and through Europe from Central Asia and the Nordic lands settled permanently in France, forming a variegated grouping almost like a series of geological strata, since they were unable to migrate any farther. The oldest and most typical piece of evidence of these migrations is furnished by the Basque people, who inhabit the area to the west of the Pyrenees, both in Spain and France. Their language, which has been the subject of numerous studies, is also spoken by a group of people who are found in the Caucasus in the southern Soviet Union. In addition to these many migrations, France was, over the centuries, the field of numerous battles and of prolonged occupations before becoming, in the 19th and especially in the 20th century, the prime recipient of foreign immigration into Europe. This situation has given birth to a unique people who, lacking even the pretensions of being a unified racial group, are less racially prejudiced than most of their neighbours. There are, nevertheless, predominant racial types, such as the French of

Over-  
crowding  
in the great  
urban  
agglomera-  
tions

the north and east or those of Normandie, who are tall, blond, blue-eyed, and dolichocephalic (longheaded), bearing little resemblance to the inhabitants of Bretagne and of the Massif Central, who are mainly short, dark, dark-eyed, and brachycephalic (broad headed), or to the people of the Atlantic and Mediterranean areas, who are tall, dark, and dolichocephalic. But this is only a generalization, and a crowd of Frenchmen is as diverse in type as the French countryside is varied.

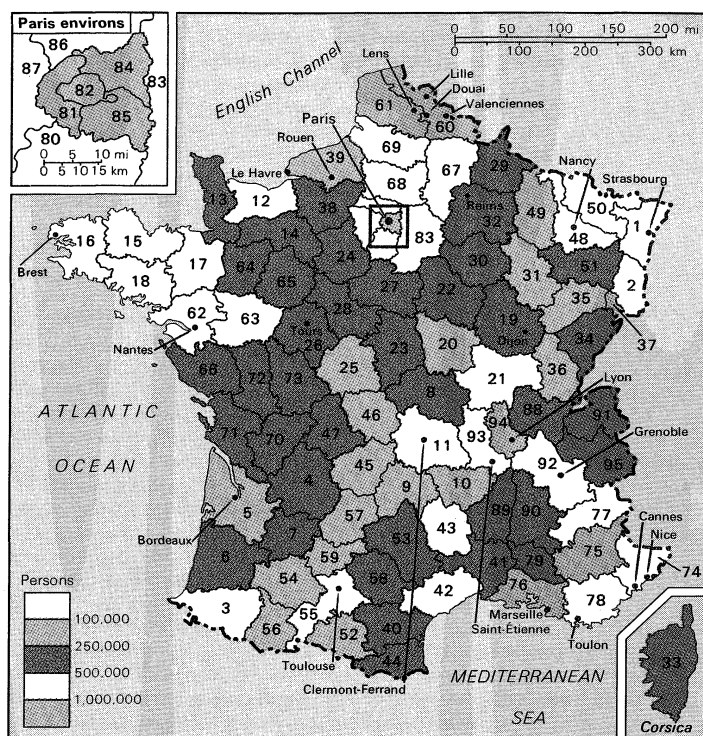

**Language.** French is the national language, spoken and taught everywhere. Brogues and dialects are widespread in rural areas, however, and many people tend to conserve their regional linguistic customs either through tradition or through a voluntary and deliberate return to a specific regional dialect, particularly among some young people. This tendency is strongest in the frontier areas of France. In the eastern and northern part of the country, Flemish and Alsatian are related to the Germanic languages; in the south, Provençal, Corse, and Catalan show the influence of Latin. But both Breton, a Celtic language similar to languages spoken in some western parts of the British Isles (notably Wales), and Basque are distinctly original languages. There have been increasing demands that these languages be studied in schools and universities and that they be given equal status with French, especially since some of them, such as Provençal and Breton, have to this day maintained a literary tradition.

**Religion.** The majority of the French people belong to the Roman Catholic Church, and 90 percent have been baptized; but that is no indication of deep conviction or diligent practice. Only one adult in five regularly participates in religious worship. The northeast (Bretagne-Vendée), the east (Lorraine, Vosges, Alsace, Jura, Lyonnais, and the northern Alps), the north (Flandre), the Basque country, and the region south of the Massif Central have a higher percentage of practicing Catholics than the rest of the country. Practice is greatest among the middle classes. The areas northwest of the Massif Central and southeast of the Paris Basin, however, have become so reprobate that they have been characterized as "mission territory." Recruitment of priests is also becoming more and more difficult, even though the church is very progressive and ecumenical. Protestants, who number around 725,000, belong to several different sects. They are numerous in Alsace, in the northern Jura, in the southeastern Massif Central, and in the central Atlantic region. There are more than 500,000 adherents of Judaism, of which half are in the Parisian area, one-quarter in Marseille, and sizable numbers in Alsace and in the large eastern towns. The presence of numerous workers from North Africa is reflected by the large number of Muslims. Finally, there are several societies of freethinkers, of which the most famous is the French Masonry, with about 30,000 adherents. Large numbers, however, especially among the working classes and young people, are simply atheists and profess no religious belief.

**Population growth.** *Changes in total population.* The population of France was 28,000,000 in 1801, 41,194,000 in 1936, and 40,125,000 in 1946. The 1968 census showed a population of 50,000,000, which means that France ranked 13th among the countries of the world in that year and that it included slightly less than 1.5 percent of the world's population in an area that covers 0.4 percent of the Earth's surface. The population in 1972 was estimated to be over 51,000,000.

In 1801, France was the most populated state in Europe; it included one-sixth of the European population. By 1936 it had fallen to fifth, with 1/13th of the European population. Although the increase between these two dates had been 50 percent, the number of people in Italy and Germany had nearly trebled and, in the United Kingdom and The Netherlands, the number had nearly quadrupled.

*The birth rate.* These changes in the French population were due to an early lowering of the birth rate, linked to birth control, which began in France at the end of the 18th century—much earlier than in other countries of the world. The birth rate fell from around

Population by *département*. Numbers of *départements* are keyed to the Area and Population table.

30 per 1,000 at the beginning of the 19th century to about 15 per 1,000 in 1934–38.

Explanations for this phenomenon have been sought in the consequences of the great economic and social movements introduced by the French Revolution of 1789; the blow to the solidarity of the family by the emancipation of the individual and by the introduction of divorce; the modification of the laws of inheritance; the erosion of class barriers; the uncertain triumphs of the power of bourgeois society; and the diminution of religious sentiment. But probably more important were the effects of a series of cruel wars: the wars of the Revolution; the wars of the First Empire; the Franco-Prussian War (1870–71); and World War I (1914–18). The last alone cost France more than 1,500,000 deaths and a consequential lowering of the birth rate. Finally, the mortality rate in France has fallen less rapidly than in similarly developed neighbouring countries. It was still 15.3 per 1,000 on the eve of World War II, reflecting both the aging of the population and the effects of such social scourges as alcoholism, which produced a high mortality rate among male adults. The population of France thus increased by only 14,000,000 in 135 years, even taking into account the high immigration rate from other countries and the increase in the average life expectancy from 30 years at the beginning of the 19th century to more than 60 years at the eve of World War II. The situation in France in 1938 was dramatic, because there had been some 30,000 more deaths than births in preceding years. World War II (1939–45), following upon these conditions, could have dealt France a mortal blow. In fact, the population decreased by 1,400,000 during the war, with 700,000 dead and the exodus of some 700,000 foreigners who were forced to flee the country.

*The legislative factor.* New legislation was passed in 1938, however, aimed at helping the French family and thus promoting population growth, and this has been continually improved and developed since. These laws, the *politique de la famille*, have been firmly applied and reinforced, and the first positive effects began to show in 1943–44. As a result, between 1946 and 1968 France gained nearly 10,000,000 inhabitants in 22 years, a major change in birth patterns. This was due to three factors:

Causes of the falling birth rate

The *politique de la famille* and its effects

Regional linguistic survivals

the return of more than 1,000,000 French who were forced to come back by the events in Morocco, Tunisia, Algeria, and Indochina; the resumption of foreign immigration; and, finally, the natural growth resulting from the excess of births over deaths.

The birth rate began to rise immediately after World War II, and it reached a maximum of 21.3 per 1,000 in 1947, owing to the increase of births in the postwar period. It then dropped slowly, however, staying at a little more than 18 per 1,000 until 1965. The rise was due to the social legislation, *la politique familiale*, which brought better health care, financial aid to families, and psychological persuasion to have more children. The assessment of the birth rate at that time showed that northern and eastern France had a birth rate five points higher than the southern and central regions of the country. With this had come the lowering, by two years, of the average age of marriage, an increase in the number of births in the early years of marriage, and a higher birth rate among middle and upper class urban dwellers. The introduction of oral contraceptives in France corresponds with a lowering of the birth rate, which became noticeable in the mid-1960s, and explains the levelling off from the high birth rate of the postwar years. In 1969 the birth rate was only 16.7 per 1,000, but it increased again slightly to around 17 per 1,000 in 1970 and 1971. Because of improved health conditions, notably through the widespread use of social security, the death rate is, nevertheless, significantly lower and did not reach more than 10.8 per 1,000 in 1971. The result is a natural increase that has maintained itself at a little more than an average of six births per 1,000 since the end of the war, although there was an excess of 358,000 births at the high point in 1948 and of 261,000 births at the low point in 1956. By 1971 the figure was nearly 330,000.

Altogether, the population of France rose by 7,100,000 between 1946 and 1968 solely by the excess of births over deaths. It was the regions of the north and of the northeast that had the most dynamic growth: the natural increase was more than 10 births per 1,000 a year in northern Lorraine and in the *département* of Doubs in 1962, compared with the national average of only 6.2 per 1,000. But there has been a negative rate of growth in the regions northwest of the Massif Central and a very low rate in the south of France, with the exception of the regions of Lyon and Grenoble.

#### CONTEMPORARY DEMOGRAPHY

**Composition of the population.** The consequences of this demographic evolution are reflected in the composition of the population. There are 1,047 women for every 1,000 men. This inequality in sexual distribution is due to two factors: the wars, which caused the death of a large number of men, and the natural inequality of life expectancy for men and women. A French woman at her birth has a life expectancy of 75.5 years, the fourth highest in the world, while a man can hope to live an average of only 68.0 years. The distribution of the population by age groups demonstrates most graphically the vicissitudes of this evolution. For each 1,000 inhabitants, France has 328 people below the age of 20, 503 aged from 20 to 60, and 170 over the age of 60. In other words, France, with The Netherlands, has the highest proportion of young people in Europe and is also among the four countries of the world having the greatest proportion of the aged. The proportion of the middle aged is abnormally low in comparison with other countries in Europe. Around 1851 only one person in ten was more than 60 years old, but by 1971 almost one person in six had passed that age. People under 40 years old, a category that comprised 50 percent of the French electorate in 1851, represented no more than 40 percent a century later, a fact that tended to favour political and social conservatism. This high proportion of the aged has created difficulties, and pension payments are a heavy burden on the national budget and on large organizations, such as the French railroads (SNCF), which listed 350,000 active employees and 410,000 retirees in 1962. There is one person over 60 years old for almost every three active men between 20 and 60, and the situa-

tion will become more acute in the future, especially if the age of retirement is lowered as demanded by the unions. Finally, there is the problem of housing and caring for the elderly, which is the responsibility of public authorities.

The paradox of contemporary France is that, while there are these problems arising from the large number of elderly, there are equal problems arising from the young. More than one in three of the French population are under 20 years old, reflecting the postwar resurgence of the birth rate. This has resulted in an emphasis on youth characterized by the growth of new commercial markets for future mothers and their children and the development of a typically Western "pop" culture, or (perhaps more accurately) counterculture, the music, fashions, and way of life aimed primarily at the teenager. Young people thus represent a distinctive group in society, rejecting in varying degrees the values of the older generation and asserting their desire to have responsibility and control over their own futures. They demand the right to vote at 18 and feel they are denied their rightful place in the nation. In addition, the problem of providing education has been an increasing one since 1950. It was necessary to hastily construct primary schools, then secondary schools, and finally universities for all of the young who were born after 1944 and who, because of a higher standard of living, pursue their studies for increasing periods of time. There are, at present, more than 10,000,000 French people of all ages in one kind of school or another (including part-time study). This figure represents about one-fifth of the population.

**Immigration and emigration.** *Outward movements.* Emigration has been of little significance. Through the centuries, small groups left to settle at first in North America, notably in eastern Canada (Quebec) and in Louisiana in the United States, in certain parts of Latin America that are to this day *départements* of France (Martinique, Guadeloupe, and French Guiana), and later in various countries of Africa and Asia that were part of France's colonial domain. Since decolonization, whether forced or voluntary, many have returned to France, but others have remained overseas, either in business or in programs of technical and cultural cooperation in most of the former French territories and notably in the republics of black Africa. Currently, small numbers of French, especially from Bretagne and Normandie, make their way to Canada; a number of Basques go to Argentina, and several thousand others go to seek their fortunes in the United States or in new countries, such as Australia.

*Traditional inward movements.* On the other hand, France has traditionally had a very high level of immigration and an open-door policy toward immigrants. This was due to a combination of liberal tradition and economic need. Political refugees of all persuasions entered France, from the White Russians, who arrived after the 1917 Revolution in the Soviet Union, to the Spanish republicans at the end of the Spanish Civil War in 1938. Between 1850 and 1914 about 4,300,000 foreigners entered France, and between World Wars I and II nearly 3,000,000 immigrants, or 6 percent of the population, came into the country. Up to the end of World War I, immigration was free and spontaneous; most of the immigrants came from neighbouring countries, such as Italy, Spain, Belgium, and Switzerland, and they were quite quickly assimilated into the national population. The slaughter of young men and the devastations of World War I stimulated the government to draw widely from the reservoirs of foreign manpower. The Italians came in greatest numbers (35 percent), followed by the Poles (20 percent), the Spanish (15 percent), the Belgians (10 percent), and a smaller number of people from central or eastern European countries, such as the Soviet Union, Czechoslovakia, and Yugoslavia. Some of these people came in small groups and were assimilated, but, as the result of international agreements, the Poles and some of the Italians settled in well-organized communities, bringing their teachers and their priests with them, conserving their languages, and living in close-knit

Liberal traditions and economic need

The low proportion of the middle aged

groups. The Poles, for example, settled in the coal-bed regions to the north of Pas-de-Calais and the Italians in the villages of the valley of the Middle Garonne. Their provincialism created a certain number of difficulties, especially in the course of World War II when large numbers returned to their former homes or left to go elsewhere.

**Recent inward movements.** Soon after the war, France, disillusioned by its recent experience, reorganized its immigration policy completely, partly through the agency of a national bureau. But the bureau controlled barely one-third of those entering, because many came into the country secretly, making it very difficult to know their exact numbers. But, from an estimated 3,000,000, there were about 700,000 Italians, 600,000 Spaniards, 550,000 Portuguese, and some Belgians and Germans. In addition, a large number came from North Africa, notably Algeria (about 600,000), Morocco, and Tunisia. Black Africans are currently becoming increasingly numerous, and the French government has signed agreements with Turkey and Yugoslavia that involve their sending some of their nationals to work in France.

These working class foreigners generally come on temporary contracts, but a certain number become naturalized. Composed for the most part of adults, this population is primarily male; 38 percent work in construction and in public works, 2 percent in metallurgy, 15 percent in mechanical and electrical industry, 8 percent in agriculture, less than 1 percent in mining, and another 36 percent in domestic and other occupations. The region surrounding Paris is the greatest employer of foreign manpower, followed by the large mining and industrial regions in the north and in Lorraine, and then by the large conurbations of Marseille and Lyon. This labour force has its advantages in its mobility and its youth, but it also has its drawbacks. The larger part of the workers are unskilled and without professional qualifications. They live in France on a very small part of what they earn and send the rest to the country of their origin. In addition, they tend to live in poor and unsanitary housing, and their morale is often low. Their coming is, however, very important for the development of the French economy, and they do not compete with the local labour force since they are generally employed in the trades that young Frenchmen do not wish to follow.

**Internal movements and urbanization.** France is also subject to large internal migrations. There is a continual drift away from the mountains to the plains, from the countryside to the small towns, and from the small towns to the cities. Hence, the urban population has increased both relatively and absolutely. In 1861, 29 percent, or 10,790,000, of the total population were urban dwellers. By 1971 this proportion exceeded two-thirds, or 35,000,000 people, and it is estimated that it will reach three-quarters of the population by the end of the century. There were 44 cities with more than 100,000 inhabitants in 1962 and 49 in 1968. This vast movement toward the cities has not been regular but it went through two periods of acceleration. The first was immediately following World War I; the second is still going on. Since 1938 the two cities that have led the country in population growth are Toulouse, with a population in 1968 of 440,000, a gain of 20 percent between 1962 and 1968, and Grenoble, with a population in 1968 of 332,500, which represents a gain of 27 percent over 1962. Montpellier experienced significant increase with the return of refugees from Algeria (37.7 percent between 1962 and 1968).

But it is Paris and its metropolitan area that has had the greatest power of attraction for immigrants for the last 150 years. It contained less than 500,000 inhabitants in 1801 and only 4.5 percent of the national population in 1848; but by 1968 this figure had reached 18.6 percent. Of the population of Paris and its surrounding area, 44 percent were born outside its boundaries, and 10 percent of these were foreigners. The largest numbers come from Bretagne, the Massif Central, and the region of the Nord. Among the cities with populations of over 100,000, some, such as Nice and Grenoble, attract an equally diverse population because of their exceptional climate and eco-

nomic conditions. On the other hand, towns such as Le Mans and the Lille-Roubaix-Tourcoing complex recruit their workers entirely from a radius of about 30 miles (50 kilometres). These migrations toward the large cities have had and will continue to have an effect on the distribution of the population as well as upon housing (thousands of abandoned homes fall to ruin in the countryside, while a grave housing shortage exists in the cities), equipment, and employment.

Most of the larger French towns have workers who commute daily from the immediate surrounding area. Once again, metropolitan Paris is the foremost example. The number of people from the Paris region who commute exceeded 100,000 at the beginning of the century and is now nearly 1,300,000. This places a heavy burden on public transport, which carries half the commuters, and it also places a burden on the roads. The Nord also has a complex pattern of daily travel around Lille (involving 37.3 percent of the active working force of the area) and in the coal-mining region; one-third of the towns in the Nord are affected by this sort of displacement.

The reasons for commuting differ greatly according to the town involved: the daily commuters number only 3 percent of the workers of Reims, 12 percent for Besançon, 18 percent for Rouen, 41 percent for Saint-Nazaire, 66 percent for Dunkerque, and 78 percent for the large Peugeot factories at Sochaux. The distances travelled also vary considerably: in the region surrounding Paris, the average commuting time is 1.5 hours per person per day. The Peugeot factories seek their manpower from as far away as 40 miles (65 kilometres). Berliet, at Lyon, transports its workers up to 50 miles (80 kilometres) by bus. Men commute more than women, and blue-collar workers more than white collar. Nevertheless, most employers favour bringing lodgings and the place of work closer together in order to cut down on the fatigue, expense, and discontent caused by such lengthy daily travel.

In certain cases, the commuting area crosses the French border, the commuters from neighbouring countries being called *frontaliers*. This situation exists especially along the northern frontier of France, where the textile factories of Roubaix and Tourcoing and the metallurgical factories of the Sambre Valley attract Belgian workers. In addition, there are a small number of *frontaliers* in industrial northern Lorraine, which attracts a few German labourers. But the reverse situation also exists, and a number of Frenchmen, mainly from Lorraine and Alsace, commute to Germany. Certain jobs, especially in agriculture, do not require a permanent working force and thus appeal to seasonal workers. This is the case in the Mediterranean wine-growing districts, where Spaniards come to pick the grapes in autumn as they have done for years. The recent introduction of grape-picking machinery, however, is probably going to diminish this seasonal migration, which, in the early 1970s, still involved more than 100,000 people (one-half Spaniards, one-third Italians, and some Belgians and Algerians).

More than 21,000,000 people take annual vacations, and the number of people travelling during their holidays is much higher in the larger cities: 58 percent of the population vacate towns of 20 to 100,000 people; 64.3 percent leave towns of over 200,000, and 85.7 percent of Parisians leave Paris for their annual holiday. This involves the movement of considerable crowds of people during the peak seasons, such as school vacations and the large number of paid holidays that fall in August, and saturates transport facilities and popular vacation spots, especially the coastal areas and mountains. More than 15 percent of the holiday takers go abroad, 44 percent to the Iberian Peninsula, and 15 percent to Italy. Conversely, a large number of foreigners visit France; but, in the early 1970s, the economic assets of tourism were almost cancelled out by the expenditure of the French abroad. In order to cater for the needs of the tourist industry, a temporary labour force is necessary, particularly for the hotels, restaurants, and specialized

Commuters and *frontaliers*

Tourism

The working class immigrant

The growth of Paris

businesses. The more affluent are not, moreover, content with one or two holidays a year, many of them having second residences where they spend their weekends. A survey in 1967 showed that one French household in five possessed a second home of this type.

**Distribution of the population.** The average population density in France is 245 per square mile (95 per square kilometre). This is high compared to the average density in the world (70 per square mile, [27 per square

kilometre]) but relatively low compared to France's neighbouring countries (Germany 620 [240], Belgium 823 [318], The Netherlands 826 [319], Italy 470 [182]).

This average density is, however, very unequally distributed. One sparsely populated zone runs south from the outskirts of the Paris Basin to the Massif Central, and there are three regions of very low population: the French-Italian border in the southeast, the French-Spanish frontier in the southwest, and the area skirting

the Atlantic Ocean between Gironde and Adour. In these zones, there is a density of less than 26 per square mile (10 per square kilometre), with a few exceptions. In general, eastern France, with 44 percent of the total area and 63 percent of the population, is more highly populated than western France; it contains 10 of the 12 largest French cities, with 14,300,000 inhabitants within only 2.6 percent of the total area of France. The more lightly populated regions coincide with mountainous areas; regions with poor soil such as Landes and Sologne; isolated rural regions, such as the countryside of the centre of the Aquitaine Basin and east and southeast of the Paris Basin; and, paradoxically, certain very fertile regions, such as Beauce, southwest of Paris, with its vast estates and mechanized farming, yet with a population density of less than 65 per square mile (25 per square kilometre).

Location  
of highly  
populated  
regions

On the other hand, the most highly populated zones correspond closely to the large urban centres. Paris has the highest population, with 8,500,000 inhabitants, followed by Lyon (1,083,000), Marseille (965,000), the Lille-Roubaix-Tourcoing conurbation (990,000), Bordeaux (550,000), Toulouse (440,000), Nantes and Saint-Nazaire (394,000), Nice (393,000), Rouen (370,000), and Toulon (340,000). The coastal areas and valleys are also areas of heavy population, as are the fertile regions, such as Alsace or Limagne, with their small or medium-size estates, or even the verdant cultivated marshes on the northern coast of Bretagne. But the present situation is only one of transition. Since the beginning of the 20th century, the mountainous regions of France have lost about one-half of their population, and, although certain regions, such as the Alps in the north, are being repopulated because of industrialization in the valleys and the construction of winter-sports resorts on the mountainsides, the southern Alps, the Massif Central, and the Pyrenees are becoming more and more depopulated. The countryside has also become subject to some depopulation, but this trend is less obvious since many non-agricultural residents live there, constituting about half of its current population of 16,000,000. In fact, about 100,000 young people leave agriculture annually, and agricultural activity now employs 16 percent of the masculine working population, compared to 35 percent before World War II.

But this movement has been very uneven. For example, less than 10 percent of the rural population remains in Bouches-du-Rhône or in Seine-Saint-Denis, but more than 75 percent still resides on the Côtes-du-Nord, in Cantal, or in Creuse. Thus, there seems to be a regrouping of the rural population: the smaller the township, the more depopulated it has become, villages of less than 100 inhabitants losing 13.4 percent of their population between 1954 and 1962. Townships with more than 1,500 inhabitants, however, have been developing rapidly and the ministry of agriculture foresees the possibility of a regrouping of rural centres with about 5,000 inhabitants, thus preventing a complete desertion of certain regions. Because of the trend toward urbanization, the smaller towns have profited from the abandonment of the mountains and the countryside; and their population, in turn, have overflowed into the spreading suburbs of the large cities.

**Demographic trends and future prospects.** The French population contains, at present, a large number of young people, and, despite the recent perceptible diminution of the birth rate since 1965, it is likely that there will be an increase in the number of births in years to come. In 1970, 848,000 births were registered, but the number exceeded 875,000 in 1971 and was expected to pass 1,000,000 by 1977. In 1970 the number of marriages passed 400,000 for the first time, an increase of 50,000 over preceding years. Since the mortality rate remains at present around 550,000 per year and is likely to remain relatively stable, given present medical and social conditions, there is only a small possibility of a natural growth in the population.

It is hoped that there will be a reduction in the infant mortality rate, even though it is already at 15.1 per

1,000, one of the lowest in the world. The social legislation adopted in 1969 tended to favour a family of four children, which indicated the desire on the part of the political leaders at that time to make every effort to maintain a positive rate of population growth.

Besides its growth, it is likely that the French population will undergo two major changes in the years to come. First, the movement away from the country toward the city and, second, the extension of the suburbs will continue. It is estimated that by the end of the century—of a population of around 75,000,000—60,000,000 people will be urban dwellers. On the other hand, the surplus of young people joining the job market now, in comparison with the number who joined it in the 1950s, is forcing the French economy to undergo transformation and rapid growth. The necessity to create an average of 200,000–250,000 new jobs each year will provide a definite stimulus. The size of the labour force, which was 19,500,000 at the beginning of the century but only 19,000,000 in 1950, grew by only 100,000 between 1954 and 1962, but it increased by 1,400,000 between 1962 and 1970. This growth of the labour force is expected to continue in the years to come, bringing with it grave economic and social difficulties. Since agriculture is rapidly diminishing as a large employer, it will be up to industry and especially to the service sector of the economy to provide the majority of the needed additional jobs.

Although many aspects of French demography are shared by other European countries, such as the low birth rate, the large proportion of the elderly, the relatively high population density, and the importance of the industrial and service sectors among the labour force, other aspects are especially relevant to France. This is particularly true of the high growth in the birth rate at the end of World War II, the high proportion of young people, the depopulation of whole areas of the countryside, and the necessity to create jobs rapidly for the growing labour force. (J.B.-G.)

### III. The national economy

#### FRANCE IN THE WORLD CONTEXT

France's chief claim to fame in the economic field in recent years is the high rate of growth achieved in the 1960s despite various structural and political difficulties. In the 1950s the French economy was one of the most cushioned in Europe; it was protected from outside competition by high tariffs and bolstered internally by heavy government subsidies. In the meantime, French industry has been widely modernized and restructured so that it can now compete on a world basis with other leading industrial nations. Between 1961 and 1971 the gross national product (GNP) grew at an annual average rate of 5.8 percent, a rate of increase bettered only by Japan and equalled only by Italy, among developed non-Communist nations. In the same period West Germany and the United Kingdom grew at the average annual rate of only 4.8 percent and 2.7 percent, respectively. Between 1970 and 1980, France is expected to maintain its position as the fastest growing industrial country in the non-Communist world after Japan. In the same group of countries, France ranks third as a producer of primary aluminum, second as a producer of pig iron, and third as a producer of crude steel. France's industrial base is still narrow, however, compared with those of West Germany and the United Kingdom, and it has fewer really big companies. Agriculture, despite a movement from the land, still plays a disproportionately important role in French economy. After the Soviet Union, France is the largest agricultural nation in Europe and one of the world's leading producers of dairy produce and wheat. With Italy, France is the world's largest wine producer. Since the European Economic Community (EEC), or Common Market, came into existence, in January 1958, France has increased its trade within it more than any other member country. It is the EEC's leading agricultural producer but second to West Germany in terms of industry. France is much less dependent on external trade, however, than the other member countries; its exports

The  
disproportionate  
role of ag-  
riculture

accounted for only 13 percent of its GNP in 1971, compared with a figure of over 30 percent for the EEC as a whole and 23 percent for the United Kingdom, which in 1973 became a member of EEC. The Common Market countries' share of French trade has grown from some 22 percent of all imports and exports to almost 48 percent in 1970, and this is a trend that shows every sign of continuing throughout the 1970s.

#### NATURAL RESOURCES

**Biological resources.** France is the largest country in Europe after the Soviet Union, with a total surface area of 136,000,000 acres (55,000,000 hectares). It contains extensive tracts of fertile soil and is characterized by a temperate maritime climate. Conditions, however, vary widely within the territory, and a wide range of climatic conditions are to be found there. The total agricultural surface area takes up 90 percent of the whole. Arable land and land under permanent crops (47,700,000 acres [19,300,000 hectares]), together with permanent meadows and pasture (34,600,000 acres), account for over 60 percent of this. Forests (34,600,000 acres) take up a further 25 percent. The amount of unused but potentially productive land is estimated at 7,400,000 acres, the highest figure in Europe. Conurbations and towns, which are widely scattered, cover a relatively small proportion of the country. Although in 1971 about 40 percent of France was still under the plow, the area under direct cultivation was dropping steadily. Livestock, notably beef and milk cattle, account for 56 percent of agricultural receipts and products of a vegetable origin for only 44 percent, almost an exact reversal of the situation before World War II.

**Agricultural produce.** France is the largest agricultural producer in Europe, a net exporter of agricultural products, and, apart from a deficiency in tropical produce, such as coffee and certain fruits, it is basically self-sufficient. Wheat, which is grown widely, is the main cereal crop, followed by barley and oats. Rice is grown in the easily irrigated alluvial plains of the Rhône Delta, and its cultivation has spread to neighbouring *départements*. Corn (maize), formerly confined to the southwest, is now grown all over France right up to the northern regions.

Annual French wine production varies between 1,600,000 and 1,700,000 gallons (60,000,000 and 65,000,000 hectolitres). The vine is grown south of a line from Nantes, in the northwest, to Reims, in the northeast, but the major producing regions are in the Mediterranean south. Half the total production, which is mainly for everyday consumption, comes from six *départements* in the south and southeast; Aude, Bouches-du-Rhône, Gard, Hérault, Pyrénées Orientales, and Var. The Bordeaux region produces the greatest amount of quality (*appellation contrôlée*) wine, followed by the southeast and the Bourgogne (Burgundy) area. Other important producing areas include Champagne, the Loire Valley, Alsace, and Charente. Fruits and vegetables are increasingly important crops, which, although widely dispersed, have been grown mainly in Comtat Venaissin (Vaucluse and Bouches-du-Rhône), Roussillon, the Saint-Pol-de-Léon region in Bretagne, Nantes, and the Paris region. These five areas account for one-half the total fruit and vegetable production, which includes a wide variety of produce, the most important being tomatoes, onions, carrots, cabbage, cauliflower, peas, French beans, artichokes, melons, apples and pears, desert grapes, cherries, apricots, peaches, and plums. Root crops, notably sugar beets, potatoes, fodder beets, and fodder turnips, are also grown. About 50,000 metric tons of tobacco are produced in the southwest and in Alsace and meet 70 percent of the country's requirements. France is a leading producer of perfume; special plants are grown for this purpose, notably in the Grasse region, near the Mediterranean, and in the Alpes-Maritimes, which produces essences from bitter-orange trees, roses, jasmine, and violets. Spike and lavender are grown in the Haute-Provence, Drôme, and Lot regions. Medicinal plants are also grown.

**Livestock.** In most areas of France stock breeding takes precedence over crop production. Cattle (about

22,000,000 head) account for over half of all livestock, followed by sheep and pigs, both of which represent around one-fifth of the total. Apart from the Mediterranean area, where their population is scant, cattle are distributed all over the country. Dairy breeds are raised principally in the north and west and, to a lesser extent, the major fattening breeds (beef cattle) in the Massif Central. The Normandy is the most important breed in France (4,500,000 head) and supplies both fatty and high-quality meat. Other notable breeds include the French Friesian (dairy produce), the Charollais, the Limousin, and the sandy Aquitaine (all meat producing). In 1971, 1,600,000 metric tons of cattle and calf meat were produced, while dairy herds yielded 33,000,000 metric tons of milk. Butter production is in surplus, and France is the second world producer of cheese. Sheep (over 10,000,000 head) are mainly concentrated in the mountainous regions of central and southern France (Causses, the southern Alps, and Corsica). They are bred primarily for meat, producing about 120,000 metric tons annually, and they also supply some 10 percent of the French woollen industry's needs. About 13,000,000 gallons (48,000,000 litres) of ewe's milk are produced annually in the Roquefort area, Provence, and in Corsica for the manufacture of cheese. Goats (about 924,000 head) are reared chiefly in western central and southeast France, where their milk is used exclusively to manufacture cheese.

**Forestry.** About one-quarter of France is covered with forests, the principal forests being the Ardennes, Compiègne, Fontainebleau, and Orléans. Where the Atlantic (maritime) climate prevails, oaks predominate, along with beeches and poplars. Much of this area, however, has been reforested with pines and other softwoods that are more suitable for commercial and industrial use. There are valuable coniferous forests in the mountains of the Alps, Jura, Vosges, and Pyrenees. The Landes region, with its maritime pine, is particularly important for resin and timber for the pit props used to support the roofs of underground passages in coal mines, railway ties, and telegraph poles. Deciduous trees (half of them oak) account for 66 percent of the total and conifers 34 percent (about two-thirds pine). The productive capacity of the French forests in timber and industrial wood is around 1,000,000,000 cubic feet (30,000,000 cubic metres) annually. This figure is currently being raised by continued reafforestation under the guidance of the Fonds National Forestier (National Forest Fund).

**Mineral resources.** With the exception of extensive deposits of coal, iron ore, and bauxite, France is not particularly rich in mineral resources. Scattered deposits of zinc, lead, copper, tin, and gold do occur in the crystalline rocks of the highlands and mountains, but they are generally small and hence supply an insignificant proportion of the country's needs. Coal is mined principally in the north alongside the Belgian frontier in the Pas-de-Calais and Nord regions (42 percent of total production) and in Lorraine to the east, in the Moselle region (32 percent of total production). Much of this coal is deeply buried, and mining tends to be both difficult and costly. Pits in Lorraine, however, have achieved the highest level of output per man in Europe. French coal reserves are estimated to be 10,000,000,000 metric tons and home production satisfies approximately 70 percent of the country's needs. In 1971 monthly average production was at the rate of 2,980,000 metric tons. France is seriously short of the coking coal necessary for smelting in the iron-and-steel industry, and, in the main, this category has to be imported. The minor coal-producing areas are in the Loire, Cévennes, Blanzy, Aquitaine, Provence, Auvergne, and Dauphiné regions. As elsewhere in Europe, coal output in France is being cut back in line with the rapid development of alternative sources of power.

France ranks third in the world as a producer of iron ore after the Soviet Union and the United States. Lorraine is the main producing area, followed by Normandie, the Anjou Basin, and the Pyrenees. Reserves are estimated at 8,017,000,000 metric tons, of which Lorraine has 6,000,000,000 metric tons, Normandie 500,000,000 metric tons, and deposits in the centre and

The major cattle breeds

Wine production

Coal reserves

Iron production

Bauxite  
and other  
nonferrous  
reserves

Pyrenees 17,000,000 metric tons. French iron ore is low grade—only 30 to 35 percent iron compared with ore of 50 to 70 percent iron content mined in other leading producer countries. It is generally easy to extract, partly because the beds are not generally disturbed by faults; hence, large-scale techniques for mechanical extraction are employed. Iron-ore production reached a peak of 66,600,000 tons in 1961 but has dropped steadily since. In 1971 total production of iron ore was 55,882,000 metric tons, sufficient to supply 90 percent of the French iron-and-steel industry's needs and to allow for sizable exports to West Germany, Belgium, and Luxembourg. As more steelworks are established on the coast, such as the plant at Dunkerque, and are thus readily accessible to high-grade imported ores, home-produced ore is bound to decrease in importance. France is one of the leading producers of bauxite, which takes its name from the small village of Les Baux, near Arles, where it was first mined in 1882. The chief workings in the early 1970s were east of there in Var, especially around Vignoles, and also in Languedoc. Total French production of bauxite was 2,997,000 metric tons in 1971, which accounted for most of the country's needs. Production of other nonferrous metals, such as zinc, lead, tin, antimony, tungsten, and vanadium, accounts for only a small proportion of the country's needs. As a gold producer, France ranks about third in Europe (48,000 troy ounces in 1969) after the Soviet Union and Yugoslavia.

A certain amount of uranium ore is mined in the Massif Central and the Vendée; a total of 800,000 metric tons was mined in 1970. Large deposits of salt are found in the Triassic rocks (about 190,000,000 years old) of Lorraine and also along the edge of the Jura Mountains, in Franche-Comté. Sea salt is also produced along the Mediterranean coast by the traditional solar-evaporation method, and there are important deposits of potash in the plain of Alsace north of Mulhouse. Total French potash production in 1971 was 13,922,000 metric tons. Potassium production in the early 1970s stood at around 1,800,000 metric tons annually, about 20 percent of total world production. France produces more than 1,800,000 metric tons of sulfur annually, mostly from natural gas.

Natural  
gas and  
petroleum

Almost all French petroleum has to be imported, although the Parentis wells in the Landes area, on the Atlantic coast, produce a maximum of 3,000,000 metric tons of oil annually, and efforts are being made to increase home production of petroleum with prospecting in the southwest, both on land and offshore and in the North Sea area. Despite France's lack of currently producing wells, the country has an important oil-refining industry that utilizes imported crude oil. Its total annual capacity in 1971 was 116,000,000 metric tons. The principal plants are in the Nord, Basse, Seine, Atlantic, Mediterranean, and Alsace areas. And, as a result of an oil strike at Lacq at the foot of the Pyrenees in southeastern France, an extremely large field of natural gas was discovered. Worked since 1957, it supplies 180,600,000,000 cubic feet (5,000,000,000 cubic metres) annually to the grid that runs from Lacq to Paris. Gas supplies at Lacq are sufficient to last until 1980. Another field discovered more recently at Meillon is thought to be half the size of Lacq but will add considerably to the country's natural-gas production, which is rapidly replacing manufactured gas. In the north and northeast, where gas requirements are currently met by gas fed into the grid by Lorraine steelmakers as a byproduct of their coking process, natural gas from the Netherlands Groningen field was expected to replace manufactured gas by 1975. Natural gas is also imported from Algeria in liquefied form and is used in the Paris area.

**Hydroelectric resources.** Because of its climate and geography, France enjoys considerable water resources, and, since World War II, there has been a rapid development of hydroelectric power. Major rivers include the Seine, Rhône, Saône, Garonne, and Loire, and there are 6,200 miles (10,000 kilometres) of navigable rivers, with an additional 3,300 miles (5,300 kilometres) of canals. Further, mountainous terrain in the Massif Central, in

south and south central France, in the Pyrenees to the southwest, and in the Alps to the east and southeast provides ample hydroelectric potential. In 1969 there were 1,640 hydroelectric stations, including the Rance tidal power station in Bretagne, which has a total rated power of 13,000,000 kilowatts.

Hydroelectric-power production is linked to climatic conditions and thus fluctuates annually, but, at the beginning of the 1970s, it stood at 57,000,000,000 kilowatt-hours, and currently it accounts for a little over 40 percent of total electricity production.

#### SOURCES OF NATIONAL INCOME

**Agriculture, forestry, and fishing.** Agriculture and forestry accounted for 6.6 percent of the gross national product (GNP) in 1970. Although agriculture's share of total production showed a steady drop during the 1960s, it was still higher than in many other industrial nations. As the leading agricultural nation in Europe, France is virtually self-sufficient as a producer, and it exports a considerable amount of produce, especially to other Common Market countries. Yet, French agriculture is the weakest sector of the economy. In general, French farms are too small; the farmers are too numerous; and the introduction of modern methods of cultivation and husbandry has been slow.

**Farming.** About half the farms are less than 30 acres (12 hectares), and, although the total number of farms is diminishing by about 2 percent annually, there are still almost 1,600,000 individual holdings. In 1968 the total agricultural population, including dependents, was over 6,000,000, including over 3,000,000 who actually worked on the land, or 15 percent of the country's total working population. This proportion again has been falling steadily, for more than 150,000 farmers have been leaving the land annually in recent years. Output per worker is still much lower than in other branches of the economy, and agricultural wages are about 30 percent below those of industrial workers.

Government policy in the early 1970s was geared to restructuring the farming industry into larger units, and, through various retraining schemes, it was encouraging subsistence farmers to leave the land. Elderly farmers who left were given a small pension. As a result of these and other factors, individual farms are gradually getting larger and more efficient, particularly in the northern half of the country, and there has been a marked growth in farming cooperatives, in which equipment is pooled or farms have been actually merged together. There were 1,448 cooperatives in 1969, compared to 363 in 1967.

While productivity per acre has doubled in France since 1949, this improved performance has been marred by overproduction in some sectors, notably of fruit, dairy products, and cheap wines. To counteract this, the government is encouraging farmers to switch to meat production and to develop the canning industry to absorb seasonal fruit surpluses. Much progress has been made to raise the overall quality of wine production (high-quality wine accounts for only 14 percent of the total), and the poorest wines are now banned from the market altogether, which has somewhat mitigated the problem of overproduction. Agricultural marketing facilities have also been improved since the government establishment of a number of regional markets outside Paris. These have helped to cut transport costs and reduce price fluctuations. The farmers themselves, with government backing, have also formed marketing groups of their own.

In general, French agriculture has benefitted from the establishment of the Common Market. Increased agricultural production by the other member countries, however, has reduced sales opportunities for French products among EEC nations. This applies particularly to cereals, France's chief agricultural export, despite the hard-fought 1967 Common Market agreement on grain prices. This minimum guaranteed price has chiefly benefitted the big French wheat growers in the north at the expense of other growers, especially in the southwest, who are relatively distant from consumer centres. France gains

The chief  
agricul-  
tural  
export

over 100,000,000 francs annually from the Common Fund (the tax on food imports from outside the Common Market, paid mainly by West Germany and Italy). This helps to reduce the cost of the French government's wheat subsidy that guarantees the price of wheat. The other sectors that have benefitted most are beet sugar, wine, dairy products, and cheese.

**Forestry.** French forests are a vital part of the economy. Roundwood production is among the highest in Europe and is topped by only Finland and Sweden. In the 1960s total production reached a high point of 58,700,000 cubic yards (44,900,000 cubic metres) annually, compared with a high point for the other two leading producers of some 69,000,000 cubic yards (53,000,000 cubic metres).

State- and community-owned forests account for 35 percent of the total forest area. Considerable replanting has been undertaken both by the National Department of Forests, established in 1964, which manages most of the controlled forests, and by the Fonds National Forestier (National Forest Fund), the basic instrument of French reforestation policy, which, since its formation in 1946, has been responsible for the reforestation of over 2,500,000 acres (1,000,000 hectares). These operations are expected to raise the productive capacity of forests in timber and industrial wood by 5,900,000 cubic yards (4,500,000 cubic metres) annually.

**Fishing.** French fish catches, at 762,000 metric tons in 1970, were the fourth highest in Europe, and the industry is of considerable domestic importance. Half the fishermen live in the coastal zone of Bretagne, where they are engaged in seasonal fishing, and five ports—Boulogne-sur-Mer, Concarneau, Lorient, Douarnenez, and La Rochelle—account for over half the total French catch, which mainly consists of cod, herring, halibut, sardine, mackerel, and tunny. There is also considerable oyster cultivation in the silted estuaries and lagoons of the Biscay coast.

**Mining and quarrying.** Just under 1 percent of the GNP is accounted for by mining and quarrying, which is a drop of 0.8 percent of the GNP in 1960. In 1967 and 1968 monthly production indexes (1962 = 100) fell below the 1966 level of 109. A recovery in 1969 pushed the index up to 116, where it remained in 1970. Other key sectors registered a marked increase in production during the 1966–70 period.

The poor performance of mining and quarrying is accounted for by the running down of the chief extractive industries: coal and iron ore. The coal industry, which was nationalized after World War II, has suffered from the competition of oil and other sources of energy. Production has been cut back from 60,000,000 metric tons in 1958 to an annual target of 46,500,000–49,500,000 metric tons in the early 1970s. The number of miners was reduced from 127,000 in 1960 to 91,000 in 1967, and some pits have been closed. In the early 1970s the industry received extensive annual government subsidies despite the often unfavourable structure of the coalfields, and many pits have been modernized and productivity raised. The output per man in the Lorraine coalfields of 7,500 pounds (3,400 kilograms) per man-day in 1971 is the highest in Europe. In recent years the industry has increased its chemical activities. This trend, together with further rationalization, or reorganization, of existing pits, will help to cushion the industry from the effects of falling production.

Iron-ore production has dropped from a peak of 67,000,000 metric tons in 1960 to 55,882,000 metric tons in 1971, because French exports have suffered at the expense of much higher grade foreign ores. Moreover, as the iron-and-steel industry shifts westward to the sea from its traditional centres on the northern coalfield and in the Lorraine Basin, imported ore will be used increasingly in France itself. The modern Dunkerque steelworks, for example, already use ore from Mauritania.

The quarrying of construction materials is carried out at a wide variety of sites all over the country, and about half the production of the main categories is exported. These categories include limestone construction blocks

(about 330,000 cubic yards [250,000 cubic metres] produced annually); granite slabs (about 160,000 cubic yards annually); sawn marble slabs (2,900,000 cubic yards annually); roof slates (120,000 metric tons annually); concrete blocks (8,000,000 metric tons annually); asbestos-cement products (900,000 metric tons annually); and ready-to-use concrete (about 5,200,000 cubic yards annually).

**Manufacturing.** France is fourth in the league of industrial nations in the non-Communist world, ranking after West Germany. Manufacturing accounted for 37.8 percent of GNP in 1970, and the overall GNP grew by 5.7 percent annually between 1965–71, a record bettered only by Japan. Despite this, however, overall industrial performance was rather variable during the period: growth was by no means steady, and some sectors fared far better than others. Between 1966 and 1970 the monthly industrial production index rose by 22 points, and the index for manufacturing industries (excluding machinery and mechanical products) rose by 29 points. The largest increase was registered by chemicals, which rose 62 points over the period. Appropriately, France is the fourth largest exporter of chemical products in the world. The index for textiles, clothing, and footwear rose by only six points. In 1967 and in 1968, the year of a general strike, relatively poor performances were registered in all sectors. In that year, car production dropped below the level of the previous year, but real output recovered in 1969 and 1970 and, over the period of the Sixième Plan (Sixth Plan [1971–75]), was expected to grow at the rate of 6 percent annually.

Although French industry has become much more competitive and exposed to international influences since the establishment of the Common Market, certain sectors lag woefully behind its main competitors. Hence, there is still considerable room for restructuring and rationalization. A major difficulty is the fact that France has fewer large firms than most other major western European countries. Of the 10 largest French production companies, moreover, three are state owned and another two are French subsidiaries of international oil concerns. Thus, the role of private French capital is relatively small. Out of a total of 689,877 firms in French industry in 1966, 614,119 employed under 10 people, and only 638 employed more than 1,000. Large- and medium-size firms, however, are as modern as any in western Europe.

The government actively encourages mergers, and industry has become much more concentrated as a result, both in the old-established industries and the newer, dynamic industries, such as chemicals and computers. In 1970, for example, Pechiney and Ugine-Kuhlmann decided to merge, thus giving France a firm of world stature in the nonferrous-metal industry and the fifth largest firm in Europe. In the steel industry two large groups, Usinor-Lorraine-Escaut and Wendel-Sidelor, account for 70 percent of the country's production; and in the period 1966–68 there were over a dozen merger and association agreements signed. In the motor industry Renault and Peugeot are working together, and the linking up of the Italian auto concern of Fiat with Citroën gives France a stake in what is now Europe's leading motor-manufacturing company (ahead of the German Volkswagen Company). These mergers appear to be intensifying in the 1970s.

France in the 1960s was able to achieve a good growth rate with a relatively low rate of investment in relation to its GNP. But a higher rate of investment, which is advocated by the government, was seen to be necessary if this progress was to be maintained. In 1970 this advocacy produced results: productive investment was 28.1 percent of the GNP, compared with West Germany's 27.3 percent. In previous years France had lagged substantially relative to West Germany and the result of this previous shortfall in investment was a lag in scientific research. Only 1.5 percent of the GNP is spent on research, compared with over 3 percent in the Soviet Union and the United States, 2.3 percent in the United Kingdom, and 1.8 percent in West Germany. The greater part of government research expenditure finances military and nuclear projects and

Industrial problems

The running down of the chief extractive industries

university research. Few French firms have research facilities adequate to compete in their fields on a world scale.

**Energy.** France's energy requirements have risen rapidly and this rise is expected to continue. The period 1966-70 showed a rise in primary-energy consumption of approximately 30,000,000 metric tons coal equivalent, from 168,000,000 metric tons in 1965 to 226,000,000 metric tons in 1970. Coal and oil between them account for nearly 85 percent of primary-energy consumption, but since 1965, when almost equal amounts of each were used, oil has been increasing its share in total consumption at the expense of coal. In 1971 France imported 100,100,000 metric tons of oil (mainly from North Africa and the Middle East), compared with only 29,200,000 metric tons in 1959. Home oil production, which varies between 2,500,000 and 3,000,000 metric tons annually, accounts for a fairly insignificant proportion of requirements. Coal production, which supplies 80 percent of the country's needs, fell from well over 58,000,000 metric tons in 1960 to 40,100,000 metric tons in 1970.

There has been a spectacular increase in the production of natural gas, which is rapidly replacing manufactured gas both in industry and the home. In 1970, 2,650,000 metric tons of liquefied gas were produced with imports (from The Netherlands and Algeria) of 181,000 metric tons, compared with a home production of 864,000 metric tons and imports of 30,000 metric tons of liquefied gas in 1959. In 1965 gas accounted for 5 percent of primary-energy consumption; by 1975 this proportion is expected to rise to 10 percent.

Although in the mid-1960s, hydraulic electricity accounted for over one-fifth of primary-energy production (18,800,000 metric tons of coal equivalent), its share of total electricity production (140,700,000,000 kilowatt-hours in 1970) had fallen because the output of thermal electricity has increased. About 30 percent of the country's hydroelectric potential remains untapped; yet, the best sites have already been utilized and the need to absorb home coal production and the relative cheapness of this fuel have favoured thermal stations.

In 1971 monthly average output of thermal electricity was 8,209,000 kilowatt-hours (4,500,000,000 in 1966), while monthly average output of hydraulic electricity was 3,969,000 kilowatt-hours. In the past, demand for electricity has doubled every 10 years. The production and distribution of energy in France is basically in the hands of the state. It is thus subject to tighter control and benefits from more detailed planning of future requirements than the equivalent industries in many other countries.

Electricité de France, formed in 1946 after the nationalization of electricity companies, accounts for over 85 percent of total electricity production. The company is France's largest single investor employing 94,400 people.

Charbonnages de France (the French coal board) controls and coordinates the management of French coal mines, which are split up into nine management areas. The industry was nationalized in 1946. The gas industry is controlled by the state company Gaz de France, which produces and distributes only about 30 percent of the country's gas consumption, partly because many industries produce their own gas or purchase it directly. The Lacq natural-gas deposit, France's main source of supplies, is worked by the Société Nationale des Pétroles d'Aquitaine, in which the state is majority shareholder.

A public concern, Entreprise de Recherches et d'Activités Pétrolières (ERAP), supplies about 40 percent of the country's crude-oil requirements; it owns various refineries in France (Ambès, Feyzin, Grandpuits, Porcheville) and abroad, competing with the international oil companies established in France (Shell, Esso, British Petroleum, and Mobil). ERAP's subsidiary company, Essences et Lubrifiants de France, handles distribution.

French refining capacity has risen steeply and stood at 116,000 metric tons in 1970. Net production from refineries in France rose from 28,000,000 metric tons in 1959 to 93,100,000 metric tons in 1970.

France ranks fourth in the world as a nuclear power and has already built five reactors of various types em-

ploying natural uranium, graphite, and carbonic gas for the generation of nuclear electricity. A sixth was due for completion in 1972. Various technical difficulties have so far held back the expected growth of nuclear electricity production, but it was expected to account for 5 percent of total production in 1972. Further, research is being pursued by France's Commissariat à l'Énergie Atomique (Atomic Energy Commissariat) on fast-breeder reactors and an experimental station of this type was opened in 1967.

**Financial services.** The state is the dominant influence in French banking and finance, and, although there are a large number of financial institutions in the country, the money and capital markets are less well developed than in other advanced economies. Equity capitalizations and new issues are much lower in relation to GNP than in other European countries, and the Paris Bourse (the main stock market) does not fulfill as important a role in the raising of industrial capital as in other countries. State loans supply much of the necessary capital. Savings in France have also tended toward state loans or bonds and (in times of crisis) gold rather than ordinary shares.

The Banque de France, the central bank, has the sole right of note issue. It was nationalized in 1946 when the state also took over the four leading commercial banks, Crédit Lyonnais, the Société Générale, Comptoir National d'Escompte de Paris, and the Banque Nationale pour le Commerce et l'Industrie. The last two later merged into the Banque Nationale de Paris. Between them, these banks account for half of all assets and liabilities among French banks. Out of a total of about 300 banks, about half are purely local. In addition to the commercial banks, there are a large number of specialized credit institutions, including national and regional agricultural credit banks, savings banks, and the Crédit Foncier de France (official loans to finance construction). Nevertheless, half of all savers' deposits go outside the banking system proper into the Caisse d'Épargne (the postal-check system) and Crédit Agricole.

The banking system has seen considerable reform as a result of administrative and legal measures taken in 1966 and 1967 to make it more up-to-date and competitive. The most important change was the abolition of the traditional legal distinction between merchant banks (*banques d'affaires*) and clearing banks, such as the commercial banks already mentioned (*banques de dépôts*). This was accomplished by allowing the former to accept small depositors and the latter to play a bigger role in industrial finance. At the same time, the treasury reduced its issues of bonds direct to the public, and, for the banks themselves, a more modern system of treasury deposits was introduced, under which the banks were no longer forced to keep a minimum holding of treasury bills. As a result, there has been greater competition for depositors' money, and the role of the banks has been strengthened and brought closer in line with practices in what French observers often term the Anglo-Saxon countries. This new competitiveness has led to a spate of mergers, notably among the smaller merchant banks.

Until 1968, French governments generally favoured a cheap-money policy, but, at the end of 1970, the bank rate was 7 percent, after falling in two stages from its earlier high point that year of 8 percent.

Since the end of the 1960s, the Paris Bourse has shown a considerable increase in its activities. In 1969, for example, running transactions increased by 45 percent for the second year in succession and more than twice the 1967 volume. Yet the Bourse's growth was still impeded by various factors, such as the government's tendency to impose an exchange control that hampers dealings in foreign shares, the general "heaviness" of shares, and the low standard of disclosure in company accounts.

Mutual funds, or unit trusts, were illegal until 1963, and they are still obliged to keep 30 percent of their portfolios in fixed-interest government bonds. But they have grown in recent years, and this has greatly increased public interest in investing in shares. There has also been some growth in insurance-linked funds that enjoy certain fiscal advantages.

**Foreign trade.** Although France's exports grew at 9 percent annually during the 1960s and showed a rise of 14.4 percent between 1970 and 1971, there has been a deficit in the visible balance of trade since 1963. Some improvement was shown when the franc was devalued by 11.1 percent in August 1969, and the balance moved into a small surplus in the early 1970s. Despite the rise in exports of goods and services, France is far less dependent on foreign trade than most other European countries. French exports account for only 13 percent of GNP, compared with a figure of over 30 percent for the Common Market as a whole and 23 percent for Great Britain.

Since the Common Market, or EEC, came into existence in January 1958, the pattern and direction of French trade has altered markedly. In 1958 imports from Common Market countries accounted for 22 percent of all French imports, but by 1970 this figure had risen to 48.3 percent. There was a similar movement in exports to the Common Market countries from 22.3 percent of the total in 1958 to 48.4 percent in 1970. Between 1965 and 1970 French exports to the EEC rose on average by 16 percent a year and imports from the EEC by 19 percent. France has increased her trade proportionately more within the EEC than any of the other member countries, her main customers being West Germany, Belgium, and Luxembourg. Although trade with countries of the franc zone (which includes most former French colonies) remains fairly steady, at around 12 percent of total trade, and France enjoys a favourable balance with those countries, trade has fallen considerably over the last 12 years. Trade with the franc zone accounted for 32 percent of the total in 1958. Outside the confines of the Common Market, France's main trading partners are the United States and Switzerland.

During the 1960s, there were significant changes in the relative importance of the main categories of goods traded. Most noticeably, imports of food, tobacco, and beverages dropped from 25.2 percent of imports in 1958 to 12.0 percent in 1971, whereas exports of food rose from 13.3 percent of total exports to 16.8 percent during the same period. And, in line with the other EEC countries, France has greatly increased her exports of machinery and transport equipment, from 23.4 percent of total exports in 1958 to 32.7 percent of the total in 1970. Imports of the same accounted for 25.0 percent of total imports in 1970, giving France a favourable balance in this sector. It seemed likely that this sector, together with chemicals and motor vehicles, which have also shown marked growth, would play an increasingly important role in French foreign trade in the 1970s.

#### MANAGEMENT OF THE ECONOMY

**Private enterprise and the role of the government.** In France the state plays a more dominant role in the management of the economy than in most of the other Western industrialized countries. The money market is generally closely supervised by the state, which, in any case, owns the three main commercial banks as well as the central bank (Banque de France). About 30 insurance companies with half the country's premium income are state owned, as are a number of credit institutions outside the banking system proper. Institutions such as insurance companies and pensions funds play a much less dynamic role in investment in France, and the stock market itself is a relatively limited source of finance for industry, which depends disproportionately on state loans. This means that the state can exercise a tight control over private-sector investment. Private industry itself occupies a relatively weak position in the economy. Out of the 10 largest production companies, three are state owned and two are French subsidiaries of international oil concerns. Investment by the public sector actually accounts for half the annual total of all investments. The sector includes coal, electricity, gas, the railways, Renault (France's largest motor manufacturer), and the tobacco industry—over which there is a state monopoly.

Under the French system of planning, which was instituted after World War II, targets are set for the various sectors of public and private industry and the whole op-

eration is controlled and coordinated by the Commissariat général du Plan (planning office). Each plan now covers a period of five years and is based on estimates of the likely growth of production and demand in each major sector of the economy and the amount of investment needed to fulfill these targets. The plans have a good record of success. During the Fourth Plan (1962–65), for example, actual annual growth of the gross domestic product was at the rate of 4.8 percent, compared with a target rate of 5.5 percent. During the Fifth Plan (1966–70), the actual rate of growth slightly exceeded the target rate of 5 percent annually. One of the basic aims of these plans has been to improve the international competitiveness of French industry, and, as such, they have played an important part in the economy's growth in recent years.

Before a plan is approved by the government, there are consultations between the plan office and the government on the aims and structure of the final document, and then detailed discussions are held within the framework of the plan office with the interested parties, various experts, and civil servants. Apart from the budget, which is geared to the aims of the plan, the government can use a number of other techniques to regulate the economy. It can adjust the amount of public-sector investment, can determine the quantity of orders placed by government departments, which play a dominant role in some sectors (e.g., the electronics industry), and can fix the price of certain basic products (e.g., steel). Price increases, generally, are subject to strict government surveillance. More indirectly the government can encourage mergers or decentralization operations favoured by the plan, with offers of various tax concessions, and specify the conditions on which state loans are granted. In addition, specific grants may be made for scientific and technical research. By keeping the various interested parties informed of the effects of their decisions and of likely movements in the economy, the plan office has been able to achieve a fair degree of harmonization of the country's economic effort. And these plans have come to be regarded as models for free-enterprise societies. Improvement of French industry's international competitiveness was a central feature of government economic policy during the Fifth Plan (1966–70), and this move to restructure French industry has been carried on as a central feature of the Sixth Plan (1971–75).

**Taxation.** Balanced budgets have not been traditional in France, although, under Gen. Charles de Gaulle during his term as president of the Fifth Republic, from 1959 to 1969, deficits were kept down to reasonable proportions and there were surpluses in some years. The budget is not the major instrument of economic policy as it is in many other Western countries, since its outlines are laid down some six months before it comes into effect and it is thus generally too inflexible to control the business cycle. Company taxes are assessed at a flat rate equivalent to 50 percent of net profits, although this may be reduced in the case of certain capital gains.

Personal income tax is assessed at progressive rates and takes into account such factors as size of families and dependent relatives. Its impact varies, depending on the source and nature of income, and there are over a dozen different categories of taxation. At present there is no "pay-as-you-earn" (PAYE) system for deducting tax from wages at the source, and evasion is widespread on all incomes. In fact, fewer than half of all French households pay any direct tax at all, and, with over two-thirds of total tax revenue coming from indirect taxes, the French tax system is among the most inequitable in Europe. Reforms introduced in the early 1970s, however, were expected to reduce the burden of indirect taxation and remove the various inequities applying to the assessment of personal income tax so that eventually it will be assessed on the same scale for everyone. To a large extent the success of these reforms depends on the eradication of tax evasion.

Social-security contributions are deducted at the source and are not included in statements of gross income. The system is financed almost entirely out of contributions

The role of economic planning

France's main trading partners

Personal income tax

levied on the first 11,970 francs of an employee's annual income. He pays 6 percent in annual contributions and the employer 20.25 percent. Total social security revenue was 14,280,000,000 francs in 1969. The government claims that about 98 percent of the population is covered for basic sickness payments.

**Trade unions and employer associations.** Strikes have been relatively infrequent in France, with the exception of the general stoppage of May 1968, which was the biggest in Europe since World War II and involved 9,000,000 people. When they do occur, strikes tend to be short-lived. Only about 20 percent of French workers are thought to belong to unions, and an even smaller proportion are fully paid-up active members. The unions tend to be divided among themselves on political and ideological grounds. In the past they have also been organized in geographical rather than industrial units, though individual sectors have grown up recently in major industries, notably chemicals, oil, gas, and electricity. The three largest unions are the Confédération Générale du Travail (CGT; Communist led and inclined), with an estimated membership of 2,400,000; the Confédération Française Démocratique du Travail (CFDT; Catholic inclined), with an estimated membership of 800,000; and the Force Ouvrière (FO; Socialist), with an estimated membership of 1,000,000. There is also a white-collar workers' union, the Confédération Générale des Cadres (CGC), with 250,000 members.

The employers' organization, the Conseil National du Patronat Français, represents 900,000 concerns employing around 8,000,000 workers. It is organized on a regional and industrial basis, with one unit for each industry in each region. At a national level these local units are then grouped into federations. There is also the Centre des Jeunes Patrons, which represents employers under the age of 45. There is no formal link between the Patronat and the unions; but discussions are held between them at a national level, and in the past they have reached a number of agreements on labour and social conditions. Collective-bargaining procedures are laid down for both the public and the private sectors of industry, although the government may enter directly into negotiations, as in June 1968; and it has been influential in bringing about a number of one-year agreements on wages and working conditions in several of the nationalized industries.

Wages in industry have tended to rise much more rapidly since the 1968 general strike than in earlier years. Average hourly rates rose by over 30 points on the wages index between 1968 and 1970, an unusually large increase. But in some sectors there is significant unemployment for the first time in many years. Like many other countries, France is now faced with the problems of trying to maintain full employment, keeping wage increases down to a reasonable rate, and maintaining her competitiveness in international markets. And, although French industry benefitted from the 1969 devaluation of the franc, inflation and the 1971 international monetary crisis threatened to remove these gains sooner than was expected.

**Contemporary economic policies.** After the relative successes of the Fourth and Fifth national economic plans, the Sixth Plan, which covers the period 1971-75, appears less certain in its objectives and quotes fewer hard figures. Over the years the French economy has become much more open to world pressures, such as the recurrent bouts of worldwide inflation; and, since the reduction and removal of the various tariff barriers, which had made France one of the most protected of world markets in the 1950s, the economy has become less easy to control. The Sixth Plan, nevertheless, looks for a growth in real output of just under 6 percent annually. This may be compared with the Organization for Economic Co-operation and Development (OECD) target rates for West Germany, Italy, and the United Kingdom over the 1970-80 period of 4.5 percent, 5.6 percent, and 3.1 percent, respectively. The main intention of the plan is to continue the reorganization and restructuring of industry begun in earlier plans, particularly in the produc-

tion of electronics, chemicals, and machinery. Improvements are also planned for the telephone service, the roads, major ports, such as Le Havre and Marseille, and amenities in rural areas. In addition, priority has been given to the development of medium-size towns, as part of the government's long-standing drive for growth in the regions outside Paris. Old-age pensions and the lowest wages will be reviewed every year, and a range of improvements is expected to be made in the social services.

**Problems and prospects.** Many of the features of the Sixth Plan imply a rapid expansion of government spending. But public investment has often been used as an economic regulator in the past, so that, if the economy has to be slowed down, money earmarked for such projects as roads, housing, telephones, and schools may not be spent. At the same time social pressures have been building up in France since the troubles of May 1968, and the unions are pressing for shorter hours and earlier retirement dates. With a budget deficit forecast for 1972, the government will have little room to manoeuvre, especially since many of the cutbacks and various restrictions in spending applied after the 1969 devaluation are still in force, although some of these have been relaxed.

France's main problem remains that her industrial base is still smaller than that of West Germany or even of the United Kingdom. Although the annual value of output per person, calculated at 39,662 francs in 1971, is higher than elsewhere in the Common Market (31,500 francs in West Germany, for example, and 21,588 francs in the United Kingdom), too many people are still employed on the land and in small businesses. In the early 1970s, the labour force is expected to rise by about 1 percent a year, thus bringing potential increases in productivity. But unemployment, which was kept down to an average of about 1 percent of the labour force between 1965-70, has been rising steadily since then. In 1971 it was not serious compared, for example, to the situation in the United Kingdom, but it provides yet another warning light to the government, which is committed to full employment. Some economists believe that many of these problems could have been ameliorated if the government had plumped for a higher growth rate when deciding the targets of the Sixth Plan. But a more rapid rate was ruled out precisely because it would have exacerbated social problems brought by the provisions of earlier plans, such as the restructuring of industry, the movement from the land, and heavy spending on capital investment at the expense of housing, education, roads, and public transport. France's goal to repeat its economic successes of the 1960s in the 1970s will not be achieved without difficulty. (E.I.U.)

#### IV. Transportation

##### THE OVERALL SYSTEM

**Geographical and economic influences.** French transportation has been influenced by a number of factors. First, the low population density in many parts of the country and the generally uneven spread of economic wealth and industrial development means that the centres of production and consumption are widely dispersed, leading to high transport costs and organizational problems. Second, the topography of the country has played a key role in the development of transport; the main routes have grown up usually along the line of the principal river valleys. Third, the concentration of one-fifth of the country's economic activity on Paris and its surrounding areas has led to the growth of a radial transport system with Paris at its centre. Finally, the rapidly expanding rate of industrialization means that new modes of transport have had to be developed, and there are inevitable difficulties in adapting a transport system that is based on a 19th-century network to the needs of the modern economy. The automobile industry is the most significant transport sector in the French economy. It consumes about 20 percent of the country's sheet steel, 50 percent of all rubber, and 90 percent of tempered glass. Although investment in all types of transportation remains high, it varies widely according to the type of transport. Thus, while investment in air transport almost doubled between

Dilemmas concerning the growth rate

The three factors influencing the transport system

The influence of world trends on economic policy

1967 and 1968 and grew by 10 percent in road transport, the French railways, the Société Nationale des Chemins de Fer Français (SNCF) showed a decline of more than 5 percent.

**Freight transportation.** The transportation of goods can be classified into three distinct categories, each of which has developed in a different way.

**Heavy-goods consignments.** First, heavy-goods consignments of 500 metric tons and over are carried either in trainloads or by waterways and pipelines. Such consignments represent one-third of the total volume of all goods transported. The principal products carried include iron ores, coal, and grains, which together represent two-thirds of the volume of such shipments; however, products such as refined hydrocarbons and chemicals are growing in importance. By 1985 the Paris region alone will require some 100,000,000 metric tons of construction materials annually, nearly half of which could be feasibly transported by shipping on the Seine.

While trainloads of such single products are some of the most profitable undertakings of the French railways, or SNCF, transportation by waterways has experienced certain difficulties. Bargemen and sailors have found it difficult to adapt to modern cargoes, despite a growing traffic in such products as grains and construction materials. Also, facilities remain generally inadequate and out-of-date, although a national plan for inland waterways has somewhat mitigated the problem with a program of conversion and modernization.

**"Truckload shipment."** The second category of goods transportation is the "truckload shipment," comprising consignments of up to several hundred tons. Such goods are transported in lots of three tons by road or five tons by rail, and this form of transport is the greatest in terms of ton-miles. The transport market in this category is divided between some 33,000 trucking firms and the SNCF, the latter showing a large deficit in this field, for it has been unable to increase its share of the traffic.

**Retail shipments and packages.** The third category is the transport of retail shipments and packages. This involves the distribution of manufactured products to retail centres; they are dispatched in consignments of low tonnage, which means a larger number of handling operations are necessary. The scattered geographical locations of the consignees and shippers of such freight has led to organizations based on the principle of group freight. Small consignments of between 66 and 330 pounds (30 to 150 kilograms) are subject to this method of handling.

The principal carriers for retail consignments are the SNCF, the railway freight agencies, the motor-freight agencies, and private trucks and delivery vans carrying their own goods. The SNCF has taken a number of measures to improve its share of the traffic in this field, and a specialized agency, the Service National des Messageries (National Carrier Service) was set up in 1970 to secure this traffic. Despite such measures, however, the carriage of retail goods by rail has continued to decline, dropping by 1970 to less than half the 3,200,000 metric tons carried in 1964. In the meantime, railroad-freight agencies have grown appreciably and now handle double the amount carried by the SNCF. These freight agencies organize the collection and local delivery of retail goods and packages, group them into larger consignments, and use the SNCF as the hauler. Competition comes mainly from the motor-freight agencies and carriers and the private trucking concerns. At least 5,000,000 metric tons annually are carried by public motor carrier transport over distances of more than 100 miles (160 kilometres).

**Combined freight transport.** There is, inevitably, co-operation between the different modes of transportation, despite the keen competition that is the general rule. By far the most significant is the combination of road and rail transport, and this is most marked by the development and growth of general container and transcontainer traffic. Transcontainers are containers designed specifically for one type of product. Although they still represent only a very small proportion of total traffic, the use of transcontainers is growing at the fastest rate. Rail traffic in transcontainers is fairly recent but has almost doubled

annually. About two-thirds of this traffic is originally ship borne and comes from the main maritime ports, the French-English trade being the most important. Containerization has given the SNCF a new opportunity to re-establish its competitiveness. A "container-express" system was established, and a Paris-Cologne connection was opened at the end of 1970. Six connections are in service, linking Paris with Metz, Strasbourg, Lyon, Marseille, Toulouse, and Bordeaux; and four connections link Bordeaux and Marseille, Toulouse and Marseille, Bordeaux and Toulouse, and Strasbourg and Marseille. About 33 inland and coastal ports are equipped for the handling of transcontainers, the ports of Le Havre, Dunkerque, and Marseille-Fos being the most important. The ports of Nantes-Saint-Nazaire, Nantes-Cheviré, and Bordeaux are also due for modernization under the Sixth Plan. Some inland ports are also being developed for container transport, notably Lille. Inland shipping has been adapted for container transport, especially by the modernization of docks at Strasbourg and Gennevilliers, which are now equipped with container cranes.

**Passenger transportation.** In France, as elsewhere, the automobile predominates as the most popular and widespread form of passenger transport. In 1971 the private automobile accounted for 250,000,000,000 passenger-miles (400,000,000,000 passenger-kilometres), compared to 25,500,000,000 for rail, 15,000,000,000 for public transport (buses and taxis), and 1,000,000,000 for domestic air transport. The late 1960s saw a remarkable rise in domestic air traffic, with an annual growth rate of about 22 percent. Automobile traffic grew by about 9 percent; but increase in rail traffic was negligible, and public motor transport declined.

#### THE COMPONENT SECTORS

**Road transport.** *The road network.* France, with Belgium, has the most dense highway network in Europe, with 9.5 miles (15 kilometres) of road per 10,000 inhabitants. The total length of roads is over 490,000 miles (789,000 kilometres) and represents 45 percent of the highway network in the European Economic Community (EEC). These figures may appear deceptive, however, since a large part of this highly developed network is only an inheritance from the 19th and early 20th centuries; but the French system is, nevertheless, distinguished from its neighbours by a considerable length of high-quality secondary roads. Only about 9 percent of the main roads, or *routes nationales*, carry more than 6,000 vehicles a day, and 85 percent of all road traffic is carried by only 15 percent of the network. Roads with three or more lanes account for only 7 percent of the main roads.

**Passenger services.** The total number of private and commercial auto vehicles in 1970 stood at 12,400,000, or one vehicle for every four people. The rural nature of France meant, however, that there were still relatively few people who travelled to work by car on a national scale. Passenger coach and bus services cover about 273,000 miles (440,000 kilometres) regularly, connecting some 36,900 towns and villages. This form of transport is in decline, however, although it is partially offset by a growth in school and factory transport, which comprises about 15 percent of the total, and seasonal tourist transport, which accounts for a further 20 percent.

**Goods services.** The transport of goods by road has grown significantly in the last 25 years, taking a larger and larger share of the total. In fact, public road carriers and haulers account for 24 percent of total tonnage. Its growth has been the result of several factors, not the least of which is that it is certainly the cheapest form of long-distance transportation. Other factors include the dispersal of the units of production of major industries throughout the country, the relatively slow rate of urbanization in France, and the increasing tendency of manufacturers to order smaller quantities of goods but at a greater frequency. An annual expansion of 6 percent is forecast for this sector during the Sixth Plan.

**Rail transport.** The French railroad network is characterized by a strong geographical centralization inherited from the 19th century and the fact that it was

The role  
of the  
SNCF

created in a predominantly agricultural France. It is centred on Paris, the country's only main rail intersection, and cross-country connections still present difficulties, with the exception of recently developed routes, such as Lyon–Nantes, Bordeaux–Lyon–Geneva (Switzerland), and Calais–Basel (Switzerland).

The SNCF (see above) was created on January 1, 1938, as the one company managing the French railroads. It is a nationalized concern, with an administrative council composed of both government representatives and administrators representing the interests of the old French railroad companies. France was the first European government to intervene directly in the management of the railroads; it did so mainly because of the lack of capital of the first railroad companies, the unprofitable nature of a large part of the rail network, and some political and strategic considerations. The state has a 51 percent control in the SNCF.

**Productivity.** Manpower on the railroads has decreased from 515,000 in 1938 to only 300,000 at the end of 1970. At the same time, the working week was reduced from 48 hours in 1960 to 43 hours in 1970. Yet, there has been a substantial increase in productivity, a total of 63 percent between 1960 and 1970. There has also been an improvement in the efficiency of rolling stock and locomotives, the number of unit-miles of traffic per locomotive in service increasing by 6.5 percent in 1970. The same year also registered an 8.4 percent increase in the efficiency ratio of vehicles to passengers.

**Rolling stock.** In 1963, 42 percent of all locomotives were still steam powered, but this figure had dropped to only 3 percent by the end of 1970, and passenger coaches are being progressively replaced and overhauled as high-speed trains are introduced. The Sixth Plan predicted that by 1975 about 80 percent of locomotives would be electric powered and the remainder would be diesel fuelled.

**The rail network.** The rail network is composed of 23,000 miles (about 37,000 kilometres) of track, of which 17,000 are open to passenger transport. About 5,800 miles (9,300 kilometres) are electrified, about one-quarter of the total working length. The SNCF is concentrating on developing maximum speeds on the main routes. By the end of 1970, 2,360 miles of line could accommodate speeds of 100 miles per hour and, on some sections, trains could travel more than 120 miles per hour. Finally, the construction of a new line between Paris and Lyon was being considered in the early 1970s, designed to carry gas turbine locomotives (turbo-trains) that would reduce the journey between the two cities to less than two hours.

**Waterways.** Inland waterways have a long history in France, and, even before the French Revolution, about 600 miles of canal were in use besides navigable rivers. The network was greatly expanded in the 19th century to serve the industrial areas, and the common pattern of centralization on Paris is also reflected in the construction of the canals.

The modern network is mainly decaying and unsuitable for current water transportation, and it is unevenly distributed throughout the country. It is not continuous, and there are significant gaps, for example on the North Sea–Mediterranean axis. The three principal parts of the network are those of Basse-Seine, the north, and the east. These regional networks are cut off by bottlenecks—for example, the present waterways linking the Rhine to the Seine or the Rhône are limited to boats with a capacity of less than 380 tons. The network is made up of 6,430 miles of waterway, of which 2,947 miles are canals and 3,480 miles are rivers. It represents about 40 percent of the European waterway network. But only about 6 percent of this system can service barges with more than 1,500 metric tons capacity. For purposes of comparison, over 25 percent of the canals in both The Netherlands and West Germany can take barges with loads of 1,500 metric tons. The French network is essentially a narrow system concentrated primarily in the north and east. Between 1920 and 1940 improvements were undertaken on the Rhine and the Rhône, and since 1945 navigation on the Rhône has been substantially improved by the construction of the Pierre Bénite barrage, which facilitated

the Saône–Rhône connection. The canalization of the Moselle was completed in 1964, and facilities in the Seine Basin have also been improved.

**Air transport.** The airplane still occupies only a small place in internal French transportation. Its traffic is comparable to first-class rail traffic on connections such as Paris–Nice, Paris–Marseille, or Paris–Lyon; but it is increasing at an annual rate of about 25 percent. Traffic carried by Air-Inter (the domestic airline) reached 807,800,000 passenger-miles (1,300,000,000 passenger kilometres) in 1970. About 80 percent of the air travellers are businessmen, and fares are relatively high, deterring the casual traveller.

In 1970, Orly and Le Bourget airports, at Paris, recorded a total of 12,532,000 passengers, an increase of 15 percent over 1969. About one-quarter of the traffic originated from France, one-half from another European country, about 10 percent from North or South America, and another 16 percent from other continents. Paris also handled about 229,000 metric tons of air freight. Although about 71 French cities have an airport nearby, more than 70 percent of the traffic with Paris is concentrated on 8 connections. The most important cross-country connections link Lyon to Nice, Mulhouse, Marseille, and Nantes.

#### THE OUTLOOK FOR FRENCH TRANSPORT POLICY

Since 1934, transport policy has been characterized by strong controls over the coordination of the various modes of transportation. Such controls have impeded the adaptation of transport to the rapid developments that have occurred since 1949 and are also contrary to the general transport policies of the EEC. The main objective of transport policy in the early 1970s was the organization of a competitive market with administrative freedom for the various sectors of transport. The first step in this direction has been achieved through the reforms noted above affecting the SNCF. Overall, these reforms aim to restore freedom of administration to the SNCF, especially in the commercial sector, and to abolish state subsidies. When this has been achieved, the government intends to reduce its constraints on other sectors, especially motor freight and the waterways. (Mi.B.)

#### V. Administration and social conditions

##### THE STRUCTURE OF THE GOVERNMENT

**The constitutional framework.** *The genesis of the 1958 constitution.* Following the insurrection of May 13, 1958, in Algeria, then still a French colony, Gen. Charles de Gaulle formed a government and succeeded in passing the constitutional law of June 3, 1958, which granted him responsibility for the drafting of a new constitution. The drafting and promulgation of the new constitution differed in three main ways from the former constitutions of 1875 and 1946: first, parliament did not participate in its drafting, which was done by a government working party aided by a constitutional advisory committee and the council of state; second, French overseas territories participated in the referendum that ratified it on September 28, 1958; and, third, initial acceptance was quite widespread, since in metropolitan France 85 percent of the electorate voted, 79 percent in favour and 20 percent against, and among the overseas territories only Guinea rejected the new constitution and consequently withdrew from the French Community.

**Electoral basis.** The constitution of the Fifth Republic of France came into effect on October 4, 1958, and is based on the principles of Western democracy, the will of the people being registered at elections and referenda. (Universal suffrage at the age of 21 has existed since 1848 for men and 1944 for women). The electorate in 1972 was about 30,000,000. The people elect both the members of the two national legislative assemblies, the National Assembly and the Senate, and the local assemblies. Since the constitutional revision in 1962, the people also elect the president of the republic, who was chosen in 1958 by an electoral college of 80,000 notables.

**The role of referenda.** The people may also be asked to ratify, by a constituent referendum (Article 89), an

Earlier  
constitu-  
tions

The three  
major  
segments  
of the  
waterways  
network

amendment that has already been passed by the two legislative assemblies. The constitution also made provision for legislative referenda, by which the president of the republic may submit a proposed bill to the people concerning the general organization of government (Article 11).

This procedure was used twice in settling the Algerian problem, first on January 8, 1961, approving self-determination in Algeria (when 75 percent voted in favour), and on April 8, 1962, approving the Evian Agreement, which gave Algeria its independence from France (when 91 percent voted in favour). The use of this latter procedure to amend the constitution without going through the preliminary phase of obtaining parliament's approval is perhaps constitutionally questionable, but it led to a positive result, on October 28, 1962, when the election of the president of the republic by universal suffrage was approved by 62.25 percent of those voting. On April 27, 1969, however, in a referendum concerning the transformation of the Senate into a simple economic council and the reform of the regions of France, only 47.5 percent voted in favour, bringing about De Gaulle's resignation. Finally, on April 23, 1972, the enlargement of the Common Market by the addition of Great Britain, Denmark, Iceland, and Norway was ratified by 68 percent of those who had voted, but since there had been many abstentions, this represented only 36 percent of those who were eligible to vote.

*Parliamentary composition and functions.* The 1958 constitution retained the parliamentary system, but it reinforced the power of the president. Under the constitution, parliament is composed of two houses, the National Assembly and the Senate. The National Assembly is made up of 485 deputies who are directly elected for a term of five years by a simple majority vote in single member constituencies, but with two ballots, only the leading candidates standing the second time. A second ballot is not necessary if any one candidate wins an absolute majority in the first ballot. The Senate is made up of 283 senators indirectly elected for nine years by a *college électoral* consisting mainly of municipal councillors in each *département*, one of the administrative units into which France is divided. Parliament retains its dual function of legislation and control over the executive but to a lesser extent than in the past. The domain of law (Article 34) is limited to determining the regulations and fundamental principles concerning such matters as civil law, fiscal law, penal law, electoral law, civil liberties, labour laws, amnesty, and the budget. In these different matters the Parliament is sovereign, and the government cannot interfere except only in order to draw up the details for the application of laws. On the other hand the government is responsible for all other matters and the Assemblies can in no way interfere. These other matters fall within the executive power of the government under Article 37, and a Constitutional Council is responsible for seeing that these legal limits are respected. Parliament can temporarily delegate part of its legislative power to the government, which then legislates by ordinances. This procedure was used eight times between 1958 and 1970 on matters concerning Algeria, social security, and the European Common Market.

The right to initiate legislation is shared by the government and parliament. The texts of bills and proposals are studied by parliamentary commissions, but putting them on the agenda remains essentially at the discretion of the government, which can, during debate, call for a single vote on the whole of the text. Parliamentary control over the government is exercised, as in the British system, by questioning members of the government in parliament about the specifics of their performance; by questions, by committees of enquiry; and especially by challenging the legitimacy of the government, a characteristic that is an integral part of the parliamentary system. Only the National Assembly can defeat the government by passing a motion of censure by an absolute majority, as on October 5, 1962, when the government of Georges Pompidou was toppled. The government can ask for a vote of confidence in its general policy or on a

single bill. In the latter case, a bill is considered adopted unless a motion of censure obtains an absolute majority.

The strong position of the president of the republic is the predominant feature of the present regime but at the same time this creates an ambiguous situation—that is, the regime has many of the characteristics of a parliamentary system: the sharing of executive power between a non-accountable head of state and a head of government responsible to parliament, and the powers of dissolution of that government by the parliament and of parliament by the government. But, at the same time, there are other features, such as the subservience of the government to the president and since 1962 his direct election by universal suffrage, which made the system very similar to a purely presidential one. This was particularly so under the strong individual control wielded first by de Gaulle (1958–69) and then by Pompidou.

*The role of the president.* The president of the republic appoints the Prime Minister and his ministers; he presides over the Council of Ministers, signs the more important decrees, appoints high civil servants and judges, and has the right to dissolve the National Assembly (which de Gaulle did twice, in October 1962 and May 1968); he can hold referenda and negotiate and ratify treaties; he is commander in chief of the armed forces. Under exceptional circumstances, Article 16 allows him to concentrate all the powers of the state in his hands. This article, enforced from April to September 1961 during the Algerian crisis, has given rise to very sharp criticism because of its undemocratic nature.

De Gaulle's great influence and the pressures of unstable political conditions tended to reinforce the authority of the presidency at the expense of the rest of the government. Whereas the constitution (Article 20) charges the government to "determine and direct" the policy of the nation, de Gaulle, in fact, arrogated to himself the right to take the more important decisions, particularly concerning foreign, military, and institutional policies. The prime minister, however, is still responsible for defending governmental action before parliament. He has certain powers of control, and the administration is at his disposal.

In practice, the transfer of governmental power to the detriment of the prime minister and to the advantage of the president of the republic is highly accentuated. All major decisions are henceforth taken at the Elysée Palace (the president's headquarters) including the dismissal of the head of government, who thus finds himself, in addition to being continuously responsible to the National Assembly, responsible by unwritten law to the head of state.

*The role of the Councils.* The Constitutional Council, which is composed of nine members appointed for nine years by the president, the National Assembly, and the Senate, supervises the conduct of parliamentary and presidential elections. It examines the constitutionality of organic laws (those fundamentally affecting the government) and rules of parliamentary procedure, but it may be consulted on the constitutionality of other legislation, international agreements, or disputes between government and parliament. There is also an Economic and Social Council, which is made up of 200 representatives from the economic and social world. It must be consulted on laws concerning long-term programs and on development plans and may be consulted on any bills concerning economic or social matters.

*Regional and local government.* The main units of local government are the *départements*, the *communes*, and the overseas territories.

*The départements.* The *départements*, created in 1790, now number 98, including Guadeloupe, Martinique, French Guiana, and Réunion, which gained *département* status in 1946, and the new *départements* in the Région Parisienne (Paris Region), which were created in 1964. The principal governing body of each *département* is the General Council, which is elected for six years with one councillor per canton. There are between 11 and 70 cantons per *département*. The General Council is responsible for all the main departmental services: welfare, health,

Relations between parliament and the executive

The National Assembly and the Senate

Internal Structure of the départements

administration, and departmental employment. It also has responsibility for local regulations, manages public and private property, and votes on the local budget. The prefect (*préfet*), whose creation dates back to 1800, represents the government in Paris within the *département*, and is the executive agent of the General Council. He directs all state administration, decides on the use of state funds, and exercises tutelary power over the deliberations of the General Council, particularly where the budget is concerned. He is assisted by a subprefect (*sous-préfet*) within each one of the 322 *arrondissements* in France, the subdivision of the *département*.

*The communes.* The *commune*, the smallest unit of democracy in France, dates back to the parishes of the "*ancien régime*" in the years before the Revolution. In 1970 there were 37,700.

The *commune* is organized according to a law of 1884 and has a municipal council with a minimum of nine members, who are elected for six years. The municipal council is responsible for running most of the municipal services, some of which are compulsory, such as the registry office, fire service, and funerals. It administers both public and private land, manages the public establishments of the *commune*, most important of which are the hospitals and the schools, employs a large number of personnel, and votes on its own budget. The council elects a mayor and his deputies. The mayor is both the chief executive of the municipal council and the representative of the Paris government in the *commune*. He is also in charge of the municipal police and through them ensures public order, security, and health and guarantees the supervision of public places to prevent such things as fires, floods, and epidemics. He directs municipal employees, implements the budget, is responsible for the registry office, and performs the duties of judicial police officer. The authorities of the *commune* are subject, particularly in financial matters, to the control of the minister of the interior, although this was relaxed somewhat in December 1970. The mayor is one of the main figures in the political and economic life of France, insofar as his functions are frequently closely linked with parliamentary or governmental mandates.

More than 24,000 *communes* have less than 500 inhabitants, and in view of their small size they have been regrouped into *commune* unions. A federal type of organization has been applied to the larger towns and cities, and urban districts were established by an ordinance in 1959 and urban communities in Bordeaux, Lille, Lyon, and Strasbourg in 1966.

The particular situation of the Parisian conurbation required a special form of organization. The capital itself, covering more than 40 square miles, has a population of nearly 2,600,000 but the conurbation includes nearly 10,000,000 people living in an area of over 4,600 square miles, which adds up to 20 percent of the population in a 2 percent area. The unity of the region is marked by the existence of an urban district created in 1961, and there is a prefect for the *Région Parisienne* as a whole. Local government in Paris has always been distinct. There is no elected mayor but instead 20 mayors who are appointed by the government. Since 1964 there has been only one elected assembly, the Council of Paris, with 90 members. There are two prefects, one for the Paris Region (*préfet de la Région Parisienne*), who performs the functions normally devolved on a mayor, and the prefect of police (*préfet de police*).

In the country as a whole, an attempt has been made to create some coordination at the regional level. There are 21 regional divisions with regional prefects and a Commission for Regional Economic Development (CODER).

*The overseas territories.* The overseas territories—the vestiges of the French empire—are scattered over four continents: in America, the islands of St. Pierre and Miquelon; in Africa, the Comoro Islands and the territory of the Afars and Issas; in the Pacific, French Polynesia, Wallis and Futuna, New Caledonia, and the Anglo-French Condominium of the New Hebrides. They enjoy a great deal of autonomy except in matters reserved for metropolitan France, such as diplomacy and defense.

They govern through an assembly elected by universal suffrage and a government council, but they are subject to the tutelage of a representative of the French Republic.

**Political parties.** Political parties played a particularly important role under the Third and Fourth republics; but the Gaullists constantly blamed the instability of former regimes on the French party system, and political parties have lost a great deal of their influence since 1958. In the early 1970s the French political situation was characterized by the existence of a majority party (the Gaullist party) and by a divided opposition.

*The Gaullists.* The Gaullist party was created in 1947 by Gen. Charles de Gaulle under the name of *Rassemblement du Peuple Français* (RPF). Its consistent opposition to governments formed by coalitions of the other parties greatly contributed to political and governmental instability under the Fourth Republic. In the legislative elections of November 1958, the party, under the new name of *Union pour la Nouvelle République* (UNR), won 212 of the 485 seats in the National Assembly. In the November 1962 elections this number increased to 284 seats, including Valéry Giscard d'Estaing's independents. After a setback in the 1967 elections, when the Gaullists secured only 244 seats, the *Union des Démocrates pour la République* (UDR), as the party was then called, reinforced by some members from the centre *Progrès et Démocratie Moderne* (PDM), won a clear victory in the June 1968 elections that followed the student disorders and the May strikes. After the March 1973 elections, the Gaullists controlled 275 seats in the National Assembly aided by 55 D'Estaing's independents and 30 Centrists. The Gaullists have also held the presidency of the republic since 1958. De Gaulle was elected in December 1958, re-elected in December 1965 on the second ballot with 55 percent of the votes, and Georges Pompidou followed him from June 15, 1969, when he was elected on the second ballot with 57.5 percent of the votes. Various Gaullists had also held the presidency of the National Assembly, the premiership, and the presidencies of all the committees of the National Assembly. Paradoxically, however, Gaullist representation in the Senate had always been in the minority (for example, 30 seats out of 274 in 1970). Likewise, the Gaullists never really succeeded in getting a foothold in the municipalities, and the number of active members was quite low. As of 1973 they and their allies held 60 percent of the seats in the National Assembly, though they represented a little less than half of the electorate.

This was the case because the 1958 constitution did away with proportional representation—which had given minority parties substantial representation under the Fourth Republic—and set up the single member majority electoral system, which favours the party that controls the largest bloc of followers, in this case the Gaullists.

There are three main opposition groups.

*The Communists.* The chief one is the *Parti Communiste Français* (French Communist Party), which claims 450,000 members and regularly secures between 20 and 25 percent of the vote. At a disadvantage because of the voting systems, it has only 73 deputies and about 10 senators and controls no big city. It supported the candidacy of François Mitterrand in the 1965 presidential elections but in the 1969 elections it presented its own candidate, Jacques Duclos, long the leader of the French Communists, who obtained 21.5 percent of the votes (about 4,700,000) in the first ballot.

*The non-Communist left.* The non-Communist left, which, with the centre "Christian Democrat" *Mouvement Républicain Populaire* (MRP), dominated the Fourth Republic, has suffered from divisions since 1958. It includes the *Parti Socialiste* (Socialist Party, which absorbed the *Convention des Institutions Républicaines* in 1970, the *Radical Party*, and the *Parti Socialiste Unifié* [PSU; United Socialist Party]). The Socialist Party—with about 100,000 members, representatives in local government and the Senate and strong organization—remains, despite a drop in electoral support, one of the main French parties. In 1965 it joined with the Radical Party and the *Convention of François Mitterrand* to support his candi-

The importance of the mayor

Opposition parties

dacy in the presidential elections. This alliance later became the Federation of the Democratic and Socialist Left (FGDS). Mitterrand obtained 45 percent of the votes in 1965 and the FGDS 24 percent of the votes and 116 seats in the 1967 legislative elections. The Federation disbanded following its defeat in 1968, when it secured only 57 seats. The unification of the non-Communist left is thwarted by the complexity of its relations, on the right, with the Radical Party, and, on the left, with the small revolutionary Parti Socialiste Unifié (psu). The Socialist Party concluded, in June 1972, an electoral agreement with the Communist Party. That agreement split the Radical Party, a wing of which led by Robert Fabre, rejoined that new coalition though the majority of the 20,000 members of the Radical Party, animated by its charismatic secretary general, Jean-Jacques Servan-Schreiber, a journalist and author, refused any agreement with the Communists and turned to the centre. In 1973 the non-Communist left got 23 per cent of the votes and 103 seats.

*Minor groups of the centre.* Finally, in the centre, a few personalities perpetuate the liberal European and parliamentary ideal of the former Mouvement Républicain Populaire (MRP) led by Robert Schuman. Although it has only a few representatives in the National Assembly, it did significantly well in the 1965 presidential elections, when Jean Lecanuet obtained 16 percent of the votes, and especially in 1969, when Alain Poher, president of the Senate and the interim president of the republic after de Gaulle's departure, obtained 42.25 percent of the votes in the second ballot. In 1973 the "Réformateurs" of Lecanuet and Servan-Schreiber won 13 per cent of the votes and 30 seats.

*Justice.* In France there are two types of jurisdiction: the judiciary that judges trials between private persons and punishes infringements of the penal law and an administrative judicial system responsible for settling lawsuits between public bodies, such as the state, local bodies, and public establishments, and private individuals.

*The judiciary.* For civil cases, the judiciary consists of 172 higher (*grande instance*) courts and 455 lower courts, which replaced justices of the peace in 1958. For criminal cases there are *tribunaux correctionnels* ("courts of correction") and *tribunaux de police*, or "police courts," which try minor offenses. The decisions of these courts can be referred to one of the 28 courts of appeal. Felonies are brought before the assize courts established in each *département*, consisting of three judges and nine jurors.

All of these courts are subject to the control of the Cour de Cassation (Court of Cassation), as are the specialized professional courts, such as courts for industrial conciliation, courts martial, and the Cour de Sécurité de l'État (Court of State Security), founded in 1963 to try felonies and misdemeanours against national security. The supreme court interprets the law and does not judge cases but can refer a case back to a lower court.

There are some 5,000 judges recruited by competitive examinations held by what was originally the Centre National d'Études Judiciaires, created in 1958, which became the École Nationale de la Magistrature in 1970. Within this elite, a traditional distinction is made between the *magistrats du siège*, who try cases, and the *magistrats de parquet* (public prosecutors), who prosecute. Only the former enjoy the constitutional guarantee of irremovability, which forbids removal of a magistrate without his consent. The Conseil Supérieur de la Magistrature (High Council of the Judiciary) is made up of nine members appointed by the head of state from among the judiciary and makes proposals and gives its opinion on the nomination of the *magistrats du siège*. It also acts as a disciplinary council. The public prosecutor's department (*Parquet*) is responsible for demanding before the courts that the law be applied. It is a hierarchical body subject to the authority of the minister of justice. Judges can successively serve as members of the *Siège* (Bench) and the *Parquet*. In cases of high treason only a high court of justice made up of deputies and senators is allowed to try the president of the republic and ministers. They can also be tried in this manner if they have committed felonies or misdemeanours during their term of office.

*Administrative justice.* The existence of a system of administrative justice, which dates back to the year VIII of the Revolutionary period (1799), is unique to the French system though later similar institutions were set up in Italy, Belgium, Luxembourg, Greece, and Egypt. Administrative courts are first-instance courts under the control of the Conseil d'État (Council of State), so far as appeals are concerned. The Council of State plays an important role since it exercises control over the government and the administration from a jurisdictional point of view and ensures that they conform with the law. It is, moreover, empowered by the constitution to give its opinion on proposed bills and on certain decrees.

*The armed forces.* The overall responsibility for national defense rests with the president of the republic, who is the constitutional chief of the armed services and presides over the higher councils and committees on national defense. He is also the person who, since a decree in 1964, can give the order to bring the air and strategic forces into action. The prime minister, assisted by the secretary general for national defense and the minister of the armed forces, coordinates military policy.

*Organization.* The organization of the military administration was for a long time based on the division of the military into the army, navy, and air force. Since 1958, this distinction has become progressively blurred and replaced by an organization based on various functions. Thus, there are strategic nuclear forces, territorial-defense forces, mobile forces, and task forces. France has had the atomic bomb since 1960 and the hydrogen bomb since 1968. It carries out nuclear testing in the Pacific, has a strategic nuclear force, and a basic delivery system.

In 1970 there were 36 Mirage IV bombers armed with a 100-kiloton atomic bomb, ground-to-ground ballistic missiles, and sea-to-ground ballistic missiles. The "Redoutable," France's first nuclear submarine, was launched in 1967, and three other nuclear submarines were planned to be brought into service before 1975. Even so, French nuclear strength is, it is claimed, 15,000 times less than that of the Soviet Union. Defense on the ground is mainly the responsibility of the land army and the gendarmerie in collaboration with civilian authorities. The coordination of defense services is ensured by the division of the country into seven military regions. The mobile forces include five mechanized divisions equipped with Patton- and AMX-type tanks, supported by tactical air commands made up in particular of Mirage III-type planes. Finally, a land-army unit is responsible for non-European missions, in particular in such African territories as Gabon and Chad, which are linked to France by defense agreements. The French Navy totals 380,000 tons, divided into two flotillas based on three maritime regions (Cherbourg, Brest, and Toulon). It includes two aircraft carriers, two cruisers, 29 frigates, 35 escort vessels, 19 submarines, and 91 minesweepers. The air force includes about 2,000 aircraft, in particular Nord 2501, Transall, and Mirage planes scattered over about 30 bases.

The military budget varies according to different estimates from 3.5 percent to 5.3 percent of the gross national product and is about 18 percent of the national budget. France withdrew from the integrated command of the North Atlantic Treaty Organization (NATO) in 1966, but remains a Western European Union (WEU) member.

*Manpower.* Every Frenchman is subject to compulsory military service, except in cases of medical exemptions and some categories of conscientious objection. The annual contingent is 420,000 men, of which 70 percent are drafted into the active army or the technical-cooperation corps. Technical cooperation personnel are put at the service of the Ministry of Foreign Affairs. They do not have a general statute, and their situation varies according to the agreements reached with each country. The number of such personnel is particularly high in North Africa, West Africa, and the Malagasy Republic. The law of July 1970 set the draft age at 19, reduced the length of service to one year, and made deferments exceptional after the age of 21, except for medical students. The total active military strength is 500,600 career personnel in addition to the draftees.

## THE SOCIAL SERVICES

**Administration and the civil service.** There are about 2,000,000 civil servants in France, including 1,300,000 civilian employees, 220,000 military employees, and 550,000 local-government employees. The largest single groups of employees are those in national education (500,000) and the post office (280,000). French administration has been strongly marked by a very strict hierarchy since the time of Napoleon. Civil servants are grouped into different corps and different ranks and are classified according to their recruitment level into four different categories. Recruitment is based on the principle of equality of opportunity, and entry is by a competitive examination. At the highest level, category A civil servants are recruited through a national school of administration, created in 1945, which gives access to the *grands corps de l'état*, which includes such bodies as the Council of State, the Court of Accounts, the Inspection of Finance, the prefectural corps, the diplomatic service, and the civil administrators' corps. The duties and rights of civil servants are defined by a general statute of 1946, which was modified by an ordinance in February 1959. Their career guarantees and their disciplinary code are extensive and are under the vigilant control of the Council of State. In return, they are duty-bound to be discreet in expressing any personal opinions, and the right to strike, which is recognized by the constitution for all Frenchmen, is more severely limited for civil servants, although this varies according to the corps. Most civil servants belong to labour unions.

**Police services.** The police are primarily responsible for maintaining public law and order. There are about 90,000 policemen in France, and they are responsible to the prefects in the *départements*, and to the prefects of police in Paris and the suburban *communes*. The police force is divided into public security forces and specialized police forces, such as the vice squad. The security police include the Compagnies Républicaines de Sécurité (CRS), responsible for public order; the judicial police, who carry out criminal investigations and hunt down suspects; and the complex internal intelligence and anti-espionage units. The municipal police forces are responsible to the mayor.

**Educational services.** The organization of national education is highly centralized. Since 1968, however, following violent student riots, a movement toward decentralization has been in progress in higher education. The students had protested the lack of contact with their teachers and their denial of any voice in university administration—for instance, in determining syllabi and the courses of study. Further, they ultimately demanded that a continuous detailed check of their work should replace the generalized system of examinations.

In France there is both public and private education. All public education is free, and the expenditure on education stands at about 20 percent of the national budget, or a little less than 5 percent of the gross national product. Public education is administered by the Ministry of National Education, which draws up the curricula, employs the staff, and exercises its authority through rectors placed at the heads of the 23 academies.

**Primary and secondary education.** Education is compulsory between the ages of six and 16. Before the age of six, children can go to *écoles maternelles* (nursery schools) or *classes enfantines* (kindergartens), and they receive their elementary education between the ages of six and 11 in primary schools. Secondary education is first given in the *lycées*, the *collèges d'enseignement général* (CEG), and the *collèges d'enseignement technique* (CET) from the ages of 11 to 15.

Further secondary education is given in classical, modern, and technical *lycées*, leading to the national *baccalauréat* examination. Courses of study lasting from one to three years can lead to professional certificates or diplomas. Experiments in educational methods have been numerous since 1960. For example, there are the "snow classes" whereby an entire class is sent to the mountains with their teacher for two weeks or a month with just a

small sum being paid by their parents. Since 1968 teachers, parents, and pupils themselves have been represented on the boards of directors of secondary schools.

**Higher education.** The law of November 12, 1968, changed higher education profoundly. Previously, universities had been divided into faculties or colleges according to the subjects taught. From 1968 on, the faculties were replaced by teaching and research units regrouped into autonomous, multidisciplinary universities co-managed by representatives elected from among the teaching staff, students, and administration. These establishments determine their own research programs, teaching methods, and means of assessment.

The state grants funds to the universities, which they divide among their departments. The degrees given are *licences* (roughly comparable to the British-American bachelor's degree), *maîtrises* (master's degree), and *agrégations* (a teaching qualification, and one of the most rigorous degrees in the world to obtain). Besides the universities there are the various *grandes écoles*, including the polytechnic and specialized colleges, and institutes such as the Institut d'Études Politiques (Institute of Political Studies).

The staff for the first degree is made up of teachers (68,000 men and 16,400 women), and for the other degrees there are professors with *licence* or *agrégation* diplomas (158,000 in secondary schools and 26,000 in higher education).

**Other features.** Private education is mostly Roman Catholic. Although the constitution proclaims that the state is secular, the "Debré law" of 1959 allows private establishments to sign contracts with the state that procure them financial support in exchange for a certain control.

School attendance in primary education in 1969 was 7,410,000, of which 6,370,000 attended public schools. In secondary education attendance was 4,200,000, and in higher education, which is almost exclusively public, there were 605,000 students (of which 280,000 were girls) attending about 60 universities. The number of foreign students totalled 30,000. The teachers are highly unionized. The Fédération de l'Éducation Nationale (FEN) and the Syndicat National des Instituteurs have 285,000 members. Other left-wing unions have nearly 100,000 members. The main student unions are the Union Nationale des Étudiants de France (UNEF), the UNEF Renouveau, which is Communist, and the Fédération Nationale des Étudiants de France (FNEF).

## SOCIAL CONDITIONS

**Housing.** France has had a continuous housing crisis since 1945. The Fourth Republic successfully carried out reconstruction after World War II, but urbanization, population growth, the repatriation of 1,000,000 Frenchmen from Algeria, immigration, and the old age of buildings continue to create growing needs. In 1970, 456,000 dwellings were built, and a rate of 500,000 per annum is forecast for the 1970s. There are 16,000,000 permanent dwellings in France, of which approximately one-third are over 100 years old and two-thirds are over 50 years old. The government itself does not build but encourages construction through premiums, loans, particularly for low-rent housing, and tax incentives. The procedure concerning the achieving of building permits was greatly simplified in 1970. City planning has become more organized with the establishment of *zones à urbaniser par priorité* (ZUP; land for immediate development) and *zones d'aménagement différé* (ZAD; land reserved for future use).

**Wages and the cost of living.** France has been living in an inflationary situation since 1914. The wage and price index, which was 100 in 1963, was 147 for prices in July 1972, and it was 218 for wages, which were thus increasing faster than prices. The rate of inflation in 1972 was about 7 percent. The increase in purchasing power, which was considerable in 1969 as a result of the increases granted after the widespread strikes in 1968, was 3 percent between 1965 and again in 1970-71. The low wage earner benefits from a minimum wage

The organization of national education

The importance of Roman Catholic constitutions

with a built-in cost-of-living increase, which is called the *salairé minimum interprofessionnel de croissance* (SMIC) and which was established in 1970. Its level is set annually, and all employers must respect it. As of July 1970, 750,000 wage earners were being paid according to this scale, which is at an hourly rate of 3.50 francs.

In 1969, 30 percent of all wage earners earned less than 750 francs a month; 24 percent from 750 to 1,000 francs; 32 percent from 1,000 to 1,666 francs; and 14 percent more than 1,666 francs. Men earn on average 30 percent more than women and up to 60 percent more in executive positions. A workman earns 80 percent more in Paris than in the poor *départements* of central France. Blue-collar workers are increasingly being paid salaries rather than weekly wages.

**Social security and health.** Almost everyone is covered by the social-security system. Social insurance was introduced in 1930 and family allowances in 1932, but the comprehensive rules for social security were not set down until the end of World War II. A network of elected social-security and family-allowance *caisses primaires* ("primary boards"), headed at the top by national *caisses*, manages a considerable budget of 75,000,000,000 francs. With the exception of the family-allowance system, the social-security system shows a deficit that is made up by the state. Receipts come from compulsory deductions from wages and from an employer's contribution. Expenditure is on retirement benefits (old-age pensions), family benefits paid for dependent children, and reimbursement of 75 percent of all medical, pharmaceutical, and hospital expenses.

French medicine complies with the principles of liberal medicine, with a free choice of doctors for the patient, freedom to decide on treatment, and a free discussion of fees. Since 1960, however, agreements have been signed at a regional level between the *caisses* and the professional medical associations. They set the level of fees, and, although doctors need not necessarily adhere to them, reimbursements from social security are very low if they do not.

The hospital reform of 1958 set up a link between hospitals and medical schools through the creation of hospital and university centres and by the introduction of common national competitive examinations giving access to both a hospital and a university career. Hospital doctors must, however, carry out full-time duties at the hospital. Private hospitals and clinics exist alongside public hospitals, and the cost of treatment in them is also partially reimbursed from social security. There are generally inadequate facilities and few hospitals and this is especially true in the case of nursing homes for the aged. In 1970 there were 68,000 doctors (one per 747 inhabitants), 20,000 dentists (one per 2,505), and more than 17,000 pharmacists.

**Social groups.** Of the total population of over 51,000,000, the working population numbers 20,500,000. Agriculture still employs 13 percent of the population, but people are constantly leaving the countryside. The *secteur tertiaire*, which includes the liberal professions, crafts, and administration, has grown rapidly from 30 percent in 1954 to nearly 44 percent in 1970. The industrial and transport sectors have varied little, employing about 40 percent of the working population. The standard of living of rural inhabitants remains low, and agricultural depression has become an almost permanent feature. As in most industrialized countries, the working class is losing its homogeneity and becoming socially and politically diversified, but social and professional mobility is still restricted. Although unemployment is under control, between 400,000 and 500,000 were unemployed in 1973.

(F.B.)

## VI. Cultural life and institutions

### THE CULTURAL MILIEU

France has an ancient civilization in which the original Celtic culture has blended with Greco-Roman and Germanic elements to form a harmonious whole.

Its rich medieval culture, fostered by scholars in monasteries and in universities, has given rise, since the end of the 15th century, to a strong tradition of Humanism.

which has always responded to the call of scientific and technical progress. Before World War II this culture was the prerogative of a still flourishing nobility, of a middle class that was ever more involved in commerce, and of an elite—often of modest means and humble background—which consisted of priests, university and scholarship students, workers, self-taught craftsmen, and members of technical societies.

Although the French had become completely literate by the end of World War I and although the general cultural level had been raised by the dissemination of information through the press and the other communications media—especially those of the cinema and of the radio—it was not until the end of World War II that a great cultural leap forward was made. Then, important governmental and parliamentary measures to provide free secondary education, to increase the number of scholarships, and to make education mandatory up to the age of 16 contributed to the social advancement of the lower classes and of the least rich members of society. In consequence, newspaper circulation rose and the setting up of permanent and mobile libraries increased the number of books in circulation—as did the publication in cheap pocket editions of outstanding works of literature, whether French or foreign. (Nowadays, a worker can—and often does—read unabridged editions of the works of Victor Hugo, Emile Zola, Shakespeare, and Pushkin.)

Nor should the effect of television, that other yet more persuasive, more attractive cultural instrument, be overlooked. Since World War II countless French families have gathered around their television sets to watch plays, films, reenactments of historical events, and art programs, as well as all kinds of educational courses and discussions of major current problems. Often a televised film or play prompts the viewer to read those works he has seen on TV or perhaps to seek out other works by the same author. On the other hand, in France as elsewhere, pictures are often substituted for text.

This modern culture reacts to life and events. The French are no longer shut in on themselves or within their own country. They feel involved in world events pictures of which they see and by which they are impressed: United Nations sessions, scenes from the wars in the Far East or in Africa, famines, earthquakes, international sports events, and space exploits. Furthermore, the French now travel, not just within France but also abroad. Thanks to aircraft and to the car, they may, even with modest means, get to know Europe and other continents. If, however, this transitory vogue for "a richer" and more varied culture in which science and technology play a large part advances at the expense of traditional culture—particularly that of Greco-Roman Humanism—nonetheless, improved health and living conditions, greater leisure, and longer vacations have all made the Frenchman of today undeniably better informed, better educated, and more cultivated than his compatriot of 50 years ago. It is, moreover, this more varied culture that he plans to exchange with people of other countries.

### THE STATE OF THE ARTS

**Literature.** In literature, one of the most important elements of contemporary French cultural life, the famous intellectual and Humanistic heritage of the past has not been lost. The great tradition of the 16th to the 19th century continues and the world-acknowledged figures—Michel de Montaigne, creator of the essay; the 17th-century dramatists Pierre Corneille, Molière, Jean Racine; Jean de La Fontaine, the poet of the fables, the great Voltaire and Denis Diderot, Victor Hugo, Charles Baudelaire, and Flaubert, creator of *Madame Bovary*; and many others—still influence modern writers. After World War II the illustrious names of such poets as Paul Valéry, Paul Claudel, and Saint-John Perse, the novelists Colette, André Gide, François Mauriac, and Henry de Montherlant continued to shine. And the year 1971 was the centenary of the birth of Marcel Proust, one of the great masters of the modern novel.

The theatre is always a living art in France, thanks to

of Greco-  
Roman  
Humanism

contemporary playwrights such as Jean Anouilh, Eugène Ionesco, Jean Giraudoux, and Samuel Beckett, a bilingual writer who made Paris his home, not to speak of Fernando Arrabal, Jean Genet, Arthur Adamov, or Armand Salacrou. Major contemporary poets include Pierre Emmanuel, Louis Aragon, Patrice de La Tour du Pin, and René Char and Yves Bonnefoy.

Philosophy counts among its thinkers the Thomists Étienne Gilson and Jacques Maritain, the Christian Existentialist Gabriel Marcel, the Catholic moralist Jean Guittou, and of course, the Existentialist and Marxist Jean-Paul Sartre.

The novelists Françoise Sagan, Simone de Beauvoir, and Françoise Mallet-Joris appeared on the literary horizon after World War II and have remained there. Sartre, as well as Gide, is always read. But André Malraux, Georges Bernanos, the "new novel" of Alain Robbe-Grillet, Nathalie Sarraute, Claude Simon, and Michel Butor—born of the *Molloy* of Beckett—are the writers and works that attract the younger generation. This generation also admires the "new criticism" of Roland Barthes, the art criticism of René Huyghe, the ethnological studies of Claude Lévi-Strauss, author of *Tristes Tropiques*. André Malraux, who awakens interest as a man and as a writer, claims the place of honour.

In the field of historical study, the loss of André Maurois has been made good by the work of Pierre Gaxotte, Antoine de Lévis-Mirepoix, and even by the *Mémoires* of Gen. Charles de Gaulle, who revealed himself as a great writer.

**The fine arts.** The fine arts—painting, sculpture, engraving, architecture, and music—are still in favour and flourishing. The state provides for the training of artists at the École des Beaux Arts in Paris and at similar schools in the provinces. At the École des Arts Décoratifs, and at institutions such as the École Boulle, training in fine cabinetwork is provided. In painters' and sculptors' studios and in the offices of architects, masters and students are brought together.

In Paris, painters and sculptors tend to congregate in Montparnasse, the Latin Quarter, and Montmartre. Both figurative art and abstract art still have their champions. Periodicals such as *Gazette des Beaux Arts* and *L'Oeil*, newspapers such as *Le Monde*, the art critic of which is André Chastel, and *Figaro*, whose music critic, "Clarendon" (Bernard Gavoty), is well thought of, educate the public and encourage artistic vocations—as do radio and television broadcasts, which are often excellent. The Conservatoire National Supérieur de Musique, the École Normale de Musique in Paris, and the Schola Cantorum have all fostered recitals by great masters or by promising young musicians. Paul Paray, Charles Munch, and Herbert von Karajan, who directed the orchestra of the Paris Opéra, revived classical masterpieces and introduced contemporary works to the Opéra and to the Opéra Comique, and the competition started by Marguerite Long helps to discover the best young musicians. Concert halls such as the Salle Gaveau and the Salle Pleyel in Paris and similar provincial halls provide a setting for musical events sponsored by young people's musical associations and by religious or secular choirs. Records and paperback books enjoy a phenomenal distribution, and it is rare nowadays for young people not to be interested in music and not to combine an interest in Bach, Mozart, and Vivaldi with their interest in pop music or Charles Trenet's and Georges Brassens' songs. Older people cannot forget Maurice Chevalier.

**The cinema.** The cinema has been developed into an art form by such great French directors as Julien Duvivier, Jean Renoir, Jean Delanoy, and Claude Lelouch; by such great actors as Fernandel, Michel Simon, Pierre Fresnay, and Jean Gabin; and by actresses such as Brigitte Bardot, Jeanne Moreau, and Simon Signoret. Above all, brilliant young directors appeared in recent years who are not unworthy of the older masters. A leader, with François Truffaut, of the so-called *nouvelle vague* ("new wave") of film makers that appeared in the 1950s, Jean-Luc Godard made the remarkable futuristic *Alphaville*, in which he tackled contemporary problems, as he did al-

so in *Week End* and *La Chinoise*. Truffaut, too, displayed great creative film talent in *La Mariée était en noir* (*The Bride Wore Black*), in which Jeanne Moreau starred. Jacques Demy must also be noted with his successes *Les Parapluies de Cherbourg* (*The Umbrellas of Cherbourg*) and *Les Demoiselles de Rochefort* (*The Young Girls of Rochefort*): in them, thanks to Françoise Dorléac and, above all, Catherine Deneuve, musical comedy was rediscovered. Louis Malle won attention with *Le Voleur* ("The Thief"), and Claude Chabrol made his mark with *Les Cousins*, *Le Scandale*, and *Les Biches* (*The Does*). Michel Deville's *Benjamin* succeeded with its lively freshness and daring—in the Gallic tradition. Earlier, the writer Jean Cocteau showed his great talents to be perfectly at home in creative cinema in *Les Enfants terribles* (*The Strange Ones*), *Orphée*, and other films.

**Museums and monuments.** The general public has benefitted from the preferential treatment given to the fine arts. The great national museums of the Louvre, Versailles, and of the Trocadéro have been enriched and remodelled, and, in such provincial museums as those at Lyon, Strasbourg, and Bordeaux, the same kind of improvements have been made. Museums such as the Musée Marmottan or the Musée Cognacq-Jay—both in Paris—have made marvellous private collections available to the public. Temporary, permanent, and travelling exhibitions are also constantly being organized.

A remarkable campaign has also been pursued on behalf of architecture. Renovations and restorations have been carried out on beautiful groups of buildings and on such historical monuments as the great houses—originally private residences—of the Marais and of the Ile Saint-Louis in Paris and also of the Grand Trianon and the opera house designed by Jacques Gabriel, both at Versailles. Throughout France, *Son et Lumière* (Sound and Light) spectacles have illuminated ancient towns as well as the ramparts at Dinan, the Place des Vosges in Paris, Le Mont-Saint-Michel, the châteaux along the Loire, and other historical buildings. A new national inventory of France's artistic heritage is being compiled with special reference to architecture. Local historical and archaeological societies, such as that in the Saint-Malo region of Bretagne, have, for example, been entrusted with compiling a preliminary regional list that will become part of a national inventory. As a result, some important archaeological finds, such as the discovery in the early 1950s of treasure (in the tomb of a Celtic princess of c. 500 BC) at the village of Vix, have been made. Historical monuments, public collections, and even private collections are open to the public, and owners of historical houses may obtain financial assistance to restore their property from the Services des Monuments Historiques, on condition that it is open to the public. Another great undertaking, initiated by André Malraux, former minister for cultural affairs, is the cleaning throughout France of historical monuments.

Traditions are being revived in the provinces—in Bretagne, Provence, Alsace, and the Basque country, among other regions—and a Fédération Régionaliste has been created, which bears witness to an interest in the regions and provinces quite different from that aroused by the desire for political autonomy. There is even, in Paris, a new museum of popular arts and traditions that provides a panorama of provincial folklore and local events. Together with the craze for regional costumes and religious festivals—particularly in Bretagne—it enables each Frenchman to come to know not only his country as a whole but also his own province.

In the larger cities there are also museums—among which the museums at Strasbourg, at Rouen, and at the Château de la Duchesse Anne, at Dinan, should be mentioned—devoted to the arts and crafts of the provinces, their usages and customs. The clearing and restoration of old monuments is often undertaken by young amateurs of memorial history who may also organize regional spectacles of a high standard. Among the folk-dance groups, those of Bretagne, Provence, Auvergne, and Alsace are particularly interesting.

In the provinces popular education takes place at all

levels. It would be unusual, even in the smallest communities, not to find that lectures, exhibitions, concerts, libraries, and trips to other regions, even abroad, were being organized. Sometimes the initiative for such events is political or religious, but there is an increasing awareness of the various forms that art may take and of history and popular traditions. Finally, French cuisine, with its many regional specialties, is not a negligible art form.

#### CULTURAL INSTITUTIONS

France's cultural institutions, which stimulate activity in the fine arts, literature, science, and technology, are ultimately responsible to the Ministry of National Education, to the Ministry of State for Cultural Affairs, to the Directorate of Cultural and Technical Affairs (Direction des Affaires Culturelles et Techniques) at the Ministry of Foreign Affairs, or to the State Secretariat for Cooperation Abroad (Secrétariat d'État à la Coopération pour l'Extérieur).

The whole nation may also continue its education with the help of educational radio broadcasts and by the lectures broadcast by universities and by public lecture courses—particularly at the Sorbonne and at the Collège de France. Furthermore, there are cultural centres in every important city, at which, with musical conservatories in the *départements*, plays, concerts, and recitals are produced. France has established the State Secretariat for Cooperation Abroad, which is responsible for sending teachers and technicians to help its former colonies and also for sending others to the advanced countries of Europe and America. Young Frenchmen may even spend time working for the secretariat instead of doing military service. The Ministry of Foreign Affairs, in conjunction with the Ministry of National Education and the Alliance Française (which does the same work as the British Council), maintains both cultural counsellors and attachés at its embassies and French *lycées* in important foreign cities. French institutes and centres for French studies are also maintained, at which books, magazines, newspapers, records of French plays and music, and French films are provided, as are lectures and courses given by the staffs. The various international Associations of French Studies (Associations d'Études Françaises), the United Nations Educational, Scientific and Cultural Organization (UNESCO), which is headquartered in Paris, the International Association of French Teachers (Association Internationale des Professeurs de Français), and the association of French-speaking universities conclude this survey of cultural institutions that are all of help to each other.

#### PRESS AND BROADCASTING

French cultural life is, in fact, based on daily newspapers, periodicals, radio, and television. Beginning with Théophraste Renaudot's *La Gazette* (started in 1631 and later known as *La Gazette de France* and published until 1917) and the *Mercure de France* (which first appeared in 1890), the number of newspapers and periodicals has continued to multiply. When France was liberated at the end of World War II, a number of newspapers and periodicals that had appeared during the occupation and had supported the Vichy government were suppressed. But some of them—in fact, quite a good number—reappeared after changing their names. Among the great periodicals, one might mention the *Revue des Deux Mondes*, the *Nouvelle Revue Française*, and *Réalités*; weekly magazines include *Paris-Match*, *Jours de France*, and *Point de Vue-Images du Monde*. *Les Lettres Françaises* and *Les Nouvelles Littéraires* are literary weeklies.

The *Figaro Littéraire* ceased publication in 1970 and is now incorporated into the Saturday *Figaro*. The *Figaro* has the highest circulation and best reputation among the morning newspapers. It is moderate and right-wing, further to the right than other daily newspapers, such as *Le Parisien Libéré*, *L'Aurore*, *Combat*, the Roman Catholic *La Croix*, or the Protestant *Réforme*. Its opposite is the Communist paper *L'Humanité*. The most important of the evening papers is *Le Monde*, an informed

paper with full coverage that nevertheless reveals a curious duality in its columns, tending to lean, in the opinion of some observers, both to the right and to the left. *Paris-Jour* and *Paris-Soir* are more popular daily newspapers.

In addition to the Paris newspapers, there are the great provincial newspapers of which the most important, *Ouest-France*, is published at Rennes and covers Bretagne, Vendée, Normandie, and Maine provinces in detail. The *Sud-Ouest* of Bordeaux should also be mentioned, as should the *Dernières Nouvelles d'Alsace* of Strasbourg, the *Républicain Lorrain* of Lorraine, the *Nice-Matin* of Nice, and many others. All these newspapers cover political events and have special daily and periodical columns covering entertainment, the stock market, science, literature, and sports. Women's periodicals, such as *Marie-Claire*, *Elle*, and the *Écho de la Mode*, have a wide circulation and a high reputation. Periodicals that specialize in the arts, literature, and science are *L'Oeil*, *La Gazette des Beaux-Arts*, *Revue d'Histoire Littéraire de la France*, *Revue de Littérature Comparée*, *Science et Vie*, and *Cahiers du Cinéma*, which was associated with the new-wave cinema.

Besides the written press the oral press of radio and television should also be taken into account. The Office de Radiodiffusion et de Télévision Française (ORTF, with television broadcasts in black and white and in colour) has its headquarters in Paris on the boulevard Kennedy and operates regional centres that also provide local news and broadcasts. The television reception area has increased tenfold with the use of the satellite Telstar relays. Both radio listeners and television viewers are offered programs ranging from political, literary, artistic, and scientific news broadcasts to reports of major events and news of celebrities, films, plays, and variety shows. The French government has centralized the oral press at the Office de Radiodiffusion et de Télévision Française, which has three channels. Television is state controlled but not unduly censored, and radio and television broadcasts range from entertainment to practical and educational programs. (C.De.)

The diversity of television and radio broadcasts

#### VII. Problems and prospects

Two events of the presidency of Charles de Gaulle (1959–69) profoundly modified the conditions that shaped the immediate future of France. The first was the conclusion of the war in Algeria, which brought to an end a vast and difficult venture in decolonization, and the second was the widening of presidential powers. France had headed the second greatest colonial empire of the world, from which it had certainly gained important advantages but which had also placed heavy burdens upon the nation. While still maintaining privileged relations with most of the countries formerly under its administration, France is free from the majority of those responsibilities, which clearly encumbered her policies. Since General de Gaulle's succession was secured without the disturbances feared by many, the unpredictable element in future domestic politics centres chiefly on the difficulty of resolving possible conflicts between the powerful office of the president and the National Assembly, as well as on the Communist Party's ambition to form, with other left-wing parties, an opposition force capable of gaining a government majority.

Economically speaking, though considerable progress has been made, future successes appear to rest on the development of the interior regions and on the growth of the Common Market. Provincial urban complexes that have stable populations and the satellite towns have been called upon to limit and, if possible, to absorb the population that has spilled over from the capital. The strengthening and expansion of the Common Market should make it possible for France simultaneously to continue modernizing its agriculture and to expand its export industries.

Whether or not Europe unites to form an economic and political buffer between the United States and the Soviet Union, France has realized that it is as impossible for her as it is for any of her European neighbours to stand

The unpredictable elements in domestic policies

The complexity of artistic and intellectual interests

alone. Through intellectual traditions, abundant resources, and the extent of the French territory, which has as yet escaped the problems of overindustrialization, France should be able to distinguish itself in the quest that becomes each day more pressing for the advanced nations of the world—that is, to reconcile the requirements of scientific and technical advance with the essential needs of man, to affirm the willingness “to be” rather than “to have” and thereby to keep or rediscover an elevated “quality of life” in a new society.

*The landscape and the people:* HILDA R. ORMSBY, *France: A Regional and Economic Geography*, 2nd ed. (1950); PHILIPPE PINCHEMEL, *Géographie de la France*, 2nd ed. (1966; Eng. trans., *France: A Geographical Survey*, 1969), includes a very complete bibliography; FRANCIS J. MONKHOUSE, *A Regional Geography of Western Europe* (1959), contains a very good presentation of the different regions of France; GEORGES CHABOT, *Géographie régionale de la France*, 2nd ed. (1969); MAURICE LE LANNOU, *Les Régions géographiques de la France*, 2 vol. (1964); *Atlas de France*, 2nd ed. (1958); *Grand Atlas de la France* (1970), excellent documentation; *Atlas économique et social pour l'aménagement du territoire*, 5 fasc. (1968–); JACQUELINE BEAUJEU-GARNIER, *La Population française*, 3rd ed. (1972) and *Le Relief de la France* (1972).

*The economy:* A brief general introduction to the contemporary French economy is CHARLES P. KINDLEBERGER, “The Postwar Resurgence of the French Economy,” in STANLEY HOFFMANN et al., *In Search of France* (1963); see also the same author’s *Economic Growth in France and Great Britain, 1851–1950* (1964). For a comparison of French economic performance with that of other Western industrial countries, see ANGUS MADDISON, *Economic Growth in the West* (1964). Various aspects of the economy are treated in ANDRE BISSON, *Institutions financières et économiques en France* (1960); DAVID GRANICK, *The European Executive* (1962); ANDRE MARCHAL, *La Pensée économique en France depuis 1945* (1953); and JOHN SHEAHAN, *Promotion and Control of Industry in Postwar France* (1963). Much has been written about the French attempt at central economic planning. Books representing different points of view include: PIERRE BAUCHET, *La Planification française*, 2nd ed. (1962; Eng. trans., *Economic Planning: The French Experience*, 1964); WARREN C. BAUM, *The French Economy and the State* (1958); STEPHEN S. COHEN, *Modern Capitalist Planning: The French Model* (1969); JOHN and ANNE-MARIE HACKETT, *Economic Planning in France* (1963); V.C. LUTZ, *French Planning* (1965); GEOFREY DENTON, MURRAY FORSYTH, and MALCOLM MACLENNAN, *Economic Planning and Policies in Britain, France and Germany* (1968); ANDREW SHONFIELD, *Modern Capitalism* (1965). For information on current economic developments, see the annual surveys published by the Organization for Economic Cooperation and Development, *Economic Surveys: France*.

*Transportation:* The two principal statistical sources relative to transport (both issued annually) are the *Annuaire statistique des transports* and the *Mémento de statistiques de la S.N.C.F.*

*Administrative and social conditions:* (*Constitutional framework*): MARCEL PRELOT, *Précis de droit constitutionnel*, 2nd ed. (1953), a good historical and judicial synthesis of French constitutions, with emphasis on the Fifth Republic; PIERRE AVRIL, *Le Régime politique de la V<sup>e</sup> République*, 2nd ed. (1966), very good political analysis of the regime; ANDRE CHANDERNAGOR, *Un Parlement pour quoi faire?* (1967), the constitutional regime seen by a member of Parliament; FRANÇOIS MITTERAND, *Le Coup d'état permanent* (1965), the Gaullist regime as seen by an opponent. (*Local structures*): BRIAN CHAPMAN, *Introduction to French Local Government* (1953); HERVE DETTON and JEAN HOURITCO, *L'Administration régionale et locale de la France*, 5th ed. (1968). (*Parties and political life*): STANLEY HOFFMANN et al., *In Search of France* (1963); ALEXANDER WERTH, *France: 1940–1955*, 2nd ed. (1966); DOROTHY M. PICKLES, *The Fifth French Republic*, 3rd ed. (1966); HENRY W. EHRMANN, *Politics in France*, 2nd ed. (1971); PHILIP M. WILLIAMS and MARTIN HARRISON, *De Gaulle's Republic* (1960); JACQUES CHAPSAL, *La Vie politique en France depuis 1940*, 2nd ed. (1969), an excellent work that puts events in their proper places; JEAN-PAUL CHARNAY, *Le Suffrage politique en France* (1965), on presidential and legislative elections and referendums; JEAN CHARLOT, *Le Phénomène gaulliste* (1970), discusses whether the Gaullist party is similar to other parties; EMERIC DEUTSCH, DENIS LINDON, and PIERRE WEILL, *Les Familles politiques aujourd'hui en France* (1966), a useful table of French political complexity. (*Justice*): ROGER AUBENAS et al., *La Justice* (1961); RAYMOND

CHARLES, *La Justice en France*, 3rd ed. (1964). (*Army*): PAUL MARIE DE LA GORCE, *La République et son armée* (1963; Eng. trans., *The French Army*, 1963); RAOUL GIRARDET, PAUL M. BOUJU, and JEAN-PIERRE H. THOMAS, *La Crise militaire française, 1945–1962* (1964), a complete, serious, and critical account of French military policy. (*Public offices*): ANDRE DE LAUBADERE, *Manuel de droit administratif*, 9th ed. (1969), a remarkable work tool; ROGER GREGOIRE, *La Fonction publique* (1954), a historical and descriptive synthesis; LOUIS FOUGERE, *La Fonction publique* (1966); BERNARD GOURNAY, JEAN-FRANÇOIS KESLER, and JEANNE SIWEK-POUYDESSEAU, *L'Administration publique* (1967); GERARD BELORGEY, *Le Gouvernement et l'administration de la France* (1967), descriptive; ANTOINE PROST, *Histoire de l'enseignement en France, 1800–1967* (1968), a very well-documented, predominantly sociological study. (*Police*): *La police en France*, special issue of the journal *La Nef* (1963), several juxtaposed analyses that give an overall glimpse. (*Education*): GERALD ANTOINE, *Réforme ou renaissance de l'université* in his and JEAN-CLAUDE PASSERONS, *La Réforme de l'université* (1966); FELIX PONTEIL, *Histoire de l'enseignement en France* (1966); BERNARD MEGRINE, *La Question scolaire en France* (1960), tells about the quarrel between Catholic and lay education. (*Housing*): GILLES EBRIC and PIERRE BARJAC, *Le Logement, dossier noir de la France* (1970), condemning report; CLAUDE ALPHANDERY, *Pour une politique du logement* (1965); ERIC G. HOWES, *Housing in Britain, France and Western Germany* (1965); GILBERT MATHIEU, *Peut-on loger les français?* (1965). (*Standard of living*): GERARD LYON-CAEN, *Les Salaires* (1967), a precise and complete account; JACQUES LECAILLON and JEAN MARCHAL, “Wage-Structure and the Theory of the Distribution of Income: The French Pattern,” in EDWARD MAURICE HUGH-JONES (ed.), *Wage-Structure in Theory and Practice* (1966); ARMAND CAPOCCI, *La Hiérarchie des salaires* (1964). (*Social security and public health*): PIERRE LAROQUE (ed.), *Succès et faiblesse de l'effort social français* (1961), an overall study carried out by the creator of Social Security; and (ed.), *Les Institutions sociales de la France* (1963), a complete and well-documented report on French social, hospital, and health structures; GUY DELAMOTTE, *La Santé des Français* (1962), a discussion of serious diseases and health facilities; DELORS LEVY, *Réflexions sur l'avenir du système de santé: contribution à l'élaboration d'un politique sanitaire* (1970), an official point of view. (*Social classes*): PIERRE LAROQUE, *Les Classes sociales*, 4th ed. (1968), a good résumé.

