Meanwhile, his oratorical genius had been revealed in the trial known as the Parson's Cause (1763). This suit grew out of the Virginia law, disallowed by King George III, that permitted payment of the Anglican clergy in money instead of tobacco when the tobacco crop was poor. Henry astonished the audience in the courtroom with his eloquence in invoking the doctrine of natural rights, the political theory that man is born with certain inalienable rights. Two years later, at the capitol in Williamsburg, where he had just been seated as a member of the House of Burgesses (the lower house of the colonial legislature), he delivered a speech opposing the British Stamp Act. The act was a revenue law requiring certain colonial publications and documents to bear a legal stamp. Henry offered a series of resolutions asserting the right of the colonies to legislate independently of the English Parliament, and he supported these resolutions with great eloquence. "Caesar had his Brutus, Charles the First his Cromwell, and George III . . ." Here he was interrupted by cries of "Treason! treason!" But he concluded, according to a likely version, ". . . may profit by their example. If *this* be treason, make the most of it."

During the next decade Henry was an influential leader in the radical opposition to the British government. He was a member of the first Virginia Committee of Correspondence, which aided intercolonial cooperation, and a delegate to the Continental congresses of 1774 and 1775. At the second Virginia Convention, on March 23, 1775, in St. John's Church, Richmond, he delivered the speech that assured his fame as one of the great advocates of liberty. Convinced that war with Great Britain was inevitable, he presented strong resolutions for equipping the Virginia militia to fight against the British and defended them in a fiery speech with the famed peroration, "I know

Speech at Virginia Convention

not what course others may take, but as for me, give me liberty or give me death."

The resolutions passed, and Henry was appointed commander of the Virginia forces, but his actions were curbed by the Committee of Safety; in reaction, he resigned on February 28, 1776. Henry served on the committee in the Virginia Convention of 1776 that drafted the first constitution for the state. He was elected governor the same year, and was re-elected in 1777 and 1778 for one-year terms, thereby serving continuously as long as the new constitution permitted. As wartime governor, he gave Gen. George Washington able support, and during his second term he authorized the expedition to invade the Illinois country under the leadership of George Rogers Clark.

After the death of his first wife, Henry married Dorothea Dandridge and retired to life on his estate in Henry County. He was recalled to public service as a leading member of the state legislature from 1780 to 1784 and again from 1787 to 1790. From 1784 to 1786 he served as governor. He declined to attend the Philadelphia Constitutional Convention of 1787 and in 1788 was the leading opponent of ratification of the U.S. Constitution at the Virginia Convention. This action, which has aroused much controversy ever since, resulted from his fear that the original document did not secure either the rights of the states or those of individuals, as well as from his suspicion that the North would abandon to Spain the vital right of navigation on the Mississippi River.

Bill of Rights

Henry was reconciled, however, to the new federal government, especially after the passage of the Bill of Rights, for which he was in great measure responsible. Because of family responsibilities and ill health, he declined a series of offers of high posts in the new federal government. In 1799, however, he consented to run again for the state legislature, where he wished to oppose the Kentucky and Virginia resolutions, which claimed that the states could determine the constitutionality of federal laws. During his successful electoral campaign, he made his last speech, a moving plea for American unity. He did not take his seat, for he died on June 6 at Red Hill, his last home, near Brookneal, Virginia.

Henry the Lion, Duke of Saxony

Henry the Lion, duke of Saxony from 1142 and of Bavaria from 1156 to 1180, was the most powerful German prince of his time, apart from the Holy Roman emperor Frederick I Barbarossa. His aim in life was above all to build a large territorial state in northern Germany extending from the Rhine to the Baltic Sea. But the almost kingly position he achieved during his reign menaced the feudal order of the Holy Roman empire and led to a rupture with Frederick Barbarossa, who had long been an advocate of Henry's policies. Henry's eventual downfall led to the territorial dissolution of northern Germany.

The only son of Henry the Proud, duke of Saxony and Bavaria, and Gertrude, the daughter of the emperor Lothair III, Henry the Lion was born in 1129 or 1130. The place and the exact date of his birth are unknown. In May 1142 he recovered Saxony, one of the two duchies of which his father had been divested by Conrad III, the first Hohenstaufen German king. In 1147 Henry laid claim to Bavaria, which Conrad III had granted to Henry II Jasomirgott, margrave of Austria, and, in 1151, he tried in vain to take possession of the duchy. In 1147 or 1148 he married Clementia, the daughter of Conrad, duke of Zähringen, but this marriage was dissolved in 1162.

When Frederick I Barbarossa of Hohenstaufen, his cousin, was elected king of Germany in 1152, the Hohenstaufen made peace with the rival dynasty, the Welfs. In 1154 Frederick granted Henry the right to invest the bishops of the new bishoprics beyond the Elbe and also recognized his territorial claims to Bavaria. In September 1156 Henry secured possession of the duchy at Ratisbon; Austria was subsequently separated from Bavaria and given to Henry Jasomirgott and elevated into a duchy.

Alliance with Frederick Barbarossa

Henry, in turn, for 20 years supported Frederick Barbarossa. He accompanied him with a large army on his first Italian campaign (1154/1155) and, after Frederick's coronation as emperor, suppressed a rising of the Romans. In 1157 he took part in Frederick's expedition against the Poles. During Frederick's second Italian campaign, Henry provided valuable assistance to the Emperor at the siege of Crema in 1160 and in the war against the Milanese cities in 1161.

One year after recovering Bavaria, he laid the foundations of the city of Munich by establishing a new market on the Isar River. But his main effort was directed toward expanding the Duchy of Saxony, especially in the lands beyond the Elbe. In 1159 he refounded the city of Lübeck on territory he had taken from Adolf II, count of Holstein, who had first founded Lübeck in 1143. By treaties with the merchants of Gotland and the princes of Sweden and Novgorod, he considerably enhanced Lübeck's position as a commercial centre. In 1160 the bishopric of Oldenburg was also transferred to that city. From 1158 on Henry had subdued the Slavic Obodrites in several expeditions, extending his power all over Mecklenburg and thus opening the way for its Christianization and colonization.

In 1160 Schwerin became the seat of the bishopric of Mecklenburg and was granted the privileges of a city. Even the princes of western Pomerania temporarily acknowledged his feudal sovereignty. When Valdemar I, king of Denmark, conquered the island of Rügen, in the Baltic Sea, a long, drawn-out struggle broke out between him and Henry that lasted until 1171, when the dispute was settled and Henry's daughter married Valdemar's son.

In those years Henry also consolidated his position in Saxony by seizing the properties of several extinct dynasties without regard to the hereditary claims of other families. He made Brunswick his capital and in front of the castle he had built he erected the statue of a lion as a symbol of his family and a sign of his sovereignty. But Henry's arrogant nature and his propensity for aggrandizement evoked growing opposition. Beginning in the middle 1150s, several Saxon princes entered into alliances against him. Ten years later, a great coalition led by Al-

bert I the Bear, margrave of Brandenburg, and the Archbishop of Cologne posed a serious threat to him. It was only after the Emperor intervened in 1168 that peace was restored in Saxony.

At that time, Henry was at the zenith of his power. In early 1168 he married Matilda, the daughter of Henry II of England, and soon afterward was sent to France and England as ambassador of Frederick I on a mission to arrange an armistice between both nations. In 1172 he went on a pilgrimage to Jerusalem with a large following and was received with great ceremony by the Byzantine emperor Manuel I Comnenus at Constantinople (now Istanbul).

When in 1176 Frederick Barbarossa asked for support against the Lombard cities in northern Italy, Henry's price for aiding the emperor was the important imperial city of Goslar, together with its silver mines. But Frederick refused to cede it, and his old alliance with Henry came to an end.

Henry's decline

When fighting broke out again in Saxony in 1177, Frederick, after his return to Germany in 1178, instituted proceedings based on the charge of the Saxon nobles against Henry for breach of the king's peace. Henry, who had refused to answer the charges in the King's court, was deprived of his two duchies and of all imperial fiefs, in 1180. The emperor then proceeded to break up Henry's former domain. In the same year the Saxon duchy was divided into two parts. The lands of the two bishoprics of Cologne and Paderborn were given to the Archbishop of Cologne as the new Duchy of Westphalia; the eastern part of Saxony was given as a fief to a son of Albert the Bear of Brandenburg. The Duchy of Bavaria was granted to an ally of Frederick's, Otto von Wittelsbach.

Henry was at first able to maintain his position against Barbarossa in northern Saxony, but in the summer of 1181 he had to submit. Allowed to retain his hereditary lands of Brunswick and Lüneburg, he was exiled for several years to the court of his father-in-law, Henry II of England. On his return in 1185 he tried to regain his influence in Saxony. For his refusal to participate in the Third Crusade or to renounce his claims to Saxony, he was again banished, in 1189, rejoining Henry II in Normandy.

After Frederick Barbarossa's death in 1190, Henry returned once more to Saxony. King Henry VI of Germany now took the field against him but made peace with him at Fulda in Judy 1190. After Henry the Lion renewed the fighting during Henry VI's campaign in Italy, the Emperor and Henry became reconciled at a meeting in 1194. On August 6, 1195, Henry the Lion died in Brunswick. He was buried in the cathedral he had built there, at the side of his wife.

Henry the Navigator

Henry, a prince of Portugal (1394–1460), later called by English historians "Henry the Navigator" because of his contribution to the science of navigation, sponsored the voyages of discovery that led to the foundation of the Portuguese empire overseas (see Portugal, History of). Under his auspices, the sailing vessel known as the Portuguese caravel was developed, the techniques of cartography were advanced, navigational instruments were improved, and commerce by sea was vastly stimulated. He was also the designer of a grand strategy—not to be brought to fulfillment until after his death—whereby Christian Europe outflanked the power of Islām by establishing contact with Africa south of the Sahara and with Asia.

Henry was born on March 4, 1394, at Porto, the third son of King John I (*q.v.*) and Philippa of Lancaster, the daughter of John of Gaunt of England. Henry and his older brothers, the princes of Duarte and Pedro, were educated under the supervision of their parents; they were taught soldiering, statecraft, and the appreciation of literature.

Capture of Ceuta

The starting point of Henry's career was the capture of the Moroccan city of Ceuta in 1415. According to Henry's enthusiastic biographer, Gomes Eanes de Zurara, the three princes persuaded their still-vigorous father to undertake a campaign that would enable them to win their knightly spurs in genuine combat instead of in the mock warfare of a tournament. King John consented and, with Ceuta in mind, began military preparations, meanwhile spreading rumours of another destination, in order to lull the Moroccan city into a feeling of false security.

Although a plague swept Portugal and claimed the queen as a victim, the army sailed in July 1415. King John found Ceuta unprepared, as he had hoped, and its capture unexpectedly easy. Though Zurara later claimed the principal role in the victory for Henry, it would seem

By courtesy of the Museu Nacional de Arte Antiga, Lisbon

Henry the Navigator, detail of a triptych attributed to Nuno Gonçalves, *c.* 1465–70. In the Museu Nacional de Arte Antiga, Lisbon.

that the experienced soldier-king actually directed the operation. That Henry distinguished himself, however, is indicated by his immediate appointment as governor of Ceuta, which did not require his permanent residence there but obligated him to see that it was adequately defended.

An emergency arose in 1418, when the Muslim rulers of Fez (Fès) in Morocco and the kingdom of Granada in Spain joined in an attempt to retake the city. Henry hastened to the rescue with reinforcements but on arrival found that the Portuguese garrison had beaten off the assailants. He then proposed to attack Granada, despite reminders that this would antagonize the kingdom of Castile, on whose threshold it lay. But his father, who had spent years fighting the attempts of the Castilians to annex Portugal, wanted peace with them and sent peremptory orders to return home.

As governor of Ceuta, Henry always had ships at his command and by 1418 had begun to sponsor voyages in a small way. In that year, two squires of his, João Gonçalves Zarco and Tristão Vaz Teixeira, rediscovered the islands of Porto Santo near Madeira and a little later Madeira itself, both of which had been visited by Genoese in the previous century.

Upon his return to Portugal, Henry had been made duke of Viseu and lord of Covilhã. In 1419 he retired

from the court and became governor of the Algarve, the southernmost province of Portugal. There, on the rocky promontory of Sagres, at the southwest tip of Portugal, he founded a small court of his own, to which he attracted seamen, cartographers, astronomers, shipbuilders, and instrument makers.

Maritime research at Sagres

In 1420, at the age of 26, he was made grand master of the Order of Christ, the supreme order sponsored by the pope, which had replaced the crusading order of the Templars in Portugal. While this did not oblige him to take religious vows, it did oblige him to dedicate himself to a chaste and ascetic life. (He had, however, not always refrained from worldly pleasures; as a young man he had fathered an illegitimate daughter.) The funds made available through the order largely financed his great enterprise of discovery, which also had as its object the conversion of the pagans to Christianity. It was for this reason that all of Henry's ships bore a red cross on their sails.

From 1420 onward he began to dispatch expeditions from the nearby port of Lagos, first with the aim of discovering more of the Moroccan Atlantic coast and later—when he began to think in terms of continents—with the aim of discovering the southerly route to India, in order to introduce Christianity there and to foster commerce. Little is known of the Prince's private life in the 1420s. Duarte and Pedro both married, but Henry remained single to the end of his life.

When Duarte succeeded King John in 1433, he did not hesitate to lecture and reprove Henry for such shortcomings as extravagance, unmethodical habits, failure to keep promises, and lack of scruples in the raising of money. This rebuke is not supported by the traditional account of the Navigator as a lofty, ascetic person, indifferent to all but religion and the furtherance of his mission of discovery.

Henry unquestionably was also—although in a different way—influenced by his older and perhaps more brilliant brother, Prince Pedro. In 1425 Pedro set out on a long tour of Europe on which he visited England, Flanders, Germany, Hungary, and the principalities of Moldavia and Walachia (now Romania) before returning home through Italy, Aragon, and Castile. In eastern Europe, he was close enough to Ottoman Turkey to appreciate the Muslim danger. The travels stimulated his interest in geography, which was further whetted in Italy, the home of most European travellers to distant parts. From Italy Pedro brought home to Portugal, in 1428, a copy of Marco Polo's travels that he had translated for Prince Henry's benefit.

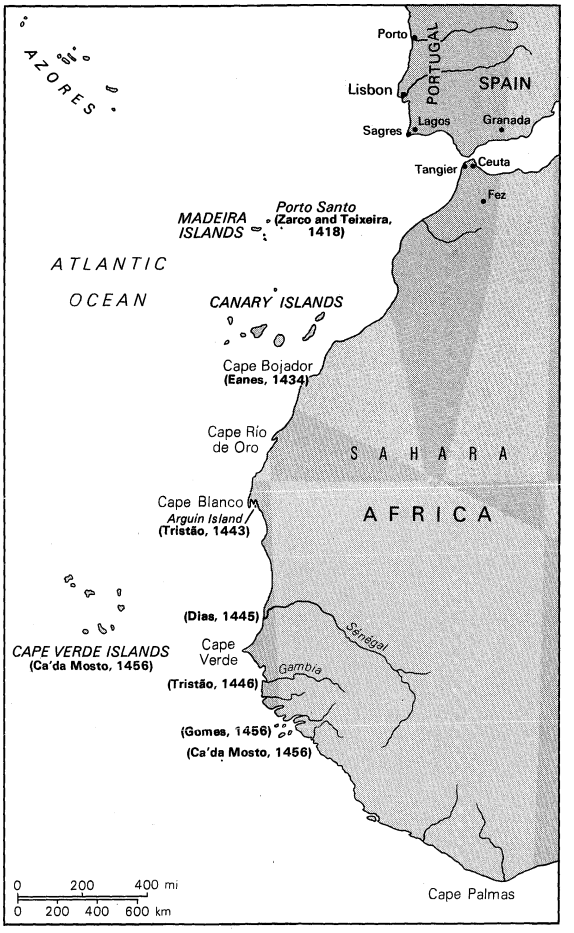
African exploration

During the five years of his brother Duarte's reign, Henry was able to persuade his captains to venture farther down the African coast. The most important achievement was the rounding of Cape Bojador by Gil Eanes in 1434, overcoming a superstition that had previously deterred seamen. During the next years, Henry's captains pushed southward somewhat beyond the Rio de Oro. They also began the colonization of the recently discovered Azores, through the orders of both Henry and Pedro.

In 1437 Henry and his younger brother, Fernando, gained Duarte's reluctant consent for an expedition against Tangier. Ceuta had proved an economic liability, and they believed that possession of the neighbouring city would both insure Ceuta's safety and provide a source of revenue. Pedro opposed the undertaking as he felt it meant deviation from Portugal's true mission, which to him was prosecution of further discovery. Henry and Fernando nevertheless attacked Tangier and met with disaster; Henry had shown poor generalship and mismanaged the enterprise. The Portuguese army would have been unable to re-embark had not Fernando been left as hostage. Henry offered himself as hostage, but as the army refused to lose its commander, Fernando remained in captivity to later die of ill treatment at Fez in 1443.

King Duarte died in 1438, shortly before Henry's return. His heir, Afonso V, was only six at the time, and Pedro assumed the regency over the bitter opposition of the boy's mother, Leonor of Aragon, who hated her brother-in-law and would willingly have accepted Henry. But Henry had no wish to govern Portugal and attempted unsuccessfully to bring about peace in the family. He felt satisfied with Pedro as regent and for himself wished only to return to Sagres and resume his maritime work. The queen-mother somewhat eased matters by leaving the country, and for most of the next decade Pedro and Henry worked in harmony, though their illegitimate half brother, Afonso, count of Barcelos, dissatisfied with his inferior position in the family, attempted to sow discord and eventually succeeded.

During these years, Henry's mission of discovery, encouraged and aided by the regent, progressed rapidly. One of his immediate aims was to find an African gold supply—the existence of which he is thought to have learned from the Moors of Ceuta—to strengthen the Portuguese economy and to make the voyages pay for themselves. In 1441 a caravel returned from the West African coast with some gold dust and slaves, thus silencing the growing criticism that Henry was wasting money on a profitless enterprise. One of Henry's voyagers, Dinís Dias, in 1445 reached the mouth of the Sénégal (then taken for a branch of the Nile); and a year later Nuno Tristão, another of Henry's captains, discovered the Gambia River. By 1448 the trade in slaves to Portugal had become sufficiently extensive for Henry to order the building of a fort and warehouse on Arguin Island; this installation was, in fact, the first European trading post established overseas.



Areas reached by explorers under the sponsorship of Henry the Navigator.

Afonso V attained his legal majority at the age of fourteen in 1446. His embittered mother had meanwhile died in Castile, and although the young king presently married Pedro's daughter, Isabel, his relations with the regent were nonetheless bad. Afonso of Barcelos now came to work on the boy's susceptible mind. His task was ren-

dered easier by the obvious reluctance with which Pedro turned full power over to the youth, whose weaknesses were already apparent.

Henry, who wished only to be a peacemaker, left Sagres and tried, unsuccessfully, to establish harmony between his brother Pedro and his nephew King Afonso. Armed conflict between the two became inevitable, and Henry in the end felt obliged to side with the King, though he remained as much as possible in the background. He took no part in a skirmish at Alfarrobeira in May 1449, in which Pedro was killed by a chance shot from a crossbowman. There is reason to believe that after this sad termination of the family feud, Henry wished to go into exile at Ceuta and spend his remaining days fighting Moors but that the King refused him permission. A historian writing 50 years later gave the impression that Henry had deserted his brother when he might have saved him. Henry's biographer, Zurara, on the other hand, declared that his hero did everything possible to prevent Pedro's death and promised to explain the circumstances further in later writings; but if he did so, the account is lost.

Final maritime ventures

After Alfarrobeira, Henry spent most of his time at Sagres, though he did not altogether abandon public life. He was accorded by the King the sole right to send ships to visit and trade with the Guinea coast of Africa. He appeared occasionally at the Lisbon court and in 1450 helped arrange for the marriage of the King's sister, to the emperor Frederick III. During most of his last decade, Henry concentrated on the sponsorship of voyages. These accomplished only minor discoveries as the Prince now seemed mainly interested in trade with the regions already contacted. The last two important mariners sent out by Henry were the Venetian Alvise Ca' da Mosto (Cadamosto) and the Portuguese Diogo Gomes, who between them discovered several of the Cape Verde Islands.