*Cultural life and institutions:* DOMINIQUE and MICHELE FREMY, *Quid? Tout pour tous* (annual); PAUL GINESTIER and ANDRE MAILLET, *Culture et civilisation françaises* (1962); volumes on *Métiers and Loisirs* in the encyclopaedia *Clartés*, vol. 7–9 (1949); *Revue de l'Enseignement Supérieur* (quarterly); *Culture Française* (4/year); *France in Les Guides Bleus* series.

    - The Fifth Republic

## I. The emergence of France

The development of France as a nation was a long process, the first stage of which can be placed in the period between the division of the Carolingian Empire in the mid-9th century and the emergence of a powerful French monarchy at the end of the 12th century.

This period, which began with the separation of the West Frankish kingdom (approximately the area of present France) from the Frankish domains in what is now Germany, was marked by a fragmentation of political power and the development of feudalism. It was a time of violence but also one of renewal, during which the culture of the High Middle Ages was formed. These trends were reflected in the country's population: stagnant and perhaps even declining during the Viking inva-

sions of the 9th and 10th centuries, it showed a slow increase after the mid-11th century and a rapid one in the 12th century. This returning vitality was accompanied by an increase in activity, political and otherwise.

### FRENCH SOCIETY IN THE EARLY MIDDLE AGES

**Religion and cultural life.** In the second half of the 9th century the only unifying factor in France was the Christian religion. It was a Christianity generously admixed with ancient pagan beliefs, and its gospel of peace had little effect in the chaotic atmosphere caused by repeated invasions of the country by the Vikings from the north and by Muslim raiders from the Mediterranean. During the last years of the century, a reaction began to occur against the decadence into which the Carolingian Church had fallen. Under the leadership of a few gifted individuals, new life was instilled into the monastic movement, and the church hierarchy began to take responsibility for maintaining order and justice.

The monastic revival became centred at the Abbey of Cluny in Burgundy (founded in 910). The Cluny community restored observance of monastic discipline under the Benedictine rule and, with its daughter houses, inspired a religious reform movement that came to exert a profound influence on the whole Western Church in the 11th century. In France, where in the 12th century the Cistercian movement continued the work of the Cluniacs, the reformed monasteries helped to create an atmosphere of solidarity on all levels of society.

At the same time, the French Church, in the absence of any strong leadership from the declining Carolingian monarchy, took the lead in attempting to discourage warfare between the powerful feudal magnates who governed the country. Ecclesiastical legislation, such as the Peace of God and the Truce of God, which forbade fighting on certain days or during certain seasons of the year, was designed to limit violence and disorder and encourage a return to more stable conditions.

The religious revival and the limitation of warfare made possible, in the 11th century, a new flourishing of the arts, exemplified by the profusion of new churches in the Romanesque style. Much of this was not peculiarly French; similar developments were occurring contemporaneously in Germany and other parts of western Europe, where the monastic-centred cultural movement of the 10th and 11th centuries spread out in the 12th century to other sectors of society, manifesting itself in the revival of Roman law, the development of Scholastic thought, and the founding of new educational institutions. France did, however, play a unique part in this movement because of the fame of its monastic centres and, later, of its schools (*e.g.*, Chartres, Orléans, and especially Paris, the intellectual home of such great 12th-century masters as Peter Abelard and Peter Lombard).

In this period the various French dialects that had developed from the "vulgar Latin" language of the late Roman Empire began to assume a literary form and were used in poetry. These dialects belonged to two main groups: the *Langue d'Oïl* in the region north of the Loire River and the *Langue d'Oc* to the south. This division is an indication of the substantial cultural differences between the two regions. The *Langue d'Oïl*, which was the ancestor of modern French, developed a rather extensive literature in the 11th century (in such forms as the warlike poems called *chansons de gestes*) that gives a valuable picture of contemporary society.

**Economic life.** As in most preindustrial societies, the main activity of the people was agriculture. Technical backwardness and the unsettled conditions of the early feudal regime tended to make each locality into a self-sustaining unit. Trade was limited to essential items such as salt. The pattern of landholding that emerged in northern France was, in the main, one of large estates or domains, each with a single proprietor (the lord). The typical domain was divided into the lord's portion and a number of smaller plots worked by hereditary tenants. The lord, in addition to the produce of his own portion (worked by the tenants), was entitled to a share of each tenant's own crop. Because he was the landowner, he ex-

*Langue d'Oïl and Langue d'Oc*

exercised various rights over the people on his domain (free and slave) and had judicial, police, and military powers. This gave the great landowners, as a class, enormous influence and imposed upon society a hierarchy in which the lord played the dominant role. The feudal system in its classic form was really confined to the area north of the Loire. In southern France smaller landholdings survived, and urban life and the Roman law tradition never completely died out.

The feudal system of economy was not one that precluded change and development. As the population increased, new land was cleared, new villages were founded, and different forms of land tenure were introduced. In the 12th century, the feudal system began to change as the European economy revived and communications improved. Increased trade brought new forms of power that the feudal magnates could not always control. The monarchy made use of changed conditions to increase its own power at the expense of the nobles.

**Feudal polity.** Feudalism, in addition to being an economic system, was also, and perhaps primarily, a political system that developed out of the one that preceded it. Although it exhibited a certain amount of diversity in different areas, there was enough similarity to create a recognizable pattern throughout the country.

As early as the mid-9th century it was clear that the West Frankish monarchy would have difficulty in exercising any centralized control over the territory allotted to it at the partition of the Carolingian Empire, the partition itself having resulted from a breakdown of central authority. Added to the problems posed by slow communications were the disrupting effects of Viking raids, which reached as far inland as Paris in 845. Establishing themselves on an island at the mouth of the Loire, the Northmen attacked Bordeaux, Toulouse, Orléans, and Angers between 863 and 873. From a base in the Somme estuary, they pillaged Amiens, Cambrai, Reims, and Soissons. But the Seine was the main attraction. In 856–860 they laid waste to the country around its lower reaches and frequently attacked Paris in subsequent years. Sometimes they were turned back by effective defenses but more often by payment of tribute. After 896 the invaders began to settle permanently in the Lower Seine Valley, where they eventually formed the Duchy of Normandy. At the same time, the Mediterranean coast was plagued by Muslim attacks and occasionally by Vikings, though the threat there was less serious.

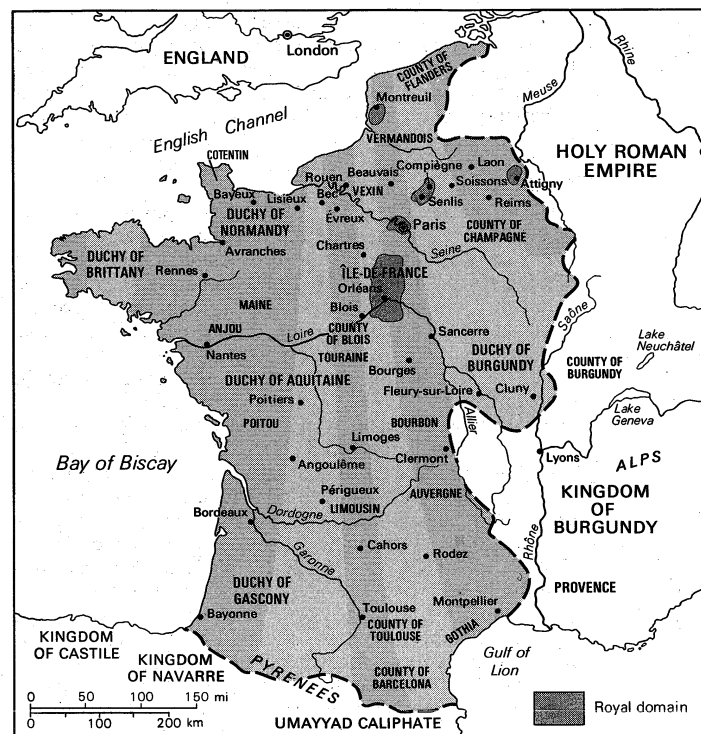

The inability of the monarchy to protect its territory soon led to the establishment of local defense systems. Before 900 the kings were already delegating authority to regional commanders for this purpose. These commanders were often great landowners in the districts where they were given control. They thus acquired great power; they were enabled to make their positions hereditary and to treat the areas under their control as their own possessions, using their delegated authority to advance their own interests. In the early 10th century these magnates built castles to defend their lands and exercised all the functions of government. Their domains formed the basic unit of the feudal polity, establishing a pattern of fragmented authority at the expense of the central power.

Feudalism did establish a kind of solidarity based on family ties and self-interest. Its internal structure was based on vassalage (the obligation owed by a lesser lord to a greater one in return for the right to a fief). As the rights conferred by possession of a fief nearly always consisted of control over landed property, the possessor sought to make it hereditary, thus stabilizing the relationship between lord and vassal from one generation to the next. The great lords were bound, at least nominally, to the king by ties similar to those which bound their vassals, thus completing a network of mutual loyalties.

The process of fragmentation continued until the middle and in some areas until the end of the 11th century, giving the political map of France the appearance of a complex mosaic. By the beginning of the 12th century, however, the trend was reversing itself; the great lords were able to assert greater control over their vassals,

whose economic difficulties cost them a certain loss of independence. The society as a whole felt the need for a more orderly kind of existence. Thus, the great fiefs once again resumed the unified appearance they had lost in the 10th century. The king, too, was able to begin re-establishing his authority.

France in 987.

#### THE POLITICAL HISTORY OF FRANCE (C. 850–1180)

**The principalities north of the Loire.** Outside of the royal domain (centred around Paris), the principal territories of northern France in this period were Flanders, Normandy, Anjou, Brittany, Blois-Champagne, and Burgundy.

The northernmost of these was Flanders, where the Carolingian king Charles the Bald installed his brother-in-law, Baldwin Iron Arm, as count in 862. Under Baldwin's successors, Baldwin II (879–918), Arnulf (918–963), Arnulf II (965–988), Baldwin IV (988–1035), Baldwin V (1036–67), and Baldwin VI (1067–70), the county, which included part of what is now Belgium, was gradually extended eastward. By 1070 it was a powerful state with centralized institutions. Under Count Robert le Frison (1071–93), towns began to develop, and the woollen industry—the basis of Flanders' economy for the remainder of the medieval period—first became important. The direct line of Baldwin I became extinct in 1119, and there was a succession dispute following the death of Count Charles the Good (1127). Stability was restored by Thierry of Alsace (1128–68) and his son Philip (1169–91). At the end of the period, Flanders remained a major power in northern France.

The Duchy of Normandy was created in 911, when King Charles the Simple granted the area of the dioceses of Rouen, Lisieux, and Evreux to the Viking chieftain Rollo. In the following years, Rollo's successors, the Norman dukes, accepted Christianity and gradually extended their authority over the other lords of the region. Because the Carolingian king Lothair refused to recognize the Norman rule over Bayeux, Avranches, and the Cotentin, Duke Richard I (942–996) allied himself with Hugh Capet, who displaced the Carolingians and founded the Capetian dynasty in 987. Duke Richard II (996–1026) continued the Norman-Capetian alliance. Under Robert the Devil (duke 1027–35) Normandy expanded

loyalties

to the west, and under William the Conqueror (1035–87) it became the strongest and best governed fief in France. William's conquest of England (1066) made him a formidable rival to the French king. At the same time, Norman power was even further increased by the establishment of Norman states in Italy.

Divided between 1080 and 1106, Normandy and England were reunited under the Conqueror's grandson Henry I of England, who was duke of Normandy from 1106 to 1135. On his death, the duchy went to his son-in-law Geoffrey Plantagenet, count of Anjou, whose son became king of England as Henry II in 1154. Henry's Angevin Empire included vast territories in France. Normandy, because of its geographical position and internal cohesion, as well as its already strong ties with England, became the centre of Angevin power on the Continent.

Anjou, on the lower part of the Loire River, southwest of Normandy, was among the territories given to Robert the Strong in 866. In the 10th century, the Angevin counts, Fulk I (died 942), Fulk II (c. 942–c. 960), and Geoffrey Grisegonelle (c. 960–987), managed to prevent its absorption by the Normans and forged it into a separate principality. Anjou's territory was increased by the annexation of Maine to the north and Touraine to the east under Fulk III Nerra (987–1040) and Geoffrey Martel (1040–60), but it never became as stable or as centralized as Flanders and Normandy.

Brittany, to the west of both Normandy and Anjou, had a strong Celtic tradition, which tended to make it an area apart. It achieved unity in the 9th century under the Breton leader Nomenoë, who seized Nantes and Rennes in defiance of Charles the Bald. Nomenoë's successors, nominally subject to the West Frankish kings, but actually autonomous, managed to defend Brittany against the Vikings. The title duke was adopted by the Breton rulers in the 10th century. The dukes of the line of Conan of Rennes (10th–12th centuries) fought a long struggle to subdue their rebellious vassals, and in the 11th century they were aided by William the Conqueror, whose successors sought unsuccessfully to gain control of Brittany. Duke Conan IV (1137–71) gave his daughter in marriage to Geoffrey, son of Henry II of England; Geoffrey succeeded Conan as duke in 1166; nevertheless, Brittany remained an independent entity until the end of the period.

The area around Blois, to the east of Touraine, was also entrusted to Robert the Strong and remained in the possession of his descendants until c. 940, when Thibaut the Old seized control of it and founded the line of the counts of Blois. His successors, Thibaut II, Eudes I, and Eudes II, annexed the counties of Sancerre (1015) and Champagne (1019–23), creating the House of Blois-Champagne. This aggregation achieved its greatest strength under Count Thibaut IV (II of Champagne, 1125–52); a formidable opponent of Kings Louis VI and Louis VII, Thibaut was one of the most powerful lords in France. This threat to the monarchy ended when Blois and Champagne were divided under Thibaut's sons.

French Burgundy, to the south of Champagne, was detached from the kingdom of Burgundy-Provence c. 880. Comprising the area between the Saône, the Loire, and the Upper Seine rivers, it came into the possession of the Capet family in the 10th century and remained under their control until 1361.

Thus, by the latter part of the 12th century, France north of the Loire was divided into a few large principalities (some of them associated with the English crown) coexisting with each other and with the French king, who lived in their midst.

**The principalities of the south.** The main territorial divisions that either existed or came into being south of the Loire in this period were Provence, Auvergne, Toulouse, and Aquitaine.

Provence, in what is now the southeasternmost part of France, was not part of the West Frankish domains; in 843 it was given to Lothair, brother of Charles the Bald. From 879 it formed the kingdom of Burgundy-Provence, whose crown was held by the rulers of Jurane Burgundy

in the 10th century and by the Holy Roman emperors in the 11th. Real power was in the hands of the local counts, who defended Provence against Muslim attacks. In the 12th century, the territory was divided between the counts of Toulouse and the counts of Barcelona.

Auvergne, centred around Clermont, though constituted as a county, remained a divided land throughout the period.

The County of Toulouse dated from 849; at that time, under Counts Frédelon (849–852) and Raymond I (852–c. 862), it included the areas around Toulouse and Rodez, some territory in the Pyrenees, and Limousin. The county became disunited after Raymond's death and remained so until the 11th century, when Counts William III Taillefer (died 1037) and Pons (1037–61) reunited it, extending their rule over much of central southern France. In the later 11th and the 12th century, Raymond IV (died 1105) and his successors gained the Crusader countship of Tripoli in Syria, but they were weakened at home by conflicts with the counts of Barcelona and the dukes of Aquitaine.

Aquitaine, which included most of western France south of the Loire, was a kingdom in the 9th century but became fragmented during the Viking invasions. In c. 950 Count William I of Poitiers assumed the title duke of Aquitaine. His successors extended their suzerainty over much of the region but failed to establish a centralized administration. Eleanor, daughter of Duke William X (died 1137), married Henry of Anjou, who became Henry II of England in 1154, and the duchy was controlled by the English crown after 1154.

None of the southern principalities had achieved much unity or cohesion by the late 12th century. This and the growing prevalence in southern France of the Cathar, or Albigensian, religious sect, condemned by the official church, made them vulnerable to the expanding Capetian monarchy in the succeeding period.

**The monarchy.** In 843 the three sons of the Carolingian emperor Louis I the Pious divided his empire among them. The western part of the Frankish realm (*Francia Occidentalis*) went to Charles the Bald.

Charles had to deal with opposition from his restless magnates, as well as the threat posed by Viking raids and the aggression of his brother Louis the German. He repelled an invasion by Louis in 858, but his assumption of the imperial crown in 878 distracted his attention from the west. It was in the subsequent period that he entrusted the defense of his kingdom to the magnates, demarcating great zones of military command that prefigured the feudal divisions of France. He sought alliances with those whom he was no longer able to crush; for example, with the Robertians, descendants of Robert the Strong and ancestors of the Capetian dynasty.

Before setting out on an expedition to Italy, Charles issued the capitulary of Quierzy-sur-Oise (877), in which he promised the magnates that during his absence no one would do anything to prejudice their position. This temporary provision, extremely favourable to them, was transformed into an inviolable principle by the magnates after Charles' death (October 877).

By force of circumstances feudalism had been established in the kingdom. Charles the Bald had had enough personal authority to withstand any unjust encroachments, and, moreover, he could rely on support of the church in so doing; but his successors were to prove incapable of following his example with success. The balance was again tilted in favour of the magnates, who now had military strength and vassals of their own.

**The last Carolingians and the Robertian interventions (877–987).** Charles the Bald's son and successor, Louis II le Bègue, or the Stammerer, died in 879, leaving the kingdom jointly to his sons Louis III (died 882) and Carloman; but when Carloman died (884) his half brother Charles III the Simple was an infant, and the West Frankish crown was taken by the East Frankish king and emperor, Charles III the Fat, only surviving son of Louis the German. Deposed by the East Franks in Germany in 887, Charles the Fat died in 888, whereupon the West Frankish magnates elected as king Eudes,

Capet

son of Robert the Strong and the first of the Robertians to take the crown away from the Carolingian dynasty. In 893, however, Charles the Simple, with the support of some of the magnates, was crowned at Reims, and, thenceforward, he and Eudes were rivals until the latter's death in 898. It was Charles the Simple who had to allow the Northmen to settle permanently in northern France. A new revolt of the magnates led to the election of another Robertian, the brother of Eudes, to the kingship as Robert I in 922. After Robert I had been killed in battle against Charles in 923, his son-in-law Rudolph (Raoul) was elected in his place; and Charles the Simple was taken prisoner (to die in captivity in 929). Yet when Rudolph died in 936, the Robertian candidate for the crown, Hugh the Great, son of Robert I, stood aside for a Carolingian restoration in the person of Charles the Simple's son Louis IV, called d'Outremer ("from Overseas") because he had been a refugee in England since his father's deposition. Louis IV achieved much to revive the prestige of his dynasty and left the crown undisputed at his death to his son Lothair in 954. On Lothair's death in 986, the crown passed to his son Louis V le Fainéant, but, already, the Robertian Hugh Capet, son of Hugh the Great, was entertaining designs on the monarchy. Louis V's early death (987) was followed by the election of Hugh Capet as king, to the exclusion of the Carolingian pretender Charles, duke of Lower Lorraine, a younger son of Louis IV. The Carolingian dynasty in France was now definitively superseded by the Capetian heirs of the Robertian kings.

Whatever their personal merits might sometimes have been, the Carolingians after 877 were at grips with a social evolution beyond their control. Occasionally, the prestige of the dynasty, strengthened by the support of the papacy, enabled the kings to prevail against their rivals, as Louis IV and his son Lothair did; but the royal house was impoverished and no longer had any property to distribute as the price for loyalty. The kings were merely tolerated or brought to power according to the interests of the great territorial princes in their quarrels with one another; for example, the dukes of Burgundy or of Normandy and the counts of Flanders.

Even so, the Carolingian dynasty had too much past glory to be left at the head of a kingdom now thoroughly feudalized. The transfer of the royal title to Hugh Capet in 987 was made largely because, despite the great extent of his inherited domain, he was the weakest of the territorial princes and could be expected to trouble no one.

*The Capetians.* The Capetian kings from 987 until 1180 were Hugh Capet (987–996), Robert II (996–1031), Henry I (1031–60), Philip I (1060–1108), Louis VI (1108–37), and Louis VII (1137–80). They succeeded to a thoroughly feudalized realm. To make themselves strong, the kings first needed to possess a wide domain and manifold rights allowing them to act in all parts of the kingdom. The royal domain was extended persistently, either by the king's fighting of rebellious lords openly or by his deft use of the rights permitted him as a sovereign such as confiscating fiefs and intervening in the rights of succession.

At the end of the 10th century the Capetians had only a diminutive domain, much smaller and weaker than that of many a great vassal. The essential nucleus of their lands was in the region of Paris, Orléans, Beauvais, Soissons, and Compiègne, though they also had various lands scattered all over the kingdom as well as numerous rights, the most important being that which the king exercised over episcopal churches and monasteries. The aim of the first Capetians was to control the regions within which there were royal lands; to achieve peace by reducing the plundering lords and petty vassals to obedience; and, in some circumstances, to increase their own possessions by confiscating the lands of factious vassals.

In their rise to power, the Capetians were supported by the dukes of Normandy and the counts of Anjou; but, once they had secured the crown, Hugh Capet and his successors found these and the other northern magnates to be dangerous rivals. Initially, they came into conflict with the counts of Blois; after the mid-11th century, their

chief opponents were the Normans and later the Angevins. Between 1154 and 1180, the English-based Angevin Empire, including a large, compact block of territory in France, was the principal check to the expansion of French monarchy. Philip I, Louis VI, and Louis VII did what they could to exploit rivalries among the magnates to their own advantage, but, although they were able to hold their own, they were not conspicuously successful in increasing the territorial possessions of the crown.

At the end of the 10th century, three elements of the rather weak royal administration existed side-by-side: the king and his household (his family and servants); the great officers of the realm; and the Curia Regis, a feudal court that theoretically brought together all the vassals to advise the king. For most of the 11th century, the influence of these institutions remained very limited, but after 1080 they began to evolve, partly in imitation of the bureaucratic structures that were emerging in the great fiefs.

In the traditional feudal sphere, the kings tried to improve the central administration and make better use of the court. The royal household was run by members of the royal family. The principal offices of the royal household (the constable, cupbearer, chamberlain, etc.) were, for the most part, reliable vassals from the *flé-de-France*. The most important exception was the *seneschal* (steward of the household), who was customarily a member of the count of Champagne's family. Because the king could not depend upon the *seneschal's* loyalty, Philip Augustus allowed the office to die out in 1191. The most important change involved the office of chancellor. Originally in charge of the royal chapel, the chancellor came to have the duty of recording and authenticating royal decrees. From the time of Louis VI, this officer was given important administrative responsibilities and became the head of a clerical staff on which the king placed great reliance. The 12th-century kings chose their chancellors with great care and saw to it that the office did not become hereditary.

Even more important than developing traditional institutions was the monarchs' skill in making use of gifted people in their service, people who might become influential without holding any particular office. An example of this was the position of Suger, abbot of Saint-Denis under Louis VI.

Outside the royal domain, the kings of this period had no administrative apparatus other than what belonged to them as feudal suzerains. The royal domain itself was administered by provosts (*prévôts*), who saw that its revenues reached the royal treasury and handled legal matters. The office of provost was hereditary in the 11th century, but Louis VII created new *prévôts* (areas administered by provosts), thus increasing royal control and preparing the way for the later creation of the appointive office of bailiff. (M.Pa.)

## II. France, 1180 to c. 1490

### FRANCE FROM 1180 TO 1328

*The kings and the royal government.* The French monarchy was greatly strengthened by Louis VII's successor, Philip II Augustus (ruled 1180–1223), who could claim descent from Charlemagne through his mother. Philip proved to be the ablest Capetian yet to reign. He was practical and clear-sighted in his political objectives; the extension of territorial power and the improvement of mechanisms with which to govern an expanded realm were his consistent policies. Perhaps it was not accidental that royal documents began to refer to the king of France (*rex Franciae*) instead of using the customary formula king of the Franks (*rex Francorum*) within a year or two of Philip's accession.

*Philip Augustus.* Philip's outstanding achievement was to wrest control from the Plantagenets of most of the domains they held in France. Intervening in struggles between Henry II of England and his sons, Philip won preliminary concessions in 1187 and 1189. He acquired strategic lands on the Norman borders following wars with Henry's sons, King Richard and King John (1196 and 1200). And when, in 1202, John failed to answer a

Capetian  
institutions

Territorial  
expansion

summons to the vassal court of his lord, Philip Augustus confiscated his fiefs. Normandy, invaded in 1204, submitted to the Capetian in 1208. Maine, Anjou, and Touraine fell rapidly (1204–06), leaving only Aquitaine and a few peripheral domains in the contested possession of England. By the Truce of Chinon (September 18, 1214), John recognized the conquests of Philip Augustus and renounced the suzerainty of Brittany, although the complete submission of Poitou and Saintonge was to take another generation.

Philip's other acquisitions of territory, if less spectacular, were no less important for consolidating the realm. In the north he pressed the royal authority to the border of Flanders. Artois, which came under his control as a dowry with his first wife, was fully secured in 1212. Vermandois and Valois (1213) and the counties of Beaumont-sur-Oise and Clermont-en-Beauvaisis were annexed during his last years. On the southern limits of the Ile-de-France Philip rounded out prior possessions in Gâtinais and Berry. Much of Auvergne, whose suzerainty had been ceded by Henry II in 1189, passed to royal control in 1214; while in the more distant south, Philip extended his influence by gaining lordship over Tournon, Cahors, Gourdon, and Montlaur in Vivarais. As the reign ended, only Brittany, Flanders, Champagne, Burgundy, and Toulouse, among great fiefs, lay outside the royal domain.

Because the territorial expansion was accomplished through traditional means—dynastic, feudal, and military—the curial administration was, outwardly, little changed. Household officers such as the butler and the constable continued to function as in the past. But Philip Augustus was even more suspicious of the seneschalship and chancellorship than his father had been; he allowed both offices to fall vacant early in his reign, entrusting their operations to lesser nobles or to clerics of the entourage. Although their activity is obscure, some of these men were beginning to specialize in justice or finance. The curia as such, however, remained undifferentiated; characteristically, the committee of regents, appointed in 1190 to hold three courts yearly while the King was absent on crusade, was expected to function both in justice and administrative review on those occasions. Prelates and nobles of the curia also served as counsellors; and enlarged councils convened, at the King's summons, on festivals or when major political or military issues were contemplated.

Innovations in royal administration

There were two considerable innovations in royal administration. First, the chancery began to keep better records of the King's activity. Documents were copied into registers before being sent out, and lists of churches, vassals, and towns were drawn up to inform the King of his military and fiscal rights. Clerks were recording the King's receipts and expenditures before (probably long before) 1202, the year for which the first written account survives.

Second, Philip acted early in his reign to secure better control of the domains he governed directly. He appointed members of his court to hold periodic local sessions, to collect extraordinary revenues, to lead military contingents, and to supervise the provosts. The new officers, called bailiffs (*baillis*), at first had no determined districts in which to serve (they resembled the circuit commissioners of Angevin government, whose office may have been the model for the Capetian institution). From the outset the bailiffs were paid salaries; they were more reliable than the provosts, who, by the later 12th century, generally farmed the revenues. In the newly acquired lands of the west and south, Philip and his successors instituted seneschals—functionaries similar to the bailiffs, but with recognized territorial jurisdiction from the outset.

Philip Augustus' policy toward his conquered domains was shrewd. He retained the deep-rooted customs and administrative institutions of such flourishing provinces as Anjou and Normandy; indeed, the superior fiscal procedures of Normandy soon exercised perceptible influence on Capetian accounting elsewhere. On the other hand, to secure the loyal operation of provincial insti-

tutions, Philip appointed men of his own court, typically the natives of the Ile-de-France. It was a compromise that was to work well for generations to come.

The character of Philip's rule may likewise be deduced from his relations with the main classes of the population. A devoted son of the church, if not unswervingly faithful, he favoured the higher clergy in many of their interests. He opposed the infidels, heretics, and blasphemers; he supported the bishops of Laon, Beauvais, Sens, and Le Puy (among others) in their disputes with townspeople; and he granted and confirmed charters to monasteries and churches. Yet he was more insistent on his rights over the clergy than his predecessors had been. He required professions of fidelity and military service from bishops and abbots, cited prelates to his court, and sought to limit the jurisdiction of ecclesiastical courts. He supported papal policies or submitted to papal directives only to the extent that these were consistent with his temporal interests.

Philip's relations with his subjects

Toward the lay aristocracy, Philip Augustus acted energetically as suzerain and protector. Indeed, no Capetian was more fully the "feudal monarch." His war with John resulted from a breach of feudal law and was fought with feudal levies. As with ecclesiastical vassals, Philip insisted upon the service due from fiefs; he exploited the feudal incidents, notably relief and wardship; and he required his vassals to reserve their fealty for himself alone. He extended his influence by entering into treaties (*pariages*) with minor lords, often distant ones; and by confirming the acts of nobles, in numbers unprecedented, he recovered the force of the royal guarantee.

His policy toward the lesser rural and urban populations was to increase their loyalty and contribution to the crown without significantly reducing their dependence on the King and other lords. Philip offered his protection to exploited villages, and, especially during his early years, he confirmed existing "new towns," extended their privileges to other villages and otherwise favoured peasant communities. Townsmen, notably those in semiautonomous communes, gained confirmation of their charters; and the King created some new communes. Most of the latter were located in strategic proximity to the northern frontiers of the expanded royal domain (this fact, together with the obligations of service and payment specified in the charters, suggests that military motives were paramount in these foundations). More generally evident in these charters, as in others, was the desire to gain the political fidelity of a prospering class. At Paris Philip Augustus acted as did no other local lord to promote the civic interest: improving sanitation, paving streets, and building a new wall. Parisian burghers financed and administered these projects; they were associated in the fiscal supervision of the realm when the King went on crusade, but they were not favoured with a communal charter.

Civic improvements

*Louis VIII.* The reign of Louis VIII (ruled 1223–26) had an importance out of proportion to its brevity. It was he (husband of the formidable Blanche of Castile and father of famous sons) who first brought Languedoc under the crown of France and who inaugurated the appanages—grants of property to members of the royal family or royal favourites—through which the expanded France of later generations was to be governed. The conquest of Languedoc, following the Albigensian Crusade (against heretics in southern France) that was only tepidly supported by Philip Augustus, was not complete until the 1240s, but the royal seneschals of Beaucaire and Carcassonne were already functioning when Louis VIII died. And it was in keeping with that ruler's will of 1225 that the great appanages passed to his younger sons as they came of age—Artois to Robert in 1237; Poitou, Saintonge, and Auvergne to Alphonse in 1241; and Anjou and Maine to Charles in 1246.

*Louis IX.* The real successor to Philip Augustus, however, was his grandson, Louis IX (ruled 1226–70), in whose reign were fulfilled some of the grand tendencies of prior Capetian history.

Louis IX, who was canonized in 1297, is the best known Capetian ruler. He impressed all who came in touch with

him, and the records of his reign—*anecdotal and historical as well as official*—leave no doubt that he commanded affection and respect in a combination and to an extent that were unique. He regarded himself as a Christian ruler, duty bound to lead his people to salvation. He led by example, precept, and correction. He earned a reputation for fairness and wisdom that enabled him to rule as absolutely as he wished; only with the crusade, perhaps, did his judgment falter. His reign was marked by consolidation, maturation, and reform rather than by innovation.

Louis IX's  
territorial  
acquisi-  
tions

In his early years baronial revolts, supported by Henry III of England, were put down by the regency, headed by the Queen Mother, with singular firmness and skill. Poitou and Saintonge remained restive largely because of the stubborn machinations of Isabella of Angoulême (King John's widow); and it was only in 1243, after a revolt planned to coincide with an uprising in Languedoc, that the feudal adjudication of 1202 was fulfilled in Aquitaine. The revolt of Raymond Trencavel, dispossessed heir to the viscounty of Béziers, halfheartedly supported by Raymond VII of Toulouse, was no more successful; its failure resulted in the vindictive destruction of the petty nobility of Languedoc, and many fiefs thereupon passed to the crown.

Such were the principal territorial acquisitions of Louis IX; but the balance of his work was to be affected further by three characteristic events. First, despite his victory of 1243, Louis remained disposed to compromise with Henry III; and in the Treaty of Paris (December 1259) Henry regained feudal title to lands and reversionary rights in Guyenne in exchange for renouncing all claims to Normandy, Anjou, Maine, Touraine, and Poitou. Similarly, by the Treaty of Corbeil (May 1258) Louis himself had abandoned ancient claims to Catalonia and Roussillon in exchange for the renunciation of Aragonese rights in Gévaudan and Rouergue. Meanwhile, upon the death of Raymond VII in 1249 the county of Toulouse had passed to Raymond's son-in-law, Alphonse of Poitiers, who proceeded to govern it as effectively as his appanage lands; and when he and his wife died without issue in 1271, their enormous inheritance reverted to the royal domain.

The ancient household administration died out in the 13th century. Offices such as the chancery and treasury became more specialized and bureaucratic, while the greater advisory personnel formed a fluctuating corps of reliable favourites: bishops, abbots, and minor nobles of the old Capetian homelands. The counsellors, meeting in diverse political and ceremonial capacities, continued to assemble with other prelates and barons during festivals or ad hoc. But the fiscal and judicial activities of the court were growing in volume and technicality. Ordinary revenues expanded apace with the royal domains; taxes ceased to be exceptional. Toward 1250, judgments of the curia began to be recorded centrally; and the judicial sessions, now often called *Parlements*, derived an ever-expanding jurisdiction from the King's repute.

Meanwhile, a real local administration evolved as the bailiffs and seneschals became well established in territorial circumscriptions. Complaints arose when these men, and more particularly their subordinate officers, abused their powers for personal profit or the King's. Commissions of investigation, first appointed in 1247, provided means for redress; and these investigators continued to function after Louis returned from his first crusade in 1254.

Domestic  
policies of  
Louis IX

Although previous rulers had legislated on occasion, Louis IX was the first to express his will regularly in statutory form. A great ordinance for administrative reform in 1254 resulted from the remedial inquiries. In other enactments, characteristically moral and authoritarian, Louis sought to curb private warfare (about 1258) and to promote the use of royal money while limiting that of baronial (1263–65).

Toward the clergy Louis IX manifested a sympathy born of conservatism and exceptional piety, but he was nonetheless a firm master. He opposed efforts to expand clerical jurisdictions. During his later years he supported

papal taxes on the clergy for the Crusade, although in the 1240s he had joined his clergy in opposing papal precepts and impositions for a war against the Holy Roman emperor Frederick II. The lay nobles found Louis IX a frustrating ruler. Sharing few of their values, his consistent policy was to limit their ability to cause disorder. He allowed royal officials to encroach on baronial jurisdiction in many cases, and he welcomed appeals from baronial judgments. On the other hand he respected such rights as were sanctioned by provincial custom and was less forceful in exploiting feudal relationships than his grandfather had been.

The royal interest in order and justice was especially beneficial to townsmen and peasants, who had most suffered from overzealous administrators and private war. Louis IX confirmed municipal charters; but he also taxed the towns heavily, and when oligarchical urban governors mismanaged finance to the disadvantage of the lower classes as well as the King, he moved energetically (1259–62) to place the fiscal administration of 35 communes directly under the crown. A peasant crusade known as the *Pastoureaux* (1251) was inspired by loyalty to the King, then in trouble in the Holy Land; when its impulse was dissipated in agitation against the propertied classes, the regent had it suppressed.

*Later Capetians.* Louis IX was succeeded by his son, Philip III (ruled 1270–85); his grandson, Philip IV the Fair (ruled 1285–1314); and three great-grandsons, Louis X (ruled 1314–16), Philip V (ruled 1316–22), and Charles IV (ruled 1322–28). The greatest of these last Capetian reigns was that of Philip IV. Worldly and ambitious, yet pious and intelligent, he was less accommodating than his forebears, more devoted to his power than to his reputation. He brought the monarchy to a degree of coordinated strength it was not again to have in the Middle Ages. But in so doing, he strained the resources and patience of his subjects. His sons had to give in to the demands of a tired country but did so without abandoning their father's objectives. When Charles IV died without male heir in 1328, as his brothers had done before him, the royal succession was claimed by a collateral Capetian family.

These reigns were marked by further territorial consolidation. Marrying his son to the heiress of Champagne and Navarre in 1284, Philip III prepared the way for a reversion no less important than that of Toulouse (1271). Philip the Fair secured the heiress to the county of Burgundy for his son Philip in 1295 and annexed southern Flanders and Lyons in 1312. Smaller acquisitions, cumulatively of great importance, resulted from purchase: the counties of Guînes (1281), Chartres (1286), La Marche and Saintonge (1308); the viscounties of Lomagne and Auvillars (1302) and La Soule (1306); and a number of untitled lordships.

Through treaties, Philip the Fair extended his jurisdiction into the ecclesiastical principalities of Viviers, Cahors, Mende, and Le Puy. With his greatly expanded domain, the King could assert unprecedented authority everywhere in France. Yet it does not appear that territorial policy as such had changed. Appanages were still to be granted and to be recovered by the later Capetians. The monarchs continued to do without Brittany, Burgundy, and many lesser lordships, which did not prevent them from legislating for these lands along with the rest.

Government became more engrossing, specialized, and efficient. Although the royal curia continued to exist as an aggregate of favourites, magnates, prelates, and advisers, its ministerial element—comprising salaried officers serving at the king's pleasure—functioned increasingly in departments. The small council acquired definition from an oath first mentioned in 1269. *Parlement*, its sessions lengthening under a growing burden of cases, was divided into chambers of pleas, requests, and investigations (1278), and its composition and jurisdiction were regulated. Older provincial tribunals, such as the Norman Exchequer and the *Jours* of Troyes, became commissions of *Parlement*. While the direction of finance was left with the council, the *Chambre des Comptes*, apart from the treasury, was organized to audit accounts.

Further  
territorial  
consolidation

Council and chamber as well as Parlement developed appropriate jurisdiction, and all three bodies kept archives. The chancery, serving all departments, remained in the hands of lesser functionaries until 1315, when Louis X revived the title of honour.

Local administration was marked by the proliferation of officers subordinate to the bailiffs and seneschals. The chief judge (*juge-mage*) assumed the seneschal's judicial functions in the south; receivers of revenues, first appearing in Languedoc, were instituted in the bailiwicks at the end of the 13th century. Commissions of investigation continued to traverse the provinces under the later Capetians, but all too often they now functioned as fiscal agents rather than as reformers.

Many of the officers who served Philip the Fair were laymen, and many were lawyers. Impressed with the power they wielded, they promoted loyalty to the crown and a conception of the royal authority approaching that of sovereignty. Without claiming absolute power for the King, they thought in terms of his "superiority" over all men within national boundaries now (for the first time) strictly determined; and they did not hesitate to argue from Roman law that when the "state of the kingdom" was endangered, the monarch had an overriding right to the aid of all his subjects in its defense. While this doctrine, in a notorious case, was made a justification for imposing on the clergy, the later Capetians did not lose the religious mystique they had inherited from their predecessors' efforts in Christian causes. Even as political loyalties were being engrossed by the lay state, the "religion of monarchy" derived impetus from the fervent utterance of those who saw in Philip the Fair a type of Christ or the ruler of a chosen and favoured people.

It was in the requirements of war and finance that the claims of the monarchy found most concrete expression. In the 1270s, for his campaigns in the south, Philip III requested military aid from men hitherto exempt from such service. Philip the Fair, renewing these demands for his wars in Gascony and Flanders, went so far as to claim the military obligation of all free men as the basis for taxing personal property. The most persistent and lucrative taxation after 1285 was that imposed on the clergy, generally in the form of tenths and annates; sales taxes, customs, tallages on Jews and foreign businessmen, and forced loans likewise supplemented older revenues of the domain to support increased administrative expenses as well as costs of war. The most unpopular fiscal expedients were the revaluations of coinage after 1295, by which the King several times increased the profits of his mints to the confusion of merchants and bankers. The imbalance between ordinary resources and the needs of an expanding government became chronic at the end of the 13th century; yet in spite of the statist arguments of their lawyers, none of the later Capetians was moved to regard taxation as an established and justified requirement of a national government.

That is one reason why, with momentary lapses, the strongest of the later Capetians was not regarded as an arbitrary ruler. Philip the Fair revered St. Louis (Louis IX) as much as did his people; like Louis he took counsel from a relatively few unrepresentative persons. But when Philip's own policies broke with the past, he resorted to great councils and assemblies, not so much to commit the nation as to justify his course. Whether a tax was sanctioned by custom or not, even if approved by assembled magnates or townsmen, he had it negotiated—re-explained and collected—in the provinces and localities. Large central assemblies in 1302, 1303, 1308, and 1312 met to enable the King and his ministers to arouse political support for his measures against the Pope or the Knights Templars (see below). Among these were the earliest national assemblies to include representatives of towns and villages, a fact that has caused historians to classify them with the Estates-General. Under Philip the Fair and his sons, however, these convocations were not yet understood to be representative of the estates of society; only when Philip V began to summon northern and southern men separately to deliberate on fiscal matters were the estates (which made up the

Estates-General) in any way anticipated. Almost simultaneously the provincial estates were foreshadowed in the petitions of magnates and towns in several regions for relief from administrative violations of traditional privilege; but the resulting charters of 1314–15 were poorly coordinated and reactionary, and they did little to limit royal power, although the fiscal rights later claimed by the estates of Normandy could be traced to the Norman Charter of 1315.

If the policies of Philip the Fair evoked the complaint of all classes of people, it was because he had favoured none in particular; in fact, except in war and finance, the later Capetians may be said to have maintained a traditional politics toward both the nobles and towns. With the church, however, it was otherwise. Philip the Fair's insistence on taxing the clergy for defense led immediately to his conflict with Pope Boniface VIII. The latter, in the bull *Clericis laicos* (1296), issued on the protest of French and English prelates, forbade the payment of taxes by clergymen to lay rulers without papal consent; but Philip's anger and his political arguments divided the clergy, and the Pope soon found it necessary to abandon his position.

The quarrel was renewed in 1301, when the King and the magnates accused the Bishop of Pamiers of treason and heresy. Boniface rebuked Philip for seizing clerical property and debasing the coinage, among other things, and he summoned French prelates to Rome to proceed with a reform of the kingdom. Once again the clergy was split; many bishops and abbots attended an assembly at Paris in 1302 where they joined men of the other estates in addressing a remonstrance to the Pope. A year later the King adopted rougher tactics: in June 1303 many prelates acquiesced in a scheme to try the Pope before a general council, and in September the King's envoy Guillaume de Nogaret and his accomplices seized Boniface at Anagni. When the aged pope died a month later, his audacious policy collapsed entirely. The Gascon Pope Clement V (reigned 1305–14) moved the Holy See to Avignon, and a mass of his compatriots were appointed cardinals. With this pliant pontiff, the way was cleared for the strangest act of violence of the reign—the destruction of the Templars, founded during the Crusades. The Templars were aged men whose privileges seemed poorly justified after the fall of the Holy Land. But Philip's case was pressed relentlessly beyond the evidence brought forth; the King had to resort to propaganda in a vast assembly held at Tours in 1308, and it was only in 1312 that the Pope, his scruples overcome by expediency, dissolved the order. The Templars' possessions were given to the Hospitallers, and their last dignitaries were imprisoned or executed.

**Foreign relations.** France assumed a more active role in the politics of Christian Europe from the end of the 12th century. Philip Augustus led French contingents on the most fully international of the great Crusades (1190–91), although having once demonstrated his energy in that work of piety he could not afterward be persuaded to renew his vow. He preferred, through dynastic schemes and opportunism, to exploit his rivalry with the Plantagenets. His ambition seems to have embraced England as early as 1193, when he married Ingeborg, whose brother, the King of Denmark, had an old claim to the throne of England. When Philip repudiated Ingeborg, she and her brother appealed to the Pope; and her case, punctuated by reconciliations with Philip dictated more by policy than by sentiment, dragged on through the pontificate of Innocent III.

Meanwhile, in 1200 Philip's son Louis married Blanche of Castile, granddaughter of Henry II, through whom another claim to England was heralded. Louis's career as prince was marked by aggressive designs against King John. Innocent III was prepared to recognize Louis as king of England in 1213; and the policy was dropped only after Louis's abortive invasion of 1216–17.

It was in the play of rival coalitions that Philip Augustus had his greatest diplomatic anxiety and success. To John's alliance with Otto of Brunswick, his nephew and claimant to the empire, Philip countered by supporting a

of the  
Templars

second claimant, Philip of Swabia. When Otto became emperor in 1209 and the counts of Flanders and Boulogne were alienated from their Capetian suzerain, Philip found himself seriously threatened in his northern heartlands. John's drive to avenge the loss of his French fiefs matured in 1214; he himself led a force from the west, and his major allies marched on Paris from the north. Philip Augustus met the allied forces at Bouvines in July 1214 and won a decisive victory. As John retreated and his coalition collapsed, there could be no doubt that Capetian France had achieved hegemony in Christian Europe.

#### Diplomacy of Louis IX

Louis IX acted astutely, though in ways unlike his grandfather's, to preserve the prestige of France. His treaties with Aragon and England, designed to extend and secure his domains, resulted from a cordiality better appreciated abroad than by the royal counsellors. From Navarre and Lorraine as well as from within the realm were brought disputes for his judgment; and in the Mise of Amiens (1264) Louis responded to the appeal of Henry III and the English barons to pronounce on the validity of the Provisions of Oxford (a written agreement between the King and magnates in England to reform the state of the realm). But the more absorbing issues of Louis's diplomacy lay in the east. He resisted papal urgings to take sides against Frederick II, believing in the equal legitimacy of empire and papacy. On the other hand, he allowed his brother Charles of Anjou to accept the crown of Sicily from the Pope; and for this enterprise, as for his own crusades, he allowed the papacy to tax the French clergy. His paramount foreign interest was to recover the Holy Places for Christ (a traditional ambition characteristically associated in his mind with the hope of converting the infidel: the Mongols or the Emir of Tunis).

Louis IX first took the cross in 1244, upon learning that a Turkish–Egyptian coalition had driven the Christians of the Levant back to precarious coastal positions. His expedition, well planned and well financed, set out in 1248, only to founder in Egypt within a few months. Louis himself was captured; upon his release, he spent four years in Syria in support of the Christian cause. He renewed his crusader's vow in 1267, in circumstances clouded by Angevin–Sicilian politics. Persuaded in secret by Charles, whose inordinate Mediterranean ambitions had little in common with the traditional crusade, the new expedition was diverted to Tunis. It broke up there with the King's death in 1270.

The prestige of France in Christendom lost little from these failures of Louis IX. Nor was it generally foreseen that Aquitaine and Sicily would become battlegrounds in the future. The apparent strength of his father's diplomacy precluded Philip III from changing it, even though circumstances had changed. When the misrule of Charles of Anjou caused the Sicilians to revolt in favour of Peter III of Aragon (1282), a test of the Angevin policy could no longer be deferred. Charles's friend Pope Martin IV (reigned 1281–85) excommunicated the King of Aragon and offered the vacant throne to Philip for one of his sons. Because at this juncture the crown of Navarre was destined for Philip the Fair, the whole Spanish March seemed ripe for recovery by the French. Yet the crusade against Aragon, blatantly political and impractical, came to a catastrophic end: the King himself died as his battered forces staggered out of Catalonia (October 1285). Charles of Anjou and Martin IV also died in 1285. Understandably, Philip the Fair, who had foreseen the folly of the ill-conceived attack on Aragon, ceased to permit his Mediterranean concerns to dominate his foreign policy. The issue over Sicily dragged on, but minor Capetian interests in the Pyrenees and in Castile were allowed to lapse.

#### Extension of French influence to the north and east

The extension of French influence and domain toward the north and east resulted from resourceful diplomacy at the expense of the empire. Philip's interest in that direction was emphasized when his sister married the son of Albert I of Germany and when he proposed first his brother and later his son as candidates for the imperial title. But it was against the English holdings in France

that Philip exercised his most aggressive and portentous diplomacy.

Questions over spheres of administrative rights in Aquitaine had been creating tensions for many years. By the Treaty of Amiens (1279) the Agenais, whose status had been left in doubt when Alphonse of Poitiers died, passed to Edward I of England, who also had unsettled claims in Quercy. Serious conflict was precipitated in 1293, when clashes between French and English seamen caused Philip the Fair to summon his vassal to Parlement. When Gascon castles occupied by the French as part of the settlement were not returned to the English on schedule, Edward renounced his homage and prepared to fight for Aquitaine. The war that ensued (1294–1303) went in favour of Philip the Fair, whose armies thrust deep into Gascony. Edward retaliated by allying with Flanders and other northern princes. His dangerous campaign, concerted with the Count of Flanders in 1297, met defeat from a French force led by Robert of Artois, and during a truce from 1297 to 1303 the rival monarchs re-established the status quo ante. Edward married Philip's sister, and a marriage was projected between the prince Edward and Philip's daughter.

The heated residue of this first war was to be the chronic insubordination of Flanders. The Count having submitted and been imprisoned, it was left to the Flemish burghers to revolt against the French garrisons, and the French knights suffered a terrible defeat at Courtrai in July 1302. Thereafter, the tide turned, but only in 1305 could a settlement satisfactory to the King be reached; even then it proved impossible to win full ratification from the Flemish townsmen, whose resistance remained an invariable factor in the latent hostility between France and England.

In 1320 Philip V obtained Edward II's personal homage, but friction was increasing in Gascony again. When Edward refused to do homage to Charles IV, an old issue relating to French rights in Saint-Sardos (in Agenais) flamed into a war that once again went in favour of the French. By the Treaty of Paris (March 1327) France recovered Agenais and Bazadais and imposed a heavy indemnity on England; but a number of issues were left unresolved. Meanwhile, having married the emperor Henry VII's daughter, Charles was tempted to negotiate for the vacant imperial title in 1324; but nothing came of this. The last Capetians, troubled at home, retained their international standing among neighbouring states no less troubled.

#### Economy, society, and culture in the 13th century.

The primary social fact of this period is the continued growth of population. All indicators suggest growth—e.g., expansion of old towns, founding of new villages, the rising price of land—but no exact measurements are possible. A register of hearths dating from 1328 has been estimated variously to point to a total population of 15,000,000 to 22,000,000; the total was probably slightly reduced after a crest toward the end of the 13th century. By the 1280s large portions of France had enjoyed many years of relative security and prosperity, even though private warfare had not disappeared, despite royal prohibitions. Brigandage seems actually to have worsened in the south earlier, around 1200, and the ravages and massacres of the Albigensian Crusade made Languedoc an insecure frontier for another generation (though it does not appear that the Inquisition seriously disrupted urban or rural prosperity after 1230 or so).

The broad tendencies of social change were in keeping with political and institutional progress. The conjugal family became better recognized: Roman and especially canon law favoured its authority over the wider solidarities of clan or kin (extended family); rulers made the hearth a basis of fiscal responsibility. While mercantile practice discouraged customary restrictions on transactions, the right of repurchase by some member of the extended family (*retrait lignager*) held out in most areas of France. Meanwhile, a new territorial solidarity of great potential significance was developing: that of the legal estate or class. This was associated with the growth of towns and fostered by the consolidation of provincial

#### Population growth

custom and the fiscal impositions of count, bishop, or king. Already in 12th-century Flanders, knights (or towns) of the countryside were acting politically; and the convocation of men from these incipient estates of society occurred elsewhere in France and more often during the 13th century. Social mobility remained considerable in spite of tendencies to restrict the ranks of urban patrician or rural noble.

**Urban prosperity.** Town life continued to flourish. A few places, favoured by political and ecclesiastical as well as by economic circumstances, grew far larger than the rest. Paris could probably count more than 100,000 inhabitants by the late 13th century, possibly many more than that; some great provincial centres—e.g., Toulouse, Bordeaux, Arras, Rouen—may have surpassed 25,000, but most of the older cities grew more modestly. Jewish communities, which existed almost everywhere, were especially important in the towns of Champagne and Languedoc. Immigration from the countrysides probably increased as peasants sought better opportunities and independence; yet the towns remained somewhat indistinct in appearance and activity from their rural surroundings. Many urban properties had agrarian attachments, often within the walls; Paris itself was, to a surprising extent, an aggregation of expanded villages. Nevertheless, the progress of commerce, together with an important ancillary development of industry, chiefly accounts for urban prosperity in the 13th century.

The trades not only grew in volume but also became more diversified and specialized. New markets, often regional ones, arose to supplement the older centres that had developed on the basis of the long-distance exchange of relatively high-priced imperishables. Regional markets

featured such agrarian staples as grains and wines as well as animals, cloth, weapons, and tools, and they facilitated the currency of foreign produce, such as glassware or spices. An increasing reliance on coinage or on monetary values may be connected with these provincial trades; sensitivity to the intrinsic values of the many French coinages was increasing everywhere toward 1200, even in the hinterlands away from main trading routes. In the late 13th century the need for money in denominations larger than the age-old penny (denarius)—primarily for use in the great commercial centres—caused Louis IX to issue the *gros tournois* (worth 12 pennies) and the gold coin (which, however, had little importance before the 14th century). A gradual long-term inflation tended to favour commercial activity.

The towns of northern France, notably in Artois, Burgundy, the Île-de-France, and especially in Champagne, prospered not only from regional exchange but also from the great overland trades connecting Normandy, England, the Baltic, and the Low Countries with the cities of Italy. The fairs of Champagne, becoming the leading entrepôt of European merchants, reached their apogee in the 13th century. Favoured by the count's privilege, the traders operated at Lagny or at Bar, or—in greater numbers—at Provins and at the "warm fair" of Troyes in June; the "cold fair" of Troyes ended the yearly cycle in October. The fairs were designated as occasions for payment and repayment, contributing significantly to the progress of banking and business accounting.

Enlarged and more diversified demand encouraged urban growth and prosperity. Townsmen were eating better: in the north, at least, the per capita consumption of meat, butter, and cheese, as well as of spices, seems to

have increased in the 13th century; as for wine, not only was more being drunk but the taste for *vins de qualité* became more acute, and the great regional vintages, notably that of Gascony, were established. Townspeople furnished their houses more amply than in the past (lamps, wooden chests, and draperies came into common use), and they produced more articles themselves.

The progress of industry, in fact, was a remarkable feature of the 13th century. Crafts in metal, wood, leather, and glass expanded in such large towns as Paris; cloth-work—weaving, dyeing, fulling—prospered in regional centres such as Toulouse, with specialities in fine cloths concentrated in Artois and Flanders. In most places, however, the crafts remained in the shadow of commercial enterprise, in which the greater fortunes continued to be made. Artisanal associations proliferated everywhere; often termed brotherhood (*confratria*, *confraternitas*), they fostered new urban and suburban solidarities for charitable and ceremonial purposes as well as promoting economic interests.

Urban  
society

Urban society became more competitive and more stratified. At Lyons, Bordeaux, and elsewhere, some fortunes were well enough established, usually from commerce, to enable their possessors to live as landlords, build stone houses, buy rural property, and aspire to titles of nobility. This patriciate, despite occasional setbacks at the hands of “new men,” dominated municipal governments, acting as mayors and magistrates (*échevins*) in the north or as consuls in the south. While not altogether self-serving—they supported civic projects such as the building or decorating of churches—they were disinclined to share power or fiscal responsibility. Below them, often as their tenants or debtors, were small entrepreneurs, middlemen in trade (or between local industry and regional trade), master craftsmen, and bankers; and below all—and increasingly restive—was a swelling class of impoverished artisans, servants, vagabonds, and beggars.

*Rural life.* Rural life changed more gradually. The expanding markets favoured well-endowed or efficient lords or peasants who could produce a surplus of goods for sale. Such conditions were less common in the south than in the north, although they could be found in most wine-producing areas. But while rising prices benefitted producers, they contributed to certain difficulties in the countryside. Fixed revenues in coin proved an unsatisfactory alternative to payments in kind, which landlords specified when new land was put under cultivation. Moreover, needs and tastes became more expensive and tended to exceed aristocratic resources; lavish generosity continued to be an admired and practiced virtue, and costly crusades—occasionally lapsing into speculative adventures—continued to be launched. Larger lordships began to employ salaried estate managers, while in the south the division of landed fortunes among numerous heirs resulted in a multiplied and impoverished petty nobility. Many rural landlords fell into debt in the 13th century. And as wealth and nobility became less correlated, some nobles, especially those hard pressed, sought to close ranks against the intrusion of new men or creditors. They insisted on noble birth as a condition for knighthood, while reserving the designation of “squire” (or *donzel*, in the south) for those of noble birth awaiting or postponing the expensive dubbing (*adoubement*). At the upper extreme a noble elite, the barons, achieved recognition in administration and law.

Peasant  
stratification

Peasant societies also became stratified. Men unable to set aside a surplus against times of famine and those who had to borrow or rent their tools or teams found it difficult to avoid dependence on other men. In some areas serfdom was renewed, or confirmed, as jurists interpreted the more stringent types of peasant obligation in the light of the revived Roman law of slavery. But here again economic and legal status did not necessarily coincide. Rich peasants who employed other men to drive their teams could be found in any village; such people as the mayor, the lord's provost, and the peasant creditor established themselves as a rural elite, whose resources insured them against calamity and opened up diverse opportunities in prospering regional economies. Where enfranchisement

occurred, the lord usually received a good payment; even when servility persisted, there was a tendency to commute the arbitrary tallage into fixed common sums. New villages continued to be established, especially in the south, where many existent communities of peasants also received charters of elementary liberties—typically including the commuted tallage—in the 13th and early 14th centuries. In many cases, notably in Gascony, security, or defense, seems to have been the chief motive behind these foundations.

These conditions notwithstanding, the manor, or *seigneurie*, resisted fragmentation. The favourable market for grain and the psychological attachment of lords to their fathers' possessions preserved demesne land as the chief source of seigneurial income through the 13th century. Nor were labour services given up, although the discrepancy increased between work owed and work needed. Accordingly, lords resorted to paid seasonal labour, so that the margin between profit and loss became a more critical calculation than in the past. A new alternative was to lease the demesne to paid managers or sharecroppers, but this practice spread more slowly in France than in neighbouring countries. Whether lords had demesnes and servile tenants or not, the association between landlordship and power remained close. Tenancies or properties smaller than the old *mansus* appeared everywhere, but especially in the north, where horsepower and three-field crop rotations were making possible a more productive agriculture. The burgeoning viticultures of Burgundy and Gascony proved incompatible with traditional demesne lordship and encouraged sharecropping and peasant initiative. Innovation was less common in the uplands of the centre and south, where the manse tended to retain its identity and fiscal utility.

*Religion.* Whether in countryside or town, the lay person's touch with Christ became more personal, more direct. It was a widely shared conviction of Jewish guilt and Muslim (and Byzantine) schism that kept the crusade alive in France; the 13th was the last medieval century in which French Jews could live securely with their Christian neighbours, and their position became progressively more difficult. The regular clergy could no longer be relied upon to set standards in piety and penitence; their observance was either too relaxed or too severe to suit the new conditions, while the whole tendency of the canonical movement of the later 12th century had been to accentuate the distinctiveness of the secular priesthood and the power of holy orders. Even as it continued to expand, the Cistercian order was incapable of sustaining its ascetic impulse completely; its houses, as well as those of the older Benedictines, found their prestige and solvency alike in decline. Nor was the higher secular clergy much better situated to fulfill pastoral obligations. The bishop was by now remote from his flock, acting usually as diocesan supervisor, judge, or lord; his subordinates—the archdeacon and cathedral canons—likewise functioned primarily as administrators. Archbishops were required by the fourth Lateran Council (1215) to hold annual synods of provincial clergy, a ruling that—although imperfectly observed—probably contributed to some strengthening of discipline.

The clergy

The critical reform was that of the parish ministry. When emphatic measures to improve the education and supervision of priests were adopted in the fourth Lateran Council, it was already too late in France. For more than a generation, anticlericalism and doctrinal heresy had been spreading, especially in the towns and villages of the east and south. There was a suspicion that sinning priests could not be trusted to mediate God's grace effectively, while many felt attracted to the virtue of poverty as an antidote to the worldly cupidity of a prospering society. The merchant Peter Valdes, giving up his property and family (1175–776), took it upon himself to preach in the vernacular to his fellow townsfolk of Lyons. His followers—the “Poor Men”—going sometimes so far as to administer sacraments, contrary to the canons, failed to win papal recognition. Nevertheless, the Waldensian mission, grimly tolerated by the authorities, spread to southern towns; and Valdes himself became active in the

campaign against the Cathar sects of southern France. Flourishing in the hill towns and villages between Toulouse and Béziers, the Cathars held alarmingly unorthodox religious beliefs; they rejected the church as the devil's work, organizing their own ministry.

For this challenge the secular clergy of Languedoc was no match. To establish an effective counterministry of learned and respectable men, the Pope deputed Cistercians to Languedoc; they were soon succeeded by St. Dominic of Calaruega, who spent a decade as mendicant preacher in Languedoc. In 1217, his order of preachers recognized by the Bishop of Toulouse and confirmed by the Pope, Dominic set out with his fellow friars to work in the wider world "by word and example."

Meanwhile, the murder of the legate Pierre de Castelnau (1208) had stirred Innocent III to promote a crusade against the heretics of Languedoc. Led by Simon de Montfort, northern barons attacked towns in the viscounty of Béziers and later in the county of Toulouse with singular fury. Despite massacres and apostasy, the failure of the enterprise as a holy war was underscored by the establishment of a papal inquisition (1233), which stiffened and institutionalized the Dominican measures of dissuasion. The procedure, which became known in many parts of France, was usually entrusted to Dominicans; it relied on the active pursuit of suspects, secret testimony, and—in case of conviction and obstinacy—delivery of the heretic to the "secular arm" for capital punishment. Taking the war and the Inquisition together, it can be said that French heresy was largely destroyed by the end of the Capetian period.

The Franciscans as well as the Dominicans had a spectacular success. Highly organized, with provincial and international administrative institutions, both orders had houses in Paris by 1220, and their members were soon working everywhere in France. Becoming preachers and confessors, they also secured chaplaincies, inspectorships, and professorships as their initiatives in piety, probity, and learning were recognized. Conflict with the secular priesthood naturally resulted; the seculars attempted unsuccessfully to exclude the mendicants from the ministry of sacraments and inveighed against conventual endowments that seemed to contradict the friars' professions of poverty. New religious orders were soon established. The friars stimulated a more active piety among lay people, favouring charitable works and foundations, private devotions, and penitential reading.

*Culture and learning.* Literacy and elementary learning became more widespread. The courtly tastes of the 12th century, while not obliterated, were overtaken by a more flexible and ironic sensibility evident in vernacular ballads, fables, satires, and moralizing literature, most popular in the northern towns. The burgher or knight began to take a keen interest in the tangible world about him. The taste for clarity, proportion, and articulation, coming to mature expression in the Gothic of Amiens, Paris (Notre-Dame), and Reims, achieved dazzling fineness in the church known as the Sainte-Chapelle, built at Paris by Louis IX in 1245–48 to house the crown of thorns. And the taste for order is illustrated by the reorganization of masters, students, and studies as *studia generalia* (or universities); Montpellier became a leading centre of medical learning; Orléans and Toulouse, the latter founded in 1229 to prepare clerks to combat heresy, were noted for law. Paris remained pre-eminent among the early universities; its famous schools became associated as the faculties of arts, canon law, medicine, and theology, gaining jurisdictional independence under papal protection by 1231.

During the same years, philosophical doctrines in conflict with Christian orthodoxy began to trouble the theologians, as translations of the metaphysical and scientific works of Aristotle and his commentators reached Paris. For a time the teaching of Aristotle was prohibited there; but by midcentury, when some of the "artists" who had been most attracted to the new philosophy were advancing to the theological degrees, efforts were made to incorporate Aristotelian learning in enlarged summaries of Christian knowledge. The *Summa theologica* (1266–72)

by the Italian Thomas Aquinas was the greatest synthesis of this type. Its serene power breathes no hint of the controversies in which its author was involved. St. Thomas had taken his theological degree, together with St. Bonaventure, in 1257, when the secular masters were bitterly disputing the friars' privileges within the university. In the end the Dominicans and Franciscans each retained a chair on condition of submitting to university regulations. Thomas' work, however, was less fortunate. As the arts faculty seemed increasingly disposed to take a naturalistic view of all reality, a reaction set in; and the bishop's condemnations of "error" in 1270 and 1277 were so sweeping as to render even Thomas suspect. His audacious brand of synthesis was to have no immediate imitators. Nevertheless, the social consequences of this newly organized learning were profound; it created new estates of professional men—lawyers, notaries, trained clerks, physicians, many of them laymen—whose rational and legalist outlook became firmly rooted in French culture.

The dogmatic condemnations of the 1270s were symptomatic. Prosperity and confidence were shaken in many ways in the late 13th century. The papacy, hitherto a support for progressive causes, found itself discredited after its fiasco in the crusade against Aragon; and while the removal of the papal court to Avignon in the time of Clement V created a new centre of patronage for arts and letters, it did little to arrest the waning prestige of the church. The burdens of renewed warfare increased social tensions in the towns and depressed civic enterprise; the Jews had their assets confiscated before being expelled in 1306, and the Lombard bankers suffered like treatment in 1311. Economic indicators—while few and difficult to interpret—are generally held to suggest retardation, at least in many parts of France. The fairs of Champagne were doing a contracting business by 1300, if not before, while records of Normandy reveal declining agrarian revenues in the half century after 1260. Some regions were "saturated" with people: their existent economic technology could no longer sustain growth. Probably the population was already levelling off, if not yet decreasing, when, in 1315–17, crop failures and famine caused serious disruption and a reversion, in some places, to subsistence farming.

#### THE PERIOD OF THE HUNDRED YEARS' WAR

*The kings and the war, 1328–1429.* At the accession of the House of Valois in 1328, France was the most powerful kingdom in Europe. Its ruler could muster larger armies than his rivals elsewhere; he could tap enormous fiscal resources, including taxes authorized by sympathetic popes of French extraction; there remained only four great fiefs—the duchies of Aquitaine, Brittany, and Burgundy and the County of Flanders—outside the direct royal domain; and the king's courts continued to press a jurisdictional supremacy that was felt everywhere in the realm. It did not follow, however, that France's superior armies would fight better than its foes or that its resources would not sometimes be dissipated or withheld. France remained a collection of traditional provinces the peoples of which believed that a king should "live of his own," while military success continued to depend on the personal leadership of dynastic rulers whose qualifications as strategists had been less refined by experience and institutional progress than their judicial or administrative attributes. The history of France in the 14th century is dominated by efforts of its kings to maintain their suzerainty over the Plantagenets in Aquitaine, efforts that, despite French advantages, were long frustrated.

*Philip VI.* Philip VI of Valois (ruled 1328–50), grandson of Philip III, was of mature age when he became regent of France in 1328. Upon the birth of a daughter to the widow of his cousin Charles IV, the familiar issue of the succession was posed anew. It was the regent's experience, together with the circumstance that Edward III of England, grandson of Philip the Fair, was under the influence of his disreputable mother, Isabella of France, that probably disposed the council at Vincennes to recognize Philip as king (April 1328).

The bishop's condemnations of "error"

Crusade of Innocent III in Languedoc

Philip's reign began well. Within months he crushed a revolt of the Flemish cloth towns (Cassel, August 1328), thereby recovering the effective suzerainty over Flanders that had eluded his predecessors for a generation. And in 1329 he obtained Edward III's personal homage for the duchy of Aquitaine—an act that not only secured Philip's leadership but nullified Edward's claim to the crown of France.

This initial success was soon undone. Jurisdictional questions in Gascony remained unsettled. In 1336 Philip VI appeared to be preparing massive support for David Bruce, the Scottish king at war with Edward; and in 1337, alleging defaults in feudal service, Philip ordered the confiscation of Aquitaine. Edward III renounced his homage and again laid claim to the crown of France, and war again was imminent. Despite the new Plantagenet pretensions, the basic causes of conflict were feudal and jurisdictional, not dynastic.

Edward proceeded deliberately and ominously. He fomented discontent among the Flemish clothworkers and then treated with the towns, so as to negate the count's fidelity to France; and he purchased the fidelity and service of many princes in the Rhineland and Low Countries. But to succeed, the English needed a prompt and massive victory on French soil, something Philip VI was able to avoid. Despite Edward's naval triumph off Sluis (Sluys, 1340), which confirmed English control of the seas, his initial advantage was lost as his resources and allies melted away. A truce in September 1340 was extended for several years, during which time Edward intervened in a disputed succession to the duchy of Brittany, while Philip's officials increased their pressure on Gascony. In 1345 English armies counterattacked French posts on the duchy's borders; their success emboldened Edward. Landing in Normandy (July 1346) with a well-disciplined army, he captured Caen, only to be overtaken in Picardy by a much larger French army as he moved to join his Flemish allies. At Crécy (August 26, 1346), despite serious disadvantages, the English forces won the first major battle of the war. Their victory, however, proved difficult to exploit; Edward moved on to capture Calais after a long siege, but he could then only return to England with more glory than accomplishment to his credit.

Nevertheless, Philip's failures were proving costly in money and political support. In 1340–41 he had been able to raise "extraordinary" revenue through taxes on sales, salt, and hearths, despite regional protests. The continuance of sales and salt taxes in 1343 could be extracted from the Estates of Paris only in return for the restoration of a stable coinage; and in the following years regional assemblies in the north proved even more obstinate. In the Estates of Paris in November 1347 the King heard ringing denunciations of his mismanagement and defeats and was fortunate to obtain new subsidies to support an invasion of England. But that prospect, like the war itself, evaporated when the Black Death struck Europe late in 1347, destroying life, fiscal resources, and resolve for several years thereafter.

Philip VI cannot be judged by his military failures alone. The royal domain was significantly enlarged by his acquisition of Dauphiné (technically an endowment for his grandson in 1343–49) and the city of Montpellier, the last (and wealthiest) Aragonese fief in Languedoc. As administrative expertise continued to progress, the services, such as Parlement and treasury, were regulated. Within the departments of the court and notably in the *Chambre des Comptes*, the exercise of power came increasingly into the hands of royal favorites, whose rivalries were stimulated by the courtly predilections of the King. Their influence and speculation together with the familiar injustices of local government came under attack in the Estates of 1343 and 1347, which, in their conditional grants of subsidy, asserted a more nearly constitutional authority than French assemblies had yet enjoyed; the fiscal powers of the provincial Estates likewise originated during the first Valois reign.

*John the Good.* John II the Good (ruled 1350–64) succeeded to a weakened authority and kingdom; he was

a mediocrity whose suspicions and impetuosity were ill suited to the changed circumstances. John hoped to rally baronial loyalties to himself. But he failed to reconcile Charles the Bad, king of Navarre, whose strong dynastic claim to the throne (he was the grandson of Louis X) was matched by his ambition; Charles's conspiracy—at first appeased, then too violently put down—seriously weakened John during the years (1355–56) when the English war broke out anew. When Charles sought alliance with Edward III, French diplomats abandoned full sovereignty over Aquitaine, a reversal of policy too gratuitous to hold for long; its prompt revocation, with papal support, encouraged Edward's son, the Black Prince, to undertake destructive raids through Languedoc in 1355. That November the Estates of Languedoc, meeting at Paris, insisted on controlling the military appropriations they voted; and when the Black Prince advanced from Bordeaux to Touraine in the summer of 1356, John hastened to prevent his union with rebellious Norman barons. The armies met near Poitiers in September. Once again the French had the advantage of numbers and position, only to suffer a disastrous defeat. King John allowed himself to be taken prisoner.

France was to experience no worse years than those of the regency of the dauphin Charles (regent 1356–61; King Charles V, 1364–80). Unpaid or poorly disciplined armies ravaged the countryside. The dynasts, nobles, and townspeople had new reasons to resist the monarchy. The Dauphin showed no sign of adjusting to meet the crisis; and the Estates convoked in 1356 to provide for the King's ransom demanded sweeping administrative reforms, even imposing a council, representing the Estates, upon the regent. Their program proved unworkable, and Charles tried to resume power on terms already rejected by the Estates. This move radicalized Étienne Marcel, provost of the Parisian merchants and leader of the urban estate. Causing the brutal murders of two of the Dauphin's noble associates, Marcel only succeeded in creating an irreconcilable breach with the Dauphin, who fled Paris and convoked his own assembly at Compiègne. Marcel's enthusiasm mounted as his position became more precarious; he drew strength from alliance with Charles the Bad but failed to win the Flemish towns to his cause. The climactic complication was a terrible uprising of the peasants (*Jacquerie*), which broke out in Picardy in May 1358 and which antagonized Marcel's noble supporters, notably Charles the Bad, who helped to quell the disturbances. Marcel was increasingly isolated when loyalist sentiment mounted and administrative failures became evident. His assassination on July 31, 1358, not only secured the Dauphin's authority but ended the burgher influence that had originated in the Estates of 1355.

Intense efforts were then made to end the English war. Negotiations dragged past the term of truce set in 1356; when a first and too humiliating treaty was rejected by the Dauphin, Edward made yet another demonstration in France (1359). At Brétigny (May 8, 1360) King John's ransom was set at 3,000,000 gold crowns, while to England was assigned full sovereignty over Aquitaine (including Poitou). Two months later John arrived in Calais, where a first payment of ransom was made. In the definitive Treaty of Calais (October 24, 1360), for reasons not clear, the monarchs' renunciations—Edward's claim to the crown of France, John's to sovereignty over the ceded territories—were postponed. The Black Prince, however, proceeded to take control of Aquitaine, while the regent tried with little success to extract additional money for the ransom from an exhausted country. When the Estates at Amiens (October 1363) refused to ratify an irresponsible agreement between the King's replacement hostages and Edward III, John returned to captivity in London, where he died a few months later.

*Charles V.* Under the former dauphin, now Charles V, the fortunes of war were dramatically reversed. Charles had a high conception of royalty and a good political sense. While he shared the Valois taste for luxury and festivity, he reverted to the Capetian tradition of prudent diplomacy. He observed the Treaty of Calais,

The regency of the dauphin Charles

Efforts to end the war

English successes under Edward III

which helps to explain why Edward III did not press to conclude the renunciations; but he reserved his authority in Aquitaine by inserting in his coronation oath a clause prohibiting the alienation of rights attaching to the crown.

The early years of his reign were filled with baronial politics. Charles the Bad once again revolted unsuccessfully, his dynastic claim to Burgundy running afoul of the King's; the succession to Brittany was settled by arms in favour of the Anglophile Jean de Montfort (who became John IV the Valiant). Most significant for the future, Charles V obtained the heiress to Flanders for his brother Philip the Bold, to whom Burgundy had been granted in appanage. Meanwhile, companies of mercenary soldiers, many based in strongholds of central France, were paralyzing the countrysides. Charles V commissioned the Breton captain Bertrand du Guesclin to neutralize them. Between 1365 and 1369 Bertrand employed the companies in adventurous conflicts in Spain; many of the mercenaries were killed or dispersed. The Black Prince had also intervened in Spain, and his taxes and administration in Aquitaine aroused protest. In 1369 the lords of Albret and Armagnac, having refused to permit levies of subsidy in their lands, appealed to Charles V for the judgment of his court. Although Charles hesitated, his eventual decision to accept the appeals was in keeping with the letter of the Treaty of Calais and his coronation oath.

#### French successes

The war with England soon broke out again. Two new factors worked in favour of France. First, Charles's alliance with Henry II of Trastámara, king of Castile, cost the English their naval supremacy; a Castilian fleet destroyed English reinforcements off La Rochelle in 1372, which effectively secured the success of French operations in the west. Second, Charles abandoned the defective policy of massive engagement with the enemy. Unable to command in person, he appointed Bertrand du Guesclin constable in 1370; the latter proceeded to harry the enemy and to prey on supplies with great effectiveness. Through skirmishes and sieges, the French forces soon reconquered Guyenne and Poitou, leaving only some port towns (Calais, Cherbourg, Saint-Malo, Bordeaux) in English hands. To finance these operations, Charles continued to levy the taxes on merchandise, salt (*gabelles*), and hearths that had been intended to raise John's ransom; despite serious inequities and defaults, these taxes persisted to the end of the reign. In Languedoc they were voted, assessed, and expended by the Estates; elsewhere, by transforming the deputies first chosen by the Estates in the time of John into royal officers, Charles created a fiscal administration independent of popular control. His military success owed much to the improved regulation of armed forces and defenses. Ordinances provided for the inspection and repair of fortifications, the encouragement of archery, a more dependable discipline, pay for fighting men, and even the establishment of a navy.

The last years of the reign brought disappointments. Truces were arranged; but, as there could be no more talk of ceding French sovereignty over Aquitaine, there could be no assurance of peace. More serious, the papal-French alliance collapsed. Charles V, unable to prevent Pope Gregory XI from returning to Rome in 1376, chose to support the candidacy of Robert of Geneva against the Italian Urban VI in 1378, but only Scotland and Naples followed the French lead. A schismatic pope could no longer help France much; rival popes could hardly promote peace between their political supporters. Although he had re-established the political unity of France, Charles V left an uncertain future.

*Charles VI.* Charles VI (ruled 1380–1422) was a minor when he succeeded his father. His uncles, each possessed of the ambition and resources to pursue independent policies, assumed control of the government. Duke Louis of Anjou soon removed himself from influence by seeking the throne of Naples; Jean, duc de Berry, received the lieutenancy of Languedoc, by then virtually an appanage; and it was left to Duke Philip the Bold of Burgundy to set the young King's policy. In Flanders,

the count of which was his father-in-law, Philip imposed his own cause upon the King. An uprising by the workers of Ghent, spreading to other towns, was met by royal force that won a crushing victory at Roosebeke in 1382. The young King returned in triumph to deal forcefully with restive populations at Paris and Rouen and in Languedoc. The provostship of the merchants was suppressed at Paris, bringing that municipality under direct royal control.

In 1388 Charles VI assumed full authority himself. He recalled his father's exiled advisers, the Marmousets, who undertook to reform the royal administration in keeping with the practice of Charles V. But the country was again wearying of taxation. The annual levies of Charles V had been discontinued in 1380 but then re-established—helping to cause the urban unrest already mentioned—and were being dissipated blatantly in royal and princely extravagance. In 1392 the King lost his sanity, a shocking event that aroused popular solicitude for the crown. His recurrent lapses into insanity, however, played into the hands of his uncles. Philip the Bold again dominated the council. Fortunately for France, England was incapable of renewing the war. The Duke of Burgundy planned an invasion of England in 1386, but it came to nothing after major preparations in Flanders. A series of truces, beginning in 1388, was followed by a reconciliation between Richard II of England and Charles VI in 1396, when the truce was extended for 28 years. Meanwhile, French nobles were reviving the Crusade, imagining a reunited West following their lead; John the Fearless' defeat at Nicopolis in 1396 was the most famous of several enterprises. To restore unity in the church, the masters of the University of Paris began to speak out vigorously; the conciliar theory that finally prevailed to end the schism owed much to them.

When conflict with England was renewed in the 15th century, circumstances had changed. Henry IV of England was committed to the recovery of English rights in France; moreover, in a civil war between Louis, duc d'Orléans, and John the Fearless (duke of Burgundy since 1404) over control of the King and the spoils thereof, both parties sought English support. And when John caused Orléans to be assassinated in Paris (November 23, 1407), the popular horror magnified the conflict. John exploited the situation by pressing for reforms; his rival's cause was taken up by Bernard VII of Armagnac, whose daughter married Orléans's sons. But John's alliance with the turbulent Parisians was no more secure than the temper of the angriest burghers; a major ordinance for administrative reform (1413) collapsed in a riot of the butchers, and in the ensuing reaction the Armagnac faction regained control of Paris. John's dangerous response was to encourage the new king of England, Henry V, to claim the French throne for himself. Henry's invasion of 1415, reminiscent of the campaign ending at Crécy, had the same result—at Agincourt the French suffered yet another major defeat, after which, characteristically, the English withdrew—but the civil war in France enabled Henry V to exploit his strength, as Edward III could not. In 1418 the Burgundian party recovered control of Paris, and the dauphin Charles embarked on a long exile in Armagnac company. But John's duplicity was limitless; while meeting with the Dauphin to betray the English, John was himself assassinated (1419). His successor, Philip the Good, renewed the alliance with Henry V. By the Treaty of Troyes (1420), the deranged Charles VI was induced to set aside the Dauphin's right of succession in favour of Henry V, who married Charles VI's daughter. The ancient dream of a dynastic union between France and England seemed to be realized; and, when Henry and Charles died within weeks of each other (1422), the infant Henry VI became king in both lands.

*Charles VII.* Charles VI's son Charles VII (ruled 1422–61), for his part, did not fail to claim his inheritance, though he had no proper coronation. Residing at Bourges, which his adversaries pretended was the extent of his realm, he in fact retained the fidelity of the greater

#### Insanity of Charles VI

part of France, including Berry, Poitou, Lyonnais, Auvergne, and Languedoc. For a time the Valois cause suffered from the ineptness of its leader and from his advisers and retainers, who prospered from the unresolved conflict. Incapable himself of military leadership, Charles put his hope in reconciliation with Philip of Burgundy—a diplomacy that thoroughly discomfited King Henry's regent, the Duke of Bedford. Nevertheless, French prestige collapsed with the abasement of the monarchy; Charles VII appears to have doubted his own legitimacy, and disorders spread again.

Joan  
of Arc

Then Joan of Arc appeared. Stirred by the popular memory of traditional French kingship, she found her way from her peasant home at Domrémy (on the border of Champagne and Bar) to Chinon, where she confronted Charles with her astonishing inspiration: her "voices" proclaimed a divine commission to aid the King. In April 1429 she entered Orléans, long besieged, rallying the garrison to effective sorties that soon caused the English to lift the siege. Other victories followed, in which Joan's influence was manifest, although probably exaggerated in tradition. On her insistence that only consecration at Reims could make a true king, chosen by God (a view doubtless supported by the chancellor Regnault, archbishop of Reims), it was decided to advance boldly across the Ile-de-France to Reims. Charles was anointed there on July 17, 1429.

**Recovery and reunification, 1429–83.** The coronation of Charles VII was the last pivotal event of the Hundred Years' War. From Reims the King's army moved on triumphantly, winning capitulations from Laon, Soissons, and many lesser places and even threatening Paris before disbanding. The revived devotion to monarchy that had produced Joan was undermining English positions almost everywhere in France; the urgent necessity to discredit her explains the callous efficiency of the inquisition to which she was subjected upon being captured by the Burgundians and turned over to the English in 1430. Condemned of heresy, confessed under duress, boldly relapsed, she was burned at the stake in Rouen on May 30, 1431.

Charles and his party made no move through ecclesiastical channels to save Joan. They then proceeded deliberately to make peace with Burgundy. In the Treaty of Arras (September 21, 1435), Philip the Good bargained strongly; confirmed in the possession of domains ceded by the English, he also obtained Charles's humiliating disavowal of the murder of the Duke's father. The act, however damaging to the royal vanity, set Charles free from political obligation to the Armagnacs; the factional king now became the supreme king of France. Within a year English support collapsed in the Ile-de-France, and royal soldiers entered Paris. The Truce of Tours (1444) provided for a marriage between Henry VI and the niece of Queen Mary of France; extensions of the truce gave Charles time to strengthen his military resources. War flared again in 1449, when England intervened against a duke of Brittany who had done homage to Charles VII. In 1449–50 a vigorous campaign resulted in the French conquest of Normandy, and in 1451 most of Guyenne fell to the French.

The end of  
the  
Hundred  
Years'  
War

When the English lost the minor battle of Castillon in 1453, the Hundred Years' War was over. That fact was not altogether clear to contemporaries, for no treaty was concluded and skirmishes were to recur for many years to come. But only Calais, enclosed in the Burgundian domains, remained of English possessions in France. Charles VII issued medals to commemorate his soldiers, and he ordered a review of Joan of Arc's trial, which resulted in a verdict of rehabilitation in 1456.

**Governmental reforms.** As hostilities were waning (1435–49), Charles VII presided over a major reorganization of government. Tested by adversity and strengthened by fortune, he had grown in political competence. The principal administrative services—chancery, Parlement, accounts—were re-established at Paris. The replacement of Burgundian sympathizers, notably in Parlement, seems to have been accomplished with moderation and tact; in local offices no purges were necessary. But it

quickly became evident that the reunited country was now too large and its officials were too numerous to get along very well with a government as centralized as Parisian bureaucrats preferred.

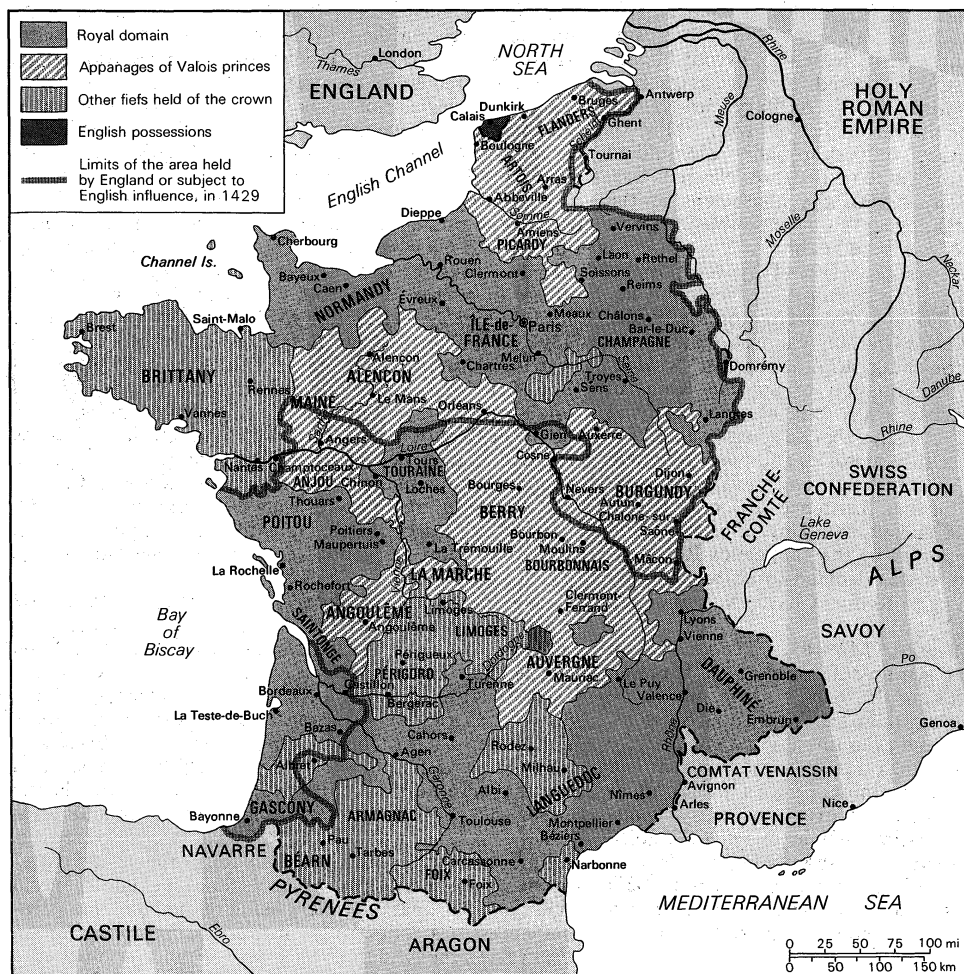

Remedial legislation was consistent with tendencies long apparent. Revenues from the domain were collected in the treasury, the work of which Charles VII reorganized in four regional offices. Extraordinary revenues had been administered since the 1350s in districts (*élections*), the numbers of which had vastly increased since the time of Charles V. The *élections* were now subordinated to four regional *généralités*, corresponding to the offices of treasury. The old Chambre des Comptes had lost parts of its jurisdiction to more specialized courts in 1390, of which the Cour des Aides (board of excise) had provincial divisions set up at Toulouse in 1439 and at Rouen in 1450. A provincial Parlement was definitively established at Toulouse in 1443, and there were to be others at Grenoble and Bordeaux. With all these changes the conciliar structure of government survived; policy continued to be made by the king in concert with favourites, whose numbers no reforms had delimited. The proliferation of lesser offices, many filled by lawyers, created a new stratum of gentlemen who enjoyed the king's privilege.

Revenues

While the reform of offices did nothing to obliterate the older distinction between ordinary and extraordinary revenue, the work of Charles VII effectively belied the notion that the monarchy should subsist on its domain alone. That the king as lord could no longer pay his officers and soldiers was apparent to almost everyone. Early in his career Charles had resorted to the Estates to raise *aides* and *tailles* (as the old levies on sales and hearths were now called); but after convocations in the 1430s, he continued these taxes through annual ordinances no longer sanctioned by the Estates. Moreover, the preparation of annual budgets for ordinary and extraordinary revenues gave way in 1450 to a single "general statement" of finance, which, being related to demonstrable necessities, effectively institutionalized taxation in France. As the Middle Ages ended, France comprised a central core of *élections*, where local Estates, when they met at all, had little to do with fiscal matters, and a surrounding belt of "lands of Estates" (e.g., Languedoc, Brittany, Normandy, and Burgundy), where custom continued to allow for consent or for the administration of taxes. Having originated in times of fiscal demands thought uncouth and excessive, representative institutions could not generally survive once the royal impositions, from very repetition, had ceased to seem arbitrary; even where Estates persisted, their votes were more like approval than sovereign consent.

**Military reforms.** The fiscal reorganization facilitated equally significant military reforms. The Peace of Arras, rather than pacifying France, had only thrown the people once again to the mercies of disbanded mercenaries and brigands. In 1439 an ordinance made the recruitment of military companies the king's monopoly and provided for uniform strength in contingents, supervision, and pay. Following the Truce of Tours in 1444 no general demobilization occurred; instead the best of the larger units were reconstituted as "companies of the king's ordinance," which were standing units of cavalry well selected and well equipped; they served as local guardians of peace at local expense. With the creation of the "free archers" (1448), a militia of foot soldiers, the new standing army was complete. Making use of a newly effective artillery, its companies firmly in the king's control, supported by the people in money and spirit, France rid herself of brigands and Englishmen alike.

**Regrowth of the French monarchy.** Thus the monarchy recovered much of the authority it had lost during the early stages of the Hundred Years' War. Although its influence in Burgundy and Flanders, now united in a formidable dynastic association, had declined, its definitive recovery of Aquitaine consolidated a direct domain, again extensive enough to free the Valois from anxiety about landed resources. It had exploited not only a widespread distaste for the destructive self-interest of barons

France in 1453.

From W. Shepherd, *Historical Atlas*, Harper & Row, Publishers (Barnes & Noble Books), New York; revision Copyright © 1964 by Barnes & Noble, Inc.

and warlords but also an incipient nationalism, which, besides reviving the "religion of monarchy," put new stresses on the foreignness of Englishmen. How renewed power and Gallicanism went together was demonstrated in the Pragmatic Sanction of Bourges (1438), by which papal benefices and revenues from France were severely curtailed and the royal influence in the French church strengthened. Nevertheless, the survival of powerful dynasts and provincial interests, as a legacy of the war and the fertility of the royal house, represented a counterpoise to the crown that Philip the Fair had never known. And with the son of Charles VII, the monarchy was to be tested yet again.

Louis XI (1461–83) was shamelessly impatient for his father's death. It must be said of this strange man that he had worthy policies to pursue: the securing of the royal domain against Burgundy, Orléans, Brittany, etc., and the promotion of commerce and industry within national boundaries. His foreign policy was less consistent, ranging from the cautious in Italy to the chimerical in Spain; yet it was at the expense of Aragon that he regained title to Roussillon and Cerdagne. His methods rather than his ends were what made the reign of this ambitious, nervous, and capricious ruler so turbulent. No French king had ever imposed himself so totally and so tyrannically as Louis XI. Forgetful of past loyalties, he was betrayed as often as he himself betrayed others. Toward the clergy as toward his officials, he could be brutal and vindictive. He antagonized the nobles by revoking the Valois pensions and ceremonial and by promoting the independence of seignorial towns. As for the royal towns, Louis respected their constitutions only so far as was consistent with royal supervision and the payment of heavy taxes; he tolerated the resurgence of urban

oligarchies. Fiscal pressures in support of the army, government, and diplomacy mounted fearfully.

Politics, under Louis XI, replaced administration as the foremost preoccupation of the realm. Arbitrary and hasty measures against the dynasts aroused the formidable League of the Public Weal, which, in 1465, appealed to the people against misgovernment and proposed a regency of the princes supported by the three estates. Louis, in turn, as on later occasions, used assemblies and proclamations to divide the princes. But the settlement of October 1465 was a grave setback for the King, whose brother Charles gained title to Normandy while Charles the Bold, soon to inherit Burgundy, acquired strategic counties and towns in Artois. To the undoing of this treaty Louis devoted great energy. Fomenting strife between Brittany and Normandy, he soon recovered the latter and isolated the former. Deaths among his rivals in Gascony enabled him to secure successions, as in Armagnac, more divided and less hostile. Increasingly, Louis's tortuous diplomacy fastened on Burgundy. The King succeeded in reconciling the Swiss cantons with Austria to form a coalition with France and the Rhenish cities; this coalition invaded Burgundy and defeated and killed Charles the Bold at Nancy (January 5, 1477). While the legal reversion of Burgundy to the crown could not be given practical effect, Louis did recover Artois. Moreover, even as he enjoyed this decisive triumph over his most dangerous rival, the entire Angevin inheritance (Anjou, Provence, and Mediterranean claims) devolved to the crown upon the death of René of Anjou in 1480. Through accident and design and the inability of the princes to collaborate effectively, Louis had succeeded in countering the threat of a princely constitution and had considerably extended the royal domain.

**Economy, society, and culture in the 14th and 15th centuries.** The long war, fought almost entirely in France, benefitted few but the captains and speculators; it injured almost everyone. Even the best disciplined companies lived off the land, so that French peasants and defeated townsfolk in effect paid the expenses of both sides; and undisciplined mercenary bands were a wearisome scourge in times of truce after the middle of the 14th century.

*Economic distress.* But the war did not alone cause economic distress. Even before it broke out, bad weather and commercial dislocations, together with overpopulation in some areas, resulted in worse famines and more frequent ones than in the past. But what most terribly damaged life and security was sickness.

The Black  
Death

The Black Death, carried on shipboard from the Levant, reached Provence in 1347, ravaged most of France in 1348, and faded out only in 1350. Bonfires to disinfect the air, collective demonstrations of penitence in northern towns, persecutions of Jews or friars—nothing worked to check the disease in populations without immunity. The mortality was staggering—the French chronicler Jean Froissart's estimate that the first wave carried off a third of the population was perhaps not far wrong; recent studies suggest that rural areas were no less afflicted than towns. And there were recurrent outbreaks of plague in later years. These afflictions and related factors were responsible for a general decline of population. Toulouse seems to have lost half of its inhabitants, falling from 40,000 to 20,000; the population of Normandy is estimated to have declined by two-thirds between 1300 and 1450. The trend was probably reversed, and perhaps strongly so, in the second quarter of the 15th century, although little is yet known about this.

The hard times affected classes and regions in different ways, degrees, and rhythms. Some places almost escaped the ravages that afflicted others repeatedly. In the countryside, especially—save for the greatest personages—those who had most to lose suffered most. Whether for landlords or rich peasants, surpluses became harder to obtain or preserve; to many lesser lords the dangerous fortunes of war probably seemed an attractive alternative to declining yields in money or produce. Standards of living, as measured in diets or furnishings, declined. Onerous obligations and services tended to disappear as shortages of rural labour made themselves felt; the transition from servile to rental tenures was largely completed in the 15th century. Peasant uprisings, such as the Jacquerie in the relatively prosperous Île-de-France and the Tuchins in Languedoc, are too poorly documented to be well understood—both betrayed desperation born of recurrent taxation and were associated with the expression of egalitarian ideas; the Jacquerie coincided with a weakened grain market and may have been hastened by efforts of lords to enforce labour services and payments after the Black Death. The manor survived, but little remained of its human identity in the 15th century. Even minor lords lived away from their peasant tenants, protected them poorly if at all, relied on salaried managers to collect payments that, in some cases, had lost all social justification; lordship had degenerated into an unsentimental economic practice.

*The cities.* Urban society was also troubled. The walled town stood out ever more starkly against the countryside as siege warfare intimidated or destroyed the suburbs that had been built in a less anxious day. Royal taxation, often inequitably administered, exacerbated old tensions in the towns; fiscal policy or the regulation of wages or supplies was largely at issue in the uprisings of Flemish towns (1323–28), at Paris (1357–58, 1380–82), and at Rouen (1382). Communes continued to be revoked in the 14th century, although the kings as a rule were less interested in governing the towns than in securing their resources and fidelity. The concentration of trades and crafts in guilds became more complete and more exclusive.

Some leading commercial centres of the 13th century suffered as new trade routes developed in the empire and by sea and as textile manufactures and money markets—

the latter suffering from unstable coinage—became more dispersed. The fairs of Champagne declined rapidly after 1310. Only a few capitals, such as Avignon, Bordeaux, and Paris, prospered; and even they were hard hit by plague. Nor did the French merchant or manufacturer progress competitively; his work often unspecialized, his bookkeeping old-fashioned, his tastes simple, he typically looked forward to securing his future by the purchase of land.

*The church.* The organized church, despite losses from war and plague, continued to be better endowed economically than morally. The popes of Avignon were less distant and—save perhaps to their French relatives, merchants, and artists—less admirable than the reformer popes of the past; and as the prestige of their schismatic successors plummeted, the higher clergy were confirmed in their incipient Gallicanism (a movement advocating administrative independence from papal control). While organized heresy had almost disappeared, reforms intended to strengthen the parish priesthood languished. Jurisdictional disputes continued to rage between mendicants and seculars and between bishops and canons or archdeacons. Christian piety even more than in the past sought encouragement in mystical or individual devotions or readings and in collective observances of the Holy Spirit or the Virgin or the patron saints of the trades that promoted elementary solidarity and charity in the towns; such confraternities were not always welcome to ecclesiastical authorities, whose deportment or jurisdiction they sometimes challenged. The popular religion of saints—more particularly of the Virgin and the Pietà—and fear of demons worked more deeply into the collective imagination, becoming very evident in the 15th century. Associated with intensified anxieties about sin and damnation, these experiences thrived in times of inscrutable and recurrent disaster.

*Culture and art.* Cultural circles remained strongly oriented to aristocratic values and the past. With the accession of the Valois came a high nobility, distinguished by lavish and exclusive conceits. When John II formed the Order of the Star (1351), an institution imitated by the great lords for their clientages, chivalry stood incorporated as the most distinguished of religious confraternities. The ideal of the crusade remained strong, notably among princes of the fleur-de-lis, who dominated the public life of Valois France to the point of eclipsing the monarch; beneath them many noble families disappeared while new ones emerged among the captains, lawyers, and patricians. Froissart spun out chronicles of the war at once detailed and grand, full of the frivolous ceremonial that marked the aristocratic life of his day. Tapestries created for courtly patrons idealized a life of enticing gardens, tournaments, and the hunt. Paintings as well as tapestries hung in chambers smaller and more elegant than the cavernous halls of earlier centuries. The rayonnant Gothic of the Île-de-France remained in favour through the 14th century, inspiring the chapel built by Charles V at Vincennes, while the decorative arts of furnishings and manuscripts exploited the Gothic tendencies to articulation and grace. The evocation of the classical past became less fantastic and more heroic in the humanist circles of Pierre Bersuire and Petrarch; their interests helped to attract copyists and artists to the papal court of Avignon. The *Book of Hours* (the most popular private devotional work of the later Middle Ages) might become "very rich," as in the case of a sumptuous manuscript undertaken for Jean, duc de Berry (c. 1410); more typically it was a pocketbook for general use by the literate, whose numbers continued to increase.

Stimulated by the commissions of Charles V, the chasm between learned and vernacular cultures narrowed: Raoul de Presles translated St. Augustine; Nicole Oresme translated Aristotle. Music resounded in old forms (ballad, virelay) even while becoming more articulate or flamboyant; Guillaume de Machaut (died 1377), the great musician-poet of the mid-14th century, composed the first polyphonic mass as well as many motets and secular lyrics. Time and space came to be better

century

represented and measured, as evidenced by the first attempts to render perspective in art and in the erection of public clocks at Paris and Caen.

Toward 1400 Paris regained cultural leadership as a result of a new synthetic (or international) style in painting and of the initiatives of the university masters in ecclesiastical politics and theology. The efflorescence, however, was soon destroyed in the civil wars, to be succeeded later in the 15th century by more provincial activities. Universities (like Parlements) proliferated at the expense of Paris, which became the preserve of an antiquated and pedantic theology. Painters, architects, and writers regrouped under princely patrons or even under bourgeois ones, flourishing in postwar trade (Jacques Coeur's palace at Bourges exemplified the flamboyantly decorated solidity of late-medieval taste in France). A new vigour and enlarged scale in painting as in architecture contrast with the more traditional style in Burgundy, where the dukes were building on a grand and continuous past. Italianate Humanism, together with the new philology, stirred in France only in the latter third of the 15th century. (T.N.B.)

### III. France, 1490–1715

#### FRANCE IN THE 16TH CENTURY

When Charles VIII (1483–98) led the French invasion of Italy in 1494 he initiated a series of Italian wars that were to last until the Peace of Cateau-Cambrésis in 1559. These wars were not especially successful for the French, but they corresponded to the contemporary view of the obligations of kingship. They also had their effects upon the development of the French state; in particular, they threatened to alter not only the military and administrative structure of the monarchy but even its traditional role.

**Military and financial organization.** The French kings of the early 16th century could look back with satisfaction at the virtual expulsion of the English from French soil in the course of the preceding century. This success offered a shining precedent for further military sallies, this time against the growing power of the Habsburgs. In 1445 the first steps had been taken to fashion a royal French army out of the ill-disciplined mercenary bands upon which French kings had traditionally relied. It was a small force—no more than 8,000 men—but it was a beginning. The role of the nobility in the army was strong, for the art of war was still considered a noble pursuit *par excellence*. The core of Charles's army that marched into Italy, the *compagnies d'ordonnance*, consisted of noble volunteers. The infantry, however, was made up of non-nobles, and by the middle of the 16th century, there were more than 30,000 infantrymen to a mere 5,000 noble horsemen. As this infantry force grew in number its organization changed. Legions, organized on a strict provincial basis (the Breton Legion, the Norman Legion, etc.), gave way to the regimental system, based on large units under a single command. This latter organization appeared during the Wars of Religion of the 16th century and survived until the time of Louis XIV. Yet such reorganization did not immediately reduce the army to a pliant tool of the crown. Not until late in the 17th century could the royal army be considered fairly under the king's control. Until then, notably during the Wars of Religion and the outbreaks of the Fronde (1648–53; see below), the loyalty of the commanders and the devotion of the troops were conspicuously inadequate. In the later part of the 17th century, the reforms of the army by Michel Le Tellier and his son the Marquis de Louvois provided Louis XIV with a formidable weapon.

The growth of a large royal army, however, was only one effect of the increased level of military activity. The financial administration of the country also underwent a drastic reorganization, which had far-reaching economic and social consequences. The king, despite his ambitions, possessed neither the resources nor the administrative machinery to maintain a large army. The medieval idea that the king should live off the revenue of his own domain persisted into the 18th century and helps to explain the formal distinction made until the reign of Francis I

(1515–47) between ordinary and extraordinary finance; i.e., between revenue emanating from the king's patrimonial rights and taxes raised throughout the kingdom. By the reign of Francis I, the king, even in times of peace, was unable to make do with his ordinary revenue from rents and seigneurial dues. In 1523 Francis established a new central treasury, the Trésor de l'Épargne, into which all his revenues, ordinary and extraordinary, were to be deposited. In 1542 he set up 16 financial and administrative divisions, the *généralités*, appointing in each a collector general with the responsibility for the collection of all royal revenues within his area. In 1551 Henry II added a treasurer general; from 1577 the *bureaux des finances*, new supervisory bodies composed of a collector general and a number of treasurers, made their appearance in each *généralité*.

Moreover, the actual collecting of taxes was increasingly handed over to tax farmers, who collected and retained a particular royal tax in place of payment to the king of an approximately equivalent sum. The more efficient methods of collection by tax farmers enabled the crown to gather a larger proportion of its revenue than previously but did not, however, solve the problem of royal finance. Even the extraordinary taxes, now added to the crown's ordinary revenue, notably the *taille*, a direct tax levied on all but the nobility and the clergy, custom duties, and the purchase tax on wine, fish, meat, and especially salt (the *gabelle*), were not adequate resources for Renaissance princes whose chief glory lay in the expensive art of war. The *taille*, the only direct tax, which weighed most heavily upon the underprivileged classes, went up from about 4,500,000 livres under Louis XI (1461–83) to 55,000,000 under Jules Cardinal Mazarin in the mid-17th century.

Successive monarchs were forced, therefore, to seek additional revenue. This was no simple matter because French kings traditionally could not tax their subjects without their consent. Indeed, there were many areas of the country where the *taille* itself could not be collected and where the king was dependent upon local agreements. The early Valois kings had negotiated with the Estates-General or with the provincial estates for their extra money; but in the middle of the 15th century, when the Hundred Years' War with England was reaching a successful conclusion, Charles VII was able to strike a bargain with the estates. In return for a reduction in overall taxation, he began to raise money to support the army without having to seek the estates' approval. In some areas of central France the provincial assemblies ceded their right to approve taxation and disappeared altogether. These provinces were known as the *pays d'élection*. But in those provinces where the provincial estates survived (the *pays d'état*), the right to vote the amount of royal taxation also survived. During the Italian wars, meetings of the estates became more frequent as the king's financial demands became more strident, and though the estates never felt themselves able to refuse to provide money, they retained the right to provide less than the monarch asked for. The king continued to rely upon the support of the provincial assemblies to provide extra revenue long after 1614, when the cumbersome Estates-General ceased to play a role in opposing financial resources for the crown.

**The growth of a professional bureaucracy.** But the king also found another means of filling his exchequer that had nothing to do with traditional methods: he began to sell offices on a large scale. Venality, or the sale of offices, was not novel in early 16th-century France. Traces of the practice can be found in the 13th century, but it was Francis I who opened the floodgates. The number of judges proliferated. In the Parlement of Paris alone the King created two new chambers, each containing 20 members and a further score of judges. In 1552 Henry II established a new kind of court, the *présidial*, whose jurisdiction lay between the Parlement and the bailiwick. Each of the 65 new courts had a complement of nine judges; this brought in a sizable revenue but appears to have made little difference to the efficiency of the judicial system. Nor were judicial offices the only

The sale of offices

The problem of royal finance

ones put up for sale; it was also possible to purchase financial offices, such as those of treasurer general, treasurer, or the immediately inferior *élu*. It has been estimated that during the 16th century some 50,000 offices were sold by the crown.

The partial rationalization of the financial system produced an increasing number of professional advisers, who formed the embryo of a bureaucratic elite. In the course of the 16th century, as specialization grew apace, the king's council became a much more complex institution. The Conseil d'État, with its various subdivisions, formed the hub of royal government. Its members were drawn from a variety of backgrounds. The king's immediate family expected to be consulted, as did great officers of the crown, such as the chancellor, the constable, and the admiral. Also included in the council were the great territorial magnates, members of powerful aristocratic families, and the country's leading prelates. There were also masters of requests (*maîtres des requêtes*), lawyers whose expertise was invaluable when the council sat in a judicial capacity. But in the council the professional element that assumed the greatest significance in the course of the 16th and 17th centuries were the holders of the office of secretary of state. In the early years of the 14th century royal secretaries had already acquired the right to sign documents on the king's authority. From this stage, granted the stability of the crown, the development of the office from a position of subordinate but considerable importance to one of complete indispensability was predictable. Henry II gave four of his secretaries the official title of *secrétaire d'état*, and in 1561 they became full members of the royal council. Closely associated with them and destined to overshadow them in importance in the first half of the 17th century were the superintendents of finance, formally established in 1564, though exercising an already well-established function. Their responsibility was to control and safeguard royal finances and especially to prepare annual budgets containing estimates of revenue and expenditure for the following year. They also played a leading part in assessing the amount to be levied each year from the *taille* and in deciding upon the imposition of new taxes. Below the superintendents but also in the royal council in the 16th century were the intendants of finance. Originally masters of requests, they became a separate group specializing in the increasingly complex task of advising the sovereign in financial matters. In time, their role outstripped in prestige that of the other masters of requests who counselled the king.

#### The new administrators

There thus grew up a more specialized class of administrators, close to the crown, whose expertise rather than birth was the key to their influence; the sale of office allowed wealthy families to establish a firm base for later political and social advancement. In addition, the needy crown was perfectly prepared to sell titles of nobility as well as offices and, in return for a cash payment, to allow both nobility and office to become hereditary. Although this advancement of new men within the government might suggest a social readjustment of considerable proportions, in fact the element of continuity was more important than might at first appear. It is true that some of the ancient noble families and the king's own relatives found it increasingly difficult to fulfill their old advisory roles; yet the new men were not rejecting the established order but rather were being absorbed into it. The king's counsellors, whatever their former background, became leading noblemen by virtue of their high office: service to the crown was what mattered and that depended on the king's choice. It was not the first time that a new wave of royal servants had begun to overtake established advisers; in the 13th century the *magistri* had ousted the great barons and prelates from the Curia Regis without effecting a social revolution. What took place in the 16th and 17th centuries was another turn of the social wheel by which new men seized the opportunity to pursue those dignities and honours held by men who were themselves descendants of new men.

**The Reformation.** The professional class that grew up in the 16th century, however, was different in one respect

from those that had gone before: it represented a predominantly secular culture—the product of Renaissance Humanism—and reflected the declining influence of the church during the Reformation. In the second half of the 16th century, the Reformation was to embroil France in a series of religious wars that were to pose a serious threat to the power of the king and his government. Lutheran works first appeared in Paris in 1519; and in 1521 Francis I, who was on the point of war with Emperor Charles V and King Henry VIII of England and who wanted to demonstrate his orthodoxy, forbade their publication. Nevertheless, interest in the new faith continued to grow, especially in the Humanist circle of Jacques Lefèvre d'Étaples. Lefèvre, who had in 1512 published an edition of the letters of St. Paul with a commentary that anticipated Martin Luther in its assertion of the doctrine of justification by faith, became the leader of a small group of moderate but orthodox reformers in the tradition of the great Dutch Humanist Desiderius Erasmus. This group included Guillaume Briçonnet, the bishop of Meaux; the mystic Gérard Roussel; and Margaret of Angoulême, the King's own sister. Although this circle was dispersed in 1525, Lutheranism had already established itself, especially in such trading centres as Lyons, where it found support among the poorer classes. The progress of the Reformation in France depended on the crown's attitude; and although Francis for political reasons had revealed initial hostility, his feelings were far from clear. He was favourably disposed toward Lefèvre and toward orthodox reform in general, though he naturally feared those extreme movements that threatened social upheaval. In addition, Francis I saw political advantages in establishing good relations with the Lutheran German princes. On the other hand, unlike them, he had no great incentive to assert his independence from Rome because the Gallican Church already enjoyed a large measure of autonomy. In 1516 the Concordat of Bologna had given the king effective control over the church in France.

In 1534, however, royal policy changed radically. Anti-Catholic placards began to appear in Paris and other major French towns, provoking a bitter Catholic reaction and a series of persecuting edicts. French Protestantism itself had changed, reinforced from the mid-1530s by the spread among the poorer classes of Languedoc and the seaboard towns of Normandy and Brittany of the ideas of John Calvin, a French exile in Geneva. Henry II (1547–59) pursued his father's harsh policies, setting up a special court (the *chambre ardente*) to deal with heresy and issuing further repressive edicts, such as that of Écouen in 1559. Yet the infusion of French Calvinism, or Huguenotism, into the French Reformation stiffened the Protestant opposition. Protestant pastors, trained in Geneva, infiltrated into the country; and by 1562 there were some 2,000 highly organized Calvinist churches in France. This spectacular spread of Calvinism persuaded the queen mother, Catherine de Médicis, who was ruling in the name of her young son, Charles IX (1560–74), to abandon the repressive religious policy of Francis I and Henry II in the name of political good sense. Guided by the moderate chancellor Michel de L'Hospital, Catherine summoned the French clergy to the Colloquy of Poissy (1561), at which an unsuccessful attempt was made to effect a religious compromise with the Huguenots; in the following year she issued the Edict of January, which allowed the Calvinists a degree of toleration. These signs of favour to the Protestants brought a violent reaction from the noble House of Guise, the champions of Catholicism in France. The first civil war began with the massacre by the partisans of François, duc de Guise, of a Huguenot congregation at Vassy (March 1562).

**The Wars of Religion.** Guise forces occupied Paris and took control of the royal family, while the Huguenots rose in the provinces and their two commanders, Louis I de Bourbon, prince de Condé, and Admiral Gaspard de Coligny, established headquarters at Orléans. The deaths of the opposing leaders—the Protestant Antoine de Bourbon, king consort of Navarre, and the Catholic

#### The influence of Calvinism

marshal Jacques d'Albon, seigneur de Saint-André—and the capture of Condé caused both sides to seek peace. After the Battle of Dreux (December 1562) the war drew to a close, despite the assassination of the Duc de Guise by a Protestant fanatic. A compromise was reached at the Peace of Amboise in March 1563 whereby liberty of conscience was granted to the Huguenots but the celebration of religious services was confined to the households of the nobility and to a limited number of towns.

The second war was precipitated by Huguenot fears of an international Catholic plot. Condé and Coligny were persuaded to attempt a coup to capture Catherine and Charles IX at Meaux in September 1567 and to seek military aid from the Protestant Palatinate. In the following brief war the Catholic constable Anne de Montmorency was killed at the Battle of Saint-Denis (November 1567); the Peace of Longjumeau (March 1568) signalled another effort at compromise. This peace, however, proved little more than a truce; and a third war soon broke out in September 1568. In an attempt to restore their authority, Catherine and King Charles had dismissed L'Hospital in that month and had restored the Guise faction to favour. The edicts of pacification were rescinded; Calvinist preachers faced expulsion from France; and plans were made to seize Condé and Coligny. The former was killed at the Battle of Jarnac (1569), and the Huguenots were again defeated in that year at Moncontour. But the Catholic side failed to consolidate its successes, and yet another compromise was arranged at the Peace of Saint-Germain in August 1570.

Coligny subsequently regained the King's favour but not the Queen Mother's, and he remained an object of hatred with the Guises. In 1572 he was murdered; and at the same time some 3,000 Huguenots, gathered together in Paris to celebrate the marriage of Marguerite de Valois (later Margaret of France) to Condé's nephew, Henry III of Navarre, were massacred on the eve of the feast day of St. Bartholomew. This notorious episode was the signal for the fifth civil war, which ended in 1576 with the Peace of Monsieur, allowing the Huguenots freedom of worship outside Paris. Renewed fighting broke out in 1577 between Catholic and Protestant noblemen, who defied the King—now Henry III (1574–89)—in his attempt to assert royal authority. The Huguenots were defeated and forced by the Peace of Bergerac (1577) to accept further limitations upon their freedom. An uneasy peace followed until 1584, when, upon the death of François, duc d'Anjou, the Huguenot leader Henry of Navarre became the heir to the throne. This new situation produced the War of the Three Henrys (1585–89) during which the Guise faction—led by Henri, duc de Guise—sought to have Navarre excluded from the succession. In a welter of intrigue and murder, first the Duc de Guise and his brother Louis, cardinal de Guise (December 1588), and then Henry III himself (August 1589) were assassinated. Henry of Navarre thus assumed the throne as Henry IV (1589–1610) but had to survive five more years of civil war and embrace Catholicism before his position was secure. In its final stages, the war became a struggle against Spanish forces intervening on behalf of Isabella Clara Eugénie, the daughter of Philip II of Spain and Elizabeth of Valois, who also laid claim to the French throne. The Peace of Vervins (1598), by which Spain recognized Henry IV's title as king and the Edict of Nantes of the same year, granting substantial religious toleration to the Huguenots, ended the Wars of Religion.

**The religious wars and the monarchy.** This succession of civil disturbances brought the French state close to disintegration and posed a threat to the crown that would not be matched again until 1789. The chief reason for this situation lay in the nature of Calvinism, which provided a rallying point for a wide cross section of opposition and the organization necessary to make that opposition effective. Each Huguenot community created its own administrative structure to provide a tight disciplinary framework, through which the community could ensure its spiritual and material independence. The new creed attracted several elements in French society: small

artisans, shopkeepers, and the urban unemployed, who were suffering in particular from steeply rising prices; many rich townspeople and professional men who thought that material advancement would be easier to procure as Calvinists; and, after the Treaty of Cateau-Cambrésis in 1559, many nobles, especially the poorer ones who had lost with the peace their best hope of wealth and status. The adherence of large numbers of the nobility had two important effects upon the movement in France: (1) it caused many peasants to join the new creed in imitation of their noble seigneurs, thus swelling the overall number and widening its social composition; and (2) it brought a new military element into the Calvinist communities. Under the leadership of the nobility, secret religious meetings were transformed into mass public demonstrations against which the king's forces were impotent. Such demonstrations sometimes involved upward of 20,000 people. Similarly, the administrative structure that was so important in aiding the survival of the proscribed faith was transformed into a military organization. This organization was ultimately headed by Louis, prince de Condé, who assumed the title of protector general of the churches of France, thus putting all the prestige of the House of Bourbon behind the Huguenot cause. By doing so he added a new dimension to the age-old opposition of the mighty feudal subject to the crown: that opposition was now backed by a tightly knit military organization based on the Huguenot communities, by the financial contributions of wealthy bankers and businessmen, and by the dedicated religious zeal of the faithful—inspired by the example of Geneva.

At a time when the threat to the crown had never been greater, the monarchy itself presented a sorry spectacle. The struggle for political power at the centre of government after Henry II's death between the families of Guise, Bourbon, and Montmorency; the vacillating policy of Catherine de Médicis; and, most important of all, the ineptitude of three successive rulers—Francis II (1559–60), Charles IX, and Henry III—meant that local government officials were never confident of their authority in seeking to curb the growing threat of Huguenotism. Indeed, the chief opposition to Protestantism came not from the crown but from the Catholic Holy League. Because of the government's inability to control the situation, local Catholic unions or leagues began to appear in the 1560s, headed by nobles and prelates. In 1576, after the Peace of Monsieur with its concessions to the Huguenots, these local leagues were fused into a national Catholic Holy League. The league was headed by the Guise family and looked for material aid to Philip II of Spain. Its chief aims were the defeat of Protestantism in France and the restoration of ancient feudal rights and privileges. It sought, like the Protestants, to attract mass support; its clandestine organization was built around the House of Guise rather than the monarchy, from which it was increasingly alienated. In 1577 Henry III tried to nullify the league's influence, first by putting himself at its head and then by dissolving it altogether. This manoeuvre met with some success; but in 1585, when the death of Henry's brother, who had succeeded him as duc d'Anjou the previous year, made a Protestant succession to the throne much more likely, a second and far more revolutionary organization appeared. This second movement was centred in Paris among middle class professional men and members of the clergy and soon spread among the Parisian artisans, guilds, and public officials. Finally, through the intervention of the Duc de Guise, it inspired the reappearance throughout the country of the old Catholic Holy League of 1576, though now in a much more extreme and threatening form. The King himself, who was considered far too tolerant toward the Huguenots, was an object of attack. In town after town, royalist officials were replaced by members of the league. In Paris, the mob was systematically aroused; and in 1588, in the famous "Day of the Barricades," Henry III was driven from his own capital. After the murder of Guise at the end of that year, the league came out in open revolt against the crown. Towns renounced their royal allegiances and set up revolutionary governments. In

The struggle for the central government

The Catholic Holy League in Paris

Massacre of St. Bartholomew's Day

Paris, however, the league was most highly organized. There a central committee called the Sixteen was established that set up a Committee of Public Safety and conducted a reign of terror in a manner similar to the much more famous Revolution of 200 years later.

Paradoxically, this genuinely democratic and revolutionary element in the Holy League paved the way for the triumph of the Protestant leader Henry of Navarre, later Henry IV. The aristocratic members of the league took fright at the direction in which the extreme elements in the movement were proceeding. Their fears reached a climax in 1591, when the Sixteen arrested and executed three magistrates of the Parlement of Paris. The growing split in the ranks of the members of the league, combined with Henry's well-timed conversion to Catholicism, enabled him to seize the initiative and enter Paris, almost unopposed, in 1594. But the threat to the monarchy and therefore to the whole French state had been of a new and fundamental kind, and the strong position that Henry IV achieved by the time of his death is that much more remarkable. Part of his success lay in the unwillingness of his great subjects to contemplate a social and political upheaval that would displace them as well as the King from their positions of power and prestige.

**Political ideology.** The religious wars also engendered a luxuriant growth of political ideas that in the end provided a strong theoretical basis for the reassertion of royal authority.

A strong element in Calvin's teaching was the importance of passive obedience to secular authority—an idea that became impossible for the Huguenots to support after the Massacre of St. Bartholomew's Day. They began instead to advocate the right to attack the king if he would not guarantee them toleration. The most important Huguenot contribution in this change was the anonymous pamphlet *Vindiciae contra tyrannos* (1579), which raised fundamental questions about the prince's power and the rights of his subjects. The pamphlet advanced the idea of a twofold contract: the first contract, between God on the one hand and the ruler and his subjects on the other, recognized the belief that the king ruled under the aegis of Divine Providence; the second contract, between the king and the people, obliged the king to govern justly and the people to obey him so long as he did so. It followed from the argument in the *Vindiciae* that subjects had the right to rebel if the prince disobeyed the laws of God or refused to govern his people justly. This twofold contract was not intended to be a license for private and personal rebellion but was interpreted as justifying the corporate opposition of whole towns and provinces.

A second element in the realm of political ideas, deeply opposed to the contractual theory of the Huguenots, was that of the Jesuit supporters of Ultramontanism, that is, the supporters of papal authority in France. The Ultramontanists feared that a strong national monarchy would mean the subordination of the church and the diminution of papal authority. They feared the triumph of both Huguenotism and Gallicanism in France. Their most effective controversialist was the Italian prelate Robert Bellarmine, whose *Disputationes* (3 vol., published 1586–93) and *De Potestate summi pontificis in rebus temporalibus* (1610) gave definite form to the theory of papal supremacy. By no means were all members of the league supporters of Bellarmine, though their extreme Catholicism made many of them sympathetic to his ideas. The definitive Gallican reply came in 1594 with Pierre Pithou's *Les Libertés de l'église gallicane*, which reiterated the basic tenets of Gallican doctrine: that the pope had no temporal authority in France and no more spiritual power than that bestowed on him by such conciliar decisions as the monarchy chose to recognize.

The growing support for Gallican opinion was a reflection of the emergence of the Politique Party after the Massacre of St. Bartholomew's Day. In the opinion of this moderate Catholic group, toleration should be granted to the Huguenots for the sake of peace and national unity. The Politiques were the spiritual heirs of the chancellor L'Hospital and represented an attitude of

mind rather than an organized movement. Under the pressure of political events this group became convinced of the need to support a strong monarchy that could resist both Ultramontane and Huguenot excesses and the divisive influence of noble factions. They therefore increasingly identified themselves with the Gallican position. The Huguenots, too, were not slow to see the advantages for themselves of this new attitude, and the ideas of the *Vindiciae* gave way to the theory of passive obedience. The wheel had turned full circle.

With this emphasis upon passive obedience, the theory emerged of the divine right of kings. The first written statement of the theory in France is contained in the works of Pierre de Belloy, especially his *De l'autorité du roi* (1588). He asserted that the monarchy was created by God and that the king was responsible to God alone. Any rebellion against the ruler, therefore, was a rebellion against the Almighty. The essential premise of the divine-right idea is that the right to command obedience cannot be bestowed by man; only God can grant such authority. God therefore chooses the king, and there can be no contractual relationship between the king and his people; to rebel even against an unjust ruler is to challenge God's choice. If the king breaks his contract with God, then he is answerable to God alone. On the wave of such ideas Henry of Navarre became king of a united France, supported by Huguenots and moderate Politique Catholics alike. The universalist doctrine of Bellarmine gave way to the national one of Pithou as the country closed ranks against Spain, the common enemy.

One other concept emerged about this time that helped to set the seal on Henry's authority: the idea of sovereignty, as expounded by Jean Bodin. In his *Six Livres de la République* (1576) Bodin argued that the political bond that made every man subject to one sovereign power overrode religious differences. Bodin provided the link divine right did not allow between the king and his people; divine right was concerned with the source of the ruler's power, sovereignty with its exercise. The needs of the political situation forced Bodin to give his sovereign virtually unlimited authority, though he insisted—as was traditionally the case in France—that the ruler should respect the sanctity of the natural law, of the fundamental laws of the kingdom, of property, and of the family. In 1614, on the occasion of the last meeting of the Estates-General before the Revolution, the Third Estate sought to have it made a fundamental law of the realm that under no pretext whatever was it permissible to disobey the king. This effort gives some indication of the extent to which the ideas of divine right and sovereignty had provided a firm theoretical base for the re-establishment of monarchical power after the dangerous years of civil war.

#### FRANCE IN THE EARLY 17TH CENTURY

**Henry IV.** The restoration of royal authority was not, of course, simply a matter of adjusting theories of kingship; there was a clear practical reason for Henry's success. The country had been torn apart for three decades, tottering on the brink of disintegration. By the time of Henry's succession, it was generally recognized that only a strong personality, independent of faction, could guarantee the unity of the state, even though that unity meant religious toleration for the Protestant minority. By the Edict of Nantes (April 13, 1598) Henry guaranteed the Huguenots freedom of conscience and the right to practice their religion publicly in certain prescribed areas of the country. As a surety against attack, the Huguenots were granted a number of fortresses, some of them, such as La Rochelle and Montpellier, extremely formidable strongholds. As individuals, Huguenots were made eligible to hold the same offices as Catholics and to attend the same schools and universities. Finally, to ensure impartial justice for them, the Edict established in the Parlement of Paris—the supreme judicial court under the king—a new chamber, the *Chambre de l'Édit*, containing a number of Protestant magistrates who would judge all cases involving Huguenots. Although the problem of religion was not finally settled by

Divine-right theories

The Ultramontanists

the Edict of Nantes, Henry did succeed in effecting an extended truce during which he could apply himself to the task of restoring the royal position.

Sully's  
financial  
reforms

The chief need of the monarchy was to improve the financial situation, parlous since the days of Henry II's wars and aggravated by the subsequent internecine conflict. Henry was fortunate in this connection to have the services of Maximilien de Béthune, duc de Sully, who was admitted to the King's financial council in 1596. Sully at once embarked upon a series of provincial tours, enforcing the repayment of royal debts, thereby increasing the King's revenues. He also provided the first real statements of government finances for many years; by 1598 he had become the effective head of the royal financial machine as well as a trusted member of the King's inner Cabinet. He held a variety of offices: superintendent of finances, grand master of artillery, superintendent of buildings, governor of the Bastille, and others. But it was in the field of finance that he made his greatest contribution to the welfare of the state. Sully was not an original financial thinker. He undertook no sweeping changes, contenting himself with making the existing system work. He succeeded in building up both an annual surplus and substantial reserves. The only measure he championed that might be described as novel and far-reaching was the introduction in 1604 of a new tax, the *paulette*, named after the financier Charles Paulet, which enabled officeholders to assure the heritability of their offices by paying one-sixtieth of the purchase price each year. The *paulette* was intended to increase royal revenues, though it had considerable political implications too, in effect making government offices practically hereditary. Politically, the *paulette* was to increase the independence of a wide range of royal officials, thereby limiting royal absolutism and strengthening the possibility of disinterested state service. In addition, Sully did much to reorganize fortifications and to rebuild roads and bridges after the devastation of the religious wars. In transportation his greatest work was the Briare Canal project to join the Seine and Loire rivers—the first such scheme in France—completed under Louis XIII.

Sully, however, favoured a much more cautious domestic policy overall than did his sovereign; and because Sully disliked merchants and manufacturers, he opposed many of the King's economic ventures. Henry IV believed in direct state intervention, and he took steps to fix wages and to prohibit strikes and illegal combinations of workmen. Henry's policies bore fruit especially in the textile industries, where the production of luxury silk goods and woollen and linen cloth greatly increased. Henry also took the initiative in making commercial treaties with Spain and England, thereby increasing the volume of French trade and stimulating the export of grain, cattle, and wine. Yet his efforts were not entirely successful, not least because merchants were more concerned with buying land and office (and thereby status) than with plowing back their profits into further industrial development. Though the country did assume a more prosperous air under Henry IV, that change was chiefly because of the domestic and foreign calm that followed the Peace of Vervins.

Henry's  
foreign  
policy

Although after Spain's agreement in 1598 to the restoration of the territorial position as it existed in 1559 Henry was not free of international complications, he was, however, able to prevent them from once more dividing his kingdom. He did have to counter a conspiracy led by one of his own marshals, Charles de Gontaut, duc de Biron, who plotted with the King of Spain and almost succeeded in raising southwest France in revolt. Henry, however, had Biron arrested and executed in 1602; this strong action against an old friend and powerful enemy had the effect of subduing the political rising and strengthening Henry's own authority. In central government Henry gave increasing power to Sully at the expense of the rest of his council; while in the provinces the use of the intendant, an official first regularly employed during the reign of Henry III, was widened to include the supervision of potentially dissident groups. The intendants also represented the crown at meetings of provin-

cial estates, enforced royal laws, and advised the king on a variety of local problems—fiscal, administrative, and military. When Henry IV was assassinated by François Ravaillac, a Catholic fanatic, in May 1610, he had gone a long way toward restoring the monarchy to a position of authority similar to that held by Francis I and Henry II and had reunified a state greatly threatened at his accession from both within and without.

**Louis XIII, 1610–43.** Henry's reign was followed by the regency of his widow, Marie de Médicis, who ruled on behalf of his young son Louis XIII (1610–43). Once more the security of the country was threatened as factions disputed around the throne. The work of Henry IV seemed likely to be undone. Crown and country, however, were rescued by probably the greatest minister of the whole Bourbon dynasty—the Cardinal de Richelieu (q.v.). Richelieu first came to the attention of the government in 1614, when he was chosen to present the final address of the clergy at the meeting of the Estates-General. His eloquence and political expertise on this occasion won him the notice of Marie de Médicis, who later appointed him her secretary. By 1616 Richelieu was secretary of state for war and foreign affairs. His career, however, received a check in the following year when he was exiled to Blois with the Queen Mother and subsequently to Avignon (1618). He began the climb back to power by negotiating the Treaty of Angoulême (1619), which reconciled Louis XIII to his mother. After the death in 1621 of Louis's favourite, Charles d'Albert, duc de Luynes, Richelieu regained effective power; he became a cardinal in 1622 and in April 1624 gained access to Louis XIII's council. On the disgrace in 1624 of the superintendent of finance, Charles de La Vieuville, he became Louis's principal minister—a position which he maintained until his death some 18 years later.

The rise of  
Richelieu

Richelieu proved an indefatigable servant of the French crown, intent on securing absolute obedience to the monarchy and on raising its international prestige. The first objective required him to crush a number of revolts of the nobles, the first of which, in 1626, involved the King's younger brother and heir, Gaston de France, duc d'Orléans. Louis acted ruthlessly, and one of the conspirators, Henri de Talleyrand, comte de Chalais, was executed. Then, in 1630, came the celebrated "Day of Dupes" when the King's life was despaired of and the Queen Mother, now allied with Gaston and the keeper of the seals, Michel de Marillac, prepared to move against Richelieu. The King, however, recovered and chose to support Richelieu against the wishes of his mother, his wife, and his confessor. Finally, at the very end of his life the Cardinal had to overcome another conspiracy headed by the young royal favourite, Henri Coiffier de Ruzé, marquis de Cinq-Mars, in which Gaston was once more implicated. Through all these crises Richelieu retained the King's support, for it was in Louis's interests, too, that such intrigues should be firmly dealt with.

In the course of strengthening royal absolutism, Richelieu also came into conflict with the Huguenots. He believed that their right under the Edict of Nantes to maintain armed fortresses weakened the King's position at home and abroad. Protestant rebellions in 1625 and 1627 persuaded the Cardinal of the need for a direct confrontation. The major Huguenot citadel of La Rochelle was attacked by royal troops in 1627 and, despite attempts by the English to assist the Protestants, fell in the following year. Another royal army marched into Languedoc, where the Huguenot forces were concentrated, and quickly overcame them. The Peace of Alais (1629) left the Huguenots free to enjoy religious and civil liberties, but they lost the military power that had made them a threat to the government. They were never to pose that sort of threat again and little more would be heard of them until Louis XIV decided to repeal Henry IV's Edict of Nantes.

Richelieu also took a great interest in economic matters. To promote economic self-sufficiency he encouraged the manufacture of tapestry, glass, silk, linen, and woollen cloth. He gave privileges to companies that established colonies in America, Africa, and the West In-

Richelieu's  
anti-  
Habsburg  
policy

dies. To protect trading and colonial interests he created a navy, which by 1642 had 63 oceangoing vessels.

On the basis of these policies Richelieu was able to pursue an increasingly successful foreign policy. His first aim was the security of France by the occupation of key points on the country's frontiers lying along imperial and Spanish territories. He thus involved France in the War of the Mantuan Succession (1628–31) in northern Italy. Through diplomatic means he worked for the dismissal of Albrecht Wenzel von Wallenstein, the brilliant general fighting on the side of the emperor Ferdinand II, whose forces were threatening to destroy the Protestant princes of Germany in the Thirty Years' War. To undermine the power of the Habsburgs, he prolonged this conflict, negotiating with the United Provinces; with Gustavus II Adolphus of Sweden, with whom he concluded the subsidy Treaty of Bärwalde in 1631, agreeing to pay the Swedish king 1,000,000 livres per year to continue the war; with Gustavus' successor, Count Axel Oxenstierna; and with Bernhard, duke of Saxe-Weimar. Eventually, in 1635, Richelieu committed France to direct conflict with the Habsburgs; and before his death he had savoured the triumph of French arms in the Spanish Netherlands, Lorraine, Alsace, and Roussillon.

The career of Richelieu bears something of a contradictory aspect. He undoubtedly added to the earlier success of Henry IV and Sully in overcoming the threat of anarchy and disorder that was the legacy of the late 16th century. Indeed, his contemporary reputation was one of supreme ruthlessness and arbitrariness in the application of power. Yet he was never more than the King's creature, incapable of pursuing a course of action of which Louis disapproved, always vulnerable to the loss of royal favour and support. He was ambitious, but he recognized that his desire for power could best be satisfied within the confines of dutiful royal service. Richelieu was no innovator: he devised neither new administrative procedures nor novel methods of taxation to secure the King's authority. Indeed, the power of the great financiers grew with the government's need for additional war revenue, posing a different threat to royal absolutism. Richelieu's unique contribution lay in the single-minded devotion he gave to his objective: the increase of royal authority at home and abroad. Richelieu died in 1642, and Louis XIII died the following year. France was once again ruled by a regent, the queen mother, Anne of Austria. But the task of governing the country fell increasingly into the hands of another cardinal, Mazarin.

Opposi-  
tion to  
Mazarin

**The Frondes.** The years of Louis XIV's minority were dominated by the Frondes, a series of civil disturbances that lasted from 1648 to 1653. (The name *Fronde* arose from window breaking as a tactic in the resistance to Mazarin. The *fronde*, a sling for propelling stones, was a popular toy.) The government's financial difficulties were once more at the root of the trouble, and in the first few years of the regency a variety of expedients were tried to raise additional revenue for the war with Spain. There was about these expedients an air of arbitrariness and compulsion that antagonized a wide cross section of Parisian society, notably the Parlement of Paris, the animosity of which was heightened by Mazarin's use of intendants in the localities to cut across traditional legal hierarchies. Although most of the disputes were on the face of it concerned with financial exactions, below the surface an older constitutional argument was developing as Mazarin followed Richelieu in attempting to dictate from the centre in the interests of the state. The climax came when the government failed to renew the *pauvette* for the members of the provincial parlements and for some of the chief legal officeholders in the capital, in the Cour des Aides, the Chambre des Comptes, and the Grand-Conseil. This decision was not a gratuitous rebuff to these magistrates but yet another attempt to gain additional revenue, this time by offering a renewal of the *pauvette* in lieu of four years' salary.

At this point, the first Fronde (the Fronde of the Parlement) began with the outraged magistrates of the three courts concerned joining with the Parlement of Paris to demand redress. Their demands included the

abolition of the office of intendant; a reduction in the level of the *taille*; and the restoration of normal judicial procedure in registering financial edicts in the Parlement. The regent and Mazarin at first took a conciliatory attitude, but each side gradually moved to more committed and extreme positions, and civil disturbances in Paris exacerbated an already delicate situation. The magistrates increasingly aimed their fire at Mazarin for he, like Richelieu before him, seemed to be taking over the King's authority and using it in uncharted and illegal areas. The magistrates, however, were not revolutionaries and the state of disorder in the capital frightened them. That fact, allied with fears of a Spanish invasion (for the war was still continuing with Spain despite the Peace of Westphalia in 1648), persuaded them, in 1649, to make the Peace of Rueil with the government, the terms of which were for the most part favourable to the magistrates' original demands. At this stage the second civil war broke out, the Fronde of the princes, headed by the Great Condé. The second Fronde was a pale reflection of the feudal reaction during the Wars of Religion; and although Condé succeeded in gaining control of Paris, he did not acquire the support of the Parlement except briefly and under duress. In October 1652 Condé fled to Spain, and Louis XIV re-entered his capital in triumph.

Neither Fronde posed the grievous threat to the very basis of the state that had existed in the previous century. Mazarin was the chief object of enmity and that fact itself helps to explain the less serious nature of the threat. What was at issue was not the King's authority *per se* but the manner in which it had been exercised since Richelieu's time, in a less personal and therefore seemingly more arbitrary fashion.

After the Frondes, Mazarin continued to play a key role in government as chief adviser to the young king, whose respect and affection he had long possessed. His career ended on a high note with a successful conclusion of the war with Spain negotiated by the Treaty of the Pyrenees (1659). According to its terms France gained Roussillon and Cerdagne in the south and Artois and a number of border towns in the north; and the Rhine became France's frontier in the east. By the treaty, too, Louis XIV was betrothed to the infanta Marie-Thérèse, the elder daughter of Philip IV of Spain. It was by any reckoning a triumphant peace, though it sowed the seeds of future European conflict over the issue of the Spanish succession (see below). When Mazarin died in 1661, Louis was confident enough to take up the reins of government without recourse to another first minister.

Before examining the most famous reign in French history, one further aspect of the previous decades requires scrutiny—the economic and social situation to which some historians have attached considerable importance, especially as an element in the so-called general European crisis of the 17th century (a series of upheavals—among them the Frondes and the English Civil War—that affected Europe in the middle of this century). A Soviet historian, Boris Porshnev, first drew particular attention to the series of local uprisings taking place in France in the first half of the 17th century. He notes that all of them contained an element of desperation as serious financial hardship brought about by exorbitant tax demands and crop failures forced the participants into action. Great fluctuations in prices and outbreaks of famine further accentuated the misery. From these observations he draws ideological conclusions that have been widely disputed. Porshnev maintains that the state was the instrument by which the dominant economic class exploited the underprivileged and that revolt was a sign of the popular resistance of the exploited masses. On the other hand, Roland Mousnier, perhaps the greatest French authority on the period, has pointed to evidence that suggests that these revolts were not always spontaneous: they were provoked in 1632 by the municipal authorities at Lyons; in 1636 by the nobility of Périgord; and in 1641 by Louis, comte de Soissons, a prince of the blood. In 1643 the conduct of bishops and magistrates in Languedoc was seen by one royal official as likely to en-

The  
European  
crisis of  
the 17th  
century

courage sedition there. From these examples and others like them, Mousnier concludes that the nobility was seeking to reverse the process by which the king's officials were extending the crown's authority at their expense, taxing peasants to such a degree as to limit the amount the peasants could afford to pay in seigneurial dues, insinuating the king's justice between themselves and their peasants, reducing their prestige in the local community, and trampling upon old rights and privileges. Mousnier asserts that the nobility, far from representing the oppressive state, was itself involved in a struggle against increasing state interference. The opposition provoked by the work of Richelieu and Mazarin fits well into Mousnier's view and gives it support. It remains true, however, that most popular revolts began as protests against fiscal demands that were intolerable to people already suffering grievous economic hardship and that they were often provoked by a particular incident, such as the appearance of a new tax collector or a new system of tax collection.

There was little sign of the revolutionary attitude that had characterized aspects of the 16th-century Wars of Religion. On the contrary, there were positive indications of continuing loyalty to the crown, with such rebel slogans as "*Vive le roi sans la gabelle*" or "*Vive le roi sans la taille*." Nor was the other great bastion of the establishment, the church, attacked. The substantial tax of the tenth continued to be paid to the church without complaint. During the Fronde, neither the nobles nor the magistrates represented a revolutionary political element, and even the rioters on the Parisian streets were simply desperately poor. There was no social revolution either under Henry IV, Richelieu, or Mazarin despite the appearance of increasing numbers of hereditary officeholders, aided in their dynastic ambitions by the device of the *paulette*. The elevation to noble rank of new families was a cyclical process in France that would continue through and beyond the reign of Louis XIV.

#### THE AGE OF LOUIS XIV

Like his predecessor Henry IV, Louis assumed plenary power at a time when few of his subjects wished to be reminded of recent civil disturbances and were content to accept his absolute authority. Throughout his long reign Louis never lost the hold over his people that he assumed at the beginning. He worked hard to project his authority in the splendid setting of Versailles, to depict it in his arrogant motto: *Nec pluribus impar* ("None his equal"), and in his sun emblem. He buttressed his authority with the divine-right doctrines elaborated by Bishop Jacques-Bénigne Bossuet and proclaimed it across Europe by force of arms. Yet he made surprisingly few institutional or administrative changes in the structure of government. Like Richelieu, Louis used the system that he had inherited and adapted it to suit his own personality and outlook. This practice may be seen first in his attitude to the machinery of central government.

**The development of central government.** His inner council was on the model of the royal council in Richelieu's days, a Conseil d'en Haut consisting of only three or four members and excluding the King's own relatives. Members of this council were known as ministers, but they held no formal right to the title and ceased to be minister if the King chose not to summon them. The first of these great men were Michel Le Tellier, Hugues de Lionne, and Nicolas Fouquet; but the latter was disgraced within a year, and by 1665 his place had been taken by Mazarin's former secretary, Jean-Baptiste Colbert. These three men dominated the government in the early years of Louis's personal reign, but always, as with Richelieu and Louis XIII, under the watchful and jealous eye of the King. Le Tellier had been secretary of state for military affairs under Mazarin's regime, and his greatest contribution under Louis was to reorganize the army along lines that were hardly changed until after 1789. He created a royal army, wearing the king's uniform, commanded by his officers, and ultimately responsible to the sovereign. It was a standing army of hitherto undreamed-of size, reaching 400,000 men in times of war

and requiring close regulation in matters of discipline, training, recruitment, supply, and overall organization. The success of Le Tellier and of his son Louvois, who succeeded him, goes far to explain the dominance of French arms in Europe during Louis's reign.

Lionne, the expert in foreign affairs, had been the chief French negotiator at the Peace of the Pyrenees. His effective influence with Louis is difficult to gauge; and certainly he was not the sole source of advice in foreign affairs. Lionne remains a more elusive personality than his colleagues, though there can be no doubt of his importance. It should be remembered that all important matters of state were reviewed at the Conseil d'en Haut; and the King's ministers were expected to give advice and opinions on all that was discussed, not simply on matters in the area of their particular expertise.

Colbert, however, remains the best known of these intimate counsellors. Of the 17 ministers summoned by Louis XIV to the Conseil d'en Haut during his reign, five were members of the Colbert family. In 1664, Colbert was appointed superintendent of the King's buildings, in 1665, controller general of finances, in 1669, secretary of state for the navy. His capacity for work and his grasp of detail were remarkable; but he was not an original, much less a revolutionary, thinker. Like Sully, his chief contribution to the King's finances was to make the machinery more efficient, not to substitute any new mechanisms. Colbert's first achievement was to present the King with a monthly statement of the financial situation, though his annual estimates for the following year never persuaded Louis of the need for economies if his mind was set in other directions. Yet within ten years of taking office Colbert, mainly by tightening up on the tax-collecting administration and by rationalizing the gathering of indirect taxes, did succeed in producing a surplus. He turned a large part of central and northern France into a free-trade area and gave the responsibility for collecting all indirect taxes there to a new syndicate of tax farmers called the Farmers-General. Under Colbert, the total sum levied from indirect taxation rose from 36,000,000 livres to 62,000,000.

In his industrial policy Colbert believed that France needed to produce for itself those manufactured goods that it was having to import. To achieve this mercantilist goal, derived from, among other sources, the ideas of Richelieu, Colbert was willing to invoke a variety of impositions: direct subsidies, exemptions from the *taille*, monopoly grants, controls exercised through town guilds. Skilled foreign workmen were persuaded to settle in France and to pass on their skills to native artisans; protective tariffs were imposed. The famous tapestry works of the Gobelins family was made a state enterprise, and France became largely self-sufficient in the production of woollen cloth. Colbert also had some success in other industries, such as sugar refining, plate-glass making, and the production of silk, naval stores, and armaments. The overall results of his hard work, however, were disappointing. France underwent no industrial revolution during the reign of Louis XIV.

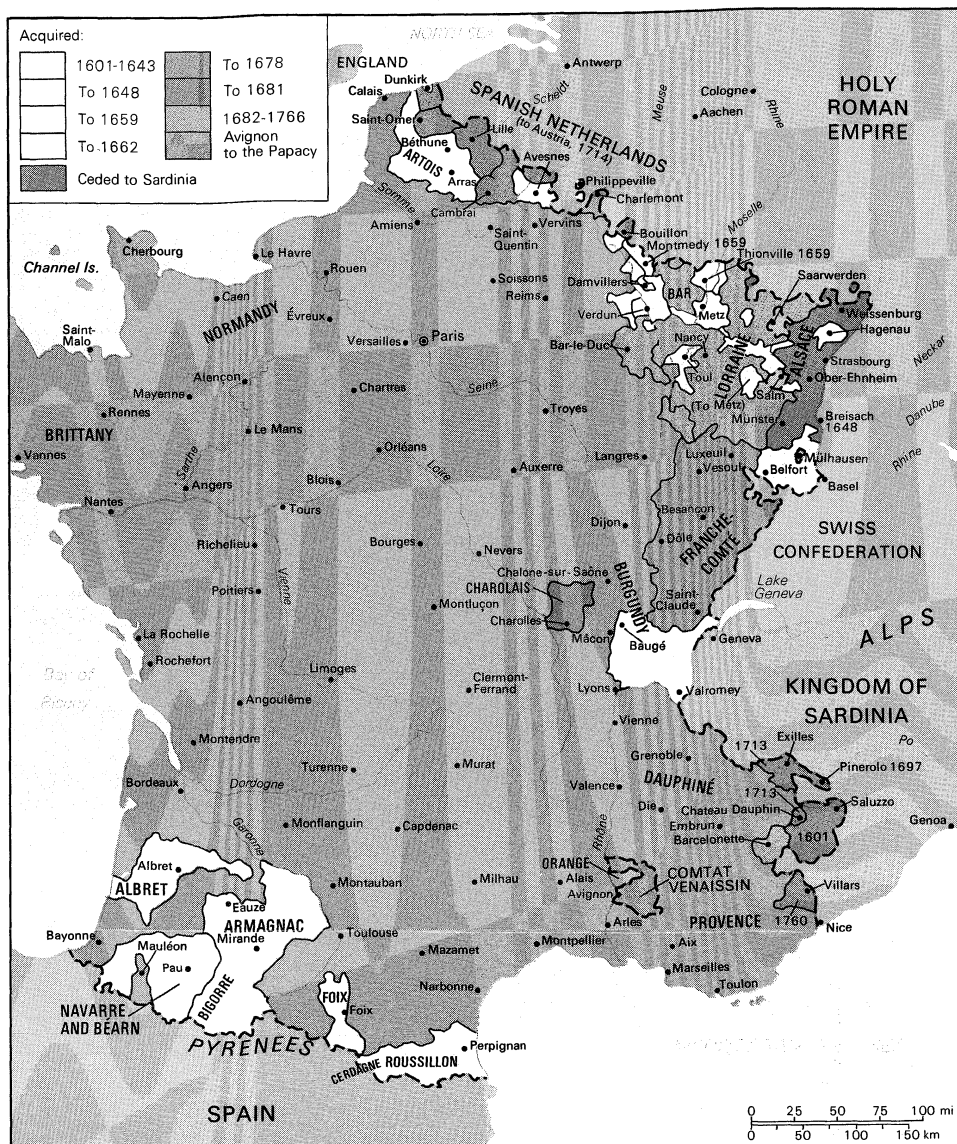

Much more successful were Colbert's efforts at fostering the growth of the navy. He reorganized the recruitment system on a rotary basis, seamen serving in the royal navy for six months in every three years. He refurbished the hospitals in each of the major ports; rebuilt the arsenals at Toulon and Rochefort; and increased the size of the navy from about 25 ships in 1661 to 144 in 1677. He also established schools of marine engineering, hydrography, and cartography. His interest in re-establishing French sea power was, in part, to challenge the commercial supremacy of the Dutch. He encouraged the building of the French mercantile marine and established a number of overseas trading companies, in particular the East India and Levant companies, neither of which had much success. He also attempted to protect French colonial interests in the West Indies and Canada.

Besides the Conseil d'en Haut, the King's council also met for somewhat less vital matters under a variety of different guises. The Conseil des Dépêches had particular responsibility for home affairs, including the activities

of the intendants; the Conseil Royal des Finances supervised important matters affecting financial aspects of the King's domain lands. These two councils, like the Conseil d'en Haut, were presided over by the King in person. But the royal council also met under three further titles to deal with judicial and administrative matters and not in the King's presence. The Conseil Privé judged disputes between individuals or bodies and dispensed the King's supreme and final judgments. The Conseil d'État et Finances expedited financial matters of secondary importance, while the Grande Direction des Finances was an administrative tribunal settling disputes between the state and individuals or corporations. Each of these subdivisions of the King's council, contained more members than the exclusive Conseil d'en Haut, made up of the secretaries of state and of financial and judicial experts.

The initial group composing the Conseil d'en Haut contributed a great deal to the basic pattern of Louis's reign, particularly in military, fiscal, naval, and commercial attitudes, partly because many of those who followed as ministers came from the same tightly knit group of royal servants. The five members of the Colbert family have been mentioned; there were also three Le Telliers; and while only one member of the Phélypeaux family, Louis II, comte de Pontchartrain, was a minister, four served as important secretaries of state. All of these counsellors reflected the attitude of the King himself: they worked

extremely hard; they proffered advice but were under no illusions about the danger of arguing once Louis had made up his mind; and they favoured a protectionist, paternalist policy, whether in the organization of industry, the administration of the colonies, or the building up of the navy.

To carry out the decisions reached in his intimate and secret Conseil d'en Haut, Louis relied chiefly on his provincial intendants. Their powers were completely undifferentiated, and their commissions varied according to changes in royal policy. Like the ministers at the centre, they depended upon the King for their security of tenure. In the provinces they could exercise powers of police; raise military forces; regulate industrial, commercial, and agricultural matters; enforce censorship; administer the financial affairs of various communities; assign and collect taxes; and wield considerable judicial authority in civil and criminal affairs. Inevitably, these agents of the central government created considerable friction and hostility. These new men, with no local roots, answerable only to the King and acting almost invariably in an authoritarian context, were deeply resented by older royal officials, by municipal authorities and guilds, and by local parlements and estates—all of whom operated through well-established channels and according to traditional local privileges. The use of intendants, who held neither venal nor hereditary office, was one way in which

The  
intendants

the limiting effect of the sale of office on royal policies could be circumvented. The authoritarian element of Louis XIV's reign is undeniable: he was determined that no institution or social class would escape the supervision of the crown and its ministers.

In particular, the Frondes remained a painful memory from his childhood, and he never allowed the great nobles a similar opportunity for revolt. Versailles became a place of surveillance for pensioned noblemen and their families whose only serious occupation was the traditional one of arms, for the pursuit of which Louis provided ample opportunities. The second rebellious group in the Frondes, the members of the Parlement of Paris, were likewise subjected to stringent controls. In 1673 Louis produced regulations stipulating that the court's remonstrances against royal enactments sent to it could only be made in future after the laws concerned had been registered. By this device the King effectively muzzled the magistrates' criticisms of royal policy.

**Louis's religious policy.** Louis was also on his guard against religious dissent, and the revocation of the Edict of Nantes in 1685 was the culmination of two decades of government hostility to the Protestants in France. Louis, like most of his contemporaries, believed that toleration had no virtue and that unity in the state was extremely difficult to maintain where two or more churches were tolerated. Consequently, especially after 1678, Louis increased the degree of persecution; churches were destroyed, certain professions were put out of reach of the Huguenots, and Protestant children were taken away from their parents and brought up as Catholics. The notorious practice of dragonnades, the billeting of soldiers on Protestant families with permission to behave as brutally as they wished, was introduced. Finally, in 1685 the Edict of Nantes was revoked in order that Louis could claim that he had succeeded where Emperor Leopold I had failed—that is, in extirpating Protestantism from his realm. The revocation of the Edict of Nantes angered Protestant Europe at a time when Louis's European designs were beginning to meet serious resistance. The revocation deprived France of a number of gifted craftsmen, sailors, and soldiers. At least 600 officers, including Marshal Friedrich, Graf von Schomberg, and Henri de Massue, marquis de Ruvoigny (later the earl of Galway), joined William of Orange, the leader of the Grand Alliance against Louis. Research, however, has reversed the earlier view that the decay of French industry at the end of Louis's reign was the direct result of the expulsion of Huguenot mercantile talent.

The same zeal for uniformity made Louis attack the Jansenists. The theological position of the Jansenists is difficult to define; but Louis, who was no theologian, was content with the simple fact that these zealous Catholics had taken up an unorthodox position that threatened the unity of the state. The movement had begun over the perennial issue of grace and free will as it was propounded in the *Augustinus* of Bishop Cornelius Otto Jansen, published in 1640. In 1653 Pope Innocent X condemned five propositions from Jansen's doctrine, but the movement grew in strength with notable adherents, including the cardinal de Retz and the great mathematician Blaise Pascal. In 1705 Pope Clement XI published the bull *Vineam Domini*, which further condemned the writings of Jansen; but the archbishop of Paris, Cardinal Louis-Antoine de Noailles, appeared ready to lead the Jansenist forces in opposition to the Pope. Under the influence of his confessor, Père Michel Le Tellier, Louis decided to ask the Pope for another formal condemnation of the creed. Finally, in 1713, the famous bull *Unigenitus* was promulgated, which, far from ending Jansenism, drove it in the following reign into a disruptive alliance with Gallicanism. Louis's real attitude in this situation is not entirely clear: certainly he was asserting his authoritarian insistence upon unity. He was suspicious of religious innovation; and his action is consistent with the increasingly orthodox and rigid mood of his last years. Yet in seeking the Pope's support in this matter, he was reversing years of bitter hostility toward Rome when, like many of his predecessors, including Francis I

and Henry IV, he had leaned heavily upon the support of traditional Gallican doctrine.

According to that doctrine, the French king possessed the right of temporal and spiritual regale—that is, the right to nominate new bishops and to administer and draw the revenue from bishoprics while they remained vacant. In 1673 Louis extended this right to the whole of the French kingdom, which had been enlarged in the recent War of Devolution (see below). The Pope opposed the extension over this enlarged area; and eventually, in 1682, the Gallican Articles were published as a law of the French state, asserting that the King was in no way subject to the Pope in temporal matters and that he could not be excommunicated and reaffirming the independence of the French Church from Rome. The mutual animosity of King and Pope only ended in 1693, when, following William of Orange's successful attempt to secure the English throne, Louis agreed to suspend the edict of 1682; but it was a suspension only, not a recantation. The tradition of Gallican independence remained.

**Absolutism of Louis.** Thus, in religious matters (except where Jansenism was concerned), in his dealings with the nobility and the Parlement, in his attitude to the economy, and in his manner of governing the country, Louis revealed a desire to exercise a paternal control of affairs that might suggest a modern dictator rather than a 17th-century king. Though such a comparison has been made, it is most misleading; neither in theoretical nor in practical terms could Louis XIV be thought of as all-powerful. First of all, the legitimacy of his position under the law—the ancient fundamental law of succession—made him the interpreter of the law and the fount of justice in the state, not a capricious autocrat. Similarly, his kingship bestowed upon him a quasi-spiritual role, symbolized by his consecration with holy oil at his coronation, which obliged him to govern justly in accordance with the laws of God and Christian morality. He was also bound by the need to take counsel; and though he always made up his own mind, he insisted on receiving advice on all important matters of state, which further restricted any arbitrary instincts. Next, there was the essentially federal nature of the country with its collection of such peripheral provinces as Brittany, Normandy, and Provence, all retaining their own estates and customs. Within both these *pays d'état* and *pays d'élection* (where the estates no longer met), there was a variety of groups and corporations, not to mention individuals, with their own legally held rights, privileges, and exemptions: the nobility, the clergy, the towns, the King's officers. To impose rigid uniformity in such a situation was both impossible and undreamed-of by contemporaries. On the contrary, one of the King's prime obligations was to uphold and respect the myriad different rights to which his subjects laid claim. Perhaps most of all the King was limited by financial stringency. Louis could and often did try to persuade the cities and provincial estates to raise their contributions and the clergy to increase the size of their *don gratuit* ("free gift"); he also created more offices and annuities. But these were mere palliatives, and the King was forced on two occasions to introduce novel measures: in 1695 he levied a capitation, or head tax, applicable to all French laymen, even to the princes of the blood; and in 1710 a *dixième* (tenth) that similarly went against the interests of the privileged classes, including the clergy, by requiring a tenth to be paid to the state from all incomes. Significantly, however, Louis made it perfectly clear on both occasions that he recognized the extraordinary and temporary nature of these impositions, made necessary by the pressures of war. It was impossible to be a despot while financial resources were so precarious. The notion persisted that the king should ordinarily live off his own *domaine*. It was also impossible while no nationwide police force existed and while the state of communications remained so poor. All these factors make it clear that a situation simply did not exist in which totalitarian government, at least by 20th-century standards, could have had any meaning.

Finally, Louis XIV remained the prisoner of France's social structure. It is sometimes alleged that the King

Jansenists

ruled through the bourgeoisie. It is true that a number of the most distinguished families of the reign were not of ancient nobility; but their faithful and effective service to the king was rewarded in an entirely traditional way; that is, by social elevation. Colbert's father was an unsuccessful merchant; but all his granddaughters married dukes. In other words, the opportunity to enter the highest ranks of the nobility, which had long been available in France, was simply emphasized by Louis XIV. As the greatest nobleman in France, he had no doubt that he must retain the prestige and privileges of the nobility, but he knew equally well that the nobility should not become a caste closed to ambitious and able men. His social conservatism both buttressed his authority and prevented him from exceeding it.

**Foreign affairs.** It is as a great European figure that Louis XIV is best known. Though from the beginning of his reign Louis pursued a vigorous foreign policy, historical opinion has tended to move away from the traditional view that Louis sought to dominate Europe, only to meet his just deserts at the end of his reign. A case can be argued for the view that Louis pursued consistent and for the most part moderate aims and pursued them successfully up to and including the Treaty of Utrecht (1713). The starting point for this interpretation is the ambiguous Peace of Münster (1648), forming part of the great European settlement of Westphalia (see THIRTY YEARS' WAR), the terms of which subsequently became a bone of contention between Bourbon and Habsburg rulers. A critical issue was the fate of the three bishoprics of Metz, Toul, and Verdun on the northeast frontier of France. These bishoprics, occupied by the French since 1552, were formally acquired in 1648 together with a number of towns in nearby Alsace. One of the main Habsburg aims in the War of the League of Augsburg, or War of the Grand Alliance (1689–97), and in the War of the Spanish Succession (1701–14) was the restoration of the three bishoprics and the province of Franche-Comté, also on the eastern frontier of France, connecting Burgundy with Alsace, which Louis had acquired at the Treaties of Nijmegen (1678–79) at the end of the Dutch War (1672–78). Louis was determined to hold on to the gains acquired, however ambiguously, in Alsace; and he hoped to add Lorraine, to the north of Franche-Comté, to further consolidate this least secure French frontier area. Lorraine was periodically occupied by French troops, notably between 1633 and 1648 and 1670 and 1697, and Louis sought through various exchange schemes to incorporate it into France. The French share of the Partition Treaties (1698, 1700) in Italy was intended as an exchange for Lorraine and not as a means of threatening English and Dutch trade with the Levant. Lorraine, however, did not become a part of France until 1766.

Louis's  
successes  
in the  
northeast

Louis's policy in the northeast was constant and understandable. Franche-Comté was one entry into France previously exploited by its enemies that Louis succeeded in closing in 1678. He had already closed another, the port of Dunkirk, by purchasing it from Charles II of England in 1662; a third gateway, from the southern Netherlands, was effectively barred by the military fortifications erected by his great military engineer, Sébastien Le Prestre de Vauban in the 1680s. The capture of Lorraine would have bolted yet one more dangerous entry. Of course the situation looked quite different from the Habsburg point of view, especially after Louis's seizure of the key city of Strassburg (1681), an episode that goes to the heart of the controversial matter of his re-union policy. Following the successful Peace of Nijmegen, Louis began to employ his own judicial courts to claim sovereignty over all the dependencies of territories that he already possessed in Alsace, Franche-Comté, Metz, Toul, and Verdun. The manoeuvre enabled him to consolidate his control, especially over Alsace and Franche-Comté, though the legality of the claims to some of the alleged "dependencies" was extremely dubious. There was no legal justification whatever for Louis's greatest coup in the area—the seizure in September 1681 of the independent city of Strassburg. To Louis this key city, the door through which imperial armies could pass

(and three times in the recently concluded war had passed) into Alsace, represented a serious threat, for Strassburg was within easy reach of the Danube Valley and Vienna. His fears in this area may best be illustrated by his offer during the War of the League of Augsburg to waive his claim to the Spanish succession on condition that Nijmegen be respected; that Lorraine be absorbed into France (with proper compensations elsewhere); and that the Spanish and Austrian lands should not be united under one ruler. The emperor Leopold immediately rejected these proposals. When the final climactic conflict of the reign, the War of the Spanish Succession, was proceeding so badly, Louis offered to relinquish all the gains he had made from the Spanish inheritance; but he desperately hoped to hold on to Metz, Toul, Verdun, Alsace, and Franche-Comté.

Louis's attitude toward the Dutch was less moderate and more bullying. His invasion of the Spanish Netherlands in 1667 and the ensuing War of Devolution frightened the Dutch into a Triple Alliance with England and Sweden, which led to the Treaty of Aix-la-Chapelle (1668). Then, in the Dutch War that followed shortly afterward (1672–78), Louis intended to warn the Dutch that France was a serious commercial competitor and to force the Dutch to give him a free hand in the Spanish Netherlands when the issue of the Spanish succession came to the fore. He learned from that war that he could never hope to incorporate a large part of the Netherlands into France against Dutch opposition; but he also continued to fear the manner in which the Dutch might try to influence the government of the Spanish Netherlands for their own economic benefit. Here again was an example of mutual hostility and suspicion in which the interpretation of motives in Versailles and in The Hague were diametrically opposed. At the Treaty of Rijswijk (1697) the Dutch gained the right to keep a series of Dutch barrier fortresses within the southern Netherlands as a check against French aggression; it was Louis's seizure of these fortresses in 1701 that precipitated the War of the Spanish Succession.

The Dutch  
War

That war has usually been depicted as the most significant element in an assessment of Louis's total foreign policy: for some historians, all his relations with the rest of Europe were geared to this great issue; for others, it was the final misjudgment born of overconfidence, provoked by his own ambitious miscalculations, and destined to ruin France. It is certainly true that the approaching end of the direct ruling line in Spain had interested European rulers for many years; and the Bourbon claim to a share in that rich inheritance—deriving from Louis's marriage to Marie-Thérèse, elder daughter of King Philip IV of Spain—was accepted as a key factor in the situation: in 1668 Louis and Emperor Leopold I had gone so far as to sign a partition treaty, more than 30 years before the death of the last Spanish Habsburg, Charles II. No European statesman was surprised, therefore, at Louis's later concern when, after the signature of the Treaty of Rijswijk in 1697, he undertook negotiations with the English king William III out of which two further partition treaties emerged. The crucial moment came when Charles II's last will was published, offering the Spanish crown, in opposition to the second Partition Treaty, to Louis's grandson Philip, duc d'Anjou (later Philip V). Louis's decision to accept did not in itself provoke war. There is evidence that both William and the Dutch believed that Charles's will would name the Habsburg candidate; and they certainly had no intention, in the light of what it did contain, of trying to force the Emperor to accept the treaty, which he had always resolutely opposed. Besides, if Louis had snubbed the Spanish offer, it would have been made to Austria, and the spectre of the restoration of Charles V's empire—probably coupled with French losses on the north-eastern frontiers—was intolerable. In addition, Louis had recently made peace after the War of the Grand Alliance, the hardest conflict in which he had so far been engaged; and he had no illusions about the difficulty of overcoming another coalition under William III's leadership. He did not seek war, therefore, but he did make mistakes

that made war likely: his recognition of the Old Pretender as James III of England; his unexplained decision to protect his grandson's right to the French throne (he was envisaging not a single, united realm of France and Spain but two Bourbon kingdoms with the senior heir succeeding in France); his occupation of the barrier fortresses; and his seizure of the monopoly of the Spanish-American trade. When peace was signed at Utrecht in 1713, however, despite the disasters of the intervening years, Louis succeeded in holding onto the gains in Europe that he had considered vital throughout his reign, including Alsace and Strassburg. In addition, his grandson remained king of Spain, despite all of the efforts of the Grand Alliance to replace him by their candidate, the Austrian archduke Charles (as Charles III). It is true that in the darkest time of the war, during the years 1708–10, the desperate King was ready to give up these precious gains and was prevented only by the intransigence of his opponents with their impossible demand that he should himself assist in driving his grandson from the throne of Spain. Likewise, a fortuitous change of government in England in 1710, which ushered in the Tory peace ministry, and the elevation of the Archduke to the imperial title as Charles VI in 1711 weakened the unity of purpose of the Grand Alliance and enabled Louis's most effective soldier, Claude-Louis-Hector, duc de Villars, to stage a military revival. Therefore, the relatively successful conclusion of the war from France's point of view was not entirely of Louis's own fashioning, and had events forced Louis to accept a total surrender, it would have been even more tempting for historians to blame the defeat upon the excessive ambitions of an arrogant man.

Nor can it be denied that Louis was arrogant and that his arrogance aroused fear and resentment in his neighbours. Equally, he was intolerant, like most of his contemporaries, and feared by Protestant powers as the leader of a new and vengeful Counter-Reformation. Both facets of the great King need to be borne in mind when assessing his overall foreign policy, and they help to counter any tendency to overestimate the defensive nature of his strategy. That defensive element, however, is of significance and has been largely lost sight of, especially in assessments of the reign written in English. Louis frightened Europe with his quest for *la gloire*, by which he meant the favourable verdict of history on his contribution to French security and territorial integrity but which his enemies interpreted more narrowly as a preoccupation with military triumphs and vainglorious display. That contemporary interpretation, still widely accepted nearly three centuries later, does less than justice to Louis's shrewd appreciation of political realities and of France's long-term interests.

#### FRENCH CULTURE IN THE 17TH CENTURY

If historians are not yet agreed on the political motives of Louis XIV, they all accept, however, the cultural and artistic significance of the epoch over which he and his two 17th-century predecessors reigned. In their different ways—Henry IV's interest lay in town planning, Louis XIII's in music, and Louis XIV's in the theatre and in landscape gardening—they all actively stimulated the emergence of great talents and were aided by such royal ministers as Richelieu and Mazarin, who were considered patrons in their own right.

From Henry IV's reign dates the rebuilding of Paris as a tasteful, ordered city, with the extensions to the Louvre and the building of the Pont Neuf and the Place Dauphine and, outside the capital, the renovations and extensions at Fontainebleau and Saint-Germain-en-Laye. He succeeded in making Paris what it had never been before—the centre of polite society—and he must therefore take some credit, though he was not personally interested in such matters, for the establishment of the famous salon of Catherine de Vivonne, marquise de Rambouillet, which flourished from 1617 until 1665. There, men of letters mingled with the great nobility to the mutual advantage of both. The guests at her salon included the statesmen Richelieu and the Great Condé; the epigrammatist the Duc de La Rochefoucauld; the letter writer

Marie de Rabutin-Chantal, marquise de Sévigné; the novelist Madeleine de Scudéry; the poet François de Malherbe; and the dramatist Pierre Corneille. Richelieu was a key figure in the artistic and architectural development of Paris during his years in power. He was fortunate to employ the great architect Jacques Le Mercier who built for him, close to the Louvre, the Palais-Cardinal, later the Palais-Royal, which contained two theatres and a gallery for the Cardinal's *objets d'art*. Under the same patron, Le Mercier also built the church of the Sorbonne, where Richelieu is buried. In the world of painting, the Cardinal supported Simon Vouet, who decorated the Palais-Cardinal, and Philippe de Champaigne, whose surviving portraits include famous representations of Richelieu himself. His most notable contribution, however, was in the field of letters, with the establishment, in 1634, of the Académie Française to regulate and maintain the standards of the French language. One of its first tasks was the production of a standard dictionary, a massive work published in four volumes in 1694. The Académie succeeded over the years in making the pursuit of letters socially acceptable, though still inferior to the pursuit of arms. Finally, Richelieu's great interest in the theatre persuaded him to patronize a number of dramatists, including Jean de Rotrou and Corneille. Richelieu's patronage of the arts was taken over by his great pupil Mazarin who collected some 500 paintings, which he housed in the Palais Mazarin (now the Bibliothèque Nationale), which itself was enlarged for Mazarin by the architect François Mansart. He also commissioned Louis Le Vau to rebuild part of the medieval castle of Vincennes, thus setting him off on his successful career.

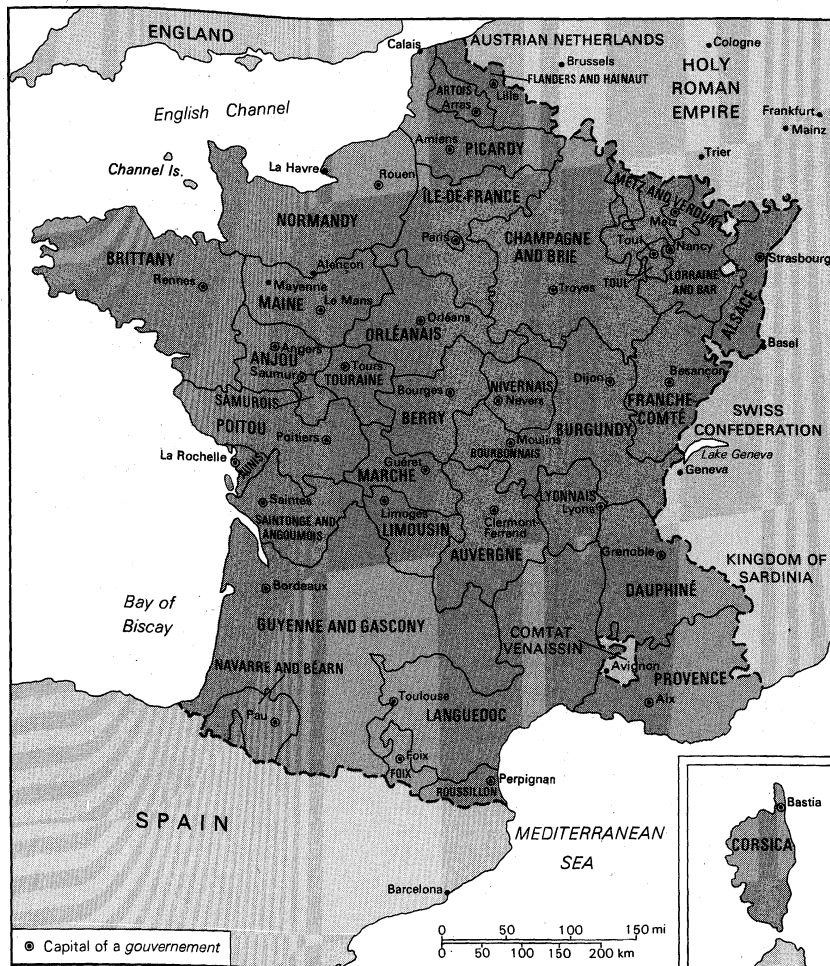

Louis XIV's patronage centred on Versailles, the great palace that also played such an important part in the political life of 17th-century France. There André Le Nôtre designed the formal gardens, which still attract a multitude of admiring visitors as they did when they were first completed. There Jules Hardouin-Mansart added the long, familiar garden facade and Charles Le Brun decorated the Gallery of Mirrors and the adjoining rooms of war and peace with unforgettable magnificence. There the composer Jean-Baptiste Lully devised and directed a number of musical entertainments with such success that Louis granted him noble status and the office of a royal secretary. There, too, the comic genius Molière was encouraged by the King's support; and after the dramatist's death Louis was directly responsible for the establishment, in 1680, of the Comédie Française. There, finally, Louis recognized the genius of Jean Racine, whose great tragedies, from *Bérénice* (1670) to *Iphigénie* (1675), earned him membership in the Académie Française and a noble office, that of *trésorier de France*, from the King.

In this burgeoning of the arts, aided though not inspired by the patronage of kings and ministers, there is a strong element of order and simplicity culminating in the classical grandeur of Racine's plays and the facade of Versailles that might seem to reflect the growth of political stability and order over which Louis XIV presided. It is, however, dangerous, of course, to tie creative achievements in the arts and sciences too closely to their political environment; and there are significant counterpoints to the theme of classical order. The philosopher René Descartes' doubting, rationalistic approach to the fundamental questions of God's existence and man's relationship to him undermined the rigid adherence to revealed truths propounded by Bishop Bossuet. The Jansenist Blaise Pascal, one of the most versatile geniuses of the century, represented and defended a minority religious movement that Louis XIV believed dangerously subversive. Toward the end of his long reign, Louis encountered the fierce social criticism of Jean de La Bruyère and the skepticism of Pierre Bayle. Yet these discordant elements are all part of the Grande Siècle, inconceivable without the regular, orthodox classicism against which they were reacting. The almost monotonous splendour of Versailles is not primarily a testimony to Louis's self-esteem any more than is the classical simplicity of Racine's tragedies: both represent a high point in creative human

achievement, and it is to his credit that the King chose to be identified with them. (J.H.Sh.)

#### IV. France, 1715–89

French society and the French government in the 100-odd years preceding the Revolution of 1789 constituted what is often referred to as the *ancien régime*. The use of one term to describe this collectivity indicates that society and the state were, at least in theory, very closely enmeshed. Ideally, in France under the old regime, there should have been no conflict between the bodies social and politic, which were thought to belong together as one organic whole. Unlike 18th-century England, the political system of which was defined by Montesquieu as one in which tensions were balanced and neutralized in part through the separation of powers, the French *ancien régime* in the eyes of its makers was conceived as a system within which there should be no conflict of any sort; hence perhaps the initial impression of concert and order associated with the *ancien régime* as it had evolved during the earlier decades of the reign of Louis XIV. And indeed it has often been argued by conservative historians that, with the exception of the last decades of the 19th century and in spite of the very strong feeling of national cohesion that emerged so strongly before and during the Revolution, the French have never reached the degree of political and social cohesion that they had achieved during the first years of the reign of Louis XV. But the symbiosis of society and the state called the *ancien régime* was not in the 18th century without defects. When, in the course of that period, French society changed economically, intellectually, and in its patterns of social relations, reform proved an ultimately impossible task. In order for society to change, the state would have had to be changed as well; and every reform of the

state, within the context of the *ancien régime*, implied some attack on vested social interest. This is not to say that the *ancien régime* was initially a static social and political system. It was not; but because it was cumbersome and largely irrational in its structure, political change could be effected only slowly. The great political problem of the *ancien régime* can therefore be described simply as the inability or unwillingness of the state to alter its structure so as to successfully encompass the transformed society of 18th-century France. By waiting too long, until the 1770s, to try to reform itself and to alter the regulations that governed the way in which Frenchmen related to each other and to the state, the French monarchy lost its chance to pass from medievalism to modernism; and in so doing it set the scene for a violent revolution that it might have avoided.

#### THE ANCIEN RÉGIME

**French government.** The *ancien régime*, then, has to be seen altogether as a set of governmental institutions and a set of social institutions and as a pattern of relations between these two. Of the governmental institutions, the most important was the monarchy and the monarchs.

**The monarchy.** The separation of office and officeholder is a modern idea; to a large degree the monarchy in 18th-century France was identified with the personality of the monarch. Before the Revolution, a charismatic king could still have given an aura of acceptability to an increasingly unacceptable institutional construct. There is no doubt that the personality of Louis XIV had much to do with the harmonious image that Frenchmen had, and that most historians have had since, of the *ancien régime* in its earliest decades. But neither of his successors—Louis XV and Louis XVI (reigned 1774–92)

Closeness  
of society  
and the  
state

Character  
of the  
monarchy

—was an impressive figure. The indolence of Louis XV and the incapacity of Louis XVI tarnished the image of the monarchy. Moreover, the lack of character of these two men had practical consequences as well, because the institutions of the *ancien régime* monarchy were so designed that they could not be reformed without a strong hand at the helm, such as there had been in the 17th century with Richelieu, Louis XIV, and Louis's ministers Colbert and Louvois.

Thus, the monarchy of the *ancien régime* consisted in the first place of a monarch. But it was also a set of rules that can be, and very frequently were, described as a constitution, albeit an unwritten one. Its most important characteristic was a mixture of legalism and absolutism. Louis XIV is said to have proclaimed that he was the state. In some respects he was, and both Louis XV and Louis XVI held fast to the same concept. But the absolutism of these three kings served not only the monarchical regime, but the defense of established and vested interest as well. In some respects the monarchy of the *ancien régime* was unlimited and authoritarian; in others it was most closely circumscribed. Louis XVI, for example, could, by using a *lettre de cachet* (written order), imprison any of his subjects without trial and forever; many leading intellectual figures of the day, including Voltaire and Diderot, were arrested in this way. But it is also necessary to add that neither of these two writers stayed in prison for very long and that most such letters were issued by the state to parents who sought to curb and imprison their rebellious children. Theoretically, the king ruled by divine right. Anointed at Reims, endowed with magical powers of healing, he was the fountainhead of all authority; and even Louis XVI asserted in 1787 that an act that he had promulgated was legal merely because he had wished it to be legal. The king's authority was supreme and was exercised by means of a centralized state, already bureaucratic in nature and staffed by men appointed by the king. At the top, the decisions of the state were elaborated in councils responsible only to the monarch, whose orders were enforced in the provinces by 33 intendants, who themselves gave orders to sub-delegates and to a small army of some 20,000 functionaries. But it must be remembered that, although centralized and absolute in principle, the *ancien régime* monarchy in the 18th century was in fact severely limited.

*The parlements.* The restraints on the power of the king were largely self-imposed, but some of them were institutionalized. Though it is true that the Estates-General had not been called together since 1614, the regional medieval estates did in some places survive, notably in the Languedoc. Their formal power was not, however, a great obstacle to the monarchy, which had much reduced their role before 1700. Far more important were the judicial courts, or parlements, the authority of which rested on a very particular conception of the nature of society. The eight parlements, and especially the Parlement of Paris, were the last courts of appeals for most of the innumerable civil law suits that were a typical aspect of 18th-century French life and that figure so prominently in the literature of the times. The parlements also decided famous criminal cases and thus participated in the business of statecraft. Most importantly, their consent was required for any innovation or reform in the nature of laws or taxes. Admittedly, the king as an absolute monarch could dispense with the approval of the parlements by calling a *lit de justice* and appearing in person before the assembled courts. But the crown as the defender of tradition and of vested interest often hesitated to exercise this prerogative, and its reluctance to act meant that the parlements were allowed to become in the last four decades of the *ancien régime* a fundamental element of the political system.

Members of the parlement owned their office. Unlike the intendants and other functionaries, or *commissaires*, the *parlementaires*, or *officiers*, with very few exceptions, were not appointed by the crown. They purchased their office; and, increasingly, once the procedure had been legalized by the beginning of the 17th century, they could inherit the office on payment of a tax called the *pauvette*.

This venality of public office was of fundamental importance. In the earlier decades of the *ancien régime*, it had insured social and political stability: the right to purchase these offices had enabled the possessing class to participate in the business of government in spite of the fact that the theory of French monarchic rule at that time had become increasingly absolutist. But during the 18th century, venality of office stood in the way of change because it insured that vested and complacent interest would be politically represented. Any attempt by the state to change the rules of the game after 1750 met the instant, institutionalized, and vocal opposition of the parlements. In this manner the problem of reform became increasingly insoluble: no longer could the monarch, even had he wanted to do so, reform the state through absolutist fiat. From 1715—when the regent Philippe II, duc d'Orléans, restored to the parlements some of the prerogatives they had lost under Louis XIV—until 1789, the problem of reform and the fate of the *ancien régime* would focus on the opposition of crown and parlements.

**Obstacles to reform.** The question of reform in the 18th century can thus be broken down in various parts: the strength of the parlements, the determination of the crown to overcome it, and the need for it to do so because of social, economic, and intellectual change. The single most important aspect of the evolution in the power of the various institutions—feudal and bureaucratic—that made up the *ancien régime* was therefore the rise in the strength of the *parlementaires* who opposed reform. The causes of this evolution were both ideological and practical. In actual fact, the *parlementaires* owed whatever representation they may have had to the fact that all Frenchmen before 1750, including the king, accepted the idea that established privilege could not be abrogated. In 18th-century France, both society and the state were based on the idea that what had been given could not be taken away. Ultimately the *parlementaires* of 1750 were able to oppose the royal will because Frenchmen—subjects and king alike—in spite of the absolutist theory of the state, accepted the privileged position of the *parlementaires* because it had a secular and proprietary basis. But the *parlementaires*—often literate, if seldom learned—also developed other abstract and theoretical justifications for their power: after 1750 they began to justify their representation in the name of fundamental natural law. Fraudulent history was also invoked by their apologists to justify the claim that the parlements derived not from the medieval parlements created as advisory bodies by the king but, rather, from the ante-Capetian and Frankish assemblies of freemen (the *judicia Francorum*).

Tradition, ideology, and history all served to increase the power of the parlements, and so did a more purely social phenomenon: the fusion of the *noblesse d'épée* (the old military aristocracy of blood) and of the *noblesse de robe* (the *parlementaires*). Ever since the beginning of the 17th century, when judicial office had become the property of the same set of established families, the owners of proprietary judicial office had drawn away from the bourgeoisie whence their lines had sprung and had moved instead toward the *noblesse d'épée*. At the hand of Louis XIV, the old aristocracy had been showered with financial and honorary favours, but it had been shorn of power. By fusing with the *parlementaires*, the older nobility regained an institutional and political focus. Intellectually more aggressive, the *parlementaires* after 1750 were also socially more assured in the opposition to the crown. Because of this, the reform of society and of the state was far more difficult to achieve after 1750 than before; vested interest was more vocal and better organized than it had been.

Even more important than the institutionalized obstacles to reform, however, was the very nature of the *ancien régime*. After 1740 the tempo of change was very rapid, and the need to reform the structure of the state was very great since society and state were so closely linked. But this very connection made progress difficult because reform in any one direction had repercussions that would be widely felt elsewhere. The fusion of the so-

cial and political purposes of the *ancien régime* was at once the source of the need for change and the principal obstacle to it.

This overlap of societal and political forms had many facets. First, society and the state in the *ancien régime* were based on similar principles. Politically, the state though absolute in theory was limited in fact. Unlike the tsar or the sultan, unlike even Frederick II or Joseph II, the French kings by and large respected proprietary and vested interest, the existence of which was as fundamental a principle of social and economic organization as it was in politics. The monarchy respected the political rights of the parlements, and similarly it felt it had to respect economic monopolies and privileges—guilds had the right to protect their members by excluding outsiders from the professions; corporations had prerogatives that were not to be interfered with. France was a society not of men equal before law but of men and corporate groups, all privileged in some way but unequally privileged, with vested interests that were sanctioned by the state and could not be ignored. Any attack upon the economic and social privileges of members of the body social would have had repercussions on the body politic, and on the church as well because Catholicism was also a principle of social and political action. The king was a Christian and Catholic king, the eldest son of the church, and France was theoretically a Catholic nation (although Protestants had secured *de facto* toleration after 1750, they were not given civic rights until 1787). Civil records were kept by the clergy, which also dispensed education at the primary, secondary, and university level and managed public charity. Religious holidays were public holidays; and, in the theory of the *ancien régime*, the king was the Christian father of his people, and he stood to them as the father stood to his children.

In short, by the nature of its fundamental principles and by the direct effect of its interventions—social, political, religious, and economic—the state served as a very pervasive framework for social action. When the purpose of the *ancien régime* state and society overlapped, as they did in the first decades of the 18th century, the state was seen as a positive force. When a difference of purpose appeared because of economic, social, and intellectual change, the state was seen as a mere constraint. Society could only evolve if the state also evolved. But because of its very principles, the monarchy of the *ancien régime* was hard put to curb the power of the parlements, who were, in turn, hardly likely to agree to reform unless coerced, because they were far more powerful in the 1760s than they had ever been before. Thus, as the century progressed, the monarchy was increasingly condemned to immobilism in a situation in which it could not afford to remain passive. As the tempo of social and economic change swelled, together with its concomitant demands for reform, the state found itself increasingly isolated, powerless, and without a political constituency.

**French society.** Because of the interaction of society and politics, the evolution of French society in the 18th century is the key to the political problem of the *ancien régime* and to the coming of the Revolution. This problem, however, is a complicated one, which has to be seen in the context of the increased sophistication and number of social forms.

Until 1715, perhaps even until 1730, with the conspicuous but ultimately marginal exceptions of the free-thinkers (the *libertins*) and the Protestant Huguenots, the society of *ancien régime* France had been reasonably uniform. The various provinces and *pays* (regions) of France had led separate existences; but they had been organized along the same social, economic, cultural, and

Immobilism of the monarchy

religious lines. During the 18th century, however, besides this traditional and catholic model, which was not fundamentally affected by economic or social change, there gradually emerged a second sort of society—urban, less hierarchic, and more mobile—in which status and power depended as much on talent and wealth as on birth.

*The new urban society.* Numerically the urban model, even in 1789, was by far the lesser of the two. In 1715 more than 90 percent of all Frenchmen lived in the country; by 1789, although Paris had reached a population of 400,000, only 15 percent of the population was urbanized. But the urban dwellers had become far more vocal and politically aware; and it was their spokesmen who would direct the course of the Revolution in all of its various vicissitudes. Intellectual, economic, and financial change must therefore be seen in the context of a change in the internal structure of society as a whole and in the balance of power between the new urban milieu and the traditional world of the *ancien régime*, which had once included the whole of French society but which during the 18th century was being increasingly rejected by its more progressive elements.

*Traditional society.* All France was changing in the 18th century, but in different ways: whereas the expanding cities were affected by the new forces of trade and free thought, problems of the countryside still revolved essentially on the classic and traditional questions of good or poor harvests, size of population, and peasant-lord relations. Three phenomena were at play—a resurgence of the aristocracy, a population explosion, and a rise in prices. The merger of the *noblesse d'épée* with the legalistic *noblesse de robe* had consequences at the level of national politics, but it had an effect in the countryside as well. The newly reshaped nobility was more able to rediscover abandoned feudal rights, and it was thenceforth more able to prosecute in the courts, where it became at once judge and jury. The rules regulating the division of common lands were altered in favour of the nobility. In the 17th century the lord of a village who had wanted to divide common village property had to prove his right to do so. This procedure was reversed in 1767 and again in 1773, and some measure of enclosure of peasant lands was made possible.

The relative well-being of the nobility increased in the later decades of the *ancien régime*. The reason for this lay in the consequence for the landowners of inflation, which saw prices rise in France by more than 60 percent between 1726 and 1789. Prices rose; real wages fell by one-half; but there was no fall in the value of rents. Payments in kind and renewable leases enabled landlords to keep ahead of the price rise. The money value of their rents rose in these same years by 98 percent. Landless wage earners thus found themselves impoverished; and the beneficiaries of the rise in prices were the landowners who secured a higher price for their agricultural produce. Moreover, the plight of the poor was aggravated by demographic expansion; not only did the landless labourer earn less but he also had more mouths to feed, and he had to compete more for jobs. Because of France's great diversity in climate and fertility, conditions were widely different from place to place: Brittany, for example, reached its demographic peak in 1700, whereas the population of Quercy rose by 70 percent between 1700 and 1786. But, in France as a whole, there were 2,000,000 more peasants in 1790 than there had been in 1700. Better preventive medicine, a decline in infant mortality, and the disappearance of famines after 1709 all served to increase longevity; the yearly number of deaths per 10,000 fell from 400 in 1750, to 350 in 1775, 328 in 1790, and 298 in 1800; life expectancy rose from 21 to 27 years. Thus the number of wage earners grew ceaselessly; but the amount of arable land did not, despite government encouragement by fiscal exemption. Because emigration to cities remained low (there were as yet few factories to absorb surplus rural labour), the situation in the countryside became increasingly critical.

In his book *L'Ancien régime et la Révolution*, Alexis de Tocqueville argued that France was the European country in which peasants were most prosperous. It would be

more accurate to say that it was the country in which they were least miserable. The French peasantry was worse off in 1789 than it had been in 1730. Although a third of the land belonged to the peasants (the aristocracy owned 20 percent, the bourgeoisie 30 percent, and the church 15 percent), most of the people who lived in the country were landless labourers, whose worsening plight coincided with the greater aggressiveness of the aristocracy.

The importance of the rural conflicts was very great. The crown was already unable to rely on the nobility, which supported the parlements against the state, and now it would be unable to count on the peasants as well. This is why the *ancien régime* folded at once and almost literally disappeared overnight during the summer of 1789. The big push, it is true, came from the cities, but it was because of generalized rural unrest that the monarchy was unable to resist the attack on tradition.

#### THE FRENCH ECONOMY IN THE 18TH CENTURY

Tensions within the rural world made political change irresistible, but the immediate pressure for revolution came from the cities and especially from Paris. There, economic change was the most crucial and visible factor. It is hard to gauge its importance with precision: in relation to what had been taking place before 1730, it was very great; but in contrast to what was happening in England at the same time, it appears to have been more tepid. There did not, for example, take place in France as there did across the English Channel a vast reordering and commercialization of agricultural practices (the enclosure movement), and this no doubt had a profound effect on the course of French history. The English aristocracy in the 1630s had already found it feasible and even desirable to make an alliance with the commercial bourgeoisie against the monarchy, which had become their common enemy by defending medieval economic practices in both town and country. In France, however, where there was little enclosure, aristocracy and bourgeoisie followed divergent paths; the landed aristocracy, although opposed to the king for its own reason, was not the ally of the commercial interests. In France economic transformations were not strong enough to unite all the propertied interests on the new basis of capitalist wealth; they did suffice, however, to wean the urban interest away from the crown. The pattern therefore was of significant but not overwhelming economic evolution.

**Industrial growth.** In 1789 French agricultural techniques remained much as they had been 70 years before. But some change was registered. Total produce rose; and, although taken individually most peasants were poorer in the 1780s than they had been before, the final value of agricultural products per active person rose from a level of 850 gold francs in 1700–10 at a yearly rate of increase of 0.2 percent for the first half of the century and of nearly 1 percent in the 1780s and 1790s. And, as the value of rural produce rose, so did rural demand for urban manufactured goods and for those luxury items (textiles, porcelains, furniture, *articles de Paris*) in the production of which the French excelled before 1800. Thus in the last 50 years of the *ancien régime*, industrial production rose yearly at a rate of nearly 2 percent. Some leading sectors rose even more quickly. Coal mining, for example, had become a major industry on the eve of the Revolution. In the 1780s coal production was 5.8 percent greater than it had been in the preceding decade. Mining attracted vast amounts of capital, some of it from the aristocracy. In 1789 the Mines d'Anzin near the Belgian border already employed thousands of workers.

Nor should it be thought that France's industrial development was very far behind that of England. There is no reason to suppose that the outmoded institutional economic apparatus of the French state seriously hindered French economic growth. Although France was a generation behind England in terms of economic innovation (in France just before the Revolution, steam-driven pumps first appeared in mines and also in Paris, where they were used to pump water up from the Seine), the rate of in-

Importance of the rural conflicts

Problems of the countryside

Rise in the value of production

dustrial growth during the 18th century in France was not inferior to that of England. English industrial production in 1790 was 190 percent greater than it had been in 1700; for France, the comparative figure was no less than 260 percent. But the absolute gap between the two countries was quite great: in England coal production in 1770 reached 6,000,000 tons as against only 700,000 in France. Nonetheless, the French before 1789, in spite of their outmoded institutions, were catching up with their only rival.

**Trade.** France's greatest source of new economic well-being in the 18th century was trade—domestic, international, and especially colonial trade. The first colonial French empire was essentially located in America, and it was immensely lucrative. From the 17th century the French had been making sustained incursions into Canada and in India. These possessions, it is true, were both conquered by England during the Seven Years' War (1756–63); but this was not seen as a great loss by the French at the time. The Caribbean remained the most lucrative source of French colonial activity in the last 100 years of the *ancien régime*. The French shared the West Indies with Spain and England: Cuba, Puerto Rico, and the western half of Hispaniola belonged to Spain; Jamaica, to England; but Guadeloupe, Martinique, and Haiti—the richest of all nonwhite 18th-century colonies in the world—were French. There, 20,000 whites stood an uneasy watch over 160,000 black slaves, imported from Africa, where they had been purchased from black slave merchants who were paid with arms, baubles, and drink. In the islands the slaves produced sugarcane and coffee, which were refined in France at Nantes, Rochefort, and Bordeaux and often re-exported to central and northern Europe. This triangular trade grew tenfold between 1715 and 1789, and the value of international exports in the 1780s amounted to nearly one-fourth of national income. The sugar trade enriched the planters, the bankers in Paris who had acted as brokers for import and re-export, and the manufacturers of luxury goods that were shipped from France to the Caribbean; the French colonial trade was a closely watched process, governed by mercantilist protective tariffs and rules.

In the last two decades of the *ancien régime*, the colonial trade lost some of its appeal. Greater profits could then be had in China, India, and East Africa. Within a decade after the monopoly position of the French East India Company ended in 1769, commerce with the Far East, for example, more than doubled. But the West Indies trade remained the single most important aspect of French commercial life in the 18th century (hence, perhaps, the fact that so many of the prominent participants of the Revolutionary drama had connections with the islands). Also significant is the fact that an antislavery movement had developed in France by 1789. Montesquieu before 1750 had already criticized the institution of black slavery. In 1788 a Société des Amis des Noirs (Society of the Friends of the Blacks) was founded in Paris and counted among its members not only Lafayette, but also Jacques-Pierre Brissot, who later became the leading figure of the Girondin faction, which dominated the Revolutionary government in 1791–92. Gradually, the immoral aspects of trade in the colonies became inescapable, but its first impact was a betterment of economic conditions in France. Obviously, only a few individuals benefitted directly from the new currents of exchange; but indirectly millions of Frenchmen were affected by the invigorated tempo of economic life. The circulation of gold specie in the kingdom as a whole rose from 731,000,000 in 1715 to some 2,000,000,000 in 1788. From America to Spain—whose trade with its colonies was under the indirect and unofficial control of French merchants—silver bullion found its way to Paris, Lyons, and from there to Geneva and central and especially southeastern Mediterranean Europe. The French national community became the basic unit of commercial life. Where, in the past, villages and even cities had lived largely closed in upon themselves or their immediate surroundings, trade became a national concept, and the awareness of the nation-state followed in its train. No

longer would Frenchmen accept as natural and harmless the multiplicity of internal tariffs and the survival of the divisive medieval administrative patterns that still coexisted with the more modern and rationalized state system, which centred on the councils and the intendants.

#### THE COMING OF THE REVOLUTION

**Effects of the Enlightenment.** Industrial and commercial change greatly affected the quality of life in urban France in the last decades of the *ancien régime*, and so did the intellectual revolution known as the Enlightenment. The effect of the Enlightenment, however, is even harder to gauge than the degree of transformation that owed to material circumstances. Today it seems hardly reasonable to suppose, as did the first historians of the Revolution and many of its contemporaries as well, that the Philosophes (the writers and thinkers of the Enlightenment) directly bore the responsibility of the Revolution. Reactionary authors throughout the 19th century were quick to blame these intellectuals whose influence was said to have imbued the French bourgeoisie with “philosophical” and abstract intellectualized visions of what was to be done. In this scheme, the protagonists of the Revolution would not have been so much the agents of some social force as the actuators of the ideas of the Enlightenment.

Not much of this narrow interpretation remains. For one, it has proved very difficult to trace precise connections between the actions of political figures and the ideas of specific philosophers. Attempts to pinpoint this relationship by enumeration and description of the books that belonged to and were presumably read by Frenchmen before the Revolution have proved largely inconclusive. What they would show is that Jean-Jacques Rousseau's political work *The Social Contract* had a very small audience indeed and that the most widely read political philosopher of the 18th century was Montesquieu, who happened to be the apologist of balanced and aristocratic government.

**Literacy.** A case for the impact of the Enlightenment can, however, be made in more general ways. Although books were very expensive, they were widely read. More than 30,000 titles were published between 1723 and 1789; and it has been estimated that by 1789 more than 9,000,000 Frenchmen could at least sign their name. No illiterate soldier could rise in the French army beyond the grade of corporal. Literacy was widespread, and the impact of literature was very great. If hundreds read Rousseau's *Social Contract*, millions had read or heard of his romantic novel *La Nouvelle Héloïse*.

**Education.** Much greater attention too was given even before 1789 to education. The economist Anne-Robert-Jacques Turgot wrote that the basis of national unity and mores was the education of children; and in 1763 an otherwise reactionary *parlementaire* named La Chalotais even put forward a scheme for lay and national primary education. An important landmark in this respect too was the expulsion from France in 1762 of the Jesuits, who had heretofore dominated French secondary education. Increasingly, the French language was substituted for Latin in the secondary schools, or *collèges* (the forerunners of today's lycées). Rhetoric gave way to an emphasis on more “natural” manners and modes of expression. History was raised to the level of a serious discipline; with Voltaire's *Siècle de Louis XIV* (1751; “Age of Louis XIV”), modern French historiography began, and there were echoes of this new attitude in the programs of the secondary schools. Mathematics, physics, and geography were also added. Finally, the whole emphasis of education shifted—before, education had had as its primary purpose the adaptation of the young to established patterns of culture and thought; now, a greater emphasis was placed on the individual desires and propensities of children.

**Principles of the Enlightenment.** Thus through the impact of the printed word, through the extension of literacy, through the new emphasis and nature of secondary education, the ideas of the Enlightenment pervaded large segments of the French population. It would be difficult

of the  
Enlightenment

and even impossible to analyze French society in 1789 without making reference to the broad ideology and principles of the Enlightenment. It is difficult today to conceive of these principles as a source of revolution, so completely is modern liberal and Western society based upon them. But in the context of the *ancien régime*, based on tradition, catholicism, ruralism, hierarchy, privilege, and corporate intermediary bodies, the new ideas were revolutionary indeed.

Rationalism, nationalism, and individualism

Rationalism was the first of these, and although the Philosophes disagreed on many things, all of them, from Voltaire to Rousseau, insisted that man, privately and publicly, must build on reason. Scientism was a further aspect of this same attitude. Balloons and experimentation with electricity were by the 1780s nationwide fads and provide a testimonial to the pervasiveness of a new approach to life.

Equally important to Frenchmen of the Enlightenment were two other concepts, since then often antithetical but then perceived as compatible and even complementary: nationalism and individualism. Here again, the importance, symbolic at least, of Rousseau cannot be overrated. It was he who emphasized both the intrinsic rights of every citizen and the need for the citizen's constant involvement in collective, communal affairs. In various ways, this was a double concern that characterized the intellectual spirit of the 1780s. Though Montesquieu had defended intermediary bodies as guarantees of civic liberty, thinkers of the Enlightenment attacked them in the name of public utility and of what would later be called the rights of man. In an article written for the *Encyclopédie*, Turgot denied the sanctity of what he called foundations: "Public utility is the supreme law, and cannot be countervailed by a superstitious respect for what has been called the intents of the founders." Most foundations, he thought, had as their only purpose the satisfaction of frivolous vanity. At the other end of the social spectrum, the Protestant Rabaut Saint-Étienne, later president of the National Assembly, argued that "every time one creates a corporate body with privileges one creates a public enemy because a special interest is nothing else than this." No distinction was drawn between private interest and factional selfishness; and in 1786 the future Girondin leader Brissot was expressing what had become a platitudinous thought when he wrote that "the history of all intermediary bodies proves, in all evidence, that to bring men and to bind men together is to develop their vices and diminish their virtues."

Traditional inherited privilege, it was thought, should no longer be the guiding principle of social action. A new society should be built in which the rights of the individual would be protected by a state unfettered in its pursuit of the common good. Private benevolence for a public purpose was typical of the 1780s, and Louis XVI's finance minister, Jacques Necker, did a great deal for his reputation by endowing a hospital for sick children, which stands to this day. Public and charitable concern by 1789 had become the themes of countless didactic works of literature and painting.

Sources of reformism and communality

**Reform movement.** The sources of this new feeling of reformism and communality are difficult to establish. Some of them have been mentioned: a more vigorous and comprehensive economic life, changes in the educational system, the overall impact of the Enlightenment. Others were more strictly institutional. Inevitably the centralization of government effected under Richelieu, carried out during the reign of Louis XIV, and perpetuated by his successors had emptied of their substance all the intermediary and nonnational bodies—the local estates, the municipal and regional institutions. In the system of the *ancien régime* all those groups and bodies that stood between the subject and the state no longer had any positive use. There was therefore no reason to suppose that they were necessary or that they justified the expense they entailed. By reaction, therefore, those thinking Frenchmen who wanted to enact social and political change looked to the nation and the state as their great hope. Symbolically enough, by 1780 the historical model that seemed to make sense to them was no longer En-

gland, as it had been for Montesquieu and even Voltaire, but Rome instead and, more generally, the city-state of antiquity, where the rights of the polis and of the citizen had coexisted harmoniously.

**Beginnings of nationalism.** So deep in fact was this transformation of opinion, which looked to equality rather than to privilege as a key to the organization of society, that it is necessary to look beyond institutional explanations in order to explain it. Nascent nationalism was also a factor. There is no doubt that for those Frenchmen whose style of life was modern, who read books, and who engaged in trade the nation became in the 18th century a far more concrete reality than it had been in the past. This can perhaps be most easily seen in the changing attitudes of French public opinion vis-à-vis the largely unchanged goals of royal diplomacy.

International goals

From 1740 onward, perhaps even from the time of the War of the Spanish Succession (1701–14), France had been too weak to try to impose its hegemony over Europe. In consequence and quite consciously, after 1740 French statesmen endeavored to secure a double goal: in Europe, the preservation of the balance of power; and, in the world at large, the expansion of the French colonial empire and the containment of England. For the first of these reasons, during the War of the Austrian Succession (1740–48) the French sided with Prussia and against Austria because Austria was then thought to be a more dangerous power. Rather reluctantly, during the Seven Years' War (1756–63), France reversed itself and fought against Prussia, whose efforts at aggrandizement had become a threat to the status quo. In the 1770s and 1780s also, France did its best to preserve both the continental status quo and the continued independence of the smaller European states, many of which were its clients or allies—notably Poland, Sweden, the United Provinces, and Turkey. In this the French were reasonably successful; although they suffered reverses in Poland, which was partitioned, and in the United Provinces, where the Anglo-Prussian Conservative Party with Prussian military help overcame the pro-French liberal groups in 1787, the balance of power in Europe was preserved in the 1770s and 1780s.

French successes vis-à-vis England, however, were checkered. Efforts to extend French rule in India or to preserve it in Canada were more or less successful in the 1740s but were totally unsuccessful during the Seven Years' War. During that conflict France suffered grievously in spite of the entente between France and Spain, both ruled by Bourbon monarchs, and in spite of the Austrian alliance. France was unable to prevail both on the Continent and in the colonies, and for having tried too much she failed everywhere. French influence was at a very low ebb in 1763. But the endemic warfare between France and England that had begun in 1688 was not ended on that note. During the U.S. War of Independence (1775–83), the French were most careful not to be also involved in the Austro-Prussian "Potato War" (War of the Bavarian Succession) of 1778–79, and, by concentrating their efforts for the first time on maritime matters, they succeeded in holding and even reversing the advance of England.

More significant, however, than the actual diplomatic success or failure of the French crown were the reactions of the public to them. In spite of its disastrous consequence, the Seven Years' War did not lead to pronounced disaffection, because Frenchmen in the 1750s did not feel themselves involved in these matters. By the time of the U.S. War of Independence, however, matters had changed greatly. The war was very popular and was seen by the public as a justified act of legitimate revenge against the English. In a commentary on the Treaty of Paris of 1763, the French foreign minister Charles Gravier, comte de Vergennes, observed:

it is enough to read the Treaty of Paris, and particularly the negotiations which preceded it, to realize the ascendancy which England has acquired over France and to judge how much that arrogant nation savours the pleasure of having humiliated us.

Many Frenchmen shared Vergennes's opinion and re-

joined in the victories during the American war of their compatriots: Lafayette, de Grasse, Rochambeau, and Suffren. In so doing they gave indirect but forcible evidence of the development in France of a new and intransigent nationalism.

*Grievances against the state and society.* Thus by the 1780s the traditional concepts of the *ancien régime* state and society were being attacked from all sides. The antiquated administrative jurisdictions, the inequalities of taxation, the concept of privilege, the existence of corporations that stood between the citizen and the state, and the noninvolvement of the citizens in the national body politic had become untenable ideas. The impossibility of perpetuating the status quo was not, however, felt equally by all Frenchmen. Those who lived in the countryside disliked it for the more ordinary and classical reasons that had always driven the exploited poor to rise up at times against their more or less oppressive betters. But in the cities resentment was of a different and more implacable sort. Buoyed up by the new prosperity and by the development of industry and trade, better educated, more quickly exasperated by irrational governmental practice, more keen on asserting the oneness of the French nation and also on asserting their rights as individuals, urbanized Frenchmen of all classes found it increasingly difficult to put up with the *ancien régime*.

*Social divisions.* In some ways, therefore, all Frenchmen shared certain grievances. But it is important to see that they were seriously disunited in their ideas of what was to be done after the *ancien régime* had been gotten rid of. The sameness of cultural disaffection can serve to explain the unique enthusiasm and fraternity of 1789 and the unanimity of feeling on the celebration of July 14, 1790, one year after the fall of the Bastille. In that first year Lafayette, Brissot, and Robespierre largely agreed on the meaning and purpose of the Revolution. But the Revolution did not progress in a uniform and unanimous way. By 1794 the unanimity of 1790 had dissolved into sectarian terrorism and counterterrorism; and this bipolarity of political behaviour presupposes that, although united in some ways, urban and modern France on the eve of the Revolution was in other ways disunited. All Frenchmen, particularly those in the cities, were affected by the increasing reality of national markets and national cultural concern, but they were also deeply separated by lines of social class as well as by the patterns of social relations in their culture.

Roughly stated, it can be said that social divisions opposed some of the aristocracy to the upper bourgeoisie, themselves opposed to the lower middle class, to the peasants, and to the embryonic urban working class. Moreover, none of these groups was characterized by that sense of civic responsibility that makes self-government possible. Nobles and nonnobles were unable to work together for a common end; a brief experiment in aristocratic rule—Polysynodie (1715–18)—during the regency that followed the death of Louis XIV spontaneously disintegrated from the quarrelsomeness of the participants and their incapacity to work out any coherent theory or practice of government.

Sources of  
division

The sources of division in France were manifold, and it should not be thought that the varying groups into which the nation was divided were separated solely or principally by economic questions, as has too often been supposed. It is a misleading oversimplification to suppose that the social history of France before 1789, as well as its political history afterward, revolve merely around the opposition of the landed aristocracy to the commercial middle classes. There was indeed animosity between the poor, and more especially the rural poor, and the urbanized rich; but the "rich" in the mind of the poor included those privileged both by birth and by skill, and these included both bourgeois and aristocrats, *noblesse de robe* and *noblesse d'épée*, small-town lawyers and big-city merchants. There were no real economic differences between those people who were politically concerned, whether nobles or nonnobles. Like the aristocrats, the bourgeois, including those engaged in trade, were landowners. As landed proprietors, thousands of

bourgeois enjoyed the exercise of feudal rights; and when the bourgeoisie attacked "feudalism," it did not think so much of feudal rights, which were no burden to it because they were paid by peasants. For the bourgeoisie feudalism meant the perpetuation of privilege and irrational institutional anachronisms. In short, the differences that separated nobles and nonnobles, grands bourgeois and petits bourgeois, were more psychological and institutional than economic; this accounted for the great mobility of opinion before, during, and after the Revolution. Like the feeling of reformism, which moved the urban population as a whole, divisive social conflict often had noneconomic roots that were ideological or institutional: political alignments were therefore subject to great and sudden fluctuations. In 1787 the whole nation was united against the state. In the winter of 1788–89 the bourgeoisie and the *parlementaires* were dead set one against the other. In the summer of 1790 unanimity reigned again, but it had once again broken down by the summer of 1791. Moreover, the nation torn by civil strife in 1794 united in 1799 under the aegis of Napoleon. These waves of political unity and disunity can only be understood by referring back to the paradoxes of social unity and disunity before 1789.

The most visible of the divisive elements that form the social background of the breakup of the revolutionary class after 1790 was the conflict that opposed the nobility to the bourgeoisie. Although, as has been seen, the transformations of the 18th century had blurred many of the social and intellectual differences that in the cities separated the bourgeoisie from the nobility, the separate and distinct existence of these two groups was still affirmed by law. Access to certain positions in the state service was limited to the aristocracy, and this was a most important consideration in a society in which there were so many bureaucrats and an official post gave much status or *considération* to its occupant. Nonnobles, or *roturiers*, did not have access to high office in the army or the church. In 1789 all the bishops and most abbots were nobles. In practice nonnobles could not become army officers, and this was a most important source of disaffection because it serves to explain why in 1789 the *ancien régime* monarchy was unable to rely on the army to suppress popular discontent. Even the upper ranks of the centralized state administration were becoming a noble preserve. Admittedly the supererogatory and honorary institutional apparatus inherited from the Middle Ages had always been an aristocratic monopoly. But whereas most of the intendants, *conseillers d'états*, and even ministers of Louis XIV had been nonnobles or recently ennobled men, their successors by 1789 were most of them securely ensconced in the aristocratic establishment. These patterns of administrative exclusion were not a lasting source of division between aristocrats and bourgeois, and, once they were abolished in 1789, the two groups found it less difficult to work together. But before 1789 institutional disqualifications weighed heavily on bourgeois perceptions of nobles and of the state.

Also of importance were the theories developed by some aristocrats and accepted by many others on the racial separateness and superiority of the aristocracy. It was argued that, unlike the members of the Third Estate who were descendants of the Gauls, the nobility had sprung from the loins of the Franks, the Germanic conquerors who had swept over Gaul in the 5th and 6th centuries. Much was made of this idea, which was taken up in reverse by bourgeois theorists, who countered that if the nobles were indeed Franks, it was now time for them to return to Germany. Equally pervasive also was the diffusion in the bourgeoisie of a new personal ethic. Hard work was increasingly seen as a good value. Bourgeois permanence was contrasted to aristocratic fantasy, and a curious manifestation of this idea was the association that was made so often by the bourgeoisie between aristocracy and costly and ephemeral fetes and fireworks. It was for that reason doubly unfortunate that fireworks following the wedding of Louis XVI were marred by a riot and stampede in which dozens of people were trampled to death. More stable and harder working, the bour-

Conflict  
between  
nobility  
and bour-  
geoisie

The new  
bourgeois  
ethic

geois of the 1780s also prided himself on being more moral and a better family man. One of the most pervasive and fundamental evolutions of French society in the 18th century lay in the development by the bourgeoisie of a new style of familial life, which in the next century would spread to all social classes. Unlike aristocrats, who would send their children to wet nurses, who sacrificed the interests of individual children to the perpetuation of secular family pride, and who led very public lives, the bourgeois family drew in upon itself. By 1789 birth control was already practiced in some instances to limit the number of children, all of whom it was now thought deserved their full share of attention and love. Architects began to draw up house plans that substituted for the older pattern of open rooms strung along a public corridor, designs in which rooms were clustered to give more intimacy and warmth. It is thus fair to say that by 1789 the bourgeoisie had developed a particular ethic, which even the Catholic Church recognized implicitly. Where poverty had been admirable in 1689, honesty and thrift were seen as more crucial by the clergy of 1789.

Differences of class separated bourgeois and nobles, and much the same was true of upper bourgeois and lower bourgeois, and of the bourgeoisie as a whole vis-à-vis either peasants or workers. For, although the bourgeoisie was egalitarian in some ways, it inherited from the aristocracy traditions of exclusivism and hierarchy. The average bourgeois may have envied the nobility, but he disapproved of social mobility. Moderately anticlerical, the bourgeois of 1789 nevertheless found it natural that his wife and daughters should be devout. More important still, the bourgeois was essentially authoritarian—fathers continued to exercise great control over their wives and children; and knowledge, art, literature, and politics were all seen in an authoritarian framework within which authority and standards flowed from above. Temperamentally, the bourgeois of 1789 was ill suited to participate in the debates or compromises that were already a part of politics in England or America. The parliamentarianism or libertarianism of 1688 or 1776 appealed to the bourgeois, but its social and intellectual foundations did not. Quite predictably, therefore, egalitarianism rather than self-government participationism would be the only durable conquest of the French Revolution. The tragedy of French society in 1789 was that it could not provide the basis of a viable political alternative to an institutional system it could no longer accept as valid. Tocqueville wrote that the French Revolution had been in men's minds before it began; it might be added that the broad outline of its unfolding was also predictable, given the structure of French society before 1789.

*Financial crisis.* The political debate of the last decades of the *ancien régime* can also be understood in this light. That the state could not go on as it was had been obvious to even its enlightened supporters for some time. Their concern was triggered by growing governmental deficits occasioned not so much by costly extravagance, as has been thought, but by war with England and by the service of the debt. In the aftermath of the Seven Years' War and at the prompting of his minister Joseph-Marie Terray, Louis XV had agreed that it would be necessary to reform and rationalize the imposition and collection of taxes, from which many nobles and many corporations were exempted and which in most of France were inefficiently collected by private tax farmers. The fiscal structure was very baroque. There were direct taxes, some of which were collected directly by the state: the *taille* (a personal tax), the capitation, and the *vingtième*, which were a form of income tax from which the nobles and officials were usually exempt. There were also indirect taxes that were paid by everyone: the salt tax, or *gabelle*, which represented nearly one-tenth of royal revenue; the *traîtes*, or customs duty, internal and external; and the *aides*, or excise taxes, levied on the sale of items as diverse as wine, tobacco, and iron. All the indirect taxes were extremely unpopular, and had much to do with the state's inability to rally the rural masses to its side in 1789. In the 1740s attempts had been made to amend this

system, but had foundered on the parlements' opposition to a more equitable distribution of taxation. By 1770 the swelling debt made it obvious that something should be done. Terray repudiated a part of the debt. There were forced loans and other extraordinary measures. Inevitably, these "absolutist" attacks on established privilege aroused the antagonism of vested interest. To forestall opposition, Terray's colleague, René-Nicolas de Maupeou, successfully outmanoeuvred the Paris Parlement, the members of which in the early 1770s were exiled to outlying provincial cities. The venal offices of the *parlementaires* were abolished, and new law courts were created to replace the Paris Parlement. How far the monarchy had travelled along the road to revolution was shown by the reaction of the public to the new institutions. Although the exile of the Parlement was an exercise of royal absolutism, it was also a reformist exercise carried out for the benefit of the nation and against particularist privilege. Yet it was not seen as such. Although Voltaire understood that the monarchy in this instance stood for rationalism and progress, most of enlightened opinion saw in Maupeou's action merely one more manifestation of ministerial despotism. In short, the monarchy had become so unpopular that reform at its hands was not acceptable even to those people who claimed to want reform above all things. Only the persistent support of the monarch, therefore, would have enabled Terray and Maupeou to push through these measures of enlightened despotism. Because the resistance of the privileged bodies coincided with the disenchantment of the enlightened public, the only constituency of the reformists was the royal will and the royal tradition of absolutism. But Louis XV died of smallpox in 1774. Although his death was in fact a great tragedy for the French crown and perhaps for the French nation as well, because it negated the possibility of peaceful reform pushed through from above, Louis's demise was not widely mourned.

*Unpopularity of Louis XV.* Genuinely popular in the earlier years of his reign, Louis XV had become thoroughly discredited by the time of his death. Although his liaison with Mme de Pompadour had borne many fruits in the form of the patronage she extended to artists as different as Voltaire and the architect Jacques-Ange Gabriel, it did nothing for the prestige of the crown. More unpopular yet was Louis XV's last mistress, Mme du Barry, a former prostitute. The King was also thought to maintain a private brothel (which was true) and to have literally starved his people by speculating on a rising price for grain (which was false).

*Incompetence of Louis XVI.* It is difficult to know if the unpopularity of Louis XV was due to himself or to a decline in the prestige of the monarchy. By contrast, Louis XV's grandson and successor, Louis XVI—well-meaning, obtuse, and sexually incompetent—was initially more popular; and this would seem to suggest that the crown in the 1770s could still tap the traditional sources of loyalty. But by the 1780s Louis XVI himself would also be held in contempt; and in 1789 his wife, Marie-Antoinette, was much hated. Never popular because she was by birth a member of the Austrian ruling house, which in France was traditionally disliked, she reached in 1781 a nadir of unpopularity during the prosecution of the Affair of the Diamond Necklace. (This case revolved around a cardinal, the Prince de Rohan, who had been tricked into giving a diamond necklace to a woman whom he thought to be the Queen; in this instance Marie-Antoinette was blameless, but what was remembered by public opinion was that a cardinal had thought it possible to seduce and bribe the Queen.) The discredit that befell the monarchy in consequence was immense, and Napoleon dated the beginning of the French Revolution from this very episode.

In any case, shortly after the death of Louis XV and his own accession, the new king, eager to please, recalled the Parlement, dismissed Maupeou and Terray, and recalled as his principal minister Jean-Frédéric, comte de Maurepas, a fixture from the unreformed period of the previous reign. The pressure for reform did not die out,

Decline  
of the  
monarchy

The fiscal  
structure

Turgot's  
reforms

however, either in the nation at large, or among those members of the royal bureaucracy who saw that the crown could save itself only by attacking privilege and rationalizing its procedures and its fiscal system; and, in late 1774, Louis entrusted the domestic administration of the kingdom to Turgot, a reforming intendant and, by birth and connection (but by these only), a member of the ruling privileged elite, the power of which he now tried to curb. Perhaps because he thought that the success of his reforms would guarantee their acceptance, perhaps also because he thought it vain to attack the Parlement directly so soon after Maupeou's dismissal, Turgot carried through his measures without first destroying the institutional bases of privileged conservatism. He left the Parlement alone and attempted instead to reduce government expenditures and to alter the methods of tax collecting. He suggested that Protestants should be given freedom of conscience, and, in accordance with his Physiocratic *laissez-faire* principles, he freed the corn trade from restraint; suppressed the *corvée*, or forced labour service, exacted from the peasants; and abolished the guilds, which had limited both access to artisanal professions and the competition within them. In short, Turgot attempted to rationalize the state and to place the organization of society on a basis of equality before the law, arbitrarily but rationally handed down by the state.

In May of 1776, however, Turgot was dismissed. Opposition to his measures had come from all sides: a poor harvest had sparked peasant disturbances, the clericalists were antagonized by Turgot's philosophical friends (his greatest and most loyal disciple was Condorcet, the future Girondin), and, when the Parlement of Paris once again refused to register the new edicts, Louis abandoned Turgot as he had dismissed Maupeou. Thenceforth, the state carried through only minor reforms, none of them on a scale commensurate to the needs that were felt by the enlightened bourgeoisie and notables of the cities and towns. The vestiges of serfdom were suppressed in 1779, and restrictions were removed from the Jews in 1784. In 1786 the salaries of the poorer country clergy were raised, and there were also improvements in the organization of the navy and the army (especially of the artillery, in which young Napoleon became a second lieutenant in 1786). Judicial procedure was also revamped: in 1780 torture was abolished, and in 1784 the king's use of *lettres de cachet* for purposes of arbitrary imprisonment without trial was considerably curtailed. But these were minor adjustments. Nothing was done to alter the fundamental problems of the organization of society and of the state in a manner that would be acceptable to progressive public opinion.

By the mid-1780s the state's position had in fact become truly hopeless. So great was the backlog of resentment that no concession would suffice. As a gift of the crown, no reform could be acceptable. Most remarkable was the lack of success of deliberative provincial assemblies, which had been designed to associate the political elites to the work of the intendants and of the centralized state. They would have been seen as an incredible concession 20 years before; in the 1770s and 1780s they were failures. The gap between the state and the public was so great that the state could now do nothing right.

But the problem of the state was complicated by the fact that in the 1780s most of what it did was actively and positively wrong. Having alienated conservative opinion by its attempted reforms and enlightened opinion by its failure to push them through, the crown had no constituency on which it could rely; and its only hope was to keep things as they were, in the hope that it would proceed somehow from expedient to expedient. The U.S. War of Independence, however, was a most inexpedient event. This was not due to its military denouement, for, in spite of some naval reverses in 1783, the French army and navy performed creditably during that conflict, and the position and prestige of France in Europe was greater in 1783 than it had been for 40 years. The French problem in that war was not military but financial. The cost

of the war was enormous, and it was met not by new taxation but by new borrowing, which doubled the size of the national debt. In the late 1780s, the service of the funds absorbed more than half the crown's income: by 1789 debt payments had risen to 300,000,000 livres from less than 100,000,000 before the American war. This could not go on forever, and indeed it was only because of the talent of Jacques Necker (Turgot's successor) in raising loans that the system went on as long as it did. But sooner or later, from sheer financial exhaustion, the state would have to turn to the nation, and at that point the whole set of conflicts in society—between country and city, bourgeois and noble—would have to be resolved.

By August of 1786 Necker's successor, Charles-Alexandre de Calonne, reached precisely that point. Although the crown had assured the moneymen that it would not default on the debt, as indeed it could not have done without alienating thousands of its natural supporters, Calonne found that he could no longer raise funds by borrowing. To resolve the ensuing impasse, in February of 1787 he summoned to Versailles the Assembly of Notables who represented the privileged orders—great nobles, bishops, *parlementaires*—in the hope that they would finally and of their own accord accept that transformation of the state that they had for so long resisted. But the notables refused again as the *parlementaires* had in 1776, this time on the grounds that Calonne's mismanagement was the only cause of the crown's problems. They argued that if Calonne were replaced by Necker, who had borrowed so successfully, all would be well. Once again, the crown yielded. Calonne was replaced by Loménie de Brienne, a cardinal, though an atheist, and a spokesman of the privileged majority of the Assembly of Notables. Almost at once, Loménie reversed himself and came to Calonne's conclusion: the state could not go on as it had; but the notables refused to be more amenable to Loménie than they had been to Calonne. Despairing of securing the consent of the privileged orders, Loménie dismissed the assembly in May of 1787, and in August the Paris Parlement was exiled to Troyes. But these were desperate measures, and already the monarchy was beginning to lose control of the political process. Indeed, for the next two years it merely floundered from one scheme to another, in the impossible hope of squaring the circle of modernistic reform, popular hostility, respect of privilege, and the preservation of royal absolutism.

For that reason, Loménie's exile of the Parlement in August of 1787 was not upheld. Essentially unwilling to force the privileged notables to yield their corporate rights, the crown was now unable to assert any coherent policy. The Parlement was therefore recalled in September of 1787, once again dismissed in May of 1788, and, in the face of a beginning of a breakdown of law and order and of the inability of officials to collect taxes, once more recalled to Paris by the crown in May of 1788. Paradoxically, the return of the reactionary *parlementaires* was saluted as a great victory by their most bitter reformist opponents. This is to be explained by the fact that the crown was now perceived by all Frenchmen as inimical: the conservative *parlementaires* opposed it from their reactionary point of view, and the reformists opposed it for its arbitrary repression even of the reactionaries. The crown was now essentially powerless, and on August 8, 1788, it tacitly accepted this fact by agreeing to call together the Estates-General on May 1 of the following year. At that juncture the monarchy in fact dropped out of the political debate that would now be structured by the tensions within French society. Censorship was in practice suspended, and thousands of pamphlets were circulated in Paris. The political debate of 1788–91 would thenceforth be freely conducted, and in the positions of the participants of that drama can be seen the echoes of the fundamental forces that united and divided the French nation.

In the first phase of the struggle, all those who desired a more modern, rationalized, and politically egalitarian society were opposed to the privileged order. The issue

control

quickly polarized on the question of the composition of the estates. Should it meet in three groups, as it had in 1614, or should the members meet together (in which case the liberal minorities of the first two orders—clergy and nobility—could combine with the third and enact liberal measures)? The Parlement of Paris, which had returned in triumph on September 23, 1788, decided on September 25 that it would meet as it had before. At once the popularity of the *parlementaires* collapsed. On September 23 they were seen by the reformists as victims of royal oppression; but two days later they had become again what they in fact had always been: the defenders of the traditional social and political fabric of the *ancien régime*. In a last and fitful assertion of authority, at the behest of Necker, once again minister, the crown decided on December 27 to overrule the Parlement. The estates, it resolved, would meet separately, but the Third Estate would have as many deputies as the other two orders combined. The stage was now set for the coming Revolution.

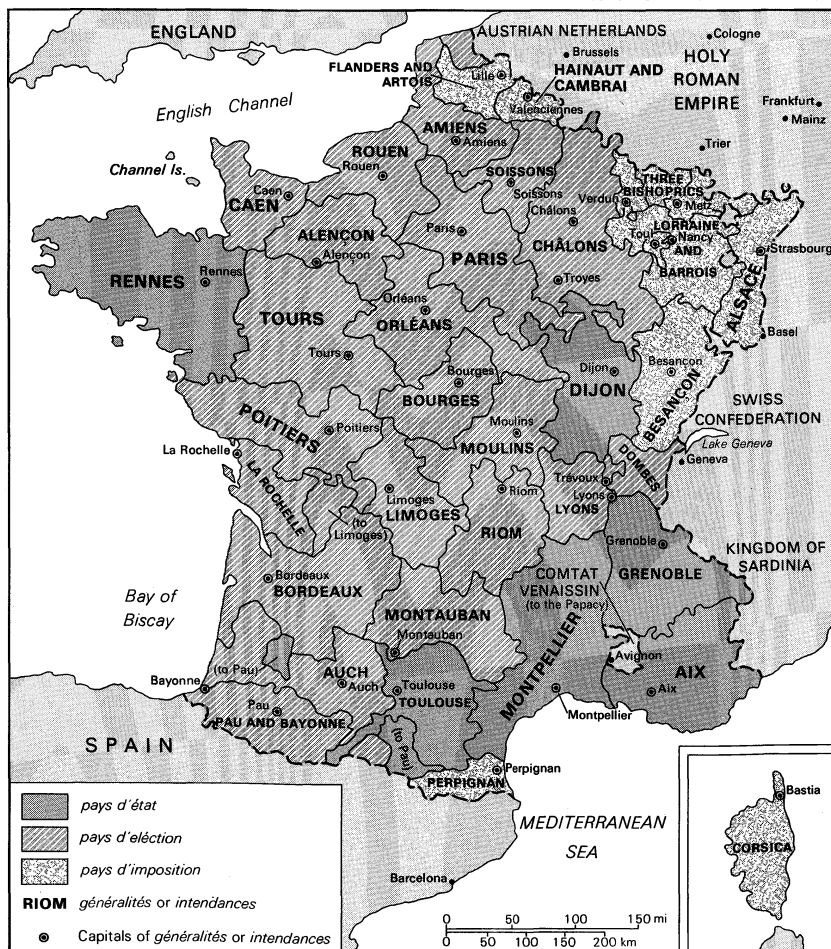

**The beginning of the Revolution.** The first phase of the Revolution had opposed various groups in French society to the French state. The second phase would be characterized by a struggle between the traditionalists and the urban reformists as a whole. Subsequently, and under the pressure of events, the unity of revolutionary reformist fervour would break up, very often along those same lines of social class—economic, psychological, and moral—that had become increasingly visible after 1750. But in 1788–90 the political problem did not yet revolve around those issues. The sequence of events in those months is therefore to be seen as the assertion, against the privileged, traditionalist order and against the state, of the united power of the reformists, some of them bourgeois, some of them nobles, many of them of

indeterminate social status. July 14, 1789, is only the vibrant and vivid symbol of the defeat of the *ancien régime*. By that date the revolutionary movement had been developing for more than a year. The aristocratic Fronde against the state had begun in the 1750s, and the revolution of the urban reformists against state and privilege was already a fact in late 1788.

The tasks of the reformists were much facilitated in the early months of 1789 by a gradual erosion of law and order in the countryside. The motives that drove the peasants to revolt were far different from those of the reformists. Both were interested in the problem of taxation; but, although the city dweller was concerned about efficiency and irrational expenditure, the peasants were simply interested in paying less. The peasants were keen also to destroy the feudal dues, which the reformers disliked abstractly but from which the peasants suffered concretely. Indeed, since thousands of city dwellers were also rural landlords and owners of feudal dues, there were many instances of armed conflict between urban militias and peasant bands in the late summer of 1789. After 1789, during the decade of revolution, these conflicts of material interests did at times become crucial. In the Vendée, for example, in 1793, the peasants even took sides for the aristocracy and against the reformist, urban bourgeoisie. But in the spring and summer of 1789, the great majority of Frenchmen—peasants, bourgeois, and reformists of all sorts—were able to compose their differences and to unite for a single political purpose: the destruction of the feudal, “privileged” establishment of church, state, and noble. In April and May there were numerous rural riots and attacks on convoys of grain, caused largely by an extraordinary and unusual rise in the price of bread. When the Estates-General met on May 5, the defenders of the *ancien régime* were thus in total

The gouvernements in 1789.

disarray. The crown was devoid of prestige, and the debris of its authority was still resented by the privileged orders, themselves unable to rely on peasant support because of the rural disorders. The victory of the reformists was therefore assured.

What followed in June and July was, if not inevitable, at least predictable. On June 17 the Third Estate declared itself to be a national assembly, and in the following days it was joined by individual reformist members of the clergy and nobility. Three days later, after having been denied admission to their usual place of meeting, the reformists met in the royal tennis court and swore an oath never to dissolve until France had secured a constitution. On June 23, in a final spasm, the crown in order to survive now sided openly with the privileged *parlementaires* and great nobles it had so recently tried to curb and made a last effort to stem the reformist tide. The King reasserted the divisions of the estates in three orders and declared null and void all the decisions taken by the Third Estate since June 17. On June 27, the crown seemed to have veered back to moderation, but in fact it persisted for some time in its attempts at resistance. Some 20,000 troops were marched in from the provinces, and it appeared that a military coup was in the offing. On July 11 the less reactionary members of the royal council were dismissed, as was Necker himself who was ordered into exile.

But this show of force was to no avail. The crown was too discredited; the army, too disloyal. Most importantly, the social forces that would traditionally have rallied to its support—traditionalist aristocrats and obtuse peasants—were too weak and indeed divided one against the other. A show of force from the side of the reformists would easily end this last-ditch effort of the *ancien régime*, and this force was provided by the Parisian crowd. Until then the political struggle had included the state, the traditionalists, and the literate reformists—some of them noble, many of them bourgeois. But now the mass of the urban population entered the political arena. In April a mob had attacked the factory of a textile manufacturer accused of starving the poor; and in early July there had been other food riots on the outskirts of Paris. By mid-July, however, the dissatisfaction of the urban poor was focussed on a more political purpose. In a show of revolutionary unity, the *sans-culottes*—the people of Paris who would later demand the blood of Lafayette, Brissot, Danton, and Robespierre himself—rose up to defend the liberal reformist cause, and, in so doing, brought down the *ancien régime* in ruins. On July 14 a crowd surged around the Bastille—that hated, though largely unused, symbol of absolutist oppression. Only seven people were imprisoned there, and two of them were mad. But, as a symbol, the fall of the Bastille could not be equalled. It sapped the will of the King to resist. On July 17 he recalled Necker and became in fact a constitutional monarch. The *ancien régime* was a thing of the past.

There were those who would say, with Edmund Burke, that now the glory of Europe was gone forever; and others who would herald instead the dawn of a new age of liberty, equality, and fraternity. What was certain, however, was that France and the world would never again be as they had been before. (P.Hi.)

## V. The French Revolution and Napoleon, 1789–1815

### THE INITIAL REVOLUTIONARY REFORMS AND THE CONSTITUTIONAL MONARCHY

**The Revolution of 1789.** No sooner had the Estates-General entered into session at Versailles than the conflict between the orders declared itself: the Third Estate demanded that powers be verified in common, which implied that the estates should vote as one assembly; this would give the Third Estate an advantage, because it was the most numerous. The question was important: either the aristocracy had to yield (which meant the end of its privileges) or the Third Estate would have to acknowledge defeat (which meant the survival of the *ancien régime*). In the words of the reformist nobleman the Comte

de Mirabeau, the deputies of the Third Estate understood that they had only “to remain immovable in order to present a formidable danger to their enemies.”

On June 12, 1789, the Third Estate began a roll call of all deputies on the question of the common verification of powers. The privileged bloc began to disintegrate. On June 13 only three parish priests answered to their names, on the next day, six. Foreseeing victory, the Third Estate pressed on. On June 17 it proclaimed itself the National Assembly. On June 19 the clergy decided to ally itself with the Third Estate.

Encouraged by the nobility, Louis XVI decided to resist and ordered the meeting place of the estates closed. On June 20, 1789, the deputies of the Third Estate, finding the doors shut, moved to the nearby royal tennis court. There, under the presidency of the old astronomer Jean-Sylvain Bailly, the delegates swore not to adjourn until they had produced a constitution for France.

On June 23, 1789, the King held a “royal session” of the Estates-General, for the purpose of annulling the decisions of the Third Estate. He himself offered a program of reforms, one that maintained the feudal rights of the nobility. Louis threatened the deputies: “If you abandon me in this great enterprise I will work alone for the welfare of my peoples. . . . I command you to separate at once.”

The King’s attempt ended in failure. The commons did not budge, though the nobility and a part of the clergy withdrew. The body confirmed its earlier decrees and declared that its members were inviolable. When the royal bodyguard was ordered to disperse the deputies, the representatives of the nobility who had sided with the Third Estate objected, and the Marquis de Lafayette and others put their hands on their swords. Louis backed down.

From then on, the triumph of the Third Estate gained momentum. On June 24 the majority of the clergy sat beside it in the National Assembly. On the 27th the King, deciding to sanction what he had been unable to prevent, wrote to the minority of the clergy and the majority of the nobility, inviting them to rejoin the National Assembly. On July 9, 1789, that body proclaimed itself the National Constituent Assembly.

Thus far, the judicial revolution had been accomplished without violence. But just at the moment when the King and the aristocracy appeared ready to accept the accomplished fact, they decided, instead, to use force to bring the Third Estate back to obedience. The King clandestinely called in 17 regiments, most of them trusted Swiss or German mercenaries, ostensibly to protect property in case of mob violence in Paris, but in reality to intimidate the Constituent Assembly.

Thus, the judicial and peaceful revolution had finally miscarried. The King’s appeal to the military emphasized the refusal of the aristocracy to make any concessions. But this was to leave the urban and rural masses out of account. In the summer of 1789, the storming of the Bastille in July and the so-called Great Fear that began July 20 unleashed a popular revolution and brought about the downfall of the *ancien régime*.

The economic crisis had already brought numerous mass disturbances that laid the groundwork for revolution. As early as April, a gunpowder factory and a wallpaper factory in the Faubourg Saint-Antoine in Paris had been sacked and pillaged. Earlier still, the harvest of 1788 had been a particularly bad one. Outbreaks at markets, looting of shipments of grain, and attacks on customs barriers multiplied. All this was taking place as the convocation of the Estates-General was raising immense hopes among the masses. Against this background, the action of the King and aristocrats in calling up the military and preventing a renewal of resistance logically gave rise to the notion of an “aristocratic conspiracy” and led the people to decide to act before the aristocrats could attack. Popular feeling intensified and spread, unnerving the troops and the mounted constabulary, inflaming the atmosphere of the cities. On the eve of the harvest of 1789 the crisis reached its peak. The idea of an aristocratic conspiracy and the fact of economic crisis became united in the popular mind. The people were no

Creation  
of the  
National  
Assembly

End of  
the *ancien*  
*régime*

longer in doubt that the King meant to use force to disperse the National Assembly, in which lay all their hopes.

On the afternoon of July 12, 1789, the news of the King's dismissal of Jacques Necker, who was thought of as a reformer, became known in Paris. The theatres closed, and there were spontaneous street demonstrations. On July 13 the electors of the Third Estate ordered the creation of a "civic militia," in theory to guard the public safety but, in fact, to be a "bourgeois militia," directed against the excesses of the royal power and its regular troops on the one hand and the threat from social categories considered dangerous on the other.

Fall  
of the  
Bastille

On July 14, 1789, after pillaging the armory at the Invalides, a mob made its way to the Bastille, an old fortress on the east side of Paris that had come to symbolize the despotism of the *ancien régime*. Artisans and journeymen of the Faubourg Saint-Antoine, reinforced by members of the bourgeois militia and by two detachments of French guards, forced the governor, Bernard Jordan, marquis de Launay, to capitulate. He ordered the drawbridge lowered, and the people rushed in.

Interestingly, the monarchy emerged from these July days singularly disabled. The King recalled Necker and on July 17 went to Paris to sanction the appointment of Bailly as mayor and Lafayette as commandant of a bourgeois municipality and national guard. The Parisian bourgeoisie had thus taken advantage of the popular victory to assume the administration of the capital.

In the provinces, the Parisian revolution of July 14 had counterparts in various actions of the so-called municipal revolution: during the weeks of July and August 1789 the old municipal governments, in fact, disappeared; the administrators abandoned their offices; the collection of taxes was suspended; and the royal power vanished. New municipal governments were established, and local life had a rebirth. France was "municipalized."

The  
Great Fear

At this point the peasants entered the scene. Famine and unemployment having vastly increased the number of vagabonds, roving bands appeared in numbers in the countryside in the spring of 1789; and the "fear of brigands" was thus added to the fear of the "aristocratic conspiracy." Local incidents brought on a series of panics—the so-called *Grande Peur*, or Great Fear—which, from July 20 to August 6, 1789, shook the entire country. The fear triggered a "defensive reaction," and the peasants armed themselves. Though the groundlessness of these popular terrors soon became apparent, the mechanisms of collective psychology worked so as to convert a "defensive reaction" to a "punitive will." Abandoning the pursuit of imaginary brigands, the peasants turned instead to the castles and burned the records of their manorial debts and feudal obligations. In only a few days the feudal regime had been overthrown.

**The abolition of feudalism.** The Constituent Assembly, during this course of events, was powerless and helpless. The majority of its members were men of property, reluctant either to sanction the peasants' actions or to widen the gulf between themselves and the peasantry and put themselves at the mercy of the King and the aristocracy.

The Assembly had no doubts at all concerning the significance of the insurrection in the countryside; breaking out at the height of the harvest season, the insurrection challenged the collection of feudal dues and the very existence of feudal rights and of tithes. Though, in principle, the bourgeoisie opposed these feudal remnants as an obstacle to the capitalistic transformation of agriculture and of the entire economy, in practice the majority of the deputies were jurists who, as such, regarded seigniorial rights as a form of legitimate individual property that could not be abolished without imperilling the social order itself. It was necessary, therefore, either to suppress the agrarian revolts or to make some immediate concessions.

The Third Estate hesitated but finally concluded an alliance with the liberal nobility. At the beginning of a memorable session on the night of August 4, 1789, Louis-Marie, vicomte de Noailles, proposed that all feudal

rights should be made redeemable in money or exchanged "at the rate determined by an equitable evaluation." Armand, duc d'Aiguillon, one of the greatest landowners in the country, next insisted that "the rights in question are a form of property" and that "all property is sacred." Hence, the "proprietors of fiefs," the "lords of estates," could not be asked to accept the pure and simple renunciation of their feudal rights, unless they were granted an equitable indemnity. Having thus safeguarded their essential interests, the deputies allowed popular enthusiasm to take over: the feudal privileges of individuals and orders were abolished, together with those of the provinces and the cities.

The "abolition" of feudalism by the Constituent Assembly, however, was more apparent than real. Subsequent decrees (those of August 5–11, 1789, and March 15, 1790) passed in pursuance of the decisions taken on the night of August 4 showed how dubious the unanimity of that night of calculated enthusiasm was and how superficial the sacrifices made by the aristocracy. Feudalism, destroyed only in its institutional and legal form, lived on as an economic reality. In this regard, a distinction between "dominant" and "contractual" feudalism had come into play. The former (*i.e.*, the right to administer justice, serfdom, forced labour and *banalités*, tolls, and hunting and fishing rights) had been abolished; the latter (*i.e.*, quitrents, ground rents, and annual dues, etc.) had been declared redeemable. A further decree of May 3, 1790, set redemption at a very high rate: 20 times the annual fee for dues in money, 25 times for dues in kind—a heavy burden for the majority of the peasants, who had no reserves.

The redemption of feudal rights constituted the economic basis of the compromise with the aristocracy that a segment of the bourgeoisie had sought since 1789—a compromise that greatly favoured the feudal lord. Only the wealthier class of peasant proprietors (peasants who owned land) benefitted economically from the abolition of feudal dues. For the mass of lesser peasants, the abolition of feudalism was, in the words of Georges Lefebvre, "a bitter deception." To obtain complete enfranchisement of the soil, the peasant revolution continued in many forms until 1792 and in some regions until 1793—constituting nothing short of a masked civil war.

**The reforms of the Constituent Assembly.** On the night of August 4 the Constituent Assembly had made a clean sweep: henceforth all Frenchmen were equal, the territory of France was unified. The next step was one of reconstruction. But if the principles were solemnly proclaimed, they were nevertheless infringed with the same realism that had governed the working out of the compromise on feudalism.

From the beginning of August the Constituent Assembly addressed itself to the task of reconstruction. It was decided that the new constitution being prepared by the Constituent Assembly must be preceded by a declaration of rights; some wanted to supplement it by a declaration of duties, and the discussion proceeded slowly. Finally, on August 27, 1789, the Assembly adopted the Declaration of the Rights of Man and of the Citizen. The great desideratum of the constituent bourgeoisie was "freedom," in its public and political aspects. According to the Declaration, freedom is an inalienable natural right limited only by the freedom of others. Freedom is seen first of all as freedom of the person: individual freedom, protected from arbitrary accusations and arrests and safeguarded by the presumption of innocence. Masters of their person, men were to be able to speak and write, print and publish freely, on condition only that the expression of opinions not disturb the order established by law, and subject to responsibility for any abuse of the freedom. The article on freedom of worship had been debated at length prior to adoption, the clergy insisting that the Assembly should confirm the existence of a state religion and Mirabeau protesting vigorously in favour of freedom of conscience and worship. In the end, the state church was recognized; but dissident cults were to be tolerated.

With freedom the declaration closely associated equal-

The Declaration of the Rights of Man and of the Citizen

Session of  
August  
4–5

ity, demanded by the bourgeoisie in opposition to the aristocracy and by the peasants in the face of the feudal lords. The declaration held that the law was to be the same for everyone, and all citizens were equal in its eyes. Dignities, offices, and employments had to be equally open to all, without distinction of birth—social distinctions were to be based only on common usefulness, on virtues and talents; taxation was to be equally distributed among all citizens, in proportion to their ability to pay.

On the political plane, the liberalism of the Constituent Assembly found expression in the Constitution of 1791, as it is called, though its principal stipulations actually had been voted as early as the end of 1789. On the basis of national sovereignty and the separation of powers, the Constitution organized a representative system characterized by the predominance of the Legislative Assembly. Political equality, however, was distorted by limiting suffrage on the basis of taxation. By the law of December 22, 1789, political rights had been reserved to a minority of property owners divided into three hierarchized categories according to the amount of taxes they paid: (1) "active" citizens grouped in primary assemblies; (2) "electors" who made up departmental electoral assemblies, and (3) citizens "eligible" for the Legislative Assembly. "Passive" citizens were excluded from the right of suffrage because they did not reach the prescribed level of taxation.

Other work of the Assembly—administrative decentralization, judicial reform, new fiscal organization, and even the reorganization of the church by the Civil Constitution of the Clergy (July 12, 1790)—was in accordance with the same preoccupation with liberalism. In the same vein, the Assembly undertook a complete administrative reorganization of the country into departments, districts, cantons, and communes, in which all administrators were elected, even bishops.

Economic freedom was not mentioned in the Declaration of Rights of 1789 or the Constitution of 1791—presumably because it was taken for granted by the members of the Constituent Assembly and also because the popular masses were profoundly attached to the old system of production and exchange, which, through regulation and taxation, to a certain extent guaranteed their conditions of life. From 1789 this attitude of *laissez-faire*, or "hands off," provided the foundation for the new economic and social institutions. Freedom of property followed from the abolition of feudalism. Freedom of agriculture heralded the triumph of agrarian individualism, even though a rural code of 1791 maintained—not without contradiction—the old medieval right of villagers to graze their animals on common land if the right was founded on custom. Freedom of production was generalized by the abolition of monopolies and guilds. The Allarde Law of March 2, 1791, abolished journeymen's associations, guilds, and secret societies, and privileged manufactures as well. The national market was unified by the abolition of customs dues and tolls.

Finally, there was freedom of work, indissolubly connected with freedom of enterprise: the Le Chapelier Law of June 14, 1791, though it guaranteed the right of association and of public meetings, prohibited *coalition* (collective resistance) and strikes. The free individual was also free to create and produce, to pursue profit and to employ it as he desired.

The new social and political order was reinforced by two closely connected extreme reform measures enacted to solve the financial crisis. On November 2, 1789, the property of the clergy was confiscated and put "at the disposal of the nation." On December 19, some 400,000,000 livres worth of these confiscated properties were put on sale, represented by an equal amount in assignats, 5 percent bonds constituting an obligation of the state and repayable in ecclesiastical properties. The operation failed, and on August 27, 1790, the assignat became a banknote. The depreciation of this paper currency, inflation, and the high cost of living rekindled social agitation and at the same time struck a hard blow at established wealth. Through the sale of national properties, which the assignat encouraged, the Revolution next moved

toward a new redistribution of landed wealth, one that accentuated its social character. It is notable, however, that, like the abolition of feudal rights, the sale of national properties did not benefit the mass of the peasantry; rather, it strengthened the preponderance of the propertied classes.

The Civil Constitution of the Clergy, which was destined to raise new difficulties for the Revolution, fell within the same framework of liberalism: it followed necessarily from the confiscation of ecclesiastical properties, as well as from the reform of the state and the administration. Religious orders were abolished on February 13, 1790, and the organization of the remainder of the clergy was based on the new administrative divisions: a diocese for each department. Bishops and parish priests were elected like other officials—the latter by the electoral assembly of the district, the former by that of the *département*. The newly elected ecclesiastics were "instituted" by their ecclesiastical superiors, not by the Pope. The church of France thus became a national church; its ties to the papacy were loosened; papal briefs were subject to governmental censorship; and annates (payments to Rome) were suppressed. Though the Pope retained spiritual primacy over the French Church, all temporal jurisdiction was taken from him. The Constituent Assembly at first left it to the Pope to sanction the Civil Constitution, but he had already condemned the Declaration of the Rights of Man and of the Citizen as impious; moreover, Avignon, a papal dependency surrounded by French territory, was demanding to be annexed to France. Pius VI temporized. Tired of waiting, on November 27, 1790, the Constituent Assembly demanded that all priests swear loyalty to the Civil Constitution of the Clergy. Only seven bishops took the oath. The priests divided into two groups, more or less equal in numbers but unevenly distributed: "refractories," or "nonjurors," in the west, and "jurors," or "constitutionals," a majority in the southeast. When, on March 10 and April 13, 1791, the Pope solemnly condemned the principles of the Revolution and the Civil Constitution, the schism was complete. The country was thus cut in two. The refractory opposition strengthened the counter-revolutionary agitation, and the religious conflict came to parallel that of the civil sphere.

#### THE RADICALIZATION OF THE REVOLUTION, 1791–93

**The end of compromise.** The constitutional monarchy as the bourgeoisie had sought to establish it had been based on an economic and social compromise represented by the redemption of feudal rights and on a system of suffrage based on taxation that sanctioned the rights of property and propertied classes. But this compromise finally became impossible in the face of the obstinate resistance of the mass of the lesser nobles, who for the most part lived on feudal dues, and that of the stubborn and aggressive determination of the peasants to abolish all survivals of the feudal system. Under these conditions, the social stabilization that would have allowed the constitutional monarchy to function was impossible.

From 1789 to 1791 the various bourgeois factions of the Constituent Assembly tried to arrive at a political compromise with the aristocracy. Three leaders in the Assembly are associated with these attempts: Jean-Joseph Mounier, the Marquis de Lafayette, and Antoine Barnave.

In the summer of 1789, Mounier had thought it possible that the three orders could unite in support of a limited revolution. In September 1789 he had sought the Assembly's approval for a political system that, after the pattern of the English Revolution of 1688, would have set the "notables" (the aristocracy and the upper bourgeoisie) in a dominant position over the popular masses. The "Monarchicals," or "Anglomaniacs," he led demanded an upper chamber that would have been the fortress of the aristocracy, and, for the king, an absolute veto. The Constituent Assembly refused, and the "Revolution of the Notables" failed. Mounier left Versailles after the October Days of 1789, when a Parisian mob marched there

and forced the royal family to return to Paris, where they could be watched.

Lafayette, whether from ambition or from incomprehension, revived the same policy with a different emphasis: he sought to reconcile the landed aristocracy and the commercial bourgeoisie in the framework of the constitutional monarchy. In 1790 Lafayette completely dominated political life; he triumphed at the Fête de la Fédération of July 14, 1790 (celebrating the anniversary of the fall of the Bastille), which appeared to seal the reconciliation between the monarchy and the nation. But when he showed his true position by approving the extremely harsh repression with which his cousin, François-Claude Armour, marquis de Bouillé, quelled the revolt of the garrison at Nancy in August 1790, his popularity went up in smoke.

Barnave and his friends in the Assembly, Adrien Duport and Charles, comte de Lameth—the Triumvirate—carried on the torch. No one better defined the essence of the political and social compromise that they sought than Barnave in a vehement speech before the Assembly on July 15, 1791:

Are we going to end the Revolution, are we going to begin it again? . . . One step further it cannot be made without danger; that in the line of liberty the first act that might ensue would be the annihilation of royalty; that in the line of equality the first act that might ensue would be an attack upon property.

In agreement with Lafayette, the triumvirs wanted to revise the constitution, to strengthen its emphasis on property qualifications for suffrage, and to increase the powers of the King. This policy demanded both the support of the aristocrats and the approval of Louis XVI. Its rejection by the aristocracy and the King, the appeal to the other European monarchs, and finally the outbreak of war in April 1792 (see below) once again ruined this policy of compromise.

Except for a minority of liberal nobles, the aristocracy totally rejected reform and remained stubbornly attached to its privileges, its haughty exclusivism, and its feudal mentality. As for the monarchy, its attitude proved, if proof was needed, that it was by its very nature allied to the aristocracy. The appeal to the military upon which the King had decided in the first days of July 1789 would have brought the end of the Revolution if the people had not intervened. The majority of the aristocracy accepted neither the decrees of August 5–11, 1789, nor the Declaration of Rights: not even, that is, the partial destruction of feudalism. It was the popular insurrection of October 1789 that had forced the King to accept the decrees of August. In 1790, while Louis XVI was making use of Lafayette (whom he hated), the aristocracy persisted in resisting, its hopes fed by the plots of émigrés to secure foreign intervention and the beginnings of the counter-revolution. At the same time, agrarian revolts, brought on in many regions by the need to redeem feudal rights, hardened its refusal. The King's unsuccessful attempt to leave the country in 1791, armed gatherings of émigrés on the Rhine, and finally the war that it had been the émigrés' policy to seek from 1791 proved that the monarchy and the aristocracy would betray the nation rather than yield.

For its part, the peasantry no less stubbornly refused the compromise of the redemption of feudalism. Despite the proclamation of the principle of redemption as early as August 4, 1789, those upon whom the burden of feudal dues fell could not begin to envisage their liberation until the passage of the decree of May 3, 1790, which organized the redemption in accordance with the provisions of the law of the preceding March 15. These delays exasperated even the least disaffected. The bad drafting of the decrees of August 5–11, 1789 ("The Constituent Assembly destroys the feudal régime in its entirety . . ."), increased the confusion; the peasants took the text literally and refused further payments. Their disappointment swiftly and inevitably gave way to anger, the more so because the feudal lords insisted on payment not only in the case of the rights that had been maintained, so long as they were not abolished, but also of the arrears due

for the abolished rights. Under these conditions, from 1789 to 1792 the peasants were pitted against the aristocracy in a civil war that varied in intensity in the several regions. There were serious disturbances or out-and-out peasant revolts from 1789 in the Aisne, the Norman Bocage, in Anjou, Franche-Comté, Dauphiné, Vivarais, and Roussillon. In January 1790, there were revolts in Quercy, Périgord, and Brittany; in May in the Bourbonnais. Quercy and Périgord were in insurrection again in the winter of 1791–92; in the spring it was the turn of the Gard, the Ardèche, and then of Provence. In equal measure with the popular movements in the towns, the peasant insurrections drove the Revolution forward.

**The King's flight to Varennes.** The King's attempt to flee the country on June 21, 1791, constituted one of the great turning points of the Revolution. At home, it proved the irreconcilable opposition between aristocratic royalty and the Revolutionary nation: it thus wrecked the experiment with constitutional monarchy. In foreign affairs, it precipitated a conflict that led to war.

About midnight on June 20, Louis XVI, disguised as a valet, left the Tuileries with his family. During the night of June 21–22 he was arrested at Varennes. The royal family was returned to Paris on the evening of June 25, amid a deathly silence, between two files of soldiers with their muskets reversed. It was the "funeral procession of the monarchy."

The Assembly maintained its composure. Creating the fiction that the King had been kidnapped, it quelled popular disturbances by using the National Guard and set about revising the Constitution, increasing its emphasis on property qualifications. The King accepted the Constitution thus revised. On September 14, 1791, he once again swore loyalty to the nation, but his attempted flight had destroyed his credibility. The split between the King and the nation was irremediable.

Meanwhile, Louis's flight and arrest had aroused an intense emotional reaction in monarchical Europe. On August 27, 1791, by the Declaration of Pillnitz, the Habsburg emperor Leopold II and King Frederick William II of Prussia threatened the Revolutionary nation with armed intervention. From that moment, war appeared inevitable.

**The outbreak of war.** From 1791 war had been the final recourse for the aristocracy and the monarchy. "Instead of a civil war, there will be a foreign war," Louis XVI was to write on December 14, 1791, to his agent, Louis-Auguste Le Tonnelier, baron de Breteuil, "and things will be much the better for it."

In the Legislative Assembly, which, succeeding to the Constituent Assembly, had gone into session on October 1, 1791, war was in fact sought by the left at the urging of new men later known as Girondins, then known as Brissotins, after their leader, Jacques-Pierre Brissot.

The left of the Legislative Assembly was made up of more than 130 deputies, chiefly members of the Club of the Jacobins. It was more particularly guided by two Parisian deputies, the journalist Brissot and the philosopher the Marquis de Condorcet; and it was influenced by a number of brilliant orators elected by the *département* of the Gironde—especially Pierre-Victurnien Vergniaud. Representatives of the upper mercantile bourgeoisie, the Girondins wanted to quash the counter-revolution, particularly to re-establish the value of the assignat—a prime necessity if business was to flourish. The aristocracy wanted war in order to bring about counter-revolution by a defeat; and the business bourgeoisie was not averse to war because supplying the armies constituted a traditional source of large profits. Moreover, both saw that to attack Europe's *ancien régime* would be to launch a final attack on the aristocracy, to unmask it, to bring it to unconditional surrender.

Despite opposition expressed by the future revolutionary leader Robespierre in great speeches ("Begin by turning your eyes back to our internal situation, restore order in your own house, before you carry liberty elsewhere"), on April 20, 1792, the Legislative Assembly declared war "on the king of Bohemia and Hungary," that is, on Austria alone and not on the empire. Though the war did not

Declara-  
tion of  
Pillnitz

fulfill the expectations of either the court or the Gironde, it did help to inflame nationalistic feeling and gave the Gironde an aura of lasting prestige that even the catastrophes that followed could not dim. If the Girondins perished in the end, it was not because they had wanted a war that finally revealed the nation to itself, it was because they had not known how to conduct it.

**The overthrow of the monarchy.** For in fact the Girondist bourgeoisie proved incapable of conducting this war against the *ancien régime* of Europe by its own unaided efforts; its fear of the popular movement caused it to refuse the cooperation of the people. Robespierre's prophetic warning that it was necessary to destroy aristocracy within the nation before fighting it beyond the frontiers proved to be justified. Military defeats of the spring of 1792, through which the Gironde saw the need for an alliance with the people if victory was to be won, revealed its hesitations if not its duplicity: it consented to appeal to the people—as in the case of the uprising of June 20, 1792—in order to exert pressure on Louis XVI, but only insofar as the people demanded nothing more than the objectives the Girondist bourgeoisie had assigned to them.

The effects of the national crisis combined with those of the economic crisis, and together they revived the popular movement in the spring of 1792. Nationalistic surge and revolutionary thrust were inseparable: a social conflict underlay and exacerbated patriotism. The aristocrats opposed the King to the nation, which they scorned; inside the country they awaited the invader, and those who had gone into exile fought in the enemy ranks. The patriots of 1792 wished to safeguard the heritage of 1789 and carry it further. On the advice of the Girondins themselves, the "passive" (voteless) citizens donned the "cap of liberty," armed themselves with pikes, and formed more and more popular associations.

By raising Revolutionary sentiment to fever pitch, the national crisis revived the social oppositions within the former Third Estate itself. Even more than in 1789 the bourgeoisie became uneasy. The rich were taxed to arm the volunteers, the ravages of inflation continued, and disturbances over provisions increased. The spectre of an "agrarian law" haunted the propertied bourgeoisie. Thus, the line that was soon to separate the Girondins from the more radical Montagnards began to be drawn. Already the deep reasons for what some historians later termed "the national failure" of the Girondins could be perceived: representatives of the bourgeoisie, partisans of economic freedom, they were alarmed by the popular tide that their war policy had raised.

The extremity of the danger was further testimony to both the incapacity of the Girondins and the duplicity of Louis XVI. On July 11, 1792, with the first entry of allied troops onto French soil, the Legislative Assembly declared "the fatherland in danger." But, dreading the popular movement, the Girondist leaders at the same time negotiated with the King, despite the fact that they had accused him of treating with the enemy. While the tide of popular anger swelled, the Girondins hesitated, then took fright in the face of a movement that they had nevertheless contributed to launching. Finally, a popular insurrection of August 10, 1792, which overthrew the monarchy and the Constitution of 1791, began and did its work, if not despite the Girondins, then at least without them.

The insurrection of August 10, 1792, was at once national and social. It was national because of the presence of battalions of *fédérés* from Marseilles and Brittany; it was social because of the participation of the "passive" citizens, who thus demolished the barriers of property qualifications. By bringing about universal suffrage and the arming of passive citizens, this "Second Revolution" integrated the lower classes into the nation and marked the advent of a degree of democracy. After abortive efforts to protest or resist, the former partisans of compromise departed. Lafayette emigrated on August 19, 1792. But, even more, the entrance of the sans-culottes (lower class artisans) onto the stage, by sanctioning the defeat of the Legislative Assembly and the constitutional

monarchy, provoked the opposition of a segment of the bourgeoisie. The radicalization of the Revolution brought on new social and political conflicts.

**The defeat of the Gironde.** The bourgeois Montagnards, realizing that they could not win without the support of the lower classes, allied themselves with the sans-culottes. This intrusion of the people on the political scene presented a serious threat to the interests of the upper bourgeoisie represented by the Gironde. Long months of struggle, from the summer of 1792 to the spring of 1793, were needed before the alliance between Montagnards and sans-culottes would end in the defeat of the failing Gironde.

The conflict became evident immediately after the insurrection of August 10: it crystallized in the desperate opposition between the Gironde and the radical organization that had directed the uprising. The conflict was intensified by the popular invasion of Parisian prisons and the massacre of prisoners from September 2–6, 1792: the insurrectionary leaders did not oppose these killings, and the Girondins accused them of complicity.

It was in this atmosphere of crisis that elections to the National Convention, made necessary by the suspension of the Constitution of 1791, took place. The new assembly met on September 20, 1792—the same day on which the Revolutionary army halted the invasion of the Prussian troops at Valmy, north of Paris. The German poet Johann Wolfgang von Goethe, who witnessed the battle, declared, "From this day and this place dates a new era in the history of the world."

On September 21, 1792, the Convention was at first unanimously in favour of abolishing the monarchy, but there soon developed a rift between the radical Montagnards and the conservative Girondins. Though this rivalry was primarily political, it had, despite their common bourgeois loyalties, an undeniable social character. The Girondins were bent upon defending property and economic freedom from the limitations demanded by the sans-culottes: regulation, taxation, requisition, enforced stabilization of the assignat. Profoundly imbued with the feeling of social hierarchies, the Girondins instinctively recoiled from the people; they reserved the monopoly of government and administration to the propertied classes, even when they declared themselves in favour of popular suffrage. Brissot inveighed against the "disorganizers," by which he meant the Montagnards, the Jacobins, the sans-culottes: "those who would level everything—properties, wealth, the price of staples, the various services owed to society."

Robespierre, leader of the Montagnards, attacked the "false patriots," who "want to set up the Republic only for themselves, who seek to govern only for the advantage of the rich." The Montagnards, and especially the Jacobins, sought to give the national reality a positive content that could rally the support of the popular masses. The Jacobin leader Louis de Saint-Just, in a speech on the food supply on November 29, 1792, emphasized the need "to relieve the people from the state of uncertainty and deprivation which corrupts them. You can, in one moment," he added, "give the French people a fatherland" by halting the ravages of inflation, by assuring the people of their subsistence, by "binding together their happiness and their freedom." Robespierre was even more outspoken on December 2, 1792, in a speech on uprisings over grain in Eure-et-Loir:

And which is the first of these rights? That of existence. The first social law is, therefore, that which assures every member of society of the means of existence; all other laws are subordinate to it.

The necessities of the war and their national sense prompted the Montagnards to join with the sans-culottes; but they would have to be won over by a new social orientation.

The trial of Louis XVI made the conflict between Girondins and Montagnards irreconcilable by defining the new political situation.

The trial began on December 11, with the reading of an act of accusation drawn up by the Jacobin leader Robert Lindet, an account of Louis XVI's duplicity at critical

Arming of the "passive" citizens

The "Second Revolution"

The trial of the King

periods during the Revolution. On December 26, the King's advocate read a speech for the defense, maintaining the thesis of royal inviolability as proclaimed by the Constitution of 1791.

Finally, on January 14, 1793, the Convention deliberated and passed judgment. Unanimously, Louis XVI was found guilty. An "appeal to the people," proposed by the Girondins, was rejected. The death sentence was imposed by a vote of 387 to 334, after an interminable individual roll call. On January 18 the question of reprieve was put to the vote; it was rejected by 380 to 310.

The execution of the King took place on January 21, 1793. It was a decisive blow to monarchist sentiment; it freed the idea of nation from its monarchical form. It made any compromise between the "regicides" and the "appellants" (the deputies who had voted for the appeal to the people) impossible. For the nation, identified with the Republic and founded on the strengthened solidarity between the Montagnard bourgeoisie and the sans-culotte populace, the execution of Louis XVI left no other way of salvation except victory.

The crisis became general: it sealed the fate of the Gironde, which was incapable of overcoming it. On February 1, 1793, the Convention declared war on England and the United Provinces of the Netherlands, then, on March 7, on Spain. Foreign reaction against the Revolutionary nation took the form of the so-called First Coalition, the moving spirit of which was England. The republican armies met with a series of defeats in March 1793. Also in March, a counter-revolutionary rebellion against military conscription broke out in the Vendée, in western France. During these crises, the Gironde refused any concession that would have allowed the people to join in a national upsurge. Finally, a new popular insurrection, encouraged by the Montagnards and the Jacobins, overcame the Girondist resistance: the Parisian sections, in revolt from May 31 to June 2, 1793, demanded and obtained the elimination of the Girondist leaders in the Convention. The role of the Parisian populace and the setback to the upper bourgeoisie emphasize the social aspect of this movement: it opened a new phase of the Revolution.

#### SUCCESS AT HOME AND ABROAD:

##### THE TERROR AND THERMIDOR, 1793-94

**Establishment of the Revolutionary government.** The Gironde had scarcely been eliminated before the Convention, now under the leadership of the Montagnards, found itself caught between two fires. Many of the Gironde's deputies fled to the provinces, where they fomented uprisings against the government in Paris. While the counter-revolution on the right gained fresh vigour from these federalist revolts, the popular movement, exacerbated by the high cost of living and the shortage of food, increased its pressure on the Convention from the left. At the same time, the governmental organization showed that it was incapable of controlling the situation: in the Committee of Public Safety, which was soon to become the chief organ of government, the Parisian leader Georges Danton was negotiating instead of fighting. The Montagnards, already hampered by their own contradictory position, hesitated, fearing to yield too much to the people but unable to fight the war without them. For several months the revolutionary initiative came from the popular masses, whose needs and hatreds drove them on: in the course of the summer of 1793, they imposed the major measures of public safety, from the *levée en masse* (the conscription law, August 23, 1793) to the general Maximum (price control law).

A revolutionary government then seemed all the more indispensable in order to discipline the thrust of the masses and to maintain the alliance with the bourgeoisie, which alone could furnish the necessary officials. On this twofold social base—sans-culottes of the cities and the countryside, and Montagnard and Jacobin bourgeoisie—a revolutionary government was organized piece by piece between July and December 1793: its most far-sighted architects were determined at all costs to preserve the unity of the erstwhile Third Estate—that is, the unity of

the nation. But the aspirations of the sans-culottes were only too likely to conflict with the interests of the bourgeois leaders of the Revolution. The national danger muted class antagonisms for the time being; but it was foreseeable that, as victory became certain, they would reappear.

The popular thrust continued to be exerted in full vigour until the autumn of 1793. It forced the reluctant Convention and its hesitant committees to adopt severe revolutionary measures. On September 11, after great popular demonstrations, a national Maximum was adopted, fixing the price of grain. On the 17th the Law of Suspects was voted. Finally, on September 29, the general Maximum—that is, a controlled economy—was instituted. The essential elements of an emergency regime, at once political and economic, were thus fitted into place, with "coercive force," that is, the Terror, as its essential instrument of control. But what was a victory of the people also had aspects of a governmental success. The popular movement had been canalized and legality safeguarded, when legal terror won the day over direct action by the masses. The Committee of Public Safety, of which Robespierre had been a member from July 27, 1793, had had the foresight to yield in time—but on its own chosen ground: its authority emerged increased. It earlier had got rid of the extreme popular opposition represented by a faction known to moderates as the "Enragés" (madmen). On September 25, in the course of a great debate in the Convention, it silenced the opposition. The results of this governmental consolidation were sanctioned by a decree of October 10, 1793, adopted on a report made by Saint-Just: the Convention declared the government of France "revolutionary until the peace."