The farthest point south along the African coast reached during Henry's lifetime is generally considered to have been Sierra Leone, though one piece of evidence suggests that his seamen progressed to Cape Palmas (off the Ivory Coast), some 400 miles beyond. So great was his investment in exploration that, despite his great revenues, Henry died heavily in debt.

Afonso V had small interest in discovery but great zeal for crusading and knight-errantry. Resuming the old attempt at Moroccan conquest, he led an expedition in 1458 against Alcácer Ceguer (now Ksar es-Shrhir), in which Henry accompanied him. The Prince, now 64, did well in the fighting; and when the town capitulated, Afonso left the surrender terms to his uncle, who showed remarkable leniency.

Henry lived for two years after his final return from Morocco, dying at Sagres on Nov. 13, 1460. The cause of his death is not recorded, but he must have known beforehand that the end was near, having spent the previous months putting his affairs in order. He was buried in the royal vault at Batalha.

The surname Navigator, applied by the English to the prince, though seldom by Portuguese writers, is a misnomer as he himself never embarked on voyages of discovery. His fame rests primarily on his patronage of navigators, for which he is rightly regarded as the initiator of the great age of discovery and the European thrust towards world dominion.

BIBLIOGRAPHY. Although GOMES EANES DE ZURARA is no longer considered an infallible authority on Prince Henry, his narrative of the discoveries, trans. as *Chronicle of the Discovery and Conquest of Guinea* by C.R. BEAZLEY and E. PRESTAGE (1896), is still the best. Lives of Henry in English include: R.H. MAJOR, *The Life of Prince Henry of Portugal, Surnamed the Navigator* (1868, reprinted 1967); E. SANCEAU, *Henry the Navigator: The Life of a Great Prince and his Times* (1947); and E.D.S. BRADFORD, *A Wind from the North: The Life of Henry the Navigator* (1960). Major and Bradford are almost entirely concerned with discovery; Sanceau provides a real biography. E. PRESTAGE, *The Portuguese Pioneers* (1933, reprinted 1966), though dealing with all Portuguese discovery, offers much useful information on Henry's life. F.M. ROGERS, *The Travels of the Infante Dom Pedro of Portugal* (1961), is concerned mostly with the older Prince but stresses strongly his relations with Henry. J.P. OLIVEIRA MARTINS, *The Golden Age of Prince Henry the Navigator* (Eng. trans. 1914), reviews the lives of Henry and his brothers until the death of Pedro. Background material is furnished in abundance by DAMIAO PERES *et al.*, in *História de Portugal: Edição Monumental*, vol. 2 (1931).

(C.E.No.)

Hepatopsida

Liverworts are low, mosslike plants that constitute the class Hepatopsida, about 300 genera and 10,000 species, of the division Bryophyta. Almost totally lacking in direct economic significance, liverworts do have an important role in nature: providing food and cover for minute animals and facilitating the decay of logs and the fragmentation of rocks by virtue of their ability to retain moisture. They also chemically etch rocks and thus promote a slow disintegration. Before 1900 the flattened liverworts were commonly accepted as medicinal herbs since, according to a theory known as the Doctrine of Signatures, the liver-like form of certain species indicated that they should be useful in the treatment of liver ailments. Liverworts usually are among the first plants to colonize denuded soil and often act to reduce erosion. Because of their clear response to changes in environment, they are frequently used as experimental materials in studying the effect of chemical and other factors on the growth process. They also have an aesthetic value, covering what otherwise might be drab components of the landscape.

General features. Liverworts range in size from minute green threads barely visible to the naked eye to pendant ribbonlike forms over 20 centimetres (eight inches) long and almost five centimetres (two inches) wide. The small, filamentous species, although provided with minute leaves, are relatively simple; some of the larger, flattened liverworts, however, are highly differentiated internally, with distinct layers of tissues in the leaflike body, or thallus. Most of the leafy liverworts are intermediate in size, provided with two lateral rows of larger leaves (phyllids) and a third, ventral row of smaller (rarely equal or sometimes lacking) leaves (amphigastria).

Distribution

The liverworts occur from the Arctic to the Antarctic; a few can live in desert habitats, and some are adapted to aquatic environments. The largest number of species are found in the moist tropics, where they may clothe the trunks of shrubs and trees or hang from branches like pendant beards.

Life cycle. The liverworts have a well-marked alternation of generations, in which sexual plants (gametophytes) bearing eggs or sperm (or both) alternate with asexual plants (sporophytes) containing spores capable of producing new gametophytes. Thus, a gametophytic generation alternates with a sporophytic one.

The male and female sex organs (antheridia and archegonia, respectively), depending upon the particular species, are borne either on fleshy stems or on the leafy surface of the plant. Some species have both kinds of sex organs on the same plant, but in species such as *Marchantia polymorpha* these organs are borne on different plants.

The eggs are borne in the basal portion of the flask-shaped archegonium and the sperm in the spherical or sausage-shaped antheridium. A moist habitat is required not only for the growth of the plants but also for the rupturing of both antheridia and the necks of the archegonia. The sperm swim by means of two tiny, whiplike cilia from one plant to another through a thin film of water.

Sperm enter the ruptured tip of the archegonium and move down the canal of the slender neck, and one sperm eventually may reach the egg and unite with it to form a zygote, or initial cell of the embryo. The young sporophyte that results remains within the slowly enlarging archegonium throughout most of its development. At maturity the sporophyte consists mainly of a sporangium, or spore capsule, a foot embedded in the base of the archegonium, and a compressed stalk (seta) between; in

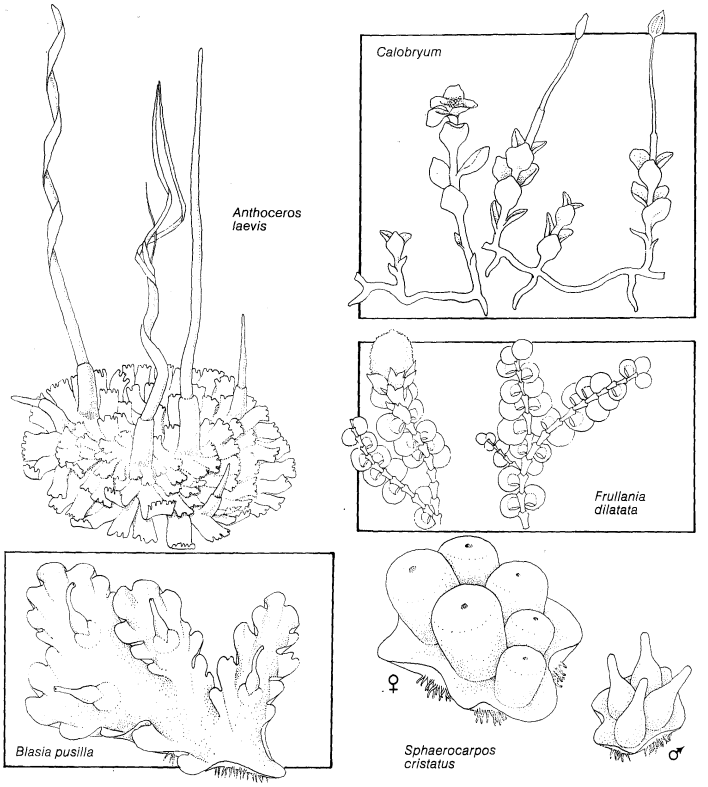


Figure 1: Diversity among liverworts. Symbols: ♀—female, ♂—male.

Drawing by M. Moran based on *An Evolutionary Survey of the Plant Kingdom* by Robert F. Scagel, Robert J. Bandoni, Glenn E. Rouse, W.B. Schofield, Janet R. Stein, and T.M.C. Taylor. © 1965 by Wadsworth Publishing Company, Inc., Belmont, California 94002. Reprinted by permission of the publisher.

most liverworts the seta elongates and carries the capsules and their spores upward. Upon being dispersed by water or wind, a spore may germinate into a very short, threadlike or platelike structure (protonema) that grows into the gametophyte.

While sexual reproduction does occur in liverworts, asexual reproduction probably accounts for most liverwort propagation. Under suitable environmental conditions, almost any living fragment seems capable of growing directly or indirectly into a new gametophyte. Many species of liverworts produce a specialized cell or group of cells that serves as a reproductive structure called a gemma. Several gemmae may be borne on the surface of stems or in specialized flask-shaped or cup-shaped structures. The gemmae may be dispersed by rain as well as by wind.

Liverworts, like higher plants, contain growth-affecting substances and respond to them. This may account for the great variability within a species in response to light, water, and other environmental factors. Plants in environments with diffuse light or excessive moisture may be much elongated and slender, in contrast with the compact nature of those in the more usual habitat. These variations often make it difficult to distinguish between related but valid species if each is collected in a different habitat.

Form and function. *Marchantia polymorpha*, a liverwort commonly discussed in textbooks, has a ribbon-like gametophyte (thallus) with an upper and a lower epidermis. The lower epidermis is provided with two kinds of hairlike cells (rhizoids) that serve to anchor the plant (absorption seems to take place throughout the entire surface of the plant). The upper epidermis has pores—surrounded by rigid, chimney-like tiers of cells—that open into chambers below. These cavities are separated by vertical, single-layered walls and within have cactus-like columns of green cells. With the exception of the rhizoids, all parts of liverworts contain the green pigment bodies, or chloroplasts, and are capable of photosynthesis.

In *Marchantia*, the sex organs are borne on highly modified upright branches of the thallus. The antheridia are borne in cavities on the flattened, upper surface of stalked heads. The archegonia and, consequently, the developing sporophytes are found beneath the arms of a stalked structure that resembles an open umbrella stripped of its fabric. The thalloid forms most related to the leafy liverworts are more simple in structure; some are only one cell in thickness.

The leafy forms of liverworts have little internal differentiation, but occasionally their leaves (phyllids) exhibit some bizarre forms, being composed of branched, hairlike segments in *Trichocolea* and having a pouch-shaped lobule bent up behind the major lobe of the leaf in *Frullania*.

Oil bodies

Most liverworts, in addition to chloroplasts and a nucleus in each cell, have oil bodies that are often distinctive and therefore useful in making specific identifications and in determining relationships that exist among species.

Evolution and classification. The variations in the structure of the liverwort gametophyte are extreme and give rise to considerable disagreement as to the origin of and evolution within the liverworts. Moreover, liverworts, because of their delicate tissues, do not preserve well in geological materials, and so known fossils are few and inadequate to suggest ancestry with any degree of security. The complex thalloid forms are thought by some botanists to be more primitive but more increasingly by others to represent the most recent and highly derived type.

Distinguishing taxonomic features. The most important features in arranging the class Hepatopsida into its two subclasses (Hepatidae and Anthocerotidae) are the basic form of the gametophyte (either thalloid or leafy) and the growth pattern of the sporophyte (apical versus basal). Orders are determined primarily by the external appearance of the gametophyte and the position of the sex organs. Microscopic anatomy is a further aid to proper taxonomic ranking at the ordinal level.

Annotated classification. The classification given below is an adaptation of a currently popular scheme.

CLASS HEPATOPSIDA (liverworts proper)

Gametophytes thalloid or "leafy" with a high degree of dorsiventrality; if "leafy," with two lateral rows and sometimes a smaller, ventral row of "leaves." Sporophytes with globular or needle-shaped capsules; capsules with relatively undifferentiated walls, opening by splitting longitudinally or

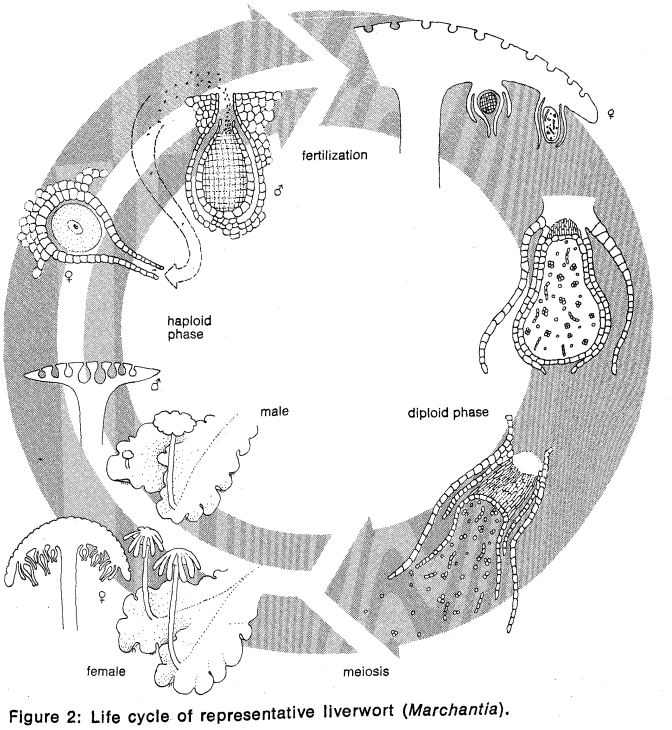

Figure 2: Life cycle of representative liverwort (*Marchantia*).

rarely by irregular erosion, without a central sterile pillar (columella) of cells, except in the Anthocerotidae, often with hygroscopic, filamentous sterile cells (elaters) between the spores. About 300 genera and 10,000 species.

Subclass Hepatidae

Gametophyte, seldom erect, more frequently leafy than thalloid, with several chloroplasts in each cell; the sporophyte with apical growth that produces a globular capsule without columella or stomates.

Order Takakiales

Unusually strange liverworts at first suspected of being algae; in the field they superficially resemble a minute green *Chara*. Archegonia often are borne on a pedestal and always without attending bracts. Antheridia, sporophytes, and rhizoids are unknown. It is represented by a single family and genus, in which 2 species, *Takakia lepidozioides* and *T. ceratophylla*, have been described. The nuclei each have 4 chromosomes, an unusually low number.

Order Calobryales

Gametophytes with radial symmetry superficially resembling mosses. Upright branches arise from buried, rhizome-like stems; rhizoids are totally absent. The archegonia have 4 vertical rows of neck cells, which is less than that in all other groups of the bryophytes. The sporophyte is of the liverwort type but is not basally surrounded by a true perianth. A small order of 1 or 2 genera and about 7 species.

Order Jungermanniales

Gametophytes consisting of 2 types as indicated below. Internal anatomy relatively simple. Capsule usually exserted on an elongated, fragile stalk (seta). The largest order of liverworts, with about 200 genera and over 8,000 species.

Suborder Jungermannineae (leafy liverworts). Gametophytes organized dorsiventrally, with 2 rows of conspicuous but delicate lateral "leaves" and often a row of usually smaller leaves underneath. External form highly variable. The archegonia and sporophytes are borne terminally on stems and branches. About 180 genera and 7,500 species are included.

Suborder Metzgerineae. Gametophytes thalloid, usually 1 cell in thickness except for the midrib (if the wings are more thickened, the midrib is absent or obscure); margins are sometimes incised or lobed, superficially resembling leaves. Archegonia and sporophytes not terminal. About 20 genera and 550 species are included.

Order Sphaerocarpales

Gametophytes small, superficially resembling fern prothallia or forms of members of the Metzgerineae. Sex organs are borne on the surface but in specialized containers. A small order consisting of 2 genera and about 20 species.

Order Marchantiales

Gametophytes dorsiventrally oriented, thalloid, multicellular in thickness with considerable internal differentiation. About 95 genera and 2,000 species.

Subclass Anthocerotidae (horned liverworts, or hornworts)

Gametophytes always thalloid with a single chloroplast per cell; sporophyte with basal growth that produces a needle-shaped capsule with a columella, multicellular elaters, and stomates. A relatively small subclass consisting of not more than 5 genera but of great interest scientifically because of the usually single, large chloroplast in each cell, the basal growth of the sporophyte, and the presence of stomates.

Critical appraisal. The order Takakiales exhibits enough differences from most bryophytes to cause some botanists to question its placement in the division. These differences include the small chromosome number of four per cell (the lowest known among the land plants) and the bractless chlorophyll-containing archegonium, which looks as if it may have been formed from a developing leaf.

The Anthocerotidae have been variously treated taxonomically. Some botanists feel that their slender, needle-shaped sporophytes with basal growth and stomates and the few (often one) large chloroplasts in each cell entitles them to class rank equivalent to Hepatopsida. Their gametophytes, however, are similar to some of the thalloid liverworts, and, until more convincing evidence is forthcoming, its seems unwise to separate them from the Hepatopsida.

Heraclius

East Roman (Byzantine) emperor from AD 610 to 641, Heraclius revived the decaying power of the Byzantine state. Most scholars now agree that it was he who initiated the militarization of Anatolia, known as the theme (military district) system, which was further developed and extended by his successors. It placed the Anatolian provinces under military governors and provided land grants not only for frontier soldiers but also for soldiers and peasants in the interior, on condition of hereditary military service. The effects were revolutionary. A flexible defense developed in depth; a free, militarized peasantry arose; agriculture revived; and the state was relieved of much of the burden of soldiers' pay. Unruly mercenaries were largely replaced by native soldiers with a personal interest in protecting the empire. Indeed, during the four centuries that the theme system remained intact, the empire could be defeated but not conquered. Byzantium withstood Islām's fierce onslaughts and sheltered Europe's infant civilization. Yet there is no known record of the inception of the theme system, and it was rather because of his epic struggle against Persia and his recovery of wood believed to be from Christ's cross that Heraclius became a hero of medieval legend.

Heraclius, gold coin, *c.* 610–641. In the Dumbarton Oaks Research Library and Collection, Washington, D.C.
By courtesy of the Dumbarton Oaks Collection, Washington, D.C.

Heraclius was born *c.* 575 in Cappadocia, in eastern Anatolia. His father, probably of Armenian descent, was governor of the Roman province of Africa when an appeal came from Constantinople to save the empire from the terror and incompetence of the emperor Phocas. The governor equipped an expeditionary force and put his devout son, the blond and gray-eyed Heraclius, in command of it.

In October 610 Heraclius dropped anchor off Constantinople, deposed Phocas, and was crowned emperor of a crumbling state, occupied by invaders and wracked with internal dissension. Slavs swarmed over the Balkan Peninsula. The Persians occupied extensive parts of Anatolia. The Turkic Avars, who ruled over the Slavic and other tribes that occupied the region between the Don and the Alps, exacted tribute. With its treasury empty, its economy disrupted, its administration disorganized, its army depleted and demoralized, its factions engaging in civil strife, its peasants enfeebled by excessive exactions, its religious dissenters alienated by persecution, its authority challenged by a powerful aristocracy, the empire lacked the strength necessary to expel the invaders, and possibly even to survive.

Campaign against the Persians

In 614 the Persians conquered Syria and Palestine, taking Jerusalem and the cross, and in 619 occupied Egypt and Libya. In an effort to placate the Avars, Hera-

clius met them at Thracian Heraclea (617 or 619). They sought to capture him, and he rode madly back to Constantinople, hotly pursued. Overlooking their perfidy, he finally made peace with them and was free to take the offensive against the Persians.

In 622, clad as a penitent and bearing a sacred image of the Virgin, he left Constantinople, as prayers rose from its many sanctuaries for victory over the Zoroastrians, the recovery of the cross, and the reconquest of Jerusalem. He was, in effect, leading the first crusade. Indeed, in the ensuing hostilities, a pious poet contrasted the dancing girls in the Persian general's tent with the psalm singers in the Emperor's. In a brilliant campaign, he manoeuvred the Persians out of Anatolia and suggested a truce to the Persian monarch. This offer Khosrow II contemptuously rejected, referring to himself as beloved by the gods and master of the world, to Heraclius as his abject and imbecilic slave, and to Christ as incapable of saving the empire. Mindful of the propagandistic value of Khosrow's response, Heraclius made it public.

The next two years he devoted to campaigns in Armenia, the manpower of which was vital to the empire, and to a devastating invasion of Persia. In 625 Heraclius retired to Anatolia. He had encamped on the west bank of the Sarus River when the Persian forces appeared on the opposite bank. Many of his men rushed impetuously across the bridge and were ambushed and annihilated by the enemy.