From then on, the Terror developed. A series of political trials began in October 1793. On October 3, 22 Girondins were made to appear before the Revolutionary Tribunal, as was Queen Marie-Antoinette, who was guillotined on October 16. When the trial of the Girondins seemed likely to drag on, the Convention decreed that the jurors could pronounce their verdict after three days of discussion; the Girondins were guillotined on October 31. During the last three months of 1793, of 395 accused persons, 117 were sentenced to death. The number of political prisoners in Paris rose from 1,500 about the end of August to 4,595 on December 1, 1793.

During this time, while the Terror was tending to be regularized under increasingly strict control by the Revolutionary government, that government itself had to face a new form of popular radicalism—de-Christianization—which posed a threat to governmental stabilization.

De-Christianization first manifested itself in the *départements*, at the instigation of "representatives on mission" appointed by the Committee of Public Safety. Joseph Fouché, the representative in the Nièvre *département*, forbade all religious ceremonies outside churches, laicized funeral processions and graveyards, the entrances to which he ordered should bear the inscription: "Death is an eternal sleep." At Paris, the Commune acted prudently. The impulse came from elsewhere: de-Christianization was imposed on the Convention from outside. On November 6, 1793, at the demand of the Commune of Menecy, near Corbeil, the Convention decreed that a commune had the right to renounce the Catholic form of worship. From then on de-Christianization gathered momentum. On November 7 the Archbishop of Paris appeared before the Convention and solemnly resigned his episcopal functions. On November 10 a festival of liberty took place in the former Cathedral of Notre-Dame, which was now consecrated to Reason. In a few days, the tide of de-Christianization carried the Parisian sections with it, and the Paris Commune closed the churches.

At the beginning of December, however, the movement was brought to a halt by Robespierre, who feared that de-Christianization might alienate neutral foreign powers. On December 6, 1793, the Convention passed a solemn decree reaffirming the principle of the freedom of worship. De-Christianization diminished but at different rates in different regions.

Despite the limited nature of its success, the Committee of Public Safety emerged the victor; it had checked the popular movement and had saved itself from being overwhelmed by the de-Christianizers. At about the same time the military situation improved. On October 16, 1793, the Austrians had been defeated at Wattignies; on December 13 and 14 the Vendéan rebels were overwhelmed in the city of Le Mans. These successes were ratified on December 4, 1793 (14 Frimaire, Year II, by the new French Revolutionary Calendar) by a constitutive decree of the Revolutionary government. The logic of events led inevitably to reconstituting administrative centralization, to strengthening the authority of the government—a necessary condition for the victory so stubbornly pursued by the Committee of Public Safety.

**The Revolutionary government, 1793–94.** From December 1793 to July 1794 and the so-called Thermidorian reaction, the dictatorship of the Revolutionary government was no longer contested and, indeed, enjoyed a certain stability. The theory of the Revolutionary government was developed especially by Saint-Just in a report of October 10, 1793, and by Robespierre in a report on the principles of the Revolutionary government (December 25, 1793) and one on the principles of political morality that should guide the Convention (February 5, 1794).

The Revolutionary government was a war government: "Revolution is the war waged by liberty against its enemies," wrote Robespierre. Because it is at war, "the revolutionary government requires an extraordinary activity, it must act like a thunderbolt." Hence it has at its command "coercive force," that is, the Terror. "Is force," asked Robespierre, "then made to protect crime?" But the Terror has a corrective—"virtue, the fundamental principle of democratic and popular government." Virtue, "which is to say, love of the fatherland and its laws, the magnanimous devotion which submerges all private interests in the general interest."

The Convention remained "the one centre of impulse of the government." It possessed supreme authority, and the Committees governed under its control. The Committee of Public Safety, re-elected each month, was "at the centre of execution"; the constituted bodies and the public functionaries were "under its immediate purview"; it directed diplomacy and the war, general policy, and the national economy. If certain members of the Committee specialized in certain activities, all of its members together shared in directing policy and conducting the war. As for the Committee of General Security, also re-elected each month, in accordance with the Law of Suspects of September 17, 1793, it had "under its particular purview" . . . "everything relating to persons and to the general and internal police." This Committee directed the political police and Revolutionary justice—it was the minister of the Terror.

The Terror constituted a means of national and revolutionary defense. In the face of an ever-resurgent aristocratic conspiracy, it manifested the "defensive reaction" and the "punitive will" of the Third Estate, though henceforth disciplined by the laws and controlled by the government. Statistical studies made in 1935, by an American historian, Donald Greer, confirm this characterization. The Terror was particularly severe in those areas in which the counter-revolution reached the point of armed insurrection and overt treason. Only 15 percent of the death sentences were pronounced in Paris; 71 percent of the victims of the Terror were attributable to the two chief centres of civil war (19 percent in the south-east, 52 percent in the west). The grounds for the death sentences agree with this regional distribution; in 72 percent of the cases, they reflected armed rebellion. Like the civil war of which it was only an aspect, the Terror purged the new nation of persons considered unsimilable because they were aristocrats or had cast their lot with the aristocracy: 85 percent of them belonged to the Third Estate, 8.5 percent to the nobility, and 6.5 percent to the clergy. In another sense, the Terror contributed to the development of a feeling of national solidarity: for the moment, it muted class antagonisms

and imposed on all alike the sacrifices required by the public safety. In particular, it made it possible to impose the controlled economy necessary to the war effort and to the salvation of the nation. In this sense it was a decisive factor for victory.

The controlled economy instituted by the Convention in the autumn of 1793 was less a reflection of a theoretical concept of social organization than it was a requirement of national defense. It was a matter of feeding, equipping, and arming the men of the *levée en masse*, of provisioning the populations of the cities, when external commerce was reduced to almost nothing by the blockade of France by foreign powers. Requisition fell upon all the material resources of the country, limiting freedom of enterprise. The peasant contributed his grains, his fodder, his wool, his hemp; the artisan, the product of his labour. Under certain exceptional circumstances civilians contributed arms, shoes, blankets, or sheets. All enterprises worked for the nation, under the supervision of the state, in order that production should be at the maximum. Taxation was the necessary complement to requisition. The economic controls of the general Maximum were imposed on commodities of prime necessity (the prices of 1790 increased by one-third) and on wages (the rate of 1790 increased by one-half). At the same time, ceilings were placed on profits: 5 percent for the wholesaler, 10 percent for retailers. Taxation checked speculation and restricted freedom of profit. Nationalization affected production in various degrees—especially the production of armaments and of war matériel in general, as well as foreign commerce—but essentially in proportion to military needs; the Committee of Public Safety refused to nationalize the provisioning of the civil population.

Yet the outlines of social democracy were beginning to appear. Saint-Just brilliantly defined this orientation: "There should be neither rich nor poor." It was not a question of abolishing private property but of limiting the right of inheritance and giving access to property to those who were without it. This led to the sale of national properties in small lots payable in 10 years and the free distribution of common lands in equal shares among the inhabitants of each community. Decrees of Ventôse (February 26 and March 3, 1794) provided that "indigent patriots" should be indemnified by distribution of properties confiscated from counter-revolutionaries. This social legislation was completed by a "law of national beneficence" (May 11, 1794)—nothing short of social security in embryo, for the benefit of the elderly and the sick, of mothers and widows burdened with children. "Let Europe learn that you will no longer tolerate the wretched or an oppressor on French soil," Saint-Just had declared. But to secure this social program at home it was necessary that French armies be victorious abroad.

It was to the republican armies that the Revolutionary government finally devoted all its energies. In the spring of 1794 the troop strength comprised more than 1,000,000 men divided into 12 armies. The officer corps had been purged of anti-Revolutionary elements, discipline had been re-established, and military command was closely subordinated to the civil power. Tactics and strategy had been transformed in accordance with the new political and social necessities. In the spring of 1794, the Revolutionary government had at its disposal an incomparable instrument of war. But it did not survive the victory.

**Fall of the Revolutionary government.** In the fall of 1793, the liquidation of the "Enragés," the halting of de-Christianization, and the veiled attacks against popular sectional organizations in Paris testified to the Revolutionary government's determination to dissociate itself from the popular movement, which, until then, it had followed rather than directed. But it thereby also put itself at the mercy of the Convention, on which it no longer had any means of exerting pressure, and left itself open to attack by its enemies both in and outside the Assembly and in public opinion. Danton, in supporting Robespierre in the matter of de-Christianization, had not been without an ulterior motive; for him, it was a means

Control  
of the  
economy

Incidence  
of the  
Terror

of mitigating the Terror and slowing down the Revolution. Danton's "indulgent" policy was opposed at every point to the popular program of economic controls, all-out war, and extreme terror supported by the Cordeliers. The government attack on de-Christianization and the lessening of the Terror in the *départements* from January 1794 were indications that the governmental committees, though without proscribing the extremists as the "Indulgents" demanded, were at least determined to restrict them little by little. The committees' continued attempt to undermine the popular Parisian organizations, the organ of the pro-sectional democracy, was a part of this program: in this way, they would have moderated the Terror while at the same time preserving it as an instrument. The attitude of the government finally favoured the "indulgent" offensive of the Dantonists.

At the end of the winter of 1793–94 the distinctive features that had evolved in the course of events from the establishment of the Revolutionary government hardened into a fixed pattern. While regulation, taxation, and the control of the economy—all demanded by the sans-culottes and opposed by the propertied classes—barely succeeded in ensuring the provisioning of the Parisian population, except for bread, the requirements of national defense, together with a bourgeois conception of political power, led the Revolutionary government increasingly to assure itself of the passive obedience of the popular organizations and to reduce the sans-culottist democracy to the Jacobin standard. Thus, the end of the winter saw the rise of a twofold social and political unrest that affected the Parisian populace in its material existence and its revolutionary behaviour.

The conflict between the "extremist" and the "indulgent" factions was intensified, the situation at Paris worsened, and a popular explosion appeared probable.

The moment seemed favourable to the radical patriots, led by the Cordeliers, for an act that would rid them of the Moderates and impose their own representatives on the governmental committees and on the Convention. On 24 Ventôse, Year II (March 4, 1794), the Cordeliers proclaimed the necessity for a "sacred insurrection," but the Parisian populace did not follow them. The attempt gave the Revolutionary government the occasion to end its immobility, however: it got rid of the twofold opposition. Arrested, tried, and sentenced, the Cordeliers were guillotined on March 24, 1794. They remain known to history as the Hébertists, from the name of Jacques Hébert, editor of *Le Père Duchesne*, the spokesman for the popular masses. The liquidation of the Indulgents followed: the government committees had no intention of letting themselves be overwhelmed from the right. During the night of March 29–30, the Parisian leaders Danton, Camille Desmoulins, and others were arrested and taken before the Revolutionary Tribunal; they were guillotined on April 5, 1794.

The drama of the Revolutionary calendar month of Germinal was decisive. The situation evolved at headlong speed. The condemnation of the Cordeliers made the sans-culottes lose faith in the Revolutionary government. Despite the executions of Danton and the moderate Indulgents, acts of repression against militants followed the great trials of Germinal, Year II (April 1794). Though of a limited nature, this repression developed a fear complex that paralyzed popular political life. Direct contact between the sans-culottes of the Parisian sections and the Revolutionary government had been broken off.

Freed from all opposition, the Revolutionary government embarked on a far-reaching attempt to regularize institutions and to unify political forces. In the face of the urgent national danger, it had consented to ally itself with the sans-culottes. But it had never accepted their social goals or their political methods. From Germinal to Thermidor (April to July 1794), centralization was increased and the Terror was intensified, especially by a law of 22 Prairial, Year II (June 10, 1794), known as the law of the Great Terror. The purged administrative authorities obeyed; the Convention voted without discussion. But what the Revolutionary government gained in "coercive force" it lost in support. Even the victory

won by the Revolutionary armies at Fleurus (June 26, 1794) was unable to revive popular enthusiasm. Under a factitious unity, indifference or hostility took possession of the popular mind. "The Revolution is frozen," Saint-Just wrote.

The governmental committees, by mitigating the popular movement, had delivered themselves from the fear of an insurrection; but at the same time they freed the Convention and deprived themselves of an instrument of pressure. With victory becoming more certain, there was less reason for the Convention to bear its continued rule. Between the Convention fretting under the yoke and the implacably hostile sans-culottes, the Revolutionary government was as if suspended in the void.

It was under these conditions that there arose a governmental crisis that hastened the downfall of the Revolutionary government: the government committees quarrelled and brought about their own ruin. The Committee of General Security took it ill that the Committee of Public Safety was encroaching on the duties assigned to it. In the Committee of Public Safety itself, division crept in, isolating the Robespierist group. Robespierre resolved to lay the dispute before the Convention.

The end came quickly. On 8 Thermidor Robespierre attacked his enemies before the Convention without naming them: all felt that they were lost. They counter-attacked the next day, 9 Thermidor, Year II (July 27, 1794): a coalition without principles made up of bribed deputies, predatory Terrorists, Indulgents, Moderates, a variety of extremists. Robespierre was ordered arrested. An attempted insurrection by the Paris Commune having failed, he was declared an outlaw. On 10 Thermidor, Robespierre, Saint-Just, and their partisans were guillotined without trial.

It was the end of the Revolution.

Fall of  
Robespierre

#### RETRENCHMENT AND STABILIZATION, EUROPEAN WAR, AND THE RISE OF NAPOLEON, 1795–99

**The Thermidorian reaction and the rule of the Notables, 1794–95.** The Thermidorian period is marked by confused rivalries, whose cross-purposes cannot hide the reality that was at stake: the "men of substance"—soon to be called the Notables—were determined to eliminate from political life the sans-culottes, the artisans, shopkeepers, and journeymen who had temporarily imposed their will upon them. As in 1793, the parliamentary struggles that pitted a radical Montagnard minority against an increasingly large conservative majority, were fundamentally paralleled by a similar conflict in society as a whole. But the popular movement, which had been an accelerating factor of the Revolution in 1793, was now disorganized and on the defensive, only able to fight in retreat.

Central to the Thermidorian policy of reaction was the abandonment of the directed economy. The Convention had accepted the Maximum only under the pressure of popular demonstrations; every sector of the bourgeoisie considered it inimical to its interests. The dislocation of the Revolutionary government and the end of the Terror necessarily brought on a slackening in controls over the economy and, finally, on December 24, 1794, the abolition of the Maximum. But the abandonment of economic restraints brought on the collapse of the assignat and the rise of severe inflation. Debtors and speculators grew rich while creditors (paid in assignats) and bourgeois of the *ancien régime* (living on fixed incomes) were ruined irretrievably. Inflation completed the social revolution. Meanwhile, the masses of the people were engulfed in despair. The winter of the Year III (1794–95) was extremely severe and only increased the wretchedness of the poor. In Paris, because of the scarcity of staples and distrust of the assignat, the price of food and fuel rose alarmingly. On the basis of 100 for 1790, the Parisian cost-of-living index rose from 580 in January 1795 to 720 in March and to 900 in April. In the spring of 1795, despair changed to rage, then to revolt.

Abandonment of a  
controlled  
economy

After the defeat of a first attempt at insurrection on 12 and 13 Germinal, Year III (April 1 and 2, 1795), the people of the Parisian faubourgs (quarters) of Saint-

Elimination of  
opposition

Antoine and Saint-Marcel rose on 1 Prairial, Year III (May 20, 1795), to the cry: "Bread and the Constitution of 1793." After overrunning the Convention, the rebellion quickly subsided for lack of party organization and of leaders capable of consolidating its success. Insurrection flared again the next day, 2 Prairial, with the same lack of results. On 3 Prairial (May 22, 1795) the Faubourg Saint-Antoine was surrounded by the National Guard. The insurgents had nothing to support them but their despair, and they capitulated without fighting. The popular movement was definitely broken.

Military  
victory

In the spring of 1795 the system of the Year II was a thing of the past. The Thermidorians had undone the work of the Revolutionary government. At the same time, they reaped the benefits of its policy of national defense. After the Battle of Fleurus, the republican armies achieved a series of victories. Belgium was conquered, then the left bank of the Rhine and the United Provinces. Meanwhile, the powers of the First Coalition fell out among themselves over the division of Poland. Prussia decided to treat with the French republic. The Treaty of Basel (April 5, 1795) stipulated "peace, friendship, and good understanding between the French Republic and the King of Prussia," the latter recognizing the French possession of German territory west of the Rhine. By the Treaty of The Hague with the Dutch (May 16, 1795), France acquired the right to occupy Dutch territory south of the Rhine and a defensive and offensive alliance. By the Treaty of Basel with Spain (July 22, 1795) France agreed to evacuate previously held territory in Catalonia and the Basque country but annexed the Spanish part of Santo Domingo in the West Indies. No agreement was reached with Austria, which refused to recognize the Rhine as the frontier of France. On October 1, 1795, Belgium was annexed. By that date, the war had been resumed.

The Thermidorians' hope of a general peace grew more remote. Their policy of annexations strengthened the bonds of the Anglo-Austrian coalition, which Russia joined in September 1795. The Thermidorians passed the heavy heritage of the war on to the Directory, the regime established by the new Constitution of the Year III.

Constitu-  
tion of the  
Year III

The voting of the new constitution by the Thermidorian Convention was the result of an alliance between the centre and the right, between the conservative republicans and constitutional monarchists. The declaration of rights that precedes the Constitution of the Year III marks a definite retreat from that of 1789. Article 1 of the Declaration of 1789 ("men are born and remain free and equal in rights") was abandoned. The Thermidorians, more prudent than the members of the Constituent Assembly, were careful to make it clear that only civil equality was in question: "Equality consists in the fact that the law is the same for all" (Article 3). There was no longer any question of the social rights that the Declaration of 1793 had recognized, still less of the right of insurrection. On the contrary, the right of property, which had not been defined at all in the Declaration of 1789, was now made explicit, as, indeed, it had been in the Declaration of 1793: "Property is the right to enjoy and dispose of one's possessions, one's revenues, and the fruit of one's labour and industry" (Article 5). This was to sanction economic freedom in the fullest sense. The declaration of duties that the Thermidorians added to the declaration of rights specified in its Article 8: "The maintenance of property is the foundation upon which the cultivation of the soil, all production, every means of labour and the whole social order rest." The right of suffrage was restricted, but the electoral qualification on the basis of taxation was more liberal than that of 1791: every Frenchman aged 21 who had been domiciled for a year and who paid any tax was an "active citizen."

The creators of the Directory thus sought to stabilize the Revolution on a narrow social base. The most conscious among the people were not content to be unresistingly thrust out of the nation and political life: the radical Gracchus Babeuf's unsuccessful conspiracy to overthrow the government (1796, see below) is proof of

that. But social fear was a powerful instrument in the hands of the regime. The propertied classes feared above all a return to the system of the Year II, when the rich were suspected, traditional social values were subverted, and political democracy was opening the way to social levelling. Along with the lower classes, the aristocracy and a segment of the old bourgeoisie were also excluded from the political system. A law of October 25, 1795, forbade the relatives of émigrés to hold public office. The Directorial bourgeoisie, whose circumstances were moderate, distrusted the bourgeoisie of the *ancien régime*, whose higher social level was nearer to that of the aristocracy. The Thermidorians, transformed into Directorials, were determined that the republic should be bourgeois and conservative; but they rejected the support of the old bourgeoisie, fearing that it would lead them toward a restoration of the monarchy.

On so narrow a social base, the application of the Constitution of the Year III, which provided for a strict separation of powers between the executive Directory and two legislative councils—the Ancients (Conseil des Anciens) and the Five Hundred (Conseil des Cinq-Cents)—with annual elections, could only encounter insurmountable difficulties.

**The first Directory, 1795–97.** Confined to the narrow limits of a republic with a restricted suffrage that excluded both the popular classes and the aristocracy, the new regime remained destined to instability. Equally afraid of royalism and democracy, the Thermidorian Notables had multiplied precautions against the omnipotence of the state; the carefully constructed constitutional equilibrium of the Year III left no alternative but governmental impotence or an appeal to force. The success of the Directorial policy of stabilization depended upon finding a solution for the fundamental problems inherited from the Thermidorian period: the war abroad and the domestic economic and financial problems. As the war dragged on, the currency declined, and the economy was disrupted; a fiscal crisis was added to the monetary crisis, and the treasury was empty.

While the Directory was being established in the autumn of 1795, inflation reached its extreme limit: the value of the assignat dropped to almost nothing. On February 19, 1796, it became necessary to stop issuing—and to abandon—the assignat. A return to metallic currency seemed impossible; and a law of March 18, 1796, created a new paper currency, the mandat territorial, also valid for the purchase of national property. In six months the mandat territorial ran the same course as that which the assignat had run in five years: depreciation reached 90 percent as early as April 20, 1796. In February 1797 the mandat was fixed at 1 percent of its nominal value, officially sanctioning a bankruptcy that had long been a fact. So ended the history of the Revolutionary paper currency.

The social consequences were, as usual, catastrophic for the populace. The winter of the Year IV (1795–96) overwhelmed the earning classes by a dizzying rise in prices. The markets remained empty: the harvests of 1795 were poor; and the peasants would not accept the currency, since requisitions were no longer demanded. Opposition to the Directory grew stronger. In Paris, the former Jacobins reassembled at the Club du Panthéon and discussed re-establishing the Maximum. Revolutionary opposition took a new form when Babeuf organized his Conspiracy of the Equals.

Conspiracy  
of the  
Equals

François-Noël (Gracchus) Babeuf was the first man of the Revolution to perceive a contradiction between the demands of the right to exist and the affirmation of the right of property: going beyond utopian egalitarianism, he advocated the "community of goods and labor." Like the Jacobins and the sans-culottes, he proclaimed that the goal of society was the "general welfare," the Revolution must ensure "equality of benefits" (*l'égalité des jouissances*). But since property necessarily introduced inequality, the only way to attain real equality was to abolish private property. Each man would be bound to the skill or the industry that he had learned, and obliged to deposit the products of it in kind in a common store-

house. A simple administration of the necessities of life would distribute them with the most scrupulous equality.

The organization of the Conspiracy of the Equals during the winter of 1795–96 represented an attempt to make a fact of this “communism of equal distribution.” It was well organized but seems to have had insufficient contact with the popular masses. Denounced by a police spy, Babeuf and his companion Filippo Buonarroti were arrested on May 10, 1796. After trial before the High Court of Vendôme, Babeuf (known as the Tribune of the People) was guillotined on May 27, 1797.

The Conspiracy of the Equals and Babouvism are merely an episode in the history of the Directory, but they exerted a strong influence on the revolutionaries of the 19th century.

The anti-Jacobin repression that followed the Conspiracy of the Equals made the Directory move toward the right and strengthened the power of the royalists. Meanwhile, the economic depression persisted. Contrary to all expectations, the abolition of paper currency did not revive economic activity. People hoarded their metallic currency instead of spending it. The plentiful harvest of 1796 caused agricultural prices to collapse, arousing discontent among the peasants.

While a powerless Directory was falling into greater and greater discredit, the prestige of victory was glorifying its conquering generals, especially the general of the Army of Italy, Napoleon Bonaparte. The days were past when the egalitarian level of the Revolutionary government and the Reign of Terror weighed on the generals: they shook off the control of the executive power and were already giving free reign to their ambitions.

The Italian campaign of 1796–97 decided the outcome of the war against Austria. His brilliant successes in 1796–97 made Bonaparte an independent force. In negotiating the Peace of Campo Formio with Austria (October 17, 1797), he completely disregarded the instructions of the Directory, organizing his conquests in accordance with his personal views. The government's policy was to establish what it regarded as France's natural frontiers, along the Rhine and the Alps. Ignoring this, Bonaparte proceeded to carve up northern Italy, ceding Venice to Austria and creating a French-dominated Cisalpine Republic in Lombardy. The Directory gave way: the domestic situation left it no alternative.

The elections of Germinal, Year V (April 1797), had indeed marked a rout of the Directorials: the monarchist right was considerably reinforced. Since the Constitution of the Year III provided no means of settling the conflict, the Directory, with Bonaparte's backing, decided to appeal to force. By the coup d'état of 18 Fructidor, Year V (September 4, 1797), it annulled the elections, dealing a staggering blow to the liberal system: the right was decimated, the legislative arm humbled and embittered, and the political influence of the army increased. The Directory now found itself more and more the prisoner of the generals, especially of the ambitious Bonaparte.

**The second Directory, 1797–99.** After the coup d'état of Fructidor and the Peace of Campo Formio, the Directory implemented an authoritarian domestic policy that in many ways foreshadowed the Napoleonic regime. But political stabilization proved impossible to realize: between the neo-Jacobin opposition and the royalists, the social base of the Directory remained narrowly Thermidorian. As long as peace prevailed on the Continent, though, the system managed to maintain itself, at the cost of new infringements of the liberal practice of the Constitution of the Year III.

After Fructidor, an emergency regime, sometimes called the Directorial Terror, was instituted; it was a pale reflection of that of the Year II; but it enabled the Directory, for a certain time, to contain the opposition of the right. The Jacobins profited by it and won the elections of Floréal, Year VI. Although the new Jacobin deputies advocated nothing that should have frightened the bourgeoisie, the Directory was determined to have a docile majority. On 22 Floréal, Year VI (May 11, 1798), the directors, claiming power to “judge” the electoral

process, annulled the elections and put the governmental candidates into the councils: by this action, known as the *coup d'état de Floréal*, the Directorial party maintained its control over the legislative majority; but the regime had further discredited itself by this recourse to hypocritical violence.

Yet for a year—from the elections of Floréal, Year VI, to those of Germinal, Year VII (spring 1798–spring 1799)—the Directory regained a certain stability and power; it was able to pursue the work of financial recovery and fiscal reform begun after Fructidor. The bankruptcy of the two-thirds was sanctioned by the law of September 30, 1797; one-third of the debt was “consolidated” by being inscribed in the Great Book, or National Debt Register. This bankruptcy in some measure cleared up the financial situation. Fiscal reorganization tended to put the budget into balance again by more regular and larger receipts. In November 1797, the system of taxation was completely revised, marking a partial return to the indirect taxes abolished by the National Assembly, which weighed most heavily on the poor. The deficit nevertheless persisted. The Directory remained at the mercy of financiers, contractors, and money speculators, who became more demanding than ever: corruption increased. The evil had deep roots, and even Bonaparte's authoritarian regime proved unable to overcome it.

Economic difficulties partly cancelled out the government's laudable efforts. Deflation brought with it high credit rates and falling prices, which, in turn, retarded the economic revival. Metallic currency in circulation was scarce: by the Year IX (1801), only about 1,000,000,000 francs were still circulating, out of 2,500,000,000 in 1789. Credit was expensive: the habitual rate of interest was at least 10 percent and 7 percent per month for short-term loans. The banking setup remained inadequate. The fall in prices that resulted from the deflation was aggravated by abundant harvests from 1796 to 1798; agricultural prices were from one-quarter to one-third lower than those of 1790, which had also been a year of plenty. Discontent increased among the agricultural producers, large landowners, and large farmers, who were generally electors; and the popularity of the regime suffered. As usual, the agricultural crisis had repercussions in industry. Foreign commerce was paralyzed: in 1797 the seagoing merchant fleet was reduced to a tenth of its 1789 strength. Trade with the West Indies dried up; the Near East was closed after the failure of Bonaparte's Egyptian expedition (1798–99, see below).

Under these conditions, the Directory's accomplishments, which chiefly resulted from the efforts of the minister of the interior, François de Neufchâteau, could only be confined to very narrow limits. To stimulate industry in the fall of 1798 he organized the first national exposition at the Champ-de-Mars in Paris. The results were not impressive. Industrial production remained below that of 1789, technical progress was slow, and the concentration of capital remained essentially commercial. The economic weakness of the Directory goes far to account for its political difficulties. Since direction of the economy and limitation of profits were outlawed, there was nothing left but to make the regime, like the armies, live on the conquered countries. But when defeat brought the armies back home in 1799, the Directory had to increase demands on the taxpayers: its unpopularity increased proportionately. Once more the political problem moved to the centre of the stage.

After Campo Formio, only Great Britain remained in opposition to France. Instead of maintaining peace on the Continent to concentrate on this one remaining enemy, the Directory embarked on a policy of continental expansion that destroyed all possibility of stabilization abroad. France, the “great nation,” surrounded itself with “sister republics,” satellite states, politically submissive and economically exploited: the Batavian Republic in the Low Countries; the Helvetic Republic of Switzerland; and the Cisalpine, Roman, and the Parthenopean (Neapolitan) republics in Italy. The Directory allowed itself to be dragged into an invasion of Egypt, un-

Fiscal reform

Napoleon in Italy

The  
Second  
Coalition

der Bonaparte's command, that extended the conflict to the Mediterranean. In the spring of 1799 the war became general. The Second Coalition brought together Britain, Austria, Russia, Naples, and Sweden. Soon Italy and part of Switzerland were lost, and the republic was reduced to fighting on its "natural" frontiers. The danger reawakened the energy of the nation and provoked a final Revolutionary thrust.

Even before the defeats abroad, the elections of the Year VII (1799) took place in a climate unfavourable to the Directory. The general discontent caused by the economic slump, the increase in taxation, and the reintroduction of conscription strengthened the Jacobin minority—but not to the extent that the Thermidorian bourgeoisie lost its position of power. In the crisis that began after the defeats of the spring of 1799, the Thermidorian majority had the last word. On 30 Prairial, Year VII (June 18, 1799) the councils purged the Directory, restored "pronounced" republicans to favour, and imposed measures that were in some ways reminiscent of those of the Year II: strict application of conscription, compulsory loans from wealthy citizens, law of hostages.

Napoleon's  
coup  
d'état

Now fear of the Jacobins, which had manifested itself as early as 1797, increased in scope, and the bourgeoisie determined to be done once and for all with the spectre of the Year II. It was under these conditions that the *coup d'état de 18 Brumaire*, Year VIII, took place, bringing Napoleon Bonaparte to power.

#### THE CONSULATE AND THE EMPIRE, 1799–1815

**The consular republic, 1799–1802.** There was a great deal of continuity between the late Revolutionary period and the Napoleonic period, both in foreign and domestic affairs. The 18th Brumaire was only the last of the coups d'état that characterized the Directory, the logical consequence of an inevitable political evolution. It did bring the republican government under the control of one man to an unprecedented degree; but the evolution of Bonaparte's personal power did not reach its final stage until 1804, when he proclaimed himself emperor. From 1792, when the Girondins had led the nation into war, an inner necessity condemned France to dictatorship, whether collective, as in the Year II, or personal, as under Bonaparte. And even personal dictatorship, no matter how great the genius and the will to power of its promoter, Bonaparte, could not impose itself on the Revolutionary nation except by maintaining the essential accomplishments of 1789.

On the day after Brumaire, Bonaparte's government was installed on the ruins of the representative system that had been established by the Constitution of the Year III.

Constitu-  
tion of the  
Year VIII

The new constitution, that of the Year VIII, was "short and obscure" in accordance with Bonaparte's wishes. It concentrated all power in the hands of Bonaparte himself, who took the title of First Consul. Accountable to no one, he appointed ministers and public officials, initiated laws and regulated their application. The power of the legislature was virtually annihilated by dividing its authority among three assemblies: legislation was debated by the Tribunat, voted on by the Legislative Body (Corps Législatif), and its constitutionality was judged by the Senate. Popular sovereignty was theoretically proclaimed; but except for plebiscites in which the people voted "yes" or "no" on a constitutional text, the right of suffrage consisted in nominating lists of candidates that could be practically ignored. The government appointed representatives and officials as it pleased. On these foundations, the Constitution of the Year X (1802), which established the Consulate for life, and the Constitution of the Year XII (1804), which sanctioned the empire, merely increased the concentration of power in Napoleon's hands.

In reorganizing the state Bonaparte was guided more by opportunism than by any systematic scheme. Above all, it was necessary to ensure the authority of the government and the First Consul. The second Directory had in many respects laid the groundwork for this.

Financial reform was most urgently needed. The first

task was to strengthen the centralized financial administration established in 1798. A law of November 24, 1799, created an administration of direct taxation to ensure a better tax base, whereas collection was restored to the state in 1800. A sinking fund was created to cover the budgetary deficits and war expenses. The need for a banking organization was also felt, particularly to facilitate discounting. On February 13, 1800, the Bank of France was created; this was a private bank formed by an association of financiers. It was not under state control, but the government did entrust it with a part of its funds. In April 1803, it was granted the exclusive privilege of issuing banknotes. The process of re-establishing a sound budget was slow, despite the revived confidence of the moneyed class. In 1802 the budget was balanced; but with the resumption of war in 1803, it was necessary to have recourse to extraordinary sources of income, and the deficit reappeared in 1804.

A monetary reform accompanied the series of financial reforms. The law of Germinal, Year XI (April 1803), fixed the monetary system on the basis of a ratio of 1 to 15½ between silver and gold, confirmed the "franc of Germinal" of 5 grams of silver ⅙ths pure; it established silver as the principal monetary metal but maintained bimetalism.

These reforms were accomplished by a reinforcement of central power. A law of February 1800 took all authority from local institutions. Local elections were abolished and the General Councils of the *départements* were chosen by the First Consul from the list of departmental notabilities, the municipal councils by the prefect from the lists of communal notabilities. But these councils were purely consultative—the representatives of the central power, chiefly the departmental prefects, held all the real authority. The prefectural corps, chosen with the utmost care, was partly inherited from the Revolution; it greatly contributed to the fame of the consular administration. The prefects, in turn, protected the interests of the Notables.

Adminis-  
trative  
central-  
ization

The judicial reform of March 1800 reconciled the judicial hierarchy of courts with the new principles of authority. The election of judges was abandoned; and salaries and advancement were entrusted to the state: despite the proclamation of their irremovability, judges were, in fact, made state functionaries. This reform of the state and the administration endured, and it constitutes the backbone of modern French administration.

In order definitely to consolidate his authority over the nation, Bonaparte had to win military success. He prepared the spring campaign of 1800 by keeping Prussia neutral and detaching Russia from the Coalition. Under these conditions the campaign proved to be essentially a duel between France and Austria. The victory of Marengo (June 14, 1800) and the Treaty of Lunéville (February 9, 1801) ensured peace on the Continent. Isolated, England chose to make peace at Amiens on March 27, 1802. France recovered its colonies, but England recognized neither France's "natural frontiers" nor the vassal republics. Despite this, Bonaparte had fulfilled the essential aspirations of the nation by imposing peace on Europe and preserving the frontiers established by the Revolution. But Bonaparte's ambition was already carrying him further. In the end, the pacification proved to be only a truce.

The victory and the peace increased Bonaparte's popularity. He took advantage of the opportunity to liquidate the opposition and to increase his powers.

An attempt to assassinate him in the rue Saint-Nicaise on December 24, 1800, gave him the excuse he needed to strike at the royalists and Jacobins. Joseph Fouché, his minister of police, proscribed 130 prominent republicans. Three columns were sent to attack the revived royalist insurrection in Brittany: by the end of 1801 it was liquidated. These emergency measures revived the opposition in the assemblies: the Brumairian Notables had wanted a strong government but not despotism. The political crisis of the Year IX (1801) caused a final break between them and the First Consul. Bonaparte's popular dictatorship was incompatible with the Notables' representative

regime, in which the people would delegate their sovereignty without ever abdicating it, and the role of the opposition would be one of information and supervision. But these ideas, though dear to a minority, were at that time foreign to the mass of the French people.

The retrograde evolution of the consular regime was suddenly speeded up in the spring of 1802. In a few months the regime was transformed. On April 8, 1802, a new religious settlement was promulgated (see below); on the 26th amnesty was granted to the émigrés and their unsold properties restored to them; on May 1, the creation of lycées (state-supported schools) was decided; the Légion d'Honneur (an order of merit for which all citizens were eligible) was instituted on the 19th; on May 20, slavery was re-established in the colonies; finally, from May 8 to August 14, the steps were taken that established Bonaparte's power as the Consulate for life. The consular republic was being transformed into a monarchy.

To complete his domestic pacification and to consolidate his power, Bonaparte thought it expedient to deprive the counter-revolution of the weapon of religion; it was necessary to rally Roman Catholicism and the refractory clergy to the new regime and so to annul the separation of church and state. The result was the Concordat (agreement with the papacy) that had been signed on July 16, 1801, and was promulgated on April 8, 1802, accompanied by a law defining the relationship of the state to religious bodies. Roman Catholicism was recognized as the religion of the majority, but freedom of worship was guaranteed. The conclusion of peace with the church reinforced Bonaparte's personal power.

The "organization of the nation" was directed to the same end. The institution of lycées (May 1, 1802) was to aid recruitment into the "social bodies," of which the Legion d'Honneur presented the first example, while at the same time the social regulations of the system were defined by the Code Civil. The Code Civil, not promulgated until March 21, 1804, but under discussion from 1801, actually represents the keystone of the structure and, as it were, the judicial monument of the new society. To the benefit of the bourgeoisie, it reconciled the concepts of the old written, or customary, law with those of Revolutionary law. Bourgeois in inspiration, the Code Civil was above all concerned with property, defined as a natural right anterior to society. It also reflected the traditional conception of the family: it accorded great importance to the marriage contract and to problems of inheritance. The authority of the father over his wife and children, weakened by the Revolution, was reinforced. But, in the spirit of the Revolution, the Code Civil sanctioned the disappearance of the feudal aristocracy, proclaiming the principles of 1789: freedom of the person, equality of all before the law, freedom of conscience and secularity of the state, freedom of work. In the eyes of the rest of Europe it appeared as the symbol of Revolution; and wherever it was applied, it contributed to establishing the essential characteristics of contemporary society.

In 1802 the authoritarian character of the consular regime provoked a resurgence of opposition, both in the assemblies and in the army. It was promptly overcome and the ground was cleared for a reinforcement of the power of the First Consul. When the Peace of Amiens was announced to the assemblies in May 1802, the Tribunat expressed the wish that Bonaparte should be given "a signal pledge of the gratitude of the nation." Seizing the initiative, Bonaparte organized a "consultation" of the French people to decide the question of whether Napoleon Bonaparte should be "consul for life": there were 8,374 opposing votes to 3,500,000 in favour.

A senatorial law of August 4, 1802, considerably increased Bonaparte's powers, giving him the right to make peace and war, the right of pardon, the right to appoint his successor. By the end of 1802 no one could any longer doubt Napoleon's ambitions: the republic was a thing of the past. From August 15, 1802, Napoleon's birthday was celebrated as a national holiday; and in 1803, his image appeared on coins.

**The Grand Empire and Napoleonic despotism, 1802–12.** The Peace of Amiens, which had allowed Bonaparte to further consolidate his dictatorial power, did not last long. Napoleon's ambition and England's desire to remain the undisputed mistress of the seas rapidly brought the resumption of hostilities.

The peace had revived the French economy, for foreign commerce especially was favoured by French domination of the Continent. This was a disappointment to the English capitalists, who realized that the economic war was continuing: they turned from a peace that was not to their profit. Bonaparte's colonial policy alarmed Britain even more. Colonial products were one of the essential objects of large-scale commerce. Bonaparte was determined to restore this source of wealth to France by recovering the Antilles. Nor did Napoleon's aggressive continental policy reassure the British, who looked on, irritated but powerless, while the French expansion continued. War was resumed in May 1803.

The first result of the war was to enable Bonaparte to re-establish a monarchy of his own. Since the initiative for the break lay with Britain, his prestige did not suffer; the British were accused of wanting to drive France back to its old frontiers. This conviction was strengthened by the support the British government gave to the royalists.

The "Anglo-royalist" conspiracy gave Bonaparte an opportunity to get rid of the opposition: Louis-Antoine-Henri de Bourbon-Condé, duc d'Enghien, a leading royalist, was seized at Ettenheim, in Baden, on the night of March 14–15, 1804, convicted of conspiracy against Napoleon by a court-martial, and shot on the morning of March 21 outside of the fortress of Vincennes. His execution or assassination sealed the rupture with the royalists and hastened the establishment of the Napoleonic empire; a new hereditary monarchy would discourage the conspirators. On April 30, 1804, a motion was made in the Tribunat "that Napoleon Bonaparte be declared Emperor and the imperial dignity be declared hereditary in his family." The Senate approved. The Constitution of the Year XII (May 18, 1804) proclaimed the establishment of the empire; in the plebiscite that followed, it was approved by more than 3,500,000 voters against about 2,500.

The coronation of the Emperor by Pope Pius VII on December 2, 1804, made it clear that Napoleon was not satisfied only with the ratification by the people but that he intended to consecrate the new legitimacy by the restoration of divine right. In the last analysis, the proclamation of the empire was the final phase of an evolution, rather than a sudden mutation. The road toward monarchy had been taken long before the rupture of the peace in 1803. The concentration of powers and dictatorship to safeguard the basic achievements of 1789 and the social preponderance of the middle class had prepared the way for it. But Napoleon's ambition, fed by his personal adherents and by the passivity of the great majority, went beyond these safeguards. Instead of moderately extending France's frontiers, he extended his conquests inordinately by an endless series of wars. He broke with equality and undertook to create a new aristocracy. Yet Napoleon could not blot out the indelible mark of the Revolutionary origin of his power: in the eyes of aristocratic Europe, he remained the soldier of the Revolution.

His campaign of conquest has been variously interpreted as the defense of the ever-threatened natural frontiers, the building of a European empire, the pursuit of a mirage, or simply ambition. Georges Lefebvre, the last great historian of Napoleon, returns to "ambition" but with the qualification: "the heroic attraction of risk, the bewitching seduction of a dream, the irresistible drive of a temperament."

The Third Coalition was broken by the campaign of 1805 and by the victories of Ulm and of Austerlitz—the latter, December 2, 1805. Meanwhile, Britain retained control of the seas, having crushed the French fleet at Trafalgar (October 21, 1805). The Treaty of Pressburg left Napoleon free to organize the Confederation of the Rhine: the Germanic Holy Roman Empire disappeared. When the Fourth Coalition was organized, Napoleon de-

Renewal  
of the war

The Code  
Napoléon

Defeat at  
Trafalgar

feated it in two campaigns. In six days two Prussian armies were annihilated in two simultaneous victories on October 14, 1806: at Auerstädt, by Louis-Nicolas Davout and, at Jena, by Napoleon himself. At Berlin, Napoleon decreed a continental blockade against British goods. After defeating the Russians at the Battle of Friedland (June 14, 1807) Napoleon made an alliance with Tsar Alexander I at Tilsit on July 7.

Spain's revolt against French rule, aided by Britain (1808), signalled the beginning of national resistances and favoured the formation of a fifth coalition. Napoleon was again the victor: defeated at Wagram (July 5–6, 1809), Austria signed the Treaty of Schönbrunn (October 14).

Napoleon was now at the apogee of his power. He was "Emperor of the French, King of Italy, Protector of the Confederation of the Rhine, Mediator of the Swiss Confederation." His brothers reigned throughout the empire: Joseph in Madrid, Louis in Holland, Jérôme in Westphalia, and his brother-in-law Joachim Murat at Naples. The Tsar was his ally. Soon the Habsburgs were to give him Archduchess Marie-Louise as his wife. In 1811 an imperial heir was born, and Napoleonic Europe enjoyed two to three years of peace: the imperial system, though still uncompleted, tended to become stabilized.

The imperial government perfected the work of the Consulate and increased administrative despotism. Public freedoms disappeared; only freedom of conscience survived, always on condition that the officially recognized cults (Christian and Jewish) should not be attacked nor atheism publicly professed. The restoration of monarchical power was accompanied by the creation of a new court, which, however, lacked the easy elegance of the court of the *ancien régime*. All the governmental machinery tended to strengthen the executive. The Tribunat disappeared in 1807; the Corps Législatif functioned in closed sessions; the Senate was quiescent. The Emperor alone governed. Administrative centralization increased. The prefects, kept well in hand by the central authority, enforced the rule of uniformity everywhere, although the government's control of the economy has been exaggerated. The Emperor was wise enough and skillful enough to reconcile divergent interests, satisfying material wants in order to silence the spirit of criticism. The press and the publishing industry were strictly supervised. Control also was exercised through the Imperial University, organized in 1807–08. Napoleon was determined to have at his disposal "a corps to regulate public morality and policy" in the manner of "the corps of *'ulamā's* among the Turks." Hence, public instruction was organized as a monopoly of the state, strictly disciplined and hierarchical, with the essential function of supplying officers and civil servants. Finally, control was exercised through the churches, which were bound to the state by the Concordat and the Organic Articles.

The influence of religion and the official system of education tended to strengthen the social hierarchy that Napoleon had sought to re-establish from the period of the Consulate. The preponderance of the Notables assured him the obedience of the immense populace of the countryside, as well as urban journeymen, petty artisans, workmen, and servants.

Going still further, after organizing the imperial court, from 1806 to 1808, Napoleon instituted a "nobility of the Empire" that received its statute on March 1, 1808: a nobility of office, dispensed by the master alone, hereditary, and accompanied by an income permitting the bearer of the title to maintain his rank. The authoritarian evolution of the regime, together with the Austrian marriage, accentuated this "aristocratization," and Napoleon might well have moved further in this direction if he had had time. But it was the most fragile part of Napoleon's great work. Nothing could fill the gulf created by the Revolution: despite the master's will, the imperial nobility and the old aristocracy did not fuse. The Emperor's efforts in the social area were effective only insofar as they followed the direction of historical evolution. More durable than the new nobility was the consolidation of the social preponderance of the bourgeoisie. By the role they played in the functioning of the system, the bour-

geois Notables increased their influence and their prestige.

Yet the more they asserted themselves socially, the more they turned away from a regime that had stripped them of all political prerogatives. Economic distress, largely occasioned by the continental blockade, increased the disaffection of the various categories of the well-to-do, whereas the popular masses found the burden of conscription and of the *droits réunis* (indirect taxation) intolerable. The Emperor's prestige remained intact; and the nation still obeyed, but it was weary. Under these conditions Napoleon threw himself into a new adventure: the Russian Campaign.

**Collapse of the Napoleonic system, 1812–15.** The Grand Empire and the continental system had been constructed on the basis of the Grand Army's (Grande Armée) victories and of Napoleon's military genius: when that genius finally vacillated, the ruin of the entire system quickly followed.

Because the very existence of the empire was founded on war, each new campaign again called it into question. The Russian Campaign, undertaken in 1812, was intended to crown the whole enterprise by doing away with the last resistance on the Continent. It ended in disaster. Napoleon entered Moscow on September 14, 1812, and ordered a retreat on October 19. In December the Grand Army no longer existed; and with it, the rampart of the empire vanished. The catastrophe was irreparable. Napoleon was not discouraged: he set about building a new army, while a sixth coalition against France was being formed. Renewed opposition by Prussia, and then Austria, brought the loss of Germany. Though the Emperor was victorious again at Lützen and Bautzen during the first campaign of 1813 and conquered again at Dresden, he was finally overwhelmed in the course of his autumn campaign at the Battle of Leipzig (October 16–19, 1813). It was the end of the Grand Empire: the French armies retreated across the Rhine.

The French Campaign (1814) was brief. It was in vain that Napoleon's genius asserted itself in a final recrudescence. Beset by a political opposition that was strengthened by his defeats, he improvised the new Army of Marie-Louise. Manoeuvring between the enemy armies, one of which was advancing through the valley of the Marne, the other through the valley of the Seine, he won a series of successes but could not prevent the allies from entering Paris on March 31, 1814. He abdicated on April 6, and after taking leave of his Old Guard in the celebrated episode of the "Farewell at Fontainebleau," he departed for his small Kingdom of Elba.

The victorious allies installed Louis XVI's brother, the Comte de Provence, as King Louis XVIII. Louis was forced to sanction the principles of 1789 and the Napoleonic reforms in a constitution known as the Charter of 1814. Reprisals taken by the returned émigrés against their enemies and the disappointment of royalists at the moderate character of the new regime hindered the functioning of the government. For Napoleon, this was the opportunity for a last adventure. Returning suddenly from Elba, he reached Paris on March 20 and took control again for the period known as the Hundred Days. War decided his fate: on June 18, 1815, the defeat at Waterloo sealed Napoleon's destiny. He abdicated for the second time on June 22; on July 15 he surrendered to the British and was exiled to the remote island of Sainte-Helena in the South Atlantic, where he died in 1821. The Emperor's exile crowned his memory with the magic of legend: a martyred victim of the kings, for the French people he became the hero of the Revolutionary nation.

#### THE NATURE AND SIGNIFICANCE OF THE REVOLUTION

The French Revolution and its Napoleonic epilogue represent the most striking episode in the history of modern revolutions. It doubtless owes this exceptional position to the obstinacy of the aristocracy, which, clinging desperately to its feudal privileges, refused all compromise, and to the contrary relentlessness of the peasant masses. The bourgeoisie had not wanted the ruin of the aristocracy; the refusal of compromise and the counter-revolu-

Creation of the "nobility of the empire"

Invasion of Russia

Defeat at Waterloo

Destruction of  
feudalism

tion obliged it to pursue the destruction of the old order. But it was able to do this only by allying itself with the rural and urban masses, which had to be satisfied; the Revolution became popular, the Reign of Terror made a clean sweep, feudalism was irremediably destroyed, and democracy temporarily instituted.

The French Revolution swept away all the survivals of feudalism, it freed the peasants from seigneurial dues and ecclesiastical tithes, it destroyed the corporate monopolies, and it established free trade within the country. These accomplishments marked a decisive phase on the road to a new economy. The essential driving force in the Revolutionary process lay in the popular masses, rural and urban. The political instrument was the Jacobin dictatorship of the lower and middle bourgeoisie, with the support of the lower classes. The popular and peasant revolution was at the heart of the bourgeois revolution and drove it forward.

At the same time, the French Revolution shattered the structure of the state developed under the *ancien régime*, swept away the vestiges of the old autonomies, and destroyed local privileges and provincial particularisms. Further, from the Directory to the empire, it made possible the inauguration of a modern state corresponding to the interests and demands of the new society.

From this twofold point of view, the French Revolution was far from being a myth, as the English historian Alfred Cobban claimed in his *The Myth of the French Revolution* (1955). No doubt "feudalism" in the medieval sense of the word no longer corresponded to anything in 1789. But for contemporaries—the bourgeoisie and still more the peasantry—the term feudalism expressed a reality that they knew only too well (feudal rights and dues, seigneurial authority) and that was finally swept away. It is also true that the bourgeois Revolutionary assemblies were not made up of businessmen but of men from the liberal professions and public functionaries. But this provides no argument against the importance of the Revolution in the inauguration of the new economic order. The essential fact is that the old system of production and exchange was destroyed and that the French Revolution proclaimed freedom of enterprise and of profit without any restrictions, thus opening the way to the new economy. The history of the 19th century would prove that this was no myth.

A necessary phase in the general transition from the traditional European society and economy to the new, the French Revolution also has its own peculiar characteristics, which are due to the specific characteristics of French society at the end of the *ancien régime*.

In recent years, certain historians, notably the American historian R.R. Palmer and the French historian Jacques Godechot, have seen the French Revolution as part of a wider European phenomenon. According to the latter in his book *La Grande Nation* (1956), the Revolution was "only an aspect of Western—or, more precisely, Atlantic—Revolution which began in the British colonies in America shortly after 1763, and was continued by revolutionary movements in Geneva, the Netherlands, and Ireland before it reached France between 1787 and 1789; from France it returned to the Netherlands and spread to the Rhineland, Switzerland, and Italy."

But to put the French Revolution and the comparatively minor revolutions in late-18th-century Geneva, the Netherlands, and Ireland in the same class ignores the dimensions and scope of the French upheaval, as well as its dramatic character. The "Atlantic" conception of the French Revolution, by emptying it of all specific content (economic: anti-feudal and capitalistic; social: anti-aristocratic, simultaneously bourgeois and popular; national: one and indivisible), would completely deny validity to a half century of French Revolutionary historiography, from Jean Jaurès to Georges Lefebvre. (A.L.S.)

## VI. France since 1815

### THE RESTORATION AND CONSTITUTIONAL MONARCHY

**Constitutionalism and reaction, 1815–30.** *Louis XVIII, 1815–24.* King Louis XVIII's second return from exile was far from glorious. Neither the victorious powers

nor Louis's French subjects viewed his restoration with much enthusiasm, yet there seemed to be no ready alternative to Bourbon rule. The allies avenged themselves for the Hundred Days by writing a new and more severe Treaty of Paris. France lost several frontier territories, notably the Saar Basin and Savoy (Savoie), that had been annexed in 1789–92; a war indemnity of 700,000,000 francs was imposed; and, pending full payment, eastern France was to be occupied by allied troops at French expense.

Within France, political tensions were exacerbated by Napoleon's mad gamble and by the mistakes committed during the First Restoration. The problem facing the Bourbons would have been difficult enough without these tensions, namely, how to arrive at a stable compromise between those Frenchmen who saw the Revolutionary changes as irreversible and those who were determined to resurrect the *ancien régime*. The reactionary element, labelled ultra-royalists (or simply "ultras"), was now more intransigent than ever and set out to purge the country of all those who had betrayed the dynasty. A brief period of White Terror in the south claimed some 300 victims; in Paris, many high officials who had rallied to Napoleon were dismissed, and a few eminent figures, notably Marshal Michel Ney, were tried and shot. The King refused, however, to scrap the Charter of 1814, in spite of ultra pressure. When a new Chamber of Deputies was elected in August 1815, the ultras scored a sweeping victory; the surprised King, who had feared a surge of antimonarchical sentiment, greeted the legislature as *la chambre introuvable* ("the incomparable chamber"). But the political honeymoon was short-lived. Louis was shrewd enough, or cautious enough, to realize that ultra policies would divide the country and might in the end destroy the dynasty. He chose as ministers, therefore, such moderate royalists as Armand-Emmanuel du Plessis, duc de Richelieu, and Élie Decazes—men who knew the nation would not tolerate an attempt to resurrect the 18th century.

There followed a year of severe tension between these moderate ministers and the ultra-dominated Chamber—tension and unrest that made Europe increasingly nervous about the viability of the restored monarchy. Representatives of the occupying powers began to express their concern to the King. At last, in September 1816, his ministers persuaded him to dissolve the Chamber and order new elections, and the moderate royalists emerged with a clear majority. In spite of ultra fury, several years of relative stability ensued. Richelieu and Decazes, with solid support in the Chamber, could proceed with their attempt to pursue a moderate course. By 1818 they were able, thanks to loans from English and Dutch bankers, to pay off the war indemnity and thus to end the allied occupation; at the Congress of Aix-la-Chapelle France was welcomed back into the Concert of Europe. In domestic politics, there were some signs that France might be moving toward a British-style parliamentary monarchy, even though the Charter had carefully avoided making the King's ministers responsible to the Chamber of Deputies. In the Chamber something anticipating a party system also began to emerge: ultras on the right, independents (or liberals) on the left, constitutionalists (or moderates) in the centre. None of these factions yet possessed the real attributes of a party—disciplined organization and doctrinal coherence. The most heterogeneous of all was the independent group—an uneasy coalition of republicans, Bonapartists, and constitutional monarchists brought together by their common hostility to the Bourbons and their common determination to preserve or restore many of the Revolutionary reforms.

The era of moderate rule (1816–20) was marked by a slow but steady advance of the liberal left. Each year one-fifth of the Chamber faced re-election, and each year more independents won seats, despite the narrowly restricted suffrage. The ultras, in real or simulated panic, predicted disaster for the regime and the nation; but the King clung stubbornly to his favourite, Decazes, who by now was head of the government in all but name, and Decazes, in turn, clung to his middle way.

The reactionaries

The advance of  
the left

The uneasy balance was wrecked in February 1820 by the assassination of the King's nephew, Charles-Ferdinand, duc de Berry. The assassin, a fanatical Bonapartist, proudly announced his purpose: to extinguish the royal line by destroying the last Bourbon still young enough to produce a male heir. In this aim he failed, for Caroline, duchesse de Berry, seven months later bore a son, whom the royalists hailed as "the miracle child." But the assassin did bring to an end the period of moderate rule and returned the ultras to power. In the wave of emotion that followed, the King dismissed Decazes and manipulated the elections in favour of the ultras, who regained control of the Chamber and dominated the new Cabinet headed by one of their leaders, Joseph, comte de Villèle.

This swing toward reaction goaded some segments of the liberal left into conspiratorial activity. A newly formed secret society called the *Charbonnerie*, which borrowed its name and ritual from the Italian *Carbonari*, laid plans for an armed insurrection, but their rising in 1822 was easily crushed. One group of conspirators—"the four sergeants of La Rochelle"—became heroic martyrs in the popular mythology of the French left. Subversion gave the government an excuse for intensified repression: the press was placed under more rigid censorship and the school system subjected to the clergy.

Meanwhile, the ultras were winning public support through a more assertive foreign policy. Spain had been in a state of quasi-civil war since 1820, when a revolt by the so-called liberal faction in the army had forced King Ferdinand VII to grant a constitution and to authorize the election of a parliament. The European powers, disturbed at the state of semi-anarchy in Spain, accepted a French offer to restore Ferdinand's authority by forcible intervention. In 1823 French troops crossed the Pyrenees and, despite predictions of disaster from the liberal left, easily took Madrid and re-established the King's untrammelled power. This successful adventure strengthened the ultra politicians and discredited their critics. In the elections of 1824 the ultras increased their grip on the Chamber and won a further victory in September 1824 when the aged Louis XVIII died, leaving the throne to a new king who was the very embodiment of the ultra spirit.

*Charles X, 1824-30.* Charles X, the younger brother of Louis XVIII, had spent the Revolutionary years in exile and had returned embittered rather than chastened by the experience. What France needed, in his view, was a return to the unsullied principle of divine right, buttressed by the restored authority of the established church. The new king and his Cabinet—still headed by Villèle—promptly pushed through the Chamber a series of laws of sharply partisan character. The most bitterly debated of these laws was the one that indemnified the émigrés for the loss of their property during the Revolution. The cost of the operation—almost 1,000,000,000 francs—was borne by government bondholders, whose bonds were arbitrarily converted to a lower interest rate. A severe press law hamstrung the publishers of newspapers and pamphlets; another established the death penalty for sacrilegious acts committed in churches.

Along with these signs of reaction went a vigorous campaign to reassert the authority of the Catholic Church, which had been undermined by Enlightenment skepticism and by the Revolutionary upheaval. Under the Bourbons, several new missionary orders and lay organizations were founded in an effort to revive the faith and to engage in good works. Catholic seminaries began to draw increasing numbers of students away from the state lycées. Charles X threw himself enthusiastically into the campaign for Catholic revival. The anticlericals of the liberal left were outraged, and even many moderates of Gallican sympathies were perturbed. Rumours spread that the King had secretly become a Jesuit and was planning to turn the country over to "the men in black."

King Charles and his ultra ministers might nevertheless have remained in solid control if they had been shrewd and sensitive men, aware of the rise of public discontent and flexible enough to appease it. Instead, they forged stubbornly ahead on the road to disaster. Villèle, though a talented administrator, lacked creative imagination and

charismatic appeal. As the years passed, his leadership was increasingly challenged even within his own ultra majority. A bitter personal feud between Villèle and Chateaubriand, the most colourful of the ultra politicians, undermined both the ministry and the dynasty. This internal conflict contributed to Villèle's downfall; the elections of 1827 brought a sharp resurgence of liberal and moderate strength. The King patched together a disparate ministry of moderates and ultras headed by an obscure official, Jean-Baptiste, vicomte de Martignac. But Martignac lacked Charles's confidence and failed to win the support of the more moderate leftists in the Chamber. In 1829 the King brusquely dismissed him and restored the ultras to power.

The delayed consequences of this act were to be fatal to the dynasty. The King, instead of entrusting power to an able ultra such as Villèle or a popular one such as Chateaubriand, chose a personal favourite, Jules-Auguste-Armand-Marie, prince de Polignac, a fanatical reactionary. The makeup of the Cabinet, which included several members of the most bigoted faction of "ultra-ultras," seemed to indicate the King's determination to polarize politics. That, in any case, was the immediate result. On the left, the mood turned aggressively hostile; the republicans of Paris began to organize; an Orleanist faction emerged, looking to a constitutional monarchy headed by the King's cousin, Louis-Philippe, duc d'Orléans. The liberal banker Jacques Laffitte supplied funds for a new opposition daily, *Le National*, edited by a young and vigorous team whose most notable member was Adolphe Thiers. A confrontation of some sort seemed inevitable.

Some of Polignac's ministers urged a royal coup d'état at once, before the rejuvenated opposition could grow too strong. Instead, the King procrastinated for several months, offering no clear lead or firm policy. When the Chamber met at last in March 1830, its majority promptly voted an address to the throne denouncing the ministry. The King retaliated by dissolving the Chamber and ordering new elections in July. Both Charles and Polignac hoped that pressure on the electors, plus foreign policy successes, might shape the outcome. Such a success was won at just the opportune moment: news came that Algiers had fallen to a French expeditionary force sent to punish the Bey for assorted transgressions. But even this brilliant victory could not divert the fury of the King's critics. The opposition won 274 seats, the ministry 143. Charles's alternatives were now clear: to substitute a moderate for Polignac and to accept the role of constitutional monarch or to risk a royal coup d'état that would leave the Charter of 1814 in tatters. Without hesitation he chose the second path. King and ministers prepared a set of decrees that dissolved the newly elected Chamber, further restricted the already narrow suffrage, and stripped away the remaining liberty of the press. These July Ordinances, made public on the 26th, completed the polarization process and ensured that the confrontation would be violent.

*The Revolution of 1830.* The July Revolution was a monument to the ineptitude of Charles X and his advisers. At the outset, few of the King's critics imagined it possible to overthrow the regime; they hoped merely to get rid of Polignac. As for the King, he naively ignored the possibility of serious trouble. No steps were taken to reinforce the army garrison in Paris; no contingency plans were prepared. Instead, Charles went off to the country to hunt, leaving the capital weakly defended. During the three days known to Frenchmen as *Les Trois Glorieuses* (July 27-29), protest was rapidly transmuted into insurrection; barricades went up in the streets, manned by workers, students, and petty bourgeois citizens (some of them former members of the National Guard, which Charles, in pique, had disbanded in 1827). On July 29, some army units began to fraternize with the insurgents. The King, on July 30, consented at last to dismiss Polignac and to annul the July Ordinances; but the gesture came too late. Paris was in the hands of the rebels, and plans for a new regime were crystallizing rapidly.

As the insurrection developed, two rival factions had

The polarization of politics

The  
abdication  
of  
Charles X

emerged. The republicans—mainly workers and students—gained control of the streets and took over the Hôtel de Ville, where on July 29 they set up a municipal commission. They looked to the venerable Marquis de Lafayette as their symbolic leader. The constitutional monarchists had their headquarters at the newspaper *Le National*; their candidate for the throne was Louis-Philippe, duc d'Orléans. Louis-Philippe was at first reluctant to take the risk, fearing failure and renewed exile; Adolphe Thiers undertook the task of persuading him and succeeded. On July 31 Louis-Philippe made his way through a largely hostile crowd to the Hôtel de Ville and confronted the republicans. His cause was won by Lafayette, who found a constitutional monarchy safer than the risks of Jacobin rule; Lafayette appeared on the balcony with Louis-Philippe and, wrapped in a tricolour flag, embraced the duke as the crowd cheered. Two days later Charles X abdicated at last, though on condition that the throne pass to his grandson, "the miracle child." But parliament, meeting on August 7, declared the throne vacant and on August 9 proclaimed Louis-Philippe "king of the French by the grace of God and the will of the nation."

**The July monarchy.** The renovated regime (often called the July monarchy or the bourgeois monarchy) rested on an altered political theory and a broadened social base. Divine right gave way to popular sovereignty; the social centre of gravity shifted from the landowning aristocracy to the wealthy bourgeoisie. The Charter of 1814 was retained but no longer as a royal gift to the nation; it was revised by the Chamber of Deputies and in its new form imposed on the King. Censorship was abolished; the tricolour was restored as the national flag, and the National Guard was resuscitated. Catholicism was declared to be simply the religion "of the majority of Frenchmen," the voting age was lowered to 25, and the property qualification reduced to include all who paid a direct tax of 200 (formerly 300) francs. The suffrage was thus doubled, from about 90,000 to almost 200,000.

The new king seemed admirably suited to this new constitutional system. The "Citizen King" was reputed to be a liberal whose tastes and sympathies coincided with those of the upper bourgeoisie. He had spent the Revolutionary years in exile but was out of sympathy with the irreconcilable émigrés; and since his return, his house in Paris had been a gathering place for the opposition. Yet in spite of appearances, Louis-Philippe was not prepared to accept the strictly symbolic role of a monarch who (in Thiers's phrase) "reigns but does not govern." His authority, he believed, rested on heredity and not merely on the will of the Chamber; his proper function was to participate actively in decision making and not merely to appoint ministers who would govern in his name. As time went by, he was increasingly inclined to choose ministers who shared his view of the royal power. The Orleanist system thus rested on a basic ambiguity about the real locus of authority.

The  
leadership  
of Guizot

In the Chamber two major factions emerged, known by the rather imprecise labels right-centre and left-centre. The former group, led by the historian François Guizot, shared the King's political doctrines; it saw the revised Charter of 1814 as an adequate instrument of government that needed no further change. The left-centre, whose ablest spokesman was the kingmaker Adolphe Thiers, saw 1830 as the beginning rather than the culmination of a process of change. It favoured restricting the King's active role and broadening the suffrage to include the middle strata of the bourgeoisie. These differences of viewpoint, combined with the King's tendency to intrigue, contributed to chronic political instability during the 1830s.

The decade of the 1830s was marked also by repeated challenges to the regime by its enemies on the right and the left and by a series of attempts to assassinate the King. Both the ultras (who now came to be called legitimists) and the republicans refused to forgive "the usurper" of 1830. In 1832 the Duchesse de Berry, mother of "the miracle child," landed clandestinely in southern France in an effort to spark a general uprising; but the scheme collapsed, and most legitimists withdrew into

sullen opposition. More serious was the agitation of the republicans, fed by rising labour discontent. In the most serious of these outbreaks (Lyons, 1831), 15,000 workers confronted the National Guard in the streets and suffered some 600 casualties before capitulating. Again, in 1834 there were serious disturbances in Lyons and Paris. In 1836 it was the turn of the Bonapartist pretender to challenge the regime. Since Napoleon's death in 1821, a legend had rapidly taken shape around his name. No longer detested as a ruthless autocrat who had sacrificed a generation of young Frenchmen on the battlefield, he became transmuted into the Little Corporal who had risen to the heights by his own talents and had died a victim of British jealousy. The Emperor's nephew Louis-Napoléon Bonaparte presented himself as the true heir; he crossed the frontier in 1836 and called on French troops in Strasbourg to join his cause. The venture failed ignominiously, as did also a second attempt on the Channel coast in 1840. Louis-Napoléon was condemned to prison for life but managed in 1846 to escape to England. Interspersed with these attempts at political risings were individual attacks on the King's person; the most elaborate of these plots was the one organized by a Corsican named Giuseppe Fieschi in 1835.

By 1840, however, the enemies of the regime had evidently become discouraged, and a period of remarkable stability followed. François Guizot emerged as the key figure in the ministry; he retained that role from 1840 to 1848. One of the first Protestants to attain high office in France, Guizot possessed many of the moral and intellectual qualities that marked this small but influential minority. Hard-working and intelligent, Guizot was devoted to the service of the King and to the defense of the status quo. He was convinced that the wealthy governing class was an ideal natural elite to which any Frenchman might have access through talent and effort. To those who complained at being excluded by the property qualification for voting and seeking office, Guizot's simple reply was "*enrichissez-vous!*" ("Get rich!"). Guizot was a shrewd political manipulator and kept a majority in the Chamber through judicious appointments of deputies or their friends to government posts.

Guizot shared with Louis-Philippe a strong preference for a safe-and-sane foreign policy. The King, from the beginning of his reign, had cautiously avoided risks and confrontations and had especially sought friendly relations with Britain. In 1830, when the revolution in Paris inspired the Belgians to break away from Dutch rule, Louis-Philippe avoided the temptation of seeking to annex Belgium or of placing one of his sons on the throne. Again, in 1840, when a crisis flared up in the Near East and Thiers (then head of the government) took an aggressive stance that threatened to coalesce all of Europe against France, the King had found an excuse to replace his firebrand minister. Guizot continued this cautious line through the 1840s, with the single exception of an episode in Spain. A long contest involving rival suitors for the Queen's hand finally tempted Guizot, in 1846, to try for a cheap diplomatic victory; it infuriated the British and helped to destroy the Anglo-French entente. One problem Guizot inherited from his predecessors was that of Algeria. Since 1830 the French had maintained an uneasy presence there, wavering between total withdrawal and expanded conquest. The decision to remain had been made in the mid-1830s; during the Guizot era, Gen. Thomas-Robert Bugeaud de La Piconnerie's forces broke the back of Algerian resistance, pushed the native population back into the mountains, and began the process of colonizing the rich coastal plain.

foreign  
policy

#### THE SECOND REPUBLIC AND SECOND EMPIRE

**The Revolution of 1848.** The overthrow of the constitutional monarchy in February 1848 still seems, in retrospect, a puzzling event. The revolution has been called a result without a cause; more properly, it might be called a result out of proportion to its cause. Since 1840 the regime had settled into a kind of torpid stability; but it had provided the nation with peace abroad and relative prosperity at home. Louis-Philippe and his ministers had

Discontent  
within the  
July  
monarchy

prided themselves on their moderation, their respect for the ideal of cautious balance embodied in the slogan *juste-milieu*. France seemed to be arriving at last at a working compromise that blended traditional ways with the reforms of the Revolutionary era.

There were, nevertheless, persistent signs of discontent. The republicans had never forgiven Louis Philippe for "confiscating" their revolution in 1830. The urban workers, moved by their misery and by the powerful social myths engendered by the Great Revolution, remained unreconciled. For a decade or more they had been increasingly drawn toward Socialism in its various utopian forms. An unprecedented flowering of Socialist thought marked the years 1840–48 in France: this was the generation of Barthélemy-Prospér Enfantin, Charles Fourier, Auguste Blanqui, Louis Blanc, Pierre-Joseph Proudhon, Étienne Cabet, and many others. Most of these system builders preached persuasion rather than violence, but they stimulated the hopes of the common man for an imminent transformation of society. Within the bourgeoisie as well, there was strong and vocal pressure for change in the form of a broadening of the political elite. Bills to extend the suffrage (and the right to hold office) to the middle bourgeoisie were repeatedly introduced in parliament but were stubbornly opposed by Guizot. Even the National Guard, that honour society of the lesser bourgeoisie, became infected with this mood of dissatisfaction.

Other factors, too, contributed to this mood. In 1846 a crop failure quickly developed into a full-scale economic crisis: food became scarce and expensive; many businesses went bankrupt; unemployment rose. Within the governing elite itself, there were signs of a moral crisis: scandals that implicated some high officials of the regime and growing dissension among the Notables. Along with this went a serious alienation of many intellectuals. Novelists such as Victor Hugo, George Sand, and Eugène Sue glorified the common man; the caricaturist Honoré Daumier exposed the foibles of the nation's leaders; historians such as Jules Michelet and Alphonse de Lamartine wrote with romantic passion about the heroic episodes of the Great Revolution.

Beginning in 1847, the leaders of the opposition set out to take advantage of this restless mood and to force the regime to grant liberal reforms. Since public political meetings were illegal, they undertook a series of political "banquets" to mobilize the forces of discontent. This campaign was to be climaxed by a mammoth banquet in Paris on February 22, 1848. But the government, fearing violence, ordered the affair cancelled. On the 22nd, crowds of protesting students and workers gathered in the streets and began to clash with the police. The King and Guizot expected no serious trouble: the weather was bad, and a large army garrison was available in case of need. But the disorders continued to spread, and the loyalty of the National Guard began to seem dubious. Toward the end of two days of rioting, Louis-Philippe faced a painful choice: to unleash the army (which would mean a bloodbath) or to appease the demonstrators. Reluctantly, he chose the second course and announced that he would replace the hated Guizot as his chief minister. But the concession came too late. That evening, an army unit guarding Guizot's official residence clashed with a mob of demonstrators, some 40 of whom died in the fusillade. By the morning of February 24, the angry crowd was threatening the royal palace. Louis-Philippe, confronted by the prospect of civil war, hesitated and then retreated once more; he announced his abdication in favour of his nine-year-old grandson and fled to England.

Abdication  
of Louis-  
Philippe

**The Second Republic, 1848–52.** The succession to the throne was not to be decided so easily, however. The Chamber of Deputies, invaded by a mob that demanded a republic, set up a provisional government whose members ranged from constitutional monarchists to one radical deputy, Alexandre-Auguste Ledru-Rollin. Led by the poet-deputy Alphonse de Lamartine, the members of the government proceeded to the Hôtel de Ville, where the radical republican leaders had begun to organize their

own regime. After considerable palaver, the provisional government co-opted four of the radical leaders, including the Socialist theoretician Louis Blanc and a workingman who called himself Albert. Under heavy pressure from the crowd surrounding the Hôtel de Ville, the government proclaimed the republic. During the next few days, continuing pressure from the social reformers pushed the government farther than its bourgeois members really wanted to go. The government issued a right-to-work declaration, obligating the state to provide jobs for all citizens. To meet the immediate need, an emergency-relief agency called the *ateliers nationaux* (national workshops) was established. A kind of economic and social council called the Luxembourg Commission was created to study programs of social reform; Louis Blanc was named its president. The principle of universal manhood suffrage was proclaimed—an almost unprecedented experiment in that day and one that increased the electorate at a stroke from 200,000 to 9,000,000. In matters of foreign policy, on the other hand, Foreign Minister Lamartine resisted radical demands. The radicals were eager for an ideological crusade on behalf of all peoples who were thirsting for freedom: Poles, Italians, Hungarians, and Germans had launched their own revolutions and needed help. Lamartine preferred to confine himself to lip-service support, since he was aware that an armed crusade would quickly inspire an anti-French coalition of the major powers.

By April 23, when Frenchmen went to the polls to elect their constituent assembly, the initial mood of brotherhood and goodwill had been largely dissipated. Paris had become a caldron of political activism; dozens of clubs and scores of newspapers had sprung up after the revolution. Severe tension developed between moderates and radicals both within and outside the government and led to a number of violent street demonstrations that were controlled with difficulty. The *ateliers nationaux* satisfied no one: for the radicals they were a mere caricature of social reform, whereas for the moderates, they were a wasteful and dangerous experiment that attracted thousands of unemployed from every corner of France. Financial problems plagued the government, which sought a solution by imposing a special 45-centime surtax on each franc of direct property taxes; this burden weighed most heavily on the peasantry and was bitterly resented in the countryside. The radicals, fearing that universal suffrage under these conditions might produce unpleasant results, vainly urged postponement of the elections until the new voters could be "educated" as to the virtues of a social republic.

The election returns confirmed the radicals' fears: the country voted massively for moderate or conservative candidates. Radicals or socialists won only about 80 of the 880 seats; the rest were bourgeois republicans (500) or constitutional monarchists (300). Lamartine led the popularity parade, being elected in ten districts. When the Assembly convened in May, the new majority showed little patience or caution; it was determined to cut costs and end risky experiments. In spite of Lamartine's efforts to maintain broad republican unity and avert a sharp turn to the right, the Assembly abolished the Luxembourg Commission and the *ateliers nationaux* and refused to substitute a more useful program of public works to provide for the unemployed.

The immediate consequence was a brief and bloody civil war in Paris—the so-called June Days (June 23–26, 1848). Thousands of workers suddenly cut off the state payroll were joined by sympathizers—students, artisans, employed workers—in a spontaneous protest movement. Barricades went up in many working-class sections. The Assembly turned to Gen. Louis Eugène Cavaignac as a saviour. Cavaignac had made his mark in repressing Algerian rebel tribes and was entrusted with full powers to do the same in Paris. He gave the workers time to dig themselves in, then brought up artillery against their barricades. At least 1,500 rebels were killed; 12,000 were arrested, and many were subsequently exiled to Algeria. The radical movement was decapitated; the workers withdrew into silent and bitter opposition.

The June  
Days

Social conflict now gave way to political manoeuvring and constitution making. Cavaignac was retained in office as temporary executive, while the Assembly turned to its central task. After six months of discussion, it produced a constitution that appeared to be the most democratic in Europe. The president of the republic would be chosen for a four-year term by universal male suffrage; a one-house legislative assembly would be elected for three years by the same suffrage. What remained unclear was the relationship between president and assembly and the way out of a potential deadlock between them.

This problem might not have been fatal if the right kind of president had been available in 1848. Instead, the voters chose Louis-Napoléon Bonaparte, who had returned from British exile in September, after having successfully stood for the constituent assembly in a by-election. He had made a poor initial impression; indeed, some politicians, such as Thiers, backed him for the presidency because they thought him too stupid to rule, so that he might soon be shunted aside for an Orleanist monarch. What he possessed, however, was a name—a name that Frenchmen knew and that conveyed an aura of glory, power, and public order. In December, Louis-Napoléon won by a landslide, polling 5,500,000 votes as against 2,000,000 for all other candidates combined. In May 1849 the election of the legislative assembly produced an equal surprise. The two extremes—the radical left and the monarchist right—made impressive gains, whereas the moderate republicans, who had shaped the new system, were almost wiped out. The moderates emerged with only 80 seats, the radicals with 200, the monarchists with almost 500. But the monarchist majority lacked coherence, being split into legitimist and Orleanist factions that distrusted each other and differed on political principles.

During the next two years President Bonaparte played his cards carefully, avoiding conflict with the monarchist Assembly. He pleased Catholics by restoring the Pope to his temporal throne, from which he had been driven by Roman republicans. At home, he accepted without protest a series of conservative measures adopted by the Assembly: these laws deprived one-third of all Frenchmen of the right to vote, restricted the press and public assemblage, and gave the church a firm grip on public as well as private education. Yet there was some reason to doubt that Louis-Napoléon really welcomed this trend toward conservatism. His writings of the 1840s had been marked by a kind of technocratic outlook, in the tradition of Saint-Simonian Socialism. His effort to please the Assembly probably derived from his hope that the Assembly would reciprocate: he wanted funds from the treasury to pay his personal debts and run his household and a constitutional amendment that would allow him to run for a second term.

By 1851, it was clear that the majority was not ready to give the President what he wanted. His alternatives were to step down in 1852, bereft of income and power, or to prepare a coup d'état. Some members of his entourage had long urged the latter course; Louis-Napoléon now concurred, with some reluctance.

On the early morning of December 2, 1851, some 70 leading politicians were arrested, and the outlines of a new constitution were proclaimed to the nation. It restored manhood suffrage, sharply reduced the Assembly's powers, and extended the president's term to ten years. Although the coup went off smoothly, it was followed by several days of agitation. Barricades went up in the streets; crowds clashed with troops and police in Paris and in the provinces; several hundred demonstrators were killed and 27,000 arrested. Once the resistance was broken, Louis-Napoléon proceeded with his announced plebiscite on the new constitution and was gratified to receive the approval of 92 percent of those who voted. But the authoritarian republic was only a stopgap. Officially inspired petitions for a restoration of the empire began to flow to Paris; the Senate responded to what it described as the nation's desires, and on December 2, 1852, Napoleon III was proclaimed emperor of the French. This time there was no open protest; and the voters, in a new

plebiscite, accorded Napoleon a handsome majority of 97 percent.

**The Second Empire, 1852–70.** Posterity's image of Napoleon III and his regime has not been uniform. Some historians have seen him as a shallow opportunist whose only asset was a glorious name. Others have described him as a visionary reformer and patron of progress, a man who successfully attempted to reconcile liberty and authority, national prestige and European cooperation. The Emperor's enigmatic character and the contradictions built into his regime make it possible to argue either case.

*The authoritarian years.* From 1852 to 1859, the empire was authoritarian in tone. Civil liberties were narrowly circumscribed; vocal opponents of the regime remained in exile or were constrained to silence; parliament's wings were clipped; elections to the Corps Législatif were spaced at six-year intervals and were "managed" by Napoleon's prefects, who sponsored official candidates. An illusion of popular control was created by the use of the plebiscite to ratify decisions already made. The Emperor and his ministers (members of his personal entourage or former Orleanist politicians) rested their authority on the peasant masses, the business class, the church, and those local notables who were willing to cooperate. Little attempt was made to install a new power elite or to create an organized Bonapartist party. Policy during the 1850s was consistently conservative; defense of the social order took precedence over reform.

The most striking achievements of these authoritarian years were in economic growth and foreign policy. France had never before experienced such vigorous economic expansion. During the Second Empire industrial production doubled, foreign trade tripled, the use of steam power increased fivefold, railway mileage sixfold. The first great investment banks were founded (e.g., the Pénard brothers' Crédit Mobilier) and the first department store (the Bon Marché in Paris). The surge of French enterprise transcended frontiers: French capital and engineers built bridges, railways, docks, and sewerage systems throughout much of continental Europe.

In part, this burst of energy had its source in favourable world conditions: the availability of more rapid steam transportation, an influx of new gold from overseas, general recovery from the slump of 1846–51. But to some degree Napoleon's government could claim credit, too—not so much by direct intervention in economic life as by creating a favourable climate for private enterprise. Many Frenchmen took advantage of the opportunities offered; they accumulated sizable fortunes and founded enterprises that still exist today. Among these entrepreneurs, however, there was a disproportionate number of "outsiders"—notably men of Protestant or Jewish origin, or former disciples of Henri de Saint-Simon. Alongside these dynamic newcomers, the older business and banking leaders continued to operate on more cautious traditional lines. From the Second Empire onward, the French economy would combine these two contrasting sectors: a dynamic modernized element superimposed upon a largely static traditional kind of enterprise.

Napoleon's foreign policy at the outset was cautious; "the empire means peace," he assured his countrymen and the nervous powers of Europe. Yet for a ruler who bore the name Napoleon, the prudent and colourless policy of a Louis-Philippe seemed hardly appropriate. Besides, the Emperor was eager to achieve recognition from the other European monarchs, who regarded him as an upstart. It was for these reasons rather than because of urgent national interest that he became involved in the Crimean War in 1854. Britain and Russia were engaged in a contest for influence in the crumbling Turkish Empire. A dispute over the holy places in Palestine gave Napoleon an excuse to offer the British his support and thus to restore the Franco-British entente. Although the Crimean campaign was on the whole a fiasco for all of the participating armies, the French forces came off less ingloriously than the others and could with some justice pose as victors. Napoleon served as host for the Paris peace conference that ended the war in 1856. Midway

Economic growth during the Second Empire

Louis-Napoléon's coup d'état

through the conference, the birth of a male heir to the Emperor and his empress, Eugénie, seemed to assure the permanence of the dynasty.

*The liberal years.* The empire thus appeared to have compiled a record of unbroken successes and to be beyond challenge by its domestic critics. Perhaps it was this stability and self-confidence that led Napoleon, beginning in 1859, to turn in the direction of liberalizing the empire. The immediate impulse for this dramatic reversal was the attempted assassination of the Emperor in January 1858 by an Italian patriot, Felice Orsini, who sought thus to draw public attention to the frustrated hopes of Italian nationalists. Napoleon, shaken by the episode and by the reminder that in his youth he, too, had fought for Italian independence, met secretly in July 1858 with Count Cavour, premier of Piedmont; the two men laid plans designed to evict Austria from northern Italy and to convert Italy into a confederation of states headed by the Pope. In return, France was promised Nice and Savoy (Savoie). The new allies provoked the Austrians into a declaration of war in April 1859, and Napoleon led his armies across the Alps. French victories at Magenta and Solferino were followed by a somewhat premature settlement in which the Austrians turned over the province of Lombardy to the Piedmontese. The campaign had aroused the passions of Italian nationalists all up and down the peninsula; revolutions broke out in some of the smaller Italian states, and in 1860 the colourful freebooter Giuseppe Garibaldi set forth from Piedmont to conquer Sicily and Naples.

These repercussions of Napoleon's new foreign policy stirred up bitter controversy in France. Conservatives were outraged and feared that the Pope would be deposed as temporal ruler of Rome by the Italian nationalists. On the other hand, the long-silent liberal and radical opposition voiced reluctant approval. It is likely that Napoleon, whose bent toward Saint-Simonian reform ideas was strong, had never been very comfortable in his alliance with the conservatives and welcomed a chance to indulge his deeper instincts. At any rate, late in 1859 he announced the first hesitant steps toward a liberal empire. Political exiles were amnestied, press controls were relaxed, and the Corps Législatif was given slightly increased authority. An even more dramatic turn toward economic liberalism soon followed; in January 1860, Napoleon negotiated a low-tariff treaty with Britain, ending the long tradition of protectionism that had insulated French producers. By this move, however, the Emperor alienated another group of constituents—the businessmen—who until now had been his strong supporters.

Some of the Emperor's advisers had sharply opposed the turn toward liberalism. Events during the next decade seemed to confirm their warnings; for the empire now ran into increasingly stormy weather. The political opposition, stifled since 1851, showed little gratitude to its benefactor and took every opportunity to harass the government. In the 1863 elections, opposition candidates polled 2,000,000 votes, and 35 of them were elected to the Corps Législatif—including such effective spokesmen as the Orleanist Thiers and the republican Jules Favre. A downward turn in the economy played into the hands of the opposition. Foreign policy errors added to the regime's embarrassment: Napoleon's ill-conceived intervention in Mexico, where he hoped to establish a client empire under Maximilian of Austria, proved costly and futile and seemed to threaten a conflict with the United States. And from the mid-1860s, a new threat began to loom up across the Rhine: the burgeoning power of Prussia, under the guidance of Otto von Bismarck.

Despite these evil portents, Napoleon clung doggedly to his liberalization venture; additional reforms were granted throughout the decade. He expressed sympathy with the workers, granted them a kind of extra-legal right to form trade unions and to strike, and helped them organize mutual-aid societies. His minister of education, Victor Duruy, carried out an enlightened program of broadened public education, including the establishment of the first secondary education for girls. In 1867 the Emperor restored quite considerable freedom of the press and of

public assembly and further broadened the powers of the Corps Législatif. Yet the response of the voters to these concessions caused some dismay; in the elections of 1869 the opposition vote rose to 3,300,000, and the number of seats held by oppositionists more than doubled.

The Emperor now faced a momentous choice: a still further dose of liberalism or a brusque return to the authoritarian empire. He chose the former alternative; in January 1870 he asked the leader of the liberal opposition, Émile Ollivier, to form a government. Ollivier supervised the drafting of a new constitution, which, though hybrid in nature, converted the empire into a quasi-parliamentary regime. The ministers were declared to be "responsible," and their powers (as well as those of the Corps Législatif) were increased. At the same time, the Emperor retained most of his existing prerogatives, so that the real locus of power in case of a conflict was unclear. Nevertheless, the voters, when consulted by referendum (May 8, 1870), gave the new system a massive vote of confidence: 7,000,000 in favour to only 1,500,000 against. Outwardly, at least, it appeared that the Emperor had broken the rising wave of opposition and had found a widely accepted solution. But war and defeat only four months later were to prevent a fair test of the liberal empire in its final form.

*The Franco-German War.* Napoleon, meanwhile, had become uncomfortably involved in a diplomatic poker game with Bismarck. Prussian victories over Denmark (1864) and Austria (1866) indicated a serious shift in the European balance of power. Napoleon, aware that he faced a severe challenge, set out to strengthen his armed forces; he proposed a tighter conscription law that would increase the size of the standing army but had to retreat in the face of public and parliamentary hostility. The crisis that finally erupted in July 1870 over the succession to the Spanish throne was clumsily handled by French officials. The French successfully blocked the accession of a Hohenzollern prince in Spain, then demanded further guarantees for the future; they thus provided Bismarck with an easy opportunity to arouse German opinion and to goad France into declaring war on July 19.

Few French or foreign observers anticipated the military disaster that followed. The French armies, sunk in routine and slow to mobilize, were not yet ready to fight when the Prussian forces under Helmuth von Moltke crossed into France. One French army, under Achille-François Bazaine, was bottled up in Metz; another, under Patrice Mac-Mahon, was cornered at Sedan. There, on September 1, the Prussians won a clear-cut victory; Napoleon himself was taken prisoner. The regime could not survive such a humiliation. When the news reached Paris on September 4, crowds filled the streets and converged on the Corps Législatif, demanding the proclamation of a republic. The imperial officials put up no serious resistance; the Revolution of September 4 was the most bloodless in French history.

### THE THIRD REPUBLIC

A provisional government of national defense was set up and took as its first task the continuation of the war against the invaders. Composed of the deputies representing Paris and formally headed by Gen. Louis-Jules Trochu, the new government's most forceful member was Léon Gambetta, hero of the radical republicans. Gambetta, a young Parisian lawyer of provincial origin, had been elected to the Corps Législatif in 1869 and had already made his mark through his energy and eloquence. As minister of the interior and, some weeks later, minister of war as well, he threw himself into the task of improvising military resistance. His task was complicated by the advance of the Prussian forces, which, by September 23, surrounded and besieged Paris. Gambetta shortly left the city by balloon to join several members of the government at Tours. During the next four months Gambetta's makeshift armies fought a series of indecisive battles with the Prussians in the Loire Valley and eastern France. But his attempt to send a force northward to relieve Paris from siege was frustrated by Moltke. Adolphe

Intervention in Italy

Further liberal reforms

The Revolution of September 4

Thiers had been sent meanwhile to tour the capitals of Europe in search of support from the powers; but he returned empty-handed. By January 1871 it was clear that further armed resistance would be futile. Over Gambetta's angry protests, an armistice was signed with the Prussians on January 28.

One provision of the armistice called for the prompt election of a national assembly with authority to negotiate a definitive treaty of peace. That election, held on February 8, produced an assembly dominated by monarchists—more than 400 of them, compared to only 200 republicans and a few Bonapartists. The decisive issue for the voters, however, had not been the nature of the future regime but simply war or peace. Most of the monarchists had campaigned for peace; the republicans had insisted on a last-ditch fight. Most Frenchmen opted for peace, though Paris and certain provinces, such as Alsace, voted heavily for republicans. When the National Assembly convened in Bordeaux on February 13, it chose the aging Orleanist Adolphe Thiers as “chief of the executive power of the French republic.” Thiers had been the most outspoken critic of Napoleon's foreign policy and had repeatedly warned the country of the Prussian danger. He set out at once to negotiate a settlement with Bismarck; on March 1 the Treaty of Frankfurt was ratified by a large majority of the Assembly. The terms were severe: France was charged a war indemnity of 5,000,000,000 francs, plus the cost of maintaining a German occupation army in eastern France until the indemnity was paid. Alsace and half of Lorraine were annexed to the new German Empire. The German Army was authorized to stage a victory march through the Arc de Triomphe de l'Étoile in Paris. After the Assembly ratified the treaty, the deputies of the lost provinces (including Léon Gambetta) resigned their seats in protest.

**The Paris Commune.** A few days later, the Assembly transferred the seat of government from Bordeaux to Versailles. It had scarcely arrived when it was confronted by a major civil war—the rebellion of the Paris Commune. This event, complex in itself, has been made even more difficult to understand by the mythology that later grew up around it. Karl Marx, who promptly hailed the Commune as the first great uprising of the proletariat against its bourgeois oppressors, was partly responsible for creating this mythology. There was undoubtedly a class-struggle element in the episode, but this was not the central thread. Parisians, tense and irritable after the long strain of the siege, were outraged by the action of rural France in electing a monarchist Assembly committed to what they regarded as a dishonourable peace. They were further angered by the Assembly's subsequent acts, notably those that ended the wartime moratorium on debts and rents, cut off further wage payments to the National Guard (which had been resuscitated in Paris after the empire fell), and transferred the capital to Versailles rather than to Paris.

Thiers, aware that Paris was in an ugly mood, thought it prudent to disarm the National Guard, which heavily outnumbered the regular army units at the government's disposition. Before dawn on March 18, he sent troops to confiscate the National Guard cannon on the butte of Montmartre. A crowd gathered; a bloody encounter ensued; two generals were caught and lynched by the mob. As violence spread through the city, Thiers hastily withdrew all troops and government offices from Paris and went to Versailles to plan his strategy. He appealed successfully to Bismarck to release French prisoners of war in order to form a siege army that could eventually force Paris to capitulate. During the next two months, this governmental force was slowly assembled. Within Paris, meanwhile, initial chaos gradually gave way to an improvised experiment in municipal self-government. On March 26 Parisians elected a council that promptly adopted the traditional label Commune of Paris. Its membership ranged from radical republicans of the Jacobin and Blanquist variety to Socialists of several different sorts—notably disciples of Proudhon, who favoured a decentralized federation of self-governing communes throughout France. These internal divisions prevented

any vigorous or coherent experiments in social reform and also interfered with the Commune's efforts to organize an effective armed force. Communes on the Paris model were set up briefly in several other cities (Lyons, Marseilles, Toulouse) but were quickly suppressed.

By May 21 Thiers's forces were ready to strike. In the course of “Bloody Week” (May 21–28), the Communards resisted, street by street, but were pushed back steadily to the heart of Paris. In their desperation, they executed a number of hostages (including the Archbishop of Paris) and in the last days set fire to many public buildings including the Tuileries Palace and the Hôtel de Ville. A final stand was made in Père-Lachaise Cemetery, where the last resisters were shot down against the Mur des Fédérés—ever since, a place of pilgrimage for the French left. Thiers's government took a terrible vengeance. Twenty thousand Communards were killed in the fighting or executed on the spot; thousands of survivors were deported to the penal islands, while others escaped into exile.

**The formative years (1871–1905).** The repression of the Paris Commune left its mark on the emerging republic. The various Socialist factions and the newly organized labour movement were left leaderless and drifting; the resultant vacuum eventually opened the way to Marxian activists in the 1880s. Much of the working class became more deeply alienated than before, but to the moderate and conservative elements, Thiers gained added stature as the preserver of law and order against “the reds.” His ruthless action probably hastened the conversion of many rural and small-town Frenchmen to the idea of a republic because the regime had proved its toughness in handling subversion. A large number of by-elections to the Assembly in July 1871 brought startling gains to the republicans: they won 99 of 114 vacancies. The voters were clearly willing to accept a republic so long as it was run by a man like Thiers.

**Attempts at a restoration.** The monarchists, however, still held a comfortable majority in the Assembly and continued to hope and plan for a restoration. Legitimists and Orleanists remained at odds, but a compromise seemed possible. The Bourbon pretender, the Comte de Chambord (“the miracle child” of 1820), was old and childless; the Orleanist pretender, Philippe, comte de Paris, was young and prolific. The natural solution was to restore Chambord, with the Comte de Paris as his successor. Chambord, however, refused to accept the throne except on his own terms, which implied a return to the principle of absolute royal authority, unchecked by constitutional limitations. The Orleanists and even some legitimists found this too much to swallow. For the time being, they, too, settled for Thiers's presidential rule.

During the next two years Thiers's position was beyond challenge; and he gave the republic vigorous and efficient leadership. He reorganized the army and worked to restore national morale; he successfully floated two bond issues that permitted the war indemnity to be paid off in 1873, thus ending the German occupation ahead of schedule. Late in 1872, however, Thiers abjured his long-held Orleanist faith and publicly announced his conversion to republicanism. The monarchists, outraged and seeing their majority in the Assembly dwindling because of by-elections, found an excuse to force Thiers's resignation as provisional president (May 1873) and hastily substituted the commander of the army, Marshal Patrice de Mac-Mahon. Behind the scenes, monarchist politicians again set out to arrange an agreement between the two pretenders. Their hopes were once more sabotaged by Chambord, who again announced that he would return only on his own terms and under the fleur-de-lis flag of the old regime. The disheartened monarchists fell back on waiting for the Bourbon line to die out. But when Chambord passed from the scene in 1883, it was too late for a restoration.

**The constitution of the Third Republic.** Meanwhile, the problem of writing a constitution for the republic could no longer be postponed. The Assembly began the task in 1873; and in 1875 it adopted a series of fundamental laws, which, taken collectively, came to be known

“Bloody Week”

Republican gains

The Treaty of Frankfurt

End of the  
provisional  
phase

as the constitution of the Third Republic. A patchwork compromise, it established a two-house legislature (with an indirectly elected Senate as a conservative check on the Chamber of Deputies); a Council of Ministers (Cabinet), responsible to the Chamber; and a president, elected for seven years by the two houses, with powers resembling those of a constitutional monarch. The label republic was approved by a single-vote margin. Monarchists believed that this system could be easily converted to their purposes once the right monarch was available. The constitution left untouched many aspects of the French governmental structure, notably the centralized administrative system inherited from Napoleon I, the hierarchy of courts and judges, and the Concordat of 1801, governing church-state relations. At the end of 1875, the National Assembly at last dissolved itself, and the provisional phase of the Third Republic came to an end.

The new Senate, which heavily overrepresented rural France, was safely monarchist from the outset; and the term of President Mac-Mahon, a loyal monarchist, ran until 1880. But when the first Chamber of Deputies was elected in 1876, the republicans won more than two-thirds of the seats. A period of severe friction between Mac-Mahon and the Chamber followed, and a crisis in May 1877 produced a total deadlock. Mac-Mahon dissolved the Chamber and called on the voters' support, but again they opted for the republic, by a narrower but clear-cut margin. Léon Gambetta, who had returned to political life and had led the republicans during the campaign, called on Mac-Mahon to "give in or get out." The President gave in, naming a premier acceptable to the republican majority. Two years later partial elections gave the republicans control of the Senate, and Mac-Mahon shortly found an excuse to resign. He was replaced by a colourless republican, Jules Grévy, who was believed to favour a reduced role for the president.

*Republican factions.* With the republican regime apparently safe from outside attack, rival factions developed among the republicans. During the 1880s the labels Radical and Opportunist began to be attached to the two wings of the republican movement. On the left, the Radicals saw themselves as heirs to the Jacobin tradition: they stood for a strong centralized regime, intransigent anticlericalism, an assertive nationalism in foreign policy, a revision of the constitution to prune out its monarchical aspects, and such social reforms as labour laws and a graduated income tax; their most colourful spokesman was Georges Clemenceau, a ferocious debater and duelist who specialized in overthrowing Cabinets. The Opportunists (so named by a satirical journalist because of their penchant for compromises and postponements) occupied the centre seats in the Chamber; their stance was more cautious, their techniques gradualist; they were content to work within the system, and they aimed to restrict governmental interference in the affairs of private citizens. Only on the issue of the church's role in politics and education were the two factions in general agreement.

Education-  
al reforms  
and  
colonial  
expansion

*Opportunist control.* Between 1879 and 1899 the Opportunists, with only brief interruptions, controlled the machinery of government. Gambetta, their most dynamic leader, had begun his career as an outspoken Radical, but in time his political instincts had prevailed. The other Opportunist leaders—men such as President Grévy and Jules Ferry—disliked Gambetta's flamboyance, however, and feared his alleged dictatorial ambitions; they kept him out of the premiership save for a brief interlude in 1881–82, shortly before his death. Ferry served as premier or in other key Cabinet posts during most of the period 1880–85 and left his mark on two institutions: the public school system and the colonial empire. His school laws made primary education free, compulsory, and secular, with religious teaching in the public schools replaced by "civic education"; a strong anticlerical bias thenceforth marked French public education. Ferry's support of various colonial expeditions—sometimes behind the back of the Chamber—gave France protectorates over Tunisia and Annam and Tongking (Tonkin),

a large new colony in the Congo Basin, and an initial foothold in Madagascar. This expansionist policy, unpopular at the time, led later generations to call Ferry the founder of the French empire.

In the 1885 elections, the monarchists, Bonapartists, and Radicals all made significant gains, partly because of boredom with the Opportunists, Catholic resentment over the school laws, and revived agitation by Socialist organizers. The Opportunists, lacking a clear majority in the Chamber, sought Radical support to form a Cabinet; the Radicals insisted on the inclusion of Gen. Georges Boulanger as minister of war. Within a few weeks Boulanger was the most talked-about man in France. He restored the tradition of military parades and rode at their head; he instituted popular reforms in the army; and he spoke out in chauvinistic fashion against the Germans, thus reviving the memory of 1871 and the lost provinces. The unnerved Opportunist leadership dropped him from the Cabinet and sent him in 1887 to an obscure provincial command. But Boulanger's backers urged him to plunge into politics and began to enter his name in by-elections. Privately, monarchist and Bonapartist agents also made contact with Boulanger, promising financial support and hoping to use him for their cause.

By 1889 the Boulanger movement had become a major threat to the regime. The government had placed him on the retired list, but this merely freed him to run openly for office on a vague program of constitutional revision. He triumphed in a series of by-elections, but his goal was the parliamentary election of 1889, which he hoped to turn into a kind of national plebiscite. Just prior to the election, however, believing that he was about to be arrested for subversive activities, Boulanger took flight to Brussels. His movement gradually disintegrated; word leaked out of his dealings with the monarchists, and his supporters fell away. The Opportunists' hold on the republic was strengthened by the discomfiture of those on both right and left who had been taken in by this adventurer.

A new crisis soon arose for the regime: the Panama Scandal. Ferdinand, vicomte de Lesseps, the noted French engineer who had built the Suez Canal, had organized a joint-stock company to cut a canal across the Isthmus of Panama. The venture proved difficult and costly; in 1889 the company collapsed, and large numbers of shareholders were stripped of their savings. Demands for a parliamentary investigation proved ineffective until 1892, when a muckraking journalist named Edouard Drumont obtained evidence that agents of the company had bribed a large number of politicians and journalists in a desperate effort to get funds to keep the company afloat. The directors of the company and several deputies and senators were brought to trial in 1893, but the outcome was on the whole a whitewash. The regime survived the scandal, but the effects were more serious than appeared to be the case. Cynicism about the honesty of the republic's political leadership gave added strength to the rising Socialist movement; in 1893 almost 50 Socialists won seats in the Chamber. Georges Clemenceau, unjustly accused of involvement in the scandal, was defeated; and many prominent Opportunists, tainted by the affair, withdrew and were replaced by such younger men as Raymond Poincaré and Louis Barthou, who thenceforth preferred to call themselves Progressists or Moderates.

The  
Panama  
Scandal

The dramatic Socialist gains in 1893 resulted only partly from the Panama Scandal. For more than a decade Socialism had been gaining strength among the increasingly class-conscious urban workers. The movement was weakened, however, by multiple splits into antagonistic factions. The Marxian Party created by Jules Guesde in 1880 broke up two years later into Guesdists and followers of Paul Brousse—the latter group popularly called possibilists because of their gradualist temper. In 1890 a third faction broke away, headed by Jean Allemane and limited to simon-pure proletarian members. Alongside these Marxian sects there were the Blanquists (disciples of Auguste Blanqui); the anarchists (whose terrorist campaign in the early 1890s earned them wide no-

Revolu-  
tionary  
syndical-  
ism

tority); and a considerable scattering of independent Socialists (mainly intellectuals, notably Jean Jaurès). By 1900 the parties had been reduced to the two led by Guesde and Jaurès, which merged in 1905 to form the Parti Socialiste, Section Française de l'Internationale Ouvrière (SFIO).

The trade union movement, however, refused to join forces with the Socialists. Trade unions were finally legalized in 1884 and joined together to form a national Confédération Générale du Travail (CGT) in 1895. CGT leaders rejected political action in favour of direct action—sabotage, boycotts, strikes, and especially the general strike, which they saw as the ultimate weapon that would transform France into a workers' state. This doctrine, known as revolutionary syndicalism, made the French trade union movement appear to be one of the most radical in Europe. The trade union rank and file, however, was less revolutionary than its leadership. It also made relations between unions and Socialists more hostile than elsewhere.

*The Dreyfus affair.* The 1890s also saw the Third Republic's greatest political and moral crisis—the Dreyfus affair. In 1894 Capt. Alfred Dreyfus, a career army officer of Jewish origin, was charged with selling military secrets to the Germans. He was tried and convicted by a court-martial and sentenced to life imprisonment on Devil's Island off the South American coast. Efforts by the Dreyfus family to reopen the case were frustrated by the general belief that justice had been done. But secrets continued to leak to the German embassy in Paris, and a second officer, Maj. Marie-Charles-Ferdinand Esterhazy, became suspect. The chief of army counterintelligence, Col. Georges Picquart, eventually concluded that Esterhazy and not Dreyfus had been guilty of the original offense, but his superior officers refused to reopen the case. Rumours and scraps of evidence soon began to appear in the press; and a few politicians, notably Georges Clemenceau, took up Dreyfus' cause. But the army high command refused to discuss the affair, although army officers leaked documents to the press in an effort to discredit the critics. Each leak aroused new controversy, and by 1898 the case had become a violently divisive issue. Intellectuals of the left led the fight for Dreyfus, while right-wing politicians and many Catholic periodicals defended the honour of the army. The Socialists were split: Jaurès insisted that no Socialist could remain aloof on such a moral issue, while Guesde called the conflict a bourgeois squabble.

In 1898 some of the army's most persuasive documents against Dreyfus were discovered to be forgeries. Esterhazy promptly fled to England. In a second court-martial, late in 1899, Dreyfus was again found guilty but with extenuating circumstances; he received a presidential pardon and was later (1906) vindicated by a civilian court. For a generation the affair left deep scars on French political and intellectual life. The Moderates, who had tried to avoid involvement in the affair and in the end had split into two warring factions, lost control to the Radicals.

Radical  
control

A coalition Cabinet headed by René Waldeck-Rousseau, a pro-Dreyfus Moderate, took office in June 1899; the Radicals dominated the coalition, and even the Socialists supported it. From then until the end of the Third Republic the Radical Party (thenceforth called Radical-Socialist) remained the fulcrum of French political life. Both the army and the church were seriously hurt by their role in the affair; republicans of the left were more convinced than ever that both institutions were anti-republican and hostile to the rights of man enunciated during the Great Revolution. The new left majority retaliated by bringing the army under more rigorous civilian control and by embarking on a new wave of anticlerical legislation. Most religious orders were dissolved and exiled; and in 1905 a new law separated church and state, thus liquidating the Concordat of 1801.

*Foreign policy.* Meanwhile, some important successes were being scored in the field of foreign policy. For two decades after 1871 France had remained diplomatically isolated in Europe. Bismarck, to ward off potential ideas

of revenge in France, had shrewdly encouraged French governments to embark on colonial conquest overseas and had negotiated alliances with all those European powers that the French might otherwise have courted. He thus kept Austria-Hungary, Russia, and Italy in tow, while Britain chose to remain aloof in "splendid isolation." Upon Bismarck's fall in 1890, the German emperor William II terminated the secret treaty between Germany and Russia. The Russians began to cast about for friends and looked with some distaste toward Paris. French policy makers encouraged French bankers to make loans to the Russian government and opened negotiations for an entente. In 1891 a loose agreement provided for mutual consultation in crisis; in 1894 this was broadened into a military alliance by whose terms each partner promised to aid the other in case of attack by Germany or Germany's allies.

French  
European  
alliances

For a decade the Franco-Russian Alliance had little practical effect (though French loans did continue to flow to Russia). French diplomats turned to winning the Italians away from the Triple Alliance, and a Franco-Italian secret agreement in 1902 substantially weakened that Italian commitment. Of more central importance throughout the 1890s was a recurrent tension between France and Britain, who had been at odds in various parts of the world and whose colonial competition at times seemed to threaten war. Britain's Boer War in South Africa added further ill feeling, and some British leaders began to urge an end to "splendid isolation" in favour of an entente with a continental power—most probably Germany, which was seen as part of an Anglo-Saxon racial bloc. But the German government responded coolly to overtures in this direction, thus feeding the fears of British leaders who saw Germany as a threat to British interests. The British turned to France instead and found a willing partner in the foreign minister Théophile Delcassé. A visit to Paris by King Edward VII in 1903 helped pave the way to the Anglo-French Entente Cordiale of 1904, which resolved all outstanding colonial conflicts between the two powers but stopped short of military alliance. The new entente was consolidated a year later, when French moves to take over Morocco as a protectorate were resented by the Germans, who thought they saw an opportunity to break up the new entente. Emperor William II offered Germany's support to the Sultan of Morocco; this action irritated the British and led them to promise France strong support. In the conference of powers that followed at Algieras (1906), France had to be content with special privileges rather than a protectorate in Morocco; but the Entente Cordiale was solidified, and it was Germany that thenceforth began to complain of isolation.

*The prewar years.* From 1899 to 1905 a fairly coherent coalition of left-wing and centre parties (the so-called Bloc Républicain) provided France with stable government. The Cabinets headed by Waldeck-Rousseau in 1899–1902 and Émile Combes in 1902–1905 managed to liquidate the Dreyfus affair and to carry through the anticlerical reforms that culminated in the separation of church and state. The Entente Cordiale and the Russian alliance ensured France a more influential voice in European affairs. France possessed a colonial empire second only to Britain's in size. A new period of economic growth set in after the mid-1890s. Not surprisingly, later generations were to look back on the pre-1914 decade as *la belle époque* ("the good old days").

Stable gov-  
ernment  
of the  
Bloc Ré-  
publicain

Still, some sources of sharp dissatisfaction and conflict remained. Many Catholics were outraged by the triumph of the anticlericals, and they responded to the Vatican's urging to sabotage the new system. They resisted (sometimes violently) the transfer of church property to state ownership and refused to establish lay associations to govern the church. By 1907, however, resistance was clearly futile, and they began to accept the separation law as an accomplished fact. A difficult period followed for the church. The recruitment of priests fell off sharply, and many Catholic schools were closed for lack of funds. In the long run, however, the separation law reduced the intensity of conflict between Catholics and anticlericals.

There was less reason for republicans to suspect and denounce a disestablished church.

A vocal minority on the right remained unreconciled to the radical republic and rallied round the banner of the Action Française, headed by Charles Maurras. This organization had developed at the height of the Dreyfus affair as a focal point for intellectuals who opposed a new trial for Dreyfus. Maurras, an aspiring young writer from the south, quickly emerged as its theorist and leader. In his view, France had gone astray in 1789 and had since been dominated by the "four alien nations"—Jews, Freemasons, Protestants, and *métèques* ("aliens"). He preached a return to stable institutions and an organic society, in which the monarchy and the church would be essential pillars. Maurras appealed to many traditionalists, professional men, churchmen, and army officers. Action Française readily resorted to both verbal and physical violence; and its organized bands, the Camelots du Roi, anticipated the tactics of later Fascist movements. By 1914 Maurras' movement, though still relatively small, was the most coherent and influential enemy of the republic.

Alienation  
of the  
working  
class

Equally serious was the alienation of much of the working class. The CGT remained officially committed to revolutionary syndicalism; it rejected political action as a useless diversion of the proletariat's energies and exalted the idea of the general strike as the proper weapon to destroy bourgeois society. Although the CGT attracted only about 10 percent of French workers (most workers stubbornly refused to join any union), it was aggressive enough to cause sporadic turmoil during the period 1906–10. Several major strikes were broken by forcible repression; the government either called out troops or mobilized the strikers (who were also reservists) into the army. Proposals for labour-reform legislation drew little support in a parliament dominated by representatives of the bourgeoisie and the peasantry.

Despite the CGT, most workers by now were voting for the new unified Socialist Party. But the SFIO refused to permit its deputies to participate in or support bourgeois Cabinets (a policy dictated to the French party in 1904 by the Second International, dominated by the German Socialists) and thus condemned itself to an oppositionist stance in parliament. This destroyed the left-wing coalition that had given France stable Cabinets from 1899 to 1905. Socialist strength continued to rise, and by 1914, the party was second only to the Radicals in the Chamber of Deputies. Although its doctrine remained rigorously Marxist, in deference to the instructions of the International, the party's conduct was much more flexible. Jaurès, whose "humanitarian" Socialism was in large part derived from an older French heritage of left-wing thought, guided the Socialists in parliament toward informal cooperation with the bourgeois left in an effort to achieve domestic social reforms and an internationalist, antimilitarist foreign policy. Jaurès' central concern during the pre-1914 decade was to avert the general war that he saw looming ahead in Europe.

Centre  
coalition  
govern-  
ments

The Socialist withdrawal from the Bloc Républicain in 1905 forced the Radicals to look to the other centre parties as coalition partners. Until 1914—and, indeed, most of the time until 1940—France was governed by heterogeneous centre coalitions in which the Radicals most often held the key posts. In 1906 the Radical Georges Clemenceau began a three-year premiership. He proposed a long list of social reforms, including the eight-hour day and an income tax, but parliament blocked virtually all of them. More surprising was Clemenceau's ruthless suppression of strikes and his vigorous, nationalistic foreign policy. In 1907 his government sponsored a rapprochement between Britain and Russia that completed the triangle of understandings thenceforth called the Triple Entente. But Clemenceau refused to risk war through all-out support of his Russian ally during the Bosnian crisis of 1908. When his Cabinet fell in 1909, Clemenceau had effectively alienated his own Radical Party and seemed unlikely ever to return to high office.

Clemenceau's successors, Aristide Briand and Joseph Caillaux, undertook a policy of détente in European af-

fairs. Briand, like Clemenceau, belied his left-wing origins by forcibly repressing a major strike in 1910; but in foreign policy he preferred a policy of co-existence with Germany. Caillaux pushed this latter experiment even further; in 1911 he had to deal with a new crisis in Morocco, where the French were again pushing toward a protectorate against German objections; when the Germans sent a gunboat to Morocco, Caillaux made an effort at appeasement, handing over to Germany a slice of the Congo as compensation. French patriots were outraged; the Caillaux Cabinet was overthrown and replaced in January 1912 by one headed by Raymond Poincaré.

Nationalist  
revival

There were signs of a changing intellectual mood in the country, especially among young Frenchmen. A nationalist revival affected many Frenchmen who for a decade had grown increasingly anxious about what they regarded as the puzzling and threatening attitude of Germany's post-Bismarckian leadership; they looked once more to the army as the nation's bulwark, and its prestige was on the rise. These nationalist tendencies found their embodiment in Poincaré, whose intransigent patriotism and determination to stand up to Germany were beyond doubt. As premier in 1912–13 Poincaré devoted himself to strengthening the armed forces and to reinvigorating France's alliance system. An agreement with the British provided for a new sharing of naval responsibilities: the French concentrating in the Mediterranean, the British in the North Sea. Poincaré made a state visit to Russia to revive the sagging Franco-Russian Alliance. In January 1913 he was elected to the presidency of the republic, where, he believed, he could ensure continuity of policy during his seven-year term. In 1913 the size of the standing army was increased by lengthening the conscription period from two to three years.

Poincaré found bitter opposition on the left. The Socialists were strongly antimilitarist and hoped for an eventual reconciliation with Germany via collaboration between the two Socialist parties. They clung to the belief that the working class everywhere could block war by resorting to a general strike. A large segment of the Radical Party followed the Caillaux line, favouring Franco-German collaboration through such ventures as banking consortia for joint investment abroad. Much of rural France also lacked enthusiasm for the new nationalistic mood. The combined strength of this opposition was revealed in the parliamentary elections of 1914, when the parties of the left won a narrow victory.

**World War I.** Before a change in policy could be imposed, however, a new crisis in the Balkans threatened a general war. The assassination of the Austrian archduke Francis Ferdinand in Sarajevo on June 28 inaugurated five weeks of feverish negotiations, in which France's role has been much debated. Some historians have accused Poincaré and his supporters of a willingness to go to the brink of war rather than seek a negotiated settlement or use restraint on the Serbs and Russians; Poincaré's state visit to St. Petersburg at the height of the crisis has been seen as an occasion for a French promise of full support to Russia. A more judicious view is that many French statesmen had long seen the possibility and even the likelihood of a general war, and they suspected that the German government desired such a war; the Poincaré group believed that under these circumstances France could not risk the loss of its allies and a return to isolation. French support of the Serbs and the Russians, according to this view, was thus inspired by a calculated judgment regarding French security.

Germany's declaration of war against France on August 3 produced a spontaneous outburst of patriotic sentiment. Trade union and Socialist leaders, some of whom had been on a governmental list of dangerous subversives to be arrested in case of war, rallied to the colours. A national union Cabinet was formed. Parliament, after voting war credits, went into an extended recess, handing over the conduct of the war to the Cabinet and the high command. During the initial months the high command made most of the crucial decisions; the Cabinet accorded almost unlimited freedom of action to the commander in chief, Gen. Joseph Joffre, assuming that the war would

German  
declaration  
of war  
against  
France

last only a few weeks and that civilian interference would only prolong hostilities.

Joffre's war plans for an immediate advance across the frontier into the lost provinces of Alsace and Lorraine were suspended when German forces struck through Belgium and threatened late in August to envelop Paris. Joffre managed to blunt the German attack and force the Germans to more defensible positions. The rival armies dug into trench positions that remained largely static until 1918. Meanwhile, the French high command continued to believe that the fate of France would be decided on the Western Front. In 1916 a powerful German artillery attack on the French fortress positions surrounding Verdun lasted from February to June and cost each side some 250,000 men. For the French, the hero of Verdun was the sector commander, Gen. Philippe Pétain.

Joffre was by now under heavy criticism in Paris. Both the Cabinet and the Chamber were determined to assert greater control over the war effort, so that the high command's authority was steadily whittled away. Joffre was finally replaced in late 1916 by Gen. Robert Nivelle. All through 1917 rival factions in the Chamber debated the conduct of the war, backing different generals and threatening Cabinet crises. Worse still, morale among the troops reached a dangerous low point in 1917, culminating in serious mutinies that affected 54 French divisions. Pétain, who replaced Nivelle in May, managed to achieve stability by a judicious combination of severity and concessions.

Nevertheless, by autumn 1917 there was widespread defeatism in France and much talk of a "white peace." The Radical leader Caillaux was prepared to try for negotiations with the Germans; but his chance never came. When the Cabinet of Premier Paul Painlevé was overthrown in November 1917, President Poincaré recalled Georges Clemenceau to the premiership. Clemenceau stood for a fight to the finish. At age 76 he still had enormous energy and doggedness, and he infused a new spirit into the country. In March 1918, when the Germans launched a last major offensive in the West, Clemenceau replaced the cautious and pessimistic Pétain with a more attack-minded general, Ferdinand Foch, and persuaded the British as well to accept him as supreme commander. The German drive was checked. On November 11 an armistice was signed in Foch's railway car near Compiègne.

The victory was won at enormous cost for France. Of the 8,000,000 Frenchmen mobilized, 1,300,000 had been killed and almost 1,000,000 crippled. Large parts of northeastern France, the nation's most advanced industrial and agricultural area, were devastated. Industrial production had fallen to 60 percent of the prewar level; economic growth had been set back by a decade. The enormous cost of the war seriously undermined the franc and foreshadowed many years of currency fluctuation. Even deeper, though largely hidden, were the psychological lesions caused by the strain of protracted warfare and by the sentiment that France could not again endure such a test.

At the Paris Peace Conference in 1919, Clemenceau, as the principal French negotiator, declared that his goal was to ensure the nation's security against a renewed German aggression. He sought, therefore, to reduce Germany's power in every possible fashion and to hedge Germany about by strong barrier nations. He knew, however, that France could not dictate the peace terms and that he would have to compromise with the Americans and British, to whom he looked for aid in case of German resurgence. His stubborn defense of French demands irritated France's wartime allies; but his willingness to compromise in the end alienated many Frenchmen, who charged him with sacrificing the nation's security. The critics—who included Poincaré and Foch—were particularly outraged when Clemenceau abandoned his initial demand that Germany give up all territory west of the Rhine and that the Saar Basin be annexed to France. These and other concessions led many right-wing deputies to oppose the Treaty of Versailles when it was presented for ratification in the autumn of 1919. Joining the op-

position were the Socialists, who argued that the treaty was too harsh and that democratic Germany should not be punished for the sins of the Kaiser. A majority of the Chamber, however, reluctantly ratified Versailles and vowed to assure its enforcement to the letter.

**The interwar years.** Frenchmen concentrated much of their energy during the early 1920s on recovering from the war. The government undertook a vast program of reconstructing the devastated areas and had largely completed that task by 1925. To compensate for manpower losses, immigration barriers were lowered, and 2,000,000 foreign workers flooded into the country. Underlying all other concerns, however, was anxiety about the nation's security and about financing the costs of war and reconstruction. The peace settlement, in the eyes of many Frenchmen, had not provided adequate guarantees; and except among Socialists and Radicals there was little confidence in the League of Nations. American and British promises to aid France in case of future attack had been written into the treaty, but they became meaningless when the United States Senate rejected Versailles.

**German reparations.** A clause in the treaty had ascribed war guilt to the Germans and their allies and had obligated Germany to make reparations; the total sum due was calculated in 1921 at \$33,000,000,000, but the French were aware that the British hoped to see this total reduced.

The general elections of November 1919 resulted in a massive majority for the right-wing coalition called the Bloc National. The new Chamber set out to enforce Versailles to the letter; it also sought traditional security guarantees, maintaining the largest standing army in Europe and attempting to encircle Germany with a ring of military allies (Belgium and Poland in 1920–21; Czechoslovakia, Romania, and Yugoslavia in 1924–27). But the central issue was that of German reparations. By the end of 1921 the British clearly favoured a reduction of the burden in order to get Germany back on its feet; this issue caused increasing strain between the British and French governments. Premier Briand, who seemed willing to compromise, was overthrown by the Chamber and replaced by the more intransigent Poincaré. Repeated German defaults on reparations deliveries led Poincaré in January 1923 to send French troops and engineers (supported by a token force of Belgians) into the Ruhr Valley to force German compliance or, if necessary, to collect reparations by direct seizure. The German government had to comply by that September. Germany agreed in 1924 to a revised reparations settlement, the so-called Dawes plan, and the French occupation forces were withdrawn. The plan enabled the Germans to meet their obligations on schedule during the rest of the decade, though only with the help of large American loans. In 1926 France and the United States finally reached agreement on another nagging problem—the repayment of French war debts for wartime deliveries of American munitions and other supplies.

**Financial crisis.** The aftermath of the Ruhr occupation was to cast doubt on its apparent success. The German republic was weakened by the runaway inflation of 1923, and its future clouded; the occupation had embittered Britain and the United States. Even among Frenchmen, the victory had left a sour aftertaste because the costs of the occupation forced an increase in French taxes. In the elections of 1924, Poincaré's Bloc National was beaten by a coalition of the left, the Cartel des Gauches, and the Radicals were returned to power. But their triumph was brief; they were confronted by the nation's worst financial crisis since the war. The shaky franc went into rapid decline until there seemed to be danger of complete financial collapse. Seven Cartel Cabinets in 1924–26 wrestled ineffectively with the problem; at last the Cartel gave up, and Poincaré returned. The latter's reputation for decisive character and conservative views enabled him to win the bankers' support and to embark on such measures as slashing government expenses and increasing taxes. The franc began to rise, and it finally stabilized at about one-fifth of its 1914 value. Poincaré was hailed as "saviour of the franc," and when he re-

Effects of  
the war

Occupation  
of the Ruhr  
Valley

signed in 1929 for reasons of health, he was acclaimed as one of the Third Republic's outstanding statesmen.

*Collective security.* Poincaré, in his final term of office (1926–29), retained as foreign minister Aristide Briand, who had been named to that post by the Cartel in 1925 and who was to remain there for seven years almost without interruption. Briand sensed a change in the public mood after the Ruhr episode and proclaimed himself “the apostle of peace”; he formulated a policy that he called *apaisement*. His goal was to work for collective security through the League of Nations, for disarmament, and for a reconciliation with those Germans who favoured peaceful and cooperative methods. Briand found a ready partner in Gustav Stresemann, the German foreign minister. By the Pact of Locarno (1925), the French and German governments bound themselves not to use force to alter the existing Franco-German frontier. In subsequent years, France sponsored Germany's entry into the League of Nations and made a series of concessions softening various aspects of the Treaty of Versailles. A revised reparations agreement in 1929 (the Young Plan) further eased Germany's obligations, and in 1930 the French ended their occupation of the German Rhineland five years ahead of schedule.

*Internal conflict on the left.* Throughout the 1920s, however, much of the working class remained alienated from a regime that showed little concern for social reform. The CGT had emerged from the war with redoubled strength and energy, its membership swelled by the workers who had poured into new war industries in the Paris region. The Clemenceau government had rewarded labour for its war effort by legislating the eight-hour day in 1919; but when the unions pushed for more reforms, a deadlock ensued. An attempted general strike in May 1920 was easily broken, and thousands of discouraged and embittered workers abandoned the CGT. Labour's strength was further dissipated by the formation of rival Catholic and Communist trade-union federations in 1919 and 1921.

Socialist  
split

The political influence of the workers was further impaired by a split in the Socialist Party in 1920. During the war, Socialist opposition to the slaughter had become increasingly vocal. The Bolshevik Revolution in Russia had reinforced this trend and offered a model that attracted many French Socialists. From 1918 onward, conflict intensified among Socialists over the possibility of joining Lenin's Comintern (Third International). At the party's annual congress in Tours in December 1920, Lenin's partisans carried the day by a large majority and shortly renamed their organization the French Communist Party (SFIC). The minority, headed by Jaurès's disciple Léon Blum, walked out of the congress and retained the traditional name SFIO. Throughout the 1920s antagonisms between these two Marxist factions hampered the left and prevented workable coalitions. Neither the Socialists nor the Communists would enter bourgeois-dominated Cabinets; the Communists refused even to make electoral agreements in support of a single left-wing candidate. The trend through the 1920s was steadily favourable to the Socialists, while the Communists steadily lost influence and members; in 1928 the Socialists won 107 seats, the Communists only 11. Many French Communists resented dictation from Moscow, and the decade saw a long series of resignations and purges; by 1930 the remnant had been thoroughly “Bolshevized” on the pattern of Lenin's own party.

*The Great Depression and political crises.* France at the end of the 1920s had apparently recovered its prewar stability, prosperity, and self-confidence. For a time it even seemed immune to the economic crisis that spread through Europe beginning in 1929; France went serenely on behind its high-tariff barrier, a healthy island in a chaotic world. By 1931, however, France in its turn succumbed to the effects of the Depression, and the impact was no less severe than elsewhere.

In 1932 the right-wing parties lost control of the Chamber to the Radicals and Socialists. The Radical leader Édouard Herriot returned to the premiership, with Socialist support but not participation. During the next two

years Herriot and a series of successors groped for a solution to the deepening crisis. French nervousness was increased by the surge of Nazi power across the Rhine, culminating in Adolf Hitler's accession to the chancellorship in January 1933. Right-wing movements in France—some openly Fascist, others advocating a more traditional authoritarianism—grew in size and activity. By 1934 the shaky coalition was at the mercy of an incident—the Stavisky scandal, a sordid affair that tarnished the reputations of several leading Radicals. Antiparliamentary groups of the far right seized the occasion to demonstrate against the regime; on February 6 a huge rally near the Chamber of Deputies degenerated into a bloody battle with armed police, during which 15 rioters were killed and 1,500 injured. Premier Édouard Daladier, confronted by a threat of civil war, resigned in favour of a national union Cabinet under former president Gaston Doumergue. The regime survived the crisis, but serious stress persisted. Right-wing agitation was countered by unity of action on the left, grouping all the left-wing parties and the CGT; even the Communists participated in this effort, which culminated in 1935 in the formation of the Popular Front.

Right-wing  
agitation

Doumergue's government had meanwhile disintegrated when Radical ministers resigned over the Premier's increasingly authoritarian tone. Doumergue was soon replaced by Pierre Laval, a former Socialist who had migrated toward the right. Laval embarked on a vigorous but unpopular attempt to combat the Depression through traditional techniques: sharp cuts in government spending and increased taxes. These policies wrecked his Cabinet early in 1936 and became campaign issues in the elections that spring. Those elections, probably the most bitterly contested since 1877, gave the Popular Front a narrow majority of the popular vote and a large majority in the Chamber. The Socialists for the first time became the largest party; but the greatest proportional gain went to the Communists, who jumped from ten to 72 seats.

Léon Blum, the Socialist leader, became premier. Blum, an intellectual, was the first French premier of Jewish origin. His ministers were mostly Socialists and Radicals; the Communists refused his urgent invitation to participate. At the very outset, a wave of sit-down strikes spread throughout the country, expressing workers' pent-up resentment toward past governments and their determination to get what they considered to be justice. Blum persuaded industrial leaders to grant immediate wage increases, which ended the strike. Then he pushed additional reforms through Parliament: the 40-hour week, paid vacations, collective bargaining, and the semi-nationalization of the Bank of France. Many other reform bills, however, were stalled in committee or in the Senate, which remained much more conservative than the Chamber.

Blum's social reforms were costly and controversial and were not buttressed by a program of economic reforms that might have stimulated production and restored confidence. Production surged briefly, then lagged again; unemployment remained high, rising prices offset wage gains, a flight of capital set in. When Blum attempted to impose exchange controls, the Senate rebelled and overthrew his cabinet (June 1937). The Popular Front held together for another year, but the Socialists and Radicals were irretrievably divided on economic policy. In April 1938 France returned once more to the usual pattern of homogeneous centre coalitions, with the Socialists in opposition. The Radical Daladier served as premier in 1938–40; his finance minister, Paul Reynaud, suspended most of the Popular Front reforms and sought economic recovery through more orthodox policies favoured by business.

*German aggressions.* Meanwhile, Hitler's accession had placed French governments in an increasingly grave foreign-policy dilemma. By 1934 many French leaders believed that a return of “Poincarism” was in order, and Doumergue's foreign minister, Louis Barthou, set out to reinforce and extend France's alliance system. He reaffirmed French ties with Poland and the “Little En-

Reinforce-  
ment and  
extension  
of alliances

tente" countries and sought new understandings with both Italy and the Soviet Union. Barthou's assassination in late 1934 weakened the new alliance policy, though Pierre Laval in 1935 paid visits to both Rome and Moscow and actually signed a mutual assistance treaty with the U.S.S.R.

Mussolini's invasion of Ethiopia in late 1935 and Hitler's military reoccupation of the Rhineland in March 1936 were serious blows to French policy. After consulting the British, the French Cabinet decided not to risk a confrontation with Hitler, who thus won a major diplomatic victory. Hitler promptly fortified the Rhine frontier, so that French guarantees of military aid to eastern European allies lost much credibility. Furthermore, Hitler and Mussolini joined forces against the status quo powers. With Italy lost, Frenchmen of the centre and right grew cool toward closer ties with the Soviet Union; they had counted on Italy to counterbalance Soviet influence. France found itself dangerously isolated, dependent on the small eastern European countries and on the uncertain prospect of British military support in crisis. Not surprisingly, French policy after 1936 showed signs of weakness and drift.

The outbreak of the Spanish Civil War in July 1936 posed a severe problem of conscience for Blum's Popular Front government: whether to send aid to the Spanish republic, the only other Popular Front regime in Europe. Reluctantly, Blum remained aloof; his Radical allies strongly opposed intervention and threatened to bring down the Cabinet. A new crisis developed in March 1938, when Hitler's troops for the first time crossed a frontier—into Austria. The French and British confined themselves to formal protests. German pressure on Czechoslovakia followed. Although France was formally committed to aid Czechoslovakia in case of aggression, Premier Daladier succumbed to British pressure to appease Hitler by a compromise settlement. The Munich Agreement of September 30 provided a breathing space but caused sharp dissension and self-doubt in France. When Hitler occupied what was left of Czechoslovakia in March 1939, it appeared to be too late for successful diplomatic or military resistance to Hitler, yet a failure to resist would hand over the Continent to German domination. From April until August the French and British sought to bring the Soviet Union into a joint pact against Hitler, with the French pressing the reluctant British to take the risks involved. A Soviet pact with Hitler instead was the last in a long chain of disasters for France. On September 3, two days after Germany invaded Poland, the French and British governments reluctantly declared war on Germany.

War  
against  
Germany

French and British attempts to aid the Poles would have been ineffective even if tried. Hitler's offer of peace immediately after Poland fell was rejected by the Western Allies. The Nazi armies smashed through The Netherlands and Belgium on May 10, 1940, and soon broke the French defensive lines near Sedan. The German blitz brought chaos all along the Allied front. In Paris, Premier Paul Reynaud (who had replaced Daladier in March) pleaded for emergency aid from Britain and the United States; the British sent some additional air units but were unwilling to denude their island of all air defense; President Roosevelt offered moral encouragement but not open intervention.

On June 10, with the Germans approaching Paris, the government departed for Tours and declared Paris an open city. British Prime Minister Winston Churchill twice flew to Tours in an effort to keep France in the war. But Reynaud, who favoured continued resistance (from North Africa, if necessary) rapidly lost ground to the defeatists in his Cabinet, headed by Pétain. On June 14 the Cabinet left Tours for Bordeaux. Churchill, in a last desperate effort, proposed a pact of "indissoluble union" that would merge France and Britain as a single nation. By the time the proposal reached Bordeaux on June 16, however, the Pétain faction had gotten control of the Cabinet. Reynaud resigned that evening; Pétain was appointed in his place and asked Germany for surrender terms. On June 22 an armistice was signed with the Ger-

mans, near Compiègne, in the same railway car that had been the scene of Foch's triumph in 1918. The armistice provided for the maintenance of a quasi-sovereign French state and for the division of the country into an occupied zone (northern France plus the western coast) and an unoccupied southern zone. France was made responsible for the German Army's occupation costs. The French Army was reduced to 100,000 men, the navy disarmed in its home ports.

Surrender  
to  
Germany

**Society and culture under the Third Republic.** Under the Third Republic the middle and lower sectors of society came to share political and social dominance with the rich notables. Universal suffrage gave them a new political weapon; France's peculiar socio-economic structure gave them political weight.

**Economy.** Republican France remained a nation of small producers, traders, and consumers. The surge of industrialization that marked the era of Napoleon III had stopped short of a full-scale industrial revolution. The new dynamic sector of the economy was far outweighed by a static or slowly changing sector. The bulk of industry remained smaller and more dispersed than in other industrializing countries. As late as the decade before 1914, 90 percent of France's industrial enterprises employed fewer than five workers each; in the extensive textile and clothing trades more than half of the employees still worked at home rather than in factories. Commerce and trade followed the same pattern, with small shops and banks surviving in profusion. Similarly, rural France was dominated by small, subsistence family farms. The proportion of farmers in the total active population, which stood at 52 percent in 1870, was still about 45 percent in 1914 and 35 percent in 1930. When grouped together, the small independent producers, traders, and farmers far outnumbered any other segment of society, including the proletariat.

The reasons given for this slow pace of socio-economic change are varied: shortages of basic natural resources; a tradition of specialization in luxury items; a code of mores that emphasized prudent management rather than risky experiment and that regarded as ideal the "family firm," small enough to be financed and managed by the owners alone. In any case, French industrialization took a different form from that of England or Germany. An initial burst of growth in the 1850s was followed by several decades of much more gradual expansion, which did not threaten the existing structure of society and the underlying value system. Most segments of society were reasonably satisfied and felt no threat to their way of life (only the members of the working class, both urban and agricultural, considered themselves outsiders and victims rather than participants); thus, the stability of the system was ensured. Not until well into the 20th century, and especially after 1918, did this state of affairs begin to change.

The governments of the Third Republic were representative of the small independents and responsive to their interests. Most of the bourgeoisie and the peasantry wanted a laissez-faire policy: low taxes, hands off the affairs of private citizens. There was little popular enthusiasm for costly ventures in foreign policy or expensive social reforms; the major exception—the conquest of colonial empire—had to be accomplished somewhat secretly and with limited resources. Only in tariff policy was laissez-faire flagrantly violated by the government, with the active consent of its bourgeois supporters. When the low-tariff treaties of Napoleon III expired in 1877, the government promptly returned to protectionism. Much of French agriculture and industry was thereby protected against more efficient foreign producers and insulated against the need for modernization. The short-range interests of the small, independent producer were thus guaranteed; the prospect of harm to his longer range interests—as well as to those of the nation as a whole—was not yet clear.

Laissez-  
faire policy

From 1873 to the mid-1890s the French economy experienced a period of slackness. This trend reflected a condition affecting most of Europe, although in France an epidemic of phylloxera in 1875–87 destroyed one-

third of the nation's vineyards. From 1896 to 1914 industrial output rose impressively, exports increased by 75 percent, prices returned to the pre-slump level; this upturn was also generally European-wide rather than peculiar to France; but some special factors, such as the opening of a vast new iron-ore field in French Lorraine, did increase the French rate of industrial expansion. By 1914 French Lorraine had become the major centre of French iron and steel production, and France had become the world's largest exporter of raw iron ore (primarily to Germany). Yet the French were being outpaced by rivals. In 1870 France had still ranked as the world's second industrial and trading nation; by 1914 it had fallen to a poor fourth. Much of the liquid capital that might have been used for business expansion at home was being siphoned off into foreign investment; by 1914 almost one-third of such available French capital had been placed abroad—one-fourth of that sum in Russia, only one-tenth in the French colonies. Yet few Frenchmen had serious doubts about the course of economic policy under the Third Republic.

Only after the war, and particularly after 1930, were such doubts widely shared. The disruptive impact of the war exceeded the understanding not only of most citizens but also of most political leaders. Efforts to return to normality were futile because the postwar world and France had changed vastly. The enormous cost of a four-year mobilization, of reconstruction, of war debts, had to be borne. By the time of the Depression the government had been forced to write off a large share of war costs by devaluing the franc (1928) to one-fifth of its old value, costing many Frenchmen on fixed incomes much of their savings and shaking their confidence in the future. Still, no large group of embittered *déclassés* was created, ripe for the appeals of a demagogue. And after 1926 there was a brief resurgence of prosperity, so that by the end of the decade the indexes of industrial production, foreign trade, and living standards had risen well above the 1914 peak. Some illusions about the future and hopes of a happy return to prewar stability could therefore be retained.

But by 1935 industrial production had fallen to 79 percent of the 1928 level and exports to 55 percent. Registered unemployment hovered at less than 500,000, but this figure concealed the fact that many urban workers were subsisting on family farms owned by relatives. Besides, the French exported much of their unemployment: thousands of immigrant workers lost their work permits and had to return home. Not until 1938–39 did a measure of recovery set in, thanks to Reynaud's business-oriented policies, plus the stimulus of rearmament. By the time war broke out again, France had barely returned to the pre-Depression level.

The workers, always outside the bourgeois consensus, were by now largely hostile to the system; most of the gains they had finally achieved in 1936 had quickly been snatched away again. But in addition, many bourgeois Frenchmen now questioned the virtues of the traditional system. The 1930s therefore brought an intense fermentation of political and social thought; dozens of study groups and movements sprang up in Paris, seeking or preaching doctrines of drastic renovation and structures of government that might carry them out.

*Cultural attainments.* The cultural climate of the later 19th century in France, as in the Atlantic world generally, was strongly marked by the current called Positivism. The post-1848 generation looked with contempt on what it considered the excesses and the bad taste of the preceding Romantic era. A new interest in science and a new vogue of Realism in literature and the arts prevailed during the Second Empire; it was best embodied in the novels of Gustave Flaubert and the paintings of Gustave Courbet. By the 1870s this mood had formed into what its advocates regarded as a coherent philosophic system, the content and label of which they borrowed from the French thinker Auguste Comte. These self-styled Positivists placed their faith in science and reason as the path to inevitable progress, with only the remnants of superstition (surviving mainly in the church) still blocking

the hopeful future. Although the two most influential thinkers of the early Third Republic, Hippolyte Taine and Ernest Renan, rejected the Positivist label, their writings strongly reinforced the cult of reason and science. Examples of the Positivist temper included the novelist Émile Zola and the Impressionist painters; e.g., Édouard Manet, Claude Monet, Edgar Degas, Pierre-Auguste Renoir. In a scientific age, Frenchmen showed great creativity in pure science and made major discoveries in a wide variety of fields. Among the most notable figures were Louis Pasteur in medicine, Pierre and Marie Curie in physics, Marcelin Berthelot in chemistry, Henri Poincaré in mathematics, and Jean-Martin Charcot in psychopathology. The social sciences attracted fewer French pioneers, though the work of Gustave Le Bon in social psychology and Émile Durkheim in sociology had a broad and enduring impact.

Although the Positivist mood prevailed at least until World War I, it was contested by a rival current of thought that from the 1890s onward began to assert itself. To some sensitive men of artistic temperament the Positivist outlook seemed arid and narrow, much too indifferent to the emotional side of man—such was the view of the school of poets, including Paul Verlaine and Stéphane Mallarmé, who called themselves symbolists. A remarkable group of composers carried this romantic mood into music: the orthodox works of Jules Massenet, Georges Bizet, and Camille Saint-Saëns were followed by the more experimental compositions of Claude Debussy and Maurice Ravel.

Of significance was the growing influence after 1890 of such writers and thinkers as Paul Bourget, Maurice Barrès, and Henri Bergson and such painters as Paul Cézanne and Paul Gauguin. Bourget's novels challenged what he called "brutal positivism"; he attacked the search for a new ethical code derived from science and asserted such traditional values as authority, the family, and the established order. Barrès preached what he called "integral nationalism"; he called for a return to "the sources of national energy," which he found in historic institutions, the soil of the fatherland, and the solidarity between the living and the dead. Bergson, the philosopher whose lectures at the Collège de France became Parisian social events, attacked scientific dogmatism and exalted man's nonrational drives—notably a creative force that he called *élan vital*, distinguishing heroic men and nations from the plodding herd.

This new spirit had its parallel in political thought and action as well: in the syndicalist doctrines of Georges Sorel, in the activism of a minority in the labour movement, and in the resurgent nationalism that strongly affected many young Frenchmen in the years just before 1914. The new mood brought a return to the church and to an intense, emotional patriotism. In the fine arts, a younger school (including Georges Braque, Pablo Picasso, Henri Matisse, and Georges Rouault) broke violently with the Impressionists and moved toward a more intense subjectivism, an attempt to express the artist's inner vision and deeper emotions. Seeking their inspiration in the work of Paul Cézanne and Paul Gauguin, they burst upon the art world in 1905 with such impact that critics took to calling them the Fauves (the wild beasts).

The terrible strain and disillusionment of World War I weighed heavily on French cultural life during the interwar era, leading to the development of the literary and artistic movement called Dadaism, the calculated nonsense of which was inspired by a deep revulsion against the insanity of war and against the Positivist view that the world had sense and meaning. Dadaism soon gave way, though, to the more durable Surrealist movement and its principal theorist, the poet André Breton. The declared goal of Surrealist writers and artists was to free man's unconscious impulses from the distorting controls of rational reflection; creativity, they said, came from deep nonrational drives.

Alongside these self-conscious literary and artistic schools, a number of France's most notable writers remained within the older humanistic tradition, yet like-

Economic  
effects of  
World  
War I

Positivism

wise reflected the doubts and neuroses of an age of crisis. Marcel Proust, whose massive multivolume novel *À la recherche du temps perdu* (*Remembrance of Things Past*) began to appear in 1913, used the stream-of-consciousness technique to probe, in minutely introspective fashion, into the recesses of his own mind and memory. André Gide, in similarly sensitive and introspective fashion, wrestled with the psychological difficulties arising from the conflict between a bourgeois society's values and the individual's instinctive drives.

As the mood of crisis deepened in the 1930s, so did the intensity of the challenge to old values, bringing men of frankly Fascist temper, such as Robert Brasillach, and brutally nihilistic literary experimenters, such as Louis-Ferdinand Céline. But other Frenchmen continued to create works in the older tradition: the social commentary of Roger Martin du Gard, Georges Duhamel, Jules Romains, and François Mauriac; the neoromantic novels of André Malraux, preaching a modern gospel of heroic activism; the first writings of Jean-Paul Sartre; and the essays of Emmanuel Mounier, who was to inspire the new Catholic left after World War II.

#### FRANCE SINCE 1940

**Wartime France.** The German victory left Frenchmen groping for a new policy and new leadership suited to the circumstance. Some 30 prominent politicians—among them Édouard Daladier and Pierre Mendès-France—left for North Africa to set up a government-in-exile there; but Pétain blocked that enterprise by ordering their arrest on arrival in Morocco. The Undersecretary of War in the fallen Reynaud Cabinet, Gen. Charles de Gaulle, had already flown to London and in a radio appeal on June 18, 1940, summoned patriotic Frenchmen to continue the fight; but few heard or heeded his call in the first weeks. It was to Pétain, rather, that most of the nation looked for salvation.

**The Vichy government.** Parliament met at Vichy on July 9–10 to consider France's future. The session was dominated by Pierre Laval, Pétain's vice premier, who was already emerging as the strong man of the government. Laval, convinced that Germany had won the war and would thenceforth control the Continent, saw it as his duty to adapt France to the new authoritarian age. By skillful manipulation, he persuaded parliament to vote itself and the Third Republic out of existence. The vote (569 to 80) authorized Pétain to draft a new constitution. The draft was never completed; but Pétain and his advisers did embark on a series of piecemeal reforms, which they labelled a National Revolution. Soon the elements of a corporative state began to emerge, and steps were taken to decentralize France by reviving the old provinces. In the early stages of Vichy, Pétain's inner circle—except for Laval and a few others—was made up of right-wing traditionalists and authoritarians. The real pro-Fascists, such as Jacques Doriot and Marcel Déat, who wanted a system modelled frankly on those of Hitler and Mussolini, soon left Vichy in disgust and settled in Paris, where they accepted German subsidies and intrigued against Pétain.

In December 1940 Pétain dismissed Laval and placed him briefly under house arrest. Laval had offended Pétain and his followers by his arrogance and his obvious taste for power. His critics charged him also with attempting to bring Vichy France back into the war in alliance with the Germans. Both Laval and Pétain had accepted Hitler's invitation to a meeting at Montoire on October 24, 1940; and during the weeks that followed, the French leaders had publicly advocated Franco-German "collaboration." Whether Laval hoped for a real Franco-German alliance remains somewhat controversial. If so, it was a futile effort because Hitler had no interest in accepting France as a trusted partner; "collaboration" remained a French and not a German slogan. Hitler tolerated the temporary existence of a quasi-independent Vichy state as a useful device to help police the country and to collect the enormously inflated occupation costs levied by the armistice.

Laval was succeeded by another prewar politician,

Pierre-Étienne Flandin, and he, in turn, by Adm. François Darlan, who was intensely anti-British and an intriguer by nature and who followed a devious path that involved continuing efforts at active collaboration with the Germans. Hitler, meanwhile, concentrated on draining France of raw materials and foodstuffs useful for the conduct of the war.

In April 1942 Pétain restored Laval to power, partly under German pressure. Laval retained that post until the collapse of Vichy in 1944. His role was increasingly difficult because the terrible drain of the war in the Soviet Union forced the Germans to increase their exactions. The Germans were short of manpower for their factories, and Laval, under heavy pressure, agreed to the conscription of able-bodied French workers in return for the release of some French prisoners of war. He also assumed the task of repressing the French underground movement, whose activities hampered the delivery of supplies and men to Germany. After the war, Laval and his friends were to argue that he had played a "double game" of limited collaboration to protect France against a worse fate. The alternative, they contended, would have been a German gauleiter who would have liquidated all resisters and deported all able-bodied men.

Much of Vichy's remaining autonomy and authority was destroyed in November 1942, in direct consequence of the Anglo-American landings in North Africa. Vichy troops in Morocco and Algeria briefly resisted the American invasion, then capitulated when Admiral Darlan, who happened to be visiting Algiers at the time, negotiated an armistice. On November 11 Hitler ordered his troops in the occupied zone to cross the demarcation line and to take over all of France. The Vichy government survived but only on German sufferance—a shadowy regime with little power and declining prestige.

**The Resistance.** Vichy's decline was paralleled by the rise of the anti-German underground. Within weeks of the 1940 collapse, tiny groups of Frenchmen had begun to resist. Some collected military intelligence for transmission to London; some organized escape routes for British airmen who had been shot down; some circulated anti-German leaflets; some engaged in sabotage of railways and German installations. The Resistance movement received an important infusion of strength in June 1941, when Hitler's attack on the Soviet Union brought the French Communist Party into active participation in the anti-German struggle. It was further reinforced by the German decision to conscript French workers; many draftees took to the hills and joined guerrilla bands that took the name *maquis*. And a kind of national unity was finally achieved in May 1943, when de Gaulle's personal representative Jean Moulin succeeded in establishing a Conseil National de la Résistance (National Resistance Council) that joined all the major movements in one federation.

De Gaulle's original call for resistance had attracted only a handful of Frenchmen who happened to be in Britain at the time. But as the British continued to fight, a trickle of volunteers from France began to find its way to his headquarters in London. De Gaulle promptly established an organization called Free France and in 1941 capped it with a body called the Comité National Français (French National Committee), for which he boldly claimed the status of a legal government-in-exile. During the next three years, first in London and then (after 1943) in Algiers, he insisted on his right to speak for France and on France's right to be heard as a great power in the councils of the Allies. His demands and his manner irked Churchill and Roosevelt and caused persistent tension. The American government unsuccessfully attempted in 1942 to sidetrack him in favour of Gen. Henri Giraud, who, immediately after the Allied landings in North Africa, was brought out of France to command the French armies in liberated North Africa and to assume a political role as well. De Gaulle arrived in Algiers in May 1943 and joined Giraud as co-president of a new French Committee of National Liberation. By the end of the year he had outmanoeuvred Giraud and emerged as the unchallenged spokesman for French resisters everywhere. Even

German control of all France

The end of the Third Republic

The Free France organization

the Communists in 1943 grudgingly accepted his leadership.

**Liberation.** When the Allied forces landed in Normandy on June 6, 1944, the armed underground units had grown large enough to play an important role in the battles that followed—harassing the German forces and sabotaging railways and bridges. As the Germans gradually fell back, local Resistance organizations took over town halls and prefectures from Vichy incumbents. De Gaulle's provisional government immediately sent its own delegates into the liberated areas to ensure an orderly transfer of power. On August 19 Resistance forces in Paris launched an insurrection against the German occupiers, and on August 25 Free French units under Gen. Jacques Leclerc entered the city. De Gaulle himself arrived later that day, and on the next he headed a triumphal parade down the Champs-Élysées. Most high-ranking Vichy officials (including Pétain and Laval) had moved eastward with the Germans; at the castle of Sigmaringen in Germany they adopted the posture of a government-in-exile.

De Gaulle's provisional government, formally recognized at last in October 1944 by the American, British, and Soviet governments, enjoyed unchallenged authority in liberated France. But the country had been stripped of raw materials and food by the Germans; the transportation system was severely disrupted by air bombardment and sabotage; 2,500,000 French prisoners of war, conscripted workers, and deportees were still in German camps; and the task of liquidating the Vichy heritage threatened to cause grave domestic stress. An informal and spontaneous purge of Vichy officials or supporters had already begun in the summer of 1944; summary executions by Resistance bands appear to have exceeded 10,000.

Retribution  
against  
Vichy  
officials

A more systematic retribution followed. Special courts set up to try citizens accused of collaboration heard 125,000 cases during the next two years. Approximately 50,000 offenders were punished by "national degradation" (loss of civic rights for a period of years); almost 40,000 received prison terms; between 700 and 800 were executed.

**The Fourth Republic.** Shortly after his return to Paris, de Gaulle announced that the citizens of France would determine their future governmental system as soon as the absent prisoners and deportees could be repatriated. That process was largely completed by midsummer 1945, whereupon de Gaulle scheduled a combined referendum and election for October. By an overwhelming majority (96 percent of the votes cast), the nation rejected a return to the prewar regime. The mood of the liberation era was marked by a thirst for renovation and for change.

New men of the Resistance movement dominated the constituent assembly, and the centre of gravity was heavily to the left; three-fourths of the deputies were Communists, Socialists, or Christian Democrats who had adhered to the new party of the Catholic left—the Mouvement Républicain Populaire (MRP).

**Constitution of the Fourth Republic.** After confirming de Gaulle in his post as provisional president, the Assembly turned to the drafting of a new constitution. Almost at once it became clear that the apparent unity forged in the Resistance was superficial and that the dominant parties differed sharply over what form the new republic should take. Most of the Christian Democrats looked to Britain or the United States for their model; they held that prewar France had been hampered by a weak, unstable executive branch and that the president and the Cabinet must henceforth be strong enough to counterbalance the power of Parliament. The Communists wanted all power vested in a one-house legislature whose members would be subject to recall by the voters at any time; the executive branch, in their view, should be merely a kind of delegated committee of parliament. The Socialists wavered and sought a compromise between these two positions.

De Gaulle remained aloof from this controversy, though it seemed obvious that he preferred the strengthened-

executive pattern. Indeed, the Communists alleged that the partisans of a strong presidency had designed it for an authoritarian occupant, de Gaulle himself; their warnings had some effect on the Socialists, many of whom were likewise suspicious of both de Gaulle and his Christian Democratic supporters. De Gaulle, sensing that the Socialists would join forces with the Communists, abruptly resigned the presidency in January 1946, announcing that his task had been completed; he expected that a wave of popular protest would follow, forcing his return to office on terms that would frustrate the aims of the left-wing parties. Most Frenchmen were astounded and confused by his actions, and no such protest followed. The Assembly promptly chose a Socialist politician, Félix Gouin, as provisional president, and de Gaulle bitterly withdrew to his country estate.

De  
Gaulle's  
resignation

In May 1946 the Assembly presented its draft constitution to the voters for approval; the document represented a compromise on many issues but leaned perceptibly toward legislative domination. A clear majority of the voters rejected the draft. A new constitution was quickly drafted; it was, in fact, a somewhat revised version of the first, with a number of safeguards introduced by the Christian Democrats. It provoked de Gaulle's active intervention; he denounced the draft as unworkable and potentially disastrous and sketched out publicly for the first time his own idea of the institutional structure France needed—a stronger, more independent executive and a greatly weakened parliament. Despite his opposition, the voters in October 1946 approved the draft by a narrow margin.

**Political and social changes.** The institutional structure of the Fourth Republic seemed remarkably like that of the Third; in actual operation it seemed even more familiar. The lower house of parliament (now renamed the National Assembly) was once more the central locus of power; shaky coalition Cabinets again succeeded one another at brief intervals, and the lack of a clear-cut majority in the country or in Parliament hampered any vigorous or coherent action. Many politicians from the prewar period turned up once again in Cabinet posts, and the revived Radical Party furnished premiers on several occasions.

Yet outside the realm of political structure and parliamentary gamesmanship, there were real and fundamental changes. The long sequence of crises that had shaken the nation since 1930 had left a deep imprint on French attitudes. There was much less public complacency; both the routines and the values of Frenchmen had been shaken up and subjected to challenge by a generation of upheaval. Many of the new men who had emerged from the Resistance movement into political life, into business posts, or into the state bureaucracy retained a strong urge toward renovation, toward a reassertion of France's lost greatness.

This altered mood helps to explain the economic growth that marked the later years of the Fourth Republic. After a painful period of slow recovery from the war, aided by massive economic aid from the United States, a burst of industrial expansion in all branches of the economy began in the mid-1950s, unmatched in any decade of French history since the 1850s. The rate of growth for a time rivalled that of Germany and exceeded that of most other European countries. The only serious flaw in the boom was a nagging inflationary trend that weakened the franc and undermined the competitiveness of French exports. Short-lived coalition Cabinets were incapable of taking the painful measures that were needed to check this trend.

Industrial  
expansion  
in the  
1950s

**Colonial independence movements.** A less fortunate aspect of the national urge to reassert France's stature in the world was the Fourth Republic's costly effort to hold the colonial empire. France's colonies had provided de Gaulle with his first important base of support as leader of Free France; and as the war continued, they had furnished valuable resources and manpower. The colonial peoples, therefore, now felt justified in demanding a new relationship with France; and French leaders recognized the need to grant concessions. But most of these leaders,

including de Gaulle, were not prepared to permit any infringement on French sovereignty, either immediately or in the foreseeable future. For a nation seeking to rebuild its power status and its self-respect, the prospect of a loss of empire seemed unacceptable; and most Frenchmen were convinced that the native peoples overseas lacked the necessary training and leadership for self-government and that a relaxation of the French grip would merely open the way to domination by another imperial power.

De Gaulle had authorized the overseas territories to elect 64 deputies to the National Assembly in 1945; but these representatives were too disparate in origin and interests to form a coherent bloc, and so they failed to have much influence in the Assembly. The constitution of 1946 provided for the conversion of the old empire into the French Union, a pseudofederal entity that allowed some narrowly limited local autonomy, plus a weak voice in decision making in Paris. The drafters of the constitution did not view this arrangement as a temporary way station toward genuine federalism; the continuing dominance of metropolitan France was strongly asserted.

This limited reform came too late to win acceptance in many parts of the empire. Leaders of local nationalist movements in Indochina, in North Africa, and in certain segments of black Africa could for the first time count on effective support, mainly from an educated colonial elite. The situation was most serious in Indochina, where France's effective control had been broken since 1940. After the war, a Vietnamese resistance movement (the Viet Minh) headed by the Communist Ho Chi Minh moved into the vacuum in the north, while de Gaulle's government regained control of the south and sought to reassert its authority throughout Indochina. Bloody fighting broke out between the French and the Viet Minh forces in December 1946 and dragged on for almost eight years at heavy cost to both sides. In the end, the financial and psychological strain proved too great for France to bear, and after the capture of the French stronghold of Dien Bien Phu by the Viet Minh, the French sought a face-saving solution. A conference of interested powers at Geneva in 1954 ended the war by dividing Vietnam temporarily into northern and southern states, both of them free of French control. Two other segments of Indochina, the protectorates of Laos and Cambodia, had earlier been converted by the French into independent monarchies; some French diplomatic and economic interests were preserved there.

France had a respite of only six months after the fighting in Indochina ended. In November 1954 the standard of rebellion was raised in Algeria. By 1958 more than 500,000 French soldiers were on service in Algeria—the largest overseas expeditionary force in French history. France's determination to hold Algeria stemmed from a number of factors: the presence of almost 1,000,000 European settlers (colons) whose roots there were deep; the strategic importance of the area, just across the Mediterranean; the legal fiction that Algeria was an integral part of France; the recent discovery of valuable oil deposits in the southern desert. The threat that Algeria's neighbours Tunisia and Morocco might seize the occasion to start parallel revolts led the French to make drastic concessions there; in 1956 both protectorates became sovereign states.

As the war in Algeria dragged on, it gravely affected the political life of the Fourth Republic. A growing number of Frenchmen silently or openly favoured a negotiated settlement. Many others furiously opposed such defeatist talk and insisted that the loss of Algeria would be an irreparable disaster. When the Socialists re-entered the governing coalition in 1956 the prospect of a negotiated peace seemed improved, though the Socialists were deeply divided at the time. This prospect led right-wing activists in Paris and in Algiers to turn to conspiracy; several extremist groups began to plot the replacement of the Fourth Republic by a tougher regime—authoritarian, or even Fascist, in temper. Some of these schemers looked to an army-led dictatorship; others hoped for de Gaulle's return to power.

These plots had not yet matured when the Félix Gaillard Cabinet fell in April 1958; almost a month was required to put together a successor. The new premier, Pierre Pflimlin of the MRP, was reputed to favour a negotiated settlement of the war. On May 13, when Pflimlin was due to present his government for approval by the National Assembly, right-wing activists in Algiers went into the streets in an effort to influence the Assembly vote. By nightfall they controlled the city and joined forces to organize a kind of emergency government called the Committee of Public Safety. After much complex manoeuvring, the adherents of a de Gaulle regime managed to win over the French Army commanders in Algiers, generals Raoul Salan and Jacques Massu. De Gaulle on May 15 announced that he would respond to a call from his fellow citizens. Many of the Fourth Republic's political leaders reached the conclusion that only de Gaulle could avert a military Fascist coup or a bloody civil war; but they wanted assurances that de Gaulle would preserve republican forms and procedures. De Gaulle, in turn, insisted on assuming power without restrictions on his authority. In the end a compromise was arranged; Pflimlin resigned, de Gaulle was properly appointed by President René Coty and approved by the National Assembly, and the Assembly adjourned after voting de Gaulle full powers for six months. The leaders of the Fourth Republic, confronted by the prospect of civil war, thus chose to abdicate rather than fight.

**The Fifth Republic.** During his years of self-imposed exile, de Gaulle had remained an unreconciled critic of the Fourth Republic and the men who operated it. At first he had sought to oppose the system through organized political channels, sponsoring a movement called the Rassemblement du Peuple Français (RPF), which ran candidates for office and for a time seemed strong enough to have a real chance at gaining power at the polls. But the RPF then lost its forward impetus; de Gaulle disbanded it in 1953 and thereafter remained for the most part in seclusion. Until May 1958 he steadfastly refused to encourage those supporters who wished to organize a plot against the regime.

Once restored to power, de Gaulle sought the cooperation of the political class in the transition to a Fifth Republic. Several leading politicians were included in his Cabinet; others shared in the drafting of a new constitution. The draft that emerged embodied most of de Gaulle's own governmental theories; most notably, it reinforced the authority of the executive branch (president and prime minister) while reducing that of the National Assembly. The president of the republic was thenceforth to be chosen by a broadened electorate of local notables rather than by the two houses of parliament as in the past. The prime minister, although selected by the president, would continue to be responsible to the Assembly; but the Assembly's legislative powers and right to overthrow Cabinets were sharply pruned back. The system embodied an odd compromise between presidential and Cabinet government. In September 79 percent of the voters who went to the polls approved the constitution. Two months later a new National Assembly was elected; a hastily organized Gaullist party, the Union pour la Nouvelle République (UNR), emerged as the largest group with 194 seats, while the parties of the left suffered a disaster.

**De Gaulle's first presidential term.** In December de Gaulle was elected president for a seven-year term and named his disciple Michel Debré as his first prime minister. De Gaulle's most immediate problems were inflation and Algeria. He attacked the former by painful but in the end salutary measures: deflation, austerity, higher taxes, and lower governmental outlay. In Algeria he seemed at first to be responding to the wishes of the advocates of military victory and of maintaining an Algérie Française. Within a year, however, de Gaulle was clearly searching for a compromise that might persuade the Algerians to accept a loose, continuing tie with France. But it was too late for the Algerian leaders to be tempted by such a solution; their unshakable goal was full independence. The die-hard colon leaders in Algeria,

De  
Gaulle's  
return

Loss of  
Indochina

increasingly suspicious of de Gaulle's aims, cried betrayal and found considerable support in the army hierarchy. Some of de Gaulle's oldest disciples also broke with him: Jacques Soustelle and Georges Bidault became leading agitators for Algérie Française and eventually went into self-imposed exile. Open sedition followed in 1961, when a group of high army officers, headed by Gen. Raoul Salan, formed the Organisation de l'Armée Secrète (OAS) in a desperate effort to hold Algeria by any means. An OAS insurrection in Algiers in April 1961 failed, whereupon the OAS turned to terrorism. Both in Algiers and in France, OAS bombings and assassinations produced a state of near civil war; de Gaulle was the target of several attacks that only barely missed their mark.

Algerian  
independence

De Gaulle had already decided that France could no longer bear the cost of holding Algeria by force, and he was prepared for a settlement that would save face while granting independence. An agreement was signed at Evian-les-Bains in March 1962, giving the Algerians full sovereignty in return for a promise to respect the persons and property of the colons; Algerian oil would be exploited jointly by the two governments. More than 90 percent of the French voters approved the agreement in an April referendum. A massive exodus of European settlers from Algeria brought 750,000 refugees to France. The burden of absorbing them was a heavy one, but the prosperous French economy was able to support the cost and to provide job opportunities.

The Algerian crisis had severe repercussions throughout French Africa. Pressures for greater autonomy had been building up through the 1950s, and the Fourth Republic had already made some concessions. In the 1958 constitution the French Union was renamed the French Community, and somewhat broader home rule was granted. Each overseas territory was authorized to choose between entering the Community or breaking all ties with France. All but one of the territories voted to ratify the constitution and thus join the Community; only Guinea chose secession (and was promptly cut loose from all French ties, including economic aid). But within two years the urge for full independence was irresistible; and the French government, mired deep in Algeria, had no choice but to give way. By the end of 1960 virtually all of the African territories had been accorded full independence; the French empire was reduced to a few small outlying possessions. Making the best of the situation, de Gaulle's government offered military support and generous economic aid to the former colonies; during the 1960s the bulk of French foreign-aid appropriation went to them, and a French-speaking bloc of nations emerged, giving greater resonance to France's voice in world affairs.

The end of the Algerian war brought France a respite after 16 years of continual colonial warfare. Prime Minister Debré resigned and was replaced by one of de Gaulle's closest aides, Georges Pompidou. Once the Algerian settlement had been signed, the tacit political truce ended and "politics as usual" again became an attractive possibility. For many politicians the goal was a revision of the 1958 constitution to restore the power of the National Assembly. Faced by this prospect, de Gaulle proposed his own constitutional amendment; it provided for the election of the president by direct popular vote, thus reinforcing his stature and authority. The opposition denounced the project as unconstitutional; the National Assembly adopted a motion of censure, which forced Pompidou's resignation and the dissolution of the Assembly. A bitter referendum fight followed; in October 1962, 63 percent of the voters ratified de Gaulle's amendment. De Gaulle was angered by the size of the opposition, but he was heartened by a smashing Gaullist victory in the general elections of November 1962, when the UNR and its allies won a clear majority in the Assembly. Pompidou was again appointed premier.

*De Gaulle's second term.* In 1965, when de Gaulle's first presidential term ended, he presented himself for a second term. The parties of the left coalesced behind a single candidate, François Mitterrand, and denied de

Gaulle a clear majority in the first ballot. In the runoff a week later de Gaulle polled 55 percent of the votes cast.

By 1968 the most serious clouds over France seemed to have been dissipated. De Gaulle could point to healthy improvement since his return to power: an end to colonial war, increased national prestige, a stabler franc, steadily rising economic levels, durable rather than collapsible Cabinets, a constitutional system that was taking root in French habits. France had adjusted to its new role in the European Common Market with profit rather than damage to the nation's economy. De Gaulle could safely indulge in such luxuries as blocking Britain's entry into the Common Market, lecturing the United States about Vietnam, and demanding the "liberation" of French-speaking Canadians. At home, most Frenchmen appeared content with the order and prosperity assured by this paternalistic system.

In these circumstances, a sudden crisis in May 1968 caught almost everyone by surprise. Student disorders in the universities of the Paris region had been endemic throughout the academic year and erupted finally on May 3, when a rally of student radicals at the Sorbonne was broken up by police. During the next ten days, the initial incident snowballed into a major confrontation: barricades went up in the Latin Quarter; violent street fighting broke out; the Sorbonne was occupied by student rebels and converted into a huge commune. The unrest spread to other universities and eventually to the workers as well; a wave of strikes rolled across France, involving almost 10,000,000 Frenchmen and virtually paralyzing the entire nation. Pompidou threw himself into round-the-clock negotiations with labour leaders; the so-called Grenelle Agreement was finally worked out, granting extensive concessions on wages and working conditions, but it was repudiated by the rank and file of the CGT, which continued the strike.

By this time various radical factions were openly seeking to turn the crisis into a true revolution that would bring down the Fifth Republic. Plans were concocted for a left-wing coalition government to be headed by François Mitterrand and Pierre Mendès-France. The Communists and the CGT, however, were reluctant to involve themselves in these schemes; party leaders evidently feared the loss of their control of the trade union movement to their more radical and anarchical rivals. In addition, many middle class Frenchmen who had initially sided with the students lost their enthusiasm as the crisis deepened. Seizing the appropriate moment, de Gaulle suddenly departed from Paris by helicopter on May 29.

Returning the next day, after having conferred with top French generals in Germany, he appeared on television with a brief but masterful appeal to the partisans of law and order. He dissolved the National Assembly, called new elections for June 23, and asserted that France faced a choice between de Gaulle and anarchy. Loyal Gaullists were instantly rejuvenated and leaped into action; anti-Gaullists of the right rallied to the standard of law and order. Left-wing resistance collapsed when the Communists refused to consider a resort to force. The crisis was transmuted onto the electoral plane and ended in a Gaullist landslide. The new National Assembly was dominated by the Gaullist UDR (formerly UNR), which, with its allies, could count on about 350 seats in a total of 487.

The consequences of the crisis were nevertheless profound. The depth and extent of the discontent shocked many Gaullists and led to governmental concessions to the protest groups. The labour unions now accepted a revised form of the Grenelle Agreement, improving wages, hours, and working conditions. The Assembly unanimously adopted a university reform bill, designed to modernize higher education and to ensure broad participation by faculty and students. De Gaulle found reason to shake up his Cabinet; the most startling change was the replacement of Pompidou by Maurice Couve de Murville, formerly foreign minister. De Gaulle evidently resented Pompidou's independent action during the May crisis, at a time when the President himself appeared to have lost his nerve and sense of direction. In foreign af-

The crisis  
of May  
1968

Effects of  
the crisis

fairs, de Gaulle muted his previously outspoken and intransigent line. At home, the aftereffects of the crisis threw the budget badly out of balance and undermined the franc. Although de Gaulle rejected devaluation, he was forced to adopt severe austerity measures to avert disaster.

Although the regime seemed to be recovering its old firmness and stability, de Gaulle remained baffled and irritated by the events of May 1968. Perhaps to reassert his leadership and to prove his hold on the mass of Frenchmen, he decided in 1969 to risk another test at the polls. He announced a new constitutional reform, designed to alter the composition and powers of the Senate and to inaugurate a new policy of regional decentralization. Both measures provoked considerable opposition and confusion. In an effort to ensure a majority in the referendum, de Gaulle threw his personal prestige into the scales, announcing that he would resign if repudiated by the voters. Every opposition faction seized upon the chance to challenge the President. On April 27 the amendment was rejected by 53 percent of the voters and de Gaulle at once announced his withdrawal from office. He returned to the obscurity of his country estate, adhering to a strict vow of silence until his death in November 1970.

*France after de Gaulle.* The presidential election that followed de Gaulle's abdication provided the first chance to test Gaullism's capacity to survive the departure of its symbol and leader. Georges Pompidou was accepted as the Gaullist candidate, even though some disciples doubted his loyalty to de Gaulle. The parties of the left, on the other hand, each insisted on entering their own candidates—in most cases a loyal but undistinguished party man. The outcome was an impressive victory for Pompidou and disaster for the left. Pompidou polled 44 percent of the votes, while his nearest rival, Senator Alain Poher, a centrist, received only 23 percent. The Communist nominee, Jacques Duclos, was the only leftist to make a respectable showing (21 percent). In the runoff Pompidou easily outdistanced Poher.

Pompidou's choice as prime minister, Jacques Chaban-Delmas, was another longtime Gaullist but likewise not of the fanatical sort. Despite their frequent protestations of loyalty to the Gaullist heritage, the new president and his prime minister adopted a different governing style, marked by greater flexibility and accommodation, in contrast to de Gaulle's somewhat arbitrary and personal techniques. The new leadership managed during the next two years to preserve the unity of the massive but fragile Gaullist majority in the Assembly. Chaban-Delmas' program put special emphasis on the creation of a "new society"—more modern, more dynamic, and more just than in the past. In foreign policy, too, there were signs of increased flexibility; in 1971 the French and British reached agreement on terms for Britain's entry into the Common Market. Thus, while Gaullists continued to govern France and to stress continuity rather than change, the era properly called Gaullist had clearly come to an end. France in the 1970s was moving imperceptibly into a new phase of its history. (G.Wr.)

and *Beauvais et le Beauvaisis de 1600 à 1730*, 2 vol. (1960), a penetrating social analysis; GEORGES LIVET, *L'Intendance d'Alsace sous Louis XIV, 1648-1715* (1956); HERBERT LUTHY, *La Banque protestante en France de la révocation de l'Édit de Nantes à la Révolution*, 2 vol. (1959-61); HUBERT METHIVIER, *Le Siècle de Louis XIV*, 5th ed. (1968); JEAN ORCIBAL, *Saint-Cyran et le Jansénisme* (1961); LIONEL ROTHKRUG, *Opposition to Louis XIV* (1965); JOHN C. RULE (ed.), *Louis XIV and the Craft of Kingship* (1969), contains a number of stimulating essays, especially R.M. HATTON's sympathetic analysis of Louis's foreign policy aims; WARREN C. SCOVILLE, *The Persecution of Huguenots and French Economic Development, 1680-1720* (1960), important in assessing the effects of the revocation of the Edict of Nantes; JOHN B. WOLF, *Louis XIV* (1968), a recent biography.

*France from 1715 to 1789*: HUBERT METHIVIER, *L'Ancien Régime*, 2nd ed. (1964), is a useful introduction, as is C.B.A. BEHRENS, *The Ancien Régime* (1967). A Marxist interpretation of French social structure in the 18th century can be found in ALBERT SOBOUL, *La France à la veille de la Révolution* (1966); and ALEXIS DE TOCQUEVILLE, *L'Ancien Régime et la Révolution* (1856; Eng. trans., *The Old Régime and the French Revolution*, 1955), is still basic; see ALFRED COBBAN, *A History of Modern France*, vol. 1, *Old Régime and Revolution, 1714-1799* (1957). There are also more detailed essays on particular aspects of French society. ROBERT FORSTER, *The Nobility of Toulouse in the Eighteenth Century* (1960), is an important book and one of the principal sources used by BARRINGTON MOORE in his *Social Origins of Dictatorship and Democracy* (1966), which deals in part with the problem of the origins and nature of the French Revolution. The reader can also turn with profit to ELINOR BARBER, *The Bourgeoisie in 18th Century France* (1955); J.H. SHENNAN, *The Parlement of Paris* (1968); and FRANKLIN FORD, *Robe and Sword* (1953). GEORGES DUBY and ROBERT MANDROU (op. cit.), is a useful survey of economic, social, and cultural history. HENRY SEE, *La France économique et sociale au XVIII<sup>e</sup> siècle* (1925; Eng. trans., *Economic and Social Conditions in France During the Eighteenth Century*, 1927, reprinted 1968), is less original but still useful. All economic histories make much use of the 18th-century work of ARTHUR YOUNG, *Travels in France During the Years 1787, 1788, 1789*.

*France from 1789 to 1815*: The classic 19th-century histories of the French Revolution are those by ADOLPHE THIERS, 2nd ed., 10 vol. (1828-29; Eng. trans., 5 vol., 1894); by FRANÇOIS MIGNET, 2 vol. (1824; Eng. trans., 1826); by JULES MICHELET, especially for its literary qualities, 7 vol. (1847-53; new ed., 2 vol., 1961-62; Eng. trans., 1967); by LOUIS BLANC, 12 vol. (1847-62). Some works that do not present a continuous narrative and are theoretical rather than historical should also be mentioned: THOMAS CARLYLE, *The French Revolution*, 3 vol. (1837, reprinted 1972); ALEXIS DE TOCQUEVILLE (op. cit.), of the utmost importance for a profound understanding of the period; EDGAR QUINET, *La Révolution*, 2 vol. (1865); and HIPPOLYTE TAINÉ, *Les Origines de la France contemporaine*, 6 vol. (1887-94; Eng. trans., *The Origins of Contemporary France*, 6 vol., 1931), marked by violent anti-Revolutionary prejudice. Studies of Revolutionary history received a fresh impetus at the end of the 19th and the beginning of the 20th century: ALPHONSE AULARD, *Histoire politique de la Révolution française* (1901; Eng. trans., *The French Revolution: A Political History, 1789-1804*, 1910); JEAN JAURES, *Histoire socialiste de la Révolution française*, 12 vol. (1901-08, reprinted 1968); P. SAGNAC, *La Révolution, 1789-1792*, and G. PARISET, *La Révolution, 1792-1799*, vol. 1 and 2 of the *Histoire de France contemporaine*, ed. by ERNEST LAVISSE (1920-22); ALBERT MATHIEZ, *La Révolution française*, 3 vol. (1925-27; Eng. trans., *The French Revolution*, 3 vol., 1956). At the present time the outstanding study is GEORGES LEFEBVRE, *La Révolution française*, 3rd ed. rev. and updated by ALBERT SOBOUL (1963; Eng. trans., *The French Revolution*, 2 vol., 1962-64). Recent findings are included in ALBERT SOBOUL, *Précis d'histoire de la Révolution française* (1962). Historical works in English include CRANE BRINTON, *A Decade of Revolution, 1789-1799* (1963); LEO GERSHOF, *The French Revolution and Napoleon* (1933, reprinted 1964) and *The Era of the French Revolution, 1789-1799: Ten Years That Shook the World* (1957); JAMES M. THOMPSON, *The French Revolution* (1943); ALFRED COBBAN (op. cit.); ROBERT R. PALMER, *The Age of the Democratic Revolution: A Political History of Europe and America, 1760-1800*, 2 vol. (1959-64). The best history of Napoleon and the Napoleonic period is still GEORGES LEFEBVRE, *Napoléon*, 6th ed. rev. and updated by ALBERT SOBOUL (1969; Eng. trans., 2 vol., 1969). See also EUGENIE TARLE, *Napoléon* (1942); EMILE TERSEN, *Napoléon* (1959); and FELIX PONTEIL, *Napoléon I<sup>er</sup> et l'organisation autoritaire de la France*, 2nd ed. (1966)—all in French. Especially from a bibliographical point of view, reference should

be made to JACQUES GODECHOT, *L'Europe et l'Amérique à l'époque napoléonienne* (1967). In English, *The Cambridge Modern History*, vol. 9 (1934); and ROBERT R. PALMER, *A History of the Modern World*, 4th ed. (1971), are to be noted.

*France since 1815*: (General surveys of the period): ALFRED COBBAN, *A History of Modern France*, vol. 2-3 (1965), a sophisticated synthesis by a British specialist; GORDON WRIGHT, *France in Modern Times* (1960), an interpretive survey from an American viewpoint. (Surveys of special topics covering all or most of the period since 1815): ADRIEN DANSETTE, *Histoire religieuse de la France contemporaine*, 2 vol. (1948-51; Eng. trans., *Religious History of Modern France*, 2 vol., 1961), a lucid account of the Church's role, by a Catholic moderate; RAOUL GIRARDET, *La Société militaire dans la France contemporaine, 1815-1939* (1953), on the changing role and composition of the officer corps since 1815; ANTOINE PROST, *Histoire de l'enseignement en France, 1800-1967* (1968), a detailed history of the French educational system seen in its social and political context; RENE REMOND, *La Droite en France*, rev. ed. (1968; Eng. trans., *The Right Wing in France from 1815 to De Gaulle*, 2nd ed., 1969), a sophisticated essay tracing changes and continuity within the Right; PIERRE RENOUVIN, *Histoire des relations internationales: le XIX<sup>e</sup> siècle*, 2 vol. (1954-55), an excellent synthesis stressing the role of France in European and world affairs; CHARLES P. KINDLEBERGER, *Economic Growth in France and Britain, 1851-1950* (1964), a provocative essay weighing rival theories about France's slow industrial development; PIERRE BARRAL, *Les Agrariens français de Méline à Pisani* (1968), a solid analysis of the changing status of the peasantry and of agrarian movements since the late 19th century. (The Restoration and constitutional monarchy): GUILLAUME DE BERTIER DE SAUVIGNY, *La Restauration* (1963; Eng. trans., *The Bourbon Restoration*, 1966), a thorough and up-to-date re-examination of the period; PAUL BASTID, *Les Institutions politiques de la monarchie parlementaire française, 1814-1848* (1954), a detailed study of how the political system worked; DOUGLAS JOHNSON, Guizot: *Aspects of French History, 1787-1874* (1963), a many-sided account of the period focussed on the work of its most notable statesman. (The Second Republic and the Second Empire): LOUIS GIRARD, *La II<sup>e</sup> République* (1968), the best recent synthesis of the period 1848-51; KARL MARX, *Die Klassenkämpfe in Frankreich 1848 bis 1850* (1850; Eng. trans., *The Class Struggles in France, 1848 to 1850*, 1924, reprinted 1964), an essay that continues to influence the work of many historians; and *The Civil War in France* (1871, reprinted 1948), another fine example of contemporary history that did much to shape the legend of the Commune; J.P.T. BURY, *Napoleon III and the Second Empire* (1964), a thoughtful and well-informed judgment; THEODORE ZELDIN, *The Political System of Napoleon III* (1958), on the composition of the political elite in the Second Empire; MICHAEL HOWARD, *The Franco-Prussian War* (1961), an outstanding study of the origins, course, and consequences of the war; STEWART EDWARDS, *The Paris Commune, 1871* (1972), one of the best of the many centennial re-evaluations. (The Third Republic): DENIS W. BROGAN, *France Under the Republic* (1940), a classic account by a British scholar—witty and sophisticated; JACQUES CHASTENET, *Histoire de la troisième république*, 7 vol. (1952-63), the most detailed treatment—lucid and lively; DAVID THOMSON, *Democracy in France Since 1870*, 5th ed. (1969), a penetrating essay stressing political and social aspects; DOUGLAS JOHNSON, *France and the Dreyfus Affair* (1966), the most convenient recent assessment of the great crisis; FREDERICK F. RIDLEY, *Revolutionary Syndicalism in France* (1970), an excellent analysis of the doctrine and action of the trade union Left in the early 20th century; EUGEN WEBER, *Action Française* (1962), a remarkable monograph that clarifies many aspects of French politics; JEAN GANIAGE, *L'Expansion coloniale de la France sous la troisième république* (1968), a convenient synthesis. (France since 1940): STANLEY HOFFMANN et al., *In Search of France* (1963), probably the most perceptive analysis of crisis and change in postwar France; ROBERT ARON, *The Vichy Regime, 1940-44* (1958), a detailed study based on extensive interviewing of Vichy leaders; CHARLES DE GAULLE, *Mémoires de guerre*, 3 vol. (1954-60; Eng. trans., *War Memoirs*, 5 vol., 1955-60), contains the story of the wartime Free France movement, as viewed by its founder; PHILIP WILLIAMS, *Crisis and Compromise: Politics in the Fourth Republic*, 3rd ed. (1964), a standard account of the political system and how it functioned; H. STUART HUGHES, *The Obstructed Path: French Social Thought in the Years of Desperation, 1930-1960* (1968), a lucid study of dominant French ideas, mainly in the postwar era; PIERRE VIANSSON-PONTE, *Histoire de la République gaullienne*, vol. 1, 1958-1962 (1970), the initial volume in an unusually well-informed history of the Fifth Republic.

## Francis of Assisi, Saint

St. Francis of Assisi, known as the "seraphic saint," was the founder of the Franciscan orders of men and women and is (with Catherine of Siena) the principal patron saint of Italy. He assumed the leadership of the religious movements of the early 13th century that were attempting to reform the medieval church, morally scarred by its struggles with civil rulers. Francis' fraternal charity and total poverty, coupled with his magnetic personality, drew thousands of followers to his side during his life and have made him in each succeeding age one of the most venerated religious figures.

Allinari—Anderson

Saint Francis, detail of a fresco by Cimabue, late 13th century. In the Lower Church of the Basilica of S. Francesco, Assisi.

### Early life and career

Francis was born in 1181/82 at Assisi in Umbria, the son of Pietro di Bernardone, a cloth merchant, and the lady Pica. Nothing certain is known of the family background. At Francis' birth, his father was away on a business journey to France, and his mother had him baptized Giovanni. On his return, Pietro di Bernardone changed the infant's name to Francesco; thus his full name was Francesco di Pietro di Bernardone. Francis learned to read and write Latin at the school near the church of S. Giorgio and later acquired some knowledge of the French language and literature, especially of the troubadours. He liked to speak French, although he never did so perfectly, and even attempted to sing in it. His youth does not seem to have been marked by serious moral lapses; nevertheless, an exuberant love of life and a general spirit of worldliness made him a recognized leader of the young men of the town.

In 1202 he took part in a war between Assisi and Perugia, was held prisoner for almost a year, and on his release fell seriously ill. After his recovery, he attempted to join the papal forces under Count Gentile against Frederick II in Apulia in late 1205; at Spoleto, however, he had a vision or dream that bade him return to Assisi and await a call to a new kind of knighthood. On his return, he began to give himself to solitude and prayer so that he might know the will of God for him.

Several other episodes make up what is called his conversion: a vision of Christ while he prayed in a grotto near Assisi; an experience of poverty during a pilgrimage to Rome, where, in rags, he mingled with the beggars before St. Peter's basilica and begged alms; an incident in which he not only gave alms to a leper (he had always felt a deep repugnance for lepers) but also kissed his hand. One day at the ruined chapel of S. Damiano outside the gate of Assisi, he heard the crucifix above the altar command him: "Go, Francis, and repair my house which, as you see, is well-nigh in ruins." Taking this literally, he hurried home, gathered much of the cloth in his

father's shop and rode off to the nearby town of Foligno, where he sold both cloth and horse. He then tried to give the money to the priest at S. Damiano. Angered, his father first kept him at home and later brought him before the civil authorities. When Francis refused to answer the summons, his father called him before the bishop. Before any accusations were made, Francis, "without a word peeled off his garments even down to his breeches and restored them to his father." Covered only by a hair shirt, he said: "Until now I have called you my father on earth. But henceforth I can truly say: Our Father who art in heaven." The astonished bishop gave him a cloak, and Francis went off to the woods of Mt. Subasio above the city.

Francis had renounced material goods and family ties to embrace a life of poverty. He repaired the church of S. Damiano, restored a chapel dedicated to St. Peter the Apostle and then the now-famous little chapel of St. Mary of the Angels (Santa Maria degli Angeli), the Porziuncola, on the plain below Assisi. There on the feast of St. Matthias, February 24, 1208, he listened at mass to the Gospel account of the mission of Christ to the Apostles: "Take no gold, nor silver, nor money in your belts, no bag for your journey, nor two tunics, nor sandals, nor a staff; for the labourer deserves his food. And whatever town or village you enter, find out who is worthy in it, and stay with him until you depart" (Matt. 10:9-11). Although a layman, he began to preach to the townspeople. Disciples were attracted to him, and he composed a simple rule of life for them. In 1209, when the group of friars (as the mendicant disciples were called) numbered 12, they went to Rome to seek the approval of Pope Innocent III, who, although hesitant at first, gave his verbal approbation to their rule of life. This event, which according to tradition occurred on April 16, marked the official founding of the Franciscan Order. The friars, who were actually street preachers with no possessions of any kind and with only the Porziuncola as a centre, preached and worked first in Umbria and then, as their numbers grew, in the rest of Italy.

### The Franciscan rule of life

The early Franciscan rule of life, which has not survived, set as the aim of the new life, "To follow the teachings of our Lord Jesus Christ and to walk in his footsteps." Probably no one in history has ever set himself so seriously as did Francis to imitate the life of Christ and to carry out so literally Christ's work in Christ's own way. This is the key to the character and spirit of St. Francis. To neglect this point is to show an unbalanced portrait of the saint as a lover of nature, a social worker, an itinerant preacher, and a lover of poverty.

Certainly the love of poverty is part of his spirit, and his contemporaries celebrated poverty either as his "lady," in the allegorical *Sacrum Commercium* (Eng. trans., *Francis and His Lady Poverty*, 1964), or as his "bride," in the fresco of Giotto in the lower church of S. Francesco at Assisi. It was not, however, mere external poverty he sought but the total denial of self (as in Phil. 2:7).

He considered all nature as the mirror of God and as so many steps to God. He called all creatures his "brothers" and "sisters," and in his "Canticle of the Creatures" (less properly called by such names as the "Praises of Creatures" or the "Canticle of the Sun") he referred to "Brother Sun" and "Sister Moon," the wind and water, and even "Sister Death." His long and painful illnesses were nicknamed his sisters, and he begged pardon of "Brother Ass the body" for having unduly burdened him with his penances. Above all, his deep sense of brotherhood under God embraced his fellow men, for "he considered himself no friend of Christ if he did not cherish those for whom Christ died."

In 1212 Francis began a second order for women that became known as the Poor Clares. He gave a religious habit, or dress, similar to his own to a noble lady of Assisi, later known as St. Clare (Clara) of Assisi, and then lodged her and a few companions in the church of S. Damiano, where she was joined by women of Assisi. For those who could not leave their families and homes he eventually (c. 1221) formed the Third Order of Brothers

and Sisters of Penance, a lay fraternity that, without withdrawing from the world or taking religious vows, would carry out the principles of Franciscan life.

As the friars became more numerous, the order extended outside Italy. Probably in the late spring of 1212 Francis had set out for the Holy Land but was shipwrecked on the east coast of the Adriatic Sea and had to return.

A year or two later, sickness forced him to abandon a journey to the Moors in Spain. In 1217 he proposed to go to France, but Cardinal Ugolino of Segni (later Pope Gregory IX) advised him that he was needed to direct the order in Italy. He did go to Egypt, where the crusaders were besieging Damietta, in 1219. He went into the camp of the Saracens and preached to the sultan, who was impressed by him and gave him permission (it is said) to visit the holy places in Palestine.

News of disturbances among the friars in Italy forced Francis to return. There were 5,000 members of the men's order, and it was continuing to grow at a faster rate than any previous religious order; yet the order had little more than Francis' example and his brief rule of life to guide its increasing numbers. To provide someone to handle the order's practical affairs, Francis appointed Peter Catani as his vicar; after Peter's early death in 1221 he chose Elias of Cortona. Francis asked Pope Honorius III for legislation introducing a year of probation (novitiate) for new friars and set about amplifying and revising the rule. After the new rule was approved by Honorius III in final form on November 29, 1223, Francis tended to withdraw more and more from external affairs.

In the summer of 1224 Francis went to the mountain retreat of La Verna (Alvernia), not far from Assisi, to celebrate the feast of the Assumption of the Blessed Virgin Mary (August 15) and to prepare for St. Michael's Day (September 29) by a 40-day fast. There he prayed that he might know how best to please God; opening the Gospels for the answer, three times he came upon references to the Passion of Christ. As he prayed one morning, about the time of the feast of the Exaltation of the Cross (September 14), suddenly he beheld a figure coming toward him from the heights of heaven. St. Bonaventure, general of the Franciscans from 1257 to 1274 and an important thinker of the 13th century, wrote:

As it stood above him, he saw that it was a man and yet a Seraph with six wings; his arms were extended and his feet conjoined, and his body was fixed to a cross. Two wings were raised above his head, two were extended as in flight, and two covered the whole body. The face was beautiful beyond all earthly beauty, and it smiled gently upon Francis. Conflicting emotions filled his heart, for though the vision brought great joy, the sight of the suffering and crucified figure stirred him to deepest sorrow. Pondering what this vision might mean, he finally understood that by God's providence he would be made like to the crucified Christ not by a bodily martyrdom but by conformity in mind and heart. Then as the vision disappeared, it left not only a greater ardour of love in the inner man but no less marvelously marked him outwardly with the stigmata of the Crucified.

Francis took the greatest care to hide the stigmata—the same wounds in his hands, feet, and side as Jesus Christ—in his lifetime. After the death of Francis, Brother Elias announced the stigmata to the order by a circular letter. Later, Brother Leo, who was the confessor and intimate companion of the saint and who left a written testimony of the event, said that in death Francis seemed like one just taken down from the cross.

Francis lived two years longer, in constant pain and almost totally blind (he had contracted an eye disease in the East). Medical treatment at Rieti was unsuccessful, and after a stay at Siena he was brought back to Assisi, where he died at the Porziuncola on October 3, 1226. He was buried temporarily in the church of S. Giorgio, at Assisi. Francis was canonized a saint on July 16, 1228, by Gregory IX; his feast day is October 4. In 1230 his body was transferred to the lower church of the basilica that was being erected in his memory by Elias at the west end of the city.

## BIBLIOGRAPHY

*The writings of St. Francis:* Critical editions by LEONARD LEMMENS (1901) and by H. BOEHMER (1904); English translations by PASCAL ROBINSON (1908), LEO SHERLEY-PRICE (1959), and BENEN FAHY, with introduction and notes by PLACID HERMANN (1964).

*Early biographies:* Thirteenth-century biographies include THOMAS OF CELANO, *First and Second Life of St. Francis, with Selections from Treatise on the Miracles of Blessed Francis*, trans. by PLACID HERMANN (1963), writings dated, respectively, 1228–30, 1247, and c. 1253—composed by a friar who knew Francis personally and had access to material furnished by his early companions; "The Legend of the Three Companions (1246)," in *St. Francis of Assisi: His Holy Life and Love of Poverty*, trans. by PLACID HERMANN (1964), likely a source for Celano's "Second Life"; ST. BONAVENTURE, *The Greater Life of St. Francis, and the Shorter Life*, trans. by BENEN FAHEY, with introduction and notes by PLACID HERMANN (1965), a theologian's approach to the saint, with some new material gathered from surviving companions (1260–62). Fourteenth-century compilations abound; the following exist in English translations: *The Mirror of Perfection*, wrongly attributed to BROTHER LEO (trans. by LEO SHERLEY-PRICE, 1959; Everyman ed., 1963); *The Fioretti or Little Flowers of St. Francis*, ed. by RAPHAEL BROWN (1958), ed. by LEO SHERLEY-PRICE (1959), Everyman ed. (1963)—though full of legends and even falsifications, the work gives a certain insight into the Franciscan spirit of self-abnegation, love, and spiritual joy. A more complete listing and critical evaluation of the sources of the life of St. Francis, together with all important studies up to 1963, may be found in the appendixes to OMER ENGLEBERT, *Saint Francis of Assisi: A Biography*, 2nd ed. rev. by IGNATIUS BRADY and RAPHAEL BROWN (1965).

*Modern biographies:* JOHANNES JORGENSEN (1907; Eng. trans., 1912; 3rd ed., 1955); FATHER CUTHBERT (1912; new ed., 1956); G.K. CHESTERTON (1924, 1957); ENGLEBERT (*op. cit.*); for others, see RAPHAEL BROWN, in Englebert's *Saint Francis*, pp. 525–527. The development of the Franciscan movement within the lifetime of St. Francis is admirably treated by CAJETAN ESSER in *Origins of the Franciscan Order* (1970); and briefly, with a biographical sketch of St. Francis, in JOHN R. MOORMAN, *A History of the Franciscan Order from Its Origins to the Year 1517* (1968). The spirituality of the saint is studied by CAJETAN ESSER and ENGELBERT GRAU in *Love's Reply*, trans. by IGNATIUS BRADY (1963).

(I.C.B.)

## Francis I of France

As full of contrasts as the period in which he lived, Francis I, king of France from 1515 to 1547, was in temperament a medieval knight-king, with a passion for feats of valour, for tournaments, and for adventures; but at the same time he was a stately Renaissance king, refined, open to new ideas, and a patron of the arts and Humanist scholarship. In a century in which the world and beliefs about it were changing drastically, he transformed his country's economy and society, uniting and enlarging a kingdom composed of different races, with different customs and languages.

**Early years.** The son of Charles de Valois-Orléans, comte d'Angoulême, and Louise of Savoy, Francis of Angoulême was born at Cognac on September 12, 1494. On the accession of his cousin Louis XII in 1498, Francis became heir presumptive and was given the duchy of Valois. With his sister Marguerite, he was raised by his mother, who had been widowed at the age of 20 and whom he deeply revered; he knelt whenever he spoke to her. No one had as much power over him as these two women. Idolized, he grew up following his own whims, without discipline and more infatuated with chivalrous romances, songs, and violent exercise than with classical studies. He was greatly admired by the gay, young circle of his mother's cultured court for his athletic build, his gentlemanly courtesy, and the elegance of his demeanour and manners. His need for female companions stemmed from this upbringing, as did his lack of realism and his chivalrous imagination.

Louis XII, distrustful of Francis, did not allow him to dabble in affairs of state but sent him off at the age of 18 to the frontiers, which had been attacked in force. There, Francis learned more about warfare and, being of a sensuous nature, about the licentiousness of camp life than about how to govern the state or, even more, to govern

Francis' vision and the stigmata of the Crucified

Francis I, portrait by Pierre Dumonstier (c. 1524–1604), after a drawing by Jean Clouet. In the Bibliothèque Nationale, Paris. By courtesy of the Bibliothèque Nationale, Paris

himself. Shortly before his death, Louis XII married him to Claude, his 15-year-old daughter. On January 1, 1515, at the age of 20, Francis became king of France.

His quick and shrewd mind, his amazing memory, and his universal curiosity compensated for his inexperience. But, because he was outgoing and trusting and incapable of dissembling, he was always a bad politician. The pomp of the Reims coronation, the sumptuous cortege of the solemn entry into Paris, and the lavish feasts revealed his love of ceremony and also pleased the people of Paris, who had been disheartened by a long succession of morose and sickly sovereigns.

**Promise of a great reign.** Louis XII had left an army prepared to reconquer the duchy of Milan. This ill-fated dream of recovering his great-grandmother Valentina Visconti's heritage—which had been lost, retaken, then lost again—fascinated Francis in his turn. Ambitious for glory and urged on by turbulent young nobles, he made sure of peace with his neighbours, entrusted the regency to his mother, and galloped off to Italy.

At the bloody Battle of Marignano, charging at the head of his cavalry, he defeated the reportedly invincible Swiss mercenaries of Duke Massimiliano Sforza and his ally Pope Leo X. After the victory, by his own wish, he was knighted by the captain who had fought most bravely: Bayard, the most famous chevalier of his time.

The Pope received his conqueror in Bologna. Surrounded by his glittering pontifical court and by his famous artists, he dazzled Francis with concerts, banquets, and theatrical performances. The Pope offered him a Madonna by Raphael and negotiated a concordat that returned to the Pope the benefices of the rich church of France, while the nomination of prelates was assigned to the King, who was desirous of strengthening his authority over a clergy grown too acquisitive and independent.

Buoyed up by a victor's prestige, the King spoke as a sovereign, using for the first time the formula of absolute power: "For such is our pleasure." Prosperity permitted him to grant a princely pension to Sforza, as well as to Leonardo da Vinci and other artists who brought masterpieces to his court. He also signed a perpetual peace treaty with the Swiss and bought back Tournai from Henry VIII of England. And, as a pledge of unalterable friendship, the first-born royal child, Princess Louise, was affianced to the Habsburg prince Charles, heir to The Netherlands and, at 16, the new king of Spain.

Everything forecast a great reign. Francis I formed a brilliant and scholarly court at which poets, musicians, and learned men mingled with rough noblemen from the provinces whom idleness was making dangerous. He welcomed lovely ladies at court, saying, "A court without

women is a year without spring and a spring without roses." The arts, elegance, and chivalrous gallantry served to refine the licentious manners of the court.

The frail queen Claude, gentle and pious, bore a child each year. Francis respected her and sought her advice. In the meantime, he loved the dark-haired countess Françoise de Châteaubriand, without, however, foregoing gay nocturnal escapades with his childhood companions, who had now become his ministers and his favourites.

Francis toured France tirelessly, showing himself to people who had never seen a king. He was constantly travelling on horseback, winter and summer, whether well or ill. He became familiar with everything: men, roads, rivers, resources, and needs. During his travels, he emptied prisons, curtailed the abuses of judicial powers by the nobles, lavished largesse on the people, and provided games and processions for them, speaking to them in his grand manner, warmly and openly: "My friends, my beloved ones . . ."

Popular, happy, the father of two sons, he was the most powerful sovereign in all Christendom when, in 1519, the German emperor Maximilian died. The election as emperor of Maximilian's grandson Charles spelled ruin for Francis I, for Charles, who was already king of Spain, now encircled France with his possessions.

**Rivalry with Charles V.** Nineteen years old, secretive, cool-headed, and a clever politician, the Emperor had his mind set on a universal monarchy. His chief obstacle was the King of France. A mortal hatred emerged from this rivalry, leading to 27 years of savage warfare, interrupted by truces that were invariably violated. In 1520, on the Field of Cloth of Gold near Calais, where both displayed unprecedented magnificence, Francis vainly sought an alliance with Henry VIII.

Hostilities between Charles V and France began in 1521 in the north and in the Pyrenees, while the two brothers of the King's mistress were losing Milan. The soldiers remained unpaid, and the army was disintegrating. The King, unconcerned, arose late, paid little attention to his council, and gave orders without seeing that they were carried out. Money disappeared into thin air. A few paymasters were hanged, though in vain.

In 1523 the King demanded the return to the French state, according to law, of the vast provinces that the great feudal duke Charles de Bourbon thought he had inherited from his wife. Incensed, Bourbon turned traitor and joined the Emperor's service, claiming that the French, weary of the prodigality of their sovereign, would rise up on an appeal from him. Commanding the imperial army, he invaded Provence, was driven back near Marseilles, and withdrew toward Italy. Francis I was pursuing him when he learned of the death of his wife Claude, at the age of 24, exhausted from seven pregnancies. The death of his second daughter followed soon after. Meanwhile, the English and the Germans were advancing in the north. In vain, his mother begged him to return: "Our good angel has abandoned us. Your horoscope forecasts disaster!" At the Battle of Pavia in 1525, defeated and wounded, he was taken prisoner. "Madame, to inform you of the rest of my misfortune, I have nothing left to me save my honour and my life."

As the price for the King's freedom, the Emperor demanded one-third of France, the renunciation of France's claim to Italy, and restitution to Bourbon of his fiefs, with the addition of Provence. "I am resolved to endure prison for as long as God wills rather than accept terms injurious to my kingdom!" replied the King.

Imprisoned in a dismal tower in Madrid, watched over day and night, the recluse composed melancholy poems, songs, and letters to his subjects, heartrending in their humility and their tender nobility. The mortifying defeat, the dangerous situation of his country, and the confinement aggravated his habitual migraines, the consequence of old wounds and of newly contracted syphilis. When he was struck down by an abscess in his head, his people, loyal in bad fortune as in good, prayed for him. The Archbishop of Tournon said a mass at his bedside, in the presence of his sister Marguerite, who had hastened to Madrid.

**Decline and death.** Although Francis finally recovered, he did not cease to suffer. His personality changed. Sudden reversals of mood, excesses of severity and clemency, inconsistencies in his statesmanship and in his personal behaviour marked him; his mind sometimes wandered.

The Emperor persisted in his exorbitant claims. Resigned to die in prison, the King abdicated in favour of his eldest son. France judged this abdication to be the worst possible move. The Dauphin was too young; the country was lost without its leader. No matter what the cost, he would have to return home. The French ambassadors, with only nominal cooperation by the King, concluded the harsh Treaty of Madrid. He signed it in January 1526, declaring that the word and signature of an imprisoned knight were valueless and that it was beyond his power to dismember his kingdom. Still bedridden, he was betrothed by proxy to Eleanor, widow of the King of Portugal and sister of his jailer. The wedding was to seal the reconciliation of the two rulers and was to follow execution of the treaty. As a last condition, Francis, grieving, had to deliver his two eldest sons, seven and eight years old, as hostages.

The surrendered provinces refused to divorce themselves from France. The Emperor, furious with the perjured King, held the children prisoner for four years. His army plundered Italy and captured Pope Clement VII. Francis could not openly engage in the war that was again flaring up everywhere against Charles V. Doomed to disavow his promises to his secret allies, he fled from their envoys, either going on hunting trips from forest to forest or travelling around the country, building fairy-like castles that he occupied only fleetingly and founding the free and secular Collège de France. Anne, duchesse d'Étampes, "the most beautiful of learned ladies, and the most learned of beautiful ladies," replaced Madame de Châteaubriand, more as a companion than mistress.

Their raging hatred impelled Charles and Francis to challenge each other to a duel, which was, however, prevented. During one of the King's relapses, his mother reached an agreement with Margaret of Austria, the Emperor's aunt, to stop this deadly struggle. The ensuing Treaty of Cambrai softened that of Madrid. In order to get his children back, Francis had to abandon his allies, give up Italy, and pay 2,000,000 gold crowns. His foolish expenditures had emptied the treasury, and the ransom was collected only with difficulty. Finally, however, the little princes were able to attend their father's political marriage to Eleanor in 1530.

In 1531 the King's mother succumbed to the plague. Marguerite, having married the King of Navarre, lived at some distance. The King, grown tragically old, in 1533 presided over the marriage of his second son, Henry, to Catherine de Médicis, the niece of Clement VII.

When religious strife broke out in France, the King—tolerant, an epicurean, an admirer of the Dutch Humanist Erasmus, and patron of the great satirist Rabelais, as well as a reader of Philipp Melancthon, the Reformer—tried to moderate the growing fanaticism. Both his sister and his mistress supported the Reformation, whereas his ministers were zealous Catholics. But the Reformers were considered republicans, and the burnings at the stake began. For five years he delayed the extermination of the Waldensian sect, only signing the order without reading it when on his deathbed.

The war with Charles V was resumed in 1536. Bereavements within the family came in quick succession. The Dauphin died at the age of 18—poisoned by Charles V, it was believed. The third son, the most dearly loved, died of the plague. One of Francis' last diplomatic achievements was an alliance with the Turks against the Emperor.

Henry VIII, by turns friend or enemy, died in January 1547. Francis, younger by two years, still had time to found the port of Le Havre, to send Jacques Cartier to Canada, to reform the judicial system, and to decree the use of French in all legal documents.

Wasting away with fever, dying, he wandered from castle to castle, carried on a litter. Finally, on March 31,

1547, the knight-king died at Rambouillet. Notwithstanding the personal afflictions of the last 20 years of his life, Francis was to his countrymen and to the succeeding generation *le grand roi François*.

## Francis Joseph I

The life of Francis Joseph I, emperor of Austria from 1848 to 1916 and after his coronation in 1867 as king of Hungary, is so intimately bound up with the destinies of Austria-Hungary that his biography is in many respects a history of that state. For one thing, the Emperor, more remarkable for his devotion to duty than for any great innate talents, remained throughout his reign the key figure of Austria-Hungary; for another, his private life, coloured by tragic events, was so overshadowed by his official position that it is impossible to separate the human being from the public figure.

By courtesy of the trustees of the British Museum; photograph, J.R. Freeman & Co. Ltd.

Francis Joseph I, 1908.

Francis Joseph was born at Schönbrunn Palace near Vienna on August 18, 1830, the eldest son of Archduke Francis Charles and Sophia, daughter of King Maximilian I Joseph of Bavaria. As his uncle Ferdinand I was childless, Francis Joseph was educated as his heir-presumptive. Particular attention was given to his military training. In the spring of 1848 he served with the Austrian forces in Italy, where Lombardy-Venetia, supported by King Charles Albert of Sardinia, had rebelled against Austrian rule. When revolution spread to the capitals of the Austrian Empire, Francis Joseph was proclaimed emperor at Olmütz (Olomouc) on December 2, 1848, after the abdication of the emperor Ferdinand—the rights of his father, the archduke, to the throne having been passed over. Hopes of a revival of monarchist sentiments were raised by his radiant, youthful appearance.

Early years

Attempts at religious conciliation

Of all his mentors, the old chancellor Metternich, with his conservative interpretation of the concept of the great European powers, probably exerted the most lasting influence on Francis Joseph. A more profound influence, however, was that of his wife, who was the duchess Elizabeth of Bavaria. He married her in 1854 and remained deeply attached to her throughout a stormy marriage.

**Neo-absolutism, 1848–59.** During the first ten years of his reign, the era of so-called neo-absolutism, the Emperor—aided by such outstanding advisers as Felix, Fürst zu Schwarzenberg (until 1852), Leo, Graf von Thun, and Alexander, Freiherr von Bach—inaugurated a very personal regime by taking a hand both in the formulation of foreign policy and in the strategic decisions of the time. Together with Schwarzenberg, who had become prime minister and foreign minister in 1848, Francis Joseph set out to set his empire in order.

In external affairs Schwarzenberg achieved a powerful position for Austria; in particular, with the Olmütz convention of November 1850, in which Prussia acknowledged Austria's predominance in Germany. In home affairs, however, Schwarzenberg's harsh rule and the formation of an intolerant police apparatus evoked a latent mood of rebellion. This mood became more threatening after 1851, when the government withdrew the promise of a constitution, given in 1849 under the pressure of the revolutionary troubles. That retraction had long after-effects and led to the Liberals' permanent distrust of Francis Joseph's rule. In 1853 the people's discontent made itself felt in an attempt on the Emperor's life in Vienna and in a riot in Milan.

After Schwarzenberg's death (1852), Francis Joseph decided not to replace him as prime minister and took a greater part in politics himself. Austria's mistaken policy during the Crimean War originated largely with the Emperor, who could not make up his mind between gratitude to Russia for its help in quelling a rebellion in Hungary in 1849 and the advantage the monarchy might derive from siding with Great Britain and France. The mobilization of a part of the Austrian army in Galicia on the borders of Russia, for which Francis Joseph was ultimately responsible, in retrospect turned out to have been a grave error. It gained no friends for Austria among the Western powers but lost considerable goodwill that Tsar Nicholas I had earlier harboured for Francis Joseph.

At home, neo-absolutism resulted in a civil service staffed by highly competent experts who tried to meet the Emperor's high standards but whose limitations nevertheless became increasingly obvious in 1859–60 as they attempted to deal with the empire's complex financial problems. Army expenditures had to be curtailed in 1859, when a series of ill-fated wars began that seriously shook Austria's military reputation. Moreover, the police regime proved to be impracticable in the long run. Thus the government made critical military decisions against a background of many unresolved problems in finances and home affairs. For many of these decisions the Emperor was responsible. This was especially true of the unfortunate outcome of the war of 1859 against the Kingdom of Sardinia and France. After provoking Austria into war, Count Cavour, the prime minister of Sardinia, planned to use the French Army to oust Austria from Italy. When the imperial commander in chief proved incapable, Francis Joseph himself took over the supreme command, but he could not prevent the defeat of Solferino (June 24, 1859). Dismayed by Prussia's demand that as a condition of its intervention on the Emperor's side the Austrian army be placed under Prussian command, Francis Joseph hastily concluded the Peace of Villafranca in July 1859, under which Lombardy was ceded to Piedmont.

Unreconciled to this settlement, Francis Joseph adopted a foreign policy that prepared the way for a passage at arms with Italy and Prussia, by which he hoped to regain for Austria its former position in Germany and Italy, as it had been established by Metternich in 1814–15.

**The years of decision, 1859–70.** The mood of crisis prevailing after the defeat of 1859 caused Francis Jo-

seph to pay renewed attention to the constitutional question. A period of constitutional experiments—alternating between federalistic and centralistic charters—kept the country in a permanent state of crisis until 1867. The congress of princes at Frankfurt in 1863, for which the reigning heads of all German states assembled with the sole exception of the King of Prussia, was a high point in Francis Joseph's life. Yet the absence of the Prussian king demonstrated that Prussia no longer regarded Austria as the leading German power.

Francis Joseph had vainly tried to postpone the decision for predominance in Germany by entering into a comradeship-in-arms with Prussia in a war against Denmark in 1864. After their victory, squabbles arose between them, and war with Prussia became inevitable. The conclusion of an alliance between Italy and Prussia pointed up the dangerous possibility that both foreign-policy problems might have to be faced at the same time, yet Francis Joseph failed in his attempt to avoid an armed conflict at least with Italy. In June 1866 Austria concluded a possibly unique agreement with Napoleon III of France that stipulated that Austrian-held Venetia was to be given to the Kingdom of Sardinia regardless of the outcome of the impending war with Prussia. As the Emperor considered it incompatible with the army's honour to cede a province without fighting, war with Italy broke out despite this agreement. In later years, Francis Joseph characterized his policy of yielding territory with one hand while fighting for it with the other as very honest but very stupid, whereas the Chancellor Friedrich, Graf von Beust, called the agreement the most shocking document that he had ever seen. Although its defeat in the war with Prussia that the Prussian prime minister Otto von Bismarck had forced on the unprepared monarchy caused Austria no territorial loss in the north, it nevertheless sealed Austria's expulsion from Germany. Nor could the victories gained by the Austrian army in the south prevent the loss of Venetia, so that Austria found itself expelled from Italy as well.

The appointment of the Saxon premier, Graf von Beust, as Austrian prime minister in 1867 shows that initially Francis Joseph was once again unwilling to accept the decision. Beust's cherished project of an Austrian–French–Italian alliance against Prussia did not materialize, however; and in 1870 the attitude of the Hungarian prime minister, Count Gyula Andrassy, coupled with the rapid military successes of Prussia, prevented Austria from joining in the Franco-Prussian War at the side of France. Andrassy, appointed imperial foreign minister after Beust's dismissal in 1871, inaugurated the policy of close collaboration with Germany that later became the cornerstone of Francis Joseph's foreign policy.

**The Hungarian compromise and the Dual Monarchy.** The failure to achieve a federalist solution satisfactory to all nationalities had exacerbated relations among them. In 1867 it had become obvious that a compromise had to be made with the restive Hungarians. The newly appointed prime minister Beust was, however, insufficiently informed about conditions in the various parts of the Austrian Empire. The result was the *kaiserliche und königliche Doppelmonarchie*, the "imperial and royal Dual Monarchy" in which an Austrian and a Hungarian half coexisted in equal partnership. The compromise, however, gave the Hungarians considerable leverage to extend their influence. The losers were the Slav peoples, for the Bohemians (Czechs) and Poles did not share in the privileged position of the German Austrians in the Austrian, or western, half of the empire, while the Croats, Slovaks, and South Slavs had none of the prerogatives enjoyed by the Hungarians in the Hungarian, or eastern, half. With this preferred treatment, which Francis Joseph recognized as such, the multinational state had violated its inner law of the basic equality of all national groups. The individual crownland's relationship to the emperor, which in each case had been the result of a long historical evolution, was now replaced by the submission of the various nationalities to German-Austrian or Hungarian overlordship. Internal restlessness thus continued unabated. A final attempt at reform by which the

## Relations with Serbia

Slavic languages were to be given equal status with Hungarian and German was vetoed by Francis Joseph under pressure from the German-Austrian nationalists. But, under the influence of the Viennese sociologist Albert Schäffle, the Emperor, who on the whole had little use for party politicians and their influence on public life, seems to have followed the continuing process of democratization in his empire with some sympathy.

The question of recognition and restoration of ancient Czech rights hobbled Austro-Hungarian foreign policy and poisoned domestic politics. Even more of a handicap was the problem of the South Slavs. From 1867 on, the Hungarian-ruled Croats found themselves subjected to a continuing process of Magyarization, Hungarian domination, eventually turned Serbia, inhabited by fellow Slavs, into the Dual Monarchy's mortal enemy.

Francis Joseph, who wholeheartedly supported the *Ausgleich* (Hungarian Compromise) as the constitution of the dual monarchy, failed to grasp the negative aspects of that highly complex document. Interested primarily in questions of foreign policy and military leadership, he paid too little attention to domestic affairs to understand the nationalities problem in all its gravity and urgency. In particular, he failed to see the connection between Austro-Hungarian internal affairs and their effect on the monarchy's relationship with Russia and on the political situation in the Balkans.

**The German treaty and the Emperor's peace policy.** Although Francis Joseph always considered foreign policy his own specialty, he was in effect guided by the ablest among his foreign ministers: Count Gyula Andrásy, Count Gusztáv Kálnoky von Köröspatak, and Count Alois Aehrenthal. Andrásy not only launched the German alliance in 1879, but, by carrying out the occupation of Bosnia-Herzegovina, which Francis Joseph had advocated and the Congress of Berlin (1878) had sanctioned, he also gained the first great foreign-policy success of the empire in the Balkans. The Emperor defended the German alliance against all opposition. He was considerably more reserved toward Italy, which had joined Germany and Austria in the Triple Alliance in 1882, and Romania, with which Austria-Hungary had concluded a secret treaty in 1883; in fact, his reticence contributed to the eventual alienation of both of those allies.

The style of Francis Joseph's foreign policy was dynastic and personal. Just as he had contributed decisively to the creation of the League of the Three Emperors (*Dreikaiserbund*) by appearing in Berlin in 1873 by the side of Tsar Alexander II, he endeavoured also on later occasions to forestall potential conflicts with Russia through personal contacts, without realizing the fundamental nature of the antagonism between the two countries. On a visit to St. Petersburg in 1897 and again after Tsar Nicholas II's visit in 1903, he tried to delimit Austrian and Russian interests in the Balkans—a policy that was rashly jeopardized by Aehrenthal during the crisis leading to the annexation of occupied Bosnia-Herzegovina in 1908. By then, however, the days were long past when foreign policy was a matter of friendships between sovereigns; conflicts of interest, or for that matter pan-Slav propaganda, could no longer be neutralized on the dynastic level. Also, the Emperor found it increasingly difficult to get along with his fellow sovereigns, many of them relatives, of the younger generation. Yet he seems to have appreciated the energetic, dashing, and optimistic manner of William II of Germany.

In the period 1908–14 Francis Joseph held fast to his peace policy in the face of warnings by the chief of the general staff, Franz, Graf Conrad von Hötzendorf, who repeatedly advocated a preventive war against Serbia or Italy. Yet, without having fully thought out the consequences, he let himself in July 1914 be persuaded by Graf Leopold Berchtold, the foreign minister, to issue the intransigent ultimatum to Serbia that led to World War I. On November 21, 1916, Francis Joseph died at Schönbrunn Palace.

**Assessment.** Although he had been raised to be a soldier and wore a uniform all his life, Francis Joseph was no more a strategist than he was a statesman. He

made up for this deficiency by the careful study of documents, by an extraordinarily retentive memory, and by being a shrewd judge of character. Invariably well informed and familiar with the reports of his envoys, he was to his civil servants an unequalled model of exactitude, devotion to duty, and justice. In his time Austria-Hungary was credited with having a civil administration that was as efficient as any in Europe. Having reserved for himself the control of foreign policy and of all matters bearing on the army, he stated repeatedly that this foreign policy was his own and that any criticism of it was in reality directed at himself. While loyal to his ministers, he refused to grant them any influence beyond the limits of their respective offices; once dismissed, a minister was no longer consulted on official business. This attitude, which many considered to be both ungrateful and ungracious, sprang in part from a punctiliousness that was hard to penetrate and rendered him incapable of true friendship. In the early decades of his reign, his correct but unapproachable bearing caused Francis Joseph to be respected but not really popular. Toward the end of his life, however, he became a universally revered man, a personality that for all its defects and insufficiencies held together the rotting structure of the multinational state.

Although a gentleman of irresistible charm in personal contact, Francis Joseph was greatly feared as the head of his house. His attitude toward his family was determined primarily by dynastic considerations. His own marriage had been a love match, and he remained devoted to his fanciful, glamorous, and intelligent wife even after the marriage had been wrecked by her eccentricities. Her assassination, in Geneva on September 10, 1898, saddened him profoundly. The tragedy of the heir presumptive, the archduke Rudolf, who dramatically shot himself in a suicide love pact with a 17-year-old baroness at Mayerling on January 30, 1889, was assuredly rooted in Rudolf's unstable character. Yet the Emperor had contributed to his only son Rudolf's instability by giving him an unsuitable education, forcing him to marry Princess Stephanie of Belgium, and dealing with him in an altogether cold and uncomprehending manner. He treated his daughter-in-law with unforgiving harshness after her second, morganatic marriage, believing that family members who married beneath their station had committed a crime against the dynasty. Nor did Francis Joseph ever become reconciled to the morganatic union of the next heir presumptive, Archduke Francis Ferdinand. His statements on receiving the report of the archducal couple's murder at Sarajevo, on June 28, 1914, shows that he looked upon their fate as a token of divine retribution. These tragedies, which became public knowledge, were underlined by an unending series of sometimes very heated family disputes in the course of which Francis Joseph forced the members of the House of Habsburg-Lorraine to conform to his own notion of an archduke's dignity and position. Yet this man who became ever lonelier as time went on could be a generous and amiable family father to his daughters and those members of the house who bowed to his wishes.

The only member of the immediate family with whom he had a closer relationship was his youngest brother, the archduke Louis Victor. While he was no more than correct in his attitude toward his younger brother, the restless, talented, and ambitious Archduke Maximilian, he bears no blame for the tragedy that ended Maximilian's brief interlude as emperor of Mexico.

Having overcome the threat to its very survival in 1848–49, Austria passed through a long metamorphosis with many ups and downs in the 68 years that Francis Joseph occupied the throne. The last half century of his reign was marked by the increasing recurrence of tensions arising from the nationalities problem. Although Francis Joseph's understanding of these problems was limited, he was able to mask this defect by the conscientious fulfillment of his bureaucratic duties. These internal stresses were reflected in a rapid change of prime ministers, whose programs were sometimes radically at variance with those of their predecessors. The direction of foreign

## Family life

## Assessment

policy, on the other hand, continued essentially unchanged. The beginning of the 20th century saw the empire's existence—considered by many to be altogether anachronistic—severely endangered at home. Francis Joseph, who would not be forced into anything against his convictions, bore a share in all the decisions of those years. Yet his many mistakes were balanced by splendid achievements. The social legislation enacted by the prime minister Eduard, Graf von Taaffe, during the 1880s, the new penal code of 1852, the trade regulations of 1859, and the commercial code of 1862 are all examples of a civil administration that was highly regarded throughout Europe. Those achievements bore the stamp of the Emperor's own silent devotion to duty.

Through the architectural style he favoured, Francis Joseph imparted a very personal touch to his capital cities of Vienna and Budapest. Although he had no artistic gifts of his own, he always gave a free hand to the artists he employed. By ennobling numerous deserving military men, civil servants, scientists, and artists, he created an aristocracy of merit that formed the so-called second society of Vienna and acted as a bond that helped hold together the empire. In the final instance, however, Austria-Hungary derived its firmest support from his own personality.

**BIBLIOGRAPHY.** The most important biographies of Francis Joseph are: E.C. CORTI, *Vom Kind zum Kaiser* (1950), *Mensch und Herrscher* (1952), and with H. SOKOL, *Der alte Kaiser* (1955), popularly written; and JOSEPH REDLICH, *Kaiser Franz Joseph von Österreich* (1928; Eng. trans., *Emperor Francis Joseph of Austria*, 1929), still considered the best biography. See also EDWARD CRANKSHAW, *The Fall of the House of Habsburg* (1963); O. JASZI, *The Dissolution of the Habsburg Monarchy* (1929); ROBERT A. KANN, *The Multinational Empire: Nationalism and National Reform in the Habsburg Monarchy, 1848–1918*, 2 vol. (1950, reprinted 1964), the best presentation on this subject; and A.J.P. TAYLOR, *The Habsburg Monarchy, 1809–1918*, new ed. (1948), imaginative but not always dependable.

## Franck, César

The work of the Belgian (later naturalized French) composer César Franck, which did not come to full fruition until the last ten years of his life (1880–90), made him the chief figure in a movement to give French music a new seriousness, an emotional engagement, and a technical solidity comparable to that of the German 19th-century composers. His *Symphony in D Minor*; *Variations symphoniques* for piano and orchestra; a string quartet, a piano quintet, and a violin sonata; *Prélude, choral et fugue* for piano; and a number of organ pieces mark him as the most powerful composer to appear in France during the second half of the 19th century.

C. Caroly—J.P. Ziolo

César Franck, portrait by J. Rongier (19th century). In a private collection.

César Auguste Franck was born on December 10, 1822, at Liège, in Belgium, of a Walloon father and a mother of German descent. He showed unmistakable musical gifts that enabled him to enter the Liège conservatory at the age of eight, and his progress as a pianist was so astonishing that in 1834 his father took him on a tour of towns, including Aix and Brussels, and a year later dispatched him to Paris, where he worked with the Bohemian composer Anton Reicha, then professor at the Conservatoire de Paris. In 1836 the whole family, including the younger son Joseph, who played the violin, moved to Paris, and in 1837 César Franck entered the conservatory. Within a year he had won a Grand Prix d'Honneur by a gratuitous feat of transposition in the sight-reading test, and this honour was followed by a first prize for fugue (1840) and second prize for organ (1841). Although the boy should now normally have prepared to compete for the Prix de Rome, a prize offered yearly in Paris for study in Rome, his father was determined on a virtuoso's career for him and his violinist brother, with whom he gave concerts, and therefore removed him prematurely from the conservatory.

In order to please his father and earn much-needed money, Franck gave concerts, the programs of which were largely devoted to performing his own showy fantasies and operatic potpourris, popular at that time. After 1840, when he turned his attention increasingly to the organ, his compositions become noticeably more serious, and three trios written at this time were to impress favourably the Hungarian composer Franz Liszt. A more ambitious work was the cantata *Ruth*, which had its first performance at the conservatory on January 4, 1846.

Unwilling concert giving, a number of bad press notices, and the teaching needed to supplement his income took a physical toll of his powers. Only when he had finally asserted himself against what amounted to the unscrupulous exploitation of his gifts by his father could he achieve maturity and peace of mind. Franck fell in love with an actress with the professional name of Desmousseaux, whose real name was Félicité Saillot, but because both her parents also worked in the theatre, the family was regarded as totally unsuitable by the elder Franck, and his son was obliged to leave home some time before marrying her in 1848.

After his marriage Franck's way of life changed little for his remaining 42 years. He earned his livelihood as an organist and teacher. He led a simple, almost ascetic life. Winter and summer he rose at 5:30, beginning his long day of teaching two hours later. Most of his composing was done in this early-morning period and during the summer holidays.

In 1851 he was appointed organist to the church of Saint-Jean-Saint-François and in 1858 to that of Sainte-Clotilde, where he was already choirmaster. From the organ loft of Sainte-Clotilde came the improvisations for which he was to become famous and also their elaboration in organ and choral works. This music, which is before all else the product of Franck's official profession, is all marked by the taste of the day, which was for a facile tenderness and saccharine sweetness in ecclesiastical music. Both Franck and his friend the French composer Charles Gounod were, however, taken to task by their clerical employers, speaking on behalf of their congregations, for the austerity and difficulty of their church music.

More important to Franck's career as a composer was his appointment as organ professor at the conservatory in 1872. This came to him as a surprise, because he had indulged in none of the preliminary intrigue customary in such cases; and his openheartedness and lack of sophistication were to make him enemies among his colleagues as well as friends among his pupils. This enmity was increased by the fact that his organ classes soon became classes of composition, and his pupils not infrequently proved superior to those of the conventional composition professors.

The nucleus of a school of disciples had already been formed by the French composers Henri Duparc and Alexis de Castillon, who studied privately with Franck

in the late 1860s, but only after the founding of the Société Nationale de Musique (February 25, 1871) was a real future assured for the deeply serious, emotionally engaged, and technically well-founded music that Franck was interested in writing and communicating to his pupils. When Vincent d'Indy, a French composer, joined the group of Franck's pupils in 1872, he brought an enthusiasm, a propagandist zeal, and an exclusive personal devotion that played a large place in restoring Franck's confidence in his powers, naturally weakened by his failure as a virtuoso pianist and as a composer. With Ernst Chausson, Pierre de Bréville, Charles Bordes, and Guy Ropartz the Franck circle was complete in the early '80s, and subsequently d'Indy's very high claims (in his biography, *César Franck*, 1906) led for a time to the suspicion that Franck was "a creation of his own pupils."

The music that he wrote between 1880 and his death in 1890 makes it clear that this is not true. Certainly his early years as performer and composer of virtuoso music left an indelible mark on his musical taste, which can be heard unmistakably in the last movement of the *Prélude, aria et final* for piano (completed 1887) and even momentarily in the *Variations symphoniques* (1885) for piano and orchestra. On the other hand, some of his weaker music represents an almost excessive reaction against superficiality and a cultivation of emotional intensity at all costs, drawing for the purpose on the examples of Franz Liszt, Richard Wagner, and, more remotely, Beethoven.

Franck died in Paris, partly as the result of a street accident, on November 8, 1890. The new seriousness of French music in the last quarter of the 19th century derived entirely from Franck and his pupils. Much has been made of his angelic sweetness and simplicity of character, his selflessness and innocence in the ways of the world. These traits are reflected in a blandness of manner, and they proved a handicap when Franck was faced with the necessity of producing strongly contrasting musical ideas, as in the oratorio *Les Béatitudes* (written during the 1870s and performed posthumously) and the symphonic poems *Le Chasseur maudit* (1882; *The Accursed Hunter*) and *Les Djinns* (1884). On the other hand, the violin sonata (1886) and the *Variations symphoniques* remain as all but perfect monuments of a warm and noble musical nature and a strong, thorough craftsmanship that have survived all changes of taste and emotional attitudes.

#### MAJOR WORKS

CHORAL WORKS: *Ruth*, a biblical eclogue (1846); *Trois Motets* (1858); *Messe à trois voix* (1860); *Trois Offertoires* (1871); *Panis Angelicus*, for tenor, organ, harp, cello, and double bass (1872); *Rédemption* (1873); *Les Béatitudes*, oratorio in eight parts (1879).

ORCHESTRAL WORKS: Five symphonic poems including *Les Éolides* (1876), *Le Chasseur maudit* (*The Accursed Hunter*, 1882), *Psyché* (1888), and *Les Djinns* (1884); *Variations symphoniques* (1885); *Symphony in D Minor* (1888).

CHAMBER MUSIC: *Quintet in F Minor for Piano and Strings* (1879); *String Quartet in D Major* (1889); *Sonata in A Major for Violin and Piano* (1886).

ORGAN: *Six Pièces* (1862); *Trois Pièces* (1878); *Trois Chorals* (1890).

PIANO: *Prélude, choral et fugue* (1884); *Prélude, aria et final* (1887).

**BIBLIOGRAPHY.** ALFRED CORTOT, "The Piano Music of César Franck," in *La Musique française de piano* (1930; Eng. trans., *French Piano Music*, 1932); VINCENT D'INDY, *César Franck* (1906; Eng. trans., 1909, reprinted 1929 and 1965); and LEON VALLAS, *César Franck* (Eng. trans. 1951); and *La Véritable Histoire de César Franck* (1955), are the classical studies of the composer. See also the special issue of *La Revue Musicale* (December 1922), devoted to Franck.

(M.DuP.C.)

## Franco, Francisco

Francisco Franco, who achieved early renown as an outstanding military leader and the youngest general in the Spanish Army, led the Nationalist forces to victory during the Spanish Civil War, and in 1936 he was made head of state. During the course of his long rule, Spain changed greatly, moving from a largely preindustrial

society in the 1940s to a partially industrialized economy with one of the world's fastest growth rates during the 1960s. Its political structure changed comparatively little, however, for Franco presided over an authoritarian regime that, though pluralistic in recognizing the claims of diverse groups, such as the church, the army, and the state worker syndicates did not rest on a system of direct democratic elections.

Franco, 1970.

Francisco Franco Bahamonde was born at the coastal city and naval centre of El Ferrol in Galicia (northwestern Spain) on December 4, 1892. His family life was not entirely happy, for Franco's father, an officer in the Spanish Naval Administrative Corps, was eccentric, wasteful, and somewhat dissolute. More disciplined and serious than other boys of his age, Franco was close to his mother, a pious and conservative upper-middle-class Catholic. Like four generations and his elder brother before him, Franco was originally destined for a career as a naval officer, but reduction of admissions to the Naval Academy forced him to choose the army. In 1907, only 14 years old, he entered the Infantry Academy at Toledo. Three years later he graduated with the rank of second lieutenant.

Franco volunteered for active duty in the colonial campaigns in Spanish Morocco that had begun in 1909 and was transferred there in 1912 at the age of 19. The following year he was promoted to first lieutenant in an elite regiment of native Moroccan cavalry. At a time in which many Spanish officers were characterized by sloppiness and lack of professionalism, young Franco quickly showed his ability to command troops effectively and soon won a reputation for complete professional dedication. He devoted great care to the preparation of his unit's actions and paid more attention than was common to the troops' well-being. Reputed to be scrupulously honest, introverted, and a man of comparatively few intimate friends, he was known to shun all frivolous amusements. In 1915 he became the youngest captain in the Spanish Army. In the following year he was seriously wounded by a bullet in the abdomen and was brought back to Spain to recover. In 1920 he was chosen to be second in command of the newly organized Spanish Foreign Legion, succeeding to full command in 1923. In that year he married Carmen Polo, by whom he had a daughter. During the crucial campaigns against the Moroccan rebels, the legion played a decisive role in bringing the revolt to an end. Franco became a national hero, and in 1926, at the age of 33, he was promoted to brigadier general and at the beginning of 1928 was named director of the newly organized General Military Academy in Saragossa.

After the fall of the monarchy in 1931, the leaders of the new Spanish Republic adopted a sharply antimilitary policy, and Franco's career was temporarily halted. The General Military Academy was dissolved, and Franco was placed on the inactive list. Though he was an avowed monarchist and held the honour of being a Gentleman

music

of the King's Chamber, Franco accepted both the new regime and his temporary demotion with perfect discipline. When conservative forces gained control of the republic in 1933, Franco was restored to active command; in 1934 he was promoted to major general. In October 1934, during the rising of Asturian miners who opposed the admission of three members of the right to the government, Franco was called in to quell the revolt. His success in this operation brought him new prominence. In May 1935 he was appointed chief of the Spanish Army's general staff, and he began the work of tightening discipline and strengthening military institutions, both seriously weakened by the republic's earlier anti-military position.

No longer able to retain control of the country, the centre-right government was dissolved, and new elections were announced for February 1936. By this time the Spanish political parties had split into two factions: the rightist National Bloc and the leftist Popular Front. The left proved victorious in the elections, but the new government was unable to prevent the accelerating dissolution of Spain's social and economic structure. Although Franco had never been a member of a political party, the growing anarchy impelled him to appeal to the government to declare a state of emergency. His appeal was refused, and he was removed from the general staff and sent to an obscure command in the Canary Islands. For some time he refused to commit himself to a military conspiracy against the government, but as the political system disintegrated, he finally decided to join the rebels.

**Franco's military rebellion.** At dawn on July 18, 1936, Franco's manifesto acclaiming the military rebellion was broadcast from the Canary Islands, and the same morning the rising began on the mainland. The following day he flew to Morocco and within 24 hours was firmly in control of the protectorate and the Spanish Army garrisoning it. After landing in Spain, Franco and his army marched toward Madrid, which was held by the government. When the Nationalist advance came to a halt on the outskirts of the city, the military leaders, in preparation of what they believed was the final assault that would deliver Madrid and the country into their hands, decided to choose a commander in chief, or generalissimo, who would also head the rebel Nationalist government in opposition to the republic. Because of his military ability and prestige, a political record unmarred by sectarian politics and conspiracies, and his proved ability to gain military assistance from Hitler's Germany and Mussolini's Italy, Franco was the obvious choice. In part because he was not a typical Spanish "political general," Franco became head of state of the new Nationalist regime on October 1, 1936. The rebel government did not, however, gain complete control of the country for more than three years.

Franco presided over a government that was basically a military dictatorship, but he realized that it needed a regular civil structure to broaden its support; this was to be derived mainly from the antileftist middle classes. On April 19, 1937, he reorganized the Falange (the Spanish Fascist Party) and made it the rebel regime's official political movement. While expanding the Falange into a more pluralistic group, Franco made it clear that it was the government that used the party and not the other way around. Thus, his regime became an institutionalized authoritarian system, differing in this respect from the Fascist party-states of the German and Italian model.

As commander in chief in the Civil War, Franco was a careful and systematic leader. He made no rash moves and suffered only a few temporary defeats as his forces advanced slowly but steadily; the only major criticism directed at him during the campaign was that his strategy was frequently unimaginative. But thanks to the relatively superior military quality of his army and to the continuation of heavy German and Italian assistance, Franco won a complete and unconditional victory on April 1, 1939.

The Civil War had been largely a sanguinary struggle of attrition, marked by atrocities on both sides. The tens of thousands of executions carried out by the Na-

tionalist regime, which continued during the first years after the war ended, earned Franco more reproach than any other single aspect of his rule.

**Franco's dictatorship.** Although Franco had visions of restoring Spanish grandeur after the Civil War, in reality he was the leader of an exhausted country still divided internally and impoverished by a long and costly war. The stability of his government was made more precarious by the outbreak of World War II only five months later. Franco was at first shocked by Hitler's unprovoked assault on Catholic Poland and carefully avoided involvement in the war. His wartime diplomacy was perhaps Franco's ablest political achievement; it was marked by cold realism and careful timing. The evidence indicates that had Hitler ever been in a position to win a quick and total victory, Franco would have been willing to enter the conflict on Germany's side. As it was, his government remained relatively sympathetic to Hitler while carefully avoiding direct diplomatic and military commitment. After his interview with Franco in 1940 at Hendaye, France, Hitler is said to have remarked that he would "as soon have three or four teeth pulled" as go through another bargaining session like that.

The most difficult period of Franco's regime began in the aftermath of World War II, when his government was ostracized by the newly formed United Nations. He was labelled by hostile foreign opinion the "last surviving Fascist dictator" and for a time appeared to be the most hated of Western heads of state; within his country, however, as many people supported him as opposed him. The period of ostracism finally came to an end with the worsening of relations between the Soviet world and the West at the height of the Cold War. Franco could now be viewed as one of the world's leading anti-Communist statesmen, and relations with other countries began to be regularized in 1948. His international rehabilitation was advanced further in 1953 when Spain signed a 10-year military assistance pact with the United States, which was later renewed in more limited form.

Franco's domestic policies became somewhat more liberal during the 1950s and '60s, and the continuity of his regime, together with its capacity for creative evolution, won him at least a limited degree of respect from some of his critics. Franco said that he did not find the burden of government particularly heavy, and, in fact, his rule was marked by absolute self-confidence and relative indifference to criticism. He showed marked political ability in gauging the psychology of the diverse elements, ranging from moderate liberals to extreme reactionaries, whose support was necessary for his regime's survival. He maintained a careful balance among them and largely left the execution of policy to his appointees, thereby placing himself as arbiter above the storm of ordinary political conflict. To a considerable degree, the opprobrium for unsuccessful or unpopular aspects of policy tended to fall on individual ministers rather than on Franco.

The Falange state party, downgraded in the early 1940s, in later years became known merely as the "Movement" and lost much of its original quasi-Fascist identity.

Unlike most rulers of rightist authoritarian regimes, Franco provided for the continuity of his government after his death through an official referendum in 1947 that made the Spanish state a monarchy and ratified Franco's powers as a sort of regent for life. In 1967 he opened direct elections for a small minority of deputies to the parliament and in 1969 officially designated the then 32-year-old Prince Juan Carlos, the eldest son of the nominal pretender to the Spanish throne, as his official successor upon his death. Franco resigned his position of premier in 1973 but retained his functions as head of state, commander in chief of the armed forces, and head of the "Movement."

Franco was never a popular ruler and rarely tried to mobilize mass support. But after 1947 there was little direct or organized opposition to his rule. With the liberalization of his government and relaxation of some police powers, together with the country's marked economic development during the 1960s, Franco's image

World  
War II

Liberal-  
ization

changed from that of the rigorous generalissimo to a more benign civilian elder statesman. The company of his six grandchildren and frequent hunting and fishing expeditions constituted the principal diversions of his later years. Franco's health declined markedly in the late 1960s, but advanced age brought no slackening of his self-confidence. He believed it within his power to bequeath to his country a stable continuation of his regime in an atmosphere of prosperity and accelerating modernization. He died in Madrid on November 20, 1975.

**BIBLIOGRAPHY.** There is no definitive biography of Franco, but the best is J.W.D. TRYTHALL, *El Caudillo: A Political Biography of Franco* (1970). The two other principal biographies are BRIAN CROZIER, *Franco: A Biographical History* (1967); and GEORGE HILLS, *Franco: The Man and His Nation* (1967). The background of the Spanish military is treated in STANLEY G. PAYNE, *Politics and the Military in Modern Spain* (1967).

## Frankfurt am Main

The largest city in the *Land* of Hessen, Federal Republic of Germany, Frankfurt am Main (Frankfort on Main) is a thriving industrial and commercial centre, lying about 19 miles east of the confluence of the Main and Rhine rivers at Mainz. The city is a main centre of communications and at the start of the 1970s had a population approaching 670,000. It is one of the federal republic's principal manufacturing towns. The birthplace of the poet Goethe and the original home of the international banking empire of the Rothschilds, Frankfurt today has both cultural and commercial fame, although it was also renowned from the 9th to the 18th century as the town in which the German kings were elected. With Germany's largest airport on its doorstep, Frankfurt has become a major centre for international trade fairs. The production of high-class sausages that immortalized its name in the "frankfurter" actually takes place in the town of Neu Isenburg, some miles to the south.

Until its destruction in 1944, during World War II, the old city of Frankfurt was the largest medieval city still intact in Germany; rapid postwar reconstruction has created an international, modern metropolis of somewhat monotonous uniformity, which is now rapidly engulfing the remaining estates, villas, parks, and gardens and the

older residential areas. Landmarks of the city's past remain, such as the round tower of the Eschenheimer Tor (1426–28), 155 feet, or 47 metres, high, and the red sandstone cathedral (dedicated to St. Bartholomew in 1239), forming a strong contrast to the background of multi-story office blocks.

**History.** There is evidence of Celtic and Germanic settlements on the cathedral hill dating from the 1st century BC, besides Roman remains from the 1st and 2nd centuries AD. The name Frankfurt (Ford [Passage, Crossing] of the Franks) probably arose about AD 500, when the Franks drove the Alemanni south, but the first written mention of Franconofurt stems from Charlemagne's biographer, Einhard, in the late 8th century. The Pfalz (imperial castle) was the residence of the East Frankish Carolingians in the 9th century, and the first imperial election in Frankfurt took place in 856, when Lothair II was elected king of the Carolingian middle kingdom of Lotharingia. Closely associated with the castle in the mid-9th century was the Salvatorkirche (Church of the Saviour), built by Louis the German in 852, which, by 1238–39, was transformed into the cathedral dedicated to St. Bartholomew.

In the 10th century the small settlement was fortified, and a wooden bridge was built across the Main River. Sachsenhausen, a suburb south of the Main, probably arose after the erection of a stone bridge in the 12th century. Conrad III erected a new castle for the Hohenstaufens in the 12th century, and a wall was constructed around the market town extending down to the river. (Remnants of this wall, revealed by bombings in 1944, were subsequently restored as historic sites.) A royal bailiff replaced the governor of the castle as the head of the town soon after 1200, and a council grew up composed of elder magistrates, counsellors, and members of the guilds.

In 1311 two mayors, annually elected, replaced the royal bailiff as head of the council, and in 1372 the town became a free imperial city, a privileged status that it retained until 1806, when Napoleon organized the Confederation of the Rhine.

Frankfurt then became the seat of government for the prince primate of the Confederation of the Rhine and, in 1810, capital of the Grand Duchy of Frankfurt created by Napoleon. From 1815, when Napoleon fell, it was

Frankfurt am Main with (centre) the cathedral dedicated to St. Bartholomew.

again a free city and, from 1816 to 1866, the seat of the German Bundestag (Federal Diet) and real capital of Germany. After the war of 1866, Frankfurt was occupied by Prussian troops and forcibly incorporated into Prussia, ending its free-city status.

The notable expansion of the city after 1333 tripled its area, and its new boundaries were fortified. Toward the end of the 14th century Sachsenhausen, too, was fortified and drawn into the city proper. From the middle of the 18th century, fine villas and garden houses had been built along the roads leading out of the city, and an increase in the numbers wishing to live there after 1866 stimulated new development. While villas lined the roads, the less wealthy moved into flats (apartments) between them. The suburbs thus created were gradually incorporated into the city.

Until World War I, the growth of Frankfurt was controlled largely by private land developers, but in the 20th century the city authorities took control in order to plan more effectively. The majority of the old city was destroyed in World War II, and postwar reconstruction has had to cater to basic public and private needs. Thus, few individual buildings in the old Gothic city have been restored exactly as before.

**The contemporary city.** *Demography.* The population of Frankfurt proper is decreasing, having fallen, for example, from 683,000 inhabitants in 1961 to 669,000 inhabitants in 1972; the numbers do not include the large number of the United States forces associated with the city. The population of the surrounding suburbs and rural communities is, however, growing rapidly. By 1970 more than 93,000 of Frankfurt's inhabitants (excluding members of the U.S. forces) were foreigners: some 21 percent of them were Yugoslavs, 19 percent Italian, 16 percent Turks, 13 percent Spaniards, and eight percent Greeks.

*Modern developments.* In the postwar efforts to build housing, speed and monotony prevailed, but in the 1960s the largest new suburb, Nordweststadt, with 25,000 inhabitants, was developed. It houses people from all classes in buildings that range from detached dwellings to 14-story blocks of flats. Facilities include quiet spots to walk and separate roads for fast and slow traffic. At the centre of the suburb are the offices for social, cultural, and commercial affairs that care for the many people in the suburb as well as those in the older, outlying parts of the city. Beneath the centre is the terminus of the subway that links Nordweststadt with the heart of Frankfurt.

*Economic life.* Trade has always accounted for Frankfurt's very existence. From being a small market serving those living around the king's palace, it grew into a flourishing city by the 12th and 13th centuries and held semi-annual trading fairs that were placed under the king's official protection in 1240. Since the majority of the sales at the trade fairs were on credit, the need for a better method of currency exchange increased and by 1585 the Frankfurt Exchange was founded. In the 14th century the Frankfurt trade fair achieved international importance as the centre of the textile trade from the Netherlands, for sales of herring from the North Sea, and for furs and wax from the East. With the advent of the printing press, Frankfurt also claimed a central role in European publishing. Although much of its trade was lost to Leipzig in the 16th century, Frankfurt had also been developing a notable talent for banking, which, with the influx of Dutch, French, and Italian brokers and bankers around 1600, led it to acquire the leading international role in that field. During the 18th and 19th centuries, the Rothschild brothers lent money to numerous countries, setting up banks in London, Vienna, Paris, and Naples and practically establishing a monopoly.

After World War II, Frankfurt was able to rebuild its commercial interests, though Hannover took over the capital-investment-goods fairs while Frankfurt kept the consumer-goods fairs. Among the many exhibitions are the fur exhibition, international book fair, international automobile fair, and the international textile fair.

Frankfurt's efforts to become highly industrialized were restricted until 1866, but today there are machine-construction firms, chemical and pharmaceutical industries,

printing works, leather-goods plants, and foodstuffs facilities. Numerous government offices are also located in Frankfurt.

*Transportation.* Frankfurt's importance as a communications centre has grown steadily since the 13th century, and the location of the city has favoured good transportation and promoted its growth in the financial and industrial world. Its location, to the north of the Oberrheinische Tiefebene (Upper Rhine Lowlands) has made the city a crossroads for land and water traffic. Regular transportation had existed on the Main and Rhine rivers since the 14th century, but it was not until the canalization of the Main in 1883–86 that freight shipping became economically important. The first of the modern inland harbours, the west harbour, was completed in 1886 but with the construction of the east harbour (1907–12) Frankfurt became a centre for inland shipping, handling nearly 7,400,000 tons in 1971.

Following the construction of Germany's second railway line in 1838–40, linking Frankfurt and Kastel, near Mainz, and the addition of lines to the south, east, and north between 1846–52, Frankfurt rapidly became the centre of west German rail communications.

Six miles southwest of Frankfurt is the point of intersection of two main *Autobahnen*, the Hamburg–Basel highway and the Cologne–Nuremberg road. Close by is Frankfurt's Rhein-Main airport, which, built in 1936, has achieved first place among European airports for its carriage of mail (63,400 tons), second place as regards freight (352,200 tons), and third place in passenger services (after London and Paris) with 10,567,000 travellers in 1971.

*Cultural life and recreation.* Commercial contacts established at the many fairs have led in turn to European and international cultural exchanges and development. During the Reformation, Frankfurt remained Lutheran and in 1554 became the home of many Protestant refugees from England and the Netherlands and for many from France in the 17th century. The refugees carried their crafts and a well-developed cultural life with them, and their expertise brought further wealth, prestige, and influence to Frankfurt. The Jewish community, too, grew in size after the 16th century, contributing to the commercial life of the city. The characteristically simple exteriors of the buildings of the new merchant class were in sharp contrast to the abundance of artistic expression within their homes and places of worship. From early times the merchant classes had been generous patrons of the arts, notably engaging Albrecht Dürer, Mathias Grünewald, and Hans Baldung to provide artworks in the Dominican Church (Dominikaner Kirche).

The Städelsches Kunstinstitut (Städel Art Institute), Frankfurt's finest art gallery, founded in 1816 at the bequest of the banker Städel, contains Italian, German, French, Spanish, and Dutch paintings from the 15th to the 18th centuries. The city's collection of sculpture, containing among many masterpieces the Greek "Athena," by Myron, is housed in adjoining Liebighaus. The most famous museum is the Senckenberg Museum of natural history established by the Senckenbergsche naturforschende Gesellschaft (Senckenberg Society for Nature Research). Johann Wolfgang Goethe's birthplace was burned to the ground in World War II but has been faithfully restored. Adjoining it is the Goethe Museum and Library, one of the city's chief attractions. The citizens of Frankfurt established the Johann Wolfgang Goethe University, one of the largest in Germany, in 1914, through the amalgamation of a number of existing institutions. Besides the metropolitan Opera House and two fine theatres, there are many private theatres performing comedy, experimental drama, and all classes of entertainment. Recreational facilities are provided by the Palmengarten (Palm Garden), founded in 1868, which is famous throughout Germany for its large collection of flowers. South of the city a municipal forest of 10,000 acres encloses a golf course, and the renowned zoological garden lies in the eastern part of the city.

## Franklin, Benjamin

Benjamin Franklin, next to George Washington possibly the most famous 18th-century American, by 1757 had made a small fortune, established the Poor Richard of his almanacs as an oracle on how to get ahead in the world, and become widely known in European scientific circles for his reports of electrical experiments and theories. What is more, he was then just at the beginning of a long career as a politician in the course of which he would be chief spokesmen for the British colonies in their debates with the king's ministers about self-government and would have a hand in the writing of the Declaration of Independence, the securing of financial and military aid from France during the American Revolution, the negotiation of the treaty by which Great Britain recognized its former 13 colonies as a sovereign nation, and the framing of the Constitution, which, for nearly two centuries, has been the fundamental law of the United States of America.

Franklin, portrait by Joseph-Siffred Duplessis, c. 1784.

By courtesy of the New-York Historical Society

And as impressive as Franklin's public service was, it was perhaps less remarkable than his contributions to the comfort and safety of daily life. He invented a stove, still being manufactured, to give more warmth than open fireplaces; the lightning rod and bifocal eyeglasses also were his ideas. Grasping the fact that by united effort a community may have amenities that only the wealthy few can get for themselves, he helped establish institutions that one now takes for granted: a fire company, a library, an insurance company, an academy, and a hospital. In some cases these foundations were the first of their kind in North America.

One might expect universal admiration for a man of such breadth and apparent altruism. Yet Franklin was disliked by some of his contemporaries and has ever since occasionally been attacked as a materialist or a hypocrite. D.H. Lawrence, the English novelist, regarded him as the

embodiment of the worst traits of the American character. Max Weber, the German sociologist, made him the exemplar of the "Protestant ethic," a state of mind that contributed much, Weber thought, to the less admirable aspects of modern capitalism. Those who admire Franklin believe that his detractors have mistakenly identified him with Poor Richard, a *persona* of his own creation, or that they have relied too largely upon the incomplete self-portrait of his posthumously published *Autobiography*.

**Early life (1706–23).** Franklin was born in Boston, Massachusetts, on January 17 (January 6, old style), 1706, the tenth of the 17 children of a man who was both soapmaker and candlemaker. He learned to read very early and had one year in grammar school and another under a private teacher, but his formal education ended when he was ten. At 12 he was apprenticed to his brother James, a printer. His mastery of the printer's trade, of which he was proud to the end of his life, was achieved between 1718 and 1723. In the same period he read tirelessly and taught himself to write effectively.

His first enthusiasm was for poetry, and in the first years of his apprenticeship he wrote two occasional ballads, no copies of which have survived. His father told him that "Verse-makers were always Beggars" (*Benjamin Franklin's Memoirs*, ed. Max Farrand, University of California Press, 1949, p. 32), and thereafter his interest in poetry was sporadic. Prose was another matter. *The Spectator*, Joseph Addison and Richard Steele's famous periodical of essays, had appeared in England in 1711–12 and was to be imitated for the greater part of a century but seldom with the persistence of Franklin, the printer's apprentice. He would read an essay, make a short note of the idea of each sentence, lay aside his notes for a few days, and then try to rewrite the essay. Comparison of his version with the original showed him the need to enlarge his vocabulary. Turning some *Spectator* papers into verse and some days later reconverting them into prose, helped.

In 1721 James Franklin founded a *Spectator*-like weekly newspaper, the *New-England Courant*, to which readers were invited to contribute. Benjamin, now 16, read and perhaps set in type these contributions and decided he could do as well himself. In 1722 he wrote a series of 14 essays signed "Silence Dogood." Satire of New England funeral elegies and of the lip service paid the learned languages at Harvard College foreshadowed later literary techniques to be used by Franklin.

Late in 1722 James Franklin got into trouble with the provincial authorities and was forbidden to print or publish the *Courant*. To keep the paper going, he discharged his younger brother from his original apprenticeship and made him the paper's nominal publisher. New indentures were drawn up but not made public. Some months later, after a bitter quarrel, Benjamin walked out, sure that James would not go to law and reveal the subterfuge he had devised. "It was not fair in me to take this Advantage," he wrote later, "and this I therefore reckon one of the first Errata [mistakes, in printer's lingo] of my Life" (Farrand, p. 50).

**Youthful adventures (1723–26).** Failing to find work in Boston or New York, Franklin proceeded to Philadelphia. One of the dramatic scenes of the *Autobiography* is the description of his arrival on a Sunday morning, tired and hungry. Finding a bakery, he asked for three pennies' worth of bread and got "three great Puffy Rolls." Carrying one under each arm and munching on the third, he walked up Market Street past the door of the Read family, where stood Deborah, his future wife. She saw him "& thought I made as I certainly did a most awkward ridiculous Appearance" (Farrand, p. 62).

A few weeks later he was rooming at the Reads and employed as a printer. By the spring of 1724 he was enjoying the companionship of other young men with a taste for reading and he was also being urged to set up in business for himself by the governor of Pennsylvania, Sir William Keith. At Keith's suggestion, Franklin returned to Boston to try to raise the necessary capital. His father thought him too young for such a venture, so Keith offered to foot the bill himself and arranged Franklin's

Youth in  
Boston

Arrival  
in Phila-  
delphia

passage to England so that he could choose his type and make connections with London stationers and book-sellers. Franklin exchanged "some promises" with Miss Read and, with a young friend, James Ralph, as companion, boarded the "London Hope" in November, expecting to find the letters of credit and introduction that Keith had promised. Not until the ship was well out at sea did he realize that the governor had not kept his promise. A fellow passenger, a Quaker merchant by the name of Thomas Denham, told him that Keith was unreliable; eventually Franklin could write charitably: "He wish'd to please every body; and, having little to give, he gave Expectations" (Farrand, p. 106).

Years in  
London

In London Franklin quickly found employment in his trade and was able to lend money to Ralph, who was trying to establish himself as a writer. The two young men enjoyed the theatre and the other pleasures of the city; before long Ralph found a milliner for a mistress. When Ralph was in the country, teaching school, the milliner occasionally borrowed money from Franklin. "I grew fond of her Company," he remembered, "and being at this time under no Religious Restraints, & presuming on my Importance to her, I attempted Familiarities (another Erratum) which she repuls'd with a proper Resentment, and acquainted him with my Behaviour" (Farrand, p. 112).

Still another "erratum" in retrospect was *A Dissertation on Liberty and Necessity, Pleasure and Pain* (1725), a deistical pamphlet that he was inspired to write after having set type for the third edition of William Wollaston's moral tract, "The Religion of Nature Delineated." Franklin argued therein that since man has no real freedom of choice he is not morally responsible for his actions. He may have been consoling himself for his treatment of Deborah, to whom he had written only once.

By 1726 Franklin was tiring of London. He considered becoming an itinerant teacher of swimming, an art in which he was accomplished, but when Denham offered him a clerkship in his store in Philadelphia, with a prospect of fat commissions in the West Indian trade, he decided to return home.

**Achievement of security and fame (1726–52).** Denham died, however, a few months after Franklin entered his store. The young man, now 20, returned to his trade and in 1728 was able to set up a partnership with a friend. Two years later he borrowed money to become sole proprietor.

His private life at the time he became his own master was extremely complicated. Deborah Read had married, but her husband had deserted her and disappeared. One matchmaking venture failed because Franklin wanted a settlement to pay off his business debt. A strong sexual drive, "that hard-to-be-govern'd Passion of Youth" (Farrand, p. 178), was sending him to "low Women" and in the winter of 1730–31 he had a son, William, whose mother has never been identified. Franklin must have known that the child was expected when, his affection for Deborah having "revived," he "took her to Wife" (Farrand, p. 180) on September 1, 1730. Their common-law marriage lasted until Deborah's death in 1774. They had two children, a son who died at four and a daughter, Sarah, later Mrs. Richard Bache, who survived them both. The illegitimate William was brought up in the household.

Wife and  
children

Franklin and his partner's first coup was securing the printing of Pennsylvania's paper currency. Franklin helped get this business by writing *A Modest Enquiry into the Nature and Necessity of a Paper Currency* (1729). For years thereafter Franklin was public printer not only of Pennsylvania but also of New Jersey, Delaware, and Maryland. Another money-making venture was the *Pennsylvania Gazette*, published by Franklin from 1729 and generally acknowledged as among the best of the colonial newspapers. Still another was the series of the *Poor Richard's* almanacs, printed annually from 1732 to 1757. Some failures of course occurred: a German-language newspaper that lasted less than a year and a monthly magazine that expired after six issues in 1741. Franklin was nevertheless generally prosperous; he made enough

to invest capital in real estate and in partnerships or working arrangements with printers in the Carolinas, New York, and the British West Indies. In 1748 he became a silent partner in the printing firm of Franklin and Hall, realizing in the next 18 years an average profit of almost £500 annually.

The first of his projects for social improvement by collective effort was the Junto, or Leather Apron club, organized in 1727 to debate questions of morals, politics, and natural philosophy and to exchange knowledge of business affairs that might be valuable to the more enterprising members. The need of Junto members for easier access to books led in 1731 to the organization of the Library Company of Philadelphia. Through the Junto, Franklin proposed a paid city watch, or police force. A paper read to the same group resulted in the organization of a volunteer fire company. In 1743 he called for a "constant correspondence" of men with scientific interests throughout the Colonies, and in the following year the American Philosophical Society was functioning. In 1743 also he perceived Pennsylvania's need of higher education and in 1749 published *Proposals Relating to the Education of Youth in Pennsylvania*; in 1751, the Academy of Philadelphia, from which grew the University of Pennsylvania, was founded. So successful was Franklin as a promoter that anyone with a good cause in mind was likely to turn to him for help.

Franklin was also early involved in politics. He was clerk of the Pennsylvania legislature from 1736 until 1751 and postmaster of Philadelphia from 1737 until 1753. Prior to 1748, though, his most important political service was his part in organizing a militia for the defense of the colony against possible invasion by the French and the Spaniards, whose privateers were operating in the Delaware River. His skill in appealing to the self-interest of the various factions in the commonwealth, among them the Quakers, is demonstrated in *Plain Truth; or, Serious Considerations on the Present State of the City of Philadelphia and Province of Pennsylvania* (1747).

In the 1740s, electricity was a novel and fashionable subject. It was introduced to Philadelphians by an electrical machine sent to the Library Company by one of Franklin's English correspondents. In the winter of 1746–47, Franklin and three of his friends began to investigate electrical phenomena. The Philadelphia weather favoured them, as did the availability of talented instrument makers. Ingenious experiments and machines were devised and described in personal letters to England, which were relayed to the Royal Society of London or the *Gentleman's Magazine*. These papers were collected in 1751 as *Experiments and Observations on Electricity*, which was printed in a French translation in 1752. Four additional English editions and two other French editions appeared before 1769; the book was also translated into German (1758) and Italian (1774).

Franklin's fame spread rapidly. The experiment that he suggested to prove the identity of lightning and electricity was first made in France before he is believed to have tried the simpler but dangerous expedient of flying a kite in a thunderstorm. He and his associates concluded early that the "Electrical Fire" was "an Element diffused among, and attracted by other matter, particularly by Water and Metals" (*Papers*, III, 129–30). When a body with an over-quantity approached one with an under-quantity a discharge equalized the electrical fire in the two. This "one fluid" theory accounted for more of the observable phenomena than had any previous hypothesis, and his suggestion that buildings might be protected from lightning by erecting pointed iron rods proved both practical and dramatic. Franklin may not have been as original as some of his admirers have thought, and his collaborators may not have received their full share of credit for their assistance, but he invented many of the terms still used in discussing electricity (positive; negative, battery, conductor, and so on), and he described the experiments with lucidity.

**Public service (1753–85).** In 1753 Franklin became deputy postmaster general, in charge of the mails in all

## Inter-colonial concerns

the northern colonies. Thereafter he began to think in intercolonial terms. His "Plan of Union," adopted by the Albany Congress in 1754, would have established a general council, with representatives from the several colonies, to organize the common defense against the encroaching French and to supervise Indian relations with new settlements. Neither the colonial legislatures nor the King's advisers were ready for such union. Reason was on Franklin's side, but the power structure was against him, and this conflict has been regarded by some authorities as the key to his entire political career.

In 1755 Franklin was nearly ruined when he promised to stand good for the loss of horses and wagons supplied by Pennsylvania farmers to support General Edward Braddock's ill-fated campaign against Fort-Duquesne at the outset of the French and Indian War. For more than two months he faced the possibility of having to pay almost £20,000 out of his own pocket. The government eventually paid.

The need of funds for defense of the frontier led the Pennsylvania legislature to seek to tax the lands of the Penn family, the proprietors under the colony's charter. Either their consent or a change in the form of government was required. In the spring of 1757 Franklin was chosen to represent the legislature in this matter, which occupied him in London for most of his time until August 1762. He negotiated a compromise, under which the Penns agreed to taxation of improved lands but not those unsurveyed. During this first mission he made close friends in England and wrote *The Interest of Great Britain Considered with Regard to Her Colonies and the Acquisitions of Canada and Guadeloupe* (1760). It was designed to urge the annexation of Canada when the war was over. There were Englishmen who preferred to leave Canada to the French, as a check on the growing strength of the 13 colonies. A simpler check, Franklin wrote, would be for Parliament to pass a law requiring midwives to stifle every third or fourth child as soon as it was born.

The Treaty of Paris (1763), ending the Seven Years' War, gave Canada to Great Britain. By that time Franklin was back in Philadelphia, where the conflict between the legislature and the proprietors continued. The legislature decided that Pennsylvania ought to become a crown colony, and by the end of 1764 Franklin was back in London to negotiate in vain for a new charter.

## Role in the Stamp Act crisis

The tribulations of Pennsylvania were submerged, however, in the flood of feeling surrounding the so-called Stamp Act crisis. Franklin opposed the Stamp Act (he had asserted in his "Plan of Union" that taxation ought to be the prerogative of the representative legislatures), but when it had been passed he made the mistake of underestimating American emotions; he ordered stamps for Franklin and Hall and nominated a friend for the post of stamp officer in Philadelphia. His fellow citizens were outraged to the verge of violence. Deborah was so fearful of her house being mobbed that she called on male relatives for armed defense. In London Franklin quickly did an about-face and threw himself into the campaign for repeal of the hated statute. He regained his prestige by a dramatic appearance before the House of Commons, where he answered 174 questions from an audience partly friendly and partly hostile. The stenographic report showed him returning again and again to the right of the Colonies to level internal taxes by their own legislation.

Although he failed to get the new charter, Franklin was kept on as London agent for Pennsylvania, and three other colonies relied on him to represent their interests—Georgia (1768), New Jersey (1769), and Massachusetts (1770). With this support and that of the British Whigs, the party of industrialists and dissenters in favour of parliamentary and philanthropic reform, he weathered the succession of crises ending with armed clashes at Lexington and Concord. He was gradually forced to the realization that there could be no reconciliation and that his dream of a British Empire of self-governing nations would not come true. He did his best to present the American case to his friends and to the British public. Between 1765 and 1775 he published 126 newspaper articles on current controversies. At the end he was

bitter, in such articles as "Rules by Which a Great Empire May Be Reduced to a Small One" and "An Edict by the King of Prussia," both first printed in the *Public Advertiser* in 1773. Taken together, they are a capsule history of the long-drawn-out contest. In January 1774, because of his share in the publication of the letters of Thomas Hutchinson, governor of Massachusetts, to his British superiors, Franklin was dismissed from the post office. In March 1775, aware that there might be war, he left England. The day after his arrival in Philadelphia he was a delegate to the Second Continental Congress, for which he served on committees for the organization of a postal system and for the drafting of the Declaration of Independence and on a commission that vainly attempted to bring Canada into the war as an ally.

In September 1776, the Congress agreed to send a commission to France to seek economic and military assistance. As one of three commissioners, Franklin arrived in Paris just before Christmas and was immediately engaged in secret negotiations with Charles Gravier, comte de Vergennes, minister of foreign affairs. Spies and informers infested his house, but Franklin was soon the hero of France, personifying the unsophisticated nobility of the New World, leading his people to freedom from the feudal past. His portrait was everywhere, on *objets d'art* from snuffboxes to chamber pots, his society sought after by diplomats, scientists, Freemasons, fashionable ladies. There was in fact a Franklin cult, not without its ridiculous side. Franklin, however, with his fur hat and spectacles, rose to the occasion with wit and social grace.

The sought-for treaties were signed in February 1778 after the British general John Burgoyne and 6,000 men had surrendered at Saratoga, New York, and it was clear that Great Britain was not going to crush the rebellion easily. Substantial loans were obtained for the revolutionists, and by the time of the final victory at Yorktown in 1781 an estimated 12,000 soldiers and 32,000 sailors had left France to support Gen. George Washington in America.

Despite these strong bonds, the peace was difficult. Spain had entered the war in 1779, hoping to recover Gibraltar but, because of the conflict of interests in Florida and Louisiana, refused to recognize American independence. France had guaranteed that there would be no separate peace. Franklin worked with Vergennes until his fellow commissioners, John Adams and John Jay, overruled him on procedure, signing preliminary agreements with Great Britain late in 1781 without prior consultation with France. The formal treaty was signed September 3, 1783.

Although Franklin wanted to return home, he was kept in Paris for two more years to help make trade treaties. His popularity unabated, he occupied himself by observing the first balloon ascension and serving on a committee appointed by Louis XVI to report on "animal magnetism," or hypnotism, a new marvel that a German physician, Franz Anton Mesmer, thought would cure many, if not all, diseases.

**Last years (1785–90).** At 79, with a large stone in his bladder that made travel by carriage an agony, Franklin was carried to the port of Le Havre in a litter. Back in Philadelphia he lived as quietly as possible, although he continued to take some part in public life. His most important service was as a member of the Constitutional Convention of 1787. There he failed to convince his associates that an executive committee would be better than a president as head of state and that there should be a unicameral legislature. On the last day of this momentous series of meetings, a colleague read for him a plea that the objections to the new form of government, his own among them, should be forgotten and that all delegates should unanimously support the instrument that they had hammered out. Franklin's motion for adoption by unanimous consent was promptly carried.

For the last year of his life he was bedridden, escaping severe pain only by the use of opium. He died on April 17, 1790, aged 84. Philadelphia gave him the most impressive funeral that that city had ever seen, and in France, where Louis XVI was imprisoned in the Tuileries, eulogy after eulogy poured forth to the man who to

the French was the symbol of enlightenment and freedom. All Europeans remembered the epigram of Turgot, the French economist: "He snatched the lightning from the skies and the sceptre from tyrants."