Emerging from his tent, Heraclius saw the triumphant Persians crossing the bridge. The fate of the empire hung in the balance. Seizing his sword, he ran to the bridge and struck down the Persian leader. His soldiers closed rank behind him and beat back the foe.

In 626 the Persians advanced to the Bosporus, hoping to join the Avars in an assault on the land walls of Constantinople. But the Romans sank the primitive Avar fleet that was to transport Persian units across the Bosporus and repelled the unsupported Avar assault. Heraclius again invaded Persia and in December 627, after a march across the Armenian highlands into the Tigris plain, met the Persians near the ruins of Nineveh. There, astride his famous war-horse, he killed three Persian generals in single combat, charged into enemy ranks at the head of his troops, killed the Persian commander, and scattered the Persian host.

A month later, Heraclius entered Dastagird with its stupendous treasure. Khosrow was overthrown by his son, with whom Heraclius made peace, demanding only the return of the cross, the captives, and conquered Roman territory. Returning to Constantinople in triumph, he was hailed as a Moses, an Alexander, a Scipio. In 630 he personally restored the cross to the Church of the Holy Sepulchre in Jerusalem.

Since the 4th century, when Roman emperors adopted Christianity, they had endeavoured to preserve uniform theological belief and, notably in Egypt, Syria, and Armenia, had persecuted those with differing Christological views. The animosities thus created had facilitated the Persian conquest, and Heraclius sought to conciliate the dissenters with the doctrine of Christ's single will (monothelitism). He failed.

Rise of Islām

At all events, it was already too late. United by Islām, the Arabs swept out of their arid homeland into Syria (634). Broken in body and spirit by disease, by long years of the cares of state, and by the wounds and emotions of 100 battles, Heraclius did not take personal command of the army, although the sight of him in battle armour would have inspired the troops and silenced the bickering generals. The Byzantines were defeated in a great battle on the Yarmuk (636). Soon, Syria and later Egypt fell to the Arabs. Heraclius returned northward, bearing the "holy wood," once the object of his greatest glory, now the companion of his deepest sorrow. Fearing water, he remained a year on the Asiatic bank of the Bosporus before summoning the courage to cross to Constantinople on a pontoon bridge with foliage hiding the water.

Heraclius' first wife, Eudocia, had died in 612. A year later, he had married his niece Martina, thus offending the religious scruples of many of his subjects, who viewed his second marriage as incestuous and Martina as accursed. It was apparently a happy marriage, Martina accompanying him on his campaigns and bearing him nine children. During his last years, Heraclius seems to have suffered from enlargement of the prostate gland, retention of urine, and a consequent inflammation. After violent spasms, he died on February 11, 641, bequeathing the empire to his two elder sons, the consumptive Constantine III of his first marriage and Heracleonas, his son by Martina.

Assessment

Although Heraclius possessed a deep Christian faith and attributed his successes to God, the once widely accepted view of him as an inspired visionary, who was capable of supreme but spasmodic efforts and wondrous achievements when acting under divine promptings, would appear to be false.

No doubt he was an inspiring military leader who fired his army with religious fervour and whose personal intrepidity, imaginative tactics, and constant concern for his men evoked their love and loyalty. But he was also a cautious and calculating strategist who did not hesitate to employ religion to serve his military ends. Thus, when in 623 his victorious soldiers wanted to penetrate deeper into Persia, contrary to his plan to retire, he referred the matter to God. After his troops had fasted and prayed three days, he opened the Bible in their presence, apparently at random, and read a passage that could be interpreted only as a divine command to withdraw. Moreover, even though he fostered the crusading spirit, he waged war in a less inhumane manner than most of his contemporaries. He did not enslave or massacre the inhabitants of conquered towns and he treated his prisoners of war well, releasing them rather than butchering them when he could not feed them. His mercy contrasted sharply with Khosrow's acerbity and probably hastened his victory in Persia.

As a statesman it is also difficult to think of him as merely a religious fanatic. Certainly he inspired an oppressed and hopeless people with a new spirit of faith, service, and self-sacrifice but the man who restored a state that was sinking under the blows of internecine strife and foreign invasion and gave it the strength to withstand Islām's assaults for four centuries, perhaps even contributed to its survival until 1453, must have had a strong will, great organizing ability, exceptional conciliatory powers, and deep insight into the needs of both state and subjects. With a keen sense of reality, he adjusted the empire to the needs of the 7th century, departmentalizing the great state offices, instituting the theme system, and replacing Latin with Greek as the official language.

Heraldry

Heraldry is the science and art that deals with hereditary symbols employed to distinguish individuals, institutions, and corporations. These symbols, which probably originated as identification devices on shields, are called armorial bearings. Heraldry treats of their use, display, and regulation.

Strictly defined, heraldry denotes that which pertains to the office and duty of a herald, an official who grew to be of considerable importance during the Middle Ages; that part of his work dealing with armorial bearings is properly termed armory. In general usage, however, the term heraldry has come to mean the same as armory.

From the second quarter of the 12th century in western

Europe, heraldic designs are found in general application. Elsewhere, a similar system is to be found only in Japan, in the *mon*, also dating from the 12th century. Other times and places are often said to have produced heraldic systems; for example, ancient Israel in the symbols of the 12 tribes, or the designs used by the Rajput princes in India. These and like instances, however, are more properly considered incipient heraldry, since they did not develop into the complex heraldic practice known in western Europe and Japan.

From 1150 to 1500, the use of heraldry in the West was utilitarian: on armour in warfare, and on seals in peace. In the latter part of that period, it was used in peaceful ways and had much artistic value. Also, because from the beginning the use of arms had been associated with the higher feudal castes, heraldry acquired in later medieval times an identification with the concept of gentility that has persisted. To bear arms was the mark of a gentleman; therefore, to possess the desirable quality of gentility, a man needed to have armorial bearings. The great majority of those who seek to use coats of arms in the late 20th century are actuated by this motive. In the use of corporate arms, the motive of prestige rather than social distinction operates. As long as the possession of arms confers any social distinction, arms will be sought and used. At no previous time has there been so widespread an employment of heraldic devices.

The use of symbols has been universal among civilized communities and also has occurred among many that are semi-civilized. But these symbols have not assumed the character always associated with heraldry. Seals, too, which have a prominent place in heraldic practice, are of an antiquity approaching that of the most ancient civilizations. They were in use in the states that from Sumer onward flourished in Mesopotamia. Their use, for example, in the Babylonian Empire was the same as in medieval western Europe: to authenticate the documents (possibly of baked brick, later papyrus, later still parchment or vellum) on which they appeared or to which they were appended. All persons, literate and illiterate alike, were able to recognize the representation or symbol of a ruler or other potentate. In 12th-century Europe, heraldry first appeared on seals in the representations of persons. There is a clear line of descent from the seals of Assyria and Babylonia to the modern company seal, which is often heraldic.

Seals as ancient devices of heraldry

Although originating in the small half continent of western Europe, heraldry has become universal, often, but not only, by way of western European colonization. Heraldry has spread to a considerable degree in both the Americas, Australia, New Zealand, and South Africa. In the former British India, the hereditary princes adopted the use of heraldry. In the numerous independent states formed in Africa from the former British colonies, official armorial bearings are generally used, and the same is true of the new states that were formerly French colonies. In Russia in the 18th century, the use of armorial bearings was adopted from the West, and state emblems are not unknown in Communist eastern Europe. In the 13th century, the Celtic princes of Wales and Ireland and the chiefs of the Scottish Highland clans took up the use of heraldic symbols from the example of the feudal lords and knights of other parts of Europe.

Other kinds of emblematic identification have some similarities with heraldry. An example is the totem system, found among the aborigines of America and Australia, in which an animal, plant, or other object serves as an emblem of family or clan and is often regarded as a reminder of its ancestry. Totemism varies greatly in different countries, as do the theories advanced to explain it. The totem poles used by the Indians of the northwest coast of North America contain a heraldic element in their use of a hereditary symbol for a family or tribe. They therefore come under the heading of approaches to heraldic designs and may be termed semi-heraldic in character.

The Japanese *mon* as a type of armorial bearing

The Japanese *mon* is very definitely a heraldic symbol, having many parallels in its use with the armorial bearings of Europe. It was used on helmets, shields, and breastplates but never, as in Europe, large enough to identify the wearer of the armour at any considerable distance. When identification was desired, the *mon* was displayed on flags. In some European languages, the *mon* has been translated erroneously as "coat of arms." The *mon* most closely resembles the heraldic badge (distinctive mark used by retainers), which in Europe often antedated armorial bearings. Further resemblances to European heraldry in the use of the *mon* include: the decorative use of the symbol on clothes, furniture, and houses; the use on the clothes of retainers of great lords; the legal requirement of registration of the *mon* (dating from the 17th century); and the reservation of the chrysanthemum *mon* to the emperor, with junior members of the imperial family using a different variety of the flower. This last distinction corresponds exactly to the rules of heraldic precedence that apply to the European royal families. That areas so far removed from each other as western Europe and Japan should have developed a system of hereditary symbolism independently of one another is not surprising, for in both areas feudalism was the prevailing medieval political and social system. As in Europe, Japanese heraldry survived the obsolescence of armour and has remained in widespread use in the 20th century.

Despite some uninformed opinion to the contrary, tartan has no connection with heraldry. It is simply a form of weaving cloth that is by no means restricted to the Scottish Highlands. Armorial bearings were adopted by Highland chiefs in imitation of the Lowland chivalry from the 13th and 14th centuries. The badge of the chief

was adopted and used extensively by the members of his clan.

Flags can be heraldic. That of the United Kingdom is certainly so; it is formed by the amalgamation of the flags of England, Scotland, and Ireland, these showing respectively the crosses of St. George, St. Andrew, and St. Patrick, all of which are displayed heraldically. The United States flag has a quasi-heraldic character and appears to owe its principal ingredients to the armorial bearings of the first president, George Washington. The flag representing the republic of France, by contrast, is not heraldic, being merely an arrangement of the national colours.

In addition to national flags, there are banners, rectangular pieces of cloth showing the armorial bearings of the owner, and standards, strips of cloth that taper gradually to the end and usually bear heraldic devices but not the owner's full coat of arms.

Like all other human creations, heraldic art has reflected the changes of fashion. As heraldry advanced from its utilitarian usages, its artistic quality declined. In the eighteenth-century, for example, heraldry described new arms in an absurdly obtuse manner and rendered them in an overly intricate style. It was not until the 20th century that heraldic art recovered and in many ways improved upon the originals, especially in displaying animals anatomically. There were still far too many drawings, however, of poor quality emanating from official sources.

This article is divided into the following sections:

I. The scope of heraldry

Institutional arms from medieval times

An early development was the extension of heraldic design from its use by persons or families to its employment by institutions and associations of various kinds, a consequence of the concept that an assembly or body of people can be personified as an individual, much as a limited company or corporation is viewed as a legal "person." Medieval times provided numerous examples of arms borne by municipalities, churches, and colleges. The arms assumed by an individual or granted to him are regarded as being peculiarly his possession, therefore caution must be used in speaking of family arms. This question can be best dealt with in connection with the royal arms of the sovereign of the United Kingdom. These arms are borne in their entirety only by the reigning king or queen. No other member of the royal family can bear the arms without a "difference" mark that will show without doubt that the bearer is not the reigning sovereign. By analogy, the same condition holds for all so-called family arms, which belong to the head of the family; all other members should strictly bear them differenced—that is, with some mark of cadency (a sign indicating the position of the bearer with respect to the head of the family). In Scottish heraldry, this rule is very rigidly enforced, but in England and elsewhere it has been allowed to fall into decay, except in the case of the royal family.

Probably the next development in the scope of heraldry was its use by ecclesiastics. The bishops and the abbots of the monasteries used arms on their seals from the 12th century onward. In this variety of heraldic usage, the arms were not those of individuals but of the body they temporarily represented—as also with arms borne by political units such as nations and cities or by educational establishments, many of which date from the Middle Ages. A great extension of medieval heraldry was connected with what came to be called the livery companies. These were guilds or associations of men in trades whose object was to uphold standards of craftsmanship. Most of them obtained charters from the crown and were granted arms. Among numerous examples in Britain are the Grocers, the Mercers, and the Glaziers companies. Membership in these still-existing companies no longer entails practice of their particular trades, but they possess property and have great charitable interests as well as considerable social esteem. Their armorial bearings are of great antiquity and are much displayed on their halls, letterheads, glass, silver, and so forth. Obviously, armorial bearings were assumed in the Middle Ages by such military bodies as the Knights Templars, the Knights of St. John of Jerusalem, the Teutonic Knights, and the great Spanish orders. Military heraldry has continued to the present: each of the three British armed forces, for example, has badges, or in some cases coats of arms, which are in the care of officers of the English College of Arms. As a matter of fact, one of the greatest modern uses of heraldry occurred during World War II when some 500 emblems were employed as divisional and other signs.

In the 20th century, the development of corporate heraldry has gone far beyond anything known before. Throughout the world, banks, insurance companies, and many other great commercial concerns use arms, together with an ever-increasing number of professional, educational, and trade associations.

Perhaps the event most illuminative of the modern scope of heraldry was the grant, in 1961, by the government of the Republic of Ireland of armorial bearings to the president of the United States of America, John F. Kennedy. Because arms are hereditary and their owners are regarded heraldically as of noble status, the grant amounted to a bestowal of nobility by a state on the head of another state, an occurrence unique in heraldic history.

THE CHIEF COMPONENTS OF ARMORIAL BEARINGS

Heraldry originated when most men were illiterate but could easily recognize a bold, striking, and simple design. The use of heraldry in medieval warfare enabled combatants to distinguish one mail-clad knight from another and thus to know friend from foe. Thus, simplicity was the principal characteristic of medieval heraldry. In the tournament there was a more elaborate form of heraldic design. When heraldry was no longer used in war and heraldic devices had become a part of civilian life, an intricate type of design evolved with an esoteric significance utterly at variance with its original purpose. In modern times, heraldry has often been looked on as mysterious, a matter for experts only. Indeed, over the centuries its language has become intricate and pedantic. Such intricacy appears ridiculous when it is remembered that in the earlier periods swift recognition of a coat of arms or badge could mean the difference between safety

The trend toward complexity and esoteric significance

The arms of U.S. Pres. John F. Kennedy. The gold helmets are a variant on the three silver helmets of an ancient Kennedy coat. The border was added as a further difference. The olive branches and sheaf of arrows are derived from those of the Great Seal of the United States. The lambrequin is blazoned as argent and gules; this is exceptional to the rule that the principal tinctures of the arms (in this case or and sable) be repeated. No motto was included in the grant. The diagonal orientation of the shield is called couché and is optional in all depictions of arms.

Drawing by Wm. A. Norman

and death, and in many medieval instances battles were lost through a mistake over the sameness of two devices of opposing sides.

The shield. The shield is the essential part of the armorial bearings; without it there can be no heraldic device, except for a woman, a distinction that calls for special treatment and is dealt with later. The word shield can be used to describe the coat of arms but in modern times is seldom employed in this way, except in a poetic context. Armorial bearings are generally referred to more briefly as "arms," or as a "coat of arms," a term derived from the surcoat of silk or linen worn over the armour to keep off the rays of the sun and to prevent rust from forming on the armour. The surcoat was a waistcoat-like garment on which were shown the same heraldic insignia as on the shield.

Every other object in heraldic achievement is dependent upon the shield or coat of arms. There can be, and quite often is, a coat of arms consisting solely of a shield without any other object, such as a crest surmounted. The arms of the Churchills of Muston, a branch of the same family to which Sir Winston Churchill belonged, have no crest. The reason is that such families possessed arms before crests became fashionable.

The crest. A crest is the object placed on top of the helmet and bound onto it by what is called the wreath of the colours, which shows the two main colours of the shield (see illustration). Crests were at first made of leather, later of light wood, and, as time went on, of more valuable materials. It is supposed that they were at first borne in tournaments; they became general in families in England from the 16th century when the venal heralds of that time persuaded crestless families to acquire the addition for a payment. Nowadays, a crest is automatically included in any grant of arms made in England, Scotland, or Ireland.

The crest and the age of the automobile

When horsedrawn carriages were in use, it was the rule to show the whole heraldic insignia on the coach or carriage door. With the advent of motorcars and their smaller door space, the arms were usually left off and only the crest and motto shown. This development may be the reason for the mistake frequently encountered in which the whole coat of arms is referred to as a "crest." It should be emphasized that while a coat of arms can exist without a crest, the existence of a crest without a coat of arms is an impossibility.

The helmet. On top of the shield is placed the helmet, upon which the crest is tied by the wreath. Originally, everything in heraldry was strictly utilitarian. As armorial bearings were used with the suit of armour, there had to be a helmet. In later centuries, rules for the depiction of the helmet were elaborated to show the rank of the bearer, with some displayed in profile and some in full face, and with different metals and accoutrements to indicate status. The shape of the helmet has varied greatly in heraldic representation. While the basic features of heraldry remain unchanged, the modes in which the insignia are shown are as subject to change and to fashion as any other human creations. The barrel-shaped helmet was that in use in the 13th century. The tournament helmet, which is often shown in drawings, was of a different type altogether, its shape resembling that of a soup tureen.

Mantling. From the helmet hung the mantling or lambrequin. This was of linen or other material and performed the useful function of shielding the wearer from the sun's rays and also served to catch or deflect sword cuts. The mantling or mantle is painted with the principal colour of the shield, while its lining is of the principal metal. More elaborately styled mantles are used for kings and princes.

Crowns and coronets. These are emblems of the rank of the bearer. With the abolition of most of the great European monarchies, the study of crowns has become mainly of historical and antiquarian interest. The most famous royal crown remaining in the 20th century is that of the United Kingdom; it appears in the sovereign's

Drawing by Wm. A. Norman

The chief components of armorial bearings as indicated on the royal arms of the United Kingdom of Great Britain and Northern Ireland. The royal cipher (ER) is not a part of the arms proper but identifies them as representing Queen Elizabeth II. The roman numeral II is unnecessary here, as the arms of Elizabeth I were different, apart from those of England. The shield shows England (gules three leopards or) quartered with Scotland (or a lion rampant within a double tressure flory counterflory gules) and Ireland (azure a harp or stringed argent). This is the quartering in use since the accession of Queen Victoria in 1837. The shield is encircled by the garter of the Order of the Garter bearing the motto of the order, *Honi soit qui mal y pense.* The dexter supporter, a royally crowned gold lion guardant, and the sinister supporter, a silver unicorn with gold horn, hooves, mane, and tufts and a gold coronet collar and chain, represent England and Scotland, respectively. Atop the full-faced helm of a sovereign with its ermine and gold mantling, or lambrequin, is the royal crown surmounted by the royal crest, a lion statant guardant crowned with the royal crown. The motto *Dieu et mon droit* ("God and my right"), first used by Richard I, appears on the scroll below. The ground beneath the full achievement, called the compartment, is strewn with the floral and plant badges of England (rose), Scotland (thistle), Ireland (shamrock), and Wales (leek).

arms upon the royal helmet and the crest of a golden lion crowned. Coronets (small crowns implying dignity inferior to that of the sovereign) are emblems of rank that are shown, when depicted, between shield and helmet. In Britain there are different coronets specified for the ranks of baron, viscount, earl, marquess, and duke. On the European continent, a much wider use of coronets has prevailed. Among the relics of this usage is the crest coronet, a coronet that supports the crest either instead of the wreath or in addition to it and resting upon it. Another is the chapeau or cap of maintenance, a cap with fur lining that was once worn on the helmet before the development of mantling and that is often used instead of the wreath to support the crest.

The myth of battle cries as sources of mottoes

Mottoes. Many myths have grown up around mottoes. They are often said to have originated as battle cries, but very few actually did. Among those that did are the *Crom a boo*, of the FitzGeralds, the dukes of Leinster, meaning "Crom [one of the family's old castles] forever"; and the "firth fortune and fill the fetters" of some Scottish families, which defies explanation and must refer to some forgotten incident. In succeeding centuries large numbers of mottoes were adopted. They are not part of a coat of arms and can be varied at the user's pleasure, though they are included in a modern grant of arms. More than one motto may be used by the same family. In Scottish arms the motto is usually shown above the crest, in all other countries beneath the arms and always contained in a scroll.

The supporters. These are the figures on either side of the shield of arms and are borne (in English heraldry) by peers, and by other bearers of orders of the highest class, such as Knights of the Garter, the Thistle, St. Patrick, and by Knights Grand Cross. In former times, supporters were used more widely, and a few English families still claim the right. In Scotland their use is much more frequent.

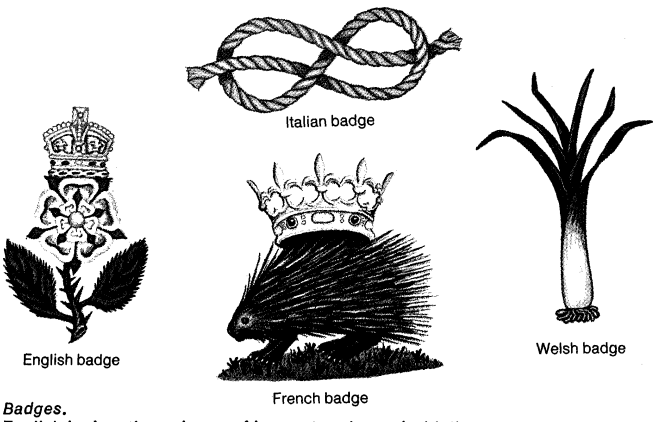
The compartment. The ground or foundation on which the supporters stand is called the compartment. In Scottish arms it is usually a rock or piece of ground strewn with some heraldic object. In England the compartment ought to be shown in the same way, and in the 20th century often is, with the scroll of the motto beneath it; but in the debased heraldic art of the 18th and 19th centuries, the supporters were generally shown as standing on a piece of ironwork or on the scroll.

The achievement. In heraldic writing, the term achievement often carries the same meaning as "arms," but probably its better usage is to describe the whole representation showing shield, helmet, crest, mantling, and supporters. The achievement belongs to only a minority of those who possess arms, since only a few have supporters. In addition, an achievement may include representation of various knightly orders or companionships of knightly orders to which the owner of the arms is entitled. For example, Viscount Montgomery of Alamein, British field marshal and World War II military leader, can show the symbol of the Order of the Garter around his shield; persons with lesser distinctions such as the Distinguished Service Order, Military Cross, and Order of the British Empire may have the decorations shown pendent from their shields. As distinctions of this kind are not hereditary, on the death of the bearer the successor to the arms must not use representations that show these honours.

Badges as symbols of persons or nations

The badge. This is older than the heraldic system. Such symbols expressing a person, a body, or an impersonal idea are found from ancient times. The eagle of Rome was one of the state's symbols and was the special device of the legions. Many such symbols bring to mind the country they represent; *e.g.*, winged bulls with human faces at once recall Assyria. On Trajan's Column in Rome, devices sometimes bear resemblances to later heraldic designs. On Etruscan vases are seen what not unfairly could be called demi-boars or bulls' heads caboshed. Nearer to heraldic times, the planta genista, or broom plant, which gave its name to the Plantaganet dynasty of England between 1154 and 1485, was a badge of the counts of Anjou before that family had armorial bearings. With the growth of heraldry, badges naturally assumed a heraldic character. They could be varied at the will of the holder, who often had more than one. Badges persist to the present and sometimes accompany a grant of arms.

Drawing by Wm. A. Norman



Badges.
English badge: the red rose of Lancaster charged with the white rose of York, surmounted by the royal crown. Italian badge: the knot of the royal house of Savoy. French badge: the porcupine of Orléans, first used by Louis XII; the crown is not always included. Welsh badge: the leek; the daffodil is also a long-established badge of Wales.

Banners and standards. The users of arms in the Middle Ages often displayed them on the fork-tailed pennons of their lances. When the forked ends were cut off, the resulting flag was square, becoming a banner. Particularly valorous conduct was often indicated in this way, and the knight thus distinguished was known as a knight banneret. This last word was sometimes corrupted into baronet, a term that the English antiquary Sir Robert Cotton (1571–1631) used when he suggested to James I of England that he should revive a supposed order of baronets. The resulting Order (1611) was hereditary, however, and had no true connection with medieval knighthood. The banner bears the owner's arms, and in the 20th century anyone who possesses arms is entitled to a heraldic flag in this form. These can sometimes be seen in Great Britain flying over a house. No banner is referred to in the grant of arms made to President Kennedy, but in due course an armorial banner was made for the occasion when his brother, Sen. Robert Kennedy, carried it to the top of a mountain in the Yukon Territory named Mt. Kennedy by the Canadian government in memory of the President. The banner showed the Kennedy arms without the crest. The maker of the banner added a long white streamer on which he put the badge, the latter being part of the Kennedy crest.

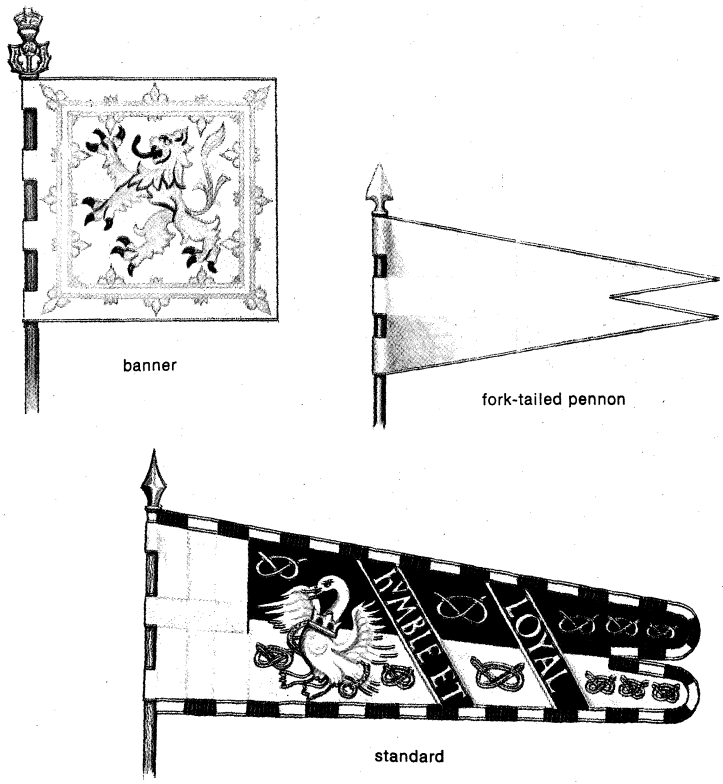
On the standard, the main colours of the arms are shown with the owner's badge.

In England flags are often seen flying above churches. When these show the flag of St. George (England's patron saint), white with a red cross, they carry in the top right-hand corner the arms of the diocese in which the church is situated. Heraldic flags also flew in countries on the Continent in a similar manner. With the disestablishment of heraldic offices in most European countries, contemporary flags are for the most part non-heraldic.

THE ELEMENTS AND GRAMMAR OF HERALDIC DESIGN

Rudiments of heraldry in about 50 terms

The general language. Provided that a few elementary principles are grasped, enough knowledge of heraldry can be acquired in a relatively short time to enable the student to understand the meaning of coats of arms. The multitude of terms used in heraldry need not worry him: once the rudiments are learned with some 50 of the terms, the meaning of the large remainder can be ascertained as the occasion arises. For example, when Queen Elizabeth II was crowned, some beautifully carved figures were made of the different badges used by her



Heraldic flags.
Banner: the blazon of the shield is applied to the whole surface of a square or a vertically or horizontally oriented rectangular flag. This is the royal banner of Scotland, which follows the blazon of the second quarter of the royal arms of the United Kingdom. Although it is the banner of the sovereign, it is widely but incorrectly used today as the national symbol. Fork-tailed pennon: shown here is that of the Sovereign Military Order of Malta; gules a cross argent. Standard: the cross of St. George at the hoist identifies this as English. The profusion of badges, the diagonally placed motto, and the border of alternating tinctures are typical. This is the standard of Sir Henry Stafford, *c.* 1475.
Drawing by Wm. A. Norman

ancestors, figures now displayed at Hampton Court Palace. They include one very rare badge—a yale. It is a mythical heraldic creature. Anyone unfamiliar with it could easily ascertain its meaning from the various heraldic glossaries. It is therefore unnecessary to burden the memory with hundreds of terms (a glossary generally contains about 800 terms).

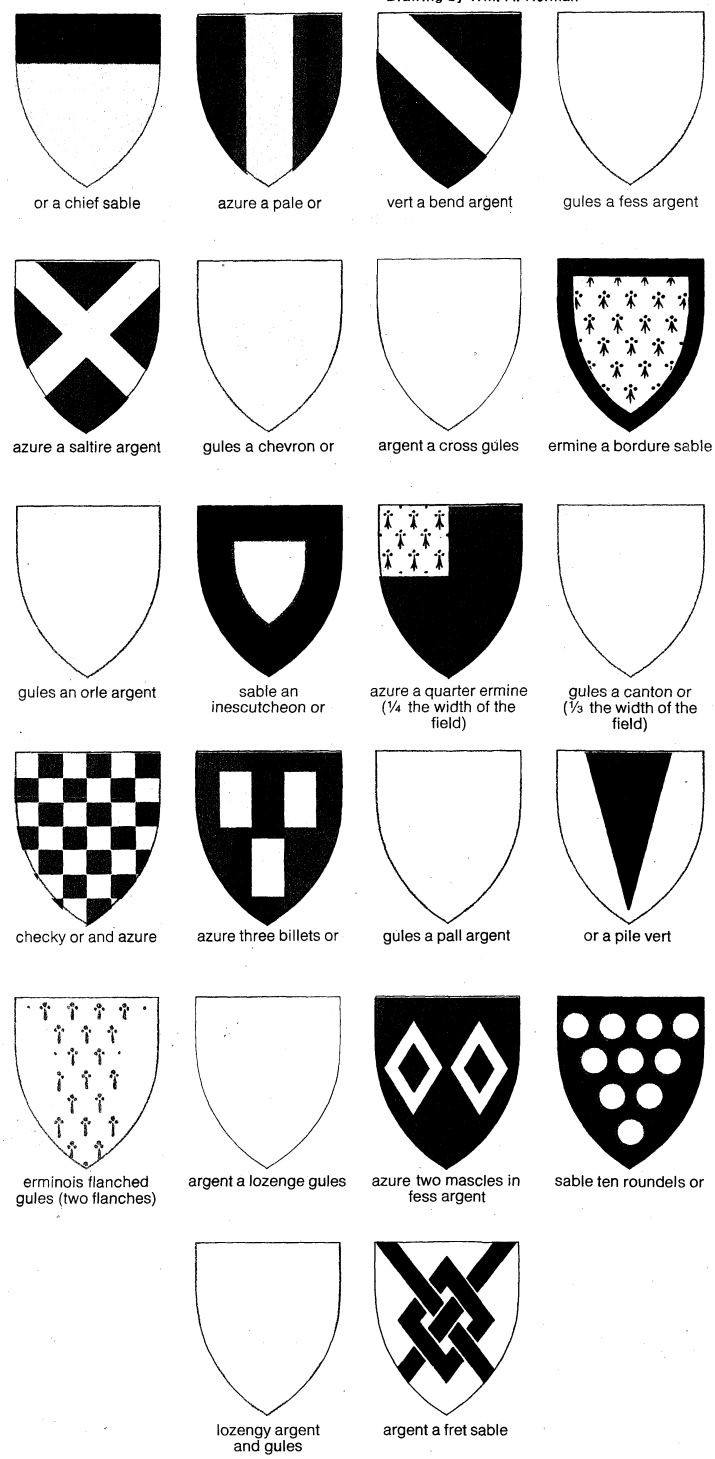
The language of heraldry has a curious look. "Azure three wheat sheaves or" has been known to call forth the question, "Or what?" When it is remembered that *or* is the French for gold, the difficulty diminishes. Much heraldic terminology is a quasi-French, archaic language. In the Middle Ages, the French language was used by the ruling class in much of western Europe, so that it was not unnatural that heraldic terms should be French. In England, by about 1400, English words usually were used in preference. Much modern heraldic terminology, however, is so obscure that it seems purposely designed to puzzle the uninitiated.

The terms dexter and sinister mean merely "right" and "left." A shield is understood to be as if held by a user whom the beholder is facing. Thus the side of the shield facing the beholder's left is the dexter or right hand, and that opposite his right, the sinister or left hand.

The field or ground of the shield. The field or ground of the shield is of one of three, and only three, kinds: a colour, a metal, or a fur. There are five main colours (known as tinctures): azure (blue); gules (red); sable (black); vert (green); and purpure (purple). In English heraldry there are also murrey (sanguine), a tint between gules and purpure, and tenné (an orange-tawny colour). The metals are or (gold) and argent (silver, which is often shown in coloured illustrations as white). The furs consist of ermine (white field with black spots); ermines (black field with white spots); erminois (gold field with black spots); pean (black field with gold spots); and vair (composed originally of pieces of fur from a species of squirrel that was blue gray on the back and white underneath, so that when several of its skins were sewn together, the result was a series of cup-shaped figures, alternately blue and white, which is the way vair is shown).

The furs —from ermine to vair

Drawing by Wm. A. Norman



Ordinaries, basic bearings that may be of any tincture and that may be combined in great variety. A combination of a cross (England) and two saltires (Scotland and Ireland) has resulted in the familiar Union Jack of the United Kingdom. Ermine and certain other textures such as ermines (black with white ermine tails) are regarded as tinctures in their own right and may bear superimposed charges. Discrete charges such as lozenges, mascles, fleurs-de-lis, etc., may be used singly, in pairs, in threes or greater numbers, sometimes in great profusion, as that of ermine tails.

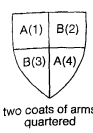
It is considered bad practice to put a colour upon a colour, a metal upon a metal, or a fur upon a fur. Many examples of such bad heraldry are found in old records, but in this as in other instances, the rules now prevalent grew up only very gradually.

The "charges" on the field. The field is said to be "charged" with an object. Heraldic objects are of an immense and growing variety; as more and more arms are devised, more and more new objects appear as charges—telescopes, aircraft, rolls of newsprint, and so on. Charges are divisible into two classes: the ordinaries (or honourable ordinaries as they are often called, deriving their name from the fact that they are so frequently used) and the others.

The ordinaries. The ordinaries comprise some 20 figures. Among them are: the chief, being a third of the shield and the top part; the pale, a third part of the shield, drawn perpendicularly; the bend, a third part of the shield, drawn from the dexter chief to sinister base; the bend, sinister, drawn from the dexter base to sinister chief; the fess, a third part and taking up the centre of the shield; and the chevron, resembling an inverted stripe in the rank badge of a noncommissioned officer. It should be noted that the bar is a diminutive of the fess, of the same shape, and can be placed in any part of the shield. The term bar sinister is often used in fiction as a synonym for bastardy. It has no such significance, bastardy being denoted heraldically in several other different ways. Since the European nations were Christian when heraldry was invented, the cross appears in many forms in heraldry. The cross in a coat of arms does not imply, however, that the original bearers were Crusaders.

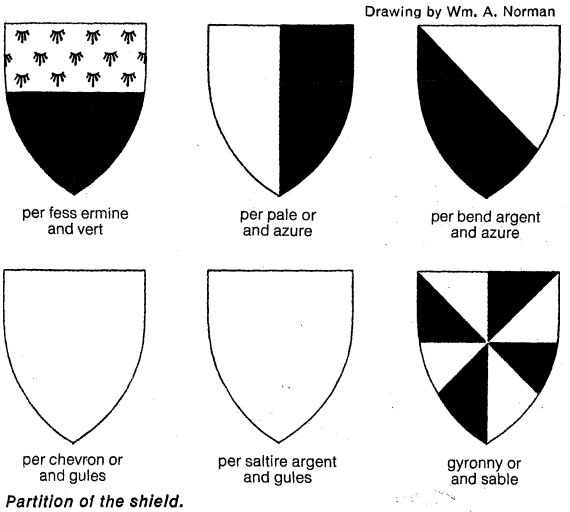
The border, or bordure, is used as a mark of difference sometimes, and in English heraldry over the last 200 years as a sign of bastardy. The orle is an inner border, not touching the ends of the shield, and in which the field is seen within and around it, giving it the appearance of a shield with the middle cut out (voided, in heraldry). The treasure, much used in Scottish heraldry, is a diminutive of the orle. The inescutcheon, a small figure shaped like a shield in the middle of the shield, is used to denote the arms of a heraldic heiress; the quarter occupies one-fourth of the shield; the canton, less than the quarter and one-third of the chief; and chequy or chequé, the field or charge divided by transverse lines horizontally or perpendicularly into equal parts. Billets are oblong figures. Should their number exceed ten, and they are irregularly placed, the field is described as *billetté;* the paile or pall is the upper half of a saltire (St. Andrew's Cross) and half a pale. The pile is in the shape of an inverted pyramid. The flanch, or flanque, is a segment of a circle drawn from a corner of the chief to the base point; the lozenge is a parallelogram having equal sides forming two acute and two obtuse angles; and a mascle is a lozenge voided; the roundel is circular in form. Lozengy is the field divided by diagonal lines transversely and the fret is a mascle interlaced with a saltire.

Minor charges. A field is said to be "powdered" or "semé" when strewn with minor charges; when charged with drops of liquid, it is "guttée." Partition lines divide the shield. The most common ones are straight. "Impalement" or "dimidiation" means the division of the shield into two equal parts by a straight line from the top to bottom. This method is used to show either the arms of husband and wife, the arms of the husband being in the dexter half, or certain types of official arms, as the arms of a bishop's see impaled with his family arms, those of the see being in the dexter half. The shield is divided into four quarters when one coat of arms is quartered with another, as when the children of a heraldic heiress (the eldest daughter of a family of no sons) use their mother's arms with their father's. (Thus in the illustration A = father's arms, B = mother's arms.)



two coats of arms quartered

Other divisions of a shield are: party per pale or simply per pale, division of the field into two equal parts by a perpendicular line (this resembles the impalement just mentioned but does not serve the same purpose of combining arms); party per fess, division into two equal parts by a horizontal line; party per bend; party per chevron; party per saltire; gyronny of eight. When the partition lines are not straight, they can be of several varieties.



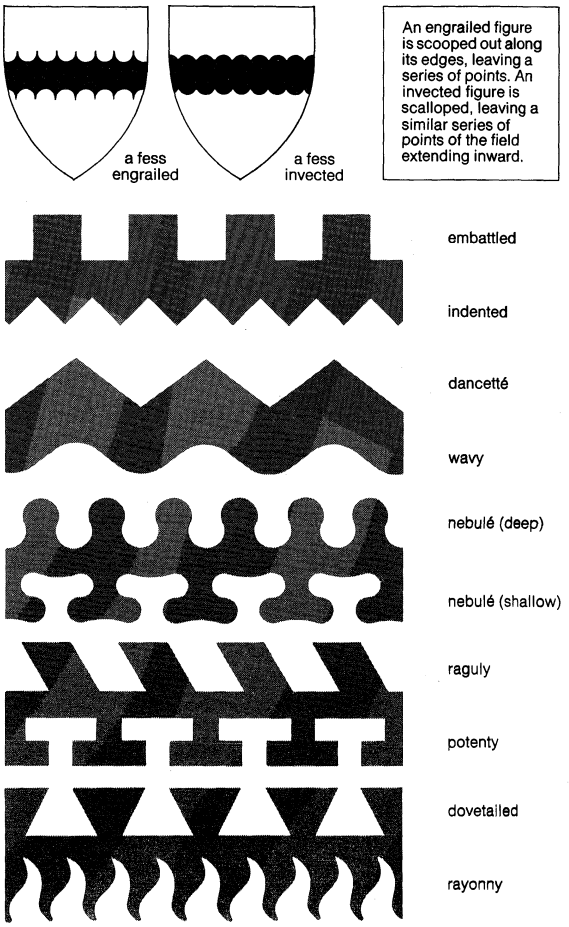
Partition of the shield.
The field is often divided along the lines occupied by ordinaries, just as quartering imitates a cross. "Per fess" means along the line over which a fess would be laid down. The ermine tails illustrated are one type of stylization among many in use. The superior dexter segment on the gyronny shield is called a gyron and is occasionally found singly.