#### MAJOR WORKS

**POLITICAL AND ECONOMIC:** *A Modest Enquiry into the Nature and Necessity of a Paper Currency* (1729); *Plain Truth; or Serious Considerations on the Present State of the City of Philadelphia* (1747); *Proposals Relating to the Education of Youth in Pensilvania* (1749); *Observations Concerning the Increase of Mankind* (1755); *The Way to Wealth* (1757); *The Interest of Great Britain Considered with Regard to Her Colonies and the Acquisition of Canada and Guadeloupe* (1760); *Positions to be Examined Concerning National Wealth* (1769); *Journal of the Negotiations for Peace* (1782).

**RELIGIOUS, PHILOSOPHICAL, AND SCIENTIFIC:** *A Dissertation on Liberty and Necessity, Pleasure and Pain* (1725); *Articles of Belief and Acts of Religion* (1728); *Experiments and Observations on Electricity* (1751).

**OTHER WORKS:** *Poor Richard's* (1732-57), an almanac containing a number of famous maxims; *Franklin's Autobiography* (1771-88); "Information to those who would remove to America" (1784).

**BIBLIOGRAPHY.** *The Papers of Benjamin Franklin*, 15 vol., ed. by L.W. LABAREE et al. (1959-71), with 25 additional volumes expected, will be the definitive collection. *The Writings of Benjamin Franklin*, 10 vol., ed. by A.H. SMYTH (1905-07), has heretofore been the chief collection. The fullest biography is CARL VAN DOREN, *Benjamin Franklin* (1938); the best brief one is VERNER W. CRANE, *Benjamin Franklin and a Rising People* (1954). The most recent life is THOMAS FLEMING, *The Man Who Dared the Lightning: A New Look at Benjamin Franklin* (1971). An interesting specialized study is BRUCE INGHAM GRANGER, *Benjamin Franklin, An American Man of Letters* (1964).

(T.Hor.)

## Fraser River

A major river of western North America, the Fraser River drains a huge, scenic region of some 92,000 square miles (238,000 square kilometres) in the central portion of the province of British Columbia. About 70 percent of the region drained is over 3,000 feet high, and human exploitation of this rather isolated area has been relatively recent and often dramatic, involving pioneer explorers and the lure of elusive gold deposits. The natural beauties of the river course (particularly its spectacular canyon section) and the surrounding countryside have nevertheless remained relatively unspoiled, although extensive timber extraction poses some threat to the forests of the region, and the potential hydroelectric power locked up in the river course may pose a threat to the passage of fish along this traditionally salmon-filled river.

The Fraser itself is 850 miles (1,368 kilometres) long, rising in the steep western slopes of the Rocky Mountains near Jasper National Park, Alberta, thrusting northward and then turning sharply south before emptying into the Strait of Georgia in southwestern British Columbia, south of the city of Vancouver. The river cuts across the physiographic region known as the Interior Plateau of British Columbia, and its eastern tributaries drain the Rocky, Omineca, Cariboo, and Monashee mountains, while the western tributaries drain the eastern slopes of the Coast Mountains. The major eastern tributaries are the McGregor, Bowron, Quesnel, and Thompson; their western counterparts are the Nechako, West Road, Chilcotin, Bridge, and Lillooet. (For related information see BRITISH COLUMBIA.)

**Exploration.** The first European known to have explored the Fraser River was the explorer and trader Simon Fraser of the North West Company, who has bequeathed the river his name. He left Fort George, a fur-trading post at the junction of the Nechako River, in late May 1808 and travelled by canoes with 21 Indian paddlers and packers. He experienced great difficulties in running, or even bypassing, the turbulent rapids in the Fraser Canyon, particularly near the aptly named Hells Gate. He reached the delta mouth of the north arm of the river in early July, but he found further exploration blocked by seemingly hostile Indians at Musqueam (now an Indian reserve on the south edge of Vancouver).

Little use was made of the river until after the discovery of alluvial gold in sandbars north of Yale in 1858. In the gold rush that followed, the central Fraser River, from Quesnel to Soda Creek, was used by flat-bottomed river steamers to transport supplies. There is, however, no present-day use of the river for water transport, except by those ocean vessels that enter the river mouth to travel for 20 miles to dock at the port of New Westminster.

**The course of the Fraser.** The Fraser River has its source at an altitude of 3,640 feet (1,109 metres) at Yellowhead Lake in Yellowhead Pass in the Rocky Mountains. The small but vigorous stream then drops about 1,200 feet in 50 miles before meandering slowly northward across the flat-bottomed floor of the landform division known as the Rocky Mountain Trench. Near McBride the river is a few hundred yards across, flowing between low, steep gravel banks. Occasional patches of agricultural land are cleared on the valley floor along Highway 16, which follows the upper Fraser Valley. The river bends westward out of the Rocky Mountain Trench, is joined by the McGregor River from the north, and then cuts down into the rolling upland of the Interior Plateau of British Columbia. At the city of Prince George, the river flows fast between steep, 200-foot gravel banks and has a mean discharge of 29,100 cubic feet per second. At this point, the Nechako River joins the Fraser from the west, draining a large area of some 12,200 square miles of the Interior Plateau.

South of Prince George the slightly entrenched river banks are lower, and the river swings back and forth across its shallow, forested valley. Its volume increases as it picks up the waters of the Quesnel River, which drains the areas of heavy precipitation in the Cariboo Mountains to the east, and also of the West Road River, which drains a drier area of the Interior Plateau east of the Coast Mountains. Although the average annual precipitation of the northern Fraser River Basin may be represented by the 24 inches (610 millimetres) recorded at Prince George (made up of 15 inches of rain falling from April to October and 90 inches of winter snow), higher precipitation totals of 60 to 80 inches are recorded on the western slopes of the Cariboo Mountains.

South of the town of Quesnel, the Fraser River begins to take on its canyon character. At the junction of the Chilcotin River, flowing in from the west, the Fraser River is about 1,400 feet above sea level, and it now has a mean discharge, near Marguerite, of 51,700 cubic feet per second. The Chilcotin River itself drains an area of 7,560 square miles on the eastern side of the Coast Mountains. The general surface of the Interior Plateau rises from about 2,500 feet above sea level near Prince George to about 4,000 feet near Clinton. While this plateau was being uplifted and covered with lava flows in the geologically recent (less than 20,000,000 years ago) Miocene Epoch, the Fraser River was able to down-cut a deep, straight course southward. To the south, therefore, the canyon walls become higher and slope steeply. The Thompson River (drainage basin of 19,520 square miles), which joins the Fraser from the east, also flows through a narrow canyon. The Fraser and Thompson rivers were both larger at the end of the glacial age; in the last 10,000 years these rivers have cut down into the glacial deposition in the valley floor so that raised terraces and narrow benches now line certain sections of the valley floor above and below their junction. Further south these strips of level land become rare, and at Hells Gate the river rushes through a steep, rocky canyon, with two railways and a highway carved out of the valley walls.

At Yale the river leaves the Coast Mountains and the valley widens; at Hope the Fraser Delta begins. At this point the river has an average annual volume of flow of 95,500 cubic feet per second, but there is a range from an average maximum of 300,000 cubic feet per second in the flood month of June, to an average flow of only 25,000 cubic feet per second at the time of low water in March. In recent decades the average discharge has been steadily increasing, perhaps as a result of increased snow-

The  
canyon  
section

fall in the mountains, and despite the diversion of Nechako River headwaters to the Pacific Coast, at Kemano, for hydropower. The much larger Fraser River of the glacial period built out a delta 100 miles west of Hope into the Strait of Georgia, but the present river has cut down about 200 or 300 feet into this older, higher glacial delta and has also developed its own recent flood plain close to sea level. The mouth of the Fraser has at least three main distributary channels as it discharges its load of silt into the Strait of Georgia. Prior to European settlement in the mid-19th century, the Fraser River annually flooded its low banks throughout the delta, but farmers had diked the main river by the end of the century. These dikes were raised and strengthened after a disastrous flood in early June 1948, when the maximum daily discharge exceeded 500,000 cubic feet per second.

**Human exploitation.** The economy of the Fraser River Basin is based mainly on forestry. Coniferous forests cover most of the Interior Plateau, except in the dry, southern valleys, which are covered with narrow strips of grassland on the lower slopes. Prior to 1940 small sawmills cut a little lumber along the three railway lines that crossed the basin. After 1950, however, the northward extension of the Pacific Great Eastern Railway (subsequently called the British Columbia Railway) and the improvement of highway facilities increased the accessibility of the forests; and the merging of smaller companies, together with the introduction of pulp mills, consuming chips and small trees, heightened the utilization of forest resources. As a result the Fraser Basin became the second area of lumber production in British Columbia. Forest products are either transported to Vancouver for overseas markets or are taken eastward by rail to central Canada and the midwestern United States. The turbulent Fraser River itself is not actually used in the forestry industry, even for the transport of logs to the sawmills.

Agriculture has not developed greatly within the river basin, except for cattle ranching on the grasslands and upper level parklands in the Chilcotin Plateau, west of the Fraser River, and the Nicola Valley, south of the Thompson River. Ranching was established in the 1860s to supply the gold mining camps and then, after gold mining declined, to supply meat to the growing city of Vancouver. The level land of the Interior Plateau around Prince George had only minor agricultural use, prior to 1940, because of the lack of any large, local urban markets. As cities such as Prince George grew, farmland expanded nearby, but, as a local occupation, farming does not compete economically with forestry.

The Fraser River is the major producer of salmon in British Columbia, and its nearby tributaries and headwater lakes are the spawning grounds of several species of salmon. These salmon ascend the river in late summer to spawn and then go downstream the following year to spend the next two or three years in the ocean. Because of these migratory habits, salmon fishing takes place mainly off the Fraser River mouth, and only Indians have fishing rights in the river basin itself. The various tributaries of the Fraser produce different numbers of salmon from year to year, depending on the two- or four-year cycles of the spawning salmon.

Although the Fraser River has an enormous potential waterpower—conservatively estimated at more than 5,000,000 horsepower, excluding its tributaries—this power remained untapped in the early 1970s, because dams could curtail or destroy the fish runs. A dam at the suggested site of Moran, north of Lillooet, for example, could produce more than 2,000,000 horsepower. If new technological advances can be used to get fish successfully past dams in both directions, then such dams would have irrigation, flood control, and recreational value, as well as being a source of power for the urban markets of Vancouver. Yet by the early 1970s the only developed waterpower sites were at Bridge River, a tributary in the southwestern part of the Fraser River Basin, and in association with the westward diversion of the headwaters of the Nechako River through a tunnel in the Coast Mountains to Kemano and Kitimat on the Pacific Coast.

(J.L.Ro.)

## Frederick I Barbarossa, Emperor

Frederick I Barbarossa (Redbeard), of the House of Hohenstaufen, was one of the greatest of the Holy Roman emperors of the Middle Ages. A crusader and an effective opponent of the papacy, he became a legendary German hero, a symbol of unity to the German people.

By courtesy of the Biblioteca Apostolica Vaticana

Frederick I as crusader, miniature from a manuscript. Henry of Schäftlarn (right) dedicates to him a copy of the *History of the First Crusade* by Robert of St Remy. In the Vatican Library (Vat. Lat. 2001).

Frederick was born c. 1123, the son of Frederick II, duke of Swabia, and Judith, daughter of Henry IX, duke of Bavaria, of the rival dynasty of the Welfs. After succeeding his father as duke of Swabia, Frederick was elected German king on March 4, 1152, in Frankfurt, succeeding his uncle, Emperor Conrad III. Frederick's contemporaries believed that because he united in himself the blood of the Welfs and the Hohenstaufen, he would solve the internal problems of the kingdom. The announcement of his election, which he sent to Pope Eugenius III, made it plain that Frederick I was not ready to recognize the pre-eminence over the emperors that the popes had won during the quarrel over the right of investiture of bishops and abbots. Frederick, moreover, filled several vacant episcopal sees, thereby violating the Concordat of Worms of 1122. Nevertheless, he was to learn that he could not prevail against the papacy as easily as the earlier emperors, Otto I and Henry III, had done because the political balance of the West had changed. Under the powerful emperor Manuel I Comnenus, the Byzantine Empire had grown to be a political factor in the Mediterranean and in Italy. Southern Italy and Sicily were united in the Norman kingdom of Roger II. The cities of the Lombards, which had been little more than a nuisance to the earlier emperors, had now become invincible.

Frederick started his struggle for the old goal of the predominance of the Empire over the European monarchies with great political skill. By not recognizing the treaty of alliance between his predecessor, Conrad III, and Manuel I Comnenus of Byzantium against Roger II of Sicily, Frederick forced Pope Eugenius III to sign the Treaty of Constance (1153) with him because the Pope was more exposed to pressure from the Norman kingdom to the south as well as from Arnold of Brescia in Rome. Frederick promised not to make peace with the

The treaty of Constance

Forest products

Water power

Roman commune, headed by Arnold (whom he hanged) or with the Normans without the agreement of the Pope. He also promised not to concede any Italian land to the Byzantine Emperor and, finally, to maintain the position of the papacy (*honor papatus*). Eugene III, on his part, promised that Frederick would receive the imperial crown and that the rights of the empire would be maintained. When Manuel of Byzantium offered Frederick a Byzantine princess as wife and attempted to induce him to fight against the Norman kingdom, Frederick refused. The successor of Eugenius III, Pope Adrian IV, honoured the Treaty of Constance and crowned Frederick emperor on June 18, 1155, in Rome.

The German princes refused to give Frederick the support necessary to attack the Sicilian kingdom, which, under Roger's son William I (reigned 1154–66), was passing through a crisis. Although Manuel now formed an allegiance with the rebellious Norman barons, the city of Genoa, and the Pope, Adrian still would not accept the Byzantine offer of help against William I of Sicily. After William had brought his crisis to an end, he was able to force the Pope to sign the Concordat of Benevento in 1156 by which Adrian gave William Sicily and the Norman principalities on the mainland as far north as Naples and Capua and granted him special rights for the Sicilian church. This new treaty was in violation of the Treaty of Constance. Cardinal Roland (later Pope Alexander III) was supposed to explain the Pope's new policy to the princes and to the Emperor at the imperial Diet of Besançon 1157. A letter from the Pope, which was translated in an inflammatory manner by the imperial chancellor Rainald of Dassel, caused a critical argument between the papal delegation and the German princes over whether or not the empire was dependent upon the papacy. Adrian explained later that he meant the word *beneficium*, which had caused all the trouble, to mean benefit and not fief.

In 1158, after Frederick had solved several decisive domestic problems (see below), he began his second campaign in Italy, seeking the complete restoration of the imperial rights. After laying siege to and conquering Milan, which had attempted to oppose him, Frederick opened the Diet of Roncaglia. The goal of this Diet was to define and guarantee the rights of the emperor, which would bring the empire an estimated 30,000 pounds of silver per year. Frederick attempted, beginning in 1158 and especially after 1162, not only to achieve the granting of these rights but also to put a systematic financial administration into effect. His goal was to reduce imperial Italy to a system of well-controlled castles, palaces, and cities, with the self-government of the cities controlled by imperial officials. What the Emperor saw as a restoration of the imperial rights, however, was considered by the cities as a curtailment of their freedom. A tax called the *fodrum* was levied on all the inhabitants of imperial Italy; in return the Italian nobles and communes were excused from service in Frederick's armies and were guaranteed his protection. A portion of the Italian money went to the German princes; this enabled Frederick to win their support without making too many political concessions to them in Germany. The ecclesiastical princes of the empire, however, still had to render full service for Italy; the archbishopric of Mainz suffered severe financial losses because Archbishop Christian was active for a long time in Italy as imperial legate. The Italian taxes allowed Frederick to enlist mercenaries (Brabantini) in order to free himself militarily, to a certain extent, from the fief holders. The money of Italy was not, however, the only motive of Frederick's Italian policy.

The Pope, as well as the cities, felt threatened by a tightly organized imperial state in Italy. In 1159 Cardinal Octavian was elected Pope Victor IV with the support of Frederick, and Cardinal Roland was elected Pope Alexander III in a tumultuous and disputed voting session. Alexander, supported by many cardinals, was also immediately recognized by William of Sicily as the true pope. At the council of 1160 in Pavia, convened by the Emperor, only Victor IV was present and was declared the rightful pope, thereby earning Alexander's hostility.

Alexander III, one of the greatest lawyers of the church, wanted to found a papacy that would be independent of the Emperor; he excommunicated Frederick in 1160. France, England, Spain, Hungary, the Lombards, and even Emperor Manuel joined Alexander's party; Alexander retired to France in 1161, where he remained until 1165. John of Salisbury asked at that time: "Who made the Germans judges of the nations?" Barbarossa's attempt to persuade King Louis VII of France to try to heal the schism when they met at Saint-Jean-de-Losne on the Saône was of no avail. Alexander attempted to bring Frederick back into the church but with no success. At Alexander's urging, the Byzantine emperor Manuel Comnenus now prepared to form an alliance with France and was ready to recognize the Pope. In 1162 Milan was destroyed by Frederick.

When Victor IV died in 1164, Paschal III (reigned 1164–68) was quickly elected as the new imperial pope on the urging of Rainald of Dassel, perhaps against the will of the Emperor. Because of friction between Louis VII and Henry II of England and because the latter was embroiled in an argument with Thomas Becket, Barbarossa decided to form an alliance with Henry II. At the Diet of 1165 in Würzburg, Frederick swore not to recognize Alexander III. The promises made by the English delegates that Frederick's political wishes would be recognized were denied by Henry II, who preferred to keep Alexander under pressure, thus making things more difficult for Becket.

Following the death of William I of Sicily in 1166, Frederick felt that the time had come to strike a decisive blow against Alexander III, who had returned to Rome, and against Sicily. The Lombard League was formed to defend against the Emperor's fourth expedition to Italy. Frederick's expedition ended in disaster, however, when malaria broke out in his army. Rainald of Dassel died in Rome at this time, causing a change in the imperial strategy. When Frederick negotiated peace between Louis VII and Henry II and then sent the Bishop of Bamberg in 1170 to Alexander III and envoys to Byzantium, a détente resulted that even Alexander could not escape. In his fifth Italian campaign (1174) Frederick did not defeat the Lombards militarily, but they were forced to subject themselves to him in the Armistice of Montebello. Because Duke Henry the Lion of Saxony refused to come to his aid, however, Frederick lost the Battle of Legnano against the Lombards. He was now ready to deal with the Pope, and in 1176 they signed the Treaty of Anagni. In the Peace of Venice (1177) Barbarossa acknowledged Alexander III as the true pope. In front of the Church of St. Mark's, Barbarossa received the kiss of peace from the Pope. At Venice the imperial delegates had been able to improve the Emperor's position. Above all was the fact that, although a truce had been negotiated with the Lombards, they were not included in the peace treaty. A treaty with the Lombards was finally confirmed in the year 1183.

Barbarossa meanwhile had also initiated sweeping changes in his empire, where Duke Henry the Lion of Saxony was the strongest prince next to him. When Barbarossa took office, Henry had laid claim to Bavaria, the domain of the margrave Henry II Jasomirgott of Austria. Barbarossa bestowed Bavaria on Henry the Lion, and as compensation he elevated the margravate to a dukedom, with special rights. The Emperor also left the dukedom of Saxony and Mecklenburg under Henry the Lion's control, and in 1154 the Duke received the privilege of investing bishops in the colonial land east of the Elbe. The year 1158 was of great importance for the empire; Barbarossa founded the imperial territory of Pleissnerland (south of Leipzig), elevated Duke Vladislav II of Bohemia to king, and granted the Archbishop of Bremen important privileges, restoring the Bishop's lost political power. Also in 1158 Frederick promised to enfeoff Waldemar I, the Great of Denmark—that is, make him his vassal with certain rights.

Meanwhile, Henry the Lion founded the cities of Munich and Lübeck (1158). The founding of Lübeck brought German merchants to the Baltic Sea. The Duke

rights

closed a contract between the Germans and the inhabitants of Gotland and sent envoys to Scandinavia and Russia. A trade agreement was closed in 1189 with Novgorod. About 1180 German merchants reached Riga; their advance was protected by Henry's conquest of Mecklenburg (1177). By 1148 Henry had the county and the town of Stade, the most important harbour on the Elbe, in his control.

At the same time German colonists had settled in Brandenburg under the margrave Albert I the Bear and in Silesia. Barbarossa had restored the dependence of the Polish dukes during two expeditions to Poland in 1157 and 1172. Henry the Lion, the most powerful prince in northern Germany, made Brunswick his residence. He had repeatedly challenged other princes in feuds, but Archbishop Wichmann of Magdeburg, Albrecht of Brandenburg, Landgrave Louis III of Thuringia, and Archbishop Rainald of Cologne offered repeated resistance. It is not completely certain that Duke Henry's refusal of aid to Frederick in 1176 was the sole cause of his downfall. Apparently his manifold breach of the peace of the land caused the Emperor to accuse him, to conquer Lübeck, and, in 1180, through a council of the princes in Gelnhausen, to depose him. Henry lost his dukedom; Westphalia was given to the Archbishop of Cologne, and Bavaria was granted to Otto of Wittelsbach. Henry, who was married to Mathilde of England, went in exile to King Henry II of England. As a result of Henry the Lion's trial, the feudal system was made a still stronger basis of the imperial constitution. Thereafter, only those princes who had received their land directly from the Emperor were admitted to the exclusive circle of imperial princes (*Reichsfürsten*). Barbarossa elevated the princes of Pomerania to dukes, and the counts of Andechs became the dukes of Merania (in the neighbourhood of Trieste). Steiermark became a dukedom. Another important measure of Barbarossa was the elevation of the Bishop of Würzburg to duke of Franconia in 1168.

Barbarossa had attempted to hold the increasing power of the princes in check. By 1152 he had found a solution for the area of Burgundy, which also belonged to the empire. He made Duke Berthold IV of Zähringen his representative for the dukedom of Burgundy as far as the Mediterranean and married Béatrix, the daughter of Count Rainald of Burgundy (1156). Barbarossa attempted to build his own imperial territory between the areas controlled by the princes. This territory was composed of castles, cities, landholdings, ministerial seats, and single rights that were more or less thickly scattered from Swabia to Thuringia. This large territory was ruled by imperial ministerials (*ministeriales imperii*). These men had great power because many of them belonged to the Emperor's circle. The most famous of them was Kuno of Münzenberg, whose castle is preserved in the Wetterau north of Frankfurt and who founded the town of Friedberg. The territorial "peace laws" belong to his efforts to keep the Emperor in power.

Chivalry gave Barbarossa's time a special stamp. He expressed his enthusiasm for knighthood as the ideal way of life at the festival of Pentecost at Mainz in 1184, where he dubbed his sons knights. This festival was surpassed by the "Diet of Jesus Christ" in 1188, when the margrave Namur was transformed into an imperial principality. More important was Barbarossa's call to the Third Crusade in the spring of 1189 to free Jerusalem from Saladin's army, which had captured it in 1187. Before his departure he returned the former possessions of the Countess Mathilde of Tuscany, a part of the papal state, to the Pope. In 1190 the Emperor drowned while trying to cross the Saleph River.

Frederick Barbarossa had attempted to continue the imperial policy of the rulers of the Saxon and Salian lines. His state was still founded upon the noble, the high noble, and above all the newly founded rank of the imperial servants. The imperial cities in Germany were governed by royal officials (*advocatis sculteti*), and the citizens had their part in the government. The cities played no role in politics. Frederick had to recognize that the church, after the quarrel of investiture, had become a firmly controlled

institution, with its powers strictly defined by law. The church had joined itself to the struggle for freedom of the economically powerful states in upper Italy. Pope Alexander III was able to force the kings of Europe (especially Louis VII of France) not to enter into a political agreement with Barbarossa. Only Philip II Augustus of France signed a treaty with Barbarossa in order to free himself from the pressures created by the Anglo-Norman occupation on the mainland. There was no chance that a continuation and increase of the imperial policy in the territories controlled by the empire would have broken the power of the princes. Germany developed into a system of territorial states after Barbarossa's death, while France developed during the time of Philip II Augustus into a centralized monarchical state. Barbarossa had a strong feeling for law and imperial prestige. His steadfast opposition to the popes and to Henry the Lion made him the symbol of German unity in the romantic glorification of the 19th century. People since the 14th century believed he was sleeping in the imperial castle of Kyffhäuser and hoped for his return. A monument to him was erected there during the years 1890-96.

**BIBLIOGRAPHY.** The chief contemporary source of Frederick's life is *Otonis episcopi frisingensis Gesta Friderici I*, ed. by GEORG WAITZ and B. VON SIMSON (1912; Eng. trans., *The Deeds of Frederick Barbarossa*, by Otto of Freising and His Continuator, Rahewin, 1953). WILHELM VON GIESEBRECHT, *Geschichte der deutschen Kaiserzeit*, vol. 5-6, 1880-88 (1895), treats Frederick from a 19th-century German nationalist point of view. H. SIMONSFELD, *Jahrbücher des deutschen Reiches unter Friedrich I*, vol. 1—till 1158 only (1908), documents all that is known about Barbarossa. PETER MUNZ, *Frederick Barbarossa* (1969), is a good English-language biography, although some points are subject to dispute. ALFRED HAVERKAMP, *Herrschaftsformen der Frühstaufer in Reichsitalien*, 2 vol. (1970-71), is a very important book on the constitutional and financial history of Frederick in Italy.

(H.Pa.)

## Frederick II, Emperor

Holy Roman emperor, German king, and king of Sicily, last of the great Hohenstaufen rulers, Frederick II was born on December 26, 1194, in Jesi, in the March of Ancona, Italy. He was the grandson of Emperor Frederick Barbarossa and the son of Constance of Sicily and Emperor Henry VI, who, at the time of his son's birth, was about to conquer Sicily.

At the end of 1196 the German princes elected Frederick king at Frankfurt. His father, however, failed in his attempt to gain the princes' support to make Frederick's succession hereditary. Just before embarking on a cru-

of Henry  
the Lion

sade to the Holy Land, Emperor Henry died in September 1197 after a brief illness, only 32 years old. Though the medieval Roman Empire was at the height of its strength, the Emperor's death brought it close to dissolution.

After the death of her husband, Empress Constance had young Frederick brought to Sicily, where in May 1198 he was crowned king of Sicily. Before her death later that year, Constance loosened the bonds that joined Sicily to the empire and to Germany by appointing Pope Innocent III her son's guardian as well as regent of the Kingdom of Sicily, which was already under papal suzerainty. In Germany two rival kings were elected, Frederick's uncle Philip of Swabia and Otto of Brunswick, as Otto IV.

Even the Pope, however, did not succeed in protecting Sicily from many years of anarchy. German and papal captains, local barons, and Sicilian Saracens, as well as the cities of Genoa and Pisa, fought for mastery of the country. The situation was not stabilized until the imperial chancellor conquered Palermo in November 1206 and governed in Frederick's name. In December 1208 Frederick, then 14, was declared of age.

In 1209 he married the much older Constance of Aragon, who brought him an urgently needed troop of knights with whose help he gained control of Sicily, defeated a conspiracy of the barons, and was partially successful in regaining the crown properties that had been lost during his minority. At this time his relations with the Pope began to show signs of strain.

Frederick's Sicilian efforts were seriously endangered when at the end of 1210 Otto IV invaded the realm on the mainland and in 1211 even threatened Sicily itself. Otto withdrew, however, when in September 1211 a number of German princes deposed him and elected Frederick king.

**Years of triumph.** Before leaving for Germany in March 1212, Frederick had his one-year-old son Henry VII crowned king of Sicily and granted various privileges to the Holy See. Having rapidly conquered south Germany, where he met almost no opposition, Frederick was elected once again king of Germany by a large majority of princes at Frankfurt in December 1212, and crowned a few days later. In the same year he concluded an alliance with France against Otto, who was decisively defeated at the Battle of Bouvines in July 1214.

In April 1220, Frederick's nine-year-old son Henry VII was elected king by the German princes, thus negating Frederick's promise to Pope Innocent that he would relinquish control of Sicily in favour of Henry, for it meant that Sicily and Germany would eventually be united under one ruler. Although Frederick sought to exonerate himself with Pope Honorius II by claiming that the election had been held without his knowledge, he had to pay for it by surrendering extensive royal prerogatives to the German ecclesiastical princes.

Crowned emperor by the Pope in St. Peter's Church, in Rome, on November 22, 1220, Frederick confirmed on the same day the legal separation of the empire from the Kingdom of Sicily while continuing the existing personal union. In addition, he granted important privileges to the Italian ecclesiastics and issued laws against heretics, and it seemed indeed that harmony had been re-established between the Emperor and the Pope for some years to come. Frederick spent the following years consolidating his rule in Sicily. He broke the resistance of the barons to revocation of certain of their privileges and defeated the rebellious Saracens (1222–24), whom he later resettled in Apulia where they became his most faithful subjects, providing him with a loyal bodyguard immune against papal influence.

In addition to erecting a chain of castles and border fortifications, he had enlarged the harbours of his kingdom and established a navy and a fleet of merchant vessels. He instituted measures designed to bring trade under state control and make the manufacture of certain products the monopoly of the state. Finally, he created a civil service for which candidates were trained at the first European state university, in Naples, which he himself founded in 1224.

In the meantime, the Pope was reminding the Emperor of the crusading vows he had taken at his coronations in 1212 and 1220. Frederick, however, was inclined to postpone such a venture until the Italian problems had been resolved. He claimed the Kingdom of Jerusalem for himself through his marriage to Isabella (Yolande) of Brienne, the heiress of the titular king of Jerusalem, who had become his wife in 1225 after Constance had died in 1222. Before embarking for the Holy Land, Frederick convened an imperial diet for Easter 1226 in Cremona, in northern Italy, in order to reinforce certain imperial rights in Italy and to prepare for the crusade. The cities of Lombardy, however, reconstituted themselves, under the leadership of Milan, as the Lombard League, and not only sabotaged the diet at Cremona but effectively opposed Frederick's reorganization of northern Italy.

In September 1227, when Frederick was at last ready to embark from Brindisi for the Holy Land, an epidemic broke out among the crusaders. The new pope, Gregory IX, a passionate man who belonged to the intellectual world of Francis of Assisi—his personal friend whom he canonized as early as 1228—brushed aside Frederick's justification and excommunicated him for his failure to carry out the crusade.

In June 1228, ignoring the excommunication, Frederick set sail from Brindisi. In the Holy Land, following complex negotiations, he obtained Jerusalem, Bethlehem, and Nazareth from the Sultan al-Kāmil of Egypt. It was certainly the impact of Frederick's personality on the Arab world, and not armed might, that made this treaty possible. On March 18, 1229, the excommunicated Emperor crowned himself king of Jerusalem in the Church of the Holy Sepulchre. This was the high point as well as the turning point of Frederick's conception of sovereignty. Eschatological prophecies concerning his rule were now made, and the Emperor considered himself to be a messiah, a new David. His entry into Jerusalem was compared with that of Christ on Palm Sunday, and, indeed, in a manifesto the Emperor, too, compared himself to Christ.

In the meantime, however, papal troops had penetrated into the Kingdom of Sicily. Frederick returned at once and reconquered the lost areas but did not in turn attack the Papal States. His diplomacy was rewarded: after the Treaty of San Germano (July 1230) he was absolved from excommunication the following month at Ceprano.

In August 1231, at Melfi, the Emperor issued his new constitutions for the Kingdom of Sicily. Not since the reign of the Byzantine emperor Justinian in the 6th century had the administrative law of a European state been codified. Frederick's codes contained many ideas that anticipated enlightened absolutism and the centralization of the state. During the same time, however, Frederick could not prevent his son, the German king Henry VII, from making a number of important concessions to the German princes. These concessions, confirmed by Frederick in 1232 at the diet of Cividale, strengthened the rule of the princes at the expense of the central power of the empire. These and other steps set back the development of communal self-government in Germany and furthered the independence of the principalities. In the meantime, relations between Frederick and Henry VII deteriorated steadily. Henry had been ruling independently in Germany since 1228, when in December 1234 he entered into an alliance with the Lombard League. This action amounted to high treason in the eyes of the Emperor. On Frederick's arrival in Germany, his son's rebellion collapsed; he died in a prison in Calabria in 1242.

His second wife having died in 1228, Frederick in July 1235 married Isabella of England. Shortly thereafter, he issued an edict of imperial peace, which also called for the appointment of a chief justice of the imperial court in order to protect the sovereign rights of the Emperor from further erosion.

After some military successes in Lombardy against the Lombard League, the Emperor returned to Germany in the autumn of 1236 to remove the rebellious duke Frederick of Austria and Styria from rule. In February 1237

Corte-  
nuova

he had his nine-year-old son Conrad IV elected king of Germany in Vienna. After several more months in Germany—it was to be his last visit—he descended into northern Italy. He defeated the Lombard League at Cortenuova, but, misjudging his strength, he rejected all Milanese peace overtures and insisted on unconditional surrender. It was a moment of grave historic importance when Frederick's hatred got the better of his judgment and blocked all possibilities of a peaceful settlement.

**Struggle with the papacy.** Milan and five other cities held out, and in October 1238 he had to raise the siege of Brescia. In the same year the marriage of Frederick's natural son Enzo with the Sardinian princess Adelasia and the designation of Enzo as king of Sardinia, in which the papacy claimed suzerainty, led to the final break with the Pope. Gregory IX deeply distrusted Frederick both in religious and political matters: Frederick was supposed to have jested that Moses, Christ, and Muhammad were three impostors who had themselves been hoodwinked; and in the political arena the Pope was fearful that the Papal States were about to be isolated and encircled, particularly because a pro-imperial party had been formed in Rome. Under the pretext that the emperor intended to drive him from Rome, Gregory excommunicated Frederick for the second time on Palm Sunday, March 20, 1239. This was the beginning of the last phase of the gigantic struggle between the papacy and the empire; it ended with the death of the Emperor and the downfall of his house.

Frederick countered the excommunication with a number of important manifestos, most of them composed by Pietro della Vigna, a member of the imperial chancery, who had outstanding literary gifts. The manifesto emphasized that the cardinals were meant to participate in the leadership of the church, and Frederick even tried to evoke solidarity among the secular princes. He also, however, intensified his military activities in northern Italy. In order to finance his constantly growing need for arms, he instituted a thorough administrative reorganization of imperial Italy (among others, the formation of ten vice regencies) and of the Kingdom of Sicily. In addition, he decreed the rigorous surveillance of the population. In central Italy he took the offensive, occupying the March of Ancona and the Duchy of Spoleto, and in February 1240 his army marched into the Papal States and threatened Rome. At the last moment, however, the Pope won the support of the Romans.

Following the defeat of a Genoese fleet bringing delegates for a papal council to Rome, more than 100 high-ranking ecclesiastics—cardinals and bishops among them—were taken as Frederick's prisoners to Apulia. This military victory proved, however, to be a political disadvantage: it provided material for propaganda depicting Frederick as an oppressor of the church.

While still encamped before Rome, Frederick received the news of Pope Gregory's death and thereupon withdrew to Sicily. In the meantime, the Mongols had invaded Europe. They were temporarily halted in the extremely bloody Battle of Liegnitz in Silesia on April 9, 1241, but probably only the sudden death of their leader Genghis Khan prevented further Mongol advances at that time.

Celestine IV's brief pontificate was followed by a long interregnum. When in 1243 Innocent IV was elected, Frederick, at the urging of the German princes and of King Louis IX of France, opened negotiations with the new pope. Agreement between the Pope and the Emperor seemed close on the evacuation of the Papal States, when in June 1244 Innocent fled the city. In Lyons he convened a council for 1245, and in July of that year deposed the Emperor, the obstacle to reconciliation apparently being the status of the Lombard communes.

The battle between the Emperor and the papacy then raged in full fury; on the papal side the Emperor was branded as the precursor of the anti-Christ; on the imperial side he was hailed as a messiah. The Emperor supported the contemporary demand that the church return to the poverty and saintliness of the early Christian community and again appealed to the princes of Europe to

join in a defensive league against the power-hungry prelates. Most of the princes, however, remained neutral, and, although two successive German antikings received little support, the Emperor steadily lost ground in Germany.

In May 1247, Frederick's planned journey to Lyons in order to plead his own case before the papal council was interrupted by the revolt of the strategically placed city of Parma. In the wake of this debacle much of central Italy and the Romagna was lost. The following year the Emperor was to suffer further blows of fate; Pietro della Vigna, for many years the Emperor's confidant, was accused of treason and committed suicide in prison. In May 1249 King Enzo of Sardinia, Frederick's favourite son, was captured by the Bolognese and was kept incarcerated until his death in 1272.

The Emperor's position, both in Italy and—through the efforts of his son, Conrad IV—in Germany, was improving when he died unexpectedly on December 13, 1250, in Castel Fiorentino in Apulia. He was buried in the cathedral of Palermo near his first wife, his parents, and his Norman grandfather.

When the news of his death was published, all Europe was deeply shaken. Doubts arose that he was really dead; false Fredericks appeared everywhere; in Sicily a legend grew that he had been conveyed to the Aetna volcano; in Germany that he was encapsuled in a mountain and would return as the latter-day emperor to punish the worldly church and peacefully re-establish the Holy Roman Empire. Yet he was also thought to live on in his heirs. In fact, however, within 22 years after his death, all of them were dead: victims of the battle with the papacy that their father had begun.

Frederick's character was marked by sharp contradictions, undoubtedly the result of his insecure and emotionally barren childhood. Enchanting amiability and gaiety were paired with cruelty; harshness and rigidity existed side by side with superior intelligence and a keen sense of reality; tolerance and intolerance went hand in hand; impulsive sensuality did not stand in the way of genuine piety; imbalance and inner discord pervaded his personality and his achievements.

Frederick cannot be considered the first modern man on the throne, nor a pioneer of the Renaissance, as some historians have maintained. Though his gifted personality heralded some of the intellectual trends of later times, he was, all in all, a man of the Middle Ages. He had indeed had the good fortune to have grown up in Sicily in a mixed culture that uniquely combined elements of antiquity, Arabic and Jewish wisdom, the Occidental spirit of the Middle Ages, and Norman realism. The intellectual life of his court reflected this heritage. A courtly "republic of scholars," it nurtured and fostered the natural sciences as well as philosophy, poetry, and mathematics, and translations as well as original writing, both in Latin and in the vernacular. The pursuit of knowledge without special respect for traditional authorities was characteristic of Frederick and his court.

Witness to the intellectual vigour and distinction of Frederick himself and those around him are the content and style of his great legal codices and manifestos, many of them serving as examples to later generations; the edifices he erected, particularly the classic style of the Castello del Monte—a fusion of poetry and mathematics in stone; and, most outstanding, his own work *De arte venandi cum avibus*, a standard work on falconry based entirely on his own experimental research.

Frederick's concept of the emperor's function was rooted in the ideology of the late Greco-Roman period and the Judeo-Christian philosophy of the Middle Ages, emphasizing the sacredness and universal character of the office. In the light of it, Frederick claimed pre-eminence for the emperor over all other secular rulers—undoubtedly an ill-timed claim in an age when separate nation-states were developing. Thus, Frederick's policies, full of intellectual and political promise, were in actuality dogged by tragedy.

## Frederick II the Great, of Prussia

Frederick II the Great, third king of Prussia, from 1740 to 1786, played a leading part in the breakup of the Holy Roman Empire and the rise of what had been a small, provincial kingdom into a great European power that eventually headed a new, united Germany. He ranks as one of history's great captains, who modernized warfare and reintroduced the strategy of attack, preceding Napoleon in the triple role of head of state, army organizer, and active commander in chief. He was also the first monarch to uphold, at least in theory, toleration of all religions and among the first to embody consciously the principle of enlightened despotism or benevolent autocracy. An absolute ruler (although he called himself "the first servant of the state" and described a crown as "a hat that lets the rain in"), he initiated the first codified German law and enforced general education in advance of other countries.

By courtesy of the Staatliche Museen zu Berlin

Frederick II, portrait by Antoine Pesne (1683–1757). In the Gemäldegalerie, Berlin.

Frederick was born on January 24, 1712, when the Prussian kingdom was only 11 years old, the third and eldest surviving son of Frederick William I and Sophie Dorothea of Hanover, daughter of George I and sister of George II of England.

**Apprenticeship.** His childhood and youth were unhappy, not least because they were overshadowed by family conflict caused by political rivalry between the two royal houses. His father, moreover, was a fanatically practical and self-righteous man, as well as a rabid militarist wholeheartedly opposed to his son's artistic and studious leanings.

Subjected from infancy to a Spartan regimen that placed army drill and the Lutheran catechism high on the educational syllabus but excluded Latin, poetry, philosophy, and music along with every form of "frivolous" comfort, Frederick's early taste for these may have developed in typical reaction. If so, an endless chain reaction resulted, in that despair at the son's unconventional preferences goaded the father to ever more rigorous treatment of him, which, in turn, widened the gulf between them. Instead of the "brotherly" love and trust that Frederick William had hopefully envisaged, their relationship became more and more one of open antipathy on his side and devious desperation on his son's.

As he experienced similar disappointments in his relations with his subjects (the streets would empty as though by magic when the patriarchal King went for his daily stroll), with his patronizing Hanoverian in-laws, and with the Emperor (who openly manipulated him), Frederick William's choler grew to pathological dimensions. That his war machine—except for one brief expedition early in his reign—never came to operate in earnest and that he suffered increasingly from gout, did not improve his state of mind. The periodical, roaring scenes within the royal apartments sometimes caused crowds to collect in the street outside. Even in public, at troop reviews and at court functions, the King would thrash the Crown Prince and force him to kiss the father's boots: this at a time when Frederick was past adolescence and, together with his favourite sister, Wilhelmina, the object of negotiations for a double marriage with their English cousins, the Prince of Wales and the Princess Amelia.

The climax came when, these negotiations finally broken off, Frederick saw no way out of his intolerable situation but to run away to England. With the help of two friends, lieutenants Hans Hermann von Katte and Peter Karl Christoph von Keith, Frederick made an attempt at escape in the summer of 1730. Betrayed by the last-minute qualms of Keith, who then himself fled the country, Frederick and Katte were arrested as deserters from the army, stripped of rank and civil rights, imprisoned, and brought to trial by court martial.

The court martial sentenced Katte to two years' fortress imprisonment and declared itself incompetent to judge the heir to the throne. But the King, having already decreed Frederick eliminated from the line of succession, overrode the verdict. He imposed the death penalty on Katte and let it be known that the same was intended for his son. By his order, Katte was beheaded within view of Frederick's cell and Frederick was forced to look on. The 18-year-old prince, who until then had conducted himself with remarkable fortitude, was thrown into such a state of abject terror that the prison chaplain was able to inform the King of Frederick's now absolute submission. The King responded with a conditional pardon. Frederick was to earn his freedom and restitution of rank and heritage by serving an indefinite term in the civil administration.

In retrospect, Frederick came to regard this period of probation as invaluable training for his future occupation, just as he subsequently saw his father's notorious parsimony and drill mania in the light of the result—the only solvent treasury in Europe and an army second to none by virtue of its strength and discipline. At the time of his working as a clerk, however, his diligence was less enthusiastic than expedient; and, at length winning full pardon and reinstatement, complete with a country residence of his own at Rheinsberg, near Berlin, he was able to nurse his cultivated pursuits out of range of the King's eye. Married in 1733, against his inclination, to Elizabeth Christine, daughter of the Duke of Brunswick-Bevern, he filled his little court with congenial company, including painters, writers, and musicians, read and wrote and played the flute to his heart's content and struck up an ardent pen-friendship with Voltaire, the uncrowned king of the progressive intellectual movement known as the Enlightenment.

**Accession to the throne.** On May 31, 1740, Frederick William I died. The new king, who had awaited this event with impatience, was prostrated with grief as much to his own astonishment as to that of his friends. His friends soon had additional cause to be astonished. Like his enemies, they, too, had precipitately hailed the dawn of a regime of dilettantism and laissez-faire, only to find "the young master worse than the old one." This, to be sure, was an exaggeration. While Frederick maintained the status quo as regards the civil and military establishment in general, his first acts as sovereign included the abolition of torture as a means of judicial inquiry, abolition of press censorship, abolition of religious discrimination, and abolition of Frederick William's darling "giant" grenadier guards—composed of men measuring never less than six feet in height—which the old king had

Attempted  
flight

avowed his "one and only vice": an expensive luxury of dubious military value. Exiled savants were recalled and foreign scientists were invited to restock the neglected Academy of Berlin, which had been founded under Frederick's grandfather on the model of the English Royal Society. Housing and employment schemes were launched; numbers of draconic laws were abrogated, and the quality of mercy, conspicuously lacking hitherto, became an express adjunct of justice.

Also, the new king hastened to make his debut in the cosmopolitan republic of letters with the publication, under Voltaire's wing, of a treatise entitled *Antimachiavel*, which, in line with enlightened principles, affirmed a princely ethic founded on virtue, justice, and responsibility. The ideas were not so new as was their being uttered by a reigning monarch, who thereby gained his ambition to qualify as a *Philosophe*.

But that was no longer Frederick's sole or even principal ambition. Fame was what he craved above all things—resounding, comprehensive glory. His opportunity came soon enough, with the death of the Habsburg emperor Charles VI only five months after Frederick's accession. The Emperor left no son, and his daughter Maria Theresa succeeded to the hereditary Habsburg crown lands. All Europe had been waiting for this moment, none more tensely than the Hohenzollern House of Brandenburg-Prussia.

**Foreign policies.** Since 1537 the margrave-electors of Brandenburg had held a legally supported claim to three Silesian duchies, which successive Habsburg rulers of the surrounding Austrian territories had persistently frustrated, though holding out repeated promises to ratify it whenever Brandenburg's political or military assistance was required. It was at once the weakness and the stimulus of Prussia's growth that many of the Brandenburg possessions were scattered, often incontiguously, in Germany, rendering consolidation an imperative need. This, along with acquiring a commensurate prestige, without which real power must remain incomplete, had long been the driving force of Hohenzollern policy. It was part and parcel of Frederick's inheritance.

In his memoirs he made no bones about his private motives for invading Silesia, which he did in the winter of 1740. "I was young, had plenty of money and a large army, and wanted to see my name in the newspapers," he wrote, characteristically unable to repress a quip however damaging to himself or embittering to others. He nonetheless believed in the fundamental legality of his aggression, as unquestioningly as he took it for granted that every major continental power would immediately make inroads on Maria Theresa's heritage.

The Emperor had sought to make provision against his decease without male heirs by means of the Pragmatic Sanction—to obtain guaranteed recognition by the European nations of his daughter's sovereignty. As a woman, Maria Theresa was excluded from candidature to the (elective) imperial office, whose security depended on the military contingents and financial subventions furnished by the autonomous states of the empire. By reason of the prolonged Habsburg tenure of the imperial throne, Austria, though technically only one among those states, had come to rely on such support by the rest. Without it, Austria would now be extremely vulnerable. All the world, therefore, took the Emperor's death as a signal for blackmail and pickings. The Austrian government itself was under no illusions as to the value of the signatures to the Pragmatic Sanction. Frederick, however, was the first off the mark and, hence, the target of international opprobrium.

Having instructed his ambassador to submit Prussian proposals to Vienna that Austria obviously could not accept—*i.e.*, an offer of military alliance plus the Brandenburg electoral vote for Maria Theresa's husband Francis of Lorraine in the forthcoming imperial election, in return for nothing less than the whole province of Silesia—Frederick marched an army of 40,000 into that province and within seven weeks made himself master of it.

The speed of his success owed something to decades of Austrian maladministration and to the oppression of

Protestantism, as well as the strategic elements of surprise and the numerical superiority of over ten Prussian soldiers to one of the Austrian garrison forces. Military resistance was slow to materialize and civil resistance nil, largely because of the liberal and orderly fashion in which the takeover was conducted. The first pitched battle of the counteroffensive, at Mollwitz on April 10, 1741, ended in victory for the Prussians.

Frederick, who had insisted on leading the campaign in person without any previous experience of war, was persuaded by the impact of a devastating Austrian cavalry charge that the day was lost, and he galloped off the field to safety. He did not see the tide turn very shortly after and did not hear the good news for another ten hours. "Let this be a lesson to young warriors, not to despair too soon," he advised the future readers of his memoirs, wherein he closely analyzed the mistakes that had been made and paid proper tribute to "the heroism and skill of those who won the day for me." Among the latter must be counted one he did not mention in the context: an old antagonist of his and bosom friend of Frederick William, Prince Leopold of Anhalt-Dessau. It was "the Old Dessauer" to whom the Prussian army owed its two unique, prime assets: the cadenced march, which had been in disuse since the days of imperial Rome, now brought to an ultimate perfection of instant, uniform mobility; and the iron ramrod, replacing the wooden, which greatly increased firing power.

As soon as his victory became known, Frederick was inundated with congratulations and overtures by virtually every European power, while Maria Theresa, on the eve of her coronation as queen of Hungary, was about to be abandoned by all, with the exception of England, where the news of Mollwitz had arrived a fortnight late. In the upshot, France and Prussia signed a secret treaty of mutual defense in June, and in October Austria and Prussia concluded an equally secret gentleman's agreement to make peace a few weeks hence: Frederick was to keep his conquests and allow the Austrian army to retire unhindered to Moravia.

For, meanwhile, the War of the Austrian Succession had broken out, in which it was the concerted objective of Bavaria, France, and Saxony to dismember the Habsburg crown lands. Their initial progress encouraged Frederick to break his unwritten pact with Austria as quickly as he had thereby violated the signed and sealed pact with the French; and there ensued behind the lines of battle such permutations of shady negotiations all around that at least one party, Frederick, privately recorded his amazement that anyone should ever bother with treaties at all.

Dissensions among the allies were aggravated by Austrian recovery. The elector of Bavaria had been elected the new emperor, but, by the time he was crowned Charles VII, the Franco-Bavarian reverses were so drastic that they made Frederick reconsider his position yet again, especially as the Prussian army in Silesia also was now in some straits. So, after another Prussian victory in May 1742—a victory, this time, under the King's own baton—Austria and Prussia, after all, honoured their secret undertaking of the preceding autumn and concluded a separate peace. In spite of Maria Theresa's particular animosity toward Frederick and Frederick's unabated need to secure his conquests by extending them, it was in the interests of neither to have the other annihilated and thus disrupt the continental balance of power. Moved by the same consideration, England acted as mediator.

The Treaty of Breslau (June 1742) left Frederick in possession of almost the whole of Silesia and his reputation finally in shreds. Even his companions in mutual admiration, the *Philosophes*, who had stuck by him through thick and thin, could not forgive his perfidy when it was France, the spiritual home of the Enlightenment, that he was breaking faith with, and not merely the reactionary power of the Habsburgs. Frederick was stung to self-defense in verse and prose, which led him on by logical stages to try his hand at historiography, an art that had lately come to be regarded as the finest form of literature. His *Histoire de mon temps*, covering the

political events of his lifetime so as to explain his actions rather than proffer excuses, did credit to his truthfulness, objectivity, and style.

Apart from the urgent need to replenish Prussian resources and integrate the Silesian acquisitions, his troubles blew over as before. The storm of moral indignation died down as swiftly as it had risen; the conqueror's aureole outshone the tarnish of treachery. Before long, those who had the best of reasons to distrust the King of Prussia wooed him again. Concurrently, however, a secret coalition formed, of Austria, England, Holland, Sardinia, and Saxony, designed to wrest from Frederick not merely his recent gains but the very holdings of his forbears. Frederick learned of this and again struck first.

Invasion of  
Bohemia

In August 1744 his army, 80,000 strong, entered Bohemia and took Prague, ostensibly to succour the Emperor, whose troops had been routed over and over, unable even to keep his own capital of Munich for him (Frederick quipped that the commander of the Bavarian forces was like a drum: one only heard of him when he was being beaten). In fact, Frederick had concluded yet another secret agreement with the French, who likewise were hard pressed by the resurgent Austrians. The enterprise, known as the Second Silesian War, did not long continue so prosperously for Frederick as it began. On the contrary, by Frederick's assessment, the honours of the campaign lay all with the Austrian field marshal Otto Ferdinand von Traun. Traun all along the line foiled Frederick's now-recognized strategy of forcing confrontation in open positions. Exhausted, without anything to show for their efforts, the Prussians had to withdraw to Silesia and presently face a Saxon army for good measure.

In the event, Frederick could afford to judge generously. It was he who won the war. Just when his fortunes stood at low ebb, a series of three battles in Silesia, in June, September, and December 1745, gained decisive victory for Prussia and for the Prussian King all the renown he could desire. After the Treaty of Dresden, in December 1745, at the age of 33 Frederick was styled "the Great." He was regarded as a hero everywhere except in Austria (though, even there, Maria Theresa's son, the future emperor Joseph II, was to conceive a kind of hero worship for him). If he now concentrated on the works of peace, nobody could say that it was by default.

While, during the next 11 years, his first concern was to practice what he preached by service to the civil state, he also proved himself an eager patron of the arts and of science, as well as exercising to the full his own literary urges. A spate of books and articles, occasional verse, and correspondence issued from his pen, besides the infinite paper work of government, which, even as his father, he refused to delegate. "I'll not attack a cat in future," Frederick had vowed at the end of the war, adding, "unless I am forced." So, concurrently, the army was refurbished, with a view to keeping ahead of imitators. The cavalry required more than that. It had proved no match against the Austrian horse, schooled in a century of war against the Turks. With the aid of two cavalry officers of exceptional dash and brilliance, the deficiency was methodically made good.

The Seven Years' War erupted in the late summer of 1756; as usual, all parties to it claimed that it was forced on them by necessity: Austria because of its vital interest in recapturing Silesia; France and Russia because of the threat inherent in a steady accumulation of power to Prussia; England because of its increasing maritime, mercantile, and colonial collisions with France, which now strongly recommended an Anglo-Prussian alliance—all the more when intelligence leaked out of a secret pact between Austria and France, burying their traditional antagonism, in formidable combination with Russia; and Prussia because the reduction of its territory to the merest nucleus was the object of that alliance, in which Saxony and Sweden joined for a share in the spoils. As ever, Frederick did not scruple to embrace the onus of firing the first shot.

At the head of 70,000 troops he invaded Saxony, leaving smaller contingents on guard over his northern fron-

tier against the Swedes and in Silesia. There had been no leak of his intention. The small Saxon army was unprepared; the large Austrian forces were scattered over Bohemia and Moravia. They were defeated, not without heavy losses on the Prussian side, and on October 15 Saxony capitulated.

But Frederick had miscalculated the pressures and dynamic animating the enemy coalition, which spoiled his chances of another short bout. Notwithstanding his apparent initiative, essentially he was on the defensive, when, as he himself taught, attack was the secret of success in war. The numbers and unexpected determination of the forces arrayed against him allowed them to dictate a strategy that made it virtually impossible to employ his own. The English subsidies and military assistance from Hanover, Brunswick, and Hesse-Kassel still left Prussia bearing the brunt of seven arduous campaigns all over central Europe.

In June 1757 the hitherto unbeaten Prussian army suffered a heavy defeat at Kolín at the hands of the Austrians: a disaster exacerbated by Prussian alarm upon this ominous break in Frederick's run of luck. French troops invaded Hanover, Brunswick, and Hesse. The Duke of Cumberland, the leader of the English army, concluded a pact with the French and retired from the fray, depriving Frederick of some 50,000 troops and leaving him exposed on the western front. Yet the Prussians succeeded in beating back the French, the Austrians, and the Russians the following summer and, although once more defeated by Austrian arms in October 1758, still managed to retain possession of Silesia.

Again and again Frederick recovered from what seemed unredeemable catastrophe—even after the Battle of Kunersdorf in August 1759, the bloodiest engagement of the war and for the Prussians the most crushing. Frederick was brought all but to his knees: "All is lost," he scribbled a message home, which he thought would be his last. "Be sure I shall not survive our ruin." Seeking death, two horses shot under him, he cried out against the bullets that would not hit himself and was with difficulty prevented from planting himself on foot in the path of a troop of enemy cavalry.

The ancient core of the Prussian kingdom, Brandenburg, was overrun: the Russians occupied the capital, Berlin. Nothing but the enemy's frequent tardiness in following up a victory could have saved Frederick—unless, indeed, it was the ensuing French project of an invasion of England and, not least, the ascendancy of English arms over those of France in the transatlantic colonies and at sea. With the recall of William Pitt to the English premiership, the Duke of Cumberland's covenant with the French in Germany was rescinded, the English subsidies to Prussia were renewed on a regular basis, and the struggle to eliminate French rule in America was prosecuted with the utmost energy. All this, coupled with the victory at Minden of Anglo-Hanoverian troops over a superior French army some days before Kunersdorf, helped to dissipate the French impetus and to undermine the unanimity of Frederick's foes. Without the transfusion of English money into his drained exchequer Frederick could hardly have kept up the fight, just as without his talents and tenacity the destiny of North America would have been different.

His genius and the extraordinary confidence that Frederick's personality inspired in his men were proved afresh in 1760 against the Austrians and in 1761 against the French. Once again Europe rang with his fame. In England, where he had never set foot, he was one of the most popular personages of the day. Nevertheless, the conquest of Canada having been accomplished, with parallel successes in India, and Pitt having been expelled from office, the British government intimated that no further aid to Prussia was forthcoming. Frederick's forces had shrunk from 150,000 to 60,000, their efficiency very much diminished through constant heavy losses and the inevitably shortened training period of recruits. But all the combatants were alike debilitated; sooner or later the war must come to an end.

Victories  
of 1760  
and 1761

Seven  
Years'  
War

That it was decided in Prussia's favour was largely due to a fortuitous event. On January 5, 1762, the empress Elizabeth of Russia died, and with her died that implacable, even personal, enmity to Frederick that had maintained Russia's long, costly participation. Elizabeth's successor, Peter III, was one of Frederick's most fervent admirers. Not only did Russia cease hostilities against Prussia but 18,000 Russian soldiers were placed at Frederick's disposal. The Russian gains were handed back to him, and Sweden, having made some headway in the north, had no alternative but to make peace also. This left only Austria and France, both impoverished in revenues and manpower. Although the coup d'état replacing Tsar Peter with his wife, Catherine II, put an end to Russian aid, the Prussians drove the French back across the Rhine, and a general peace was concluded in February 1763.

Prussia was confirmed in its acquisitions of 1740-45, including the repute of invincibility, although without any further gains. Habsburg Austria had lost its grip on the Holy Roman Empire, which itself, moreover, had been exposed as a hollow anachronism, unable to enforce on Frederick the imperial ban that had been solemnly pronounced on him. In name, the empire was to linger until 1806, when it collapsed forever under the onslaught of Napoleon. In effect, the disunited states of Germany had begun to look for leadership to Prussia some 40 years earlier. France had lost the American dominion to England, the only combatant to come out of the war with vast, unchallenged gains overseas. The causes and trends leading to the French Revolution had received a powerful push forward.

Frederick did not live to see the Revolution; nor did he perceive the portents. To him, the institution of monarchy appeared unshakable. By precept and example he succeeded in at once humanizing and depersonalizing it. The state, no longer seen as a dynastic adjunct but as a supreme object in itself, had supreme call on the sovereign and the people alike.

**Domestic policies.** The welfare of the state was the prerequisite to its growth, and growth in the course of nature meant expansion: "For every state, from the smallest to the greatest, the principle of enlargement is the fundamental law of life," Frederick wrote. The idea that the state might exist for the welfare of the individual, though a direct development of the idea of the state's separation from the person of the monarch, never impinged on Frederick's philosophy. At all events the axiom of Louis XIV, "L'état c'est moi," was henceforward superseded by Frederick's axiom of service.

His activities for the remaining 23 years of his life were nothing if not an illustration of this axiom. With the same obstinate vigour that had weathered the war, he set himself to the task of reconstruction. He himself had emerged from the ordeal physically an old man, racked with rheumatism and other afflictions contracted over the years of stress and harsh living conditions. For he had made a point of sharing the discomforts of his soldiers as well as their perils, and ever after he cultivated a shabbiness of attire that more than verged on the slovenly. He, who in his youth had loved silks and sumptuous colours, habitually wore the Prussian uniform he had once dubbed "the shroud." Threadbare blue coat soiled with snuff, haggard and bent, accessible to a point where petitioners would corner him on his own unguarded terrace, the lighted window of his study a familiar landmark far into the night—thus the image of "Old Fritz" impressed itself upon the nation. His silver-handled walking stick and the flute on which he continued to perform until the loss of his teeth stopped him became symbols of a living legend.

Conduct of  
his regime

Frederick pursued the same mercantilistic internal policy as his father and governed by the same central absolutism. The King's cabinet ministers were little more than secretaries. From the highest to the lowliest in the land, everyone was directly answerable to the sovereign; but so, too, might every subject feel free to appeal directly to the sovereign. Frederick's humanity in not a few individual cases was offset by the unchanged brutalities of

army discipline that he had vehemently condemned in Frederick William's time. Conscription continued to be supplemented by the press-gang and outright abduction. The admirable impulse given to husbandry with the systematic introduction of the potato and the sugar beet and to trade and manufacture by similar practical encouragement was offset by stringent crown monopolies and an oppressive excise system which—together with a swarm of petty officials versed in it—Frederick imported from France. This, in particular, impaired his popularity at home, which altogether declined in his later years. While rarely hesitating to overtax his subjects for the greater good of the state, Frederick frowned upon royal interference in civil process. He had long since set up safeguards against this at home, in the shape of the comprehensive Codex Fridericianus and an independent law court, established soon after his accession, to render justice immune to arbitrary pressure from any quarter whatsoever. Admittedly, he was not entirely consistent in respecting this himself; yet it gave him the greatest satisfaction to hear of a subject's invoking the law against the king. Yet, while scoffing at the mystique and trappings of anointed kingship, Frederick took pains to perpetuate a rigid class structure, in which the nobles formed a military upper caste, the burghers were committed to industry and commerce, and the soil-bound peasantry furnished the rank and file of the standing army.

Criticism or lampoons directed against his person touched him not at all; affronts to his royal dignity and aspersions on the army, however, would be visited with sharp reprisals. The celebrated dicta, "In this country everyone shall go to heaven his own way," and "All religions are equal," were by no means fully born out in Frederick's attitude to the Jews, for whom he had small regard, although he availed himself of their services and discountenanced persecution. His love of music and literature did not extend to composers like Mozart or the new wave of specifically German writers among whom was the young Goethe. Mozart he described as a "cater-wauler," Goethe as an imitator of "barbaric" Shakespeare. Taught from childhood by Huguenot émigrés, as were so many noble scions of the time, the language of France was to him the only civilized modern idiom. He spoke broken German and fairly massacred that language in his pithy marginal comments to official documents: all his serious writing was in French. His manifold building projects drew on French models; classical and French literature, French and Italian painting, opera, and chamber music provided the only forms he recognized as art.

Cultural  
interests  
and  
friendships

His friendships with the artists and writers he liked to have around him were somewhat one-sided: the vaunted freedom of speech that prevailed at Sanssouci, his favourite residence, near Potsdam, was mostly reserved for the King himself. The friendship with Voltaire, who spent some time at Frederick's court, turned sour partly from that cause, partly deteriorating from mutual disenchantment and subsequent scurrilities and chicanery. As for Frederick's relations with his wife, these appear to have been purely formal, except, possibly, for a period at the beginning of their marriage. He had no children and appointed a nephew to succeed him.

To the end of his life, he commanded a high degree of respect abroad. The world having finally condoned the seizure of Silesia, the partition of Poland in 1772, by which nearly one third of that politically retarded country was divided between Russia, Austria, and Prussia, was a deferred consequence. Frederick gained at long last the missing territorial link between the eastern Prussian dominions and the lands of Brandenburg. When his kinsman, the Bavarian elector Maximilian Joseph, died in 1777, the emperor Joseph II, Maria Theresa's eldest son, showed that his admiration of Frederick did not exclude ambitions after the Frederician pattern: he promptly attempted to annex Bavaria. The heirs of the elector Palatine, who was the lawful heir of Maximilian Joseph, appealed to Prussia for intervention. Frederick reluctantly complied and marched into Bohemia. Such was the prestige of himself and his army that, without

bloodshed, though not without prolonged manoeuvring, peace was restored in 1779. Austria received a small portion of the Bavarian inheritance and Prussia reimbursed itself for its trouble in the Franconian provinces.

That was the last occasion when Frederick took the field—indeed, the last time in his reign that the Prussian army marched. It was this incident, however, that directed his foreign policy henceforth, culminating the year before his death in the League of Princes, which was formed under Frederick's aegis for the purpose of defending the integrity of the sovereign German states against imperial incursions.

He died on August 17, 1786, following a chill sustained during a troop review in pouring rain. His death was largely unregretted by his subjects. His most unpopular measures—tax farming, the tobacco monopoly, and the duty on coffee, were quickly abolished by his successor. His coffin was placed in the royal vault, where Napoleon paid it a courtesy call and Hitler deposited a golden wreath.

Personal  
life and  
reputation

His precise appearance is uncertain because in maturity Frederick declined to sit for his portrait and refused every request to put up statues or other monuments to him. The famous death mask is believed to have been tampered with by the sculptor entrusted with the casting. Another thing that has been much debated is the sexual aspect of Frederick's character. His one reputed love affair, with a married lady of Küstrin (modern Kostrzyn, Poland), remains a matter for conjecture. He was charged with homosexual practices, notably in relation to Katte and to his later factotum and confidant the valet Fredersdorf. There is no conclusive evidence in any direction.

Few historic reputations have fluctuated more than that of Frederick the Great, thanks to his intimate connection with a Prussian-dominated Germany and depending on that country's fortunes and its role in world affairs.

**BIBLIOGRAPHY.** THOMAS CARLYLE, *The History of Frederick II of Prussia, Called Frederick the Great*, 6 vol. (1858–65), remains the most comprehensive biography in English, though erring somewhat on the side of open hero-worship. Altogether the literature is bedevilled by bias, for and against; but a vast amount of reliable, documented information, especially rich in political detail, is furnished by LEOPOLD VON RANKE, *Friedrich II, König von Preussen* (1847–48); and also by Frederick himself: *Die Werke Friedrichs des Grossen in deutscher Übersetzung* (1913–14; originally *Oeuvres*, 1846–1857). J.D.E. PREUSS, *Friedrich der Grosse, eine Lebensgeschichte*, 4 vol. (1843), copiously fills in the personal background. REINHOLD KOSER, *Geschichte Friedrichs des Grossen*, 4 vol. (1893–1903), adds further data to the diplomatic setting. FRANZ KUGLER's book by the same title (1840), is of interest mainly because of Adolf Menzel's wonderfully convincing illustrations, based on minute research. Useful on the military side are KARL VON CLAUSEWITZ, *Strategische Beleuchtung mehrerer Feldzüge . . .* (1863); B.H. LIDDELL HART, *Great Captains Unveiled* (1927); GORDON A. CRAIG, *The Politics of the Prussian Army, 1640–1945* (1955); and an exhaustive treatment of Frederick's wars, *Die Kriege Friedrichs des Grossen*, 12 vol., issued by the PRUSSIAN GENERAL STAFF (1890–1904). F. MEINECKE, *Die Idee der Staatsraison* (1924); and F.L. CARSTEN, *The Origins of Prussia* (1954), throw light on relevant political philosophy. K. HINRICHS, *Der Kronprinzenprozess* (1936), deals with the trial of Frederick as a deserter; O. HINTZE, *Die Seidenindustrie*, 3 vol. (1892); and S. SKALWEIT, *Die Berliner Wirtschaftskrise von 1763* (1937), with his economic policy. Biographies in English include: P. GAXOTTE, *Frédéric II* (1938; Eng. trans., *Frederick the Great*, 1942); and G.P. GOOCH, *Frederick the Great: The Ruler, the Writer, the Man* (1947). LORD ACTON's essay in *Lectures on Modern History* (1906); and EDITH SIMON, *The Making of Frederick the Great* (1963), are recommended for clarity and balanced judgment; the latter also contains a concise bibliography covering every aspect of the subject.

(E.Si.)

## Frederick Henry, Prince of Orange

A renowned general and skilled politician, Frederick Henry, prince of Orange, was the first of his line to assume, as leader of the United Provinces of the Netherlands (Dutch Republic), a semimonarchical status and thus to determine foreign as well as domestic policies.

Frederick Henry was born at Delft on January 29,

Frederick Henry and his wife, Amalia van Solms, painting by Gerrit van Honthorst (1590–1656). In the Mauritshuis, The Hague, The Netherlands.

By courtesy of the Mauritshuis, The Hague

1584, less than half a year before the murder of his father, William the Silent, the principal leader of the Dutch struggle for independence from Spain.

As a younger son, he was destined by his mother, a daughter of the Huguenot leader Gaspard de Coligny, for a career in her native France; but his half brother, Maurice of Nassau, who had succeeded their father as stadtholder, as well as the States General, insisted that Frederick Henry serve his country. He was accordingly educated at the University of Leiden and made a member of the council of state at the age of 17. He began to take part in most of Maurice's military expeditions and was sent on various foreign missions. During the politico-religious crisis of the years 1617–19, precipitated by a doctrinal conflict within the Reformed, or Calvinist Church, Frederick Henry, like his mother, kept cautiously to the middle of the road.

Until the age of 40, Frederick Henry was reputed to be "too fond of women to tie himself permanently to one of them" but under strong pressure from Maurice, who had no legitimate offspring, and, almost at the latter's deathbed, he married. His wife, a lady-in-waiting to the exiled queen of Bohemia, soon acquired a fair amount of political influence as well as a universal reputation for venality, but she also managed to endow The Hague in the 17th century with some semblance of Baroque court life.

At Maurice's death, in 1625, Frederick Henry became stadtholder in five of the seven United Provinces; a sixth, Groningen, was added in 1640. Even in Friesland, the eventual succession to the office of stadtholder was assigned to Frederick Henry's son, William (born 1626). Although in theory no more than the appointed "servants" of the different assemblies of the estates, provincial and general, the princes of Orange, by establishing hereditary succession to the various stadtholderships, were clearly on their way to acquiring the status of a sovereign. In view of Frederick Henry's anomalous, somewhat awkward position as a minor princeling at the helm of the government of a federation of oligarchic republics, anachronistically flourishing in a world drifting toward absolutism, his ambition was normal.

As a strategist, Frederick Henry proved himself to be the foremost disciple of his brother, Maurice, and the Dutch wars against the Spanish continued to be considered a kind of military academy for young European noblemen. The prince's universally recognized strength lay in capturing fortified "places"; once he was even heard to exclaim: "God deliver us from pitched battles," and every one of his yearly campaigns had the conquest

Stadt-  
holder and  
captain  
general

of some important town or fortress as its aim. Hence, the borderline between the modern kingdoms of Belgium and The Netherlands came to be drawn largely according to Frederick Henry's successes and failures.

By far the most spectacular of these sieges was that of Hertogenbosch, but if the capitulation of this city marked Frederick Henry's proudest moment, it also demonstrated the inherent weakness of his position. Although his contemporaries present the prince as little short of omnipotent in the Dutch Republic, his power was based on the delicate balancing of various elements. To counterbalance the oligarchy in Holland, which contributed over 58 percent to the federal budget, the prince needed the support of the six minor members of the United Provinces and that of the Puritan masses of the country, including those in Holland.

Although not irreligious, Frederick Henry was, like his father, a champion of as far-reaching a religious tolerance as circumstances allowed. In this respect he displayed, paradoxically, a much closer affinity with his political opponents, the Holland oligarchy, than he did with his traditional supporters. Yet as far as policy making was concerned, this affinity was of little avail; for the Hollanders remained stubbornly opposed to a costly warfare, which, moreover, if waged too successfully, threatened to reintegrate the port of Antwerp as a formidable rival for Amsterdam into the political body of the free Netherlands. To make his yearly campaigns politically acceptable absorbed almost more of Frederick Henry's energies than the campaigns themselves. Clever tactician that he was, he managed, however, unlike his brother, Maurice, before and his son, William II, after him, to avoid an open conflict with the assembly of Holland.

Until about 1640, Frederick Henry alone was responsible for the United Provinces' foreign policy. From the dynastic point of view, his activities were crowned by the marriage in 1641 between his heir, William II, and Charles I's eldest daughter, Mary. Consequently, during the English Civil War, the stadtholder sided unconditionally with the King, whereas the Holland oligarchy favoured Parliament.

More important was Frederick Henry's French policy culminating (1635) in the so-called treaty of partition between the two countries and stipulating a partitioning of the southern Netherlands, if conquered by arms from the Spanish. The treaty further provided for the yearly payment of a considerable French subsidy, thus enabling the prince to continue the war in spite of the reluctance of the war-tired assembly of Holland to finance it. But the very first campaign, of the combined French and Dutch armies under Frederick Henry's command, nearly ended in disaster, and, in spite of his conquests of the cities of Breda and Hulst, the alliance never regained its momentum. The trend toward peace with Spain became more and more irresistible, and, largely through the influence of his wife, even Frederick Henry was eventually won over to the peace party. Prematurely aged after long years of suffering from gout, he did not live to see the peace officially concluded in January 1648. He died on March 14, 1647, in his palace at The Hague and was interred with great pomp in the family vault at Delft.

## Frederick William IV of Prussia

Frederick William IV, king of Prussia, a fervent believer in a God-given medieval kingship, had the misfortune to

become ruler of his country at a time of social unrest and increasing demands for German national unity. Yet, though Frederick William was impressionable of character, indecisive in action, and counselled by narrow and inept men, his reign was more ineffectual than calamitous. Prussia's spirit of traditional loyalty to the crown and its deep clan divisions helped to preserve the monarchy.

Frederick William IV, detail from a portrait by Franz Krüger (1797-1857). In Monbijou Palace, Berlin.  
Foto Marburg

Frederick William was born in Berlin on October 15, 1795, the son of the future king Frederick William III and Louisa of Mecklenburg-Strelitz. He was educated by tutors, mainly experienced civil servants. Though he was completely unsoldierlike by nature, his experiences in the German War of Liberation (1813-15) against Napoleon left lasting traces on his political and intellectual development. He became and remained a disciple of the German Romantic movement, with its nostalgia for the Middle Ages. Romanticism appealed to his extremely sensitive dilettante artistic nature. A draftsman and interested in architecture and landscape gardening, he was a patron of Christian Daniel Rauch, a noted sculptor, and Karl Friedrich Schinkel, an architect and city planner. His marriage in 1823 to Elizabeth of Bavaria, a convert to Lutheranism, proved happy; they had no children.

As crown prince, Frederick William developed romantic-conservative convictions that led him to approach even politics as a question of ideas and problems rather than as a matter of hard reality. Conservative philosophers, men of letters, and politicians were among his friends and the men he admired. Even though barely 20, he used his influence to restrict the promised constitution of 1815 to the creation of district and provincial estates, in which the landed aristocracy had an overwhelming majority. For him liberalism meant revolution: a modern constitution was "a scrap of paper" interposed as an intolerable barrier between the patriarchal king by divine right and his people. Though he was no absolutist and had no genuine will to domination, yet, by his romanticizing mystique and his unlimited respect for the alleged "organic growth" of the medieval estates, he stood irreconcilably opposed to the political ideas of the 19th century and to the heritage of the French Revolution. Tensions were not lessened by his genuine personal piety. As for him, cultural homogeneity outweighed political unity, but he was fundamentally opposed to the movement toward a German national state; after Prussia's occupation by Napoleon, he regarded his country's close alignment with Austria as essential. He never contested the Habsburg empire's primacy, which he saw as consecrated by history; for the king of Prussia he claimed only the military dignity of an "arch-general" of the empire.

Frederick William quickly disappointed the great hopes

French  
alliance

Enemy of  
liberalism

aroused by his accession in 1840, for he was by no means willing to fulfill the constitutional aspirations of the Liberals. In 1842 he permitted only "united committees" of the provincial estates; and in 1847, after long delay, he summoned not a popular representative assembly but the United Diet, comprising all the provincial estates, with the right to grant taxes and loans but without the right to meet at regular intervals. This unwieldy body remained his ideal, even though the narrow limits of his concessions immediately produced a conflict (the diet's refusal of the proposed loan for the Berlin-Königsberg railway) and even though this first assembly of all Prussia powerfully increased the people's self-confidence on the eve of the Revolution of 1848.

Revolution  
of 1848

Despite belated attempts to organize a common resistance by the German governments, Frederick William IV was eventually completely overwhelmed by the revolution in March 1848 that had been inspired by the revolution of the preceding month in France. He could neither prevent the street fighting in Berlin by last-minute concessions nor ride the wave; after the withdrawal of the troops to barracks, he masked his submission to the revolution by a processional ride through Berlin under the black and red and golden flag, the symbol of the united Germany, by paying homage to the bodies of the victims of the soldiery, and by his promise that "Prussia is henceforth merged in Germany." Finally he had to convene a Prussian national assembly. Under the influence of his entourage, however, he roused himself to a stubborn resistance: he appointed his uncle, the Count of Brandenburg (a son of Frederick William II's last morganatic marriage), prime minister; removed the assembly from Berlin and then dissolved it; and imposed a constitution the first moderately liberal draft of which was modelled on that of Belgium. These measures restored the leading role to the crown and its instruments, the army and the bureaucracy, firmly supported by the recently formed Conservative party.

When, on April 3, 1849, Frederick William refused the imperial crown offered by the national assembly in Frankfurt am Main—because as a true conservative he would only accept it from the German princes—he destroyed the constitution drafted by that assembly. Under Russian and English pressure, moreover, he had withdrawn Prussian support of the rising in the duchies of Schleswig and Holstein, aimed at overthrowing Danish rule there. Next, however, largely contravening his previous policy, he attempted to establish a German union under Prussian leadership (1849–50)—though this, as a "Little German" federation, should remain allied with a "wider" federation embracing Austria. When Austria challenged this union, the King shrank from war, preferring capitulation at the Punctation of Olmütz convention. Though Prussia had to return to the federal diet at Frankfurt am Main, Prussian leadership of the German customs union, which excluded Austria, remained unchallenged.

In religious affairs Frederick William, in 1841, settled the "Cologne church conflict" on terms very favourable to the Roman Catholics, with whom, largely influenced by his love for the old and picturesque, he had great sympathy; he also furthered the reconstruction of Cologne cathedral. On the other hand, he actively promoted the joint Anglican-Lutheran bishopric of Jerusalem.

Final years

The final years of his reign were a period of reaction. Frederick William, rejecting the bureaucratic absolutism of his prime minister Otto von Manteuffel, worked above all for recasting the constitution of 1848 in a conservative mold. This included the disastrous introduction of three-class suffrage according to income in 1850 instead of universal suffrage, the retention of the monarchical character of army and bureaucracy, the re-establishment of the conservative district assemblies and the provincial diets, and the conversion (1854) of the first chamber into a house of lords entirely dominated by the predominantly aristocratic landowners. He believed this house of lords to be modelled on the English upper house, but in a political testament he implored his successors to refuse to take the oath on the Prussian constitution.

In 1857 a stroke resulted in paralysis. From this time on, with the exception of brief intervals, the King's mind was clouded, and his brother William (afterwards emperor) took on the duties of government, becoming regent in 1858. Frederick William died at Sanssouci Palace in Potsdam on January 2, 1861.

**BIBLIOGRAPHY.** Although there is no definitive biography, E. LEWALTER, *Friedrich Wilhelm IV* (1938), in German, is still indispensable for the study of Frederick.

(Ha.He.)

## Frederick William, the Great Elector

One of the most remarkable absolute monarchs of the 17th century, Frederick William of Brandenburg, known as the Great Elector, was the first of the three great rulers of the Hohenzollern dynasty, who also included King Frederick William I and King Frederick II the Great, of Prussia. He was the founder of the state of Brandenburg-Prussia, which he built from disorganized war-ravaged territories into an integrated state with a centralized administration and an efficient army.

Foto Marburg

The Great Elector, portrait by Adriaan Hanneman (1601–71). In the castle at Dessau, East Germany

Frederick William was born on February 16, 1620, in Cölln (later united with Berlin) on the Spree, the eldest son of the elector George William and Elizabeth Charlotte of the Palatinate, a granddaughter of William the Silent, prince of Orange.

Early  
years

He grew up amid the chaos of the Thirty Years' War, in which Brandenburg suffered particularly heavily, and was forced to spend his childhood years far from the Berlin court in the fortress of Küstrin, where he was educated in the Calvinist faith. His stay in Holland between his 14th and 18th years, the time divided between the University of Leiden and the court of his future father-in-law, Frederick Henry of Orange, at The Hague, left him with lasting impressions. The future elector was, above all, impressed by Holland's imposing maritime and commercial power, as well as by its pioneering achievements in military technology and organization. He retained a marked preference for Dutch architecture and agriculture and a strong desire to open Brandenburg to international commerce and maritime trade.

**Attempts to establish balance of power.** When Frederick William, completely inexperienced in politics, succeeded his father as elector in December 1640, he took over a ravaged land occupied by foreign troops. Under his father's powerful favourite, Graf Adam von Schwarzenberg, Brandenburg had changed sides from the Swedes to the Habsburgs and had thus been drawn into the struggle on both sides. Residing until 1643 not in Brandenburg, the heartland of his domain, but rather in Königsberg (since 1945 Kaliningrad, U.S.S.R.), the capital of the

Creation of  
his army

remote duchy of Prussia, the Elector at first pursued a policy of cautious neutrality in order to escape the pressure of the rival powers. He discharged the Brandenburg troops in the service of the Habsburg emperor and concluded an armistice with Sweden.

He soon recognized, however, that without an army he could never become master in his own house. In 1644, at the beginning of negotiations to conclude the Thirty Years' War, he had already started to organize his own military force. Though his army was small, Brandenburg could not support it without requisitioning funds from the duchy of Cleves, in the west, and from the duchy of Prussia. For the first time Brandenburg's territories, united only by their allegiance to the person of the Elector, were drawn together for a political purpose. The standing army was the first institution used by the increasingly absolutist rulers of Brandenburg to combat the privileges of the estates of the individual territories. It was never entirely disbanded and became the core of the 18th-century Prussian army.

This army was not big enough to allow Frederick William to conduct an independent foreign policy. Moreover, his marriage in 1646 to Louise Henriette of Orange failed to bring the anticipated Dutch support. Lacking the support of friendly great powers at the peace congress of Westphalia in 1648, he did not attain his aim of acquiring all of Pomerania, with the Oder estuary and the important harbour of Stettin (since 1945 Szczecin). He had to be content with eastern Pomerania, the secularized dioceses of Minden and Halberstadt, and the promise of the archbishopric of Magdeburg, all of which were, however, important as links to his western German possessions.

After seven years of peaceful reconstruction, Frederick William saw his political and military ability put to a difficult test with the outbreak of the First Northern War (1655–60). By invading Poland, King Charles X Gustav of Sweden sought to expand the power in the Baltic that Sweden gained by the Peace of Westphalia. Frederick William, as duke of Prussia, owed fealty to the Polish king, but, when offered an alliance by Sweden in return for control over the East Prussian ports, the Elector chose armed neutrality. When Charles Gustav rapidly overran Poland and advanced against East Prussia, Frederick William had to exchange Polish for Swedish suzerainty and provide armed support to Charles X Gustav. In the three-day Battle of Warsaw in July 1656, the untied army of Brandenburg, under the Elector's command, passed its test of fire. To keep the Elector on his side, the Swedish king granted him full sovereignty over the duchy of Prussia. This did not prevent Frederick William, when Sweden's military position deteriorated, from entering into negotiations with Poland, which now renounced suzerainty over East Prussia. With his new allies, Poland and the Habsburg emperor, the Elector drove the Swedes from western Pomerania. French intervention, however, forced Frederick William once again to give up his Pomeranian conquests. Ratified in the Treaty of Oliva in 1660, this renunciation was balanced by confirmation of the Elector's full sovereignty over the duchy of Prussia.

The Elector's ability to gain his ends arose not only from the ease with which he changed sides but also from his success in forcing the provincial estates to support the standing army independently of tax appropriations by the diets. In the second half of his reign, he removed control of taxation and finances from the estates altogether, thereby laying the groundwork for the powerful bureaucracy of later Prussian absolutism, with its standing army, fixed taxes, and an officialdom dependent on the sovereign alone.

The year 1661, in which Louis XIV assumed the reins of government in France, ushered in an era of vast power struggles in Europe. In the conflict erupting between Austria and Spain, on the one side, and France and Sweden, on the other, the Elector hoped to maintain the balance of power by preventing either side from achieving predominance. He sought not a simple policy of neutrality but rather, as he recommended to his successor in his

political testament of 1667, to advance the interests of his house by always joining the weaker power against the stronger. Here lies the basis for the continual shifts in his policy of alliances: "Brandenburg's intermittent fever," which became proverbial in the 17th century.

In 1672, when Louis XIV prepared for the invasion of Holland, Frederick William, still true to his policy of supporting the weaker power, allied himself with the Dutch states-general. Their sole European ally, he concluded an aid agreement with them, fully aware of the danger from France to his territories of Cleves on the lower Rhine. But after the unexpectedly rapid collapse of the Netherlands forced him to make a separate peace with France in 1673, the Elector adopted a policy of neutrality, which he abandoned only when the Holy Roman Empire declared war against France. In July 1674 he joined the alliance of the Habsburg emperor, Spain, and the Netherlands. Frederick William's military expectations were disappointed by the slow progress of the allies on the upper Rhine. He also suffered a more serious personal loss with the death of the gifted young heir to the throne, Karl Emil.

When the Swedes invaded Brandenburg, the Elector turned northward, and under his command his army, in June 1675, scored its first independent victory. In a contemporary folk song Frederick William was for the first time called the "Great Elector." In the same year, allied with the Emperor and with Denmark, he once more began to retrieve the spoils of the Thirty Years' War from the Swedes. For the second time he gained western Pomerania by the sword, only to lose it again under French pressure. Abandoned by his allies, he had to yield the fruits of his victory in the Peace of Saint-Germain-en-Laye in 1679.

**Later policies.** Frederick now decided to gain in alliance with France what he could not obtain by opposing it. In 1679 he concluded a secret pact with France, committing himself, in return for large subsidies, to support French candidates in the next elections for king of Poland and for emperor. The alliance endured as long as the Elector believed that Louis XIV would help him gain possession of western Pomerania. When he realized that this hope was vain, Frederick William changed political partners, for the last time, in 1685. The Elector's disillusionment with Louis XIV coincided with the assumption by William of Orange (later King William III of Great Britain) of his historical role as founder of the Grand Alliance against Louis XIV. The Elector, impressed that William was a prince of Orange and his own nephew, concluded a defense pact with the Netherlands in 1685. He drew still closer to William's side with the issuance of the Edict of Potsdam on November 8, 1685, in which he granted asylum to all Huguenots expelled from France by Louis XIV after the revocation of the Edict of Nantes. Thus, at the end of his life, the Great Elector returned to the political ties of his early years. He did not live to witness the great shift in the European balance of power that his nephew was to effect through his landing in England and his succeeding the Catholic Stuart King James II. But he was aware of William's plans when he died in Potsdam on May 9, 1688, the year of England's Glorious Revolution.

**Assessment.** The Great Elector bequeathed to his son Frederick (after 1701, Frederick I, king of Prussia) a well-organized state, widely respected for its sound finances and efficient army. Frederick William had gone far toward integrating his inherited and acquired territories by establishing national institutions and central administrative bodies. He did, however, endanger the further integration by endowing the children of his second marriage, contracted in 1668 with Dorothea of Holstein-Glücksburg, with semi-autonomous principalities. Many of his ambitious plans were not realized. Just as he was unable to provide a pathway to the Baltic for his country, his attempt to establish a colony on the Guinea coast of Africa remained only an episode in Brandenburg-Prussian history. He was far more successful in the economic field. The systematic colonization of the sparsely populated country, the improvement of trade routes

Last  
political  
shift

Dutch  
alliance

through canal construction, and the establishment and operation of factories after the mercantilist model were begun under Frederick William. In this area, too, the Elector established a tradition that was broadened by his 18th-century successors.

Frederick William adopted the so-called government in council form of monarchical rule, whereby the ruler exercised his power with the aid of his principal council and functioned almost as a president. He always listened to his advisors' opinions but made all important decisions himself.

The political views of all rulers of that period were rooted in religion. For the Great Elector royal power was a God-given duty, a common Christian viewpoint that was given a special character by the Elector's Calvinist beliefs, which bind the ruler, just as the least of his subjects, to prove himself visibly in his daily duties. Here lies the religious basis of Frederick William's ambition for political power and of his immense, yet restrained, energy, which is still evident today in Andreas Schlüter's famous equestrian statue of the Great Elector in Berlin.

**BIBLIOGRAPHY.** HERMAN VON PETERSDORFF, *Der Grosse Kurfürst*, new ed. (1939), the standard biography, now in need of revision; FERDINAND SCHEVILL, *The Great Elector* (1947), the best account in English; CARL HINRICHS, "Der Grosse Kurfürst: 1620-1688," in *Die Grossen Deutschen: Deutsche Biographie*, vol. 1 (1956), a new appraisal of the Elector's personality and statesmanship; FRANCIS LUDWIG CARSTEN, *The Origins of Prussia* (1954), deals with the social and economic problems of the Elector's reign; GERHARD OESTREICH, "Friedrich Wilhelm (Grosser Kurfürst)," in *Neue Deutsche Biographie*, vol. 5 (1961), contains a very complete bibliography.

(S.Sk.)

## Free Churches

A "free church," in the widest use of the term, is to be distinguished from a state-supported church as being self-supporting. Examples of such free churches are the Baptists in Scotland, where the established church is Presbyterian; the Presbyterians in England, where the Anglican Church is established; the Waldensian Church in Italy, where the Roman Catholic Church is established; and the Mission Covenant Church in Sweden, where the established church is Lutheran. The attribute "free" affirms that such a church is free of governmental or external ecclesiastical control. In the narrower sense, the term free churches was first applied collectively to four nonepiscopal Protestant evangelical communions in England that convened the first Free Church Congress in 1892 and combined in 1896 to form the National Council of the Evangelical Free Churches. In taking this step the English Baptists, Congregationalists, Methodists, and Presbyterians were acknowledging an affinity that had existed for three centuries in the case of the three orthodox "dissenting denominations" and for two centuries in the case of the Methodists. First known as Puritans before 1662, then as Nonconformists, and later as Dissenters, they preferred to be known as Free Churches at the end of the 19th century. The reasons for the positive designation were several: among them were the impact of the new unitive impulse of the ecumenical movement; a fear that the high church movement then making rapid strides would threaten the Protestantism of the national church; and a growing sense of the importance of these four denominations in the English-speaking world, especially in the United States, where their numbers and influence were great. Approximately two-fifths of the denominations represented at the opening meeting of the newly inaugurated World Council of Churches at Amsterdam in 1948 belonged to the free church family. In the English-speaking countries, the voluntary principle had won its most signal triumph in the separation of church and state.

**History.** The term free churches may be relatively recent, but the phenomenon is as old as the left wing of the 16th-century Reformation. The original free church is almost certainly to be found among the greatly maligned

and much persecuted Anabaptists, who led a harried life in Europe until they found tolerance and a welcome in Commonwealth England after a respite in libertarian Holland.

The Anabaptists were chiefly interested in restoring the life and order of the New Testament Church, a church that grew by obedience to the power of the Holy Spirit, not through the coercion of the earthly magistrate. They protested against a merely nominal Christianity, believing that the church should consist only of converted Christians, for which reason they baptized all who had been "christened" as infants; hence they were known as "rebaptizers" or "Anabaptists." They often called themselves "disciples" or "brethren." They celebrated the Lord's Supper as a memorial to Christ's reconciling love and as a badge or token of their faith. They also inculcated brotherly humility by keeping the feet-washing ordinance. The autonomous constitution and government of their churches expressed the priesthood of all believers. They were biblical and social radicals, denying the state's right to compel belief, refusing (except in England) to take civil oaths or to take up arms, and opposing usury. Some of them practiced a temporary Christian communism. The negative aspect of religious liberty took the form of separation of church and state, first nationally affirmed in the United States in 1775 but constitutionally guaranteed much earlier through the founders of two of the original American colonies, Roger Williams in Rhode Island and William Penn in Pennsylvania. The positive ground was the "Crown Rights of Christ the Redeemer," which he and not some outsider held in his own church, and the view that compelled religion is the parent of hypocrisy.

The free church represents a third pattern of Christianity: its first predecessor was the medieval Catholicism established in a parochial pattern of uniform Christianity, with the theoretical coordination of the rule of spiritual pope and temporal emperor; the second was the territorial church established at the religious Peace of Augsburg (1555) on the basis that the prince's religion would be the people's faith (*cujus regio ejus religio*). Unorthodoxy in religion was punished by the secular arm in the territorial national churches as vigorously as in medieval international Catholicism. An uncoerced, voluntary Christianity—to be spread by conviction, not by compulsion—was the renewal of a conception that had existed in pre-Constantinian Christianity (to the opening of the 4th century).

The magisterial Reformers believed that behind the national and territorial church organizations the one holy catholic church existed, made up of the predestined saints (Calvin) or the assembly of true believers (Luther). The radical Reformers rejected the doctrine of predestination and the concept of the invisible church (of the elect known only to God) and insisted on creating fellowships of regenerate saints (the Anabaptists and Baptists) or visible saints (the Independents) on the free, voluntary principle. The 16th-century Anabaptists left no continuing congregations in Europe, while the Baptists returned to the Continent only when the Enlightenment had disintegrated Christendom rather than converted Christians to toleration. It was only when they came to England and thence to America that they found the peace and comparative security to flourish and to make their remarkable contribution to Anglo-American democratic life.

**Teachings and practices.** The fundamental principles that have animated the free churches in their government are fivefold. Their primary conception of the Christian community is that it constitutes a "gathered church," consisting of those who have been called out of the world by Christ to minister in the world and who have responded by a conscious dedication of their lives to the only king and head of the church. The free churches claim that Christians are made, not born: they are made by the divine initiative in grace and the human surrender in free faith. Founded upon a covenant relationship, which is an engagement of heart and mind as well as will, these

Anabaptists

Five fundamental principles

churches are utterly opposed to any merely nominal relationship to Christ and his church. Thus they prefer to express the "obedience of faith" in covenants and testimonies rather than to give a merely intellectual assent to historical affirmations and doctrinal tenets enshrined in creeds.

Secondly, their forms of church polity conserve the right of the Holy Spirit to rule in the churches, unfettered by the dictates of ecclesiastical hierarchy or the favour or displeasure of the political ruler. Their Christocracy (rule of Christ) gives every member an equal vote in determining the policy of the church as it seeks to perform the will of Christ in the community.

Thirdly, they witness to the priesthood of all believers and the apostolate of the laity. By this principle they declare positively that each church member is a witness to the Christian faith, and negatively they dissent from a double standard of Christian life (first-class celibate and second-class noncelibate) and all sacerdotalism and triumphalism. Free churchmen claim that their view of the church is the true middle way between an Ultramontanism that claims too much for the church and an Erastianism that claims too much for the state. Their assertion of the priesthood of all believers is the secret of their contribution to democracy, by transference from the religious to the political arena, and the secret of their success in evangelism, by the employment of lay preachers.

In the fourth place, it was the 17th-century amalgam of English Calvinism—in its Presbyterian and Independent forms—and Anabaptism that produced the free church sense of the primacy of the Gospel over the church and of revelation over its institutional expressions and that has resulted in such flexibility as is rarely seen in Catholic structures of organization. As P.T. Forsyth, a Scottish Congregationalist, has written in *Faith, Freedom, and the Future*:

Upon English soil alone were the two great movements of the Reformation age adjusted and consummated—Reformers and Anabaptists; the Evangelical and the Libertarian; the Word and the Spirit; Fixity and Freedom; Faith and Inspiration; Reformation and Renovation; and it was in Independency that the most fruitful union took place.

In the fifth place, it is significant that Independency, the assertion and expression of the autonomy of the local church, unites Congregationalists and Baptists as well as several other denominations that are their imitators. This is authentic grass-roots religion. It provides the simplest kind of organization and one that survives persecution well.

**Contributions to religion and life.** Apart from their insistence upon spiritual freedom, the chief contributions of the free churches have been in the areas of worship, missions, and public life.

#### Worship

In worship they have pioneered by providing the "free prayers" of their ministers as an alternative to the set forms of a stated liturgy as well as by producing metrical psalmody and hymnody. The first national handbook for worship that the English Independents and the Scottish and English Presbyterians produced in conjunction during the days of the Commonwealth was the Westminster Assembly's *Directory for the Publick Worship of God . . . in the Three Kingdoms of Scotland, England, and Ireland* (1645). This handbook determined the character of the worship of the free churches for three centuries throughout the English-speaking world. No words were prescribed for prayers but only "the general Heads, the Sense and Scope of the Prayers . . ." This brought a new freedom and flexibility in worship.

The free churches have also pioneered in the writing of hymns in the English language. The first hymnodist in England reputedly was the Baptist minister Benjamin Keach, though his Christian lyrics were rather prosaic. The great transition from the mere recasting of psalms to the composing of Christian hymns was made by the Congregationalist minister Isaac Watts. He and Charles Wesley, the Methodist, produced some of the greatest hymns in the English language. Their lyricism, freshness, sincerity, and, above all, their celebration of the mighty acts of

God in Christ has made them the sung confessions of faith of the free churches of England and beyond.

The members of the free churches have always held the highest opinion of preaching. Free church sermons have been characterized by biblical fidelity, by spiritual and psychological penetration, and by passionate urgency. Among the great free church preachers have been Thomas Goodwin in the 17th century; John Wesley and Jonathan Edwards in the 18th century; C.H. Spurgeon, R.W. Dale, Joseph Parker, and John Clifford in the 19th century; and Leslie Weatherhead in the 20th century.

In general, free church worship is marked by evangelical obedience, simplicity, flexibility to suit different persons and conditions, and spiritual fervour.

The spiritual fervour of the free churches, along with Pietism, promoted the modern missionary movement in Protestantism. The Baptist cobbler William Carey, whose watchword was "Expect great things from God and attempt great things for God," contributed to the founding of the Baptist Missionary Society in 1792, when Napoleon was threatening to invade England. Three years later the London Missionary Society was formed with the help of Congregationalists (in the majority), Presbyterians, Wesleyan Methodists, and some evangelical Anglicans. This pioneer ecumenical venture was founded to allow missionaries to set up whatever form of church government (episcopal, connectional, or independent) seemed most suitable to them. The most famous free church missionary was David Livingstone (1813–73) of the London Missionary Society, whose name is forever associated with Africa.

In public life, the discussion and self-rule (at the local level) of the autonomous free churches have promoted the development of democracy in the English-speaking nations. Perhaps of even greater significance has been the attempt of the free churches to mold public life according to the ethical imperatives of the Gospel, a concern that neither Erastian nor pietistic religious communities have shared to the same extent. The free churches have played a most significant role in the creation of a public opinion that demanded the extension of the franchise, the improvement of prison conditions, the provision of universal national education, and the ending of human slavery, whether that of Africans through the slave trade or that of "these young Africans of our own growth" as Charles Lamb called the child slaves exploited in the English factories. The free churches witnessed powerfully to the theocratic impulse, so powerfully that "the Non-conformist conscience" was recognized as a significant political phenomenon.

#### BIBLIOGRAPHY

*History:* F.H. LITTELL, *The Free Church* (1957), an analysis of the concept of liberty underlying the free church view and of its aim to reconstitute the New Testament Church, and *The Origins of Sectarian Protestantism* (1964), a useful account of the Anabaptists in Europe and their ecclesiology; G.H. WILLIAMS, *The Radical Reformation* (1962), a superb classification and account of the major forms of radical religious protest in 16th-century Europe; P.T. FORSYTH, *Faith, Freedom, and the Future* (1912), an analysis of the distinctive contribution of the Calvinists and Anabaptists to Independency in 17th-century England; E.A. PAYNE, *Free Church Tradition in the Life of England* (1944), a good brief account of its subject, although modern thought and history are more fully covered in J.W. GRANT, *Free Churchmanship in England, 1870–1940* (1955); E.K.H. JORDAN, *Free Church Unity: History of the Free Church Council Movement, 1896–1941* (1956), an account of the modern attempt of the free churches to federate and present a common witness.

*Teachings and practice:* Two modern accounts are H. TOWNSEND, *Claims of the Free Churches* (1949), interesting though apologetical in outlook; and E.A. PAYNE, *Free Churches, Unrepentant and Repentant* (1965), an evaluation of the contemporary free church witness and its roots, both sympathetically and critically; C.P. DRIVER, *A Future for the Free Churches?* (1962), an important critique by a free churchman.

*Contributions:* H. DAVIES, *The English Free Churches*, 2nd ed. (1963), a short history written to emphasize the positive contributions of the free churches and, *Worship of the En-*

glish Puritans (1948), the fullest account of the origins and early development of free church worship; G.P. GOOCH, *English Democratic Ideas in the Seventeenth Century*, 2nd ed. (1927); A.D. LINDSAY, *Essentials of Democracy* (1929); and R.G. COWHERD, *Politics of English Dissent* (1956), three books concerned with the contribution of the free churches to English political life, the first two with the 17th and the third with the 19th century.

(H.M.D.)

## Frege, Gottlob

Friedrich Ludwig Gottlob Frege, a German mathematician and philosopher, was the founder of modern mathematical logic. Working on the borderline between philosophy and mathematics—viz., in the philosophy of mathematics and mathematical logic (in which no intellectual precedents existed)—Frege discovered, on his own, the fundamental ideas that have made possible the whole modern development of logic and thereby invented an entire discipline. Although he confined his philosophical work to the above two areas, it has proved to be of revolutionary importance for contemporary philosophy in general; for a long time, however, his ideas were transmitted principally through the works of others, such as the Italian logician Giuseppe Peano and influential philosophers such as Bertrand Russell, coauthor of the classic *Principia Mathematica* (1910–13), and Ludwig Wittgenstein, the dominant figure in the schools of logical positivism and of linguistic analysis. Recognition of Frege's importance, however, was delayed until long after his death.

Gottlob Frege.

Back-  
ground,  
education,  
and  
vocation

**Early life.** Frege was born on November 8, 1848, at Wismar, where his father, Alexander Frege, was principal of a girls' high school. His mother, Auguste Frege, née Bialoblotzky, who was perhaps of Polish origin, outlived her husband, who died in 1866. Frege entered the University of Jena in 1869, where he studied for two years, and then went to the University of Göttingen for a further two—in mathematics, physics, chemistry, and philosophy. Frege spent the whole of his working life as a teacher of mathematics at Jena: he became a *Privatdozent* in May 1871, was given an *ausserordentlicher* (special or personal) professorship in July 1879, and became statutory professor of mathematics in May 1896. He lectured in all branches of mathematics (though his mathematical publications outside the field of logic are extremely few) and also on his own logical system. A great many of his publications, however, were expressly philosophical in character: he himself once said, "Every good mathematician is at least half a philosopher, and every good philosopher at least half a mathematician." He kept aloof from his students and even more aloof from his colleagues.

Though Frege was married, his wife died during World War I, leaving him no children of his own. There was an adopted son Alfred, however, who became an engineer.

Frege was, in religion, a liberal Lutheran and, in politics, a reactionary. He had a great love for the monarchy and for the royal house of Mecklenburg, and during World War I he developed an intense hatred of socialism and of democracy, to which he came to ascribe the loss of the war and the shame of the Treaty of Versailles. A diary kept at the end of his life reveals, as well, a loathing of the French and of Catholics and an anti-Semitism extending to a belief that the Jews must be expelled from Germany.

Frege had a vivid awareness of his own genius and a belief that it would one day be recognized; but he became increasingly embittered at the failure of scholars to recognize it during his lifetime. He delighted in controversy and polemic; but the originality of his own work, the almost total independence of his own ideas from other influences, past or present, was quite exceptional and, indeed, astonishing.

In 1879 Frege published his *Begriffsschrift* ("Concept-script"), in which, for the first time, a system of mathematical logic in the modern sense was presented. No one at the time, however—philosopher or mathematician—comprehended clearly what Frege had done, and when, some decades later, the subject began to get under way, his ideas reached others mostly as filtered through the minds of other men, such as Peano; in his lifetime there were very few—one was Bertrand Russell—to give Frege the credit due to him. He was not yet too downcast by the failure of the learned world to appreciate the *Begriffsschrift*, which, after all, discourages the reader by the use of a complex and unfamiliar symbolism to express unfamiliar ideas. He resolved, however, to compose his next book without the use of any symbols at all.

There followed a period of intensive work on the philosophy of logic and of mathematics, embodied initially in his first book, *Die Grundlagen der Arithmetik* (1884; Eng. trans., *The Foundations of Arithmetic*, 2nd rev. ed., 1953). The *Grundlagen* was a work that must on any count stand as a masterpiece of philosophical writing. The only review that the book received, however, was a devastatingly hostile one by Georg Cantor, the mathematician whose ideas were the closest to Frege's, who had not bothered to understand Frege's book before subjecting it to totally unmerited scorn.

Wounded by the reception of his second book, Frege nevertheless devoted the next decade to producing a series of brilliant philosophical articles in which he elaborated his philosophy of logic. These articles contain many deep insights, although, as Frege systematized his theories, there appeared a certain hardening into a kind of scholasticism. There followed a return to the philosophy of mathematics with the first volume of *Grundgesetze der Arithmetik* (1893; partial Eng. trans., *Basic Laws of Arithmetic*, 1964), in which Frege presented, in a modified version of the symbolic system of the *Begriffsschrift*, a rigorous development of the theory of *Grundlagen*. This, too, received only a single review (by Peano). The neglect of what was to have been his *chef d'oeuvre* finally embittered Frege, who had complained, in the preface, of the apparent ignorance of his work on the part of writers working in allied fields. The resulting bitterness shows in the style of Frege's controversial writing. Seldom has criticism of previous writers been more deadly than in his *Grundlagen*; but it is expressed with a lightness of touch and is never unfair. In volume 2 of the *Grundgesetze* (1903), however, the attacks became heavy-handed and abusive—a means of getting back at the world that had ignored him.

**Later life.** A worse disaster than neglect, however, was in store for him. While volume 2 of the *Grundgesetze* was at the printer's, he received on June 16, 1902, a letter from one of the few contemporaries who had read and admired his works—Bertrand Russell. The latter pointed out, modestly but correctly, the possibility of deriving a contradiction in Frege's logical system—the celebrated Russell paradox. The two exchanged many letters;

First  
publication

Failure of  
critics to  
understand  
his work

and, before the book was published, Frege had devised a modification of one of his axioms intended to restore consistency to the system. This he explained in an appendix to the book. After Frege's death, it would be shown by a Polish logician, Stanisław Leśniewski, that Frege's modified axiom still leads to contradiction. Probably Frege never discovered this. Even a brief inspection, however, of the proofs of the theorems in volume 1 would have revealed that several crucial proofs would no longer go through; and this Frege must have found out.

In any case, 1903 effectively marks the end of Frege's productive life. He never published the projected third volume of the *Grundgesetze*, and he took no part in the development of the subject, mathematical logic, that he had founded, though it had progressed considerably by the time of his death. He published a few polemical pieces; but, with the exception of three essays in the philosophy of logic produced after the end of the war, he did no further creative work. In 1912 he declined, in terms expressing deep depression, an invitation by Russell to address a mathematical congress in Cambridge.

At the very end of Frege's life, he again started to work on the philosophy of mathematics, having arrived at the conclusion that one of the fundamental bases of his earlier work—the attempt to found arithmetic on logic—had been mistaken; but the work did not progress very far and was not published.

Up to an advanced age, Frege hiked every summer in Mecklenburg, his native region. He finally retired during World War I and went to live in Bad Kleinen, in Mecklenburg, where he died on July 26, 1925.

**Assessment.** Frege's work represents the beginning of modern logic because of his invention of the notation of quantifiers and variables. (In natural language, generality is represented by inserting an expression like "everything" or "something" in the argument-place of the predicate; in the notation used in logic since Frege, the argument-place is filled by a variable letter, say  $x$ , and the resulting expression prefixed by a quantifier, "For every  $x$ " or "For some  $x$ ," said to "bind" that variable.) By means of this notation he solved the problem that had baffled the logicians of the Middle Ages and prevented the further advance of logic ever since, viz., the analysis of sentences involving multiple generality. In him there also appeared the first clear separation between the formal characterization of logical laws and their semantic justification. His philosophical work is of an importance far more general than the area to which he principally applied it, the philosophy of mathematics: he initiated a revolution, in fact, as profound as that of René Descartes in the 17th century. Whereas Descartes had made epistemology the starting point for all philosophy, however, Frege gave this place to the theory of meaning or the philosophy of language. His work has been influential because he made the restricted part of philosophy in which he worked basic to all the rest. The effect was imparted in the first place, however, through the work of others, particularly that of Wittgenstein, who visited him in 1914 and who revered him. But, since John Austin's translation of the *Grundlagen* into English in 1950, the direct influence of Frege's writing among English-speaking philosophers has been very great. No one supposes that Frege said the last word on any topic; but there is scarcely a live question in contemporary philosophy of language for whose examination Frege's views do not form at least the best starting point.

#### BIBLIOGRAPHY

**Works:** The principal English translations of Frege's works are: J.L. AUSTIN (trans.), *The Foundations of Arithmetic: A Logico-Mathematical Enquiry into the Concept of Number*, 2nd ed. rev. (1959), a two language version; PETER GEACH and MAX BLACK (eds.), *Translations from the Philosophical Writings of Gottlob Frege*, 2nd ed. (1960); MONTGOMERY FURTH (ed. and trans.), *The Basic Laws of Arithmetic* (1964); J. VAN HEIJENOORT (ed. and trans.), "Begriffsschrift," in *From Frege to Gödel* (1967); and A. and M. QUINTON (trans.), "The Thought," in PETER F. STRAWSON (ed.), *Philosophical Logic* (1967). The German texts of most of Frege's works, including the *Grundgesetze*, are now, for the most part, reprinted and are listed together with a few other English translations in the bibliographies of the following two books: H. HERMES, F.

KAMBARTEL, and F. KAULBACH (eds.), *Nachgelassene Schriften* (1969), a reprint of all Frege's surviving posthumous manuscripts other than letters; and G. GABRIEL (ed.), *Schriften zur Logik und Sprachphilosophie* (1971), a selection from the manuscripts.

**Critical sources:** E.D. KLEMKE (ed.), *Essays on Frege* (1968), contains most of the recent critical work on Frege of serious interest. See also LUDWIG WITTGENSTEIN, *Tractatus Logico-philosophicus* (1922; Eng. trans., 1961) and *Philosophische Untersuchungen* (written 1936–49; Eng. trans., *Philosophical Investigations*, 1953); BERTRAND RUSSELL, "On Denoting," *Mind*, 14:479–493 (1905, reprinted in *Logic and Knowledge*, ed. by R.C. MARSH, 1956); MICHAEL DUMMETT, "Frege, Gottlob," *Encyclopedia of Philosophy*, vol. 3 (1967); and the essay on Frege in G.E.M. ANSCOMBE and PETER GEACH, *Three Philosophers* (1961).

## French Guiana

French Guiana (La Guyane Française) lies on the northeast coast of South America to the north of the Equator. Bounded by Surinam (Netherlands Guiana) to the west and by Brazil to the south and east, it has an area of 34,749 square miles (90,000 square kilometres) and at the 1967 census had a population of 44,392. As a French overseas *département* (administrative district), its economic and political status differs little, legally, from that of a *département* in metropolitan France. French Guiana forms an integral part of the French Republic, forms part of the European Common Market, and is represented in the French Parliament by a senator and a deputy. The capital is Cayenne (population about 20,000).

With a territory about the size of Austria, French Guiana remains underpopulated and underdeveloped. It has a population density of only about one person per square mile. Although its reputation has improved since the notorious penal colony, associated with the name of Devil's Island (Île du Diable), was closed in 1945, the territory has experienced few other changes since that time. What roads exist are found only in the coastal region, and communication with the largely uninhabited interior is by river transport. Despite a little mining, fishing, and lumbering, French Guiana still remains economically dependent upon France.

**The landscape.** Geologically, the rock underlying French Guiana forms part of the Guiana Highlands, which is a crystalline massif (a large elevated block of rock) to the north of the Amazon Basin dating from the Precambrian Period (from about 4,600,000,000 to about 570,000,000 years ago). French Guiana's many rivers, most of which flow generally northeastward to the sea, have greatly eroded the rocky massif, so that no mountain ranges worthy of the name remain. Along the watershed that forms the southern frontier with Brazil, some peaks rise to about 2,300 feet (700 metres), with one peak rising to about 2,600 feet (800 metres) a little to the north. Parts of the coastal plain, which is formed of alluvium deposits, reach heights of about 650 feet (200 metres). The underlying Precambrian rock nevertheless crops out on the beaches of Cayenne and also forms the Îles du Salut, consisting of the islets of Royale, Saint-Joseph, and the Île du Diable (Devil's Island), all of which lie offshore in the vicinity of Kourou. To the southeast of Cayenne, recent marine alluvial deposits have formed a swampy coastal plain, constituting a region dominated by mangroves and grasses. Similar swampy patches occur to the west of Cayenne, but most of the plain here consists of older alluvial deposits, which form a savanna (grassy parkland) region. The remainder of the territory is covered with dense tropical evergreen forest, the character of which varies according to the type of soil and the amount of water.

From east to west, the main rivers are the Oyapock (with its tributaries the Yaroupi and Camopi); the Approuague; the Orapu; the Comté; the Kourou; the Sinnamary, joined by the Courcibo; the Iracoubo; the Mana; and the Maroni, which in its lower reaches forms the border with Surinam and into which flow the Tampoc, Inini, and Abounamy, all from French Guiana territory.

**Climate.** French Guiana is situated between 2° and 6° N, so that the climate is characterized by high tem-

Signifi-  
cance of  
his work

Forest  
areas

peratures, with monthly averages at Cayenne varying between 77° to 80° F (25° to 26° C). Rainfall is heavy from December to July; at Cayenne the yearly average is about 150 inches and may surpass 157 inches in places a little further southeast. In the northeast, rainfall is less plentiful, amounting to 98 inches a year, but it is more evenly distributed. The northeast trade winds blow constantly inland from the sea. Storms are rare and there are no hurricanes.

**Vegetation and animal life.** The vegetation is primarily tropical rain forest, which covers almost 90 percent of the land surface. The trees are almost all hardwood species. Few species of the larger wild animals are to be encountered, although among them are the tapir (a hoofed animal of the rhinoceros order), the caiman (related to the alligator), and the ocelot (a spotted leopard-like cat). Among the more exotic animals are the sloth, the great anteater, and the armadillo. There are many kinds of birds, fish, snakes, rodents, and insects. Flocks of parrots and several kinds of monkeys are common.

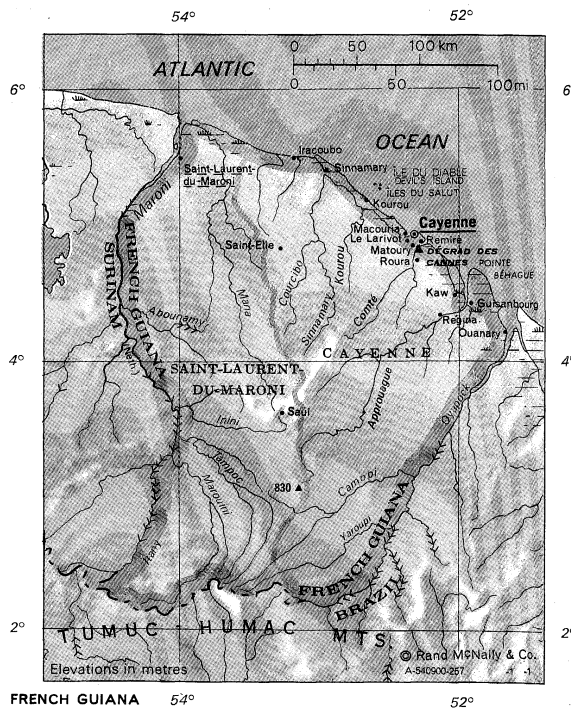

**The landscape under human settlement.** Rural settlements are divided into *communes* (the smallest of French territorial divisions), the most important of which are

supplied with running water and electricity. Most houses are of wood and are usually covered with corrugated iron roofs. Each house usually has a garden attached in which coconut, mango, lemon, and orange trees are grown, as well as vegetables and spices, such as pimento. Poultry are also raised. Crops are usually grown by shifting methods of cultivation at some distance from the settlements; agriculturists often live near their holdings or else live there temporarily in small shelters called *carbets*. Negroes live in African-style villages composed of wooden cabins, which are often artistically decorated. Indians, who are few in number, form small groups located on the upper reaches of rivers or in the northeastern coastal region; they live in *carbets* without walls, and sleep in hammocks.

In Cayenne, the capital, wooden buildings are slowly giving way to modern houses, although the past still predominates. The town is well laid out and has now spread beyond its original boundaries; new districts are being built on the outskirts. Traffic is increasing and stores carry on a thriving trade. A modern town was recently established at Kourou, northwest of Cayenne, near the proving ground at the Guianan Space Centre which was opened in 1966.

The Kourou space centre

**History.** Vicente Yáñez Pinzón, an associate of Christopher Columbus, explored the Guianan coast in 1500. He was followed by a host of adventurers seeking the mythical El Dorado (City of Gold) that was believed to be located in the region. Financed by Henry IV of France, a French nobleman named La Touche de la Ravardière chose the site of Cayenne in 1604; the town itself was founded by a company of merchants from Rouen in 1637. The first French attempts at colonization failed. The Dutch established themselves at Cayenne but were evicted by the French in 1664. The Guiana settlement was then sacked by the English in 1667 and by the Dutch in 1676. A frontier dispute between the French and the Portuguese appeared to have been settled in 1700 when the Portuguese accepted the Amazon River as the southeastern boundary of the settlement; but in 1713, under the terms of the Treaty of Utrecht, the frontier was moved 37 miles (60 kilometres) to the north. In the 50 years that followed, French Guiana was administered by a series of governors of differing capacities and grew slowly in both population and prosperity. Upheavals occurred, however, such as the expulsion of the Jesuits in 1762, accompanied by the dispersal of 10,000 Amerinds associated with the Jesuit missions. The Kourou expedition (1763 to 1765) was an abortive attempt at colonization; due to poor planning and tropical disease, about 14,000 people, many recruited in Europe, died. Later, from 1796 to 1799, many people were deported from France to Guiana, a large number of whom died. Under governors such as Pierre Victor Malouet (governor from 1776–78), however, the colony again grew prosperous. The French Revolution had relatively little effect; after slavery was abolished in 1794, a kind of forced labour was introduced until the re-establishment of slavery once more in 1802. Throughout the period from 1794 to 1805 political deportees were sent from France to Guiana, which was nicknamed the "dry guillotine" because of the heavy death toll that ensued among the deportees. In 1809 the colony was seized by the Portuguese but was restored to France in 1817. In the years that followed, a degree of prosperity ensued, and the interior of the country was explored. From 1827 to 1846, Mother Anne-Marie Javouhey, superior of the community of Saint-Joseph de Cluny, organized a flourishing colony for freed slaves at Mana. The final abolition of slavery in 1848 brought ruin to the plantations. Several different immigrant groups were introduced to provide labour, but only the Asian Indians were at all effective. The situation worsened when gold was discovered in 1855, after which labour was lured away from agriculture to the mines, while an influx of a variegated population of adventurers also occurred. In 1852 the first of several convict settlements was established at Saint-Laurent-du-Maroni; that on Devil's Island was to become the most notorious, although it was the least important of the prisons. Although

the European convicts proved unable to work in the tropical climate and died quickly, the penal colonies were continued for over 90 years, thus bringing French Guiana into disrepute. The penal system was not abolished until 1945.

The inhabitants of French Guiana have had full French citizenship and the right to vote since 1848 and representation in the French Parliament since 1870. They rallied to France in the wars of 1870 and 1914, and in World War II joined the Free French cause in 1943. The territory became a French *département* in 1946.

**Peoples and population.** Out of the total population of about 44,000 at the 1967 census, about 36,000 lived in Cayenne or its vicinity. About 25 percent of the population consists of Europeans. The majority of the population is, however, Creole, although there are some Negroes, Amerinds, and immigrant minorities. The Creoles stem from the continual ethnic and social intermixture of the groups that entered the country from Europe, Asia, and Africa, as well as from other parts of South America. Following a European style of life, they speak an Antillean Creole dialect, as well as French.

Some of the Indians and Negroes live as Europeans, but most follow their traditional patterns of living. All are French citizens with the right to vote. The "Negroes of the Woods," as they are called, who are the descendants of escaped slaves, live on both banks of the frontier rivers, particularly the Maroni River; they form a community of about 4,000, living under either French or Dutch protection. While they have preserved an African tribal mode of life, their language has absorbed English, French, Spanish, and Dutch influences.

The Amerinds, who are the original inhabitants of Guiana, number scarcely more than 1,000, as compared with 15,000 at the end of the 17th century. They are divided into the Galibi, Arawak, and Palicur (Palikour) tribes on the coast, and the Wayana, Oyampi, and Emerillon tribes in the hinterland. The coastal groups participate in the cash economy to some extent, while those in the hinterland live by hunting, fishing, and shifting agriculture; their numbers are increasing slowly.

Among other minorities, ethnically separate communities are formed by the metropolitan French (most of whom remain only a few years), the Lebanese, and the Chinese, both of whom arrived in the 19th century under Catholic auspices. There is also a small Indonesian community, which came from Surinam in 1952. Religious affiliations are varied, but Catholicism, rather than Protestantism, predominates. The Negroes and Amerinds have preserved their traditional religions, as also have the Chinese and Indonesians. The population as a whole is increasing.

Source: Official government figures.

**Economy.** French Guiana has an artificial economy, sustained by aid from France. Agriculture is far from meeting the demand for food, which has to be increasingly imported. There is little stock raising. Fisheries, however, are able not only to meet local demand but also produce enough for export. Two shrimp canning and freezing factories, supplied by 200 trawlers, supply the American market. Some shrimps are also exported to France. Forestry, which has a considerable potential, has encountered some difficulties. Some gold, obtained by panning, is exported. The quantity varies from year to year; in 1969, for example, it represented only 3 percent of the value of all exports. There are prospects for exploiting bauxite deposits at Kaw, which amount to 50,-

000,000 tons. The fact that economic and social legislation requires that salaries match those paid in metropolitan France has hindered further economic development, for which prospects are not bright.

**Transport.** A road in the coastal region links Cayenne with Saint-Laurent-du-Maroni; from Saint-Laurent-du-Maroni one may cross the Maroni River by ferry to Surinam. There are no other major roads, although one is being built to link Cayenne to the Brazilian frontier. Access to the hinterland is by river or by air. Rivers are easily navigable for the first 10 or 15 miles, after which rapids are encountered. A private air service maintains seven airports for domestic flights. From the international airport at Rochambeau, near Cayenne, regular flights leave for France (via Martinique and Guadeloupe) and for Brazil. There is a port at Cayenne and landing places at Larivot on the Cayenne River, Kourou, and Saint-Laurent-du-Maroni. A port to accommodate larger ships is under construction at Dégad des Cannes on the Mahury estuary. Shipping arriving in French Guiana consists almost entirely of cargo vessels.

**Administration and social services.** As a French overseas *département*, French Guiana is administered by a prefect and has an elected council-general of 16 members. It is also represented in the French Parliament through one deputy each in the National Assembly and Senate. Education, public health, and social security services are patterned on those provided in France. A number of students travel to French institutions in the Caribbean, or to France itself, for further education; many do not return. Radio and television programs are broadcast in French and Creole; cinemas, libraries, museums, and tropical research institutes, including the Institut Pasteur, are in Cayenne. Traditional culture has been preserved by the Amerinds and Negroes. Creole cultural manifestations include carnivals, dancing, and music, but Creole culture is slowly fading.

**Prospects for the future.** Prospects for future development are at best uncertain. It had been hoped that with the establishment of the Guianan Space Centre proving ground, and the associated establishment of a new town at Kourou, there might be some acceleration of local economic development; there is little sign that this has occurred. It appears likely that it will be many years before French Guiana begins to develop economically, nor is it as yet possible to see what form this development will assume.

## French Polynesia

French Polynesia comprises about 130 islands with a total land area of some 1,500 square miles (4,000 square kilometres) scattered over an area of the south central Pacific between latitudes 7° to 27° S and longitudes 134° to 155° W. The islands form an overseas territory of France. Their population in 1971 was approaching 120,000.

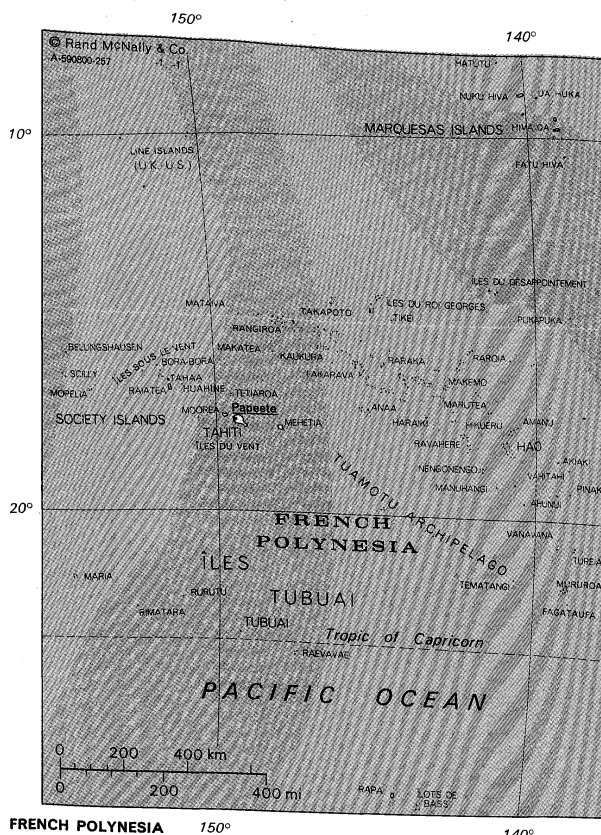

(H.La./J.Fa./C.R.)

**History.** European discovery of the islands of French Polynesia was gradual. The southern Marquesas Islands; were discovered in 1595 by Álvaro de Mendaña de Neira; his successor, Pedro de Quiros, in 1606 discovered some of the Tuamotus. The Dutch explorer Jacob Roggeveen in 1722 discovered Makatea, Bora-Bora, and Maupiti. Capt. Samuel Wallis in 1767 discovered Tahiti, Moorea, and Tubuai-Manu. The Society Islands were named after the Royal Society, which sponsored the expedition under Capt. James Cook that observed from Tahiti in 1769 the transit of the planet Venus. In that year Cook discovered the Huahine islands, Raiatea, Tahaa, and also Rurutu in the Îles Tubuai; Tubuai itself was discovered on Cook's last voyage (1777). Rapa was discovered by George Vancouver in 1791, and in the same year Capt. Joseph Ingraham of the U.S. trading vessel "Hope" traversed the Marquesas Islands and discovered their northern group. The Îles Gambier were discovered in 1797 by Capt. James Wilson of the British missionary ship "Duff."

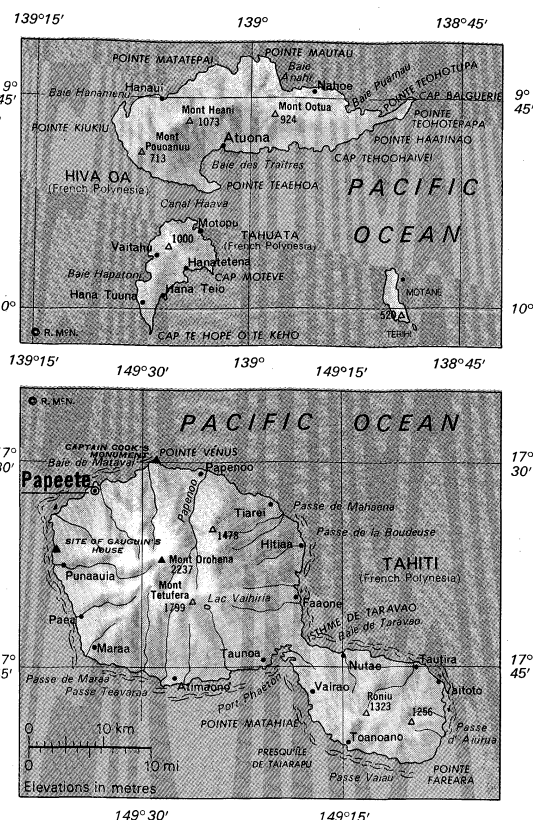

Lack of roads

A predominantly Creole population

The "Negroes of the Woods"

FRENCH POLYNESIA

The history of the Society Island groups is virtually that of Tahiti, which was made a French protectorate in 1842 and a colony in 1880. French missionaries went to the Gambier group in 1834, and in 1844 a French protectorate was proclaimed, followed by annexation in 1881. The Îles Tubuai were also evangelized from Tahiti, and as late as 1888 Rimatara and Rurutu sought British protection, which was refused. They were placed under the French protectorate in 1889 and annexed in 1900. The Tuamotus were part of the kingdom of the Pomare family of Tahiti, which came originally from Fakarava. These islands were claimed as dependencies of Tahiti within the protectorate by France in 1847 and became part of the colony in 1880. In the Marquesas, Nuku Hiva was annexed to the United States in 1813 by Capt. David Porter of the frigate "Essex," but the annexation was never ratified. French occupation of the group followed the landing of forces from a French warship, requested by the chief of Tahuata (near Hiva Oa). Soon after there was a quarrel with the French; in 1842 the chiefs ceded sovereignty to France. (F.J.W.)

The islands (administratively termed French Colony of Oceania [EFO]) were originally ruled by a naval government, which was dissolved by an organic decree of 1885. The nearest thing to a constitution that the EFO ever had, the organic decree provided for a French governor and Privy Council and for an 18-member General Council, representing the islands, that had some control over fiscal policies. The powers of the General Council, however, were cut back in 1899, and in 1903 it was replaced by an advisory council that had none of the powers of its predecessor and the function of which was purely administrative. This situation, which was unsatisfactory to the native inhabitants, continued until French Polynesia was made an overseas territory of France in 1946. (Ed.)

**The landscape.** Five distinct sets of islands may be discerned, all protrusions of parallel submarine ridges trending from the northwest to the southeast.

**The Society Islands.** These are the most westerly of the group and the most important in terms of land area (40 percent) and population (80 percent). Except for a few small atolls, they are of the "high island" type, resulting from the emergence of underwater volcanoes.

The volcanic cones are highly eroded and cut up into high crests and deep, radiating valleys. The often lushly vegetated mountains drop abruptly to narrow coastal strips or directly into lagoons or the sea—from the direct assaults of which the islands are protected by almost completely encircling barrier reefs.

The largest and most highly populated of the Society Islands are Tahiti and its neighbour, Moorea, both situated in the eastern Îles du Vent, or Windward Group. Tahiti, formed of two ancient volcanic cones, is particularly striking, because of its dramatic silhouette, which rises 7,333 feet above sea level. The mountains are empty of all human settlement, habitation and planting being limited to the coastal strip and valley outlets. Moorea, separated from Tahiti by a 12-mile-wide channel, is also a high island and is encircled with very white coral sand beaches. It is well connected to Tahiti by boat and taxi planes—a consequence of the booming tourist industry.

Ninety miles to the west of Tahiti are the Îles sous le Vent, or Leeward Islands, made up of five high islands and four atolls. They closely resemble the Îles du Vent in appearance. Raiatea is the largest and most densely populated; it has a coastal plain with coconut groves where stock raising is carried on. Vanilla was once an important crop but is now on the decline. Its port is Uturoa, the second city of French Polynesia. To the east of Raiatea is the island of Huahine, a volcanic structure bisected by a shallow arm of the sea. It is very picturesque and will probably develop as a tourist attraction.

Finally, to the west of Raiatea, lies the beautiful little island of Bora-Bora. It is formed from a volcanic peak rising up to 2,385 feet and dropping down abruptly to the lagoon. It is one of the centres around which the tourist trade revolves in French Polynesia.

**The Tuamotu Archipelago.** Lying to the east of the Society Islands, this archipelago of 325 square miles and some 7,700 inhabitants consists of more than 80 islands. These are low, flat islands or atolls of coral origin, surrounding a lagoon. The size varies greatly: the largest ones, such as Rangiroa, reach 29 square miles; the smallest are made up of a few acres of land barely protruding above the surface of the sea. Lacking soil, and with no permanent streams, they have no agricul-

Tahiti and Moorea

tural potential aside from the ever-present coconut trees. The lagoons, however, are a source of fish, pearls, and mother-of-pearl shell. Only Rangiroa, with its airport, is in close contact with Tahiti. Elsewhere, living conditions are so hard that the people are only too eager to emigrate to Tahiti. In the Tuamotus are situated the French nuclear installations. Test sites are on Mururoa and Fangataufa; the military base on Hao has an airstrip that handles military jets.

*The Îles Gambier.* Morphologically different, the Îles Gambier lie at the southern extremity of the Tuamotu Archipelago and include four large, high islands and a few islets (14 square miles, some 600 inhabitants). The main island is Mangareva.

*The Marquesas Islands.* There are 14 Marquesas Islands lying 900 miles to the northeast of Tahiti. They have a land area of 255 square miles and a population of about 5,600. Some of them are high islands (over 3,000 feet), with sharp and twisting contours. Unlike the Society Islands, they are not protected from the sea by a barrier reef, with the result that they lack a coastal plain. Approaching the islands from the sea is difficult. People live exclusively in the valleys, where they engage in farming.

*The Îles Tubuai.* Situated 450 miles south of Tahiti, the Îles Tubuai, or Austral Islands, make up the southernmost part of the territory.

This chain of four islands, with the addition of the isolated island of Rapa in the southeast, covers 54 square miles and contains over 5,000 inhabitants. All of the islands are of volcanic origin but of little height (300 to 1,000 feet) and with unpronounced contours. Income is derived from agriculture (taro, market vegetables) and pandanus plaiting. This plait work is sold in Papeete.

Like the Marquesas and the Tuamotu-Gambiers, the Tubuai group have poor connections with Tahiti. As elsewhere, the hard living conditions provoke a rural exodus, to the benefit of Tahiti and Papeete.

Administratively part of French Polynesia is the island of Clipperton (10° 18' N, 109° 15' W), some 600 miles off the coast of Mexico. An atoll of about five miles in circumference, it is presently uninhabited.

*Climate.* The climate is tropical—warm and humid. There is a warm rainy season from November until April and a relatively cool dry season from May until October. The dispersion of the islands through 20° of latitude, however, results in local and regional climatic variation. Except in the Marquesas and the northern Tuamotus, rainfall is abundant, falling in the form of violent showers. As much as 120 inches fall on the coastal areas. There are local variations due to differing exposures; on average, the coasts exposed to the winds receive more precipitation.

The temperature varies but slightly throughout the year. At Papeete, the mean average annual temperature is 79.0° F (26.1° C); the high mean average is 90.7° F (32.6° C) in March and the low mean average 70.0° F (21.1° C) in August. The Îles Tubuai (Austral), further south, enjoys a cooler climate; the low mean average can go down to 64° F (18° C) in September. The relative humidity is always high—80 to 90 percent on the average. The high areas are continually enveloped in a heavy cloud formation.

The territory is in the trade-wind zone. The dominant winds thus blow from the north and northeast, but they tend toward the southeast between May and October. There are large periods of calm (April, May, June) but with occasional tropical hurricanes or cyclones. Land breezes cool the night to 13° F (7° C) below the daytime temperature.

*Vegetation and animal life.* Because of the recent origin and the isolation of the islands, there is little variety in terrestrial flora and fauna. Most of the plant species were introduced by the first Polynesians, others being introduced by Europeans.

The vegetation's appearance varies with the ecological conditions. On the limestone soils of the atolls, it has a pronounced xerophious (desert-plant-type) character. On the high volcanic islands it is more diversified; ferns have

French Polynesia, Area and Population

often conquered the hills and plateaus, whereas rain forests are established in the upper valley areas. On coastal plains flourish coconut, breadfruit, and various fruit trees.

The land fauna is especially limited, and most of the species have been introduced. No mammal is indigenous, but certain ones live wild: goats, pigs, horses, cattle, and, of course, rats.

The streams are inhabited mainly by a fish, *nato*, and a shrimp (prawn) highly esteemed by gourmets. The marine fauna is rich, with fish of every shape and colour.

*Human geography. Patterns of settlement.* On the high islands, homes are scattered through the coconut groves along the coastal roads. Every two or three miles occurs a village in which are grouped together the church, the government house, the school, a shop (usually run by a Chinese), the pastor's home, and a few residences. The contemporary rural house is of concrete construction in a yard shaded by fruit trees, with a separate kitchen made from traditional materials (palm, bamboo) where food is prepared and eaten. On the atolls, the population is usually grouped together in villages located close to the passes through the surrounding reefs.

Population and business activity tend to concentrate in the Papeete area. The town consists of the old colonial city (still the business centre), residential areas (often on the heights), and tin-pan alleys hidden by foliage; it extends some 20 miles along the sea front and creeps into the valleys, that are walled in by nearby mountains.

Urban services—water supply, sewage, electricity, and public transportation—remain inadequate, especially in the areas recently occupied by immigrants pouring in from the outer islands.

This influx is connected with the development of a class of salaried workers in French Polynesia that represented 74 percent of the economically active population in 1969.

*The people.* Most of the people throughout the islands may be classed as Polynesian, speaking eastern Polynesian languages. Polynesians and part Polynesians (called Demis) make up 85 percent of the total. Minority groups consist of Chinese (11 percent) and Europeans and Americans (3 percent). Although relatively few in numbers, the Demis, as a result of their position between two cultures (Polynesian and European) constitute a very important economic force and even more vital political force. Over 60 percent of the population is of protestant persuasion (Evangelical Church of Polynesia); some 30 percent is Roman Catholic, the remainder belonging to various other Christian denominations.

After half a century of decline the population stabilized between 1900 and 1920 and then underwent a considerable increase; in 1968 the birth rate was 4.57 percent and the death rate .91 percent. Polynesian emigration to New Caledonia almost stopped around 1963–64, when the French nuclear testing headquarters was established but then recommenced in 1969 with the expansion of the nickel industry in New Caledonia. With a high birth rate and the death rate reduced by sanitary developments, the population of the territory is likely to double in 20 years. In 1971, one Tahitian out of two (55 percent) lived in Papeete and its suburban area.

tempera-  
ture

**Economy.** Many resources are used for local subsistence, including fruits, products from fishing and planting, and materials for the construction of traditional types of houses and canoes. The main exports—copra, vanilla, and mother-of-pearl shell—have greatly declined. Exports in 1970, in fact, for those products (by volume) were 62, 20, and 32 percent, respectively, of levels of 1960. This, however, has been partially compensated for by an increase in income from tourists, who increased more than twelve-fold in numbers between 1960 and 1971.

The gross internal product in 1969 was 19,185,000,000 Pacific francs (CFP 100 = \$1 U.S.; CFP 240 = £1 sterling, on October 15, 1971), 9 percent of which came from agriculture, 18 percent from industry and the building trade, 3 percent from tourism, 41 percent from business and various services, and 29 percent from salaries of civil service employees.

There have been considerable developments in transportation facilities since the early 1960s, including the construction of a modern port in Papeete, construction of an international airport, and development of air services with some of the outlying islands: Moorea, the Leewards, the western Tuamotus, the Marquesas, and the Tubuai. Schooner connections within the region and with other Pacific areas are still, however, very irregular, and road systems are inadequate or nonexistent.

**Administration and social conditions.** Represented in the French parliament by a deputy and a senator and placed under French law, the territory is administered locally by an elected assembly and a governor. The latter is head of the territory and is appointed by the French government. Since the early 1960s a large fraction of the population has been demanding a statute of internal autonomy, with enlargement of the prerogatives of the Assembly, creation of ministerial portfolios, and the formation of a cabinet responsible to the electorate.

Schooling is compulsory and conducted largely in government-aided mission schools; literacy is 95 percent. The population has average health facilities (one doctor for 1,750 inhabitants, one hospital bed for 120 inhabitants). The standard of living is relatively high, annual per capita income being U.S. \$1,450, but there are wide differences of income between the various social groups.

**Cultural transition and prospects.** Profoundly influenced by the West, French Polynesia's cultural and artistic traditions have been reduced to a sort of folklore, a process stimulated greatly by the tourist trade. In spite of the existence of an ethnographic museum and a local learned society, a great effort is needed to preserve the territory's cultural heritage. The absence of newspapers in Polynesian, the small amount of broadcasting in the Tahitian language, and the nonrecognition of vernacular languages as official languages on a level of equality with French all constitute a real handicap to the protection of indigenous culture.

An ethnically diverse society located at a crossroad of civilizations, French Polynesia is hunting for a cultural identity. This still-confused aspiration is expressed through the medium of political struggles centred around the demand for internal autonomy. The ties of economic dependence with France however, are being reinforced to a dangerous degree, in spite of worthy efforts at all levels to ensure substitutes for activities connected with the French nuclear program.

**BIBLIOGRAPHY.** PATRICK O'REILLY and EDOUARD REITMAN, *Bibliographie de Tahiti et de la Polynésie française* (1967), is an exceptionally useful tool for scholars and laymen; it includes more than 10,000 entries with many accompanied by brief summaries. Little has been published in geography; see FRANÇOIS DOUMENGE, *L'Homme dans le Pacifique Sud* (1966), for the best general survey. For general documentation about pre-European ethnography, one may consult the Bernice P. Bishop Museum Bulletins; No. 9 for the Marquesas, 48 and 90 for Tahiti, 157 for Mangareva, and 70 for Tubuai. PIERRE VERIN, *L'Ancienne civilisation de Rurutu (îles Australes, Polynésie française)* (1969), is a recent work in Austral island archaeology and ethnohistory; JOSE GARANGER, "Archaeology and the Society Islands," in GENEVIEVE A. HIGHLAND et al. (eds.), *Polynesian Culture History* (1967); and YOSHIKO H.

SINOTO, "Position of the Marquesas Islands in East Polynesian Prehistory," in I. YAWATA and Y.H. SINOTO (eds.), *Prehistoric Culture History* (1968), give general insights into recent archaeological advances in French Polynesia. The Chinese minority is studied in GERALD COPPENRATH, *Les Chinois de Tahiti, de l'aversion à l'assimilation, 1865-1966* (1967). Contemporary social change is documented in BENGT DANIELSSON, *Work and Life on Raroia* (1956); BEN R. FINNEY, "Polynesian Peasants and Proletarians" in *Polynesian Society Reprint Series* No. 9 (1965); PAUL OTTINO, *La Pêche au grand filet ('Upe'a rahi) à Tahiti* (1965); PAUL KAY, "Aspects of Social Structure in a Tahitian Urban Neighbourhood," *Journal of the Polynesian Society*, 72:325-371 (1963); and by ALLAN F. HANSON, *Rapan Life-Ways* (1970). The only synthesis, written by an economist, a sociologist, and two geographers, about the contemporary situation and transformations induced by the implantation of a military base for atomic tests is JEAN FAGES et al., *Tahiti et Moorea: études sur la société, l'économie et l'utilisation de l'espace* (1970). On Gauguin in Tahiti and the Marquesas, the best documented study is BENGT DANIELSSON, *Gauguin in the South Seas* (1965).

(H.La./J.Fa./C.R.)

## French Revolutionary and Napoleonic Wars

The wars of the period 1792 to 1815, between France and alliances of the other major European powers, were a mixture of old and new. Broadly speaking, the weapons were old. While muskets, bayonets, guns, and cavalry weapons had been slightly improved during the 18th century and continued to be improved during these wars, the slow-firing and cumbersome smooth-bored, muzzle-loaded hand and field weapons of the War of the Spanish Succession (1701-14) were still, in basic essentials, the weapons used 150 years later in the Crimean War (see also EUROPEAN DIPLOMACY AND WARS [c. 1500-1914]).

The new element in these wars was political. The aims of the French Revolution were proclaimed to be liberty and equality, an end to autocratic regimes, and government by and for the people. If men had these rights, however, they had a corresponding responsibility to defend them against attack: the corollary of the vote was the duty of military service. In practice this meant large conscript armies instead of relatively small professional ones. As the great military writer Karl von Clausewitz was to point out, while armies of the 18th-century type still existed in France at the outbreak of the Revolution, it was not long before

... such a force as no one had had any conception of made its appearance. War had again suddenly become an affair of the people, and that of a people numbering thirty millions, every one of whom regarded himself as a citizen of the state.

This vital change led to much larger armies and, in consequence, to important developments in strategy and tactics. After 1800 Napoleon normally fought his campaigns in command of 250,000 men and occasionally many more, in contrast to the 60,000- to 70,000-man armies of the early and middle 18th century. Moving armies of that increased size swiftly across western and central Europe required good road- and river-transport systems and created a need for supplies that could be satisfied only by some measure of local requisitioning or by living off the land, in contrast to the elaborate and restrictive depot methods of the 18th century. On the battlefield the massed infantry column became an alternative to the thin firing line, partly because the column offered an acceptable way to deploy large numbers of rapidly trained new recruits.

One other general matter must be mentioned. If the French entered these wars in 1792 as a crusade, at first to defend the Revolution in France against the invading armies of Austria and Prussia and then to spread the Revolution to less fortunate nations, that phase of the wars came to an end by 1800, if not before. Certainly from 1805 onward and in some respects during his campaigns against the Second Coalition in 1798-1802, the wars of Napoleon were aggressive, nationalist wars designed primarily to expand French influence either by direct territorial aggrandizement or by the creation of satellite states. As a result, the armies of France, which

Develop-  
ments in  
transporta-  
tion

New  
elements  
in the  
wars

had once been welcomed by those whom they appeared to emancipate, later found themselves opposed as aggressors by men with those same patriotic sentiments that had inspired early Revolutionary governments. Spain, Austria, Prussia, and Russia all reacted in this way to some degree and their combined efforts were sufficient, in the end, to complete the overthrow both of Napoleon himself and of much of the Revolutionary legacy he had inherited.

This account of these wars is therefore divided into two main sections, fitting the overall pattern of political and military events. The first section includes the campaigns of Revolutionary governments down to and including those waged against the Second Coalition; toward the end of this period, Napoleon, as first consul, emerged as the undisputed leader of France. The second section, covering the period of France's attempted expansion, is divided into three parts. The first begins with the resumption of hostilities between Britain and France in 1803 and ends with the Treaty of Tilsit in 1807—a period that saw the high-water mark of Napoleon's success both as general and as statesman. The second part continues to 1811, during which time Napoleon attempted to establish his position as overlord of Europe on a permanent basis, only to encounter increasing patriotic opposition first from Spain and then from Austria; while, in the background, Britain increasingly waged economic warfare against France and a steadily growing military war in Spain. The third part is the period of Napoleon's defeat and overthrow, from the invasion of Russia in June 1812 to the final catastrophe at Waterloo in June 1815.

This article is divided into the following sections:

- I. The French Revolutionary Wars, 1792–1802
  - The new French armies
  - The outbreak of war
  - The war at sea and in the colonies
  - The French expedition to Egypt and Syria, 1798–1802
  - The continental campaigns of the Second Coalition, 1798–1801
- II. The Napoleonic Wars, 1801–15
  - Lunéville to Tilsit, 1801–07
  - The coercion of Europe, 1807–11
  - The defeat of Napoleon, 1812–15

## I. The French Revolutionary Wars, 1792–1802

### THE NEW FRENCH ARMIES

At the outbreak of the Revolution in 1789, the French Army was probably the most efficient and progressive army in Europe, thanks to a variety of reforms introduced during the previous 20 years. The number of officers had been greatly reduced and many military sinecures abolished. A better system of training for young officers, together with improved methods of regimental accounting and administration, had been introduced. Organization into divisions, certainly for training purposes, had become standard. French artillery was being steadily improved, both in equipment and in organization, in ways from which the generals of the Revolution and Napoleon himself greatly benefitted. Finally, there were other reformers—for example, the Comte de Guibert, who published his *Essai générale de tactique* in 1773—who criticized what they considered the restricted tactical and strategic practices of 18th-century armies and who envisaged swifter, more ruthless warfare designed to achieve much greater political success.

Guibert argued that 18th-century warfare was ineffective because it was waged with relatively small armies hampered by restricted finance and led by overcautious generals. He wrote,

But suppose that there should arise in Europe a people endowed with energy, with genius, with resources, with government; a people which combined the virtues of austerity with a national militia and which added to them a fixed plan of aggrandizement; which never lost sight of this system; which, as it would know how to make war at small cost and subsist on its victories, would not be compelled by calculations of finance to lay down its arms. We should see that people subdue its neighbours and upset our feeble constitutions as the north wind bends the slender reeds.

These may have seemed wild words to Guibert's con-

temporaries, but the events of the Revolution and then of Napoleon proved them true.

But, however progressive the French Army may have been in 1789, it was still the instrument of an autocratic government and of an aristocratic social system. The officer establishment numbered fewer than 10,000, of whom over two-thirds were noblemen and hardly more than 10 percent were officers of fortune. Moreover, of the 285 members of the chamber of nobles in the States General (assembly of the clergy, nobles, and commons), over 50 percent were officers. The main problem for the National Assembly at this time, therefore, was not so much to ensure the continuation of a large and efficient army for purposes of law and order as rather to make certain that a basically royalist army did not become a centre of hostility to the new Revolutionary government. To some extent the problem was solved by emigration. Officers of noble rank were angered and made apprehensive by measures designed to embody the new ideals of liberty and equality. In February 1790 a new military constitution prescribed that all citizens were theoretically eligible for every military employment and rank, and the purchase of commissions was abolished. With the coming of the Legislative Assembly in September 1791, a new military oath was introduced in place of the oath of allegiance to the king. In response to such measures, officers of noble rank emigrated in great numbers, and, by the end of 1794, well over 5,000 of them had gone. At the same time insubordination spread rapidly. In some regiments, officers were summarily cashiered by their men, and others were elected by popular vote in their place. Political associations appeared within regiments.

By the summer of 1791 the National Assembly decided that this process had gone too far. War had not yet begun, but it was becoming more likely; and the army was growing weaker. In June, therefore, the Assembly decided to raise 170 new battalions—more than 100,000 men in all—consisting of volunteers from the National Guard. Many of these volunteers, who had been in the royalist militia originally, proved to be valuable troops. In the spring of 1792, with another 75,000 men needed, the voluntary principle of enlistment was breached for the first time; each *département* was allotted a quota and instructed to enroll by ballot if volunteers proved insufficient. A year later, with a demand for a further 300,000 men, the National Convention ordered the conscription of unmarried men between the ages of 18 and 40, again to make up any shortages in voluntary enlistment. Six months later still, in August 1793, the National Convention introduced the *levée en masse* by a decree putting all Frenchmen in permanent requisition for the nation's armies until all foreign enemies had been defeated. It was decreed,

All Frenchmen, . . . are called by their country to defend liberty. . . . From this moment until that when the enemy is driven from the territory of the republic, every Frenchman is commandeered for the needs of the armies.

Thus, the "nation in arms" was announced. By the spring of 1794, France had more than 700,000 men in its armies, and Europe was treated to its first display of total war in modern times. Thus began the process whereby Napoleon was able to command 200,000 men and more in his great victories of 1805–06 and nearly three times that number when he invaded Russia in 1812; and, in response to that threat, the Allies were able to oppose him with armies of equal size and even greater size in the years 1813–15.

There were, however, limitations in the practical application of this principle of universal military service. First, many groups, such as priests and married men, were exempt from the obligation. Next, it became the custom that a man could buy himself out of his obligation by finding and paying for a substitute, a practice that clearly favoured the rich. Thirdly, Napoleon increasingly favoured an elite professional army, which he developed in the Imperial Guard—but the most suitable men for such a force were usually those with long service, and men were often retained in the army when, by the rules

of conscription, others should have taken their places. Finally, the system worked erratically. In the middle of his career, Napoleon used many foreign regiments, thus lessening the call on Frenchmen. Even in his preparations for the 1812 campaign, only about 50 percent of those eligible for military service were actually called to the colours. In the years of defeat (1813–15), however, with few foreigners to call upon, youths below the legal age for military service were called by anticipating future obligations. This practice produced a sense of hardship and bitterness in France that had not been present in the days of great victories and, in turn, led to increased evasion of a duty that the Revolution had proclaimed a privilege.

France's example in these matters did have some influence elsewhere in Europe. Armies grew in size, and liability for military service was extended. Since political revolutions did not take place inside those countries that were the major enemies of France, however, the most important factor in the development of the concept of the nation in arms was missing. In several countries—e.g., Spain, Austria, and Russia—there was a strengthening of nationalist sentiment against the French invader, and that sentiment proved to be, to some extent, an effective substitute for the demagogic appeal of the *levée en masse*. In Prussia, however, the example of France was analyzed and then, in some important ways, deliberately copied; indeed, it is arguable that the rationale of the nation in arms was more carefully worked out in Prussia than in France.

For Prussians their defeats at Jena and Auerstädt in 1806 were not only humiliating but astounding as well. The only explanation for Prussian statesmen and soldiers

of the complete overthrow of the military machine created by Frederick the Great was to argue not that the French were better professional soldiers led by a better general but that the French were inspired by something that Prussian soldiers lacked. Clausewitz called it national spirit. If Prussia was to avenge its disastrous defeat at the hands of Napoleon, it could do so only by creating a people's army that, like the armies of France, would be composed of free men fighting for themselves and for what they believed. Free men would make better citizens; better citizens, better soldiers. The old class-ridden, savagely disciplined professional army of Frederick the Great was to be replaced by

... universality of responsibility for service in war, binding upon every class of civil society. Through this it will be possible to inculcate a proud warlike national character, to wage wearying wars of distant conquest and to withstand an overwhelming enemy attack with a national war.

The Prussian reforms from 1807 onward were designed to this end, despite opposition from the King of Prussia. Civil reforms were accompanied by attempts to reform officer training while opening up the opportunity for commissions to many more men than before; *Landwehr*, or reserve service, was added to compulsory service in the regular army; a general staff was developed in a deliberate attempt to improve provision for both planning and supply. Some of these reforms, particularly the attempt to build up a large trained reserve on the basis of short periods of initial service in the regular army, were blocked by the French at least until after the Russian Campaign in 1812. Nevertheless, the basis was laid for a rapid expansion of Prussian forces in the war of national liberation from 1813, a war in which Prussian

troops fought with much the same inspiration as that which had moved the French levies of 1793 and 1794.

For Clausewitz, as has already been seen, war in this period approached its total or absolute form more closely than hitherto in modern Europe because it had now become "an affair of the whole people." And he was correct in his emphasis. It was in human more than in material resources that nationalization took place. (This legacy, although temporarily laid aside after 1815, nonetheless had a profound effect on military thinking and organization and on the debate about civil-military relationships in Europe throughout the 19th century.)

#### THE OUTBREAK OF WAR

#### Early campaigns

The early campaigns of the Revolutionary Wars lack the clear pattern and something of the decisive military quality of Napoleon's campaigns between 1800 and 1807. The fighting of these early years, however, was of critical importance for the future of the Revolution; only by defeating its foreign enemies could France pursue its own chosen political course.

In June 1791 Louis XVI and his family fled from Paris, hoping to take refuge with the still largely royalist army on the eastern frontier of France. Just short of their destination, they were recognized and brought back virtually as prisoners. At this point the monarchs of Austria and Prussia began to show concern about the fate of their fellow monarch in France, and in late August 1791 they issued the Declaration of Pillnitz. The declaration appealed to the other European rulers to act together with Prussia and Austria with

the most efficacious means, relative to their forces, in order to enable the king of France to consolidate in the most perfect liberty, the basis of monarchical government equally suitable to the rights of sovereigns and the welfare of the French nation.

Though certainly not a declaration of war, this pronouncement was bound to be taken by the French as an unwanted sign of interference in their national affairs; and France's relations with Austria and Prussia steadily worsened during the winter of 1791-92.

War was at last declared by France against Austria and, in practice, against Prussia as well, on April 20, 1792. The Legislative Assembly, as seen above, thereupon called for further volunteers to add to those already recruited from the National Guard in 1791 and also introduced the first measure of conscription. The campaign developed very slowly on both sides. The French were not sure of themselves; and the Allies assumed, overoptimistically, that no haste was necessary because the French would almost certainly give way before a threat of force. On July 30 the Allied commander, the Duke of Brunswick, crossed the Rhine and slowly advanced westward. On September 20 he faced the French, commanded by François-Christophe Kellermann and Charles-François Dumouriez, at Valmy, about 40 miles (64 kilometres) west of Verdun, having manoeuvred himself into a position between the French and the road to Paris via Châlons. The Allies numbered some 35,000 men; the French, about 50,000. After preliminary skirmishing, an artillery barrage on both sides began a little after noon at a distance of about 1,300 yards (1,189 metres). The firing was intense—Dumouriez claimed that the French fired 20,000 rounds—but the casualties were few because the distance between the armies was beyond the effective range of the guns. At one stage it appeared that the French might break; but their line was reformed, and, when Brunswick began preparations for an infantry and cavalry attack in midafternoon, he realized that the French line was still virtually intact. At that point he called off the battle, reinforced in this decision when rain began to fall. Ten days later—with the threat of bad weather, his army gravely weakened by sickness, and his line of communications insecure—Brunswick withdrew beyond the east bank of the Meuse. Dumouriez then returned to his original plan to attack the Austrian Netherlands. He won a pitched battle against the Austrians at Jemappes on November 6 and entered Brussels on November 14, overrunning the whole of Belgium by the

end of the month. The Scheldt (Escaut) was declared an open river, and plans were begun for an invasion of the United Provinces of the Netherlands.

Valmy had been a mixture of good luck and tough resistance on the French side and of dilatoriness and inefficiency on Brunswick's part. Although Brunswick was correct to withdraw when he did and for the reasons given, in fact he could and should have got the fighting over sooner and then, probably, with success. No one anticipated the victory of the French—a victory that, in effect, saved the Revolution.

All was not yet plain sailing, however, for the armies of the Revolution. The sheer chanciness of Valmy was illustrated by serious reverses in 1793, a year that began badly for France. In February it declared war against Great Britain and the United Provinces—the former antagonized both by the execution of Louis XVI and by the opening of the Scheldt, the latter still threatened with invasion. In March, France declared war on Spain. From then on France was faced with a hostile array—the First Coalition, consisting of Austria, Prussia, Spain, the United Provinces, and Britain. The alliance was not, however, well knit; there were deep differences between Austria and Prussia, largely over former Polish territory, while the United Provinces and Spain had individual policies that made possible separate bargaining with the French. In March, Dumouriez was defeated by the Austrians at Neerwinden, and soon afterward he defected to the Allies. In April the French were forced to evacuate the Austrian Netherlands; in July they were defeated on the Middle Rhine at Mainz and, in November, at Kaiserslautern.

#### The First Coalition

At that point the Revolutionary government—the Convention—broke all traditional bonds in organizing France virtually for total war. The *levée en masse* was declared, and Lazare Carnot, an artillery officer who later became known as the "organizer of victory," was elected to the Committee of Public Safety in charge of military affairs. The results of these changes were soon apparent. In October 1793 the French general Jean-Baptiste Jourdan defeated the Austrians at Wattignies, compelling the Austrians to raise their siege of Maubeuge and removing the immediate threat to Paris from the north. In May and June 1794 the French defeated the Austrians and British in the north at Turcoing and Fleurus, forcing the British to withdraw to the United Provinces and the Austrians to the Rhine.

With the Allies in full retreat, the danger of foreign invasion of France was past. That was not, however, the end. French army forces under Charles Pichegru in the north and Jourdan on the Rhine were soon busy expanding French territory. In the winter of 1794-95, Pichegru overran Brabant and reached Amsterdam. In the east Jourdan pursued the Austrians and Prussians to and across the Rhine. In addition, Spanish attacks in the south were pushed back, and Catalonia was invaded. By the spring of 1795, France had reached its natural frontiers; it could safely pause for breath and attempt to reach terms with some of its enemies. Prussia had withdrawn from the Allied coalition in the autumn of 1794, showing far more interest in the affairs of Poland than in those of France; in April 1795 Prussia came to terms with France, signing the Treaty of Basel, and remained a friend, if not an active ally, until 1806. In May 1795, the United Provinces, too, came to terms and became the Batavian Republic. Two months later Spain made peace with France, although a treaty was not signed for another year.

Thus, by the time the Directory came into power in France, in November 1795, only Austria, Sardinia, and Britain remained to be dealt with. In June 1796 the armies of France under Jourdan and Jean-Victor Moreau advanced into the Holy Roman Empire along the lines of the rivers Main and Neckar but were forced back across the Rhine in September. In the meantime, Napoleon was undertaking the first of his remarkable campaigns, in northern Italy, against an alliance of Austria and Sardinia. By January 1796 the French Army of Italy, commanded by Barthélemy Schérer, was stretched out along

#### Napoleon's first campaign

the road from Nice to Genoa. Urged by the Directory to attack the enemy, Schérer complained that he needed reinforcements and supplies and then resigned his command. On March 27 Napoleon took command and immediately began to carry out an already carefully planned strategy. Basically—and this was a type of strategy he employed on the other occasions, most notably at Waterloo—he set out to strike at Allied armies where their lines of communication converged and, by attacking them separately there, to force them back on divergent lines of communication. In this case the Allies converged down the valleys leading to the Mediterranean coast west of Genoa—the Sardinian line going back northward to Turin; the Austrian, northeastward and then eastward via Acqui, Milan, or Piacenza and thence to the line of the Minzio.

Napoleon began the campaign with 40,000 men, opposed to 50,000 of his combined enemies. Moving his troops very rapidly on interior lines, he first forced the Austrians back and then switched his troops to concentrate against the Sardinians. Within three weeks he had forced the Sardinians to capitulate and to sign an armistice at Cherasco. Then, his own lines of communication safe both along the coastal road to Marseilles and over the Alps via the Mt. Cenis Pass, he turned against the Austrians. On May 15 he entered Milan, giving the people of Lombardy their first unpleasant taste of how French armies lived off the land. Dagobert Siegmund Wurmser retreated still farther along his line of communication, and by early August he had withdrawn to Mantua, where he was besieged by Napoleon throughout the winter of 1796–97.

Mantua was of vital importance. In the summer of 1796, Napoleon hoped that its eventual capture would open up the way into the Tirol and effect his junction with the Army of the Rhine. In fact, that army had been pushed back across the Rhine well before Mantua capitulated to Napoleon in February 1797. Turning back southward briefly, to deal with a minor threat from the Pope and a temporarily threatening Sardinia, Napoleon again turned northward and drove the Austrians back beyond the lines of the Piave and Isonzo. In August preliminaries of peace between France and Austria were signed at Leoben, followed by the Treaty of Campo Formio in October 1797.

Campo Formio was the first of Napoleon's great political successes and the first formal stage in the territorial expansion of France. Austria ceded the Austrian Netherlands (later Belgium and Luxembourg) and the left bank of the Rhine to France and recognized two new French satellite states in northern Italy in the Cisalpine and Ligurian republics. Austria, having given up Milan, gained Venice instead.

#### THE WAR AT SEA AND IN THE COLONIES

The governments of Revolutionary France had far less success in the war at sea. The French Navy fell well below the standard of the French Army in 1789 and was then equally demoralized by indiscipline, desertion, and emigration during the early months of the Revolution; moreover, it was a very much smaller navy than Britain's—an inferiority rendered all the more serious because, at least at the outset of hostilities, Britain could count on help from the navies of the United Provinces and Spain. In August 1793 conditions reached such a pitch that royalist mutineers handed over Toulon to the British Royal Navy while, almost simultaneously, a French squadron sailing out of Brest was forced to put back to port by another mutiny. At this point the French Navy found its organizer in Jeanbon Saint-André.

Saint-André was not a professional sailor, but he was a professional revolutionary who believed that France's fortunes at sea could be revived by first getting rid of all traces of the *ancien régime* and then by imbuing officers and men alike with republican fervour. Things began badly for him; in December 1793 the British burned 42 French ships of all classes when they were forced to evacuate Toulon. At Brest, however, he did better—he reorganized the arsenal there, got rid of many officers of

the royalist navy who were inefficient or disloyal, and rapidly promoted others who were willing to accept the Revolution. The first big test came in June 1794 when he sent a fleet out of Brest commanded by Adm. L.T. Villaret de Joyeuse to protect a convoy coming in from America. Villaret encountered a British fleet, and a major battle took place off Ushant on June 1. Although the convoy was saved, the French battle fleet was defeated. Villaret lost a number of his ships of the line and suffered more than 5,000 casualties. As a result, the democratization of the navy was reversed, a return to professionalism and strict discipline was encouraged, and a process of reorganization was carried out during the rest of the life of the Convention and under the Directory.

Meanwhile other European navies had come under French control either directly or as a result of alliances. The United Provinces and Spain, originally Britain's allies in the First Coalition, were out of the war by 1795 and in it again, this time on the side of France, by 1796. This improved situation at sea, accompanied by French successes on land (particularly Napoleon's campaign in northern Italy), led the Directory to attempt invasions of Ireland in December 1796 and Wales in February 1797. Both attempts failed, but in the latter month a much more important action took place. The British admiral Sir John Jervis, commanding a squadron of 15 ships of the line, encountered and routed a Spanish fleet almost twice as big off Cape St. Vincent. Thus, although Britain was by now excluded from the Mediterranean, it still held Gibraltar and was in command of the Atlantic seaboard of Spain. Farther north and despite mutinies at Spithead and the Nore in April and May 1797, things went well for Britain, too. All that summer the Dutch fleet in the Texel awaited the first suitable opportunity to invade Ireland or England. In October it sailed, only to be caught off Camperdown and defeated as handsomely as the Spanish fleet had been.

By the time of the Treaty of Campo Formio, therefore, the navies of France and its allies were back in their ports blockaded by the British Royal Navy, which in three major battles had demonstrated its superiority, based largely on better training, discipline, and tactics. On land France was supreme; at sea it had so far failed.

European waters, however, were not the only scene of important naval activity in those early years; there were operations in colonial areas as well. While attempting to gain a foothold in Europe, whether in the Mediterranean, in Brittany, or in Flanders, the British planned to deprive France of its colonies, both in order to cut off its supply of colonial raw materials and to secure the colonies for Britain itself. Britain's small army—only 20,000 men were available at the outbreak of war in 1793—made it virtually impossible to conduct an effective worldwide strategy and only too easy to fritter away precious resources on too many objectives. While colonial gains could be important to the British in securing existing supplies of raw materials or in denying vantage points to the enemy, expeditions to such places could be and often were extremely costly in terms of human life and made no direct contribution to the defeat of France in Europe. Had the 40,000 British dead lost in the West Indies by 1796 and nearly the same number rendered unfit for military service been made available for the campaign to preserve the former status of the Austrian Netherlands and the United Provinces, they might have done great harm to the enemy.

In 1794 a British force in the West Indies captured Guadeloupe and St. Lucia and established itself in the French part of Haiti. The Haitian ports were of crucial importance for the control of West Indian trade, not least because they were France's only base for operation of its cruisers to the west. Taking them, however, proved also a deathtrap for the British. The black slaves, led by Toussaint-Louverture (*q.v.*), were more concerned with their own freedom than with the Franco-British colonial war being waged over their heads. Soon they and the yellow fever had inflicted far more casualties on the British than the latter had on the French. There were, however, other British gains—the Cape of Good Hope in Africa and

Colonial  
operations

British  
naval  
superiority

Ceylon in the Orient were taken from the Dutch, together with such places as Trincomalee, Pondicherry (India), and Malacca. Thus—and again by the time of Campo Formio—the British could claim that they had begun to put a stranglehold on French colonial trade or, conversely, that they had acquired enemy colonial possessions that could later be used as valuable pawns in a treaty of peace. Whether they were so used remained to be seen, and whether they were worth the price paid for them in terms of the critical war in Europe is another matter (see also *LATIN AMERICA AND THE CARIBBEAN, COLONIAL: The Wars of Independence*; HAITI, HISTORY OF).

#### THE FRENCH EXPEDITION TO EGYPT AND SYRIA, 1798–1802

It was at that point, with only Britain still at war with France, that the Directory appointed General Bonaparte (that, strictly, was still his proper title, although this narrative will continue to call him Napoleon) to command the army that was planning to invade Great Britain. Napoleon took command in mid-February 1798. Within a few days he concluded that invasion was impossible until France had won command of the sea. He suggested, instead, an invasion of Egypt.

Napoleon was not the first Frenchman to be attracted by this idea. In his *Considérations sur la guerre actuelle des Turcs*, the intellectual Constantin Volney, just before the Revolution, had written that, through Egypt, France could reach India and make Suez, rather than the Cape of Good Hope, the main route to the East. Egypt was a long way from India, however, whether by sea or land. By land, the route was difficult to negotiate and even more difficult to keep open. By water, everything depended upon command of the sea between Toulon and Alexandria, on the one hand, and Aden and the ports of western India, on the other. An expedition might escape a controlling enemy squadron, but no sound strategic estimate could count on a safe return. The fact that Napoleon himself evaded the Royal Navy in getting to Egypt and then in returning to France does not invalidate that view; on his return he sailed alone because he could not hope to do so safely otherwise.

Such grandiose projects, however, are not the only possible motive for Napoleon's expedition. The conquest of Egypt and particularly gaining the goodwill of Turkey as a result of dealing with the insubordinate Mamlûks would present a serious threat to Britain's Middle East trade routes. That threat would be made yet more serious if some island posts on the way, such as Malta, could be brought under French control and if the Red Sea area could be controlled from the Egyptian side. Finally, the mere threat to some of Britain's routes to India might encourage action against Britain by some of its enemies there. Thus, the Directors were persuaded, and an expedition was agreed to.

Napoleon sailed from Toulon on May 19, 1798, at the head of 40,000 men and with much apparatus designed to reorganize the whole system of government and society in Egypt. On the way, he captured Malta from the Knights of the Order of St. John and, more by luck than good judgment, evaded a British squadron under Horatio Nelson (q.v.) and landed safely in Egypt. Once ashore his covering fleet anchored in Aboukir Bay; there, on August 1, it was surprised by Nelson's returning squadron and promptly attacked from both the landward and the seaward sides in the Battle of the Nile; 11 French ships were destroyed or taken and only two escaped, while none of Nelson's ships was irreparably damaged.

The Battle of the Nile was one of the decisive battles of history. Britain won command of the Mediterranean and retained it. Napoleon could still operate in freedom on land, but he had virtually no hope of reinforcements or rescue; and the morale of the French Navy received a shock from which it did not recover.

Apparently undaunted, Napoleon went ahead with his plans. Gen. Louis C.A. Desaix de Veygoux left Cairo in late August to undertake the conquest of Upper Egypt, while Napoleon brought the Lower Nile area under control in preparation for further expeditions. Early in 1799 Napoleon learned that the Pasha of Syria had invaded the

Suez Desert. It was clear to Napoleon by then both that he must expect the active hostility of the Ottoman sultan, and that his own next step must be an invasion of Syria as the first move to bringing the Middle East under French control. His advance began in early February and by mid-March had reached Acre. Both Napoleon and his British opponents well understood the strategic importance of Acre, a fortress that, guarding the entry into Palestine, would either protect or deny Napoleon's further successful progress. Writing some weeks later, Napoleon forecast that, if he captured Acre, he would advance upon Damascus and Aleppo, fire the discontented masses with enthusiasm for his cause, advance on Constantinople, and overthrow the Ottoman Empire.

These predictions, however, proved to be dreams. The British had command of the sea; Sir Sidney Smith, with a small squadron lying off Acre, fed help and advice to the garrison and resisted the French siege until Napoleon was forced to accept defeat and begin his withdrawal on May 20. By mid-June Napoleon was back in Egypt; and there he stayed until, moved much more by developments in France than by any dreams of an eastern empire, he sailed in secrecy from Alexandria with a few of his closest staff and landed at Fréjus, in southeastern France, on October 9. He left the Army of Egypt behind and never, himself, set foot in the Middle East again. His threats against Britain—first from a cross-Channel invasion in 1798 and then from Egypt and Syria in 1799—had been in vain.

The story of operations in Egypt is best taken to its conclusion here, although to do so involves anticipating later developments to some extent. Throughout the rest of 1799 and 1800 the French remained in Egypt—admittedly in control of that country but not extending French influence—cut off from the mainstream of events on the European mainland. Jean-Baptiste Kléber, left in command by Napoleon, was virtually powerless in the face of Britain's control of the sea. In January 1800, therefore, he signed the Convention of al-'Arish (el-Arish) with the Turks, by which he agreed to evacuate Egypt on condition that he be transported with his army back to France. The British government, however, refused to be a party to the arrangement, and the French stayed on. A year later, in March 1801, a British force landed in Egypt. The French made an unexpectedly weak resistance and, within six months, were defeated and on their way back to France.

This victory proved of little value to Britain in the subsequent Treaty of Amiens signed in March 1802. Of its colonial conquests it kept only Ceylon and Trinidad, while Malta, captured from the French in 1800, was returned to the Knights of St. John. Egypt reverted to Turkey, while France evacuated Naples and the Papal States. By not protesting against them, moreover, Britain accepted the French conquests in the Batavian (formerly the United Provinces), Helvetic (Swiss Confederation), and Cisalpine (northern Italy) republics.

#### THE CONTINENTAL CAMPAIGNS OF THE SECOND COALITION, 1798–1801

Peripheral operations of the kind described above were of little concern to Britain's Allies—the continental land powers opposed to France. The Royal Navy was valuable to them if it could encourage and support operations on the European mainland. This situation became obvious during the winter of 1797–98. Negotiations between Britain and Austria, which also involved Prussia and Russia, made it clear that an Austrian condition for declaring war against France once more was the dispatch of a British fleet into the Mediterranean—a move designed to support land operations from the sea and to encourage the Mediterranean powers generally to unite against the Directory. In May 1798 a British squadron under Nelson did sail into the Mediterranean, as seen above, and virtually wiped out the French fleet at the Battle of the Nile. From then on conditions were ready for the formation of the Second Coalition against France.

Successive acts of aggression by France had aroused bitter feelings during 1798. In February the French had

Coalition

driven the Pope from Rome and established a republic there; in March they invaded the Swiss Confederation and then established the Helvetic Republic; in July they began their takeover of Piedmont; in January 1799 they entered Naples and proclaimed the Parthenopean Republic; and two months later they overran Tuscany. As a result the Second Coalition against France began to take shape in the winter of 1798–99, composed of Britain, Russia, the Ottoman Empire, Naples, and Portugal; by March Austria at last declared war on France and itself joined the Coalition.

From the beginning the principal Allies were at loggerheads, and they never developed a coherent and unified strategy. Broadly speaking, the British and Russians wanted a main attack across the Rhine into France; but they fell apart after an unsuccessful joint expedition to the Helder in the autumn of 1799. Austria, on the other hand, while undoubtedly anxious about French expansion to and across the Rhine, had ambitions in Italy and was unwilling to be diverted from them.

Nevertheless, 1799 began well for the Allies. The French planned a triple attack on Austria, with one wing advancing across the Rhine and along the Danube to Vienna, a second from the Helvetic Republic into the Tirol, and a third in northern Italy to drive the Austrians back across the Adige River and on to a line of retreat via the Minzio. In March the northern attack under Jourdan was stopped by the archduke Charles at Stockach, and Jourdan withdrew back across the Rhine. In April and May the French in northern Italy were defeated first by the Austrians and then by the Russians, compelling a French army in southern Italy to withdraw northward via Genoa. Further defeats followed—at Novi in August and at Genola in November. The overthrow of the Parthenopean, Roman, and Cisalpine republics followed.

As already seen, however, the Allies disagreed over the correct strategy in pursuing these victories to the final overthrow of France; moreover, they suffered several setbacks. The joint Anglo-Russian invasion of the Batavian Republic, designed to distract the French from the Middle and Lower Rhine, succeeded in capturing the Dutch fleet but had no success on land and withdrew. In the Helvetic Republic the French general André Masséna defeated the Russians and, by forcing their withdrawal from that country, also threatened the Austrian army to the north commanded by the archduke Charles, compelling him in turn to withdraw from the Rhine to the Danube. Masséna's position in the Helvetic Republic was exposed; but the Allies were by then too divided to act energetically to outflank him. Thus, when Napoleon arrived back in Paris in late 1799, the French were again in command of the Batavian and Helvetic republics, and the left bank of the Rhine; their major setback had been in Italy, where they held only Genoa.

Meanwhile, in France the coup d'état of 18 Brumaire, year VIII (November 9, 1799) had occurred, placing Napoleon, as first consul, in charge of his own strategy. His approach to the 1800 campaign was to settle with Austria first, expecting this to destroy the Second Coalition, all the more so because he had already taken the precaution of detaching the Russian tsar Paul from the alliance with the promise of Malta. The French campaign was planned and carried out along two supporting lines. First, one French army under Moreau crossed the Rhine through the Black Forest to drive the opposing Austrians back toward Ulm and thus afford protection and, if necessary, reinforcements from the north for French operations in northern Italy.

It was in this latter theatre that Napoleon planned his second attack. Genoa held out against a besieging Austrian army, thus dividing the available Austrian forces between the plain of Lombardy and the Ligurian coastline. Napoleon planned to advance across the Alps via the Great St. Bernard Pass, capture Milan, advance southeastward to capture Piacenza, and cut off the Austrians from their main line of retreat to the Minzio. Then, controlling both banks of the Po, he planned to turn back westward to attack the Austrians in their main concentra-

tion area at Alessandria, doing so from the Austrian rear. (This outflanking move to the enemy's rear was a strategic approach used on other occasions by Napoleon, notably at Ulm, and with great success.) In late May Napoleon crossed the Alps; he entered Milan on June 2, crossed the Po at Piacenza on the 7th, and defeated the Austrians at Marengo on the 14th. In the meantime, Genoa had fallen to the Austrians on June 4, a victory that came too late to affect the outcome of the campaign.

This defeat did not quite finish Austria. A new agreement with Britain a week after Marengo promised further resistance to Napoleon. French successes in Germany and Italy in November and December, however, developed into a serious threat to Vienna, and the emperor Francis asked for terms. By the Peace of Lunéville between France and Austria (February 1801), Austria kept Venice but surrendered all its territory west of the Rhine, including the Duchy of Luxembourg and what is now Belgium, to France; it also recognized the Cisalpine, Helvetic, Ligurian (formerly Republic of Genoa), and Batavian republics and was forced to accept the line of the Adige as the boundary between its possessions and those of France in northern Italy. In effect, the Holy Roman Empire was a thing of the past, and both western and central Germany now lay at the mercy of France. In Italy, also, French influence had now supplanted that of Austria.

## II. The Napoleonic Wars, 1801–15

### LUNÉVILLE TO TILSIT, 1801–07

Neither the Treaty of Lunéville nor that of Amiens contained the seeds of a long-term peace—the first, because Napoleon gradually broke all its terms in the interests of French aggrandizement; the second, because both parties had signed it out of temporary exhaustion and did not regard it as satisfactory.

After Lunéville Napoleon, who became first consul for life in 1802 and emperor in 1804, lost no time in consolidating and strengthening French power, particularly in Germany and Italy. In February 1803 the Diet of Regensburg approved French plans for the reorganization of Germany, which led to the formal death of the Holy Roman Empire in 1806. This reorganization, to some extent made necessary by French expansion to the Rhine, led to the suppression of ecclesiastical states and to considerable gains by the more important lay princes. In the process, French patronage became the controlling influence in Germany. The United Provinces—now the Batavian Republic—was bound yet closer to France by late 1801. In 1802 the Cisalpine Republic became the Italian Republic, with Napoleon as its president. In 1802 Piedmont was also incorporated into France. In 1803 Napoleon mediated in a civil war in the Helvetic Republic (which then became Helvetia) and followed that action with a new constitution strengthening French influence. Later in 1803 the French entered Hanover and took it under French protection. (Small wonder that the governments of other European countries felt that there was no predictable limit to the ambitions of the first consul.)

After Amiens Britain, although nominally at peace with France, found no basis of mutual trust for the future. Apart from Napoleon's continued aggression on the Continent, he was already imposing restrictions on British trade and, in 1803, was suspected of encouraging rebellion in Ireland. Napoleon complained that the British had not surrendered Alexandria or Malta (he was correct) and that Britain was sheltering and encouraging French émigrés. It was not therefore surprising that the two powers found themselves at war again in May 1803.

**The war against Britain, to Trafalgar.** At this stage Britain had no allies and would have none for nearly two years. Hostilities with France on this one-to-one basis revealed more clearly than before the stalemate that could be reached in a situation in which a great land power was opposed to a great sea power with neither able seriously to oppose the other in his own element. Napoleon could assemble 100,000 men at Boulogne—a far larger and more experienced army than anything Britain could oppose him with—but had no way of getting his soldiers

Consolidation and strengthening of French power

The  
French  
campaign  
of 1800

into action. The Royal Navy could prevent the French Army from crossing the English Channel but had no means of attempting, let alone ensuring, the defeat of that force.

The British, first with Henry Addington and then (from May 1804) with William Pitt (see PITT, WILLIAM, THE YOUNGER) as prime minister, set about sweeping up the remaining French colonial possessions. St. Lucia, Tobago, and Guiana were taken in 1803 in the Western Hemisphere; in the same year French influence in India was further weakened by the defeat of its friends there. Then, beginning in mid-1804, Pitt began his attempts to divert and thus weaken Napoleon by rebuilding a continental coalition. In June 1804 he had reached an understanding with Russia that was converted into a formal alliance in April 1805. That August Austria joined again, and the Third Coalition was in being.

The  
Third  
Coalition

Meanwhile the war at sea continued. Napoleon attempted to stop Britain's trade with the Continent: he seized Cuxhaven for this purpose, only to meet with a British blockade of the mouths of the Elbe and Weser, which considerably damaged Napoleon's friend Prussia. The French also continued their attacks on British sea-borne trade by means of privateers. The most important aspects of this war between France and Britain, however, were French preparations for an invasion of Britain by a cross-channel attack and Britain's blockade of the ports of France and her allies.

The naval defeats of the 1790s had not persuaded Napoleon against building new fleets. Nevertheless, his resources were decidedly inferior to those of the Royal Navy in all classes of vessels, and his own admirals preferred a defensive "fleet-in-being" strategy combined with occasional brief sorties. For Napoleon himself the chief hope lay in a possible invasion; during 1803–04 troops were assembled in the Boulogne area, together with 2,000 transports. His plans for invasion varied between one employing a heavily protected force and one conducted simply in small boats, on their own, while French squadrons provided diversions elsewhere and drew away the blockading British squadrons. The right combination of successful diversion, weather, and tide was never found. Napoleon had broken camp at Boulogne and begun a long march to the Danube against Austria seven weeks before Nelson won a great victory at Trafalgar.

For Britain the basic response to invasion was the blockade, both close and distant. British squadrons were spaced off major naval ports—from the Texel along the French and Spanish coasts off Brest, Ferrol, Cádiz, and Toulon—to prevent French and Spanish squadrons from putting to sea with supporting frigates for intercommunication. Because invasion of England or Ireland was the chief danger, it was established that squadrons would fall back to a position off Ushant if one or more powerful squadrons broke the blockade and thus threatened to act as an invasion escort. (Allowing for all the differences between warfare at sea and on land, this was not dissimilar to some important aspects of Napoleon's own strategy.) A constantly successful blockade, however, was too much to expect, and both Napoleon and the Royal Navy knew that. British forces had to be split into small squadrons. Long periods at sea meant ships would sometimes be absent for refitting without adequate replacements, and the uncertainties of the weather sometimes helped the blockaded. Once the French were at sea, the Royal Navy, despite all its precautions, was almost inevitably caught in some degree of uncertainty as to where the French would go.

End of the  
war at sea

On March 31, 1805, Adm. Pierre-Charles Villeneuve, commanding the French squadron in Toulon, evaded Nelson's blockade and broke out of the Mediterranean, heading for the West Indies. Meanwhile, the other major French squadron was blockaded in Brest. Nelson chased Villeneuve to the West Indies and back, while other Royal Navy squadrons swarmed in the Channel to prevent a French concentration that could be used to convey an invasion force. Villeneuve returned and took refuge in Cádiz; and Nelson, convinced that the French had plans for the Mediterranean, followed him there. On October

20 Villeneuve, who could not stay in Cádiz because he lacked supplies and facilities, left there and was caught by Nelson off Cape Trafalgar. The French had 33 ships of the line to 27 of the British; but the latter had a tactical plan, and Villeneuve lacked one. In the Battle of Trafalgar (October 21), 18 French ships were totally lost and the rest fought their last action. This was the last battle-fleet action of these wars, and the danger of an invasion of England was ended.

**The campaign against Austria, 1805.** As a result of its defeat in 1800–01, Austria's influence in Germany had been greatly weakened. The old Holy Roman Empire in practice no longer existed, a fact recognized by Francis II himself when he was proclaimed emperor of Austria in August 1804. During this time Britain and Russia were drawing closer together; Alexander I of Russia broke off diplomatic relations with France in the autumn of 1804 and signed a treaty of alliance with Britain in 1805 designed to drive the French from northern Germany, Holland, Switzerland, and Naples. Austria, still weakened by the effects of past defeats, hung back. But, when Napoleon had himself crowned king of Italy in 1805 and then incorporated Genoa and the Ligurian Republic into France, Austria finally entered the Third Coalition with Britain and Russia in August of that year. Napoleon gave up his plans for invading England to deal with Austria and Russia. Writing to the French statesman Talleyrand on August 13, Napoleon announced,

My course is settled. I shall raise my camps [*i.e.*, at Boulogne] . . . by 23rd September I shall be in Germany with 200,000 men, and have 23,000 men in Italy . . . I shall march on Vienna and compel Austria to sue for peace.

The campaign conformed very nearly to that forecast.

Napoleon was faced with three problems. First he had to keep the Austrian Army separated from the Russians and persuade it to fight on its own; he planned to advance from the Middle Rhine on Vienna, if possible cutting the Austrian line of communication with Vienna somewhere between Ulm and there, thus catching the Austrian Army with an attack from its rear as he had done at Marengo. The second problem was to move 200,000 men across Europe from the Channel coast to the Middle Danube in the space of about six weeks and yet retain the ability to concentrate this vast army, if necessary within a day or two, at the critical time and place; he planned to make maximum use of the army corps system, the corps having become a unit of all arms, capable both of combining with other corps in a major battle and of operating on its own, even if only in a holding or defensive capacity, against a major enemy force. The final problem was that of provisioning so many men during so rapid an advance.

Regarding provisions, each corps had its own wagon train, and magazines were sometimes established at the most important towns en route. That system, however, did not provide enough; if magazines were not available, French armies, using this blitzkrieg strategy, had to live off the land by requisitions. Each corps was allotted a requisition area strictly in relation to its prescribed line of advance. Commenting on this later, Napoleon wrote,

We have marched without magazines; circumstances have forced us to do this; but although we have been continually victorious and found vegetables in the fields, we have nevertheless suffered a great deal, and, in a season when potatoes cannot be had from the fields a lack of magazines would lead us into the greatest misfortune.

Gen. Karl Mack, commanding the Austrian Army of about 85,000 men, played into Napoleon's hands. At the beginning of September he advanced westward through Bavaria toward Ulm without waiting for his Russian allies. At Ulm he hoped to command the line of the Danube, with his front and right protected by the Black Forest. By this advance, however, he had greatly lengthened his line of communications; and, even as late as October 9, he was still separated from his Russian allies, who were at Linz, by nearly 200 miles (322 kilometres).

Meanwhile, Napoleon's advance guard crossed the Rhine on September 24, and his army advanced on the Danube from the north and west on its prescribed corps fronts. On October 6 his forces were in the area of Do-

The army  
corps  
system

Austrian  
defeat

nauwörth-Neuberg and then crossed the Danube, leaving Gen. Michel Ney with 40,000 men to cover Austrian escape routes to the north. Napoleon then continued to envelop Mack in the south. Mack made two unsuccessful attempts to break out of the ring and then capitulated at Ulm on October 20 with 50,000 men. (If great victories consist of beating an enemy at a minimum cost in actual fighting, then Ulm was one of the greatest of Napoleon's victories.)

Austria was not yet completely defeated. On November 13, three weeks after Trafalgar, Napoleon entered Vienna; but he still faced a combination of Russians commanded by Gen. Mikhail Kutuzov and two Austrian armies from Italy and the Tirol. Moreover, Napoleon himself was now operating at the end of a long line of communications. Had the Allies waited—they were, after all, on their own ground—time would almost certainly have been on their side; but some of them, particularly Tsar Alexander, were impatient and chose to attack. On December 2 Napoleon routed them at Austerlitz, a battle-field victory even more complete than the victory at Ulm.

In the resulting Peace of Pressburg, signed at the end of 1805, Austria ceded its last Italian possession, Venice, to France, gave the Tirol to Bavaria, and recognized the rulers of Bavaria and Württemberg as independent kings. Already cut off from the Rhineland, Austria was excluded from Italy and gravely weakened in southern Germany.

#### The campaigns against Prussia and Russia, 1806–07.

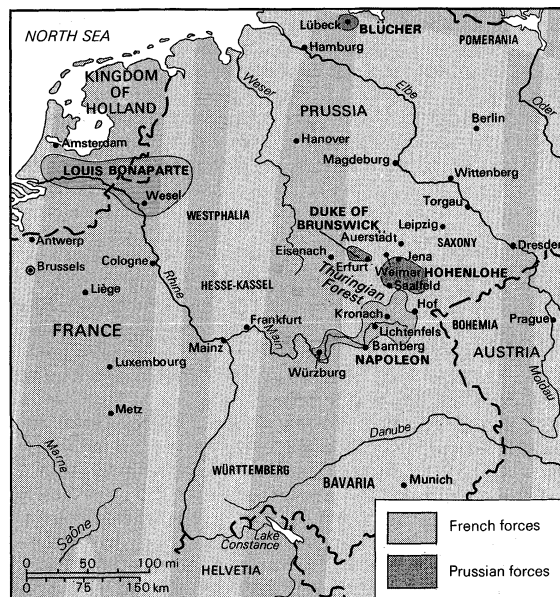

During the 1805 campaign Prussia had been tempted to join the Allies; such a move might have threatened Napoleon's left flank as he moved along the Danube Valley and perhaps even have denied him victory. Frederick William III, however, delayed acting until after Austria had been defeated, thus weakening his position when he himself was attacked.

Throughout 1806, relations between France and Prussia steadily worsened. Despite his continued gestures of friendship toward Prussia, Napoleon appeared determined to weaken Prussian influence in northern Germany, and his independent negotiations with Britain over Hanover underlined this. Furthermore, after Austerlitz Napoleon kept the bulk of his army in Germany, stretched out along the line of the Main River; by October 1806 he had about 200,000 men on a line running from Lichtenfels through Bamberg to Würzburg. The Prussians regarded this troop concentration as a threatening gesture; Russia, too, was suspicious of Napoleon's intentions. On September 26, Frederick William III of Prussia sent an ultimatum to Napoleon demanding that the French withdraw west of the Rhine and agree to the formation of a north German confederacy under Prussian leadership. Napoleon rejected the ultimatum. On October 8 Prussia, in alliance with Russia, declared war on France.

The overall strategic situation was not unlike that in 1805. With promises of help from Russia and from Sweden and Britain too, there was much to be said for the Prussians staying on the defensive on the line of the Elbe and waiting until help arrived. The Elbe formed the great natural defense of Prussia against attack from the west, and the main passages across the river were guarded by the fortresses of Magdeburg, Wittenberg, Torgau, and Dresden, which also controlled the principal routes into Berlin and East Prussia. The one advantage of advancing west of the Elbe was that Saxony and Hesse-Kassel might join with Prussia if protected in this way but probably not otherwise. Indeed, Saxony could help Napoleon directly by offering him an unopposed passage of the Elbe at Dresden.

In fact the Duke of Brunswick, in command of the Prussian army, advanced west across the Elbe, then divided his forces in two—the main part under his command concentrated in the area of Erfurt, the other part south of him, commanded by F.L. Hohenlohe-Ingelfingen and concentrated between Hof and Saalfeld in the Upper Saale Valley. These two forces were separated by the difficult terrain of the Thuringian Forest.

For Napoleon the possible routes from the Rhine into

Prussia were either from Wesel across Westphalia and Hanover, from Frankfurt via Eisenach and Weimar to Leipzig, or from Frankfurt via Bamberg to the south of the Thuringian Forest and thence either by Leipzig or Dresden. He treated the first route, the most northerly, as cover against possible enemy retaliation, leaving a corps under E.A. Mortier to link up with a force under Louis Bonaparte, whom Napoleon had made king of Holland. This tactic meant that, with a northern escape route safe, he could risk his other lines of communication. He then planned his advance along the third route, telling Louis weeks in advance that he intended to be in position to attack the Prussians on October 12. He left Mainz on October 1, used magazines at Würzburg and Kronach on the way, and crossed the frontier of Saxony on October 8. His rapid deployment took the Prussians by surprise, and Hohenlohe promptly began to retreat north-eastward toward the Elbe when contact was established on October 12, as Napoleon had predicted. On October 14 Napoleon overwhelmed Hohenlohe at Jena, while Louis-Nicolas Davout, sent round the flank to block a Prussian retreat, encountered the main Prussian force at Auerstadt and defeated them also. The battle had not gone quite in detail as Napoleon planned, but in general execution he had dictated the critical time and place and had made the Prussians conform to his own movements.

Prussian retreat followed. On October 25 Napoleon entered Berlin, and ten days later the Prussian rear guard under Gebhard Leberecht von Blücher capitulated at Lübeck. Prussian resistance was at an end. Russia, however, was still in the war; in November Napoleon invaded East Prussia and then Russian-controlled Poland, occupying Warsaw a week before Christmas. Marching still farther eastward, he met the Russian Army under Leontyevich Benningsen at Eylau (February 8, 1807), fighting a bloody and indecisive battle. In mid-June, despite his long line of communications and his earlier losses, Napoleon routed Benningsen at Friedland, driving the Russians back across the Niemen while he himself entered Königsberg.

The war was over, and peace was signed at the Treaty of Tilsit on July 9. This treaty really dealt with Prussia rather than Russia. Prussia lost all its territory west of the Elbe and the part of Poland it had gained most recently. Its territory was thus halved and its army reduced to 40,000 men, one-fifth of its previous size. (Prussia lost more, at one blow, than any other of Napoleon's principal enemies.)

Russia emerged virtually unscathed from the 1806–07 campaign. Indeed, it became an ally of France, and the

The  
Treaty of  
TilsitPrussian  
advance

events of the next few years were, to some considerable extent, based upon this Franco-Russian alliance.

**Napoleonic warfare.** Some characteristics of Napoleon as a strategist are clear. First, he devoted infinite care to the preparation of a campaign in all its aspects. He examined the chosen theatre of operations, however far away, in all available detail beforehand and laid down a full timetable of operations; approach routes and requisition areas were prescribed. Second, he analyzed the enemy's likely plans and reactions as carefully as his own and, in many cases, in terms of the known characteristics of individual commanders. Third, he used time and distance to surprise and deceive the enemy, catching him a day or two sooner than expected; such manoeuvres gave French forces a number of options at their disposal, thus continuing to leave the enemy uncertain of French intentions until a few hours before fighting began. (It is important to remember, however, that the blitzkrieg strategy based on these principles of action demanded good road and river transport systems for rapid and alternative movements and also a fairly high level of agricultural production to provide adequate requisitions. When he operated later in Russia, Napoleon found very different conditions from those to which he had grown accustomed in western and central Europe.)

On the battlefield, at the tactical level, Napoleon was a great general though not an innovator. He made maximum use of the weapons and tactical doctrines he inherited. Above all and like Clausewitz he believed that great strategic results can normally be achieved only by great battles; therefore, it was always his object to rout the enemy, whether on the battlefield or in retreat, and he was willing to accept heavy losses among his own men in order to achieve this result. On the battlefield, broadly speaking, his objective was to punch a hole in the enemy lines and then exploit it. For this reason, while well aware of the value of great firepower inherent in infantry line formations, he also used the heavy-infantry column. Similarly, while rarely deploying more or heavier guns than his enemies, he often massed them for concentrated force; and he sometimes used concentration of cavalry on the battlefield for the same purpose as well as for subsequent exploitation. The essence of his tactical doctrine was concentration of power, just as the essence of his strategic approach was to make that concentration available where and when it suited him best.

#### THE COERCION OF EUROPE, 1807-11

With the signing of the Treaty of Tilsit, Napoleon found himself at the peak of his power. So long as he and Alexander I could agree and, in agreeing, coordinate their policies, Napoleon could anticipate a time when all continental Europe would lie under his control. The Continental System that he organized in detail was the most obvious expression of his power. The first signs of decline, however, coincided with the period of ostensibly greatest power. As the expansion of French power became increasingly identified with blatant imperialism, the seeds of nationalist revolt began to bear fruit—first in Spain and then in Austria—producing movements that, in the end, broke Napoleon's power. Moreover, the Continental System was too ambitious politically, administratively, and economically, and it weakened its creator as much as it strengthened him.

**The Continental System.** Trade war against Britain was not initiated by Napoleon. After war broke out between Britain and France in 1793, the republic did its best to exclude British goods from the areas under its control. The Directory stepped up measures against British trade and ordered the seizure of all vessels that put in at British ports and then sailed on to France. Moreover, the theoretical inspiration of this kind of warfare was similar both before and after Napoleon became first consul. A well-established mercantilist strain in French thinking on these matters held that the best way to defeat a major trading power such as Britain was to stifle or cut off its exports and thus reduce its stocks of gold; this view was itself based on the theory that gold, produced by a favourable balance of trade, was a vital indicator of na-

tional power. Napoleon based his Continental System on these theories. The difference between him and his predecessors was a practical one—his conquests and particularly his conquest of Prussia and subsequent agreement with Russia enabled him to apply such a policy on a genuinely continental scale. Although he was a radical in his approach to methods, he remained a conservative (some would say a reactionary) in his economic theories. Finally, after Trafalgar and even more so after Britain's seizure of the Danish fleet in 1807, Napoleon had no reasonable hope of resuming normal warfare at sea; and even the threat of his privateers was severely reduced in face of an increasingly effective convoy system carried out by the Royal Navy. To that extent and whatever Napoleon's original hopes of its success, the Continental System can be regarded as a method adopted for lack of something better.

The defeat of Prussia at Jena meant that Napoleon could control a long stretch of the Baltic coast. On November 21, 1806, Napoleon issued his Berlin Decree, which placed the British Isles in a state of blockade. This action meant that trade with Britain was prohibited and that all vessels coming to ports under French control directly from Britain or its colonies would be seized. With Russia adhering to the System and with Portugal and Spain coming under French control in 1808, Napoleon could well claim that he hoped to conquer the sea by the land. The government in London retaliated with a series of Orders in Council in 1807, the object of which was essentially to bring seaborne trade with Europe as far as possible under British control by allowing such trade in neutral ships to take place only by license. This neutral trade was considerable—in 1807 about 44 percent of all trade passing through British ports was in neutral ships, and these ships were to come under British direction as well as provide a useful source of income for the treasury through the issue of licenses.

Napoleon's reply to the Orders in Council was to take his own system a stage further. By the Fontainebleau and Milan decrees of 1807, he ordered that all neutral ships conforming with the rules laid down by the Orders in Council should be treated as enemy ships and, where possible, seized. Thus, neutrals had either to risk detention by the British or confiscation by the French; and that dilemma applied particularly to U.S. vessels. A further Fontainebleau decree of October 1810 strengthened the law against contraband and also ordered the public burning of captured British manufactures. Other decrees that year were designed to tighten up Napoleon's own system of import and export licenses.

The restrictions imposed by the Continental System and by Britain's countermeasures had serious effects upon Britain and also upon France and its continental allies and satellites. During 1808 there was a considerable drop in British exports—a fall of about 10 percent from 1806. Cotton and grain imports were also affected, leading to shortages, high prices, and unemployment. The shortage of timber hit hard at both naval and merchant shipbuilding. There was an improvement from Britain's point of view in 1809, when Portugal, Spain, and Spain's colonies escaped from French control and when the Ottoman Empire signed an agreement with Britain.

But 1811 was the most critical year of all for Britain. Its Baltic trade suffered a severe blow when Sweden was included in Napoleon's System. In that year exports to northern Europe were only one-fifth of the previous year's total, and exports to the United States were down by a quarter. Overall, British exports dropped by about a third. The trade crisis was worsened by a monetary crisis in which the pound depreciated and reserves dropped dangerously low. Many Britons talked of peace at any price; had Napoleon—who had recently agreed to the export of French grain to Britain partly to placate French farmers and partly in pursuit of his mercantilist theories—chosen to deny wheat exports to Britain at this point, hunger riots might have tipped the scale in forcing the British to make peace.

While it did produce these undoubtedly serious effects, the Continental System failed in its prime objective of de-

Conti-  
nental  
System

feating Britain by crippling its trade and thus ruining its credit. Napoleon's unsuccessful attack on Russia in 1812 meant that the sizable cracks in the System that had already appeared in Europe became great holes. This situation helped offset some of the effects of the outbreak of war in that year between Britain and the United States, itself a result partly of disputes about the freedom of the seas. Behind these important ups and downs of fortune, however, lay one constant factor—Britain's command of the sea. As the U.S. naval historian Alfred Thayer Mahan has pointed out, Napoleon was bound to lose a trade war against a country that, because of its vast navy and mercantile marine, could offset losses in one area of the world by opening up opportunities elsewhere. And that is precisely what Britain did. Its national debt grew enormously; but basic prosperity was founded upon increasing industrial production and trade, and Britain emerged from the war much wealthier and stronger than it had entered it.

The effects of the Continental System upon France itself were more generally damaging. Napoleon faced two problems. The first was how to make his allies and satellites continue to accept restrictions that were often harmful to them; in the end resentment about the System helped to turn allies into enemies. The second problem was in France, where his situation was equally difficult. It is true that he was always willing, perhaps wisely in a political sense, to sacrifice the interests of his European allies to those of France itself. This favouritism came out quite clearly in licenses granted much more freely to French traders. This preference, however, made little difference to French trade in the long run. At first some French traders welcomed the advantage conferred by the removal of British competition; but France, like other European countries, needed markets and colonial raw materials such as cotton and sugar. Customs receipts and exports fell drastically. Gradually Napoleon lost the support of the middle class, who had gained so much from the Revolution and on whose efficiency and loyalty Napoleon himself depended. Ersatz industries were an adventurous experiment, and some came to stay. By and large, however, the Continental System undermined—or certainly was thought to undermine—prosperity, and Napoleon could not afford that.

**Austria's war of liberation, 1809.** Angered by the terms imposed upon Austria after Ulm and Austerlitz and offended even more by Napoleon's further aggrandizement after the defeat of Prussia, the emperor Francis of Austria and his advisers thought they saw an opportunity for revenge in 1809. The French Army was heavily committed in Spain; and there was rising discontent in Germany, as elsewhere, from the effects of the Continental System. Moreover, the Austrian government had carried out reforms in the army after 1806 and had a military-reserve system by 1808. The tide of public opinion was moving against Napoleon; and, although there was no strong German nationalism evident in Austria or elsewhere at that stage, there was much local patriotism—for example, in the Tirol.

Napoleon was aware of events in Austria and had carefully made his plans by assuring himself of Russia's neutrality. Prussia could safely be ignored for the time being. Moreover, although he spent the winter of 1808–09 in Spain, Napoleon was back in Paris before Austria declared war on France in April 1809. By calling up 150,000 conscripts, he had 300,000 men at his command for operations in central Europe, in addition to the troops committed in Spain.

The Austrian plan was to attack the French in Italy and Dalmatia; to advance into Poland, forestalling help from Russia and the Grand Duchy of Warsaw; and to advance westward along the Danube Valley to drive back the French concentrated at Regensburg and Augsburg before Napoleon could cross the Rhine and come to their aid. The archduke Charles, in command of this last Austrian army, was much too dilatory and allowed Napoleon to join up with Davout's forward army corps. By mid-April Napoleon had concentrated his forces and advanced toward Vienna, defeating the Archduke at Eckmühl on

April 22. The Archduke was forced north of the Danube, and Napoleon entered Vienna on May 13.

The Austrians remained strong both north of the Danube and farther south in the Tirol. Napoleon concentrated his attention on the archduke Charles and his army north of the Danube. On May 20 Napoleon crossed the river by the island of Lobau, and a battle took place at Essling-Aspern on May 21–22 in which, though not completely defeated, Napoleon was mauled seriously enough to retrace his steps across the river. He then fortified his position and, in early July, was reinforced by the army of Eugène de Beauharnais, which had come up from the south. On July 5 Napoleon crossed the Danube again with an army of more than 150,000 men and the next day defeated the archduke Charles at Wagram. An armistice was signed a few days later.

By the Peace of Schönbrunn (October 1809) Austria was yet further humiliated. It lost its Illyrian provinces and ceded much of Upper Austria to Bavaria and most of western Galicia to the Grand Duchy of Warsaw. Its efforts, however, had not been in vain; French troops were withdrawn from Spain. Moreover, Napoleon's greed in taking more Austrian territory for his satellites offended his friends as well as his enemies.

**The Spanish rising and the Peninsular Campaign.** A more prolonged and in many ways very different campaign was meanwhile going on in Spain and Portugal. Spain had been entirely subservient to French policies since 1796; and, although there was a flicker of resistance during the campaign against Prussia, the French victory at Jena brought Spain once more to heel. By then Napoleon was intent on compelling all Europe to accept the Continental System, and Portugal, for so long the ally of England, was an obvious gap in the System. By the Treaty of Fontainebleau of 1807, the Spanish government agreed that French troops could cross Spain on their way to conquer Portugal, and in November the French entered Lisbon. These policies led to deep differences in Spain. In May 1808 the king, Charles IV, abdicated, and in June Napoleon appointed his own brother Joseph as king of Spain. There had already been a popular rising against the French at Aranjuez in March 1808, and the events of that summer spread the flames of insurrection against what was regarded as French tyranny. A national rising against France was the result.

The importance of war in Spain was twofold. Politically it was the clearest indication to date of nationalist resistance to Napoleonic domination, even though it was not a national movement inspired by liberalism. Militarily, it afforded Britain an opportunity to undertake land operations on the mainland of Europe that, at last, were significant in relation to the operations of its allies. For the first time sea power was directly related to land power. The Iberian Peninsula was easy for Britain to get to and to use, and it was difficult for Napoleon to defend. The logistic and military basis of Britain's whole operation was Portugal, which offered a first-rate entry, via the Tagus and Lisbon, and a sound defensive position.

Napoleon himself took command in Spain late in 1808 and very nearly caught a British force before it managed to escape via Coruña. Early in 1809, however, he returned to Paris. In April 1809 Sir Arthur Wellesley (later the duke of Wellington) landed at Lisbon and took command of all British and Portuguese forces there; he had come carefully prepared and had already formed some views about the best ways to fight the hitherto invincible armies of Napoleon.

At a tactical level, Wellesley believed in the value of highly disciplined firepower delivered by an infantry line protected, wherever possible, by natural features or by such man-made features as walls; and he also believed in the importance of light infantry. Secondly, Wellesley was determined to establish an efficient supply system within his army so that it became independent, as far as possible, of army requisitions and could thus move or stay in its positions as the military situation demanded. He abhorred the French system of living off the land, and he considered that it forced the French to move when often they would have served their military purposes better by

Austrian  
opportu-  
nity for  
revenge

War in  
Spain

staying in position. Thirdly, he developed a highly efficient staff system, all the more necessary in a campaign with frequently divided forces; and his staff gave him, among other things, an invaluable series of maps that enabled him to move in difficult country with certainty and speed.

Wellesley's  
strategy

Wellesley's strategy was to use Portugal as his base, with its land frontier defended by a number of great fortresses and with a final defensive area behind the lines of Torres Vedras around Lisbon. The sea was his chief line of supply. In 1809 Wellesley (Viscount Wellington from September 1809) had some early success, driving the French from Portugal and in July defeating them at Talavera; but by the autumn he was back behind the Portuguese frontier.

In 1810, with Austria defeated at Wagram, Napoleon sent reinforcements to Spain; and the positions were reversed. By that autumn the French had captured the Portuguese frontier fortresses and then occupied all of Portugal except the area behind the lines of Torres Vedras.

From then on, Wellington was more certain of his own strength and of enemy weaknesses. In 1811 he began the process of recovering Portugal and, principally, its frontier fortresses. In May he defeated André Masséna at Fuentes d'Onoro and captured Almeida—the first in a series of defeats suffered by the French. In 1812 he captured Ciudad Rodrigo and Badajoz before the end of April, and, in July, he routed the French at Salamanca, going on to enter Madrid in August, thus compelling French forces to withdraw from southern Spain. In the autumn of 1812, however, Wellington ran into strong French resistance as he tried to capture Burgos, and once more he withdrew to winter quarters in Portugal. In 1813 he advanced again, defeated the French at Vitoria, forced them to evacuate central Spain, and began an invasion of southern France across the Pyrenees; by the end of the year he was threatening Bayonne, and in February 1814 he captured Bordeaux. The Peninsular Campaign was now complete. Wellington's advance had been fused into the general Allied attack on France that was to bring about Napoleon's first abdication.

#### THE DEFEAT OF NAPOLEON, 1812–15

Although the Treaty of Tilsit had been, ostensibly, a Franco-Russian alliance and although Alexander I had refrained from embarrassing Napoleon in the difficult situation of 1809, there were increasing causes of tension between Napoleon and the Tsar. Alexander was anxious to extend Russian influence southward through the Balkans, and Napoleon wanted to prevent that influence from reaching the Mediterranean. Napoleon had created the Grand Duchy of Warsaw, and Alexander was suspicious of French influence so close at hand, particularly if Napoleon had it in mind to re-establish the old Kingdom of Poland. Finally, the working of the Continental System produced as much discontent in Russia and in areas of Russian influence as it did elsewhere.

Causes of  
Franco-  
Russian  
disagree-  
ment

**The Russian Campaign, 1812.** These general causes of disagreement partly came to a head in 1810–11. In February 1811 Napoleon seized the Hanse towns and the lands of the Tsar's brother-in-law—the Duke of Oldenburg. That May, when a Frenchman, Jean Bernadotte, was elevated to the throne of Sweden, it seemed to Alexander a French step toward encircling him—although, in fact, Bernadotte (Charles XIV John) proved no friend to Napoleon. In January 1812 Napoleon issued a list of grievances against Russia to his German allies, and in April Alexander presented an ultimatum to Napoleon demanding French evacuation of Prussia, compensation for Oldenburg, and virtually the creation of a neutral zone between the two power blocs. In May, Russia concluded a treaty with the Ottoman Empire and thus freed itself from trouble in the Balkans. In July 1812 a treaty of alliance was signed among Sweden, Russia, and Great Britain.

Meanwhile, Napoleon had already decided that he would invade Russia in June, and he concentrated a vast army of about 600,000 men in the Grand Duchy of War-

saw, drawing heavily on troops from allies and satellites. About 450,000 men actually crossed the Niemen River at the beginning of the campaign and were opposed by fewer than half that number in the Russian forces.

Napoleon had the choice of three good roads leading from west to east and toward Moscow—from Kovno via Vilna, Vitebsk, and Smolensk; from Grodno via Minsk and so to Vitebsk; and from Brest-Litovsk via Kiev to Smolensk. He decided to take the first, the most northerly route, using the Grand Duchy of Warsaw as his strategic base and with his lines of communication lying back through what he thought were friendly areas of Poland and Prussia. His strategic approach, after assembling his armies behind the line of the Vistula from Warsaw to the coast, was to use his right flank as a defense and to attack on his left flank from Kovno eastward with his largest army under his own command.

The Russian forces were deployed in two armies. The larger of the two, commanded by Mikhail Barclay de Tolly, was along the line of the Niemen north of the Pinsk Marshes (*i.e.*, on the right, or north, flank) and comprised about 135,000 men. The Russian left-flank army, commanded by Pyotr Ivanovich Bagration, was to the south of the Pinsk Marshes in Volynia and had a smaller force of about 50,000 men. From the start, the Russian commanders were well aware of the risk of separation and envelopment and were determined on a strategy of withdrawal upon converging lines. Writing to the King of Prussia months before the campaign began, the Tsar said,

The system which has made Wellington victorious in Spain, and exhausted the French armies, is what I intend to follow—avoid pitched battles and organise long lines of communication for retreat, leading to entrenched camps.

Russian  
strategy

Quite apart from avoiding the risk of defeat on the battlefield, such a strategy was bound to impose a heavy strain on Napoleon's forces in their search for food and fodder and in a constantly lengthening communications system in an enemy country. (When Clausewitz wrote some years later that one of the main strategic advantages of the defensive was the ability to make use of the goodwill of the local population, he almost certainly had this particular campaign in mind.)

Two further points of general strategic importance can be made. First, the roads in areas in which Napoleon planned to operate were mostly of poor quality and distinctly inferior in standard to the road systems of western and central Europe. Second, it was normally possible to continue campaigning in western Europe until late in the year without serious inconvenience, but, in Russian winter conditions, victory consisted of survival rather than of defeating the enemy forces; and in the search for survival Napoleon's troops were at a great disadvantage.

On June 24–25 the entire French left wing crossed the Niemen at Kovno almost unopposed. Napoleon expected soon to be behind Barclay, but, when he arrived at Vilna on June 28, he found that Barclay had moved eastward and escaped the net. Moreover and despite the summer weather, logistic problems were already retarding the speed of Napoleon's movement. Although continuing his advance against Barclay, Napoleon turned his attention southward to Bagration, wrongly supposing that the latter was retreating in a northeasterly direction and planning to prevent the two Russian armies from uniting in the area east of Vilna. But Bagration had gone south-eastward instead via Minsk, thus escaping in his turn. Moving again to the north, Napoleon tried to encircle Barclay both at Vitebsk in late July and at Smolensk in mid-August. On both occasions the Russians slipped out of the net again and retreated toward Moscow.

By then the French advance was running into serious supply difficulties, which robbed Napoleon of mobility and imposed on him a blunt frontal attack strategy in place of envelopment. After a bloody action at Borodino on September 7, the Russians continued their retreat; and the pursuing French at last reached Moscow in mid-September. There they found the city devastated by fire but showing no sign of capitulation. After a month in Moscow, Napoleon himself began to retreat, and, al-

The  
French in  
Moscow

though he was at no time defeated by the Russians, he was forced, by the fact that they followed fast on his heels and preyed on his flanks, to follow the route by which he had earlier advanced, but now substantially denuded of supplies. This fact and the severe weather conditions took their toll. Napoleon reached Smolensk on November 8 and crossed the Beresina on the 17th. On December 5, hearing rumours of a conspiracy against him in Paris, Napoleon left his army and made for home. That army was now experiencing the Russian winter; by the time it reached and crossed the Niemen in mid-December, the temperature was  $-30^{\circ}\text{F}$  ( $-35^{\circ}\text{C}$ ), and only about 30,000 men had survived out of the 600,000 Napoleon had so hopefully assembled the previous summer. At the Niemen the Russian pursuit stopped, and the remaining French forces continued their wretched withdrawal unopposed.

Napoleon's military power was not annihilated, as the campaigns of 1813–14 were to demonstrate. But he had lost invaluable troops; his reputation was at last open to question; and his enemies had been given a morale boost that it would take many French victories to destroy. The Russian Campaign was the real turning point in Europe's wars against France.

**The campaigns of 1813–14 and Napoleon's surrender.** Napoleon's prospects were not hopeless in the spring of 1813. Opinion in Prussia was still divided about the advisability of declaring war on France. Russia itself had suffered severely during the 1812 campaign, and many influential Russians argued that, their country once made safe, there was no point in fighting to save the rest of Europe. Austrian attitudes were equivocal; Metternich showed no eagerness to join a crusade against France and seems, in some ways, to have preferred the prospect of a negotiated peace placing Napoleon in power as emperor. (After all, Napoleon was by then married to an Austrian princess—the archduchess Marie-Louise.) Russia and Prussia did, however, conclude the Treaty of Kalisch in February 1813, which was a treaty of alliance against France. During March 1813 the French forces in Prussia were driven back westward, and by mid-March they were back on the line of the Elbe. Meanwhile, Sweden had joined the Allies.

Napoleon's  
choices in  
1813

Napoleon's choices, although not entirely clear, were by no means unpromising. His opponents were divided in their political aims, as they later demonstrated at the Congress of Vienna (1814–15). He might have negotiated with them separately, thus dividing them and achieving at least a compromise peace for himself; or he could have cut his losses in Spain and restricted his fighting to the area east of the Rhine. But he was unwilling to accept the limitations implicit in such choices, and he chose instead to attempt everything without negotiation.

The campaign of 1813 consisted of two parts. The first part began when Napoleon arrived on the line of the Elbe on April 28. He had by then called up the conscripts of the classes of 1813 and 1814 and had 150,000 men at his disposal in Germany. He wanted to cross the Elbe again, strike at the heart of Prussia before it was fully ready for war, and, by threatening the Russian line of communications, draw both Prussian and Russian armies away from Austria, whose neutrality might thus be maintained. One way to do this was to advance directly on Leipzig and Dresden, compelling his enemies to accept battle or withdraw beyond the Elbe. An outright victory was an essential part of this strategy and was necessary to keep Austria and the states in the Confederation of the Rhine friendly toward France; but that victory was denied to Napoleon. Two inconclusive battles took place—the first at Lützen, southeast of Leipzig, on May 2, in which the Allies were worsted but withdrew in good order; the second at Bautzen on May 20–21, with much the same result. But Napoleon had accepted heavy losses in these battles, and he was at that point much less able to accept them than were the Allies. Further, he signed an armistice with Prussia and Russia at Pläswitz on June 4, which lasted until August 20; this, too, was more helpful to his enemies than to himself—it gave time for Prussia to mobilize its reserves and for Austria to decide to join the

Allies—and, when the armistice ended, Napoleon was relatively worse off than when it had begun.

In the second part of the campaign of 1813 the Allies put three armies into the field, comprising some 600,000 men, against whom Napoleon mustered 400,000. The Allies planned to converge from Prussia and Silesia upon Dresden; as on previous occasions, Napoleon's plan was to engage and defeat them separately. A number of distinct but related battles followed. On August 26 and 27 an Austrian army was defeated at Dresden, but on August 30 and then on September 6 the French were defeated, first at Kulm and then at Dennewitz. For Napoleon these defeats were more important than the earlier victory because the Allies continued to threaten him, gaining relatively in strength all the time. During the first part of October the Allies converged on Leipzig, where the Battle of the Nations (October 16–19) took place. By then Bavaria had joined the Allied cause, and Napoleon found himself fighting with an army of 160,000 against combined enemies who could bring against him double that number. Moreover, his enemies knew the danger of accepting battle separately and the need to maintain contact with each other.

At first Napoleon held his own. But on October 18 the Saxon forces went over to the Allies and on October 19 Napoleon was forced to retreat toward France, defeating a Bavarian force at Hanau on October 30. On November 2 Napoleon's army fell back across the Rhine at Mainz with fewer than 80,000 of the men with whom he had begun the campaign. By then virtually deprived of allies, this campaign was a blow, added to the disaster of 1812, from which Napoleon could hardly hope to recover.

Retreat to  
France

Yet the Allies themselves were still not set upon the overthrow of Napoleon. In November 1813 they offered him peace if France surrendered all its conquests beyond the Rhine, the Alps, and the Pyrenees. As Napoleon knew, however, there were some among the Allies who advocated harsher terms; the British, for example, were anxious to achieve the independence of French-held Dutch and Belgian regions, and that entailed further French concessions. In the end, between Allied differences of view and Napoleon's own doubts about the possibility of continuing in power on such terms, the Allies failed to provide a basis for peace, and they determined to invade France in 1814.

The campaign of 1814, like that of the previous year, was divided into two parts. The Allies planned to move into France from the north via Dutch and Belgian territory, across the Middle Rhine in the area of Mainz and from Switzerland around the Jura Mountains—an overall plan similar to the one they would adopt in 1815. Napoleon, fighting with numerically inferior forces, decided to tackle the Allied armies separately. In the first part of the campaign (late January and February 1814) Napoleon inflicted heavy defeats on the Prussian and Austrian armies advancing from the Middle and Upper Rhine. The Allies appeared to be breaking up at this stage until more determined counsels prevailed. On March 1 Prussia, Russia, Austria, and Great Britain signed a new alliance committing themselves to war and to peace terms only on conditions agreed to by them all.

The Allies were then set on attacking Paris, and the second stage of the campaign began. Napoleon hoped to draw them off by moving into Lorraine and thus threatening their line of communication, while Paris accepted siege and resisted. The Allies, however, were not diverted by this threat, despite minor local reverses. Moreover, they were by now aware of Napoleon's plan, having captured some of his dispatches; and they also knew that many in Paris were anxious for peace. On March 30 the Allied armies reached the Paris suburbs, and resistance there soon ceased. On April 6 Napoleon abdicated and was soon on his way to exile on the island of Elba, while Louis XVIII returned to Paris as king on May 3.

Napoleon's  
abdication  
and exile

Meanwhile, the Allies settled down to the task of resetting Europe after the long wars; they were still arguing the details when they found themselves at war with Napoleon again.

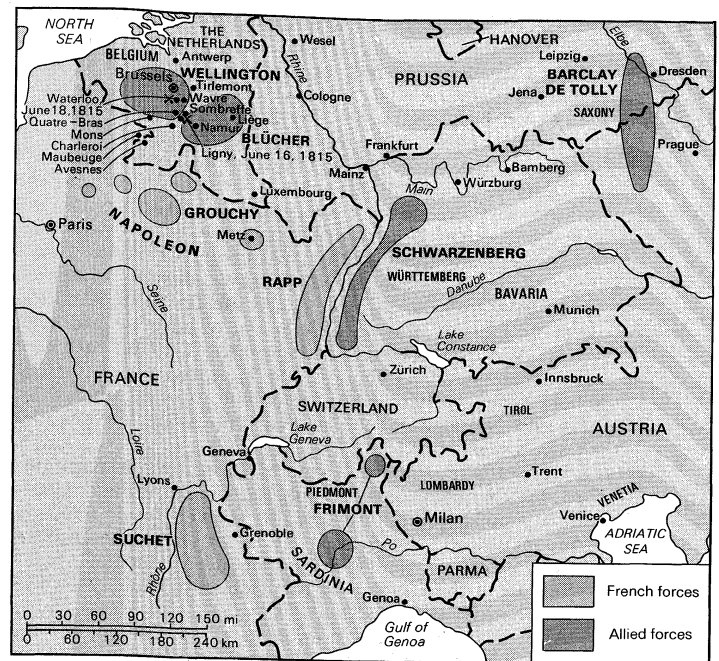

**The Waterloo Campaign.** On February 26, 1815, Napoleon escaped from Elba; he landed on the mainland of France near Antibes on March 1. He set out for Paris via the Dauphiné and on March 7 entered Grenoble without any opposition. With towns and garrisons welcoming Napoleon in what proved to be a triumphal journey, Louis XVIII left Paris on March 19; Napoleon entered the capital the next day. A week before that, the representatives of the Allies at Vienna declared Napoleon an outlaw, describing him as "the enemy and disturber of the peace of the world." The three eastern monarchies—Russia, Prussia, and Austria—together with Great Britain, made a new defensive alliance against Napoleon (only a few weeks before, those same powers had been acting more like enemies than friends in their attempts to settle the affairs of Europe), and each undertook to supply 150,000 men for the armies of the alliance and to keep them in the field until Napoleon was finally defeated.

After the failure of some diplomatic manoeuvres designed to detach Britain and Austria from the alliance, Napoleon realized that there was no alternative to fighting; and he prepared himself for an offensive campaign. First, however, he had to raise armies and equip them. There were many veterans of the Prussian and Italian campaigns in France, a large number of them already committed to serving Louis XVIII, and Napoleon found no difficulty in winning them back to his cause. Conscription of new recruits was politically dangerous; and, if Napoleon planned an early offensive, new recruits could hardly be trained in time anyway. So the existing regulars were supplemented by recalling all undischarged soldiers and those who had deserted since April 1814. Thus expanded, Napoleon's army for the 1815 campaign totalled about 250,000, of whom roughly half were available for his striking force and the rest for frontier and garrison duty. In fact, Napoleon did call up the class of 1815 at the end of May, and during June about 50,000 of them were in barracks; but they played no part in the Waterloo Campaign.

#### The Allied Coalition

The Allied Coalition—the seventh formed against France between 1792 and 1815—planned to raise five armies. An Anglo-Dutch army of 90,000 men commanded by Wellington and a Prussian army of 120,000 commanded by Gebhard Leberecht von Blücher were to operate from the Brussels region into France; an Austrian army of 225,000 men commanded by Karl Philipp zu Schwarzenberg was to operate on the Upper and Middle Rhine; a Russian army of 170,000 men under Barclay de Tolly was to form a strategic reserve; and, finally, an Austro-Italian army of 60,000 commanded by Johann Maria Frimont was to operate from northern Italy. The Allies planned a concentric advance on Paris beginning in late June. Early in April, Wellington left Vienna on his way to Brussels; he met Blücher at Tirlemont on May 3. These two did not expect Napoleon to take the offensive against them but agreed that, if he should do so, they would concentrate on the line between Quatre-Bras and Sombreffe. Accordingly, Blücher moved his headquarters from Liège to Namur, and Wellington established his headquarters at Brussels.

Napoleon's plans, as seen above, were basically offensive. He wanted to meet and defeat some of his enemies before the others were ready and then to go on to deal with them piecemeal while they were still concentrating. The enemy armies posing the most immediate threat were those of Wellington and Blücher. Napoleon therefore decided to attack the combined Prussian and Anglo-Dutch forces himself, in command of the Army of the North, 125,000 strong. Leaving generals Jean Rapp and Louis-Gabriel Suchet on the defensive along the Rhine and opposite the approaches from Switzerland and Italy, Napoleon's approach in the theatre he was directly concerned with was in principle similar to his first great campaign in northern Italy in 1796. He faced an enemy stronger than himself but composed of two armies converging on a common line of advance into France. If those two armies could be attacked at their "hinge" (i.e., where their lines of advance converged and joined) and all the more so if they could be attacked separately,

Waterloo Campaign.

they might be prevented from combining and even be driven back upon their divergent lines of communication. Wellington's line ran back through Brussels to Antwerp; Blücher's, via Namur, Liège, and Cologne. Napoleon's aim, therefore, was to advance from Paris to Charleroi and there force himself between the two enemy armies. If they could both be defeated, he would turn back south-eastward, join Rapp opposing Schwarzenberg, and then deal with the latter. This strategy was an adventurous approach because Napoleon had few of his old marshals with him, training time had been short, and many of his senior officers were strangers to the men they led.

On June 3 Napoleon ordered the Army of the North to concentrate in the area Maubeuge-Avesnes, about 25 miles (40 kilometres) southwest of Charleroi. On June 14 he moved his own headquarters to the Charleroi area, with Wellington and Blücher still unaware of what the French were doing. By nightfall on June 15, Napoleon's forces were disposed in such a way that they could manoeuvre against either enemy as circumstances dictated. Wellington, in fact, had unintentionally helped—fearing that Napoleon might outflank him on the right and so cut off his line of retreat to Antwerp and the sea, Wellington detached a corps to cover the roads leading from Mons and Ath to Brussels, thus moving his centre of gravity eastward and away from Blücher.

Instructing Michel Ney, on the left, to occupy Quatre Bras and thus block Wellington from using the Nivelles-Namur road, Napoleon attacked the Prussians at Ligny, on the Allied left or eastern flank, on June 16. The purpose of this operation was to drive Blücher back eastward and northeastward away from Wellington, and Napoleon counted on support from Ney to reinforce his own left wing to make this possible. The Battle of Ligny was indecisive: the Prussians were, indeed, driven back, but Ney failed to understand Napoleon's strategic plans and did not send the help that might have turned the Prussian retreat into a rout. The next mistake was Napoleon's. He had assumed that, once forced back, Blücher would retreat roughly northeastward via Namur and so move away from Wellington. The Prussian commander, however, was aware of the vital need to maintain contact with Wellington and chose, therefore, to retreat northward in the direction of Wavre. Emmanuel Grouchy, who had been instructed to pursue the Prussians, thus took the wrong road; and Napoleon realized too late that his assumption was incorrect.

The third mistake was also Napoleon's. The essence of

Napoleon's mistakes

his earlier strategy in such a situation was to act more quickly than his enemies and, by gaining even a few hours, to deny them time to settle down and recover. This time Napoleon's conduct of operations fell below his own best standards. The night of June 16 and the morning of June 17 were wasted. When at last Napoleon began to move toward his left at about noon on June 17—a move designed to attack and defeat Wellington—the latter was already well aware of Napoleon's plans and had been given time to draw his army up in a strong defensive position just south of Waterloo. Moreover, Napoleon's march, already begun late, was further hampered by heavy rain. As a result, when the Battle of Waterloo was fought on June 18 all element of surprise had been lost. And by the early evening on the 17th Blücher kept his promise to Wellington and appeared on the battlefield with invaluable reinforcements, turning the scales against Napoleon at the critical time. Waterloo was Napoleon's last battle.

Up to the morning of June 16 Napoleon's preparations for the Ligny–Waterloo Campaign suggested that his military genius was unimpaired. He moved faster than his opponents, and, as far as it lay in his power, he laid the foundations of victory. It was in his conduct of operations from the evening of the 16th until midday on the 17th that he failed.

After Waterloo, Napoleon retreated southward, and on June 21 he entered Paris. The next day he abdicated. A fortnight later Wellington and Blücher also entered Paris, bringing Louis XVIII back with them; 23 years of war were ended.

Result of  
the wars

**Conclusion.** The political result of these long wars seemed, at first, to be simply a restoration of legitimate monarchs and a return to the *ancien régime*. But the political map and, even more, the political temper of Europe had changed, and nothing could put things back as they were. In warfare something of the same sort of contradiction is evident. In the century after Waterloo, war in Europe appeared to lose its total quality; the wars of the 19th century were limited wars—wars involving political change but also wars for limited areas of territory. Yet the total quality was dormant, not dead. It influenced men's arguments and theories, if not always their actions. As the 19th century progressed, the concept of "the nation in arms" was debated more and more against the background of a steady spread of the nation-state and of democratic forms of government. Finally, total war made its appearance again with the great wars of the 20th century, which, although fought with entirely new weapons, were fought also with the ideas and the emotional impulses of a century earlier.

## Freshwater, Geochemical Properties of

The compositions of freshwaters—that is, waters that are dilute and generally potable or suitable for drinking—vary greatly in the proportions and concentrations of contained solutes (dissolved substances). Freshwater properties are the result of the phenomena that are the concern of geochemistry, which is the study of the struc-

ture and composition of the Earth in terms of the physical and chemical processes and principles that produce and modify the minerals and rocks of the Earth. In general, this article is restricted to freshwaters on and below the land surfaces and their precursors and deals with waters that have but a few hundred milligrams per litre of total solutes, although the processes discussed are capable of yielding much larger concentrations.

Water on or within the land may have more than 1,000 milligrams per litre of any number of solutes, commonly including the cations, or positive ions (an ion is an atom or group of atoms that has lost or gained one or more electrons and as a result is negatively or positively charged), sodium ( $\text{Na}^+$ ), calcium ( $\text{Ca}^{2+}$ ), magnesium ( $\text{Mg}^{2+}$ ), potassium ( $\text{K}^+$ ), and ferrous iron ( $\text{Fe}^{2+}$ ) or the anions (negative ions) chloride ( $\text{Cl}^-$ ), bicarbonate ( $\text{HCO}_3^-$ ), carbonate ( $\text{CO}_3^{2-}$ ), or sulfate ( $\text{SO}_4^{2-}$ ). It is difficult to establish a satisfactory upper limit for solute concentrations to define freshwater in terms of potability, because some waters are considered nonpotable by human beings on the basis of taste, odour, or the known presence of certain solutes. Also, bacterial contamination or parasitic infestation may render freshwater nonpotable, and there may be more compelling reasons for a nonpotable classification, such as, for example, lethal concentrations of arsenic or other poisonous substances.

Difficulty  
of defining  
potability

Similar difficulties in definition are encountered if suitability to species other than man is considered. Water suitability depends not upon salt concentration alone but also upon nutrients and poisonous substances. Boron compounds, such as boric acid ( $\text{H}_3\text{BO}_3$ ) and borate ion ( $\text{H}_2\text{BO}_3^-$ ), in concentrations harmless to man can be lethal to citrus plants, toxic to stone-fruit trees, and not harmful to other vegetation. Nor does the origin of freshwater offer a useful criterion.

Most freshwater is precipitated as snow and rain, but freshwater is also formed by repeated freezing and thawing of sea ice; the salts are excluded by fractional crystallization, yielding freshwater. Freshwaters are also formed by the condensation of natural steam in geothermal fields, such as those in Yellowstone National Park in the United States, southwestern Iceland, the upper basin of the Waikato River in New Zealand, and a number of other countries.

For information on the several water environments within the hydrosphere, see PRECIPITATION; HUMIDITY, ATMOSPHERIC; RIVERS AND RIVER SYSTEMS; LAKES AND LAKE SYSTEMS; ICE SHEETS AND GLACIERS; ICEBERGS AND PACK ICE; and GROUNDWATER. The interrelations are covered in the article HYDROLOGIC CYCLE. For more detailed treatment of water chemistry, see SOLUTIONS AND SOLUBILITY; ACID–BASE REACTIONS AND EQUILIBRIA; and WATER. See also GEOCHEMICAL EQUILIBRIA AT LOW TEMPERATURES AND PRESSURES.

## FRESHWATER COMPOSITION

Evaporation from the seas, the ultimate reservoir, yields water vapour and extremely small particles of salt, aerosols that may blow in over the land. The evaporation changes the water composition markedly because the water vapour cannot take with it the solids that are in solution in the water. There is a change not only in the water's chemical composition but also in its isotopic (isotopes are varieties of a chemical element that differ in atomic weight but are very much alike in chemical properties) composition. Because of difference in molecular motion, oxygen-16 (the elemental oxygen of atomic weight 16) tends to escape more rapidly than oxygen-18 (so-called heavy oxygen, the nonradioactive isotope, which has atomic weight 18). Hydrogen also has a greater tendency to escape from liquid water during evaporation than its heavier stable isotope, deuterium (D). Thus the water vapour is enriched in oxygen-16 and hydrogen and is isotopically lighter. If the water vapour were to stay in contact with the seawater, the exchange across the interface would yield predictable equilibrium ratios of oxygen-18:oxygen-16 and deuterium:hydrogen. Removal of the water vapour, which may be swept away by the wind, precludes the equilibrium, so that the ten-

Evapora-  
tion effects

dency persists for the water vapour to be lighter isotopically than the liquid water.

Upon precipitation, the heavy oxygen and the deuterium tend to condense first, and there is another isotopic separation of fractionation, the precipitation being heavier isotopically than the remaining water vapour. The remaining water vapour condenses, yielding precipitation progressively lighter with the diminishing concentrations of the oxygen and hydrogen isotopes in the water vapour. The isotopic composition of a single storm's precipitation cannot be forecast; in part, it depends upon the origin of the water vapour. Storm systems with isotopically light polar water vapour yield isotopically light precipitation; conversely, storms with isotopically heavy tropical water vapour yield isotopically heavy precipitation. In addition, the fractionation upon condensation may vary with meteorological conditions. Though the isotopic composition of precipitation along a storm track or at a given point the storm passes cannot be accurately predicted, water can be said to be generally lighter inland and toward the poles. Only a part of the precipitation remains for long near the point at which it falls. The small amounts of precipitation that penetrate to the water table (*i.e.*, the top surface of the water-saturated layer within the soil) are homogenized by dispersion, and groundwater (the slowly percolating water below the water table) has an isotopic composition in deuterium: hydrogen and oxygen-18:oxygen-16 that is characteristic of the locality. Water quickly lost to flow in open channels soon shifts its isotopic composition by nonequilibrium evaporation.

In addition to changes in isotopic composition, changes in chemical composition occur with phase changes. The water vapour condenses on dust or aerosol particles that are more or less soluble, and, as they fall, the drops capture more particulate matter and also dissolve gases from the air. Despite such solution reactions, precipitation is the purest water commonly found in nature. Although very dilute and hence having a high potential for dissolving matter, the capacity of precipitation to dissolve is small. Precipitation is poor in reactive ions, such as the hydrogen ion; there is too little carbon dioxide in rainwater to yield much hydrogen ion by the reaction

In areas of heavy precipitation, much material within the soil may be leached (*i.e.*, removed by the percolating actions of groundwater) away, but the effect will be accomplished by very dilute solutions, a large quantity of which will remove as much material as a smaller amount of more concentrated solutions.

The most dramatic change in the composition of the precipitation occurs when it reaches the solids of the Earth's surface. Rain, which usually contains only a few milligrams per litre of dissolved matter, may be abruptly changed by reactions on foliage or the ground where concentrations rise to tens of milligrams per litre. If some of the rainwater returns to the atmosphere by evaporation or transpiration of plants there may be an increase in solute concentration in the remainder. Precipitation usually penetrates the ground in its flow to stream channels. The zone of the soil in which water does not fill all available pore spaces, the unsaturated zone, transmits water in part to the water-saturated zone (at and below the water table) and laterally down to stream channels. The most rapid changes in freshwater compositions generally occur between the surface and the water table, for groundwaters, or in the channel, if the water drains from the unsaturated zone without joining the groundwater body in the saturated zone. Within the unsaturated zone the changes in freshwater compositions are caused by leaching of the minerals present and the resultant mineral changes, termed weathering, and are a factor in soil formation. Biologic agents, which include an immense number of micro-organisms—*e.g.*, bacteria, fungi, algae, and protozoa—greatly enhance the solution reactions. Burrowing organisms—*e.g.*,

moles, ground squirrels, worms, slugs, lizards, snakes, and many insects—open channels, increasing water flow; many micro-organisms—*e.g.*, fungi, actinomycetes, and most soil bacteria—also may extract nutrients from the soil and, upon decay, may leave the mineral constituents in a form more readily soluble in infiltrating water. The greatest effect on the compositions of infiltrating water is caused by plants. Plant roots respire carbon dioxide ( $\text{CO}_2$ ), tending to increase the hydrogen-ion ( $\text{H}^+$ ) concentration in the water present. Most of the reactions among minerals and water involve the hydrogen ion ( $\text{H}^+$ ). In water under grasslands, the concentration of carbon dioxide is approximately 1,000 times that of water in equilibrium with air. Thus, the incoming rain would have only  $\frac{1}{1,000}$  the carbon dioxide content of the infiltrated water in and below the roots of the grasses; hence rainwater is far less potent a solvent than the carbon dioxide-rich water resulting from plant-root respiration. Forests commonly increase the carbon dioxide content of soil and groundwater 100 times above the content of rainwater, and even the sparse vegetation of deserts adds two to ten times the  $\text{CO}_2$  found in rain.

**Values of pH and chemical reactions.** *Relative ion concentrations.* The hydrogen ion ( $\text{H}^+$ ), which is of great importance to geochemical reactions, is involved in most of the reactions that control the composition of freshwaters. The effective concentration of the hydrogen ion is called the activity of the hydrogen ion and is expressed by the use of the pH scale, which is a means of representing the acidity or basicity of a solution.

Water ionizes as  $\text{H}_2\text{O} \rightleftharpoons \text{H}^+ + \text{OH}^-$ , and, when the concentrations of the hydrogen ion ( $\text{H}^+$ ) and the hydroxide ion ( $\text{OH}^-$ ) are equal (each is  $10^{-7}$ ), which is expressed as pH 7, the water is called neutral. The ionic product of water is  $10^{-14}$  at  $25^\circ\text{C}$ , so that an increase in the concentration of either the negative or the positive ion results in a decrease in the concentration of the other. Accordingly, when the concentration of the hydrogen ion ( $\text{H}^+$ ) is increased, for example, to  $10^{-4}$ , the solution is acid, and the hydrogen-ion concentration is expressed by a pH number of less than 7 (pH 4 in the foregoing example). Conversely, an increase in concentration of the hydroxide ion ( $\text{OH}^-$ ) to  $10^{-4}$  results in a decrease in hydrogen-ion concentration to  $10^{-10}$ , and the pH number is 10 for the resulting alkaline or basic solution.

In this article, low pH means concentration of the hydrogen ion ( $\text{H}^+$ ) greater than that of the hydroxide ion ( $\text{OH}^-$ ) and an acidic solution; high pH means concentration of the hydroxide ion greater than that of the hydrogen ion and a basic, or alkaline, solution.

**Buffer capacity.** Although pH values give the effective concentration of hydrogen ion ( $\text{H}^+$ ), they do not indicate the capacity to supply  $\text{H}^+$  as it is used up in various reactions. The reaction yields  $\text{H}^+$  as  $\text{CO}_2$  reacts.

The amount of  $\text{CO}_2$  available is the buffer capacity of the system, which reacts to resist changes in pH when either acids or bases are added. In effect the hydrogen ion,  $\text{H}^+$ , may react with the bicarbonate ion,  $\text{HCO}_3^-$ , and be stored as carbon dioxide and water with only a small pH change. The reaction is reversible; a small change in carbon dioxide will cause a small change in hydrogen ion and bicarbonate ion. The greater the concentrations of dissolved carbon dioxide and bicarbonate ion, the larger the buffer capacity; that is, the larger the capacity for the solution to react. Solutions rich in carbon dioxide are aggressive solvents not only because of their low pH but also, and more importantly, because they have a larger buffer capacity and, by supplying more  $\text{H}^+$ , can continue to react and dissolve more minerals.

The bicarbonate ion also acts as a buffer at higher pH values as

This reaction is also readily reversible; if  $\text{H}^+$  is used up,  $\text{HCO}_3^-$  ionizes to yield more, and, if  $\text{H}^+$  is added, the

The activity of the hydrogen ion

Capacity for chemical reactions

$\text{CO}_3^{2-}$  reacts to store much more of the added  $\text{H}^+$  as  $\text{HCO}_3^-$ .

The carbon dioxide and bicarbonate-ion concentrations are equal at 25° C at pH 6.4. The bicarbonate-ion and carbonate-ion concentrations are equal at pH 10.3. The carbon dioxide, bicarbonate-ion, carbonate-ion buffers are the dominant buffers in most freshwaters, and it is unusual to find freshwaters outside the pH range of 6 to 9. The most common causes of pH values less than 6 are oxidation of sulfides or ferrous iron. Some well waters contaminated by recently used portland cement may have pH values greater than 9. Uncontaminated waters of pH greater than 11 have been ascribed to reactions with magnesium-iron silicates (olivines and pyroxenes).

Differences  
in rock-  
mineral  
reactions

**Composition generalizations.** Observations of compositions of freshwaters lead to some crude qualitative generalizations, meant only to serve as a guide to what is usual. More detailed and exact relations will be developed later. The generalizations apply to waters from most igneous and metamorphic silicate rocks and to some, but certainly not all, sedimentary rocks. Hydrologic conditions to be described may also give rise to exceptions to the generalizations.

With these qualifications, it may be said that calcium-bearing minerals seem to react most readily with infiltrating waters. Calcium-ion ( $\text{Ca}^{2+}$ ) concentrations are usually higher than the concentrations of other cations. Sodium-ion- ( $\text{Na}^+$ ) bearing minerals seem less reactive, and the  $\text{Na}^+$  concentrations are usually below those of  $\text{Ca}^{2+}$ . Minerals bearing magnesium ion ( $\text{Mg}^{2+}$ ) seem even less reactive in freshwaters than those bearing the sodium ion. Potassium-ion- ( $\text{K}^+$ ) bearing minerals apparently have even lower solubilities, and usually  $\text{K}^+$  is the least concentrated of the common cations.

The composition ranges most commonly encountered in freshwaters are, for calcium, sodium, and magnesium ions, a few to tens of milligrams per litre, in most cases, the relative concentrations will be  $\text{Ca}^{2+} > \text{Na}^+ > \text{Mg}^{2+}$ . Potassium-ion ( $\text{K}^+$ ) concentrations usually are in the range from a few tenths to a few milligrams per litre.

**Cations.** Two types of reactions supply the cations to freshwater, congruent and incongruent. Congruent reactions are those that dissolve the mineral completely, as for quartz (silica,  $\text{SiO}_2$ ),

As simple as the reaction seems, quartz rarely is the mineral that supplies the silicate found in freshwater. Observations show that at temperatures much below 200° C (about 400° F), quartz dissolves and precipitates very sluggishly. Other silica-containing minerals react more rapidly and supply the  $\text{Si(OH)}_4$  found in freshwaters. Gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ) and anhydrite ( $\text{CaSO}_4$ ) also dissolve congruently as

Calcite ( $\text{CaCO}_3$ ) and dolomite,  $\text{CaMg}(\text{CO}_3)_2$ , dissolve congruently as

As salts accumulated in saline or alkaline soils dissolve, other congruent reactions may be found, but, although such reactions are of great local importance, they are not the sources of most of the cations.

The greatest source of cations are aluminosilicate minerals. In general they react incongruently (*i.e.*, only part of the mineral dissolves, or if the mineral dissolves entirely some constituents reprecipitate). For the potassium feldspars ( $\text{KAlSi}_3\text{O}_8$ ), the solution reaction yields more potassium ion,  $\text{K}^+$ , than silica,  $\text{Si(OH)}_4$ , and more silica than aluminum (in its various forms) to solution. Observations on calcium, sodium, and magnesium aluminosilicates are the same. Thus for the most common and most concentrated cations the general reaction is cation aluminosilicate  $\rightarrow$  cation + aluminum-rich silicate. The result is aluminum-enriched, cation-depleted materials and ultimately leads to clays in mature soils.

It is important that incongruent reactions yield cations without corresponding anions demanded by the laws of electrostatics. The pH of most dilute waters is too low for appreciable anionic silica or aluminum. The key to the leaching process is the ubiquitous carbon dioxide-bicarbonate-ion ( $\text{CO}_2 \rightarrow \text{HCO}_3^-$ ) relation. As the attack on the silicates proceeds, hydrogen ion ( $\text{H}^+$ ) is used up and is replaced by other cations such as the calcium, sodium, magnesium, and potassium ions ( $\text{Ca}^{2+}$ ,  $\text{Na}^+$ ,  $\text{Mg}^{2+}$ ,  $\text{K}^+$ ). Not only is the electrical charge balance maintained by replacing  $\text{H}^+$  by other cations, the reaction shown below provides the balancing anion  $\text{HCO}_3^-$ :

Demands  
of electro-  
static laws

**Anions.** With the exception of the congruent reactions, the sources of the anions are different from the sources of the cations. The bicarbonate ion is supplied chiefly by plant-root respiration; its source is thus, indirectly, the Earth's atmosphere. Mineral sources must be sought for other anions.

Sulfate ions are the easiest anions to account for. Locally, the important sources may be gypsum or anhydrite in sedimentary rocks or in salt accumulations in some soils; more generally, the sulfates come from oxidation of sulfide minerals. Sulfide minerals commonly occur in minor amounts in igneous, metamorphic, and sedimentary rocks. Infiltrating waters may oxidize the sulfide minerals, usually in incongruent reactions. The most common sulfide mineral is pyrite ( $\text{FeS}_2$ ), and, usually, if the water contains dissolved oxygen, the reaction yields sulfate ion ( $\text{SO}_4^{2-}$ ) in solution and mixtures of iron oxyhydroxides that are grouped under the name limonite.

Chloride-ion sources have long been a subject of speculation. Few common minerals have much chloride in their structure and certainly yield less chloride ion ( $\text{Cl}^-$ ) than sodium ion ( $\text{Na}^+$ ). It is a continuing problem to account for the  $\text{Cl}^-$  found in natural freshwaters. A supply certainly must be available to account for the sodium chloride-type brines, such as those of the Great Salt Lake of Utah. Chloride-ion sources to account for the composition of freshwaters remain a problem for further investigation. Chlorides are, of course, added by such human activities as waste disposal and salting of roads either for dust abatement or ice removal.

Anions that are minor but sometimes important include fluoride ( $\text{F}^-$ ), arsenates ( $\text{H}_2\text{AsO}_4^-$ ,  $\text{HAsO}_4^{2-}$ ), nitrate, and phosphate. Fluoride ion ( $\text{F}^-$ ) substitutes freely for hydroxide ions ( $\text{OH}^-$ ) and may be a minor constituent of many hydroxyaluminosilicates, such as clays and micas;  $\text{F}^-$  also substitutes for  $\text{OH}^-$  in the common mineral apatite,  $\text{Ca}_5(\text{PO}_4)_3(\text{OH},\text{F})$ . Leaching of any of the minerals containing fluoride ion may yield  $\text{F}^-$  in solution, commonly at most a few milligrams per litre, although much higher concentrations may be found. Arsenate ions generally stem from oxidation of mineral sulfides such as orpiment ( $\text{As}_2\text{S}_3$ ) and realgar ( $\text{AsS}$ ), minor sulfosalts, native arsenic, or the fairly common arsenopyrite,  $\text{FeAsS}$ . Once oxidized, the arsenic may form any of a number of fairly soluble arsenate minerals that may be further leached.

Nitrates in water are usually the result of the oxidation of nitrogenous wastes or leaching of fertilizers, although oxidation of naturally occurring ammonium ion ( $\text{NH}_4^+$ ) also is observed. The nitrogen compounds are nutrients

Organisms and freshwater composition

for a large number of organisms and, where present in high concentrations, foster unusually heavy growths of aquatic organisms. Small concentrations less than one milligram per litre of the nitrate ion,  $\text{NO}_3^-$ , may be caused by natural nitrogen fixation in soils.

Phosphates are also biologically active, being essential nutrients. High concentrations in water may promote quite heavy growths of aquatic organisms. High phosphate concentrations usually result from leaching of fertilizers or from wastes. Under natural conditions, phosphate ( $\text{H}_2\text{PO}_4^-$  and  $\text{HPO}_4^{2-}$ ) concentrations are of the order of a few hundredths to a few tenths of a milligram per litre. The low concentrations reflect the insolubility of the most common phosphate material, apatite. Precipitation of iron phosphates in soils and removal of phosphates by organisms also helps to keep phosphate concentrations at low levels.

#### CHEMICAL REACTIONS

**Cation exchange.** The solutes in freshwater are constantly reacting. In addition to the congruent and incongruent reactions, there is a constant exchange between solutes and coexisting solids. A very important type of exchange is cation exchange. Most minerals, except for native (*i.e.*, uncombined) elements and sulfides, may be thought of as an oxygen-cation framework. The cations that hold the structure together, such as silicon, aluminum, magnesium, iron ( $\text{Si}^{4+}$ ,  $\text{Al}^{3+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Fe}^{2+}$ ,  $\text{Fe}^{3+}$ ) and the like, are much smaller than the oxygen ( $\text{O}^{2-}$ ) ions. As a consequence, the surfaces of most minerals are occupied by oxygen anions ( $\text{O}^{2-}$ ), in part bound ionically to the cations in the interior of the mineral. Rather weak ionic bonds may hold cations onto the surface  $\text{O}^{2-}$  ions. The reactions that involve the exchange of cations between the surface of the mineral and the solution are quite rapid; the rapidity of exchange brings about an adjustment of cation proportions at the surface to approximately the cation proportions in the solution. There are, of course, exceptions. Potassium ion ( $\text{K}^+$ ) is such a good physical fit in the clay mineral illite that it nearly excludes other cations. Cationic-exchange sites range widely in selectivity for the cations, depending in part on physical dimensions and in part on charge distribution.

The reactions that remove or add solvents may be thought of in terms of transport continuity. If a solute is in solution all along the part of the water path studied, the transport is continuous; if for any of a number of physical reasons the solute precipitates, the transport is discontinuous. Many of the discontinuities in transport lead to commonly observed geologic features, such as rapid changes in water properties, distribution of mineral deposits, and biological growths on the beds of water channels. The study of reactions may be made quantitative, so that the amounts or proportions of the components of a mixture are determined through the use of thermodynamics (*i.e.*, the study of the laws of transformation of energy from any one form to another).

Thermodynamics treats the energy relations inherent in the chemical composition of matter; one of its most useful concepts is that of equilibrium, which is the state of saturation and can be accurately described. A significant part of present geochemical study is the accurate determination of reaction quotients (*i.e.*, the relationship between solute concentrations present and those required for undersaturation, equilibrium, and supersaturation) and changes in free energy, such as result when matter is dissolved in water, to discover the conditions necessary to dissolve and precipitate geologic materials.

Continuity of transport depends fundamentally on change in free-energy relations. During water evaporation, the reaction quotient values may exceed equilibrium conditions (at which the products of a chemical reaction themselves react to reform the original substances, and the rates of formation of the products and of reformation of the reactants are equal); deposition of material then occurs. Discontinuous transport may also occur because of chemical incompatibility; for example, two water masses within the ground may be in hydraulic

continuity but, because of different flow paths through different environments, the waters may have different compositions. Even if the two water masses are in equilibrium with the same mineral, they may be incompatible. The reason for the incompatibility is that dispersion of one water into another is directly proportional to the concentrations of ions in each mass and the relative quantities of the waters mixed. The thermodynamic state is nonlinear (*i.e.*, the relationship between reactions and solute concentrations is not directly proportional), as may be shown in the Figure. Even though waters A

Thermodynamic concentrations of  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  in two water types, A and B, which are in equilibrium with calcite. All mixtures of waters A and B are supersaturated with respect to calcite and accord with the straight line plot as shown. Q and K refer to the quantities of solvent and solute present, respectively.

and B are in equilibrium with calcite ( $\text{CaCO}_3$ ), all mixtures are supersaturated (*i.e.*, hold more than the maximum equilibrium quantity of dissolved matter,  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  in this case, for the given temperature). Along the boundaries of such water masses, a potential exists to precipitate calcite. The boundaries may be self-perpetuating because any precipitate that forms tends to seal the boundary.

**Boundary reactions.** It is quite important to recognize and understand reactions—*e.g.*, oxidation, precipitation, or dissolving of minerals—on the boundaries of environments. Observations lead to the conclusion that along boundaries of geochemical environments, the water properties change rather rapidly in time if not in space. On the boundaries, change in free-energy values for reactions may be large. Reactions in response to change in free-energy values are rapid in comparison to groundwater-flow rates, yielding reaction products over only a few centimetres to a few metres. Surface-water flow rates may be rapid enough to spread reaction products over long distances (up to several kilometres). The response to changes in free-energy values, the difference between actual and equilibrium states, is not necessarily to come to an equilibrium state. The reaction may simply reduce the available energy to a value insufficient to drive the reaction.

Along boundaries between different geochemical environments are found the highest free-energy value changes in nature. If reactions are to occur at all it will be along such boundaries. Changes in free-energy values are potentials; there can be no reaction except to reduce them. Minerals can only dissolve into unsaturated solutions; and minerals can only precipitate from supersaturated solutions. Responses to potentials are matters for observation in that they cannot be accurately predicted at present.

**Observed ionic behaviour.** Rough guides to reactions are available from observation or experience. The rules of behaviour depend on the cations, the anions, the ions in the water, and the water. A cation in solution is positively charged. From the laws of electrostatics, nega-

Energy relation and geologic developments

Ion associations in solution

tive charges are attracted to the cation. All anions will tend to associate with the positive ion to various degrees. The water molecules themselves will be attracted: the oxygen toward the cation, the hydrogen ions away from the cation. The smaller the cation or the higher the charge of the cation, the more water molecules and anions in solution will be attracted. As in the case of cation exchange, both physical dimensions and charge distribution are important. The smaller the cation, the fewer anions or water molecules may be in close association. The higher the charge of the cation, the greater the attraction to the water molecules or anions. Descriptions of the behaviour of the cations depend upon their size, charge, and the anions in solution, taking into consideration, also, that water molecules and hydroxide ( $\text{OH}^-$ ) ions are always present.

**Maximum response potentials.** Potentials for reactions reach a maximum along boundaries of geochemical environments, but the responses to the potentials are dependent upon the sizes and charges of the cations, the size and charge distribution of minerals present, and the nature of the anions present and in competition with the ubiquitous water molecule and hydroxide ion. With so many limitations imposed, mineral-solution behaviour comparisons are best restricted to simplified geochemical environments. As more environments are carefully investigated the rules for behaviour will be more clearly defined.

**Precipitation reactions.** *Silicon.* The silica ion ( $\text{Si}^{4+}$ ) is a good example of a very small cation with a high charge. Unhydrated silica ion is unknown in freshwaters because it will dissociate water as

Competition between ions

There is a competition between  $\text{Si}^{4+}$  and  $\text{H}^+$  for oxygen ion ( $\text{O}^{2-}$ ). Silica ion is larger than hydrogen ion but has four positive charges. At low pH values for waters, wherein the  $\text{H}^+$  activity is high, the  $\text{Si}^{4+}$  competes successfully for hydroxide ion ( $\text{OH}^-$ ). Only at high pH values, above pH 9.6 and 12, where  $\text{H}^+$  activity is low, is the hydrated silica,  $\text{Si}(\text{OH})_4$ , ionized to yield hydrogen ion ( $\text{H}^+$ ) and  $\text{Si}(\text{OH})_3^-$  or  $\text{Si}(\text{OH})_2^{2-}$ . In most freshwater, silica ion is tightly bound (or coordinated) to hydroxide ion. In most silicate minerals, silicon ( $\text{Si}^{4+}$ ) is in tetrahedral (fourfold) coordination with oxygen ( $\text{O}^{2-}$ ), as  $\text{SiO}_4^{4-}$  tetrahedral groups form much of the structure. The ionic bonds of  $\text{Si}^{4+}$  with  $\text{OH}^-$  and with  $\text{O}^{2-}$  are both very strong because of the high charge and small size of the silicon ion. Consequently, compounds containing  $\text{Si}^{4+}$  undergo sluggish and asymmetrical reactions. The difficulty of breaking the ionic silicon-oxygen bonds that extend throughout quartz renders the mineral very slow to dissolve. Upon dissolving, the Si promptly transforms into silicic acid, which is precipitated as amorphous, highly hydrated silica instead of quartz. Even when the hydrated silica assumes a crystalline form by taking on an orderly internal arrangement of the ions, it is rarely quartz that results. Usually, the crystalline material has the internal structure of  $\beta$ -cristobalite, a much more open structure than that of quartz. The compositions of freshwaters at saturation with the three forms of silica are quite different at mean annual temperatures of freshwater. Saturation with quartz yields about seven milligrams per litre  $\text{SiO}_{2(\text{aq})}$ , saturation with hydrous  $\beta$ -cristobalite yields about 70 milligrams per litre  $\text{SiO}_{2(\text{aq})}$ , and the amorphous silica hydrate yields approximately 125 milligrams per litre  $\text{SiO}_{2(\text{aq})}$  at saturation.

**Aluminum precipitation.** In solution aluminum also tends to associate with water and hydroxide ion. In the case of the aluminum ion,  $\text{Al}^{3+}$ , with its somewhat larger size, the coordination is sixfold, with the coordinated water molecules or ions forming an octahedral figure. More accommodating than silicon ion, which associates chiefly with the hydroxide, fluorine, and oxygen, aluminum ( $\text{Al}^{3+}$ ) associates with hydroxide ion, water, sulfate ion ( $\text{SO}_4^{2-}$ ), and other ions. As in the case of silicon, aluminum tends to coordinate with oxygen in aluminosili-

cates, but with octahedral (sixfold) coordination. In solution, aluminum tends to be much more hydrated than in the solid. With both a larger size and a smaller charge, aluminum behaves somewhat more regularly and rapidly than silicon; aluminum precipitates tend to crystallize much more rapidly than silicon precipitates. Crystalline aluminum precipitates that form at low pH values tend to be gibbsite [ $\text{Al}(\text{OH})_3$ ]; those formed at higher pH values tend to be one or more of the polymorphs the composition of which is  $\text{AlO}(\text{OH})$ . Apparently, the crystalline matter reflects in part the form of the ion in solution. At high pH values the hydrate tends to ionize, and the lower hydrogen ion ( $\text{H}^+$ ) content of the ionized hydrate is carried into the solid. If true, then it would follow that at yet higher pH values the anhydrous mineral corundum ( $\text{Al}_2\text{O}_3$ ) should form. It is little wonder that the behaviours of the most common and abundant minerals, the aluminosilicates, are so difficult to predict.

**Precipitation of iron.** Ferric ion,  $\text{Fe}^{3+}$ , is larger than  $\text{Al}^{3+}$  and has a precisely predictable solubility as ferric hydroxide,  $\text{Fe}(\text{OH})_3$ . The precipitation prediction is far more dependable than those for either silicon or aluminum. Thus, as the size increases, behaviour becomes more regular and predictable but still does not approach a minimum state of free-energy change for the least soluble (most stable) minerals. Ferric hydroxide,  $\text{Fe}(\text{OH})_3$ , is far more soluble than the least soluble (most stable) ferric iron oxide: the mineral hematite ( $\text{Fe}_2\text{O}_3$ ). The solubility of  $\text{Fe}(\text{OH})_3$  is 1,000,000 times the solubility of hematite. Observations of natural environments have shown that if the potential ( $\Delta G$ ) exists to dissolve hematite, the rocks are free of hematite ( $\text{Fe}_2\text{O}_3$ ). At just barely supersaturation, ferric hydroxide,  $\text{Fe}(\text{OH})_3$ , precipitates. Thus, ferric iron ( $\text{Fe}^{3+}$ ) also behaves asymmetrically;  $\text{Fe}(\text{OH})_3$  readily precipitates,  $\text{Fe}_2\text{O}_3$  dissolves. Magnesium ion ( $\text{Mg}^{2+}$ ) is of a lower charge and of about the same size as  $\text{Fe}^{3+}$ . Because of the lower charge, magnesium ion has much less tendency to form hydroxy precipitates than either  $\text{Al}^{3+}$  or  $\text{Fe}^{3+}$ . Magnesium hydroxide,  $\text{Mg}(\text{OH})_2$ , forms in freshwater when the pH is 11 or greater. The potential apparently required for precipitation of  $\text{Mg}(\text{OH})_2$  is apparently equal to or possibly less than is required for the precipitation of ferric hydroxide,  $\text{Fe}(\text{OH})_3$ . The study of ferrous hydroxide,  $\text{Fe}(\text{OH})_2$ , is complicated by the fact that it precipitates simultaneously with magnesium hydroxide to yield a solid solution,  $\text{MgFe}(\text{OH})_2$ . The waters that yield magnesium hydroxide and ferrous hydroxide in solid solution have less ferrous ion,  $\text{Fe}^{2+}$ , than magnesium ion,  $\text{Mg}^{2+}$ , in solution, presumably reflecting the lower solubility of ferrous hydroxide as compared to the solubility of magnesium hydroxide.

**Geochemical limitations.** If the comparison of precipitation reactions were to proceed, the rarely found mineral portlandite [ $\text{Ca}(\text{OH})_2$ ] would be considered. Freshwaters containing calcium ion ( $\text{Ca}^{2+}$ ) and ferrous ion ( $\text{Fe}^{2+}$ ) and the ubiquitous bicarbonate ion ( $\text{HCO}_3^-$ ) much more commonly yield siderite ( $\text{FeCO}_3$ ) and calcite ( $\text{CaCO}_3$ ). The promising comparison of hydroxide-ion and cation relations reaches a natural limit, and a change of grounds is required for comparison of the geochemical behaviour of the cations. In spite of the larger size of  $\text{Ca}^{2+}$  compared to  $\text{Fe}^{2+}$ , siderite and calcite precipitate and dissolve with about the same change in free-energy values. Another geochemical limitation is that the freshwater must contain no dissolved oxygen if ferrous and calcium ions are to be compared. Dissolved oxygen and ferrous ion ( $\text{Fe}^{2+}$ ) are incompatible, and the behaviour of ferric hydrate,  $\text{Fe}(\text{OH})_3$ , may not be compared to the behaviour of calcite,  $\text{CaCO}_3$ , on common grounds. Although it is helpful to compare cation reactions on the base of charge-size relations, the nature of the anions must be taken into account.

In solutions free of dissolved oxygen, sulfide is often found as either dissolved hydrogen sulfide,  $\text{H}_2\text{S}$ , or bisulfide,  $\text{HS}^-$ . As an approximation, the  $\text{H}_2\text{S}$ - $\text{HS}^-$  distribution may be taken to be the same as the hydrogen-ion and hydroxide-ion ( $\text{H}^+$ - $\text{OH}^-$ ) distribution. Neutral pH values (near 7) yield about equal amounts of  $\text{H}_2\text{S}_{(\text{aq})}$  and  $\text{HS}^-$ . Acid solutions (pH less than 7) have

Predictability of behaviour of ferric ion

more  $\text{H}_2\text{S}$  than  $\text{HS}^-$ , and basic solutions (pH more than 7) have more  $\text{HS}^-$  than  $\text{H}_2\text{S}$ . The behaviour of pyrite ( $\text{FeS}_2$ ) has been observed on the same grounds as ferric hydroxide,  $\text{Fe}(\text{OH})_3$ . For the reaction

in which the ferrous ion is oxidized with the loss of two electrons and pyrite is precipitated, enormous supersaturations have been found, without observable precipitation of the common mineral pyrite ( $\text{FeS}_2$ ). The nature of dissolved  $\text{H}_2\text{S}$  accounts for the lack of predictability. In the absence of hydrogen sulfide, the reactions between water and ferrous ion, resulting in ferrous hydroxide precipitation, and between water and pyrite, in which pyrite is dissolved, are very near to equilibrium as observations have shown. The behaviour of hydrogen sulfide is also revealed in studies of cupric sulfide ( $\text{CuS}$ ) and cuprous sulfide ( $\text{Cu}_2\text{S}$ ). Observations have shown that the reactions yielding cupric sulfide and cuprous sulfide are as far from equilibrium as that yielding pyrite,  $\text{FeS}_2$ .

**Bacterial reduction.** A common origin of hydrogen sulfide ( $\text{H}_2\text{S}$ ) and bisulfide ( $\text{HS}^-$ ) in freshwaters is bacterial reduction of sulfate ion,  $\text{SO}_4^{2-}$ . Organic material is commonly incorporated in sediments and may survive for geologic time. A number of reactions may occur as freshwater passes through such sediments. Oxygen is lost from solution as the organic matter oxidizes. Depending upon flow rates and the reaction rates of the organic material, the decrease in dissolved oxygen may be quite abrupt; concentrations may fall from saturation with air (approximately ten milligrams per litre) to below detection (less than 0.01 milligram per litre) within a few centimetres. As the dissolved oxygen,  $\text{O}_{2(\text{aq})}$ , drops below detection, the ferric ion,  $\text{Fe}^{3+}$ , of the limonite minerals ( $\text{FeOOH}$ ) is reduced to yield ferrous ion,  $\text{Fe}^{2+}$ . From oxidation of the organic matter, whether by dissolved oxygen,  $\text{O}_{2(\text{aq})}$ , or by ferric hydroxide,  $\text{Fe}(\text{OH})_3$ , carbon dioxide,  $\text{CO}_2$ , is produced. Rising carbon dioxide and ferrous-ion concentrations may cause the solubility control on  $\text{Fe}^{2+}$  to pass from ferric hydroxide,  $\text{Fe}(\text{OH})_3$ , to siderite,  $\text{FeCO}_3$ . Sulfate may be reduced by bacteria on the surface of the organic material as in the reaction

There is a consumption of hydrogen ion and a tendency for a pH increase. The pH rise is in part offset by the carbon dioxide, which ionizes. Generally, freshwaters are so well buffered that large pH increases resulting from sulfate-ion reduction do not occur. The rise in hydrogen sulfide concentrations may greatly supersaturate the water with respect to metal sulfide minerals. Enormous supersaturations are needed to precipitate sulfide minerals.