The nature and origins of heraldic terminology. Fanciful explanations have been advanced to account for heraldic charges: for example, argent to denote purity, the bend derived from the military cross belt—the cross a sign of a crusading ancestor—and so on. Since no one wrote about heraldry until it had existed for more than 200 years, these explanations of its symbolism can be discounted. With very few exceptions, the origin of the charges is unknown. The Stourton arms ("sable a bend or between six fountains proper") refer to the six springs in the park of their ancestral estate that are the source of the river Stour. A heraldic fountain does not resemble a real fountain but is put in the form of "roundel wavy argent and azure" (a silver and blue circlet of wavy lines), unless it is expressly stated that the fountain is "proper"; *i.e.*, a natural fountain. The word proper is always used to denote a charge shown in its natural colours or natural form.

Augmentations of honour

The derivation of heraldic charges is more easily discerned in the augmentations of honour, as they are called, when something has been added to a coat of arms by the (British) crown in recognition of services rendered. The arms of the British naval hero Admiral Horatio Nelson show fresh heraldic charges added to his ancestral arms as his victories were gained. Within the past 300 years, augmentations have generally been recorded. An example is the augmentation granted by Queen Victoria to commemorate the discovery by the English explorer John Hanning Speke of the sources of the Nile. The honour, granted posthumously, consisted of the addition to the existing arms of a chief azure upon which appeared a representation of flowing water proper superinscribed with the word Nile in gold lettering. Usually, however, the origins of the various objects used in heraldry are not known. Numerous historical instances of augmentations of honour occurred in continental Europe, especially in connection with the Holy Roman emperors. Frederick II, for example, granted to Conrad Malaspina an augmentation of a chief of the empire, thereby adding an eagle displayed sable to the Malaspina arms of per fess gules and or overall a thorn branch vert with five flowers argent in pale.

Heraldic descriptions are called blazons. The term is derived from the French *blason*, the etymology of which is uncertain. Originally, it denoted the shield of arms



Types of divisions between tinctures.
A line described as flory, or flory counterflory, employs a series of small fleurs-de-lis that have substance of their own beyond the two areas being divided. Rayonny (or *rayonné*) may alternate straight points with curved points.
Drawing by Wm. A. Norman

itself and still retains this meaning, but it is now generally used in a derivative sense as meaning the description of the arms. Blazon is thus a noun, and there is also the verb to blazon; *i.e.*, to describe a coat of arms.

There are four generalizations that are useful in the deciphering of blazons. First early coats of arms are simple because they were original and there were so few of them that elaborate differentiation was not required. As time brought many more coats of arms into being, simple coats became much rarer, and the passing of warlike usage made arms much more complicated. Second, punning or canting arms are very common as, for example, trumpets for Trumpington, a spear for Shakespeare. It is notable, however, that many armorial allusions which were formerly obvious now require research for elucidation. Other allusions have been lost entirely. Third, in grants of arms to people bearing the same name but having no relationship with each other, difference marks have had to be put in. Again, in consequence, blazons have become much more complicated. Finally, in the course of centuries and frequent intermarriages among arms bearers, many quarterly and grandquarterly coats have come about. Quarterly and grandquarterly coats are much more difficult to describe than the simple coats.

Apart from the ordinaries and those other charges that have been mentioned incidentally, there are some peculiarities of heraldic charges that need to be noted. Mythical birds and animals are much used, the product of ancient and medieval natural history—or the lack of it. Such are the dragon, griffin, wyvern, harpy, phoenix, and martlet. In addition, there are some creatures bearing the names of real animals but not resembling them in all respects. The heraldic tiger is more like a lion or a wolf in some features. When the real tiger became known to heraldry, it was described as a Bengal tiger

Heraldic descriptions of animals and their postures

The heraldic description of animals is very important. Rampant means on the hindlegs, while rampant guardant is the same posture but full faced. Reguardant means looking back; passant, walking. Combattant signifies two animals fighting on hindlegs. Couchant is lying down; dormant, sleeping; and sejant, sitting. A beast of the hunt is called at gaze when looking full face, trippant when at trot, with one foot raised, and statant when standing. Parts of an animal may be a charge—a demi-lion or demiwolf, a lion's or bear's gamb or foreleg. Heads are described as erased when cut off by a jagged line, couped when cut by a straight line, and caboshed when the severed head looks straight forward. A bird shown with wings expanded is said to be displayed. Creatures placed back to back are addorsed. A fabulous bird, the phoenix, is known to heraldry, as was the legendary pelican that fed her young on her own blood and was called "in her piety," then being considered an emblem of Jesus Christ, who fed or redeemed his flock with his own blood. The martlet is another fabulous bird widely known outside heraldry, owing to John Milton's reference to the herald's martlet, which has no legs. It is a frequent charge, resembling a swallow, and is used in cadency to denote the fourth son. Other terms have special heraldic significance. Armed is used of the horns, teeth, or claws of a beast, or the beak or talons of a bird, and of the human being when in armour. The term slipped applies to flowers and fruit when the stalk is seen. Counterchanged refers to the field when it has two tinctures, a metal and a colour, and when one is the background for the other on one side of the shield and then their relationship is reversed on the other side. An example is the Warner arms: "Per bend argent and gules two bendlets between six roses all counterchanged"; where the three roses on argent will be gules and three on the gules will be argent. The field is separated by a partition line and the charge or charges of the arms are said to be countercharged when the charge or portion of a charge that lies on the metal is of the colour and vice versa.

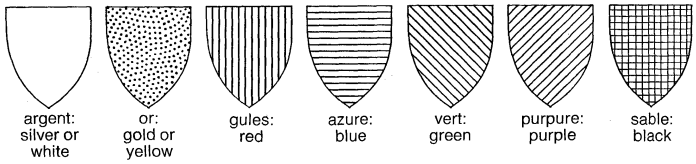
Canting, or punning, arms, derived from the literal meaning or from the sound of a name.
(Left) Shelley: sable a fess engrailed between three whelk shells or. (Centre) Wellwood: argent an oak tree growing out of a well all proper. (Right) Keyes: per chevron gules and sable, three keys or.

THE READING OF HERALDRY

The Petra-Sancta system of denoting colour by black-and-white patterns

A method has been devised to indicate heraldic colours in black-and-white illustrations. Known as the system of Sylvester Petra-Sancta, an Italian herald, it makes use of the following equivalents: or is denoted by dots or points; azure by horizontal lines; vert by lines from dexter chief to sinister base; purpure by lines from sinister chief to dexter base; argent by a plain field; gules by perpendicular lines; sable by cross lines horizontal and perpendicular. Furs are depicted with black or white spots on the appropriate ground; vair and countervair are shown by alternate lines and plain surfaces.

Describing, or blazoning, of arms must always begin with an identification of the ground of the shield, such as argent or gules or ermine. For a woman who is not married, the arms normally appear on a lozenge, not a shield, but the field or ground in this instance, too, must



Conventional representations of tinctures used by engravers and others when actual colours are not practicable.
Drawing by Wm. A. Norman

be the start of the blazon. Then come the charges. A typical blazon is thus: "sable [ground of shield] a chevron ermine between three lions rampant argent crowned or" (arms ascribed to a family of Hinstoke). The chevron is a fur; the lions are silver, appear on the sides of the chevron and its base, and have gold crowns. One important feature in heraldic writing is economy of words; technically, it should be possible to avoid punctuation marks, thus: "azure a fess between three stags trippant or" (Hird). Here both fess and stags are in gold. When three beasts are depicted, they are shown in the most convenient way around the main charge; that is to say, two in the upper part of the shield and one below. A straightforward coat with only one charge on the field is that of the Italian Segni family of Agnani, which gave to the church three popes, Innocent III, Gregory IX, and Alexander IV: gules an eagle displayed chequy sable and or. Economy, however, can be carried too far as in the following: "azure a lion rampant double queued barry of ten argent and gules armed and langued of the last crowned or, within a bordure of the second and third" (Mountbatten). Here is an example of a usage that grew up in past centuries designed to avoid repetition of the name of a tincture but in reality serving to create confusion. "Of the last" means that the lion's claws and tongue are in red or gules. "Of the second and third" means simply argent and gules. There is no real economy since more words actually are used and reference has been made to the earlier parts of the blazon. This type of blazon is used when a large amount of heraldic insignia has to be described, but it makes such long blazons unnecessarily complicated. Anyone who is writing a blazon should not use this jargon of last, first, second, and so on.

The helmet is the next item to be characterized, although in blazons it is usually taken for granted and left undescribed. When it is mentioned, it is said to be "befitting his degree." Although the helmet need not appear in written descriptions, it always should be depicted in illustrations. It is a bad feature of many drawings that the helmet is absent, showing the crest as if it were airborne above the shield and thus unsupported.

Blazoning the crest

The crest must always be mentioned when, as in the vast majority of cases, one exists. In formal blazons, the wreath (also called the torse) is given as well; thus, crest —"on a wreath of the colours, a wolf passant proper" (Trelawny). The wreath is not usually mentioned, however, because like the helmet it is always assumed to be there. The term colours refers to the two chief colours of the ground of the shield. As with the shield, the older the crest the simpler it will be. Most people can envisage on a knight's helmet the figure of a wolf walking, but it is difficult to picture someone in armour wearing as his head crest "the stern of a Spanish man-of-war on waves of the sea all proper thereon inscribed 'San Josef' with the motto above, 'Faith and Works' " (Nelson). This latter example belongs to the period of decadent heraldry in the late 18th century and 19th century in England.

The mantling, or lambrequin, is mentioned in formal descriptions but not in general usage. The supporters and compartment pertain only to a few classes of arms bearers, and in descriptions the supporters are blazoned after the crest (or crests). The compartment is not usually described but sometimes has to be, as in the arms of the earl of Perth: supporters (two savages = two ancient Caledonians) stand on "a compartment strewn with caltraps" (from "caltrops," iron instruments designed to maim horses' feet and used by the Scots with great effect at the Battle of Bannockburn, 1314).

The motto comes at the end of the description, not being part of the arms. The badge is rarely found, except among very historic families (and by a strange inversion in some 20th-century grants), but when it occurs it, too, comes at the end of the blazon. It can be very simple, as with that of Lord Mowbray, Segrave, and Stourton—"a sledge or." It may be very elaborate, as with Constantine—"a hurt [*i.e.*, a roundel in azure] charged with a leopard's face and surmounted upon the edge with two fleurs-de-lis in pale or, and as many roses in fess, argent, barbed and seeded proper." In this example the roses are silver but the leaves are proper. Coronets of rank are not usually mentioned in English or Scottish heraldry, but caps of maintenance and crest coronets must be blazoned with the crest. Banners and standards are not as a rule mentioned in blazons, though they may be when they occur in a modern grant.

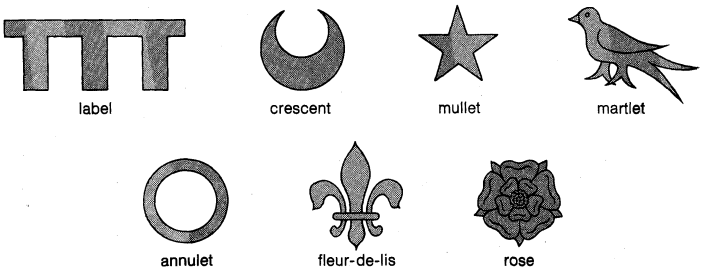
MANIPULATION OF HERALDIC DESIGN

It is clear that the vast majority of heraldic charges are without the foundation of legend often assigned to them, though in many instances the real origin of the charge is lost. A Jacobean dramatist could write of a family as old as the first virtue that merited an escutcheon—a nice poetic flourish that should remain in poetic realms. In modern grants the heralds try to give some allusion to the grantee's work and achievements and his place of origin, and canting arms still appear. Many arms are recondite, however, in their significance, and much has to be learned before the significance of the charges is known.

Cadency. The rules evolved over the centuries to denote particular distinctions in heraldry are fairly straightforward. Cadency is the use of various devices designed to show a man's position in a family, with the aforementioned basic aim of reserving the entire arms to the head of the family and to differentiate the arms of the rest, who are the cadets, or younger members. Heraldic works in the 16th century refer to cadency marks as: a label for the eldest son during his father's lifetime; a crescent for the second son; a mullet (five-pointed star) for the third; a martlet (a mythical bird), the fourth; an annulet (a small ring), the fifth; a fleur-de-lis, the sixth; a rose, the seventh; and so forth. These marks were not always used in the Middle Ages. Differences might be shown instead by a change of tincture, by adding small charges to the field, and the like. Both on the Continent and in England, rules of cadency have long ceased to be used. It is customary for

The use of devices to show position in family



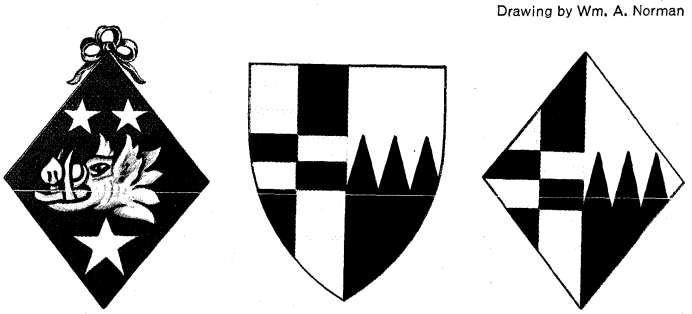
Marks of cadency, used to difference the arms of cadets of the same family. The label, the mark of the eldest male heir, is a notable feature of the arms of the prince of Wales, the heir to the throne. The second cadet displays a crescent, the third a mullet, and so on. These symbols may be of any tincture and may be used otherwise than as signs of cadency.

Drawing by Wm. A. Norman

all members of a family to use the entire arms of the head. There are, however, two exceptions. Very occasionally, a crescent is used for difference by a noble family showing descent from a second son. The other exception occurs in the arms of the British royal family, in which the cadency system exists in rigour. The reason is that the royal arms are arms of sovereignty and cannot be shared. The sovereign alone can have the whole undifferenced arms. Nor does any member of the royal family—not even the prince of Wales—have any right to the use of arms until they have been granted to him by the sovereign. A label of difference with marks is placed on the arms; a three-pronged label for the children of the sovereign, a five-pronged label for grandchildren. The Duke of Windsor after his abdication as Edward VIII in 1936 was granted arms with a label.

In Scotland the position on cadency is very different. Since heraldry is regulated in Scotland by acts of the Scots Parliament before the Union in 1707 with England, and confirmed by the British Parliament, the regulation of arms is very precise. The strict observance of cadency is probably because the Celtic clans formed the original social system in Scotland before the advent of feudalism. Thus only the chief of the name can have the entire arms. He matriculates, or enters his arms, in the registers of the Lord Lyon King of Arms (whose court has jurisdiction over armorial bearings in Scotland). This registration also applies to his eldest son (subject to suitable differencing of the arms) who inherits them in due course. The younger sons must petition for a matriculation of the paternal arms with a suitable difference indicating the position of each in the family. As families from the descendants of the original grantee continue to be established, so there is matriculation and rematriculation, in a carefully prescribed manner.

Drawing by Wm. A. Norman



Arms of women.
A woman adopts the undifferenced arms of her father. An unmarried woman: the arms of her father are displayed on a lozenge; a true lover's knot signifies unmarried status. A married woman: the wife's arms, to the sinister, impale those of the husband, to the dexter; the husband displays the combined arms as head of the family, and the wife shares his escutcheon. A widow: the woman's arms revert to the lozenge, retaining the deceased husband's impaled arms.

Arms of women. Arms of women are shown during spinsterhood or widowhood on a lozenge, not on a shield, without a crest (except in Scotland, where a woman who is chief of a clan and head of the name, such as MacLeod of MacLeod, is allowed a crest). A woman divorced and not remarried also uses a lozenge. The arms of a married woman are shown in conjunction with her husband's by impalement, the division of the shield into two equal portions, the husband's arms on the dexter and the wife's on the sinister. Should she be a heraldic heiress, the arms of her family are placed upon an inescutcheon (originally inner escutcheon) or "escutcheon of pretence" (a small shield whose position in the fess point of the huband's shield gives it precedence over all of the other parts of the shield). The only exception to these rules for women is that of a queen regnant like Elizabeth II, who, being sovereign and thus considered in heraldic terms to be herself the source of honour for all her subjects, possesses the full arms of sovereignty of her royal house and kingdom.

In the Middle Ages, arms for women were often shown on shields, and those like Joan of Arc who bore arms in battle may have used crests.

Quarterings and marshalling. In the quarterings and the marshalling arrangement of more than one coat of arms in the same shield, the position of heiresses must be considered first. The children of a heraldic heiress are entitled on her death to quarter her arms with their father's (the arrangement is to show the shield divided into four quarters so that quarters 1 and 4 are the father's arms, 2 and 3 the mother's). This positioning of the quarterings is also used in England when an additional

Picturepoin

surname and arms are taken, almost always in obedience to a will. This is the "name and arms" clause peculiar to English law. Its operation over the last 200 years is responsible for the double- or treble-barrelled surname common in England and also found in Scotland. Thus in Salusbury-Trelawny, the original Trelawny arms appear in quarters 1 and 4 and the assumed additional arms for Salusbury in 2 and 3. A famous historical case is that of King Edward III of England, who in 1340 claimed the throne of France in right of his mother, a French princess. He then quartered the lilies of France (the fleurs-de-lis) with the lions (leopards) of England. England should have been placed in 1 and 4, but Edward gave this position to France, probably because of the greater size and resources of France at that time. In this form, the royal arms continued until 1800, when the empty title of king of France was dropped and the lilies went out with it.

When quarterings are inherited from a woman, no crest

Marshalling of several coats of arms.
(Left) The arms of the Cameron-Ramsay-Fairfax-Lucy family, blazoned: arms-quarterly, 1st and 4th gules semé of cross-crosslets, three lucies hauriant argent, a canton of the last (Lucy); 2nd, grand quarter counterquartered, 1st and 4th argent. Three bars gemel sable surmounted of a lion rampant gules, armed and langed azure (Fairfax); 2nd parted per pale argent and or, an eagle displayed sable, armed beaked and membered gules (Ramsay); 3rd counter-quartered, 1st and 4th azure a branch of palm between three fleurs-de-lis or; 2nd and 3rd gules three annulets or stoned azure. In the centre of these quarters a crescent or (Montgomerie); 3rd gules, three bars or, on a bend ermine, a sphinx between the badge of the royal [Portuguese Order of the Tower and Sword] and the gold medal presented to Col. John Cameron of Fassifern by command of the Grand Signior, in testimony of that sovereign's high sense of his services in Egypt, and on a chief embattled a representation of the town of Aire in France, all proper (Cameron of Fassifern). (Right) representation of two coats of arms quartered.
Drawing by Wm. A. Norman

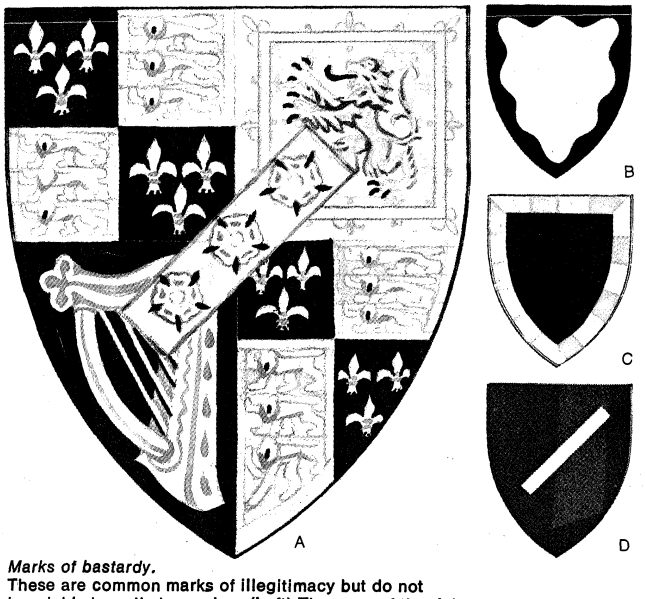
is transmitted with them, because a woman cannot pass on a crest. The matter alters, however, when additional arms are taken in obedience to a will; then a double crest is likely. There is no reason why a further assumption may not occur, so that triple or quadruple hyphenated names are found: for example, the English county family Sawbridge-Erle-Drax has quarterly arms, 1 and 4 Drax, 2 Erle, and 3 Sawbridge. This type of quartering is not difficult to follow, but real problem in marshalling several coats in one shield arises when more than one heraldic heiress occurs in the same family. Some families of long descent—like the dukes of Westminster in England—have often married heraldic heiresses and thus acquired many quarterings. Sometimes several hundred quarterings are attributed to the head of a great family. A splendid instance of quartering occurred in the achievement of the empress Maria Theresa. Before her accession to the imperial throne she was queen of Hungary and Bohemia and by marriage grand duchess of Tuscany. As a sovereign in her own right she bore a shield on which there were 29 quarterings. The dukes of Rohan-Chabot in France bore a quartered shield with Navarre, Scotland, Brittany, and Flanders; overall was an escutcheon of Rohan quartering Chabot.

Problem of marshalling several coats in one shield

Even without such large numbers of arms to deal with, the marshalling of quarterings is still a problem. Various methods have been tried, often with results as difficult to decipher. An interesting illustration of the marshalling of several coats of arms is that of the baronet Cameron-Ramsay-Fairfax-Lucy. The arms are said to be quarterly with the arms of Lucy in 1 and 4. Then in 2, the description runs, grand quarter counterquartered. This means that quarter 2 is itself a quarterly coat, 1 and 4 of which are for Fairfax, 2 for Ramsay, with the third quarter counterquartered; *i.e.*, itself quartered, showing two coats of arms. The third quarter is that for Cameron.

Arms of bastardy. The heraldic illustration of bastardy was achieved in several ways in the older days of chivalry. Little social or moral obloquy attended the status of bastardy, possibly because of the late marriages of the upper classes and their arranged unions. Thus the arms of a bastard were merely differentiated as perhaps those of a distant cadet line would be. From early times the bend or bendlet sinister was used. The erroneous use of bar sinister might have come about because the French for bend sinister was *une barre*. In the arms of British royal bastards like the dukes of St. Albans, of

Drawing by Wm. A. Norman



Marks of bastardy.
These are common marks of illegitimacy but do not invariably have that meaning. (Left) The arms of the duke of St. Albans debruised by a baton sinister, in this case charged with three roses. (Right, top) The bordure wavy (or a bordure wavy sable). (Centre) The bordure compony (vert a bordure compony argent and gules). (Bottom) The baton sinister (purpure a baton sinister argent).

Buccleuch, of Grafton, and others, a baton sinister is used to denote bastardy. The royal arms of these illegitimate scions are said to be "debruised" (crossed or partly covered) by the baton sinister. English heralds in the last 150 years have often signified bastardy by the use of the bordure.

Nonfamilial heraldry. The arms of other than families or individuals will often be encountered, especially in modern times when the granting of arms to private persons has ceased in some countries but where grants of corporate arms are frequent. Such is the case in Sweden, where grant of neither title nor arms occurs, but where grant of arms to public bodies, such as local administrative units, is frequent. Historically, it was an easy passage from the arms of individuals to those of personifications. This is particularly evident in the military sphere, where the great crusading orders led to the many important orders of chivalry in the principal European countries. The Elephant of Denmark, the Golden Fleece of Spain and of Austria, the Holy Spirit of France, the Garter of England, and the Thistle of Scotland, were all preceded by the orders of military monks, and all have insignia that contain heraldic features and that occur in many arms illustrations. Most of the older bishops' sees have official arms; in the Anglican Church, the diocesan bishops as well as the missionary bishops have arms. In the Roman Catholic Church, the episcopal sees all have arms; and new arms are granted by the pope, who, as head of the Vatican state, is a temporal sovereign as well as spiritual head of the Church. The arms of the popes often contain charges that are added to their individual arms after their election to the papacy or to earlier ecclesiastical office.

The military orders of chivalry

Dominion and colonial arms are necessarily interconnected with royal arms, since the British crown in each country is or was the source of honour and must have granted arms to its various territories. Because of the vast extent of the former British Empire, the richest collection of arms of dominion is to be found in the numerous members of the Commonwealth. Canada, for instance, has arms for the sovereign of Canada as authorized by George V in 1921, and the 12 provinces of Canada have similar arms approved by the sovereign. Much the same is true of the former French colonies, though there was no sovereign to grant the arms. The arms of political units are used throughout the Western world. The cities and boroughs of the United Kingdom, for example, have their heraldry, as do the states of America.

Drawing by Wm. A. Norman

The arms of Canada, derived from the royal arms. The three maple leaves in the base, originally green, were altered to red to conform to the new national flag adopted in 1964. French traditions and ties are represented by the gold fleurs-de-lis and the white lilies in the compartment.

The blazoning of these nonfamilial arms is conducted on the same principles as for family arms, except that the explanation of the charges is usually forthcoming.

II. Historical development of heraldry

The exact date or place of origin of the heraldic system in western Europe in the 12th century is not known; neither are the precise reasons for its first employment. But limits can be drawn to indicate generally when heraldry began, and probable reasons for its emergence can be deduced. In the Bayeux Tapestry (in Bayeux, France), produced in the last quarter of the 11th century, is to be found a pictorial record that shows conditions in everyday life and in warfare at the time of the Norman Conquest of England. The English and Norman soldiers are armed alike. None of the Englishmen has a design of any kind on his shield or armour. In a few scenes, Normans or Frenchmen have designs on their shields that have a rough heraldic resemblance. In scene VIII of the tapestry, four of the followers of Guy, count of Ponthieu, have shields with these devices: some kind of creature holding what appears to be a fish in its mouth, a rough design emerging from the left side of the shield, a cross, and an animal rather like a sheep. In scene XII the messenger of William the Conqueror bears a winged creature on his shield, and this reappears in scenes XIII and XV. In scene XVIII a cross or a variant of it is seen on a shield, but probably as a boss (metal protuberance) to strengthen it. Scene LXXV has a Norman knight with a design of a birdlike creature on the shield, but generally the Normans shields have only bosses in the middle.

Bayeux Tapestry and its record of shields

In 1066, at the time of the Conquest, heraldry clearly did not exist. The most that can be said is that possibly some of the rudiments out of which it emerged were then present. Even a generation later, in 1095–99 at the time of the First Crusade, there is evidence that heraldry was not yet in use. *The Alexiad*, the history of the Emperor Alexius (reigned 1081–1118) written by his daughter, the princess Anna Comnena, contains a vivid description of the Frankish barbarians—as the Crusaders appeared in the eyes of the civilized Byzantines. The Princess gave a very careful account of the Crusaders' armour. She said that Alexius exhorted his archers to shoot at the Franks' horses rather than their riders because their armour rendered them practically invulnerable. "For the Frankish weapon of defence is this coat of mail, ring plaited into ring, and the iron fabric is such excellent iron that it repels arrows and keeps the wearer's skin unhurt. An additional weapon of defence is a shield which is not round, but a long shield, very broad at the top and running out to a point, hollowed out slightly inside, but externally smooth and gleaming with a brilliant boss of molten brass." In her description, therefore, are the same shields as depicted in the Bayeux Tapestry. Thus, all the pictures from later times of King Alfred the Great, William the Conqueror, or Charlemagne bearing coat armour can be disregarded as anachronisms.

EARLY ROOTS OF HERALDRY

It is not until a generation after the First Crusade that unmistakable evidence of heraldic designs appears. The earliest evidence is in an enamel (Musée de Tessé, Le Mans, France) made not later than 1151 showing Geoffrey, count of Anjou, bearing a shield azure with possibly four rampant golden lions (the exact number is not discernible because of the position in which the shield was depicted). The count was the son-in-law of King Henry I of England (reigned 1100–35), and, according to a chronicle, Henry in knighting Geoffrey bestowed upon him a shield that bore painted lions. In addition, from 1136 heraldic devices appear on seals. It is possible that the insignia were first used on seals and then spread to the shields of the warriors. Simultaneously, body armour was becoming all enveloping, and some means of distinguishing men in full armour became necessary. The heavy barrel-type helmet closed in the face of the wearer except for the opening of his visor, and a mix-

The first unmistakable evidence of heraldic designs

Giraudon

ture of plate and ring mail enclosed the whole body. Yet another factor was the influence of the Crusades, in which men from a dozen different lands had to be distinguished from one another.

Whatever the reasons for its origin, heraldry within a few years was found throughout all of western Christendom. The first English king to bear arms was the crusader, Richard I the Lion-Heart (1157–99). The three gold leopards or lions of England have been used by every dynasty since his time.

Seals. The earliest body of evidence of heraldic insignia is found in seals, large numbers of which have been preserved in England, France, and Germany, with fewer surviving in Spain and Italy. For the first century of heraldry, indeed, seals supply the bulk of information. It is, for instance, from seals that the rise and development of the English royal arms can be traced. In the first years of his reign, Richard I's seals show the design of a lion rampant to the left side. Some think that two lions were used since only half of the shield can be seen. At the end of his life, Richard's seals indicate clearly the rise of the three lions or leopards used by all sovereigns since. The adoption of the same coat of arms by subsequent dynasties is also found in the royal arms of Sweden and of Denmark; but unlike the English, those royal families place their family arms on an inescutcheon in the middle of the shield.

Roll of arms. Next to seals as evidence of heraldic usage come the rolls of arms, which in England date from about 1250. These are lists of arms, often with pictures drawn ("tricked") on the rolls, of persons who were present on a particular occasion, such as at a tournament or on a military expedition. England and Belgium (Flanders) are rich in the rolls of arms. France, Spain, and Scotland have fewer surviving examples. In place of the rolls, collections of painted books of arms have been preserved in Germany. A notable roll is the *Armorial de Berry*, dating about 1445, the work of a French herald, Gilles le Bouvier, who travelled widely and recorded arms borne in France, England, Scotland, Germany, Italy, and other European countries.

The *Armorial*

Records in stone and glass. Another very important source of information is to be found in representations on stone, wood, glass, and in books and engravings. Over the gateway of Bodiam Castle in Sussex can be seen the arms cut in stone of three owners of the castle, the families of Bodiam (who took their name from the place), Wardedieux, and Dalyngrygge. Of such arms nothing would be known without these centuries-old memorials. In Rome, many examples occur of the arms of various popes in their palaces and other buildings, for instance the bees of the Barbarini pope Urban VIII in the Palazzo Venezia. Heraldic glass is usually much more recent in origin but of immense value in supplying information as it is always in colour, while other memorials often are not. Very few churches of any great age in western Europe are without armorial illustration. Switzerland in particular has splendid memorials in stained glass; for example, the Dom, or main Protestant church in Berne, has windows that are aflame with glorious heraldic colours. Sweden has a fine collection of coloured plaques of arms in the House of Nobles in Stockholm; Denmark in the Castle of Fredericksburg houses the shields of the Knights of the Order of the Elephant, in which can be read the history of heraldry over several centuries.

Church brasses. Brasses in churches are an important source of heraldic information. It was formerly the custom to put a brass tablet over the grave slab, and on this would be shown a figure of the deceased with his armorial bearings. Many fine examples of this are found in old English churches. A very fine collection of floor brasses is in the small church of Stopham in Sussex, which has been the memorial place of the local Barttellot family for many centuries. Also found in churches are hatchments, heraldic paintings on wood that were made for deceased persons and hung over their house doors, being later set up in the local church where they have often been preserved.

As for written material—such as official enactments, grants of arms, and books—nothing is dated earlier than the 14th century.

GROWTH OF HERALDRY AFTER THE 13TH CENTURY

The heralds. The initial meaning of the term herald is uncertain. Some authorities derive the word from two German words—*Heer*, "a host," and *Held*, "a champion" —not a very obvious etymology. It is clear that heralds were in existence from the 13th century, if not earlier. In their beginnings they were more or less menials, ranked with the jugglers and the minstrels, dependent on the great lords. First used as messengers who wore livery, they later were used in the jousts and tourneys to announce the contenders. To identify the knights, they had to know the arms on the shields, and from this grew their knowledge and skill in the art of heraldry.

Messengers and aides at jousts and tourneys

Heraldic colleges and offices. From this lowly origin have come the colourful figures of the English College of Arms, who now alone, save for the Scottish heralds, possess a high position in the modern world. The Lord Lyon, the head of the Scottish heralds, derives his office from a much higher source than do the heralds in other parts of Europe. The Sennachie, or official bard of the Scots' king, was the record keeper of the old Celtic kingdom of Scotland, and from the Sennachie is derived the Lord Lyon, a great officer of state in Scotland.

The older statements found in many books that the medieval heralds were either identical, or in some way connected, with the old Greek *kēryx* or Latin *fetialis* need only be stated to be dismissed. Since ancient times men have been found who, because their persons were accepted as sacred, were able to carry messages and other communications between nations either hostile or strange to one another. These ambassadors bore several names before the development of a diplomatic corps. In the earlier Middle Ages, for instance, churchmen, monks, or priests were used for this type of service. When William I the Conqueror sent a messenger to Harold II of England, it was a monk who carried William's denunciation of Harold. Heralds were not then in existence.

As they ascended the social scale, heralds began to serve as ambassadors between the different courts, a function that was still theirs in the first half of the 17th century. In 1627, for example, Sir Henry St. George was joined in a commission with Lord Spencer and Peter Young to present the insignia of the Order of the Garter to Gustavus II Adolphus, king of Sweden, who then knighted Sir Henry and granted him an augmentation to his arms showing the royal arms of Sweden.

At first every great noble had his herald, and the royal heralds were distinguished from the others by the greater importance of their masters. Gradually, it came about

The herald in the illuminated initial wears a tabard that bears the king's arms front, back, and repeated on the sleeves, and a coronet as a mark of royal authority. In the collection of the Worshipful Company of Tallow Chandlers, London.

that a king would form his heralds into a college or corporation. The King of France did so in 1407; it was not until 1484 that the King of England followed by establishing the College of Arms, which has been housed for 300 years in the same building in London. The English College, sometimes called the Heralds' College, has outlived all similar elaborate establishments in Europe, except that in Scotland. Outside Great Britain, heraldic offices are found in the 20th century in Sweden, Denmark, the Republic of Ireland, and Spain.

The English College

The English College is under the control of the earl marshal, an office that has been hereditary for the past 300 years in the family of the duke of Norfolk. The holder of the dukedom is always earl marshal. Under him are 13 officers of arms; three kings of arms (Garter, Norroy and Ulster, and Clarenceux); six heralds (Windsor, Richmond, York, Lancaster, Chester, and Somerset); and four pursuivants (Rouge Dragon, Rouge Croix, Bluemantle, and Portcullis). These medieval names are derived from sources connected with royalty, titles, badges, or orders of knighthood. Pursuivants are "followers," or junior heralds. In Scotland the Lord Lyon is the head of the heraldic officers, of whom there are three heralds (Albany, Marchmont, and Rothesay) and four pursuivants (Carrick, Kintyre, Unicorn, and Ormond). In England and Scotland, the officers are not civil servants but members of the queen's household. In both countries there are also heralds extraordinary, who are appointed at times for special reasons or functions.

Heraldic visitations from 1530 to 1686

Records and grants. In England an important development came with the Heraldic Visitations. From 1530 in the reign of Henry VIII to 1686 in the reign of James II, commissions were issued by the sovereign to the heralds directing them to proceed to a county in England or Wales and to inspect the arms in use there. The records of the Visitations have been preserved and constitute a valuable body of genealogy as well as of heraldry. From the period of the Visitations the heralds built up huge collections of family history and began to record pedigrees in their registers.

From about a half century before the foundation of the College of Arms, the English heralds are found to be issuing grants of arms on behalf of the sovereign. This is some 300 years after the first appearance of heraldry, which obviously much antedated not only royal colleges or corporations of heralds but even the existence of heralds themselves. From this evidence, it seems clear that in the early days of heraldry men assumed arms to suit themselves without reference to any authority. A very simple coat of arms would not be difficult to invent. That three unrelated persons from three different counties could bear these same arms is not only not surprising but proof that the arms were self-chosen. When disputes over ownership among the three came up, the matter was referred to the king. His judgment was final, but it is noteworthy that one of the defeated, compelled to give up his arms, then consoled himself with a new coat that was also self-derived and -assumed. Unquestionably, the great majority of ancient coats of arms, borne before 1500, were never granted but were taken by the owners.

Writers on heraldry. The earliest writing on heraldry extant is a short treatise by Bartolo da Sassoferrato, whose *Tractatus de insigniis et armis* ("Tract on Insignia and Arms") was published about 1356. In his small book Bartolo describes the various categories of arms bearing and how they have been assumed. He refers specifically to arms granted by a prince and gives reasons for their value but asks why one man may not bear arms identical with those of another.

In 1355 Bartolo had been sent to Pisa from Perugia as an envoy to the Holy Roman emperor, Charles IV, from whom he received many privileges, including a grant of arms, which were the same as those of the Emperor as king of Bohemia but with changed tincture: "or a lion rampant with two tails gules." An American scholar, L.M. Mladen, remarked of this grant and others made by Charles IV at the same time: "Charles was in all probability the first ruler ever to grant arms. To my knowledge, no earlier occurrence has been found."

The first English heraldic writer was John of Guildford, or Johannes de Bado Aureo, whose *Tractatus de Armis* ("Tract on Arms") was produced about 1394. Then came a Welsh treatise, the *Llyfr Arfau* ("Book of Arms"). Nicholas Upton, a canon of Salisbury Cathedral, about 1440 wrote *De Studio Militari* ("On Military Studies"). John of Guildford's treatise was printed in 1654 with Upton's work and the *Aspilogia* of Sir Henry Spelman by Sir Edward Bysshe, Garter king of arms, who edited and annotated all three works. The whole was in Latin; no complete English version of Upton's book has been published.

These books are by authorities who were concerned with the realities of heraldry in their own day. A tendency away from actuality and toward the fanciful and absurd manifested itself from the end of the 15th century. Some of these farfetched conceits showed themselves in *The Boke of St. Albans* (1486). Yet by comparison with the vast mass of nonsense contained in the folios of the 16th century, those conceits were reasonable. The works of Sir John Ferne, *Blazon of Gentrie* (1586), Gerard Legh, *The Accedens of Armorie* (1562), and John Guillim, *A Display of Heraldrie* (1610) not only perpetuate the nonsensical natural history of olden days but are largely responsible for the belief that heraldic charges have a definite symbolic meaning and that they were granted as the reward of valorous deeds.

The trend to the nonsensical after the 15th century

Continental versus British heraldry. Much greater significance was attached in former times to heraldic insignia, though the attitude varied from country to country. Heraldry has become more widespread than at any other time, but as a sign of rank it has hardly any remaining value.

A distinction can be made between the Continent and Great Britain regarding medieval and later heraldry. The doctrine of the Seize Quartiers (16 quarterings) prevailed over most of the Continent but not in Britain. This theory required that all of a person's 16 ancestors (16 great-great-grandparents) should have been entitled to bear arms. This is known as the "Proof of the Seize Quartiers" and was the reason why Frederick II the Great of Prussia, though professing the views of the Enlightenment in the Age of Reason, diligently scrutinized his courtiers' quarterings. The theory is based on the rigidity of a noble caste that married only with its own kind. On the Continent, every member of a noble family is noble; hence the enormous numbers of titles. Similarly, the continental royalty tended to marry only with other royal families. As a result both royal and noble families formed a class apart from the bulk of the people.