Pyrite often is found as a surface-coating on the organic matter in sedimentary rocks. There is a large energy difference between sulfate ion,  $\text{SO}_4^{2-}$ , and organic matter, and bacteria utilize part of the available energy in their life processes. The bacterial wastes provide the highest sulfide concentrations along the boundary between the organic matter and the water, and the sulfides, chiefly pyrite, form there.

**Changes in water character.** The dissolved oxygen-free water may flow for long distances without changing its character. It may flow parallel to water containing dissolved oxygen,  $\text{O}_{2(\text{aq})}$ , in which case the two waters will react along the boundary, yielding limonite cements. In the course of time, the reduced (oxygen-free) waters will discharge into an aerobic (oxygen-containing) environment, and oxidation reactions will quite rapidly change the character of the solutions. If hydrogen sulfide ( $\text{H}_2\text{S}$ ) is present, organisms utilize part of the change in free energy that results from the incompatibility of  $\text{H}_2\text{S}_{(\text{aq})}$  and oxygen,  $\text{O}_{2(\text{aq})}$ . In channels with rapid flow, very pale yellow growths attached to the bed are common in-

dicators of biologic hydrogen sulfide oxidation; in more sluggish reaches or quiescent pools, jet-black organisms may dominate. In any event, the hydrogen sulfide ( $\text{H}_2\text{S}$ ) is oxidized to sulfate ion ( $\text{SO}_4^{2-}$ ) or to native sulfur. Ferrous ion,  $\text{Fe}^{2+}$ , is oxidized to ferric hydroxide,  $\text{Fe}(\text{OH})_3$ , by organisms. A common observation in swampy areas is an iridescent "oil" film on the water surface. If the film remains broken when disturbed, it is a very thin film of  $\text{Fe}(\text{OH})_3$ . Oil films rapidly coalesce after being disturbed.

The oxidation reactions may produce quite low pH values. Both hydrogen sulfide and ferrous-ion reactions yield hydrogen ion ( $\text{H}^+$ ):

and

In addition, the organisms that oxidize the  $\text{Fe}^{2+}$  live attached to the stream bed and may smother other bottom-dwelling organisms. The high  $\text{H}^+$  concentrations may prove toxic to some aquatic organisms.

The variations in dissolved oxygen content of freshwater may interrupt the transport of sulfur, iron, oxygen, carbon dioxide, and other species. Usually, the reactions occur at the boundaries between different environments. The distance over which the reactions are spread depends on the rate of the chemical reaction and the rate of flow of the water. Generally, groundwater flows are sluggish and boundaries of geochemical environments tend to be abrupt. Surface-water flow in channels may be fast enough to spread reactions over distances as great as kilometres. It should be noted that none of the discontinuities in transport of ions has required a phase change of the water. Neither evaporation nor freezing is required to deposit any of the minerals described.

Calcite (calcium carbonate) undergoes discontinuous transport in three rather common ways. In temperate or tropical regions of low rainfall, soils may be quite dry. Permeability decreases with decreasing moisture content. Precipitation falling on such a dry soil may not penetrate to the groundwater body before being withdrawn by transpiration and evaporation. When there is evaporation, the nonvolatile solutes accumulate. Widespread accumulations of calcite in layers below the soil surface in temperate or tropical regions of low precipitation are evidence of subsurface evaporation caused by a steep temperature gradient.

A second type of calcite deposition occurs because of carbon dioxide losses. As a result of plant-root respiration,  $\text{CO}_2$  contents of waters below the surface may be much higher than would be found at saturation with air; waters of high carbon dioxide content may be saturated (i.e., may hold the maximum equilibrium quantity of dissolved matter). Upon emergence of the water onto the land surface, algal photosynthesis reduces the  $\text{CO}_2$  content and drives the solution supersaturated, often to the extent of precipitating calcite. A third situation has been described in which water in a channel is rich in carbonate ion ( $\text{CO}_3^{2-}$ ), but groundwater entering from below the bed is rich in calcium ion ( $\text{Ca}^{2+}$ ). In the dispersion zone between the two waters, calcite precipitates. In all three cases, free-energy values rise to the point at which calcite,  $\text{CaCO}_3$ , deposits are formed.

**BIBLIOGRAPHY.** The important geochemical aspects of freshwaters are illustrated in the following works: JOHN D. HEM, "Study and Interpretation of the Chemical Characteristics of Natural Water," *Wat. Supply Pap., Wash. 1473* (1970); IVAN BARNES and FRANK E. CLARKE, "Chemical Properties of Ground Water and Their Corrosion and Encrustation Effects on Wells," *Prof. Pap. U.S. Geol. Surv. 498-D* (1969); ARLO W. GAMBELL and DONALD W. FISHER, "Chemical Composition of Rainfall, Eastern North Carolina and South-eastern Virginia," *Wat. Supply Pap., Wash. 1535-K* (1966);

## Freud, Sigmund

As a physician who specialized in treating the mentally ill, Sigmund Freud developed a comprehensive theory concerning the psychological structure and functioning of the human mind. He demonstrated that many illnesses with no apparent organic explanation could be treated by psychiatry or psychoanalysis. He identified and explored hidden motivations in the subconscious mind, and he perfected psychoanalytic techniques for analyzing the development and functioning of both normal and abnormal behaviour. His original and often controversial ideas have had wide applications—even beyond psychiatry—in understanding processes of artistic creation, education, and political conduct.

Freud, 1938.

### EARLY LIFE

Freud was born on May 6, 1856, in Freiberg, Moravia (now Příbor, Czechoslovakia). Ernest Jones, the English analyst who became Freud's biographer, has declared that Freud inherited "his sense of humour, his shrewd skepticism . . . his custom of pointing a moral by quoting a Jewish anecdote, his liberalism, and free thinking," from his father, who was a wool merchant. Freud claimed that he drew his "sentimentality" or "temperament" from his mother. According to Jones, Freud's intellect "was his own."

**Significant childhood events.** Four childhood events always stood out in Freud's memory. Before the birth of his younger brother Julius, he had had the almost exclusive love of his mother, but after the birth he admitted having had evil wishes against Julius, who suddenly died at the age of only eight months. Freud later viewed the death as a fulfillment of his evil thoughts, thereby beginning a lifelong tendency to self-reproach. Years later he wrote that he had been sexually aroused by seeing his mother naked, an event to reverberate years afterward in *Three Essays on the Theory of Sexuality*. Thus two of the problems that were to preoccupy him throughout his psychoanalytic career entered his actual experience at a time when he could not understand their true significance. First came early family conflicts between parents and children, and second, the existence of infantile sexuality.

On another occasion he recollected having deliberately urinated in his parents' bedroom at the age of seven or eight, prompting his father to remark: "That boy will never amount to anything." Beginning at an early age, allusions to this scene, accompanied by demonstrations of actual "accomplishments and successes," constantly recurred in dreams.

The fourth powerful memory destined to haunt Freud

was based on his father's account of the Gentile who knocked his new fur cap into the gutter one day and shouted: "Jew—get off the pavement." When the 12-year-old boy inquired of his father how he reacted to such treatment, he replied: "I stepped into the gutter and picked up my cap." The remark permanently damaged the father's image in the boy's eyes.

**Education.** At nine years of age Freud entered high school (Sperl Gymnasium), quickly became head of his class, and graduated summa cum laude. Traditionally, the choice of a career for a Viennese Jew was limited to four fields—law, medicine, industry, or business—but none of these appealed to Freud, whose intense intellectual abilities had quickly become clear. Deeply impressed by Charles Darwin and his theory of natural selection, he could not at first quite reconcile his work with his own cultural and philosophic aspirations. A public reading of Goethe's *Ode to Nature* resolved his dilemma, but he became a medical student primarily to gain knowledge about human nature, not to alleviate suffering.

After he entered the University of Vienna in 1873 at the age of 17, Freud's attention was directed into correlative fields, including a seminar in philosophy. Freud later wrote:

Medical studies

During my first three years at the University I was compelled to make the discovery that the peculiarities and limitations of my gifts denied me all success in many of the departments of science into which my youthful eagerness had plunged me.

At length he found a congenial place in the physiology laboratory of Ernst Brücke, who agreed with the view advanced by the German physicist Hermann Helmholtz that "no other forces than the common physical chemical ones are active within the organism." Freud's first excursion into psychological theorizing may have begun when he met Jean Charcot, the French neurologist, but the principles from which he later constructed his system were acquired as a medical student in the Brücke Institute. There, he did original research that clearly indicated his brilliance. According to Freud, he passed his medical examinations with excellent grades because his photographic memory enabled him to give verbatim answers directly from textbooks.

Meanwhile, the young man who seemed to thrive on work suddenly found his professional life seriously disturbed by an experience that would not surrender to the rigorous control he exercised over the other aspects of his life—he fell in love. By the summer of 1882, Martha Bernays had not only spoken of her own feelings for him but indicated that expectations of marriage were not out of place. Freud then decided to abandon science and enter the General Hospital of Vienna in order to qualify for private practice, from which he might hope to support a wife. In the course of his betrothal Freud wrote more than 900 letters to Martha, some of them warm love letters entirely at variance with the common image of him as a cold, scientific man. But poverty delayed the marriage year after year.

Freud next served for a few months in Nothnagel's division of internal medicine in Vienna. On October 12th, 1882, he joined the staff of Theodor Meynert's psychiatric clinic, where he was at once appointed *Sekundararzt* ("assistant physician"). He regarded Meynert as a brilliant anatomist of the brain and a reasonably good psychiatrist. A disorder, then known as Meynert's Amentia (hallucinatory psychosis), gave Freud the first hint of a hypothesis he later developed, the so-called wish fulfillment mechanism, which was to play an important part in his major work *The Interpretation of Dreams*.

The years from 1883 to 1885 were rich in success. He finished important research on the medulla, a region of the brain; became a *Privatdozent* ("lecturer") in Neuro-pathology, made discoveries on the physiological effects of the drug cocaine; and met Charcot, who dominated the world of neurology in the Salpêtrière Hospital in Paris.

**Marriage.** On the point of discovering the anesthetic properties of cocaine in Vienna in 1885, Freud had the

opportunity to visit his fiancée, Martha Bernays, whom he had not seen for two years. He hastily wrote a brief monograph summarizing his research on cocaine and hurried to meet her. Simultaneously he wrote to an eminent German ophthalmologist, suggesting an investigation of the anesthetizing properties of cocaine for eye treatment. On returning from a brief visit to Martha, he found that decisive experiments had empirically confirmed his speculations—but that they had been done by another scientist.

Between 1882 and 1886 occurred a number of stormy scenes with Martha, the climax to which came when he asked her to denounce her brother as a scoundrel because of his alleged misuse of her funds. This unhappy event suggests the tumultuous passions that often stirred his life, in contrast to the calm, scientific person he is often supposed to have been. He married Martha in 1886, with full confidence in the future well-being of his family. Similar hopes were not at once fulfilled in his private practice, however. In 1890, as the newlyweds continued to suffer from poverty, money began to play a special role in Freud's life. By now a man of 35, he had grown into a person the power of whose presence created the illusion of height in his personality, but he was barely five feet seven inches in height. His fine moustache and intelligent eyes gave a certain flair to his appearance. Several references in his writings show his special need for either a loved friend or hated enemy. Despite his reputation as a cantankerous individual, the general trend of his moods was quite different. He could love and hate with equal passion, and, although he did not set out to charm or please, many who met him did not find him at all a difficult person.

Appearance and personality

#### CAREER

**Development of psychoanalysis.** *The role of Anna O., Josef Breuer, and Charcot.* Freud's important relationship with Breuer, the Viennese physician and physiologist, began in 1882. Breuer had treated a 21-year-old girl who had developed complex psychosomatic symptoms after the death of her father. This patient became famous in psychoanalytic history as Fraulein Anna O. After her father's death, Anna's sight and speech were seriously disturbed, her limbs frequently became paralyzed, and she recoiled from food. She could change with remarkable facility from relatively normal behaviour into the role of a recalcitrant child with alarming symptoms—a now familiar case of hysteria. Once, while the girl related to Breuer the details of one severe episode, he observed, to his astonishment, that the symptoms gradually disappeared. Breuer then supplemented his procedure by inducing hypnosis, and the results were, for a time, startlingly successful. Freud discussed the details of the case "over and over again" with Breuer. In 1885 Freud travelled to Paris for his famous encounter with Charcot, whom he tried to interest in "the talking cure," as the patient had nicknamed it, but Charcot seemed preoccupied with other matters.

The encounter proved salutary, however, for Charcot demonstrated that he could use hypnosis to induce such conditions as tremors, paralysis, anesthesia, and many other symptoms of spontaneous hysteria. In effect, Charcot's demonstrations meant that the symptoms of hysteria could be removed by thought alone and that there thus must be a powerful psychogenic factor in their origin. Later, Freud formulated the principle that "hysterical symptoms originate through the energy of the mental process being withheld from conscious influence and being diverted into bodily innervation (conversion)."

**Psychoanalytic technique.** In 1893 Breuer and Freud published "The Psychical Mechanism of Hysterical Phenomena" and expanded it two years later into *Studies in Hysteria*. The joint paper is the opening chapter of the book, followed by five case histories, a theoretical essay by Breuer, and a final chapter by Freud. Historically this book marked the beginning of psychoanalysis, but it was not well received in the medical world, and it was denounced in particular by the German neurologist Adolph von Strümpell, whose review so disturbed Breuer

that it permanently undermined his confidence in his own theory.

Freud had already developed the technique of free association and was gradually abandoning the old process of hypnosis. The first steps toward free association consisted in getting the patient to concentrate on a particular symptom while "attempting to recall any memories that might throw light on its origin." From a difficult, long period of refinement of hypnosis, questioning, and suggestion emerged a new technique between the years 1892 and 1895. Simultaneously, Freud's remarkable relationship with Wilhelm Fliess continued to develop. Fliess was a nose and throat specialist whose powers of bold speculation about the nature of the human psyche had already strongly attracted Freud. By 1894 they were corresponding with one another.

Jones later wrote that Freud now acted out his love-hate relationship with his father with a number of people—Fliess among them. First, he was obliged to leave his famous teacher Brücke; then, Meynert withdrew because he could not countenance Freud's growing interest in hysteria and hypnotism.

Toward the end of the 1880s, Breuer found himself unable to share Freud's growing preoccupation with sexual etiology. If Breuer and Fliess both held Helmholtz' view that the medical sciences "should aim to describe their findings in terms of physics," Fliess, unlike Breuer, did not recoil from sexuality as a basis of human behaviour. Indeed, it slowly became the core of his work. Thus, for a time, Fliess and Freud shared intellectual excitements and corresponded at length, exploring one hypothesis after another. Freud developed an exaggerated reverence for Fliess's powers and came to treat him as mentor, father figure, and passionate friend, but this relationship broke down in the end. It should be emphasized that Freud, at this stage, was a very different person from the highly independent man who dominated what came to be called the "Psychological Wednesday Circle" in Vienna with such inflexible purpose and creative power.

Turning away from clinical neurology, Freud developed a deepening interest in clinical psychopathology. Patient after patient slowly convinced him that sexual etiology played a powerful role in many forms of neurosis. "With previously healthy men an anxiety neurosis is rooted in abstinence: with women it occurs mostly through coitus interruptus," he wrote. Thirteen fully analyzed cases amply substantiated what he meant: "the cause of hysteria is a passive sexual experience before puberty: i.e., a traumatic seduction." Time and again patients made the remarkable statement that one parent had attempted or achieved their seduction as children. Freud then made another discovery—that these childhood seductions had in fact never occurred, but were at first fantasies, and then the reversal of a desired role.

The year 1897 was significant in many respects, not the least of which was because Freud then began to analyze himself—what many analysts today regard as an impossible feat. During most of the 1890s he himself suffered from a powerful psychoneurosis. His self-analysis not only threw him into the expected turmoil but also offered a new solution to the puzzle of childhood seduction. After observing a number of hysterical symptoms in his brother and several sisters, he concluded that even his own father might not have been free of "incestuous in-crimination." Six months' further work suddenly revealed the solution: the incestuous impulse certainly arises and is sometimes fulfilled by parents, but much more widespread and representative are the wishes of children to sleep with parents of the opposite sex. The concept of the so-called Oedipal complex thus began to take form.

In the same year (1897), he discussed in his correspondence the importance of dreams in psychoanalysis: they contain "the psychology of the neuroses in a nutshell."

**Influence of home life and lecturing.** The Bergasse, where Freud lived, opened off Vienna's historic junk market, the Tandelmarkt, and ended at the Votivkirche, the Gothic cathedral that dominates one of the most ornamental squares of Vienna. The ground floor included

Freud's  
children

a butcher's shop; on one side of the entrance a name plate read "Prof. Dr. Sigm. Freud," and on the other was the plate of the butcher, whose first name was also Sigmund. Freud had been forced by his growing family to rent a second flat in the house. One of the three rooms was the patients' waiting room, a second the consulting room, and a third the study, later to become famous in the literature. Six children were born to the Freuds in their first home, three daughters, Mathilde, Sophie, and Anna, and three sons named Jean Martin after Charcot, Oliver after Cromwell, and Ernst after Brücke. Freud remarked in a letter to Fliess that he spent a considerable amount of his life either with patients in the ground-floor flat or rushing up the stone steps that led to the mezzanine floor to visit with his family. He was devoted to his children and took an active part in their upbringing. That he had time for leisure in his very full life seems remarkable, but when he managed to relax, he played chess, patience, or the Viennese card game of Tarok. Occasionally he attended the theatre, but only the music of Mozart lured him to the opera. Still suffering from professional ostracism in many quarters, Freud joined the B'nai B'rith Society, or Jewish Club. His interest in antiquities simultaneously satisfied his fascination with the beginnings of civilization and his aesthetic sense.

By 1900 Freud was a seasoned lecturer. Fritz Wittels, a doctor-teacher-writer who belonged to the early group of Freud's followers, gave a vivid description of one occasion at the Psychiatric Clinic of the General Hospital, where Freud spoke without notes for 60 minutes to a small audience, which appeared to "hang on his words." Wittels recalled:

His black hair, slightly grizzled, was smooth and parted on the left side. His beard was small and trimmed to a fine point. . . . His eyes were dark brown and lustrous and made a quick penetrating scrutiny of anyone who asked questions.

One other characteristic stood out in Wittels' memory—the student's stoop in his figure. Freud lectured that particular day on the shortcomings of traditional psychology as taught by Wilhelm Wundt and remarked that the old psychology had since been killed by his own new dream doctrine. According to Freud, Wundt, in continuing to follow outdated theories, was rather like the giant in Ariosto's *Orlando Furioso* who went on fighting even though his head had been cut off.

"**The Interpretation of Dreams.**" *Preparation.* Between 1895 and 1899 Freud was deeply engrossed in researching and writing what is generally regarded as his major work, *The Interpretation of Dreams*. To Fliess on February 2, 1899, he wrote of work "to which every effort of thought has to be given . . . which gradually absorbs all other capacities . . . a sort of neoplastic substance that infiltrates into one's humanity and then replaces it." Freud, who was most at ease when he was busiest, declared that "I get on best when there is a great deal of work." He also needed a "moderate amount of misery" before he could work at full pitch. Of *The Interpretation of Dreams* he wrote, "My style in it was bad because I was feeling too well physically."

Freud worked on *The Interpretation of Dreams* while he continued his self-analysis in the years 1898 and 1899. He had many fluctuations of mood, but on March 10, 1898, in a letter to Fliess, he outlined one of the main themes of the book:

It seems to me that the theory of wish fulfillment gives us only the psychological solution—not the biological. . . . It seems to me that biologically the dream life proceeds altogether from the relics of the prehistoric period. . . . I surmise the formula: what was seen in that prehistoric period gives rise to dreams: what was heard to phantasies: what was sexually experienced to psychoneuroses.

Bursts of writing, when the book ran smoothly, were often followed by periods of frustration and doubt. In May 1898 he commented that the book was probably "the only one of my discoveries which may survive me," but by June "the whole matter resolves itself into a platitude." There were long unhappy hours when the thought of leaving to the world such a book was a tremendous "consolation," and times when he wrote rapidly

"as if in a dream." Approaching with trepidation the last chapter, in which he was to describe the psychology of the dream processes, Freud wrote it as if the chapter were itself a dream to which he had surrendered himself.

*The constancy principle.* *The Interpretation of Dreams* is regarded as Freud's most original work, because in it he brilliantly analyzed the dream mechanisms of condensation, displacement, and secondary elaboration and discussed the latent content of dreams; explained the principle of wish fulfillment; described the Oedipal complex; and showed the overwhelming influence of infantile life in conditioning the human adult. Dream mechanisms condensed one subject into another, displaced one person on to another, and elaborated what sometimes turned out with cunning detail. Dreams also were seen, at this stage of his theory, as attempts to fulfill a wish. The Oedipal complex involved the emotional sexual complications between parents and children. The seventh chapter also gave Freud's fullest exposition of his theory of the mind. Between the time he wrote the "Project for a Scientific Psychology" in 1885 and *The Interpretation of Dreams*, Freud constantly refined this theory. The working principle of his model is that of "neuronic inertia," or the constancy principle, according to which the apparatus works toward the reduction of any tension that can be identified with an accumulation of "energy," variously interpreted as sexual or psychic. The primary functions are complicated by both internal and external stimulations, but the constancy-principle model describes memory formation in terms of two different classes of neurones. The secondary function of the mind is not to eliminate tensions but to maintain an optimum tension that tends toward its lowest possible level.

Six hundred copies of *The Interpretation of Dreams* were printed, and review copies were circulated. According to Jones, few scientific or general journals attempted anything resembling a serious review, although Henri S. Ellenberger, in the *Discovery of the Unconscious*, states that *The Interpretation of Dreams* had some ten reviews in learned journals within a year of publication, only one of which was unfavourable. In the first six weeks, only 123 copies were sold and another 228 in the following two years. But his work was no longer ignored.

**The Psychological Wednesday Circle.** The beginnings of the Vienna Psycho-Analytical Society can be traced to the year 1902, when Freud sent postcards to four comparatively unknown men, suggesting that they might organize a small group at his home once a week to discuss psychoanalytic matters. These four men were Alfred Adler, Max Kahane, Rudolf Reitler, and Wilhelm Stekel; with Freud and occasional visitors they became known as the Psychological Wednesday Circle.

Although a certain careful deliberation had entered into the conception of the Psychological Wednesday Circle, its meetings, in practice, were casual. After supper a varying number of doctors and professional men would gather around the table in Freud's waiting room to await his brisk entrance. Through the open study door it was possible to see the famous couch with the armchair, the collection of statuettes and the book-lined walls. Mrs. Freud always served cigars and black coffee before the meeting began. Freud, a heavy smoker, sometimes consumed as many as 20 cigars a day. When Freud presented a paper to the circle he would, according to Wittels, "enunciate his main contentions categorically so that they were apt to repel," but the charm of his exegesis quickly modified early resistances. Wittels stated that Freud desired "to have his own thoughts passed through the filter of other trained intelligences," and immediately qualified that statement by saying that "he wanted to look into the kaleidoscope lined with mirrors that would multiply the images he introduced into it." The Wednesday Circle slowly grew from five members in 1902 to 22 in 1908, among them Carl Jung, who was destined to become Freud's chief rival. The group developed into the Vienna Psycho-Analytical Society (1908), which in turn became The International Psycho-Analytical Association (1910). His fame rapidly spreading throughout Europe,

pretation  
of Dreams*

Freud in 1908 was invited by G. Stanley Hall, the president of Clark University, to give a course of lectures in America. The tour, which took place in 1909, was moderately successful.

**Private practice.** Freud returned in 1910 to Vienna, where his life was once again filled with work. Because he sometimes wrote late at night, he arose with difficulty early in the morning at 7 o'clock. After a quick breakfast and a glance at the newspaper, he was ready for his first patient at 8 o'clock. Infallibly punctual, he gave each patient exactly 55 minutes. After a five-minute interval, when he might rush into the family flat to communicate briefly with his wife, he was ready for the next patient. Lunch at 1 o'clock usually became a family affair with the children present; his frequent taciturnity and silence were the cause of embarrassment when guests were present. After lunch he felt free to walk, shop, and buy his favourite cigars until the precise hour of three, when he donned his professional frock coat. Therapeutic work then continued without a break until nine or 10 in the evening. Surprisingly, he sometimes found it difficult to keep professional confidences.

Two patients, James Strachey and his wife, had undertaken an unusual joint analysis, Mr. Strachey visiting Freud in the mornings and his wife in the afternoons. At the conscious level, Mrs. Strachey found Freud to be a simpleminded, rather gullible man, with a conventional outlook, no intellectual intolerance in his makeup, and almost too ready to respond to ideas. He made two startling statements to her: "I don't really think I'm a frightfully good analyst—I'm too impatient," and "The greatest invention some benefactor can give mankind is a form of contraception which doesn't induce neurosis."

Reacting against rumours of disturbances in Freud's family life, Jones, in his official biography, may have exaggerated the extent of family harmony. However, the suggestion is false that his sister-in-law, known as Tante Minna, replaced his wife in his emotional life, although she certainly understood Freud's work better than his wife did and must have shared his intellectual life in much greater depth. Although Jones draws an idealized picture of Freud the family man, it is certainly true that Freud allowed his children to develop freely at a time when very austere systems of upbringing were commonplace.

#### Writing habits

His writing habits varied. Instead of planning to write a certain number of words at one session, he would wait until "the spirit moved him," but a painful struggle to write even three lines might then ensue, or there might be a spontaneous flow that produced an important paper within a few weeks. Freud's writing, whenever it occurred, was not continuous but had to be fitted into his analytic work.

Prolonged feuds and quarrels caused successive defections from the Psycho-Analytical Society. They began as early as 1908 and throw many sidelights on the complicated characters of the men involved, including Freud. By then Freud had written several more important works, including *Psychopathology of Everyday Life* (1904); *Jokes and Their Relation with the Unconscious* (1905); and his *Three Essays on the Theory of Sexuality* (1905), which brought dismay to the medical world. He analyzed what he had learned from patients about their sexual development in earliest childhood, and he dared to suggest not only that children were subject to sexual urges but also that those urges frequently involved their parents.

Another shock for the medical world was the publication of the Dora analysis, "Fragments of an Analysis of a Case of Hysteria," which described a young girl with tendencies toward sexual perversions and was published without her permission (Dora was a cover name).

**Break-up of the Wednesday Circle.** By 1911 differences within the International Psycho-Analytical Association had become serious, and one founding member after another resigned or left the circle. It was as if every member, inspired by Freud, desired to match or challenge his creative outpourings. Adler, for example, developed a breakaway school, which differed in three major points

from Freud's: (1) that regression was not a motivating force in neurosis; (2) that patients experienced inferiority feelings in connection with certain organs; and (3) that some patients feared the feminine role and reacted with a "masculine protest."

In her biography of Adler, Phyllis Bottome wrote that Freud, jealous of his brilliant and ambitious younger colleague, may have been responsible for setting in motion the persecution of Adler that followed. There is, of course, considerable doubt that Freud followed such a course. His friends claimed that during the long period of wrangling and resignations, he was driven by one dominating motive—to establish conditions that would preserve for the future the purity of psychoanalytic practice as he saw it. This involved the acceptance of a minimum number of basic concepts, which included the "existence of unconscious psychological processes, the theory of resistance and repression, the appreciation of the part played by sexuality and the Oedipus complex."

Adler, the first of the early circle to break away, was followed by Stekel, and finally by the man whom Freud had once nominated as the leader of the association, Carl Jung. There was much bitterness on both sides. "So we are at last rid of them," Freud wrote to another devoted member, Karl Abraham, "the brutal sanctimonious Jung and his disciples." Jung claimed that "after my break with Freud all my friends and acquaintances dropped away." As the stresses and tensions subsided, an inner council of trustworthy members of the association was formed and became known as the Committee. Freud presented to each member an antique Greek stone engraving, to be mounted in a gold ring, signifying the close harmony of their intellectual views—a somewhat mystic gesture.

Surprisingly, Freud's first systematic statement about the unconscious was not made until 1912, in response to an invitation from the London Society of Psychological Research for a contribution to its *Proceedings*. Freud stated: "We obtain our concept of the unconscious from the theory of repression." Thus when a thought was repressed out of consciousness, it remained in the mind unconsciously. In those days he freely acknowledged the source of a number of his hypotheses, and there is no doubt that the idea of an unconscious was a familiar one in the 19th century; e.g., Eduard von Hartmann's book *The Philosophy of the Unconscious* (1893). Freud wrote *Totem and Taboo* in 1913 and *A General Introduction to Psychoanalysis* in 1915–16.

Freud suffered severe hardships during World War I. In 1917 he noticed a worsening of a painful swelling in the palate of his mouth, a symptom unmistakably connected with cigar smoking.

His next important book, *Beyond the Pleasure Principle* (1920), seemed to leave the limitations of biology to enter the field of transcendental metapsychology. He restated his belief in both the pleasure-unpleasure principle and homeostasis. The pleasure-unpleasure principle involved the process of adjustment from the pleasure-seeking impulses to the harsh realities of the external world. Homeostasis was the mental activity that attempted to reduce tensions to the lowest possible level. In formulating the theory of repetition compulsion—the drive to repeat fixed patterns of behaviour—he came to the conclusion that the fundamental aim of all instincts is to revert to an earlier state.

#### FINAL YEARS

Preservation of harmony within the Committee was very important to Freud, but by 1923 serious dissension once again brought it almost to the point of disintegration. In the same year the first serious signs of the disease that was to kill him became apparent. In a letter he wrote to Jones dated April 25, he said: "I detected two months ago a leucoplasic growth on my jaw and palate right side . . . I am still out of work and cannot swallow." Freud later consulted Marcus Hajek, a leading rhinologist, who advised a "very slight operation." Without telling his family, Freud went to Hajek's clinic, and shortly afterward he sat in the outpatient department of the

Freud's  
view of  
the un-  
conscious

clinic with blood all over his clothes, a man grimly determined not to utter a word of complaint. As Jones wrote: "The operation had not gone as expected." Only at this point did he allow his family to be informed. This was the first of 33 operations, all of which Freud bore with stoical fortitude. He made a pact with his daughter Anna that they should view his illness with cool detachment and no sentiment. Only minor concessions were made to the pact.

Notwithstanding his medical condition, he continued to publish important books. In *The Ego and the Id* (1923), he discussed further his tripartite division of the mind into id, ego, and superego. He conceived of the id as the reservoir of the instinctive impulses; the ego as a portion of the id influenced by the external world; and the superego as "the inhibitions of instinct characteristic of man." In *The Future of an Illusion*, Freud, in 1927, speculated philosophically on the nature of man, religion, and God, much to the displeasure of those who believed his undoubted erudition in psychoanalysis did not qualify him for philosophy.

Although he rejected any belief in God or an afterlife, he remained what many people called a cheerful pessimist. As his illusions slipped away in his last years, however, he gradually became a pessimistic realist. This view was confirmed by the arrival of the Nazis in Vienna in 1938. Jones had great difficulty in persuading him to leave the city, partly because he was a very sick man. Jones pointed out to him that he was not alone in the world, and that his life was very dear to many people. But Freud replied: "Alone—ah, if I were only alone I should long ago have done with life." When the Nazis actually entered his house and attempted to loot his private safe, his frail figure, white-haired and gaunt, suddenly appeared in the doorway with his eyes blazing. Even the Nazis were momentarily intimidated. At last he made the exhausting journey to England and settled into a house in London.

The cancer slowly ate its way through his cheek, and, although life became for him a long torment of pain and discomfort, he bore it with incredible stoicism. A huge prosthesis designed to shut off the mouth from the nasal cavity had become necessary, and as a result Freud's speech became thick and blurred. At last, on September 21, 1939, he said to his doctor: "My dear Schur . . . you promised me you would help me when I could no longer carry on." Schur gave him "adequate sedation," and Freud sighed with relief and fell into his last sleep just before midnight on September 23, in London.

**Assessment** Freud spent most of his life refining and elaborating the brilliant theories by which he reinterpreted the nature of the human psyche. But if he had wanted his basic concepts to remain as immutable as Moses' tablets, he would be a disappointed man today. Wilhelm Reich, Karen Horney, Erich Fromm, Melanie Klein, and R.D. Laing have revised or further developed his main ideas. Moreover, serious qualifications of the sexual etiology of human behaviour have been put forward. The power of socio-economic factors in the formation of human personality and the growth of doubt about the exact relation between nature and nurture have blurred theories he once thought to be clear and distinct. Perhaps the most extreme criticisms have come from an essay entitled "What Is Wrong with Psycho-analysis?" The author, H.J. Epenck, points to the distinction German philosophers have made between *verstehende* psychology, or common-sense psychology, which tries to understand human beings, and *erklärende* psychology, which seeks a scientific description and explanation of behaviour. He states that psychoanalysis belongs to the first category—i.e., it is essentially nonscientific—and, in the last analysis, is a matter of faith rather than proof. He also doubts its therapeutic value. These criticisms do not in any way diminish the stature of Freud, whose brilliant theories, therapeutic techniques, and profound insights into the submerged areas of the human psyche opened up a whole new field of psychological study. He was an original thinker who radically altered prevailing views of human nature.

## MAJOR WORKS

With J. Breuer, *Studien über Hysterie* (1895; *Studies in Hysteria*, 1955); *Die Traumdeutung* (1899, dated 1900; *The Interpretation of Dreams*, 1953); *Zur Psychopathologie des Alltagslebens* (1904; *Psychopathology of Everyday Life*, 1960); *Drei Abhandlungen zur Sexualtheorie* (1905; *Three Essays on the Theory of Sexuality*, 1953); *Über Psychoanalyse* (1910; *The Origin and Development of Psycho-Analysis*, 1955); *Totem und Tabu* (1913; *Totem and Taboo*, 1955); *Zur Geschichte der psychoanalytischen Bewegung* (1914; *On the History of the Psychoanalytic Movement*, 1957); *Vorlesungen zur Einführung in die Psychoanalyse* (1917; *A General Introduction to Psychoanalysis*, 1920); *Jenseits des Lustprinzips* (1920; *Beyond the Pleasure Principle*, 1955); *Das Ich und das Es* (1923; *The Ego and the Id*, 1961); *Selbstdarstellung* (1925; *An Autobiographical Study*, 1959); *Hemmung, Symptom und Angst* (1926; *Inhibitions, Symptoms and Anxiety*, 1959); *Die Frage der Laienanalyse* (1926; *The Question of Lay-Analysis*, 1959); *Die Zukunft einer Illusion* (1927; *The Future of an Illusion*, 1961); *Das Unbehagen in der Kultur* (1930; *Civilization and Its Discontents*, 1961); *Neue Folge der Vorlesungen zur Einführung in die Psychoanalyse* (1933; *New Introductory Lectures on Psycho-Analysis*, 1964); *Der Mann Moses und die monotheistische Religion* (1939; *Moses and Monotheism*, 1960).

**BIBLIOGRAPHY.** ERNEST JONES, *The Life and Works of Sigmund Freud*, 3 vol. (1953–57), a thorough, accurate biography partly based on firsthand knowledge, although with an occasional hint of unnecessary esteem and an uneven style; *The Life and Works of Sigmund Freud*, ed. and abridged by LIONEL TRILLING and STEVEN MARCUS (1961), the best condensed account in one volume; MARIE BONAPARTE, ANNA FREUD, and ERNST KRIS (eds.), *Sigmund Freud, the Origins of Psychoanalysis: Letters to Wilhelm Fliess, Drafts and Notes (1887–1902)* (1954), a basic sourcebook for psychoanalytic history; SIGMUND FREUD, *Selbstdarstellung* (1925; Eng. trans., *An Autobiographical Study*, 1959), Freud's all too brief account of his own career and theories; *Letters of Sigmund Freud, 1873–1939*, selected and ed. by ERNST L. FREUD (1961); *A Psycho-Analytic Dialogue: The Letters of Sigmund Freud and Karl Abraham 1907–1926*, ed. by HILDA C. ABRAHAM and ERNST L. FREUD (1965); WILHELM FLIESS, *In eigener Sache* (1906), pamphlet (in German) about the very revealing Freud–Fliess correspondence and relationship; FRITZ WITTELS, *Sigmund Freud* (1924; Eng. trans., 1924), an anecdotal account of his personality, education, and lecturing; HANNS SACHS, *Freud: Master and Friend* (1944), a brief but sympathetic account of the author's lifelong friendship with Freud; PHYLLIS BOTTOME, *Alfred Adler*, 2nd ed. (1946), a not very satisfactory biography, biased in favour of Adler and against Freud; THEODOR REIK, *From Thirty Years with Freud* (1940, reprinted 1963), memories and impressions of Freud chiefly as a man and scientist; HELEN W. PUNER, *Freud* (1947), his life with hints about unconventional aspects in Freud's family; WILHELM STEKEL, *Autobiography: The Life Story of a Pioneer Psychoanalyst* (1950), criticizes Freud during the period of the dissolution of the Wednesday Circle; JOSEPH WORTIS, *Fragments of an Analysis with Freud* (1954), a critical account of an analysis with Freud; CARL JUNG, *Memories, Dreams, Reflections* (1963), recollections recorded and edited by ANIELA JAFFE, throwing valuable sidelights on his relations with Freud; ERICH FROMM, *Sigmund Freud's Mission* (1959), an analysis of Freud's personality and influence; MARTHE ROBERT, *La Révolution psychoanalytique: la vie et l'oeuvre de Sigmund Freud*, 2 vol. (1964; Eng. trans., *The Psychoanalytic Revolution: Sigmund Freud's Life and Achievement*, 1966), a substantial, detailed account of Freud's life and work; HEINZ F. PETERS, *My Sister, My Spouse* (1963), first biography of Lou Andreas-Salomé, who played a part in the Wednesday Circle and the Vienna Psycho-Analytical Association; LOU ANDREAS-SALOMÉ, *In der Schule bei Freud: Tagebuch eines Jahres 1912–1913* (1965; Eng. trans., *The Freud Journal of Lou Andreas Salomé*, 1965), day-to-day account of encounters with Freud and other members of the Wednesday Circle; C. GIOVANNI, *Sigmund Freud* (1967), a short but good biography; VINCENT BROME, *Freud and His Early Circle* (1967), a detailed account of the early personal struggles between members of the Vienna Circle, with new material not used by Jones.

*Books qualifying Freud:* KAREN HORNEY, *New Ways in Psycho-Analysis* (1939); WILHELM REICH, *The Discovery of the Orgone* (1942); H.J. EYSENCK, *Uses and Abuses of Psychology* (1953); M. KLEIN, P. HEIMAN and R.E. MONEY-KYRLE (eds.), *New Directions in Psycho-Analysis* (1955); HERBERT MARCUSE, *Eros and Civilization* (1956); J.A.C. BROWN, *Freud and the Post-Freudians* (1963); PAUL ROAZEN, *Freud: Political and Social Thought* (1969).

(V.Br.)

## Friends

Friends is the name of a Christian group that arose in the mid-17th century in England and the American colonies, dedicated to living in accordance with the direct inward apprehension of God, without creeds, clergy, or other ecclesiastical forms. As most powerfully expressed by George Fox (1624–91), Friends (or Quakers, as they were more often called) felt that their “experimental” discovery of God would lead to the purification of all of Christendom. It did not; but Friends founded one American colony and were dominant for a time in several others, and though their numbers in the early 1970s (about 200,000) were relatively small, they continued to make disproportionate contributions to science, industry, and especially to the Christian effort for social reform.

### NATURE AND SIGNIFICANCE

Trust in the “Inward Light” is the distinctive theme of Quakerism. The Light should not be confused with conscience or reason; it is rather “that of God in every man,” which allows men an immediate sense of God’s presence and his will for them. It thus informs conscience and redirects reason. The experience of hearkening to this inner Guide is mystical but corporate and practical. Meetings to worship God and await his word (always open to anyone who wishes to come) are essential to Quaker faith and practice; although the inward Seed can work in a solitary person, Friends do not meditate like monks, isolated in their cells. It is in the pregnant silence of the meeting of true waiters and worshippers that the Spirit speaks. Sometimes the meeting is too dull or worldly for any message to be heard, and sometimes there are altogether silent meetings, which are spiritually beneficial to the participants; but ideally someone has reached a new understanding that demands to be proclaimed. He or she—for Friends have always given women equality in worship—speaks or prays and thus ministers to the meeting, which weighs this “testimony” by its own experiences of God. Friends historically have rejected a formal or salaried clergy as a “hireling ministry.” If God can provide his own living testimony, the Bible and the learning necessary to read it can take a subordinate place, and creeds and outward sacraments can be dispensed with altogether. But despite their emphasis on silent waiting and their distrust of “creaturely” activity, Friends are no more habituated to passive than to solitary meditation. Often the “opening” of the Inward Light is a “concern” for the sufferings of others and a mandate laid upon the conscience to take action to alleviate that suffering. Such concerns typically are laid before a meeting and thoroughly considered; any corporate action taken must be unanimous. But slow and unorganized as such action sometimes is, Friends have been led to oppose slavery, brutality in prisons and insane asylums, oppression of women, militarism, and war. Their history is thus the story of their experiences with the Inward Light and what they have had to do to be faithful to it.

### HISTORY

**The rise of Quakerism.** There were meetings before there were Quakers. Small groups of Seekers gathered together during the Puritan Revolution in the reign of Charles I to wait upon the Lord because they despaired of spiritual help either from the Established Church or the existing Puritan bodies—Presbyterians, Congregationalists, and Baptists—through which most of them had already passed. Among these Seekers, Fox and James Nayler were perhaps the most eminent, but Edward Burrough, William Dewsbury, and Richard Farnworth also were active. The cradle of the movement was northwest England and specifically Swarthmoor Hall in northwestern Lancashire, which after 1652 became the centre of an evangelistic campaign by travelling ministers. Within a decade perhaps 20,000 to 60,000 had been converted from all social classes except the aristocracy and totally unskilled labourers. Heaviest concentrations were in the north, southwest, and in London. Travelling Friends and

Cromwellian soldiers brought Quakerism to the new English settlements in Ireland; Wales and especially Scotland were less affected.

The Puritan clergy, in England and New England, greeted the rise of Quakerism with the fury that an old left often reserves for a new. Friends’ religious style was impulsive and nonideological; Quakers seemed to ignore the orthodox views of the Puritans and pervert their heterodox ones. The Restoration of Charles II in 1660 was only a change of persecutors for the Quakers, with their former tormentors now sharing some of their sufferings. From the Quaker Act of 1662 until the de facto toleration of James II in 1686, when he began dispensing from taking oaths required by the Test Act (de jure toleration came in the Toleration Act of 1689), Friends were hounded by penal laws for not swearing oaths, for not going to the Church of England, for going to Quaker meetings, and for refusing tithes. Some 15,000 suffered under these laws, and almost 500 died in prison, but they continued to grow in numbers until the turn of the century.

At the same time they were converting and peopling America. In 1656 Quaker women preachers began work in Maryland and in the Massachusetts Bay Colony. The magistrates of Boston savagely persecuted the visitors and in 1659 and 1661 put four of them to death—the only Friends anywhere to be executed for preaching their faith. Despite this, Quakerism took root in Massachusetts and flourished in Rhode Island, where Friends for a long time were in the majority of the settlers. There were also many Friends in New Jersey, where English Quakers early secured a patent for settlement, and in North Carolina. Yearly meetings were established for New England (1661), Maryland (1672), Virginia (1673), Philadelphia (1681), New York (1695), and North Carolina (1698). The most famous Quaker colony was Pennsylvania, for which Charles II issued a charter to William Penn in 1681. Penn’s “Holy Experiment” tested how far a state could be governed consistently with Friends’ principles, especially pacifism and religious toleration. Toleration would allow colonists of other faiths to settle freely and perhaps become a majority; consistent pacifism would leave the colony defenseless against enemies who might have been provoked by the other settlers. Penn, entangled in English affairs, spent little time in Pennsylvania and showed consistently poor judgment in selecting his non-Quaker deputies, who were almost always at odds with the Quaker-dominated legislature. Penn also went bankrupt through mismanagement; but the Quaker influence in Pennsylvania politics remained paramount until 1756, when legislators who were Friends could no longer find a saving formula allowing them to vote support for military operations against the French and Indians fighting settlers in western Pennsylvania. Voltaire’s description of Penn’s agreements with the Indians as the only treaties never sworn to and never violated was slightly exaggerated; but Friends’ relations with the Indians were more peaceful than those of other settlers, and had Quakers remained the only settlers, the colony might have been spared Indian wars.

**The age of quietism.** The achievement of religious toleration in the 1690s coincided with a quietist phase in Quakerism that lasted until the 19th century. Quietism is endemic within Quakerism and emerges whenever trust in the Inward Light is stressed to the exclusion of everything else. It suits a time when little outward activity is demanded and when the peculiar traditions of a group seem particularly worth emphasizing. In the 18th century Friends had gained most of their political objectives. Their special language and dress, originally justified as a witness for honesty, simplicity, and equality, became passwords and uniforms, respectively, of a group now 75 to 90 percent composed of second- and third-generation Quakers. Strict enforcement of rules prohibiting marriage without parents’ consent or to nonmembers led to the disownment, according to one estimate, of a third of the English Friends who got married in the latter half of the 18th century. More were disowned than converted,

Persecution of Quakers

William Penn’s “Holy Experiment”

The “Inward Light”

and since most members were the children of members, it is not surprising that Friends eventually came to recognize a category of "birthright" membership, which seemed to relax the expectation of conversion.

Seemingly self-absorbed in other ways, Friends in the age of quietism deepened and intensified their social concerns. English Friends were active in the campaign to end the slave trade, and American Friends, urged on by John Woolman and others, voluntarily emancipated all their own slaves between 1758 and 1800. Meetings, though slow to adopt this concern, pursued it absolutely and thoroughly; in Rhode Island Stephen Hopkins, who was governor nine times, was disowned because he would not free his one slave.

**The impact of evangelicalism.** Imbued with quietism and with few converts with experience of other churches, Friends might have remained in secluded religious life had it not been for the evangelical movement associated with John and Charles Wesley. Evangelical Friends were concerned with emphasizing the inerrancy and uniqueness of the Bible, the incarnation and atonement of Christ, and other characteristic Protestant doctrines which, although seldom denied by Friends, tended to be subordinated to the quietistic emphasis on the Inward Light. In the early 19th century most leading English Friends were sympathetic to evangelical ideas, although they did not lose their unity with more traditional-minded Friends.

In America unity proved more difficult. Friends had gone west—from Virginia and North Carolina because of difficulties over slavery, but also from Pennsylvania. As new yearly meetings were formed—Ohio (1812), Indiana (1821), Iowa (1863), Kansas (1872), Oregon (1893), California (1895), and Nebraska (1908), among others—ties with the London Yearly Meeting, the "mother" meeting, became weaker, and no American yearly meeting had a predominant position. Leaders of Philadelphia Yearly Meeting, mostly rich merchants with strong ties to England, were sympathetic to Evangelicalism; but many poorer country Friends left the meeting, no longer feeling a unity with the beliefs of the Philadelphia ministers and elders or with the way they exercised their authority. Elias Hicks (1748–1830), whose name was applied to these separatists, placed extreme emphasis on the Inward Light; he wrote that it might be a good thing if God withdrew the Bible, since he could inspire worshippers to write new scriptures that would probably be better than the originals. Since the various American yearly meetings corresponded with one another, the Hicksite separation spread to other yearly meetings that had to decide to which portion of Philadelphia Yearly Meeting to write. A pastoral visit to America (1837–1840) by the leading English evangelical Friend, Joseph John Gurney (one of the few systematic theologians ever produced in the Society of Friends), led to a further separation when the evangelical or "Gurneyite" New England Yearly Meeting disowned John Wilbur, an orthodox quietist Friend.

Schism is often a sign of religious vitality, and so it proved now. Whether Hicksite, Wilburite, or Gurneyite, all branches of Quakerism began to show vigour unknown in their days of torpid unity. With more vital preaching, many converts not devoted to the inherited peculiarities of Quaker tradition joined Friends; to them it seemed more important to assure a saving ministry than to preserve the traditional mode of worship. There thus grew up, especially in the Midwest and Far West, "pastoral meetings" in which a paid minister assumed the functions of delivering a sermon and exercising pastoral care of members. Such meetings often called themselves "Friends' Churches"; congregational singing was a part of the service, which might have only a few moments of silence, and baptismal and marriage ceremonies were introduced. In doctrine, worship, and polity they were not unlike Congregational churches, though they remained faithful to Friends' social testimonies. Even in England, where such innovations were not introduced, Friends, under the influence of the evangelical revival,

discontinued disownment for irregular marriages and curtailed the powers of elders and overseers, which had been a profoundly conservative force.

**The 20th century.** Friends in 1900 were divided into three groups. Yearly meetings of evangelical, or "orthodox," Friends were in fellowship with one another and with the London and Dublin yearly meetings. In America these Gurneyite meetings in 1902 formed the Five Years' Meeting (now the Friends United Meeting). The "conservative" American yearly meetings, in fellowship with one another, maintained traditional Quaker customs and mode of worship. The Hicksite yearly meetings, which formed the Friends General Conference in 1902, remained the most open to modern thought. During the century these divisions have been much softened. Theological distinctions have receded in importance, and the habit of cooperation in such agencies as the American Friends Service Committee has drawn Friends together. Also, "independent" meetings, often composed largely of students, have not perpetuated old divisions.

The 20th century has also seen the extension of Quakerism to Africa and continental Europe. There are now more Friends in Africa (35,531 in 1969) than in the homeland of Quakerism (20,910 members in Great Britain and 1,759 in Ireland). There are over 33,000 Friends in Kenya alone. Quakerism took root in the Netherlands in the 17th century but died out in the mid-19th, as did groups in Congénies, France, and Bad Pyrmont, Germany. Quaker relief work in World War I and its aftermath produced new yearly meetings in Germany, The Netherlands, France, Sweden, and Switzerland, but numbers remain small: 85 in France, 126 in The Netherlands, and 151 in Switzerland in 1969, for example.

#### ORGANIZATION AND PUBLIC CONCERNS

**Polity.** Insofar as George Fox is the "founder of Quakerism," he is so chiefly because of the system of meetings for church business that he established in the years immediately after 1667, which essentially stands today. The most important meeting is the monthly meeting, which considers all applications for membership, in some localities manages Friends' properties, and acts on members' concerns. Generally, in the United States each congregation has a monthly meeting; in England and in some parts of the United States several meetings for worship combine in monthly meeting. Several monthly meetings form quarterly meetings, which are combined in yearly meetings, of which there were, in 1970, 49, ranging in membership from under 100 to over 60,000.

This array is less hierarchical than it sounds. Any Friend can attend any meeting, which tries to remain open to his concerns or the service he can perform (much in the spirit of a meeting for worship). Furthermore, all decisions must be made unanimously. The responsibility of the clerk is not to preside in a parliamentary manner but to feel for a "sense of the meeting," which draws together the thinking of the meeting to the point of action.

Though Friends have no ordination, they have always given a special place to Recorded Ministers (or Public Friends). Recorded Ministers are those whose testimony in local meetings has been officially recognized; they are free to "travel in the ministry" by visiting other meetings, should they be led to do so. Pastoral meetings maintain their Recorded Ministers, who also do much of the work of seeing to the relief of the poor, care of properties, and discipline of erring members, which elsewhere was done by elders and overseers. Ministers have usually had their own meetings together, and in most yearly meetings executive responsibility had been taken by a meeting like the Meeting for Sufferings in London (these are also called Representative meetings or committees or Permanent boards). London Meeting for Sufferings in the 17th century served as a political pressure group, lobbying Parliament for relief from persecution and using the press for public appeals; in the 19th century they extended their care to sufferings everywhere.

**Corporate and personal concerns.** The "public testimonies" of Friends from the very beginning included the

Evangelical  
Friends

Pastoral  
meetings

Relief  
work

plain speech and dress and refusal of tithes, oaths, and worldly courtesies—all clearly entailed in the Quaker message. To these was added in a few years an explicit renunciation of participation in war; within the next century bankruptcy, marriage out of meeting, smuggling, and dealing in or owning slaves also became practices for which an unrepentant Friend would be disowned. These latter, especially those relating to slavery, became matters for discipline because a comparative minority of Friends persuaded the rest that they were inconsistent with Friends' principles. But not all social concerns were corporate in this sense or were enforced by sanctions. Friends' relief work, for example, has usually arisen from an individual response to suffering, often as the result of war. From the time of the American Revolution, Quakers have been active in ministering to refugees and victims of famine—so much so that the entire Society of Friends is sometimes taken for a philanthropic organization; yet this work, recognized in 1947 by the award of the Nobel Peace Prize to the American Friends Service Committee and the (British) Friends Service Council, has mobilized many non-Quakers and thus exemplifies the interaction between the Quaker conscience and the wider world.

There have always been Friends whose concerns went well beyond what meetings were willing to adopt. Most Friends were not abolitionists before the American Civil War; they probably did not approve of the Underground Railroad nor share the early feminist views of Lucretia Mott and Susan B. Anthony. The social views of some American Friends are not unfittingly represented by the two presidents of Quaker background, Herbert Hoover and Richard M. Nixon. Often the issue has been the relationship between private witness and public policy. Some Quaker pacifists are concerned enough to make an absolute personal stand against war (for example, by refusing to register for selective service and thus forfeiting conscientious objectors' status); others are more willing to sacrifice purity for effectiveness, by working for an alleviation of international tensions even at the cost of less rigorous application of their principles.

## INFLUENCE OF FRIENDS

Quaker customs and the restricted place of Friends in the social order have greatly concentrated their secular achievements. Plainness meant that painting, music, and the theatre were proscribed. For a century trust in the Inward Light inhibited the foundation of schools (though in the 19th century American Friends founded colleges like Earlham, Haverford, and Swarthmore; and individual Friends founded Bryn Mawr College, Cornell University, and Johns Hopkins University). Friends' schools put an emphasis on science; the chemist John Dalton, the geneticist Francis Galton, the anthropologist E. B. Tylor, the astronomer Arthur Eddington, and Joseph Lister, discoverer of antiseptics, were all Friends. Ruth Fry has estimated that an English Quaker has almost 50 times as great a chance as someone in the general population to be elected a Fellow of the Royal Society. In commerce Friends were trusted and got customers; they trusted one another and extended credit; thus the many successful Quaker firms and banks, of which Barclay's and Lloyd's are the best known. Friends also pioneered in inventions, developing the puddling process for iron, and the safety match, and promoting the first English railroad line.

Disdaining formal education and a clerical intelligence, Friends, not surprisingly, often failed theologically (that is, could not solve some of the intellectual problems of their faith). But they would agree with the 19th-century Danish religious philosopher Søren Kierkegaard that "the highest of all is not to understand the highest but to act upon it." The cause of schisms in the past—the tension between entire reliance on the Inward Light and the profession of orthodox Christian doctrines—remains unresolved. It also remains to some extent a barrier to ecumenism; the London Yearly Meeting in 1940 declined to join the World Council of Churches out of uneasiness

with its creedal basis, though some U.S. groups of Friends sent delegates to the first meeting of the council in 1948. Looked at in the context of Christendom as a whole, Friends offer a distinctive opportunity for spontaneity of worship, fellowship in mysticism, and proving mystical insight in labour for a suffering world. Many alienated from institutional Christianity have found this combination attractive; they may well feel more comfortable identifying themselves as Friends than as Christians. This may make it more difficult for Quakerism to be subsumed into a reunited Christian church; but the faith of most Friends has always been that, as Albert Schweitzer wrote in *The Quest of the Historical Jesus*, as "we do the work of Christ we shall come to know who he is."

**BIBLIOGRAPHY.** Good introductions to Quakerism may be found in the *Handbook of the Religious Society of Friends*, 5th ed. (1967), produced by the Friends World Committee for Consultation; and in the interpretations by D.E. TRUEBLOOD, *The People Called Quakers* (1966); and in L. BENSON, *Catholic Quakerism* (1966). The standard histories are W.C. BRAITHWAITE, *The Beginnings of Quakerism*, rev. ed. (1955), and *The Second Period of Quakerism*, rev. ed. (1961); and R.M. JONES, *The Quakers in the American Colonies* (1911), and *The Later Periods of Quakerism*, 2 vol. (1921). Many Friends' practices are codified in the London Yearly Meeting *Book of Discipline*, 2 vol. (1960); and in the Five Years' Meeting *Uniform Discipline* (1902). The masterpiece of Quaker theology is R. BARCLAY, *Theologiae verè Christianae Apologia* (1676; Eng. trans., *Apology for the True Christian Divinity*, 1678). W.C. BRAITHWAITE best explains how Friends' polity should work in *Spiritual Guidance in the Experience of the Society of Friends* (1909). See also G. WILSON, *Quaker Worship* (1952). The autobiographical work of C.E. PICKETT, *For More than Bread* (1953), an account of work with the American Friends Service Committee from 1929 to 1952, is unusually good. Quaker social thought on contemporary issues may be found in S. ALEXANDER (ed.), *Quaker Testimony Against Slavery and Racial Discrimination* (1958); and the FRIENDS HOME SERVICE COMMITTEE, *Towards a Quaker View of Sex* (1963).

## Froebel, Friedrich

Remembered mainly for his development of the kindergarten, Froebel's life and career were dominated by the conviction that all human beings have an undeniable right to self-realization through self-education.

By courtesy of the Staatliche Museen, Heidecksburg

Froebel, drawing by Friedrich Unger. In the Staatliche Museen, Heidecksburg.

Friedrich Wilhelm August Froebel was born April 21, 1782, in the town of Oberweissbach in the Thuringian Forest of Germany, the fifth child in an orthodox clergyman's family. He was only nine months old when his mother died. The trauma caused by that loss and his father's absorption in the demands of his parish, as well as his stepmother's indifference, rendered him moody,

introspective, slow in learning to read, and unresponsive to intellectual interests, Denied schooling and normal contacts with children of his own age, he developed an obsessive attachment to the world of nature. He learned to observe keenly, made intuitive scientific deductions, and at a very early age formulated a profound spiritual philosophy concerning the unity of the universe.

After apprenticeship to a forester, he pursued some informal university courses at Jena until he was jailed for an unpaid debt. After brief periods as a surveyor, estate manager, and private secretary, at 23, cutting short his preparations for architecture, he impulsively took a teaching appointment in a progressive model school in Frankfurt that was run on lines advocated by the Swiss educator J.H. Pestalozzi.

A crucial turning point came in June 1806, when he entered the household of Baron von Holtzhausen as tutor to his three sons. The Baron's failure to manifest interest in the rearing of his sons confirmed Froebel's conviction of the vital need for both father and mother to participate in the education of children. In the Baroness he saw the embodiment of ideal motherhood, and he nurtured an affinity for her, regarding her as his spiritual bride. In June 1811 he suddenly left the household to continue university study, but he kept up a secret correspondence with the Baroness for several years.

At the University of Göttingen, Froebel enunciated his "law of the sphere," his symbol of the divine forces operative in the universe, which he dreamed of applying to a comprehensive reconstruction of science and culture. He began by studying crystallography, but soon became engulfed in the Napoleonic Wars, and while a soldier developed the idea of regenerating Germany through a basic restructuring of its educational system. Returning to the University of Berlin in 1814 he became curator of its mineralogical museum, but two years later he was back in Thuringia, in the village of Griesheim, to establish his own school, which he described as the "Universal German Educational Institution." Three orphaned nephews, a brother, his sister-in-law, and her two sons comprised the household staff and student body. Froebel, despite his emphasis on the importance of the family as the true root of human life, did not marry until 1818, when he took Wilhelmine Hoffmeister, a refined and spiritually sympathetic partner, as his bride. After a year he moved the school to neighbouring Keilhau, and it soon expanded into a flourishing institution.

Froebel, unable to win government support for his project, continued to devote himself unstintingly to the school. He wrote numerous articles and in 1826 published *The Education of Man*, a philosophical presentation of principles and methods pursued at Keilhau. In 1828 the Keilhau school became suspect to the authorities as a "nest of demagogues," and, although officially absolved, Froebel was removed from direct control in 1832. After five years in Switzerland, he returned to Germany and realized only two of his ideas: the Child Nurture and Activity Institute, which by happy inspiration he renamed the Kindergarten, and a small boarding school for future teachers. Wilhelmine died a year before the official founding of the Kindergarten, in June 1840. He also started a publishing plant for play and other educational materials, including a collection of *Mother-Play and Nursery Songs*, with lengthy explanations of their meaning and use. This immensely popular book was translated into many foreign languages. He insisted that improvement of infant education was a vital preliminary to comprehensive educational and social reform. His enthusiasm was spurred on by Louise Lewin, a zealous woman 30 years his junior, whom he had helped rear at Keilhau; they were married in 1851.

Froebel won effective worldwide support of the kindergarten movement, despite its ban as subversive by the Prussian government from 1851 until 1860. The Baroness of Marenholtz-Bülow, deeply impressed by what she had observed of Froebel's kindergarten at Marienthal in Thuringia, established kindergartens in England and throughout Europe.

Froebel died at Marienthal on June 21, 1852.

**BIBLIOGRAPHY.** IRENE M. LILLEY, *Friedrich Froebel: A Selection from His Writings* (1967), is the most recent documented presentation, emphasizing aspects of Froebel's life often neglected in other studies. WILLIAM H. KILPATRICK, *Froebel's Kindergarten Principles Critically Examined* (1916), is a penetrating analysis by a celebrated educator.

(S.B.I.)

## Frontenac, Comte de

Louis de Buade, comte de Frontenac et Palluau, was a governor of New France and one of the architects of French expansion in North America. He was born at Saint-Germain on May 22, 1622. His father, Henri de Buade, was colonel of the Régiment de Navarre and a member of Louis XIII's entourage; his mother was Anne Phélypeaux, of the influential Pontchartrain family; Louis XIII was his godfather. He served with the French armies during the Thirty Years' War; in 1643, at the age of 21, he was colonel of the Régiment de Normandie and in 1646 was appointed a *maréchal de camp* (brigadier general). In 1648 he secretly married Anne de La Grange-Trianon, who, in consequence, was disowned by her wealthy father.

Frontenac had great personal charm and much influence at court, but he was also egoistic and unscrupulous, as well as extravagant; by 1663 his debts amounted to over 350,000 livres. In 1669 he took service as lieutenant general with the Venetian forces defending Crete against the Turks, but he had not been on the island long before he was dismissed from his post for intriguing against his superior officers.

*First service in New France.* In 1672 he was appointed governor general of New France. Within a year of his arrival in the colony, he had founded a fur-trading post, Ft. Frontenac, on Lake Ontario. Shortly afterward he became associated with the Sieur de La Salle, who, with Frontenac's support, obtained royal consent to continue the explorations of Louis Jolliet down the Mississippi to its mouth. La Salle took advantage of this to found fur-trading posts at the foot of Lake Michigan and on the Illinois River, from which his men, with the connivance of Frontenac, illegally engrossed a large part of the western fur trade. This brought them into conflict with the Montreal fur traders, dividing the colony into two hostile factions. Despite repeated warnings from Louis XIV and his minister J.-B. Colbert, Frontenac also disputed violently with the officials and clergy of New France.

While these conflicts were raging within the colony, a much more serious external problem was developing. Until 1675 the Five Nations of the Iroquois Indian confederacy had remained on good terms with the French because they were under attack from the Andaste and Mohegan tribes; but in that year the Iroquois subdued the other tribes and immediately began to contest the French hold on the western fur trade, their aim being to divert it from Montreal to Albany, with themselves acting as middlemen. When they attacked the tribes allied to the French and threatened the French themselves, Frontenac tried to appease them, doing nothing to strengthen the colony's almost nonexistent defenses. This policy merely encouraged the Iroquois to press their attacks with greater vigour, until the French were in danger of being driven out of the west. During these years, too, the English Hudson's Bay Company established posts in James Bay, posing another threat to the Canadian fur trade, one that Frontenac chose to ignore. In 1682 Louis XIV recalled Frontenac because of his misgovernment. (His successor, Le Febvre de La Barre, attempted with little success to subdue the Iroquois and in 1685 was replaced by the Marquis de Denonville, who brought the Indians to terms.)

*The war with England.* When England declared war on France in May 1689, Frontenac was given command of an expedition to conquer the province of New York. At the same time he was reappointed governor of New France, and Denonville was recalled for service in Europe. Frontenac's expedition was delayed by adverse weather, however, and he did not reach Quebec until October 12. The Iroquois, meanwhile, learning of Anglo-

Formative experiences as a private tutor

The spread of the kindergarten concept

### The expansion of New France

French hostilities before the news reached New France, had launched a furious assault on the unsuspecting colony on August 5, inflicting great damage and killing or capturing about 100 Canadians. This attack, and the lateness of the season when Frontenac reached the colony, made it impossible to invade New York in force; but in January he sent three war parties to attack the English frontier settlements at Schenectady, Ft. Loyal, and Salmon Falls. All three places were destroyed with heavy loss of life for the defenders, and as a result the northern English colonies united for an assault on New France. The attacking forces, led by Sir William Phips, were repulsed at Quebec by the French under Frontenac, who distinguished himself by his prudent tactics.

During the next few years the fighting was confined to sporadic raids on the Canadian settlements by the Iroquois, but this did not prevent a rapid expansion into the west by the Canadian fur traders. Frontenac concerned himself far more with the fur trade than with pressing the war to a successful conclusion. Despite the fact that the policy of Louis XIV was to curb expansion into the interior in order to strengthen the central colony, old fur-trading posts were strengthened and new posts established by Frontenac until French influence extended beyond Lake Superior, and the flood of furs coming down to Montreal glutted the market in France. After much urging from his subordinates and the receipt of explicit orders from the minister of the marine, Frontenac finally undertook in 1696 an expedition that destroyed the villages of two of the Iroquois nations. The following year the war between England and France ended, but it was not until 1701 that a peace treaty was ratified with the Iroquois by Frontenac's successor. After a brief illness, Frontenac had died at Quebec on November 28, 1698.

Frontenac was one of the more colourful personages in North American history. His connections at the court of Louis XIV enabled him to survive failures that might have destroyed another man and won him credit for the achievements of his subordinates. It was, however, under his regime that the English and Iroquois attacks on New France were finally repulsed and the French extended their North American empire from Montreal to Lake Winnipeg and from Hudson Bay to the Gulf of Mexico.

**BIBLIOGRAPHY.** FRANCIS PARKMAN, *Count Frontenac and New France Under Louis XIV* (1877), a romantic account of Frontenac's career that extols his virtues and minimizes his flaws; W.J. ECCLES, *Frontenac: The Courtier Governor* (1959), a critical biography incorporating some new material.

### Frost, Robert

Robert Lee Frost used colloquial language, familiar rhythms, and symbols taken from common life to express in his poetry the quiet values of rural New England. Long denied recognition—his first book did not appear until he was nearly 40 years old—Frost himself became, toward the end of his long life, a symbol of craggy independence, laconic piety, and the courage to endure.

**Life and works.** Frost was born in San Francisco, California, on March 26, 1874. His father, William Prescott Frost, Jr., a New Englander and a graduate of Harvard College, was serving as headmaster of a private school in Lewistown, Pennsylvania, when he met and married a Scottish-born schoolteacher, Isabell Moodie. He took his bride to San Francisco, where he became a newspaper reporter. When Robert was 11 years old, his father died of tuberculosis. The widow and her two children (a daughter had been born in 1876) accompanied the body to Lawrence, Massachusetts, for burial; thereafter, Mrs. Frost, too poor to return to California, supported the family by teaching school in Massachusetts and New Hampshire. She exerted a strong influence on her son's personal and literary development: her Scots loyalties and her intense religious leanings may have contributed to the blend of practicality and mysticism in his poetry.

As a boy Frost was fond of baseball and football, not school books. With some difficulty, even with his mother's help, he finished grammar school in Salem, New

Frost, 1954.  
Ruohomaa—Black Star

Hampshire. His attitude changed as soon as he entered high school at Lawrence, from which he was graduated in 1892 as co-valedictorian, sharing the honour with Elinor Miriam White, whom he later married. In his valedictory address he spoke warmly of the poet's responses to experience—a further indication of an interest already well established, for he had published several poems in the school paper while he was its editor.

Frost's paternal grandfather, who wanted him to become a lawyer, sent him to Dartmouth College at Hanover, New Hampshire, the following fall. But the young man, once more impatient with academic routine, stayed less than a term, departing without notice. During the next few years he lived at home in Lawrence, writing poetry and intermittently earning money as a schoolteacher, mill hand, and newspaper reporter. For two years after his marriage in 1895 he and his wife helped his mother conduct a small private school. Throughout this period he sent poems to periodicals, with little success. The first poem he sold, "My Butterfly: An Elegy," appeared in 1894 in *The Independent*, a weekly literary journal.

In the fall of 1897 Frost entered Harvard College to prepare himself for teaching Latin and Greek at the high school level. He received excellent grades in these subjects, but after less than two years he withdrew because of illness. Warned that he might be tubercular, he changed his way of life drastically, becoming a poultryman at Methuen, Massachusetts. The venture succeeded at first, and in 1900 he moved to a farm at Derry, New Hampshire, purchased for his use by his grandfather. The Frosts' first child had been born in 1896, but the boy died just before the move; their second child, a girl, was less than a year old at the time. Four other children were born to the Frosts at Derry. After Frost failed as a farmer, he turned again to teaching (1906–12).

Many of Frost's best known poems were written at Derry, but editors showed little interest. In 1911 the title to the farm passed to Frost, who had for some years been receiving a small annuity from the estate of his grandfather, who had died in 1901. Frost promptly sold the farm and took his family to England the following year, intending to give all of his time to writing. He settled at Beaconsfield in Buckinghamshire and assembled a collection of the lyric verses he had written at Derry. The manuscript was accepted by the first London publisher to whom he submitted it, and *A Boy's Will* appeared in 1913. The next year the same publisher issued Frost's collection of narrative poems, *North of Boston*. British reviewers responded so enthusiastically that overtures were soon made to him by three American publishers. In England he made the acquaintance of Ezra Pound, Edward Thomas, W.W. Gibson, T.E. Hulme, Lascelles Abercrombie, and others. Invited to a rural setting by the Georgian poets Gibson and Abercrombie, he moved to the Gloucestershire countryside in 1914. After the onset of World War I the Frosts returned to the United States, in February 1915, just when his first two books

Academic training and school-teaching career

First acclaim in England

were being published in New York. He bought a small farm at Franconia, New Hampshire; and the warm response to his poetry in the U.S. ended his obscurity.

He served as a professor of English at Amherst College (1916–20); was poet-in-residence at the University of Michigan (1921–23); returned to Amherst (1923–25) and the University of Michigan (1925–26); and thereafter taught part-time at Amherst until 1938. From 1939 to 1943 he was Ralph Waldo Emerson fellow of poetry at Harvard; from 1943 to 1949 he was Ticknor fellow in the humanities at Dartmouth College; and from 1949 to his death on January 29, 1963, in Boston, he held a sinecure as Simpson lecturer at Amherst.

**Relationship between his life and his career.** Any attempts to describe the characteristics and personality of Robert Frost are difficult to make because he was an extremely complicated man. Those individuals who became well enough acquainted with him to call him a friend found him a very sympathetic person, outgoing and eager to help. For example, one such friendship began with John Bartlett, a student of Frost's while he was teaching in 1909 at the Pinkerton Academy in Derry Village, New Hampshire. This friendship, which lasted as long as Bartlett lived, is recorded in Margaret Bartlett Anderson's *Robert Frost and John Bartlett: The Record of a Friendship* (1963).

There was an entirely different side to Frost's capacity for making friends. In his travels or even on the street of any of the many towns in which he lived he frequently struck up a conversation with a stranger to ask information about some point that interested him. The stranger, unaware that he was talking to a famous man, merely realized that the questions being asked him made sense and were easy to answer. Such a conversation might last for several minutes, and the stranger was almost always charmed by the simplicity and directness of Frost's manner. Under such circumstances the conversation would usually end with a natural leave-taking without any exchange of names.

Reference has already been made to the fact that, because of doctor's orders, Robert Frost became a poultry farmer and later an ordinary farmer in Derry, New Hampshire. During the years on the farm in Derry, Frost demonstrated that he was really not cut out to be a farmer. In later years, he repeatedly confessed that he failed as a farmer because he was too lazy. Some of his attempts to solve various problems that annoyed him in the life of a farmer are entertaining. For example: because he liked to sleep late and to stay up late at night either reading or writing poetry, he resented the requirement that his one cow had to be milked early in the morning. He solved this problem by easing the cow's milking schedule around until he was milking her at midnight and noon.

Interest in  
botany

Before he went to the Derry farm he had become an enthusiastic botanist. As a result, he devoted far more time to botanizing on his farm at Derry than he devoted to farming. As soon as his children were old enough to share his botanizing interests, he took them on many walks far beyond the limits of his farm. And, indeed, there are more poems concerned with botanizing than with farming in his first book of poems, *A Boy's Will*.

Frost's continuing interest in farming, such as his purchasing the Franconia farm immediately after his return from England, can be explained partly by his fondness of playing at farming (so long as it did not involve too much hard work) and by the fact that in his first two books he had repeatedly spoken with the voice of a farmer. In his poetry he deliberately wished to preserve the notion that he was a farmer. Within a few months after he bought the farm in Franconia, however, he accepted a teaching job at Amherst College and took up residence with his entire family in Massachusetts. For the next few years the farm in Franconia became a retreat during vacations from Amherst.

As he began to give readings further away from home, Frost still took pleasure in referring to himself not only in his poems but also in his talks as a New England farmer. When he wrote his poem entitled "New Hampshire"

(1923), he included the following witticism near the end of the poem:

I choose to be a plain New Hampshire farmer  
With an income in cash of, say, a thousand  
(From, say, a publisher in New York City).  
... At present I am living in Vermont.

By the time the poet wrote these lines, he had bought another farm, at South Shaftsbury, Vermont. Although Frost made many boasts to his friends about his plan to raise large crops of apples on his new farm, with the help of his son Carol, the farm never became a financial success.

It would be a mistake to conclude that, because Frost was never a successful farmer on any of the various farms he owned, there was only a poetic significance in his repeated desire to associate himself with farms that he actually owned. These farms were much more than an important retreat from the social life that he knew as a teacher or as a reader of his poems. There was a religious significance in nature for Frost. Day after day he was content to go walking by himself across the meadows and through the woods of his own farm or beyond to property owned by a friend who would not mind his trespassing. These walks were made as happily with a companion as alone. But it was clear that he often walked alone on these rambles because it gave him time for his own thoughts and the discovery of the beginning of new poems. His motions as he walked were really those of a botanist who deeply loved what he saw on both sides of the path as he walked. His favourite time for such walks was always in the spring of the year, and the number of wild flowers that he could call by name was extraordinary.

Of particular interest to him were the wild orchids; the names of some of his favourites crop up in several of his poems: rose pogonias, ram's horn orchid, yellow lady's slipper, and the queen's head orchid. During such walks, whenever he was surprised by a plant that he had not recently seen, he frequently would exclaim aloud, "Hello!" His walks in the summer or in the fall took on an entirely different quality of botanical concern as his eyes looked for and found signs of flowers that had already gone to seed.

Although Frost was always more of a botanist than he was a farmer, he cherished ever since his Derry days the thought that sometime he might be wealthy enough to own a farm that could be run for him by one or more hired men, so that he might play at the game of farming as much or as little as he pleased. He finally did achieve a circumstance that came close to fulfilling his dream. In 1939, the year after the death of Mrs. Frost, he bought near the Bread Loaf School of English in Ripton, Vermont, a good-sized farm known as the Homer Noble farm after its previous owner. The farm spread out on a southerly slope and about one hundred yards above the farm house was a well-built cabin.

Frost's  
Vermont  
farm

At that time the head of the Bread Loaf Writer's Conference was Theodore Morrison. He was also head of a special English program at Harvard College. Frost had taken up his winter residence in an apartment on Beacon Hill in Boston, and Mrs. Morrison was serving as his secretary, helping him arrange his schedule of public readings. Frost proposed to the Morrisons that they might like to live in the Homer Noble farmhouse each summer with their two young children and that he, then, would live in the cabin up the hill and eat his meals with the Morrisons in the farm house. The plan was accepted and went into effect in the summer of 1940. Immediately thereafter, plans were made to find a married hired man who would handle the necessary farm duties throughout the year. After one unsuccessful adventure, Frost found and hired an extremely competent farmer named Stafford Dragon. Each summer before Frost and the Morrisons arrived at the Homer Noble farm, Stafford had plowed, fertilized, and planted a good-sized vegetable garden. In this way Frost did acquire a farm on which he could work as much or as little as he wished.

**Appraisal.** The poetry of Robert Frost appeals to an unusually wide variety of readers because it can be en-

joyed in so many different ways. Eschewing the experimentation of many 20th-century poets, Frost repeatedly said he was content with "old ways to be new." From the 19th-century English Romantic poet William Wordsworth he learned that incidents and situations from common life can be described lyrically in a language close to that actually used by ordinary men and women—a point of view that made his work seem "unpoetic" by comparison with the contrived, sentimental verse in vogue before World War I. From another 19th-century English poet, Robert Browning, Frost adapted certain principles of dramatic monologue and dialogue. His study of ancient Greek and Latin authors, particularly Theocritus and Virgil, grounded him in the pastoral conventions of the eclogue, a bucolic poem usually in dialogue.

Many of Frost's readers are content to enjoy his precisely recorded observations of little-noticed details in the appearance of natural objects and the behaviour of rural characters; but his poetry offers much more. From the beginning of his literary career he endowed his rural imagery with symbolic and even metaphysical meaning. As a consequence, his best poems subtly transcend the immediate relationships of the outward individual to the interior self, to others, to nature, and to the universe in a way that illuminates the values on which his profound religious faith was built. Although his wide range of poetic mood includes fear and doubt, the affirmations predominate.

#### MAJOR WORKS

POEMS: *A Boy's Will* (1913), includes "Mowing," "My November Guest," "A Prayer in Spring," "Reluctance," "Storm Fear," and "The Tuft of Flowers"; *North of Boston* (1914), includes "After Apple-Picking," "Death of the Hired Man," "Home Burial," "Mending Wall," and "The Wood-Pile"; *Mountain Interval* (1916), includes "Birches," "The Impulse," "Loneliness," "An Old Man's Winter Night," "Out, Out—," "The Oven Bird," "The Road Not Taken," and "The Sound of Trees"; *New Hampshire* (1923), includes "Dust of Snow," "Fire and Ice," "The Onset," "The Runaway," "Stopping by Woods on a Snowy Evening," and "To Earthward"; *West-Running Brook* (1928), includes "Acquainted with the Night," "Bereft," "Once by the Pacific," "A Soldier," and "Tree at My Window"; *A Further Range* (1936), includes "Departmental," "Desert Places," "Neither Out Far nor In Deep," "Two Tramps in Mud Time," and "A Lone Striker"; *A Witness Tree* (1942), includes "Come In," "The Gift Outright," "The Lesson for Today," "The Most of It," and "The Silken Tent"; *Steeple Bush* (1947), includes "Directive"; *In the Clearing* (1962), includes "Away!"

VERSE PLAYS: *A Masque of Reason* (1945); *A Masque of Mercy* (1947).

**BIBLIOGRAPHY.** *Selected Letters of Robert Frost*, ed. by LAWRENCE THOMPSON (1964), is a sampling of his correspondence. The official biography authorized by Frost is LAWRENCE THOMPSON, *Robert Frost*, vol. 1, *The Early Years, 1874–1915* (1966), vol. 2, *The Years of Triumph, 1915–1938* (1970), and vol. 3, *The Glory Years, 1938–1963* (in prep.). Earlier biographical studies include: GORHAM B. MUNSON, *Robert Frost: A Study in Sensibility and Good Sense* (1927); SIDNEY COX, *A Swinger of Birches: A Portrait of Robert Frost* (1957); and ELIZABETH S. SERGEANT, *Robert Frost: The Trial by Existence* (1960). REUBEN A. BROWER, *The Poetry of Robert Frost* (1963), is the best critical study. See also *Robert Frost: A Collection of Critical Essays*, ed. by JAMES M. COX (1962), a broad collection. W.B.S. CLYMER and CHARLES R. GREEN, *Robert Frost: A Bibliography* (1937), is now considerably out-of-date but at present the only Frost bibliography.

(L.R.T.)

## Frost

Frost is a term used in two senses: (1) atmospheric water directly crystallized on the ground and on exposed objects; and (2) the occurrence of subfreezing temperatures that affect plants and crops. Frost crystals, often called hoarfrost in the aggregate, form by the passing of the invisible water vapour of the atmosphere into the ice-crystal phase without going through the intermediate liquid phase. Hoarfrost lightly covers fields and rooftops under conditions that would form dew (*q.v.*) if the temperature were above freezing at the point of formation. Sometimes the freezing temperature will be reached after dew has already formed, producing frozen dew, but this

usually cannot be readily distinguished because crystals ordinarily will start forming at about the same time the freezing starts. Pertaining to plant culture, frost refers to the freezing of the aqueous solutions in the plant cells, causing these to burst and destroy the plant. Only plants containing plentiful and dilute solutions in their leaves, fruits, etc., are easily damaged. The occurrence of a killing frost without a hoarfrost deposit is sometimes popularly called a black frost.

In physiography and technology the term frost is applied to a variety of freezing processes. Thus, one speaks of the depth of frost penetration in the soil, meaning depth of frozen ground; frost action in the erosion of rocks; frost heaving of soils; frosting of surfaces by other vapours as well as that of water; frost damage to structures, newly laid cement, etc.

The most important aspect of frost in relation to plants is its determination of the length of the growing season: the period from the last killing frost in spring to the first killing frost in autumn, with reference to the tenderest crop plants. There are regions of the earth where the season reaches critically short proportions for the maturing of most usable crops, and others where the season is so long that more than one planting of such crops as corn (maize) and alfalfa can be brought to harvest. In regions where frost is rare or absent, other factors take on more importance.

One of the most critical situations for frost is encountered in the citrus-fruit regions. There the few killing frosts likely each winter are combatted by a variety of methods, including heating the groves with special burners using oil or a petroleum-derived solid fuel, mixing the air with large fans mounted above the trees, or casting a fine water spray over and on the trees to keep the temperature at or very near the nondamaging level of 32° F (0° C).

In citrus-growing regions in the United States the government meteorological offices developed special frost-warning services with a high degree of usefulness to growers (see WEATHER FORECASTING). In the Pacific Coast fruit regions the service was extended to make it possible to prevent frost damage to deciduous fruit crops during the period of blossoming, both in the United States and in Canada. Protection of orchards was undertaken less extensively in the eastern deciduous fruit regions. Atlantic Coast and Wisconsin cranberries are protected from frost at critical times of the growth cycle by flooding the cranberry bogs with water.

The crystalline and other forms of frost deposit are a subject of aesthetic as well as scientific interest. The structures differ in some respects from those of snow (see SNOW and SNOWFLAKES). Granular forms are called rime and are produced by the freezing of droplets of liquid water (technically called supercooled droplets), that are carried in the air at temperatures below freezing. Rime is best developed on mountaintops enveloped in supercooled clouds (*q.v.*). It is a common form of icing on aircraft. It also occurs in steam fogs around open springs, streams, lakes, or ponds in very cold weather and, in extreme conditions, around chimneys from the water vapour condensed in the flue gases.

True crystalline hoarfrost is of two classes, that which assumes columnar forms and that which assumes tabular, or platelike, forms. Generally the crystals of these two classes do not occur together on a single night; rather, one or the other will greatly predominate. Columnar or needlelike forms are found at the higher subfreezing temperatures whereas plate crystals predominate under colder conditions. In their pristine state both forms are hexagonal crystals, the columns having a hexagonal cross section and the plates appearing as flat hexagons. Because they must grow outward from some supporting object they rarely assume the perfect symmetry found in many snow crystals. Over ice-covered ponds and rivers, beautiful clusters or rosettes of fernlike or jewel-like frost collect on the surface of the ice. At very low temperatures cubical crystals are sometimes found.

Children and adults alike in cold climates have been

Types of  
hoarfrost

fascinated by the beautiful and varied frost forms found on the inner surfaces of windowpanes in buildings. In most cases with heated rooms the vapour condenses as a liquid first, but if the conditions are right, as in an unheated room, the delicate, pure crystalline forms are predominant. These often resemble forests of fir trees, ferns, starry skies, castles, or submarine gardens with corals, starfish, and plants.

**BIBLIOGRAPHY.** U. NAKAYA, *Snow Crystals: Natural and Artificial* (1954), contains microphotographs of snow and frost crystals with explanatory text. "Frost and Prevention of Damage" is a U.S. DEPARTMENT OF AGRICULTURE pamphlet, occasionally revised, that emphasizes the protection of tree fruits.

(H.R.B.)

## Frostbite

Frostbite, a literal freezing of living tissue, superficial or deep, occurs whenever heat loss from a tissue is sufficient to permit ice formation. The freezing-thawing process causes mechanical disruption from ice, intracellular and extracellular biochemical changes, tissue dehydration, local oxygen depletion, and eventually disruption of the blood corpuscles, thrombosis, or clotting, within the small blood vessels, and tissue gangrene if these conditions are not relieved.

Chilblains (an inflammatory swelling), trench foot (a painful disorder similar to frostbite), and immersion injury result after prolonged exposure to low but nonfreezing temperatures and may be recognized by changes in the character of the skin, in blood flow, and in motor and sensory responses.

To preserve vital body warmth, man, in his phylogenetic development, has evolved a private "inner climate," with a near-constant temperature of 37° C (98.6° F).

General hypothermia, or depression of the inner climate body temperature, is critical and often fatal. Below 34° C (93° F), metabolic temperature control is unstable and, if cooling persists, is lost. Coma, cardiorespiratory failure, and death may ensue, even before the level of 31° C (88° F).

Man's constant, cold-repelling temperature is maintained by a complex metabolic furnace (see METABOLISM). Ingested food is fuel for the furnace and some of the energy from its oxidation is converted into heat. This heat, transferred as needed throughout the body, principally by the blood, is contained in a skin shell that traps or dissipates warmth. Heat can be further conserved by man-made objects such as shelter and clothing.

Because tissue freezes near -5° to -6° C (23° to 21° F), the shell of the interior climate must be breached and the temperature must fall from 37° C to levels lower than -5° C before freezing occurs at a specific area. This occurs in Arctic and sub-Arctic regions, temperate zones in winter, and high altitudes throughout the world. Cold, wind, and decreasing oxygen supply encourage the condition.

**Conditions conducive to frostbite.** Frostbite can occur whenever the ambient temperature falls below 0° C (32° F). Without adequate food, clothing, or shelter, heat is lost successively from the interior of the body to the skin, to the layer of still, insulating air surrounding the skin, and finally to the ambient cold air. High velocity wind blowing away the insulating air cover, or the wetting of the skin, hastens the outward transfer of heat. Thus ice fishermen, hunters, trappers, campers, mountain climbers, and even the inebriate, unconscious in the alley, may all become victims of excessive heat loss.

All too impressive is the injury and death toll from cold during time of war. Armies that suffered as much from the cold as they had from the enemy include Xenophon's Greeks in Armenia (400 BC); the Swedish troops of Charles XII in the Ukraine (1708); and the army of Washington at Valley Forge (1777-78). Most classic is the saga of the Napoleonic forces fleeing Russia (1812-13). Pursued by a relentless enemy, surrounded by the hostile cold of winter, staggering onward without food, water, rest, adequate clothing or footwear, thousands of troops suffered from frostbite or froze to death. Modern

armies in the Crimea, World Wars I and II, and Korea, have fared only a little better. Ancient and modern man alike, individually and in groups, and under varying conditions of peace and war, have demonstrated that unrelied heat loss at temperatures below 0° C leads to tissue freezing, or frostbite.

Three types of individual physical and health factors can contribute to frostbite. They are (1) those conditions encouraging heat loss; (2) mechanical or physical impedance of circulation to the extremities; and (3) problems that decrease the ability of the patient to cope with the cold.

Conditions encouraging heat loss are (1) the excessive intake of alcohol, causing capillary dilation, flushing, and dissipation of heat; (2) wet clothing, permitting outward heat conduction, local cooling and freezing, often associated with hyperhidrosis, a condition in which there is an increased tendency to sweating; (3) exposed flesh; (4) fever, with radiation of heat; (5) injury, with hemorrhage, anoxia, and shock, causing general body cooling; and (6) overexercise, as in forced survival marches, draining unreplaced calories and heat.

Factors that mechanically impede circulation to the extremities, and thus favour cooling and subsequent freezing, include (1) tight boots, gloves, or clothing; (2) blood vessel diseases that diminish the flow of blood to the extremities; (3) any injury to the blood vessel network causing local tissue oxygen depletion; (4) crushing injury or fracture, resulting in circulatory slowdown; and (5) constriction of small blood vessels as a possible result of drug action.

Conditions that decrease the ability of a person to avoid cold insult include (1) emaciation, fatigue, and inability to cope with the cold; (2) dehydration, a major problem in the cold, with subsequent blood acidity, mental derangement, coma, and death; (3) neuromuscular disease, or previous freezing or nonfreezing cold injury, with resultant sensory loss, predisposing to further cold injury; and (4) psychosis from any cause, allowing behaviour contributory to freezing, with mental disorganization, loss of thermoregulation, and resultant fall of body temperature.

**Recognition and treatment.** Frostbite is identified from a history of exposure to freezing temperatures in addition to clinical signs and the appearance of the affected part. Before thawing, the part is hard, cold, white, or bloodless. The skin is rigid and the depth of freezing difficult to determine. Freezing is described as either superficial, involving skin and subcutaneous tissues, or deep, involving muscle, nerve, vessels, cartilage, and bone.

In dealing with frostbite body temperature is usually restored to as near normal as possible before thawing. Rapid thawing of the hands or feet in warm water baths is a presently favoured method of therapy. Thawing time is determined by the temperature of the bath and the depth of the freezing; thawing is complete when the tip of the extremity flushes pink or red. After rapid thawing small blisters appear rapidly, spontaneously rupturing in four to ten days. A castlike scab, often black, forms after the blisters rupture. Normal tissue may have already formed below. The thawed part is usually protected to avoid both refreezing and excessive heat. Neither bandages nor dressings are used and the area is cleansed with benign soaps. Constant digital exercises are performed, to preserve joint motion. Early surgical removal of unhealthy tissue (debridement) and amputation is avoided. Whirlpool action will debride devitalized tissues.

Antibiotics are used if necessary; toxoid booster injections are a recommended precaution. After thawing, further treatment is aimed at the prevention of infection and preservation of function.

The outlook is logically best when: the frozen state is of short duration; thawing is by rapid rewarming; and blisters develop early, pink and large, and extend to the tips of the hands or toes.

The outlook is uncertain when: thawing is spontaneous, as at room temperature; the frozen state is of long duration; and the freezing is superimposed on top of a fracture or dislocation.

Conditions encouraging heat loss

## Complications

The outlook is poor when: thawing is delayed, as in ice and snow; thawing is by excessive heat—e.g., greater than 46° C (115° F); the blisters are dark or hemorrhagic and do not extend to the distal tips; a nonfreezing cold injury is followed by freezing; and when freezing, then thawing by any means, is followed by refreezing. The last two conditions are disastrous and almost invariably necessitate amputation of the affected part.

Major complications after freezing, and following treatment, may be infection and tissue death, requiring amputation. Less tragic aftereffects are increased sweating, sensory loss, diminished subcutaneous fat pad of the toes and fingers, persistent deep pain, limitation of joint motion, and nail-bed changes. Other permanent effects include fixed scars, wasting of the small muscle, joint deformity, arthritic changes in bone, and neurovascular involvement in the extremities resulting in the inability to protect against lowered temperatures, coupled with increased sensitivity to cold.

**Frostbite prevention.** The prevention of frostbite is theoretically simple but occasionally impossible to accomplish. To avoid freezing, one obviously needs only to maintain the internal body temperature at the constant physiological level, to provide fuel for continued heat, and to avoid sudden or slow but continuous heat loss from the surface of the body.

Clothing in freezing weather should be dry, layered, and with warm, loose hand wear and footwear. Tight, restricting bands should not be worn. Exposed flesh should be protected from the wind—face masks, hoods, and earmuffs are helpful.

In cold, man must remain alert, avoid the excessive use of alcohol and tobacco, or drugs inhibiting his mental or physical capability.

Should freezing follow an accident, whether or not the victim is injured, intoxicated, or otherwise affected, major efforts must be made to avoid further heat loss in order to prevent death, and in any situation in which freezing has occurred, thawing should be prevented if refreezing may take place. Man survives local freezing of an extremity, even with amputation, but loss of vital temperature may result in hypothermia and death.

By any and all means, the body's internal environment must be kept at its normal temperature. Physically conditioned persons are able, better than those who are not, to withstand cold, avoid cold injury, wind chill, and mental and physical fatigue. Man in the cold must "think warm," and, most importantly, be informed regarding the effect of his geographic environment on his internal environment. To maintain body temperature is to survive the cold, no matter what the external environmental temperature.

## Fruits and Fruit Farming

The subject of fruit and nut production deals with intensive culture of perennial plants, the fruits of which have economic significance (a nut is a fruit, botanically). It is one part of the broad subject of horticulture, which also encompasses vegetable growing and production of ornamentals and flowers. This article places further arbitrary limitations in that it does not encompass a number of very important perennial fruit crops covered elsewhere, including vanilla (see SPICES, HERBS, AND FLAVOURINGS), coffee (see COFFEE PRODUCTION), and the oil-producing tung tree and oil palm (see OILS, FATS, AND WAXES).

Botanists define a fruit in broad terms as the fleshy or dry ripened ovary of a plant surrounding the seed. A pomologist, or specialist in the science and practice of fruit growing, defines it somewhat more narrowly as the fleshy edible part of a perennial plant associated with development of the flower. A nut is any seed or fruit consisting of a kernel, usually oily, surrounded by a hard or brittle shell. Most edible nuts—e.g., almond, walnut, cashew, pecan, pistachio, etc.—are well known as dessert nuts. Not all nuts are edible. Some, used as sources of oil or fat, may be regarded as oil seeds; others are used for ornament. The botanical definition of a nut, based on features of form and structure (morphology), is more restrictive: a hard, dry, one-celled, one-seeded fruit that does not split open at maturity. Among the nuts that fit both the botanical and popular conception are the acorn, chestnut, and filbert; other so-called nuts may be botanically a seed (Brazil nut), a legume (peanut), or a drupe (almond and coconut). In this article the term nut is used in its broadest sense unless otherwise indicated.

The first section of this article deals with fruit and nut growing from the standpoint of classification, economics, and geography, and the second section with basic problems and practices of fruit and nut growing, crop composition, movement, uses, and disposal.

The article is divided into the following sections and subsections:

- I. Classification, economics, and geography
  - Fruit and nut growing in the tropics
  - Fruit growing in the subtropics
  - Fruit and nut growing in the warm temperate zone
  - Fruit growing in the cool temperate zone
- II. Basic practices in fruit farming and marketing
  - The variety: its propagation and improvement
  - The site
  - Planting and spacing systems
  - Training and pruning
  - Soil management, irrigation, and fertilization
  - Pollination
  - Thinning
  - Pest control and preservation
  - Harvesting and packing
  - Postharvest physiology of fruits
  - Waste materials, other uses

### I. Classification, economics, and geography

Table 1 lists common and scientific names for fruits and nuts, probable original source, and important uses. Tables 2 and 3 give information on world production of some of the most important fruit and nut crops. The data are somewhat incomplete since they represent only commercial production and movement. Most fruits and nuts are used locally, in large quantity, and never pass beyond village markets. Mango, avocado, coconut, and banana, for example, are very important to diets of large populations in their areas of production. Furthermore, reasonably accurate and up-to-date production data are difficult to obtain from some countries. Based on world consumption, it is reasonably certain that the most im-

portant fruits are grape, banana, orange, apple, and mango. In second rank of importance are strawberry, olive, pear, peach, and plum, followed by pineapple, lemon, lime, grapefruit, cherry, fig, cacao, apricot, avocado, the brambles and bush fruits, and others.

Although annual yields of nuts tend to fluctuate rather widely, the filberts led as a world nut crop in the 1960s, followed closely by the pecan, English walnut, almond, and cashew. The macadamia nut, while low on the list, is likely to increase markedly in the years ahead as demand continues to exceed production.

Improvements in technology and consolidation of the fruit and nut industries in the most favoured climates have been responsible for a steady increase in yield per unit of land or per tree or plant. Thus, the total acreage or number of plants devoted to various fruit and nut crops has dropped, remained about the same, or not risen in proportion to the increase in the respective crop production.

Increased  
yields

#### FRUIT AND NUT GROWING IN THE TROPICS

Although the principal perennial fruit and nut plants of these warm regions differ in many ways, most of them are evergreen and are seriously injured or killed by freezing temperatures.

**Avocado.** At the time of the Spanish conquests, the avocado tree was under primitive culture in the cool tropical regions of Central and South America and on some of the Caribbean islands. In recent years intensive selection of superior varieties has formed the basis for a commercial industry on a substantial scale in the U.S., South Africa, and Mexico, and on a smaller scale in Chile, Brazil, Hawaii, and Australia. The avocado has narrow limitations in climatic adaptability. There are also inherent problems of harvesting and postharvest care. These have been largely overcome for the better shipping variety, Fuerte, whose quality, however, leaves something to be desired. Export avocados are sold mostly in luxury markets though many are purchased by former natives of tropical areas such as Puerto Rico who have emigrated to northern cities. Among the most important varieties are Fuerte, Zutano, Lula, and Booth 8.

**Banana.** Cultivated throughout the tropics, the banana is a highly important source of food. The ease with which this giant herb (3–6 metres high; leaves 3 metres  $\times$  650 millimetres) may be propagated from pieces of rhizome (rootstock) has made it possible for vast acreages of a few seedless varieties to be planted in widely separate regions. Important among the varieties are Gros Michel, Cavendish, and Mysore. Although the fruit (in bunches of 50–150 bananas per plant) is highly perishable, its ability to develop good eating quality after having been harvested green has permitted the efficient operation of intricately coordinated agencies of the plantation, shipping, and marketing phases that bring bananas to the temperate zone cities throughout the year. Perhaps three-quarters of the bananas for these distant markets originate in Central America, northern South America, and the islands of the Caribbean. Dried banana “figs” and other palatable products are made from bananas, but most of the fruit is sold for fresh consumption. The large green plantain type of banana is cooked and eaten in the tropics and is occasionally exported to persons who have migrated to temperate zone cities.

**Pineapple.** The pineapple has been distributed around the world in the humid tropics during relatively recent times. This small (about 750 millimetres) semiherbaceous perennial with drought-resistant leaves of an epiphyte, or air plant, can be cultivated successfully in somewhat drier and cooler tropical areas than the banana. Easy vegetative propagation from slips or suckers has permitted heavy concentration on a few seedless varieties, the most important of which are Smooth Cayenne, Red Spanish, and Queen. At present about half the world's commercial production originates in the Hawaiian Islands and a third in the Caribbean Islands, Central America, and northern South America. Although shipment of fresh fruit, harvested a little green, is considerable, the

canned fruit is the most important commercial product for distant markets, accounting for practically all of the Hawaiian output.

**Mango.** Under cultivation in the tropics for centuries, the mango is widely distributed and consumed on a local basis. In India alone, there are more than 14,000,000 acres occupied by mango trees. A small commercial industry exists in the U.S. This large evergreen tree (10–20 metres) produces best in tropical regions with a considerable dry season that coincides with the annual period of bloom. Many varieties have been selected and propagated by graftage; among the most important of these are Mulgoba, Saigon, Carabao, Haden, and Julie. In spite of its importance as a food in the regions where it is grown, there are no reliable statistics on world production. The extreme perishability of the fresh fruit and special problems of harvesting and storage have discouraged shipment to distant markets. Improved modern handling techniques may help to correct this. No appreciable volume of the fruit is processed commercially as a canned or frozen product, although considerable quantities are used for preserves and chutney.

**Papaya.** The papaya is a palmlike tree reaching a height of eight metres but less woody than a typical palm. The succulent fruits, resembling cantaloupes, are attached to the trunk and contain hundreds of black round seeds six millimetres in diameter attached to the inside wall of the single large cavity. This seed-propagated tree grows rapidly, bearing at the end of the first year and living for five years or more. The tree does not branch laterally and is covered by deeply lobed leaves up to 600 millimetres across and borne on hollow petioles up to 600 millimetres long. There are male, female, and hermaphroditic (plant with both female and male flowers) tree forms. Papaya is grown throughout the tropics, chiefly for local consumption. Hawaiian annual production approaches 9,000,000 kilograms, with about 1,400,000 processed. About 450,000 kilograms of papayas are harvested each from Florida and Puerto Rico. A large volume of preserved papayas are exported by Mexico, Australia, and Taiwan; fresh papayas by the Bahamas; and papaya paste and pulp by Nicaragua and Australia. Shipment overseas is largely by air; some are shipped under controlled atmosphere conditions using 2 percent oxygen with low temperature control to increase market life. At 7° C (45° F) papayas keep satisfactorily for one to three weeks and ripen at 21–26° C (70–80° F) for retail sale. A half-cup of papaya cubes contains about twice the daily vitamin C requirement for an adult and three-fifths the vitamin A, and is low in sodium and calories. Papain in papaya juice is noted for its meat-tenderizing quality.

Air  
shipments

**Coconut.** This nut is one of the most important food sources for indigenous populations of the tropics. The coconut palm reaches a height of 30 metres, is resistant to hurricane winds, has a slender, leaning trunk with annual rings and a swollen base. The top is crowned with typical palm leaves. Flower stalks push out at the base of the older leaves, bearing about 10,000 male flowers and 30 female flowers. Fifty to 100 fruits ripen in a year. The fruit is egg shaped, 300–450 millimetres in length and 150–200 millimetres in diameter. The shell is 12–18 millimetres thick with hard fibres on the outside and white meat clinging to the inside. The three “eyes” at the stem end of the fruit are the three ovarial cavities; they may be punched to withdraw the nutritious milk from the large cavity. The white meat (called copra when dried) may be grated, and has numerous culinary uses in salads, curries, candies, cake and pie toppings, etc., and as a source of coconut oil.

**Cashew.** This tropical bushy tree (up to 12 metres high), is grown in Central America, South America, and the West Indies, India, and East Africa. The mature tree lives 20–45 years, is widely adapted to soils, requires a minimum of attention, withstands very light frost, and produces about 30 kilograms and occasionally as high as 90 kilograms a year. The hooked beanlike nut within a shell is attached at the base of a fleshy, pear-shaped

"apple" about 30 millimetres in diameter and 40 millimetres long. Though used locally in beverages, jams, and jellies, the apple is unimportant commercially. The cashew ranks high in world trade among nuts. Some 60,000 metric tons from East Africa are shipped annually to India where they are processed along with some 80,000 Indian-grown metric tons, and exported. The U.S. is the chief importer. The nut is roasted and canned, sometimes mixed with other nuts.

**Brazil nut.** This large picturesque tree is 30–50 metres tall, 1.2–1.5 metres in diameter, and has a smooth trunk. Branching at the top, it is tardy and light in bearing and grows mainly in the Amazon Basin of Brazil. Hard-shelled at maturity, the fruit is 100–150 millimetres in diameter and contains eight to twenty-four angular seeds or nuts arranged tightly. Seeds are about  $25 \times 35$  millimetres with white solid flesh. They are shipped and sold mostly unshelled. On arrival at destination they are stored at 1–7° C (34–45° F) and 65–70 percent relative humidity.

**Macadamia.** Also called the Queensland nut, the macadamia is grown commercially in Hawaii (where the trees occupy more than 3,000 acres from sea level to elevations of 800 metres) and to some extent in Australia. A small industry is developing in California. There are several species, but the "smooth-shell" *M. integrifolia* is preferred. The handsome tree begins bearing in 6–7 years, resembles an orange tree in shape and size, with long narrow prickly serrated leaves. It needs wind protection when young and judicious pruning, training, and fertilization. The macadamia tree requires 1.25–3.0 metres of rainfall, well distributed, and a good, well-drained soil, (pH 4.5–6.5) but can be grown on rocky slopes where sugar and pineapples do not thrive. The nuts are spherical, 15–20 millimetres in diameter, and contain light tan, pleasantly crisp kernels, appetizing and slightly sweet in flavour. Hawaiian improved clonal (vegetatively propagated) varieties are Kakea, Ikaiki and Keauhou. These varieties look promising in California plus the rough-shelled varieties Burdick and the Australian Elimbah. Macadamia is mainly a dessert nut and goes well at cocktail time. Demand for this nut exceeds supply; hence the price is relatively high.

**Paradise nut.** This nut (also called monkey pot and sapucaia nut) borne on a big forest tree in Brazil and Guiana, resembles the Brazil nut, though it has a softer shell and kernel. Nuts, 50 millimetres long, irregular-oblong and ridged, are crowded in a woody fruit  $200 \times 250$  millimetres, which has a lid that pops off when mature, leaving the nuts hanging and dropping from vegetative (funicular) strings. Monkeys, either baited or in attempts to get the nuts, may get their heads caught in the "pot."

**Oyster nut.** Though long popular in its native East Africa, this "nut" (actually a gourd seed) has been marketed elsewhere as a dessert nut only since World War II. The seed is flat, from 30–50 millimetres in diameter, and covered with a fibrous layer that unfortunately prevents the use of mechanical crackers.

**Swarri.** This South American nut, also called the souari or butternut, from the Guianas, is sometimes imported into Europe and North America. It is about four times the size of a Brazil nut with a thick (over ten millimetres) hard shell enclosing a soft white kernel with a good flavour.

#### FRUIT GROWING IN THE SUBTROPICS

Perennial fruit species successful in subtropical regions possess some resistance to injury from freezing temperatures during the winter months. They also benefit from the slight seasonal periodicity of the climate. Like species of the tropics, they are usually evergreen.

**Date.** The majestic date palm, 20–25 metres high and crowned with pinnate leaves 3–6 metres long, is native to desert oases of the Persian Gulf. For thousands of years the fruit has been an essential part of the diet of indigenous populations living in the eastern Mediterranean basin and north Africa. Iraq leads in production,

with Algeria and Tunisia also very important. Date production has almost doubled since the 1940s. Although the palm has been distributed widely in modern times, nine-tenths of the commercial production comes from the areas of ancient culture. This may result largely from three circumstances: (1) a desert climate with no rainfall during most of the period of fruit development is essential for a marketable product, yet there must be ample soil moisture during this same period; (2) the product is stable and there is a sufficient output in the indigenous region to satisfy most of the world demand at moderate prices; (3) propagation of the superior varieties must be by offshoots from relatively young palms, and the supply is so limited as to make establishment of new date gardens in distant countries slow and expensive. In spite of this, however, a small industry based on Old World varieties, of which Deglet Noor is the most commonly planted, is flourishing in California.

Date varieties selected over the past centuries may be divided into three classes according to their physical properties and sugar content. Dry dates (sometimes called bread dates), firm and relatively low in sugars, are important locally in the Old World desert region for daily nourishment; the Thoory variety is an example. Semidry varieties soften at maturity; because they are firm enough to pack and ship well, they are the most important commercially; Deglet Noor, Dayri, and Zahidi are examples. Soft dates, used mainly as confection, are the most difficult to handle; examples of this kind are Barhee, Khadrawy, and Hayany. In Old World areas the date trunk is used for timber, leaf midribs for furniture and crates, leaflets for basketry, leaf bases and fruit stalks for fuel, and seeds for cattle feed. None of the plant is wasted.

**Citrus.** Introduced to the Western world by traders from southeastern Asia during the period from the 12th to the 18th century, the most important citrus fruits are now produced in large quantity in tropical and subtropical America, the northern and eastern Mediterranean, Australia, and South Africa. Orange, mandarin (tangerine), and grapefruit trees are most productive and develop the best quality in regions where there is some seasonal periodicity of climate. Since they are able to withstand exposure to a few degrees below freezing in midwinter, they may be intensively cultivated in regions where occasional light frosts occur as well as in the milder subtropics. Leading orange-producing countries include the U.S., Israel (Jaffa oranges), Morocco, Spain (Seville oranges), and South Africa. The mandarin orange (tangerine) is important in the U.S., Brazil, Spain, Italy, Mexico, and Japan. About 90 percent of the world's grapefruit is grown in the U.S., with Israel, Jordan, South Africa, and Brazil following. Mexico is the leader in world lime production, with Egypt second and the U.S. third. The U.S. and Italy are premier lemon producers, followed by Spain, Greece, Turkey, and Argentina. In Florida, which produces 70 percent of U.S. oranges, the four principal varieties are Parson Brown, Hamlin, Pineapple, and Valencia; the first two are sent to the early fresh-fruit market whereas perhaps half of the Pineapple and Valencia crops are sold fresh and the rest are processed into frozen concentrate. California is responsible for most of the rest of the orange crop. The main grapefruit varieties are Marsh Seedless, Foster, Ruby, and Duncan. Among tangerines, Dancy is a popular variety, much grown in Florida. There are two relatively large-fruited lime varieties: Tahiti and Bearss; the "Key" lime, once grown extensively on the Florida Keys, has almost disappeared. The main lemon varieties are Lisbon, Eureka, and Villafranca. Much of the fruit is sold fresh but increasing amounts have been processed into frozen concentrate or canned juice.

#### FRUIT AND NUT GROWING IN THE WARM TEMPERATE ZONE

Most perennial fruit species adapted to the warm temperate zone are deciduous, passing the winter leafless. A few (e.g., the olive) are evergreen. Practically all resist temperatures below –7° C (20° F) during winter

Uses for  
date trunk

Table 1: Scientific Names, Probable Original Source, and Uses of Fruits and Nuts

common name	scientific name of main crop	probable original source	principal uses*
<b>Fruits</b>			
Apple	<i>Malus pumila</i>	southeastern Europe, southwestern Asia	food, fire wood
Apricot	<i>Prunus armeniaca</i>	China	food
Avocado (alligator pear)	<i>Persea americana</i>	Mexico to Colombia	food
Banana	<i>Musa sapientum</i> (common) <i>M. cavendishii</i> (dwarf) <i>M. paradisiaca</i> (plantain)	Asia (southeastern)	food
Blackberry	<i>Rubus allegheniensis</i>		food
Blueberry	<i>Vaccinium corymbosum</i>	North America	food
Cherry	<i>Prunus cerasus</i> (tart); <i>P. avium</i> (sweet)	western Asia and eastern Europe	food, wood
Citrus			
Orange	<i>Citrus sinensis</i>	Malay archipelago	food
Grapefruit	<i>C. paradisi</i>	Jamaica (?)	food
Lemon	<i>C. limon</i>	E. Indian archipelago	food, oil
Lime	<i>C. aurantifolia</i>	E. Indian archipelago	food, oil
Cranberry	<i>Vaccinium macrocarpon</i>	North America	food
Currant	<i>Ribes sativum</i> (red) <i>R. nigrum</i> (black)	western Europe	food
Date	<i>Phoenix dactylifera</i>	southern Iraq	food
Fig	<i>Ficus carica</i>	Mediterranean area	food
Gooseberry	<i>Ribes hirtellum</i> (American) <i>R. uva-crispa</i> (European)	North Africa, western Europe	food
Grape	<i>Vitis vinifera</i> (European) <i>V. labrusca</i> (American)	Caspian Sea area Atlantic slope, North America	food
Guava†	<i>Psidium guajava</i> (common) <i>P. cattleianum</i> (strawberry)	tropical America	food
Mango	<i>Mangifera indica</i>	East India, Burma, Assam, Malaya	food
Mangosteen†	<i>Garcinia mangostana</i>	Southeast Asia	food
Olive	<i>Olea europaea</i>	E. Mediterranean area	food, oil
Peach	<i>Prunus persica</i>	China	
Papaya	<i>Carica papaya</i>	Central America, Mexico	food, papain (meat tenderizer)
Passion fruit	<i>Passiflora edulis</i>	tropical America	food flavouring
Pineapple	<i>Ananas comosus</i>	West Indies	food
Plum	<i>Prunus domestica</i>	Caucasus area	food
Raspberry	<i>Rubus idaeus</i> (red) <i>R. occidentalis</i> (black) <i>R. neglectus</i> (purple)	eastern Asia	food
Strawberry	<i>Fragaria</i> sp. (8)	Americas	food
<b>Nuts</b>			
Almond (sweet)	<i>Prunus amygdalus</i>	W. temperate India and Persia	food
Almond (bitter)	<i>P. amygdalus</i> , var. <i>amara</i>	W. temperate India and Persia	flavouring extract
Almond, Indian	<i>Terminalia catappa</i>	W. temperate India and Persia	food
Almondette	<i>Buchanania lanzan</i>	India, Burma	food
Araucarian pine nut (piñon, pinyon)	<i>Araucaria araucana</i>	Chile	food
Arnut (yer-nut, earth chestnut, hawk nut, lousy-nut)	<i>Bunium</i> species	W. Europe to Caucasus	food
Australian nut, <i>see</i> Macadamia			
Babassu nut	<i>Orbignya oleifera</i>	Brazil	food, fuel oil
Bambara groundnut	<i>Voandzeia subterranea</i>	tropical Africa	food
Barbados nut (physic nut)	<i>Jatropha curcas</i>	tropical America	medicine
Baroba	<i>Dispidiscus paniculatus</i>	Philippines	starchy seeds boiled and eaten
Beech nut, American	<i>Fagus grandifolia</i>	E. United States	
Beech nut, European	<i>Fagus sylvatica</i>	Cent. Europe, S.W. Asia	salad oil
Ben nut	<i>Moringa oleifera</i>	India, West Indies	artists' oil, lubricant
Betel nut (areca nut, pinang)	<i>Areca catechu</i>	E. tropics	masticatory
Bladder nut	<i>Staphylea</i> species	temperate North America, S. Europe, S. Asia	necklaces
Bomah nut	<i>Pycnocomma macrophylla</i>	Africa	tanning, poison
Bonduc nut	<i>Caesalpinia bonduc</i>	Tropics	medicine, beads
Brazil nut (castanea, creamnut, para nut)	<i>Bertholletia excelsa</i>	Amazon Basin, Brazil	food
Breadfruit, African	<i>Treculia africana</i>	tropical Africa	seeds ground for meal
Bread nut	<i>Brosimum alicastrum</i>	tropical America	food
Butternut (long or white walnut)	<i>Juglans cinerea</i>	E. United States, S.E. Canada	food
Butter pit, <i>see</i> Naras nut			
Candle nut	<i>Aleurites moluccana</i>	Malaysia	drying
Cashew (acajou, caju, cajou)	<i>Anacardium occidentale</i>	West Indies, Brazil	food, oil, wood, varnish, paint
Castanopsis nut (golden chinquapin, wild chestnut)	<i>Castanopsis</i> species	S.E. Asia, California	food
Chestnut	<i>Castanea</i> species	E. United States, S. Europe, N. Africa, Asia	food
Chile hazel	<i>Gevuina avellana</i>	Chile	food
Chinquapin	<i>Castanea</i> species	S.E. United States, China	food
Chufa (rush nut, earthenut, ground almond)	<i>Cyperus esculentus</i>	S. Europe	food
Cobnut, <i>see</i> Filbert			
Cobnut, Jamaican	<i>Omphalea diandra</i>	West Indies, tropical America	food, oil
Coconut	<i>Cocos nucifera</i>	Old World tropics	food, oil
Cohune nut (cahoun nut)	<i>Attalea cohune</i>	Honduras	oil
Cola nut, <i>see</i> Kola nut			
Coquilla nut	<i>Attalea funifera</i>	Brazil	turnery
Coquita nut (coker nut)	<i>Jubaea spectabilis</i>	Chile	oil, food
Coumara nut, <i>see</i> Tonka bean			
Dika nut	<i>Iringia gabonensis</i>	W. Africa	food, oil
Doum nut (dom nut)	<i>Hyphaene thebaica</i>	N. and central Africa	turnery, vegetable ivory

\*All fruits listed are eaten fresh. Most fruits can be canned, although some freeze better such as blueberry, strawberry, raspberry, cranberry, and peach. Jellies, jams, juices, cider, and spirits are products of most fruits although some are better adapted than others, such as apple and peach. Some fruits are adapted to drying, particularly those relatively high in sugar, as prune, some peaches, fig, and some grapes. †Noncommercial.

dormancy. Most cannot be grown commercially in the subtropics or tropics because of their relatively short chilling requirement of temperatures below 7° C (45° F) for normal growth and flowering. Winter hardiness is not great. A long, warm growing season may be necessary for satisfactory productivity and fruit quality; hence, they are not well adapted to cooler regions.

**Grape.** The Old World grapevine (*Vitis vinifera*) is by far the most important perennial fruit in the world. It has been cultivated for thousands of years in the Mediterranean basin and southwestern Europe. In the last half of the 19th century the grape phylloxera, a plant louse carried on stock from the U.S. to France, ravaged the vineyards of central Europe until resistant rootstocks were obtained from the U.S. Although more than two-thirds of the world's grapes still come from these areas, there is now important production on all continents in the milder parts of their temperate zones, whether north or south latitude. France, Italy, and Spain are the biggest grape producers, followed by Hungary, Turkey, U.S.S.R., Algeria, Argentina, Greece, Portugal, Romania, Yugoslavia, and the U.S.

The fruit from this species may be consumed fresh, dried for raisins, or used for wines and alcoholic distillates. By far the largest part of the European and Mediterranean production goes into wine. Only a small portion is eaten fresh or made into raisins. The California vinifera industry, on the other hand, dries more than half its production (though this has been decreasing), ships 10 to 15 percent as table and canning stock, and uses the remaining third for wine. The important varieties differ in their versatility for these uses. Sultanina (Thompson

Seedless) and Muscat of Alexandria are grown in quantity for all three purposes; the Flame Tokay and several others are used both for fresh fruit and for specialty wines. On the other hand, Zante currant is grown only for its raisins, and a number of varieties including Zinfandel, Carignane, and Alicante Bouschet are produced exclusively for red wine.

**Olive.** The olive tree was under cultivation in warmer parts of the eastern Mediterranean basin some 3,000 years ago, and its spread into North Africa and southern Europe was undoubtedly completed during the Arab invasions if not before. Introduction to the New World by Spanish colonists resulted in small industries in South America and California. The world's supply of this important fruit and its oil, however, comes almost entirely from the countries bordering the Mediterranean, with Italy, Spain, Greece, and Turkey leading. Although evergreen and able to grow normally under subtropical conditions, the tree does not flower unless exposed to temperatures below 7° C (45° F) for a considerable period of time. The tree is tolerant to winter temperatures as low as -9° C (15° F), but the fruit is injured at temperatures slightly below freezing. This resistance to cold, coupled with endurance of hot summer weather and rather severe moisture deficiency, has caused the olive to be planted in many areas not suitable for other fruit crops.

The fruit is pickled in brine, canned ripe, or pressed to make olive oil. Most European production is used for olive oil, although Spain produces substantial quantities of pickled olives. Examples of important olive varieties are Manzanillo, Barouni, and Mission. Only varieties high in oil are useful for extraction; the others are processed as fruit.

**Fig.** Like the olive and grape, the fig tree was under cultivation in the warm temperate climate of the Mediterranean basin long before the time of Christ. Some of the varieties of that region have probably been carried down to modern times by vegetative propagation for over a thousand years. Practically all commercial production (mostly Brown Turkey variety) comes from Italy, Portugal, Spain, Turkey, Greece, and Algeria, with small production in the U.S., Mexico, Brazil, Peru, Argentina, and Australia.

The tree withstands cold to 9° C (48° F) and has a relatively short chilling requirement. Some varieties, in fact, grow and fruit satisfactorily in the tropics. Plants vary from a low bush to trees 12 metres high; leaves are wide, corrugated, and lobed to almost entire margins. The most favourable climate for growing figs is semi-arid with irrigation water available and no rain during the period of fruit maturation and drying. Such a climate facilitates sun-drying, and inhibits bacterial and fungus infection in maturing fruit. Some varieties are grown under humid conditions, however, for local sale or canning. In the U.S. the main production area is the irrigated Central Valley of California with rainfall ranging from 250 to 500 millimetres annually, and a long hot growing season. The most important varieties are Calimyrna (Lob Injir), Adriatic, Mission, and Kadota (Dottato). The first two varieties account for three-quarters of the production; practically all are dried. Mission may be dried or marketed fresh and Kadota is canned in light syrup.

**Apricot, peach, nectarine, plum, prune, and almond.** These six kinds of fruit grow on small deciduous trees of genus *Prunus* whose climatic requirements are satisfied in the warm temperate zone and whose culture extends to the milder parts of the cool temperate zone, although some plums are quite resistant to low winter temperature. All of them are cultivated widely in the climatic regions of the world to which they are adapted.

The apricot, originating in China, is somewhat more restricted climatically than the peach and plum partly because it has a shorter chilling requirement and blooms earlier, making it frost susceptible in many areas, and partly because of its great susceptibility to fungus diseases (brown and green rots), which make culture difficult in regions where summer rainfall is high. is the leader in apricot production, followed by Iran and Syria in Asia, and by Spain, France, Italy, and Yugoslavia in Europe. Local climatic conditions determine whether the main outlets are for fresh fruit, drying, or canning; these outlets in turn may determine the varieties and cultural practices. Thus, where an early harvest season gives the industry opportunity to exploit a premium market for fresh fruit, the main variety has been Royal (similar to Blenheim). In the regions that have midseason harvest, the drying outlet predominates and the Tilton variety has been most important. In the cooler, more northern sections, where canning and late market are the dominant outlets, Moorpark and Large Early Montgamet are important.

The peach also originated in China. Although there are varieties adapted to climates ranging from the subtropics to the milder parts of the cool temperate zone, the most important peach regions of the world have long hot growing seasons and mild winters lasting at least three months during which freezing temperatures occur frequently. The U.S. and Italy produce about half the world's crop. They are followed by France, Spain, Greece, Argentina, Japan, Turkey, Canada, South Africa, and Australia. The chilling requirement for flower buds depends on the variety; for Florida and Texas varieties it is 300–500 hours below 7° C (45° F), but up to 900 hours for some varieties grown in colder regions. Leaf buds require slightly more chilling (100–200 hours) than flower buds. As with apricots, there are three outlets for this fruit and varieties differ in accordance with them. Clingstone varieties such as Gaume, Paloro, and Halford are usually canned. Drying is also a by-product or distress outlet for other varieties like Muir and Lovell, which are especially desirable because of their relatively high-sugar and dry-matter content. The fresh-fruit market is served by a long list of delicious freestone varieties including Redhaven, Sunhigh, Triogem, Blake, Elberta and Rio-Oso-Gem.

In recent years the demand for the nectarine, essentially a fuzzless peach, has been growing. In California, the LeGrand, Late LeGrand, Sun Grand, Early Sun Grand, and Sunrise are important. In the eastern U.S., the New Jersey Nectared series is being planted.

The original plum comes from Persia. The world's plum and prune industries, however, are based mainly on two species of different origin and adaptation. The Japanese plum, *Prunus salicina*, is a small, vegetative tree with approximately the same climatic requirements as the apricot. It is most successful in semi-arid, irrigated, warm-temperature climates. Because the fruit is very high in moisture and soft, it is not useful for canning. Difficulties of handling and storage limit the opportunities for large-scale exploitation in fresh-fruit markets. The principal European species, *Prunus domestica*, is responsible for most of the commercial plum and prune production of the world. The climatic adaptability of the tree straddles the warm and cool temperate zones, and it is tolerant both to semi-arid and humid climates. European plums will withstand more soil moisture and heavier soils than peach, almond, or apricot. The most important varieties produce fruit that may be harvested in a firm condition and that has storage and shelf life of a month or more. Some varieties are very high in sugar and total solids and may be dried for prunes, as French Prune and Imperial Epineuse.

Leading countries in plum and prune production are, in order, Yugoslavia, Romania, U.S., West Germany, U.S.S.R., Bulgaria, and Hungary. World production is about 4,000,000 metric tons.

In the U.S., practically all the Japanese plums are grown in California; important varieties are Beauty, Santa Rosa, and Duarte. European plums are an important crop in Oregon, Idaho, Washington, and California. California produces all the dried prunes of the U.S.; the variety French Prune accounts for over 90 percent of the acreage. In the south of England, several varieties of the Green Gage group, Czar, Giant Prune, and Victoria are prized for their dessert qualities.

The almond tree, originating in Persia, resembles the peach but is not as hardy. It flowers earlier and may be subject to frosts in some regions. Hence, the commercial industry is confined to a climate similar to the Central Valley of California. The fruit resembles the peach, except that the outer tissues (mesocarp and exocarp) develop into a leathery hull that splits along the suture line, curls outward, and can be separated from the endocarp or shell around the kernel. There are two types of almonds, sweet and bitter, with the sweet being the well-known edible almond. Bitter almonds, which are inedible, are a source of oil (50 percent) used in flavouring extracts.

The sweet almond is cultivated in suitable regions between 28–40° north and 20–40° south of the Equator. Leading countries exporting shelled almonds in order of importance are Italy, U.S., and Spain, followed by Iran, Morocco, and Portugal. World production is approaching 150,000 short tons annually.

The Jordan variety is grown in Europe. California has developed most of its varieties from seedlings and by breeding, namely, Nonpareil, Drake, Peerless, Ne Plus Ultra, Texas or Mission, IXL, Jordanolo, and Davey. Several new varieties have been introduced recently, including Thompson, Merced, and Kapareil. The almond rootstock is commonly used, but where the water table is high, peach rootstock is used, and where oak root fungus is a problem, the Marianna plum is used. For pollination purposes, about four rows each of Ne Plus Ultra or Peerless, Nonpareil, and Mission or Drake, are alternated across the field.

In modern harvesting, a hydraulic trunk shaker jars the nuts to the leveled ground and a rotating brush set at an angle pushes the nuts into a windrow where they are picked up by a machine that blows off the dirt, leaves, and debris, and loads the nuts into a bin pulled behind. Almonds are used extensively in candies, bakery products, and in cooking. Hulls of the soft-shelled varieties are fed to livestock with barley and alfalfa.

**Filbert.** The filbert grows as a shrub or a tree up to 8 metres in height; most commercial trees are about 4.5 metres tall. Leaves are rugose (veinlets sunken and the spaces between elevated), about the size of an apple leaf and roundish in shape. Male catkins and female flowers are borne separately on the same plant. Female flowers are borne in small scaly buds with the stigmas visible during flowering. Like almonds, filberts bloom early and hence may suffer from frost; flowers can withstand temperatures to –9° C (16° F). Most filberts do not fruit if pollinated by another tree of the same variety; two or more varieties must be interplanted. They are unusual among fruit trees in being wind pollinated rather than insect pollinated. The filbert shell, about 1.5 millimetres thick, is the ovary wall; the kernel is largely embryo. After pollination, several months pass before the nut begins to develop. Then the shell forms rapidly and the embryo develops. Filberts grow best in a medium loam: light sands and heavy clays are not very satisfactory. They are more tolerant of heavy clays than pecan or walnut but cannot tolerate excessive moisture. Unlike most nut trees, the filbert does not have a tap root and hence transplants easily. Commercial trees are planted in rows 6 metres apart, with similar intervals between trees in each row.

Filberts reach maximum production between 15 and 25 years of age, yielding in some years 1,400 kilograms or more per acre. Mechanical harvesting and handling is now used in the U.S. The European and giant filbert, together with some of their several hybrids, furnish the main commercial varieties in Europe and Turkey. Barcelona and DuChilly are leading varieties in the U.S., with some Brixnut. Leading filbert-producing countries in the world are Turkey, Italy, Spain, and the U.S. Yields vary widely from year to year.

Filberts are eaten fresh or roasted. Dried filberts are added to chocolates and other confectioneries; powdered nuts are mixed with wheat and rye to make bread or cake. Pickled in bay leaves and vinegar, they make a

Harvesting techniques

Origin of the plum

sauce. A paste of roasted and mashed filberts with sugar may be added to ice cream or cheese and dairy spreads. In Arabia filberts are used in manufacturing soaps.

**Walnut.** The English walnut is one of the world's five most commercially important nuts. The orchard tree reaches a height of 13–16 metres; wild specimens may reach 30 metres, with 1.5–2 metre trunk diameter. When young the tree has a whitish smooth trunk which turns to gray and is fissured with age. Most orchard trees have high trunks to permit intercropping. Leaves are compound with five to nine or more pinnate leaflets. Fruit is roundish with about a 6-millimetre green hull that breaks away at maturity. The nut shell shatters rather easily. Kernels are rich in oil, food energy, and protein.

While the trees can be grown in a cool temperate climate, warmer and longer seasons are needed for good kernel development. Leading producing countries are the U.S., France, Italy, India, Turkey, Syria, Iran, and Yugoslavia in the order listed. The U.S. produces around 90,000 short tons annually.

Leading California varieties are Franquette, Payne, Hartley, Eureka, Placencia, Concord, Mayette.

The black walnut is distributed widely in the U.S. but is rarely grown in orchards. Most trees grow haphazardly over the landscape as seedlings, averaging 15–25 metres in height but reaching 45 metres with 2-metre-diameter trunk. The wood is particularly valuable for furniture, panelling, and gun stocks because of its colour and freedom from cracking and deterioration.

Leaves are pinnately compound. Nuts are borne in twos and threes and vary greatly in size among seedlings. Black walnut meat is oily, flavourful, and high in calories and energy. The nut is eaten out of the hand and is used in candy, toppings, and baked goods.

**Pecan.** The orchard pecan tree is 9–12 metres high, though some specimens may reach a height of 50 metres with a 2-metre-diameter trunk. Native to North America, the pecan is grown mainly in the southern U.S. and northern Mexico, with limited cultivation in Australia and South Africa. Though the pecan tolerates up to 40° C (110–120° F) it performs best around 26° C (80° F), with warm days and nights.

Leaves are compound, with nine to 17 finely toothed leaflets arranged in fern fashion. The male catkins are readily apparent in spring, while the small female flowers grow in tight clusters at the base of the shoots. At maturity, the hulls of the clustered nuts will dry, split at the four suture lines, and gradually free the nuts. The "shell out" (relative amount of meat to shell) depends on the variety; one with a high percentage of meat to shell is Success. Kernels are high in fat content, having a calorie count close to butter. Though confined mainly to the U.S. the pecan ranks highest in world nut production. Kernels are high in energy and vitamins B<sub>1</sub> and B<sub>2</sub>. The oil is used in cooking and salads and has good keeping qualities. Kernels are widely used in candies, baked products, and in general cooking. Crushed shells are mixed with sand to form a good rooting medium for greenwood cuttings.

**Pistachio.** This nut, also called pistache, is believed to be native to Iran. It is grown in Afghanistan, India, and the Mediterranean region, with Sicily and India large exporters. It differs from all other nuts in the characteristic green colour of the kernel. A popular snack nut, it is salted, roasted, and eaten out of the shell and is used in grated form for ornamenting dishes. It has a pleasant mild flavour and good keeping qualities.

**Pine Nut.** Pine "nuts" (seeds), or pignolias, usually from the European stone pine (*Pinus pinea*), are relished by many people and much used in vegetarian cookery as a substitute for animal fat. As dessert they may be eaten raw, salted, and roasted, or made into sweetmeats. The seeds of many other pines also are eaten. In North America they are obtained from nut pines or piñons.

#### FRUIT GROWING IN THE COOL TEMPERATE ZONE

The perennial fruit species best adapted to this zone are deciduous and have relatively long chilling requirements,

are able to withstand subzero (F) temperatures when dormant, and can produce fruit of satisfactory quality in a growing season of six months or less.

**Apple.** The apple is distinguished from the pear by being free of grit cells. Apples are propagated by budding and grafting onto seedling stocks or clonal (vegetatively propagated) stocks depending upon the type and size tree desired. Trees may reach a height of two to three metres (compact) or six to nine metres with about equal spread, depending upon the root and/or interstock used. Leaves are simple and deciduous. Most apple varieties can be identified readily by leaf characteristics such as hairiness, serrations, shape, size, etc. Fruit is epigynous (the ovary in the flower is below the floral parts); the edible fleshy part is largely receptacle. Fruits are borne terminally on spurs with some borne laterally on shoots.

In recent years there has been a world trend toward use of vegetatively propagated dwarfing stocks, closely planted, to keep the trees lower and easier to manage and harvest. Orchard trees on seedling stock may number 28 to 50 an acre, whereas those on extreme dwarfing stocks may number over 500 trees per acre planted as close as 2–3 metres in rows 3.5–4 metres apart. A trellis may be used with dwarfing or semidwarfing stocks since the roots are relatively shallow. Initial cost of orchards on dwarfing stock is considerably higher but the trees come into bearing within three to five years and pay for themselves sooner with higher yields.

The apple originated in Afghanistan where wild apple forests still exist. It is grown in the cool temperate climates and stands second to the grape in total tonnage of fruits and nuts produced throughout the world. The U.S. and France are the largest producers, with Germany, Switzerland, Italy, and the Balkan countries also important. About a fourth of the U.S. crop is Red Delicious, which is a popular variety (along with Golden Delicious) around the world; another 10 percent of the U.S. crop is McIntosh, followed in order by Golden Delicious, Rome Beauty, Jonathan, Winesap, York, and Stayman, the latter six of which are grown regionally. Delicious and Golden Delicious are showing marked increases in plantings, while McIntosh, Rome, Jonathan, York, and Stayman are showing modest increases. Cox Orange and Boskoop are popular in Europe; Bramley Seedling in the United Kingdom and Belgium; Yellow Transparent, Antonovka, McIntosh, Rhode Island Greening, and Sturmer Pippin in Russia; and Granny Smith in Australia, New Zealand, Argentina, and Chile.

The consuming public demands high-colour and quality Fancy and Extra Fancy fruit, except in eastern Europe where general-run fruit is marketed. Lower grades, with less colour and specified damage, go to processors for sauce, cider, baked apples, canning, freezing, or for pies. Fresh or frozen cider is popular the year round and is becoming more profitable to growers. In Europe, much of the apple crop goes into a carbonated sparkling cider; special varieties are grown for this purpose.