Seize Quartiers

Continental heraldic insignia, therefore, from their origins until the late 18th century, provided symbols to indicate a higher caste and, in fact, were signs of nobility. Yet, strangely, in several countries heraldry was in wide general use as a means of identification, serving in the same way as a surname. In France, for example, it is abundantly clear that from the 13th century, not only the bourgeoisie of the towns but also the peasants bore heraldic arms. The usage had percolated down from the noble class. The earliest example of the use of arms by a peasant is that of Jaquier le Brebiet in 1369, whose arms show a punning allusion to his name (*brebis*, "sheep"—three sheep held by a girl). In other European lands—Hungary and the Low Countries—burgher or peasant arms were also found, but neither in these lands nor in France were the possessors regarded as noble.

Peasant and bourgeois arms

In France the regulations of arms followed a quite different course from those in England. Although King Charles VI had in 1407 led the way in creating a college of arms, his heralds lost influence over the next two centuries. They had no power, unlike their Scottish and English counterparts, to grant arms and they gradually faded into insignificance. To overcome the loss, Louis XIII in 1615 appointed a *juge général d'armes* ("general judge of arms"), an official whose powers resembled those of the Lord Lyon. The French royal government showed itself very broad-minded on the possession of arms. A decree of Louis XIV in 1696, designed to raise money, ordered all persons who bore arms to register

them. Even those who were not part of the arms-bearing population were forced to buy arms. Later, in 1760, an ordinance was framed by which the lesser townsfolk, artisans, and peasants were to be excluded from the use of arms—after these classes had used them for 400 years. But the Parlement of Paris refused to allow the ordinance to be implemented. Later, during the French Revolution (1789), arms were suppressed as signs of feudalism.

The view of arms held in England was and is quite different. No such thing as a noble caste has ever existed in England. Only the reigning peer and his wife are regarded as noble; the rest of the family are commoners, and only a few of them bear what are called courtesy titles. Moreover, except for the Hanoverian (1714–1837) and Victorian (1837–1901) epochs, the royal house has not necessarily married royalty but much more often the nobility, a practice to which it has returned in the present century. As a result, the Continental doctrine of Seize Quartiers does not apply in England. It cannot, since noble and non-noble are so mixed. Nor are there any such things as non-noble arms. All arms are on the same basis; all are signs of gentility—nobility, in fact. Arms then have long had a high social significance in England; those who possess them have social prestige. The situation is somewhat different in Scotland where arms are bound up with clanship and family solidarity. To the Scotsman arms are not so much a matter of social status as of family or clan, and he proves his right to them by process of law in Lyon Court.

A matter of clan and family in Scotland

TWENTIETH-CENTURY HERALDRY

The survival of the heraldic tradition. *France and Italy.* Without a monarchy, heraldry can still flourish, but it does not normally do so. The French Revolution abolished arms, which returned with the monarchy, and now, although France is a republic, a person assuming arms to which he is not entitled may be prosecuted. In the same way, it is not permissible to assume a name of a great family. In England, however, the assumption of the name Windsor (the name of the British royal family) is possible for anyone. There is, however, no recognized heraldic authority in France, nor for that matter in other European countries that have abolished their monarchies. Most such republican states have associations that seek to maintain heraldic standards. Thus in Italy the Collegio Araldico (Heraldic College) consists of experts whose main object is to promote heraldic and genealogical studies. An association of nobles was formed as the National Heraldic Council of the Italian nobility, under the authority of former king Umberto II; it tries to regulate the use of arms and titles.

Many changes in heraldry have taken place since 1945, as it is not a static subject.

Communist countries. In Communist European countries, the study of genealogy and heraldry has been generally suppressed. Since about 1956 it has been possible to obtain much more statistical information from the U.S.S.R. than formerly, but no heraldic data are supplied. Much the same is true of the other Communist countries in Europe, except Czechoslovakia. In Communist lands, heraldry is viewed as it was by the French revolutionaries, as part of the feudal past, although there is reason to believe that in these countries heraldic archives are carefully preserved.

Ireland. A different development occurred in two of the republics that have emerged from the British Empire —Ireland and South Africa—both of which have set up their own heraldic offices. As early as 1382, there was an Ireland King of Arms who was responsible for all matters armorial in that country. The last holder of the office died in 1487, and in 1553 Edward VI created a new armorial king under the title of Ulster, to control bearings throughout Ireland. His place of business was in Dublin Castle. When the Irish Free State, or Eire (now the Republic of Ireland), was established in 1921–22, the Ulster Office was reserved as an appointment of the British crown with the then-current Ulster to hold office for life. After his death in 1940, an arrangement was made between the British and Irish governments by which the heraldic office in Dublin Castle with its records was taken over by the Irish authorities. Photostat copies were made of the records and sent to the College of Arms, London. The Irish government appointed a Chief Herald of Ireland, and the Ulster Office became known as the Genealogical Office. A civil servant was then appointed as Chief Herald of Ireland. The office of Ulster King has now been united with that of Norroy King in the College of Arms, London. The Irish Herald carries out the duties formerly performed by Ulster in the 26 counties of the Republic of Ireland; Norroy and Ulster has jurisdiction over the six counties of Northern Ireland (Ulster).

Chief Herald of Ireland

South Africa. In South Africa an act was passed in 1962 under which was established a Bureau of Heraldry and a Heraldry Council for the grants, registration, and protection of coats of arms, badges, and other emblems. A state herald is appointed as head of the Bureau of Heraldry. The Heraldry Council consists of the state herald and at least seven other members appointed by the government minister responsible.

The United States. There has been a remarkable evolution of heraldry in the United States. Ever since the American Revolution, the use of arms, especially of arms of English families with whom the users were related or whose surname they bore, has continued. The English College of Arms claims heraldic jurisdiction over persons of English and Welsh descent (Wales has been reckoned with England in this and all other administrative matters since the union of England and Wales, 1542). The Lord Lyon of Scotland claims jurisdiction likewise over persons of Scottish descent throughout the world. In addition, the English College at one time claimed a worldwide imperial jurisdiction over anyone who could be brought within the definition of British subject. Under this jurisdiction even the Indian princes were occasionally granted arms by the College of Arms, although they were not British subjects but independent rulers who had entered into treaty relations with the British crown. Many Americans have been granted arms by the college by virtue of their descent from English or Welsh forebears, or by the Lord Lyon if they are of Scottish descent. Irish Americans often were granted arms from Dublin, either from the Ulster King or his successor. Americans of Northern Irish descent have been granted arms by Norroy and Ulster. In addition, there are several states of the United States that were formerly Spanish territory, and the Spanish Kings of Arms, the equivalent of the English and Scottish heralds, exercised a heraldic authority over persons of Spanish descent in the old Spanish Empire. By extension, they have recently granted arms to Americans who are resident in those formerly Spanish states but who are not of Spanish descent.

Heraldry in states from the old Spanish Empire

To these classes of arms obtained by Americans from overseas must be added such instances as the award of arms to Pres. Dwight D. Eisenhower in Denmark. Also, Americans of French, German, Italian, Polish, and other European origins have inherited from their immigrant ancestors arms once granted or recorded by heraldic authorities no longer in existence. All these classes of arms share one feature whatever their origin: they are hereditary honours granted to American citizens by other countries. As they do not carry titles, they do not contravene the principle of the American Constitution on this subject. An American who receives a knighthood of some foreign state possesses only an honorary knighthood; he is not "Sir." But for the citizen of an independent sovereign power to approach and receive from another power a hereditary honour has seemed to many Americans an undesirable procedure. There have been and still are thousands of assumptions of arms by Americans on consideration of mere mail-order salesmanship; arms in these transactions are, at the best, supposed to be those "of the name" (that is, belonging to a name rather than a person), a view for which no justification exists.

Endeavours have been made to set up American authorities who would not only record but also grant arms. The New England Historic Genealogical Society of Boston appointed a Committee on Heraldry that since 1928 has issued rolls of arms, in which have been entered the

names and arms of those who have submitted their claims to its judgment. The use of this method of issuing or publicizing arms recalls the usage referred to above, which has not been practiced in Europe for the past 400 years. In the introduction to the second roll (1932) it is stated: "There is certainly no legal reason, perhaps no reason at all, why an American gentleman should not assume *in more majorum* any new coat that pleases his fancy, but he should not assume an old coat, for if he does, he is very likely denying his own forefathers and he surely is affirming what he has no sufficient reason to be true." Not only have British-derived arms been registered but also continental European arms. In addition, the committee has assisted inquirers in devising new coats of arms, not only for schools, colleges, and other bodies, but also for individuals. In the introduction to the first roll a very reasonable view toward heraldry was expressed: "Taking into consideration the early history of coat armour there seems to be no reason in this country at least, why anyone provided he observes the simple rules of blazon and does not appropriate the arms of another, may not assume and use any coat he desires." The American College of Heraldry and Arms, Inc., was established in the state of Maryland in 1966. It has two divisions: The American College of Arms, which is concerned with the arms of individuals, their registration, and more important, the granting of arms; and the College of Arms of the United States, which deals with arms, crests, standards, devices, and the like for all manner of corporate concerns. Arms were granted by the college to Pres. Lyndon B. Johnson during his term of office, to Pres. Richard M. Nixon, and to Vice Pres. Spiro T. Agnew.

Revival of England's ancient Court of Chivalry

England. Heraldic development has also occurred in England, where in 1954 the ancient Court of Chivalry was revived. This was once the court of the lord high constable and of the earl marshal, and it dealt with matters relating to knights and gentlemen. Although it was concerned also with matters of military discipline, it was not the forerunner of the modern court-martial in the armed forces. The court gradually declined in the 17th and 18th centuries and had not sat from 1735 until its revival.

The office of lord high constable has long ceased to be hereditary or of permanent status in England. During coronations, however, a constable is appointed for the occasion. Therefore, in the revived court that sat in 1954 to deal with a test case, the *Manchester Corporation* v. the *Manchester Palace of Varieties*, the earl marshal (the duke of Norfolk) presided with a surrogate, who was the lord chief justice of England appearing in his capacity of a doctor of civil law. As a result of the sitting, the jurisdiction of the court was confirmed, and the City of London recorded its crest and supporters.

The unorganized condition of heraldry in many European states has spurred private attempts to bring some order into the field. The movement known as the International Congresses of Heraldry and Genealogy began in 1928 with a meeting in Barcelona, Spain. A second Congress was held in Rome and Naples in 1953, and from that time regular meetings occurred at two- or three-year intervals. Out of these was established an international organization, El Instituto Internacional de Genealogia y Heraldica (The International Institute of Genealogy and Heraldry), with its office in Madrid.

Uses of heraldry for study and verification. The incidental uses of heraldry, apart from its general significance in providing distinguished symbols, are considerable. Heraldry illustrates much in history and literature that is otherwise obscure. Heraldry on buildings, in manuscripts, and in paintings is of immense value for purposes of identification. It serves to link one person with another, to connect families, and to disclose origins of states and of institutions. With the use of heraldry in connection with genealogy, from which it cannot easily be separated, much that is difficult to follow becomes easy to interpret. In every building that contains armorial engravings, or other pictures of arms, there is in fact a concise history of the place, which enables the onlooker who understands the subject to have a useful clue to the background and details of the building.

In law, the place of heraldry is sometimes, as in modern Scotland, very precise; in England, on the other hand, it is most involved. To understand the latter is to gain an insight into the development of English law. Similarity of arms does not always indicate identity of family. Identity of arms may denote merely assumption of devices. Because of the English laws of inheritance, not only an estate but a surname and arms can pass by eventual succession to persons unconnected by blood with the original owner. Thus in the families of Lytton, Carew, and branches of Trelawny, instances occur in which possession of the name and arms is no proof, but the contrary, of blood relationship. Sometimes, however, identity of a name with a puzzling discrepancy in the arms can only be explained by a study of the family's heraldry.

BIBLIOGRAPHY. There are large numbers of guides to heraldry, the majority of a sameness that makes them apparently derived from an old original. Among the most useful for the beginner are: A.C. FOX-DAVIES, *Heraldry Explained* (1906, reprinted 1971), a small, well-illustrated book, written by the clearest expositor of heraldry as practiced today; CHARLES MACKINNON, *The Observer's Book of Heraldry* (1966), a very useful and clearly written work; and SIR ANTHONY R. WAGNER, *Heraldry in England* (1946, reprinted many times), a very brief account but with 15 plates in colour. L.G. PINE, *Teach Yourself Heraldry*, new ed. (1972), is designed for the beginner and has a glossary of terms. Also very good for the beginner is J.R. PLANCHE, *The Pursuivant of Arms or Heraldry Founded upon Facts* (1852).

More specialized works include an English translation of the *Armorial de Berry*, originally written *c.* 1445, which can be found in the *Proceedings of the Society of Antiquaries of Scotland*, 72:84–114 (1938); A.C. FOX-DAVIES, *A Complete Guide to Heraldry* (1909, revised and reprinted many times), a very helpful guide to anyone concerned with blazons either drawn or written (with nearly 800 illustrations); and *Armorial Families: A Directory of Gentlemen of Coat Armour*, 2 vol. (1929–30, reprinted 1970), a rich store of coloured and black-and-white illustrations, which gives the student the opportunity to practice and to observe blazons. The writings of OSWALD BARRON should be read as a correction to some of Fox-Davies' theories on heraldic history. Barron's works contain much fascinating heraldic lore, delightfully set out, learned yet not abstruse. Some of his best work may be found in the 12 volumes of *The Ancestor* which he edited in 1902–05. This series also includes many informative articles by writers of the calibre of J.H. ROUND and SIR HENRY MAXWELL-LYTE. Two volumes now reprinted in one constitute *A Treatise on Heraldry: British and Foreign* by JOHN WOODWARD and GEORGE BURNETT (1892, reprinted 1969), which contains some inaccuracies because the authors were not able to check all instances of heraldic descriptions sent to them. It is, however, most rewarding to the student, beautifully illustrated, with examples of practices drawn from all over Europe. SIR THOMAS INNES, *Scots Heraldry*, 2nd ed. rev. (1956), not only introduces the reader to Scots heraldry but explains much in heraldic practice that may not otherwise be clear. A work by another Scottish writer who gives a good view of heraldry in the international sense is *The Nature of Arms* by G.R. GAYRE (1959). For information on Irish heraldry, see SIR CHRISTOPHER and ADRIAN LYNCH-ROBINSON, *Intelligible Heraldry* (1948). *Boutell's Heraldry* has been edited and re-edited again and again since its first appearance in the last century. The editions of V. WHEELER-HOLOHAN, C.W. SCOTT-GILES, and J.B. BROOKE-LITTLE are all very useful. A large book, *Shield and Crest* by JULIAN FRANKLYN (1960), gives much otherwise not easily obtained information.

Very little continental work on heraldry has been translated into English. This applies not only to the lesser known European languages, as in Scandinavia, but also to French, Spanish, Italian, and German. Perhaps the best course is to consult periodical publications like *The Augustan*, which contains articles from a wide variety of sources, more than are likely to be found in any one European country. Several non-English-language encyclopaedias, such as the *Enciclopedia Italiana* (1929–37), have excellent articles on heraldry. Many non-English writers do transcend their national boundaries in writing on the subject. REMI MATHIEU in *Le Système héraldique français* (1946), not only writes illuminatingly of French heraldry, but helps to clarify the whole subject. On Spanish heraldry, see JOSE ASENSIO Y TORRES, *Tratado de heraldica y blason*, 3rd ed. rev. (1854, reprinted 1929); and LUCAS DE PALACIO, *De Genealogia y heraldica* (1946), the latter author being especially interested in the connection between totem-

ism and heraldry; the Japanese *mon* is exhaustively dealt with by CARROLL PARISH in *The Augustan*, vol. 11, no. 1 (1968).

Other works that will help the student after he has acquired a sound knowledge of this subject are: SIR ANTHONY R. WAGNER, *Heralds and Heraldry in the Middle Ages* (1939) and *Historic Heraldry of Britain* (1939); and L.G. PINE, *The Story of Heraldry* (1952, reprinted many times), an account of much controversial matter, including the present English heraldic position in law; G.D. SQUIBB, *The High Court of Chivalry: A Study of the Civil Law in England* (1959); C. PAMA, *Lions and Virgins* (1965), which discusses the history of arms in South Africa from 1487 to the present; and *International Heraldry* (1970), concerned with heraldry throughout the world.

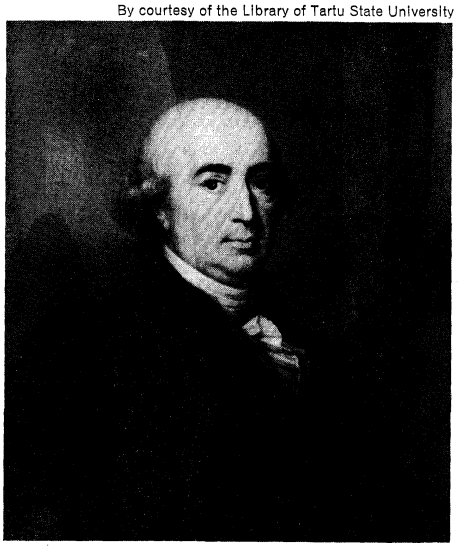
Works of reference in English are easily available. SIR J.B. BURKE, *General Armory* (1883, reprinted 1969), gives the description under alphabetical order of surnames of scores of thousands of coats of arms. JOHN WOODY PAPWORTH, *Ordinary of Arms* (1858–74, reprinted 1961), is the equivalent of the *General Armory* turned inside out, the idea being to enable the seeker to trace a coat of arms when he does not know the owner's name. Both books contain inaccuracies, small blame to the compilers who had to deal with much uncheckable material, at least at the time when they wrote. JAMES PARKER, *A Glossary of Terms Used in Heraldry*, new ed. (1970), with 1,000 illustrations, is a helpful book. Editions of *Debrett's Peerage*, of *Burke's Peerage*, and of *Burke's Landed Gentry* abound in illustrations and descriptions of arms. Recently published sources on the European continent, such as the *Grand Armorial* of France and the *Libro d'Oro* of Italy, have useful information on the heraldry of these countries.

(L.G.P.)

Herder, Johann Gottfried von

Herder, a German critic, philosopher, and Lutheran theologian of the 18th century, exerted a great influence in the history of German thought through his broad scholarship and prolific and fertile writings. His significance lies in his capacity to transcend the perspectives of his day, which were limited by the Enlightenment's extolling of reason, and to interpret human culture and history afresh. His influence, augmented through his contacts with the young Goethe, made him a harbinger of the Romantic movement.

By courtesy of the Library of Tartu State University



Herder, oil painting by Gerhard von Kügelgen, 1808. In the Library of Tartu State University.

Herder was born on August 25, 1744, at Mohrungen, in East Prussia, the son of poor parents. Beginning in the summer of 1762, he studied theology, philosophy, and literature at Königsberg, coming into close contact with Immanuel Kant, the founder of critical philosophy, as well as with Johann Georg Hamann, one of the Enlightenment's prominent critics.

Early travels and first works. In November 1764 Herder went to teach and preach in Riga. There he published his first works, which included two collections of fragments, entitled *Über die neuere deutsche Literatur: Fragmente* (1766–67; "On Recent German Literature: Fragments") and *Kritische Wälder, oder Betrachtungen die Wissenschaft und Kunst des Schönen betreffend* (1769 and 1846; "Critical Forests, or Reflections on the Science and Art of the Beautiful").

Self-discovery on a sea voyage

In the summer of 1769, he set out on a sea voyage from Riga to Nantes, which brought him a deeper understanding of his destiny. The *Journal meiner Reise im Jahr 1769* (1769; "Journal of My Voyage in the Year 1769"), which he concluded in Paris in December, bears witness to the change that it effected in him. Herder saw himself as a groundless being who had left the safe shore and was journeying into an unknown future. It would be his vocation to unveil that future through insights gained from the past, so that its character might be felt by his contemporaries. In his fruitful criticisms of his own time, Herder anticipated the possibilities of the developments generations ahead, among them, the ideas of Goethe, the brothers August Wilhelm and Friedrich von Schlegel, and Jacob and Wilhelm Grimm in poetical and aesthetic theory; Wilhelm von Humboldt in the philosophy of language; G.W.F. Hegel in the philosophy of history; Wilhelm Dilthey and his followers in epistemology; Arnold Gehlen in anthropology; and the Slav nationalists in political thought.

During a visit to Strasbourg, where he arrived in September 1770, as the companion of Prince Peter Frederick William of Holstein, Herder experienced a momentous meeting with the young Goethe, who was stirred to recognize his own artistic faculties through Herder's observations on Homer, Pindar, Shakespeare, and on literature and folk songs.

Career at Bückeburg. In April 1771 Herder went to Bückeburg as court preacher. The works that he produced there were fundamental to the *Sturm und Drang*, a literary movement with Promethean and irrationalist motifs, without which German Romantic literature could not have arisen. In the Romanticism Herder espoused, the medium of thought is feeling (*Gefühl*), which he compared to the sense of touch. Whereas sight apprehends things at a distance, feeling enjoys an immediate experience of reality, which it apprehends as a power reacting against man's own vital energy. Yet man at the same time experiences his own body, in which his vital power asserts itself against the world. At the moment when man recognizes the limits imposed by his environment without becoming dependent on it, a balance of forces is achieved between the two in which the individual body is converted into the aesthetic gestalt (or integral structure) and the identification of the individual with reality is consummated. (See his book *Plastik*, 1778.)

Among the works of this period is his *Abhandlung über den Ursprung der Sprache* (1772; "Essay on the Origin of Language"), which finds its origin in human nature. For Herder, knowledge is possible only through the medium of language. Although man and the world are united in feeling, they separate themselves in consciousness in order to link themselves anew in the "intentional," or object-directed, act in which the objective meaning of a *word* is rooted. Thus, what earlier had been apprehended dimly but not specifically recognized in feeling is expressly designated. Feeling and reflection thus interpenetrate each other; and the word, being at once sound and significance, is the cause of this union. Every signification of something therefore includes a certain emotional attitude toward it that reflects the particularity and the outlook of its users. Thus, the structure of language is a true image of human nature.

Whereas the psychologists of the time were carefully distinguishing man's various faculties (conation, feeling, knowledge), Herder stressed the unity and indivisible wholeness of man's nature. Consciousness and *Besonnenheit* ("reflective discernment") are not simply "higher" faculties added to an animal foundation; instead, they designate the structure of man as a whole with qualitatively unique human desire and human sensitivity. But, because in man instinct and sensitivity are subject to reflection, or "broken off" (*gebrochen*), man is "the first liberated member of creation."

Beginning of Herder's philosophy of history

Herder's philosophy of history also began to take form at this time, growing up from his attempt to use the past in order to assess the present situation and future probabilities. He had already outlined in the *Fragmente* the scheme of a typical historical development on the analogy of the ages of a man's life. By this means he tried to determine the situation of German poetry that was then current. The essay on Shakespeare and *Auch eine Philosophie der Geschichte zur Bildung der Menschheit* (1774; "Another Philosophy of History Concerning the Development of Mankind"), opposing Rationalism in historiography, were the first writings to show a deeper understanding of historical existence as the product of the contradiction between individuation and the whole of history; this contradiction itself forms the logical basis of historical development. If two forces are in conflict, one can be seen as striving to persevere and to emerge from the whole as an individual structure. Yet the whole is not satisfied with any single form: in historical catastrophes it frees itself to shape a new form of things, which is shattered again in turn when its time is past. The individual is not only an end but also a blind, unfree instrument taken or rejected by God. Even the philosopher can see the future only by tracing its conditions from patterns of past development, in order to counteract it.

Further works prepared during this period were his *Älteste Urkunde des Menschengeschlechts* (1774–76; "Oldest Records of the Human Race") on Hebrew antiquities, and his *An Prediger: Funfzehn Provinzialblätter* (1744; "To Preachers: Fifteen Provincial Papers"). Two especially important works were his essay on Shakespeare and "Auszug aus einem Briefwechsel über Ossian und die Lieder alter Völker" (1773; "Extract from a Correspondence About Ossian and the Songs of Ancient Peoples"), published in a manifesto to which Goethe and Justus Möser, a forerunner of *Sturm und Drang*, also contributed. As Herder showed in his exposition of Shakespeare and Homer, in the genuine poetic utterance, hitherto-hidden aspects of man's life are revealed by virtue of the creative function of language. "A poet is the creator of the nation around him," he wrote, "he gives them a world to see and has their souls in his hand to lead them to that world." Poetic ability is no special preserve of the educated; as the true "mother tongue of mankind" (Hamann), it appears in its greatest purity and power in the uncivilized periods of every nation; this for Herder was proved by the Old Testament, the *Edda*, and Homer: hence Herder's concern to retrieve ancient German folk songs and his attention to Norse poetry and mythology, to the work of the minnesinger, and to the language of Luther.

First years at Weimar. Thanks to Goethe's influence, Herder was appointed general superintendent and consistory councillor at Weimar in 1776. There, anticipating Goethe, he developed the foundations of a general morphology, which enabled him to understand how a Shakespearean play, for instance, or the Gospel According to John, in the historical context of each, was bound to assume the individual form that it did and no other. Herder's method achieves its results by recognizing contradictions and by resorting to a higher unity—a method by which Herder earns a place in the history of dialectical logic: compare his treatise "Über die dem Menschen angeborene Lüge" (1777; "On the Innate Lie in Man").

It was at this time also that Herder completed his transition to Classicism. Among the works of this period are *Vom Erkennen und Empfinden der menschlichen Seele* (1778; "Of the Knowing and Sensing of the Human Soul"), *Briefe, das Studium der Theologie betreffend* (1780–81; "Letters Concerning the Study of Theology"), *Vom Geist der ebräischen Poesie* (1782–83; Eng. trans., *The Spirit of Hebrew Poetry*, 1833), and his collection of *Volkslieder* (1778–79; "Folk songs"). Herder regarded poetry as a mode of coming to terms with reality. Whereas most of his contemporaries saw it either as a product of learning or as a means of amusement, he considered poetry to spring from the natural and historical environment experienced by feeling, rather as an involuntary reaction to the stimulus of events than as a deliberate act. Such feeling is the organ of a dynamic relationship between man and the world, which is expressed far more readily in the sounds, stresses, and rhythms of speech than in an image. This "voice of feeling" achieves the status of art only when it is detached from the man and from the historical environment that created it and becomes rounded off to constitute a world by itself.

Summit and later years of his career. Herder's work at Weimar reached its peak in *Zerstreute Blätter* (1785–97; "Sporadic Papers") and in the unfinished *Ideen zur Philosophie der Geschichte der Menschheit* (1784–91; Eng. trans., *Outlines of a Philosophy of the History of Man*, 1800). In the latter work, the result of his intercourse with Goethe, Herder attempted to demonstrate that nature and history obey a uniform system of laws. Already in the development from earth to mankind, a striving of forces was at work, aiming to balance one another by generating determinate forms or individual existents. This same phenomenon could be observed as a law of "humanity" in man's communal life, in which contending forces are reconciled. At any passing moment the measure is individual, but the principle of the development toward form is general. But too often man, in his freedom, works against nature, for his sense of the measure of things and his reason are immature. One must trust, however, that growing insight and goodwill will lead men to act according to the truth that they recognize and, through the conflict of nations, will reach the equilibrium of a structure embracing all mankind.

The attempt to unite nature and history

The basic premises underlying the *Ideen* are resumed in the dialogues *Gott: einige Gespräche* (1787; 2nd ed., *Einige Gespräche über Spinozas System*, 1800; "Several Discourses on Spinoza's System"), in which Herder combines the views of the Rationalists Gottfried Wilhelm Leibniz, Benedict de Spinoza, and Anthony, earl of Shaftesbury.

Financial difficulties, differences of opinion over the French Revolution, and, above all, his self-assertive nature, which could not bear the proximity of a greater man, led to an estrangement of Herder from Goethe. On Herder's side this resulted in a bitter enmity toward the whole Classical movement in German poetry and philosophy. His *Briefe zu Beförderung der Humanität* (1793–97; "Letters for the Advancement of Humanity") and his *Adrastea* (1801–03; treatises on history, philosophy, and aesthetics) emphasized the didactic purpose of all poetry, thus contradicting that very theory of the autonomy of the work of art that he himself had helped to establish. With the *Christliche Schriften* (1794–98; "Christian Writings"), the *Metakritik zur Kritik der reinen Vernunft* (1799; "Metacritique of the Critique of Pure Reason"), and the *Kalligone* (1800; metacritique of Kant's *Critique of Judgment*), Herder began his attack on Kant, whose philosophy he saw as a threat to his own historical view of the world. In this attack he had the support of Christoph Wieland, an influential poet and novelist.

Herder died at Weimar on December 18, 1803. The first collected edition of Herder's works was produced by his widow (45 vol., 1805–20). There is also a critical edition by B. Suphan (33 vol., 1877–1913; reprint, 1967–68).

BIBLIOGRAPHY. The authoritative biography is still R. HAYM, *Herder nach seinem Leben und seinen Werken*, 2 vol. (1880–85; 2nd ed., 1954). Important supplements are provided by A. GILLIES, *Herder* (1945); and by R.T. CLARK, *Herder: His Life and Thought* (1955, reprinted 1969), which has a detailed bibliography. The leading monograph written according to a comparative method is T. LITT, *Kant und Herder als Deuter der geistigen Welt* (1930; 2nd ed., 1949). For special aspects, see R. STADELMANN, *Der historische Sinn bei Herder* (1928); F. MEINECKE, *Die Enstehung des Historismus*, 2 vol. (1936). F.M. BARNARD, *Herder's Social and Political Thought* (1965); J.K. FUGATE, *The Psychological Basis of Herder's Aesthetics* (1966); and H.B. NISBET, *Herder and the Philosophy and History of Science* (1970). For further bibliography, see K. GOEDEKE, *Grundriss zur Geschichte der deutschen Dichtung*, 3rd ed., vol. 4 (1916); E. KEYSER (ed.), *Im Geiste Herders* (1953); W. WIORA (ed.), *Herder-Studien* (1960); and F.W. KANTZENBACH, *Johann Gottfried Herder in Selbstzeugnissen und Bilddokumenten* (1970).

(H.D.I.)

Heredity

Heredity is a complex of biological processes that result in progeny resembling their parents in many characteristics; progeny are not exact duplicates of their parents but usually differ in many traits. This difference is called variation. Heredity and variation, two sides of the same coin, are the subject matter of the science of genetics (*q.v.*).

The following sections are included in this article:

I. Early conceptions of heredity

PRE-MENDELIAN DISCOVERIES AND SPECULATIONS

Heredity was for a long time one of the most puzzling and mysterious phenomena of nature. This was so because the sex cells, which form the bridge across which heredity must pass between the generations, are usually invisible to the naked eye. Only after the invention of microscopes early in the 17th century, and the discovery of the sex cells, could the essentials of heredity be grasped. Before that time, Aristotle (4th century BC) speculated that the relative contributions of the female and the male parents were very unequal—the female was thought to supply what he called the "matter" and the male the "motion." The *Institutes of Manu*, composed in India between AD 100 and 300, consider the role of the female like that of the field and of the male like that of the seed; new bodies are formed "by the united operation of the seed and the field." In reality both parents transmit the heredity pattern equally, and on the average, children resemble their mothers as much as they do their fathers. Nevertheless, the female and male sex cells may be very different in size and in structure; the mass of an egg cell is sometimes millions of times greater than that of a spermatozoon.

The ancient Babylonians knew that pollen from a male date palm tree must be applied to the pistils of a female tree to produce fruits. R.J. Camerarius showed in 1694 that the same is true in corn (maize). C. Linnaeus in 1760 and J.G. Kölreuter, in a series of works published from 1761 to 1798, described crosses of varieties and species of plants. They found that the hybrids were on the whole intermediate between the parents, although in some characteristics they may be closer to one and in others closer to the other parent. Kölreuter compared the offspring of reciprocal crosses; *i.e.*, of crosses of variety *A* functioning as a female to variety *B* as a male and the reverse, variety *B* as a female to *A* as a male. The hybrid progenies of these reciprocal crosses were usually alike, indicating that contrary to the belief of Aristotle, the hereditary endowment of the progeny was derived equally from the female and the male parents. Many experiments on plant hybrids were made in the 1800s. These investigations revealed that hybrids were usually intermediate between the parents. They more or less incidentally recorded most of the facts that later led Gregor Mendel (see below) to formulate his celebrated rules and to found the theory of the gene. Apparently, none of Mendel's predecessors saw the significance of the data that were being accumulated. The general intermediacy of hybrids seemed to agree best with the belief that heredity was transmitted from the parents to offspring by "blood," and this belief was accepted by most 19th-century biologists, the evolutionist Charles Darwin being included among these.

Blood theory of heredity

The blood theory of heredity, if this notion can be dignified with such a name, is really a part of the folklore antedating scientific biology. It is implicit in such popular phrases as "half blood," "new blood," "blue blood," etc. It does not mean that heredity is actually transmitted through the red liquid in blood vessels; the essential point is the belief that a parent transmits to each child all its characteristics and that the hereditary endowment of a child is an alloy, a blend of the endowments of its parents, grandparents, and even more remote ancestors. This idea appeals to those who pride themselves on having a noble or otherwise remarkable "blood" line. It strikes a snag, however, when one observes that a child has some characteristics that are not present in either parent but are present in some other relatives or were present in more remote ancestors. Even more commonly one sees that brothers and sisters, though showing a family resemblance in some traits, are clearly different in others; how could the same parents transmit different "bloods" to each of their children?

Mendel disproved the blood theory. He showed (1) that heredity is transmitted through factors (now called genes) that do not blend but segregate; (2) that parents transmit only one-half of the genes they have to each child, and they transmit different sets of genes to different children; and (3) that although brothers and sisters receive their heredities from the same parents, they do not receive the same heredities (an exception is identical births). If the eminence of some ancestor was really the reflection of his genes, it is quite likely that some of his descendants, especially the more remote ones, would not inherit these "good" genes at all. In sexually reproducing organisms, man included, every individual has a hereditary endowment, or genotype, uniquely his own.

BIOLOGICAL AND LEGAL INHERITANCE

In many languages the same words are used for both the inheritance of biological traits and the inheritance of property. Biological and legal inheritances are, however, very different processes. Inherited objects are actually transferred from one owner to another; inherited traits are not. In 1580 the French writer Montaigne wondered how he could have inherited gallstones from his father when his father did not have them until 25 years after the son was born, and the son himself did not have them until he was 45 years old. This seemed sheer mystery. Of course nobody inherits a gallstone (or even a gallbladder for that matter); what parents transfer to their offspring in the sex cells are the genes, and some genes, when they interact with some environments, allow the formation of gallstones.

The hereditary endowment received in the sex cells comes to be realized in the processes of the individual development through a sequence of stages from a single cell, to an embryo, an infant, a child, a youth, an adult, a senescent, a cadaver. In all of these stages heredity acts under a particular set of environmental conditions: what develops, then, depends both upon the heredity of the organism and upon the environment in which the organism develops. W. Johannsen in 1909 distinguished two important concepts—the phenotype and the genotype of the organism. The phenotype is what the organism actually is: its outward appearance, its bodily structures,

Distinction between phenotype and genotype

physiological processes, behaviour, etc. The phenotype changes continuously; the same individual shows different phenotypes in childhood, in adulthood, and in old age. The genotype, on the other hand, is the hereditary endowment, the sum total of the genes that the individual has received from its parents. It can be said that the genotype does not change during an individual's life. This statement must be carefully qualified; it does not mean that the genotype is isolated from its surroundings; far from that, the gene is among the most physiologically active constituents of cells and organisms. The genes, in fact, engender the synthesis of their own copies (see GENE). An adult has not only the genes that were present in the sex cells from which he came but also millions of true copies of these genes (unless some of them have changed by mutation; see below).

In man, skin coloration is certainly inherited, and yet exposure to the sun may make the skin darker and protection from the sun may make it paler; in insects, individuals that develop from starving larvae may be dwarfs compared to those coming from well-fed larvae; in some plants, leaves that are formed when the plant grows on land are quite different in shape from those formed under water. Is, then, the pale or the tanned skin, the dwarf or the giant size, the entire or the lacy leaf inherited? Not really, what is inherited is the norm of reaction of the developing organism to its environments. The genotype determines which phenotypes can arise in any given sequence of environments in which the individual who carries that genotype lives and develops. Except in albinos, the norm of reaction of most human genotypes permits a certain latitude of skin pigmentations to develop depending on exposure to or protection from sunlight; the norm of reaction of some insect species allows a great variety of body sizes to develop depending upon ample or scarce diets; the norm of reaction of some plant species allows a variety of leaf shapes to develop depending on local environment. Given a certain genotype, what actually develops is decided by the environments: given an environment, what develops is decided by the genotype.

The genotype–phenotype distinction is still not comprehended by many people, including some scientists. Lamarckism is a school of thought that assumes that characters acquired during an individual's life are inherited by his progeny, or, to put it in modern terms, that the modifications wrought by the environment in the phenotype are reflected in similar changes in the genotype. If this were so, the results of training or exercise of a person's abilities or of his musculature would make the training and exercise much easier or even dispensable in his offspring. Not only the pioneer French evolutionist Jean Lamarck but also other 19th-century biologists, including Charles Darwin, accepted the inheritance of acquired traits without hesitation. It was questioned by August Weismann, whose famous experiments in the late 1890s on amputation of tails in generations of mice showed that such somatic modification resulted neither in disappearance nor even in shortening of the tails in the descendants. Weismann concluded that the hereditary endowment of the organism, which he called the germ plasm, is wholly separate and is protected against the influences emanating from the rest of the body, the somatoplasm or soma. The germ plasm–somatoplasm are related to the genotype–phenotype concepts, but they are not identical and should not be confused with them.

Superstitions regarding heredity

The noninheritance of acquired traits does not mean that the genes cannot be changed by environmental influences: X-rays and other mutagens (see *Changing heredity*, below) certainly do change them, and the genotype of a population can be altered and molded by selection. It simply means that what is acquired by parents in their physique and their intellect is not inherited by their children. Related to these misconceptions are the beliefs in "prepotency"—that some individuals impress their heredities on their progenies more effectively than others—and in "prenatal influences" or "maternal impressions"—that the mental states and the sights experienced by a pregnant female are reflected in the constitution of the child to be born. How ancient these beliefs are is suggested in the Book of Genesis, in which Laban produced spotted or striped progeny in sheep by showing the pregnant ewes striped hazel rods. Another such belief is "telegony," which goes back to Aristotle; it alleged that the heredity of an individual is influenced not only by his father but also by males with whom the female may have mated and who have caused previous pregnancies. (An ancient English law holds a man who seduces the wet nurse of the heir to the throne guilty of polluting the "blood" of the royal family.) Even Darwin, as late as 1868, seriously discussed an alleged case of telegony: that of a mare that was mated to a zebra and subsequently to an Arabian stallion by whom the mare produced a foal with faint stripes on his legs. The simple explanation for these results is that such stripes occur naturally in some breeds of horses.

All these beliefs, from inheritance of acquired traits to telegony, must now be classed as superstitions. They do not stand up under experimental investigation and are incompatible with what is known about the mechanisms of heredity and about the remarkable and predictable properties of the genetic materials. Nevertheless, some people still cling to these beliefs. Some animal breeders take telegony seriously and do not regard as "pure bred" the individuals whose parents are admittedly "pure" but whose mothers had mated with males of other breeds. Weirdest of all were the Lysenkoists. The agronomist T.D. Lysenko (*q.v.*) was able for close to a quarter of a century, roughly between 1938 and 1963, to make his special brand of Lamarckism the official creed in the Soviet Union and to suppress most of the teaching and research in orthodox genetics. He and his partisans published hundreds of articles and books allegedly proving their contentions, which effectively abrogate the achievements of biology for at least a century. They were discredited in 1964.

II. Mendel's experiments and their significance

DISCOVERY AND REDISCOVERY OF MENDEL'S LAWS

Gregor Mendel (*q.v.*) published his work in the proceedings of the local society of naturalists in Brünn, Austria (now Brno, Czech.), in 1866, but none of his contemporaries appreciated its significance. It was not until 1900, 16 years after Mendel's death, that his work was rediscovered independently by H. de Vries in Holland, C.E. Correns in Germany, and E. Tschermak von Seysenegg in Austria. Like several investigators before him, Mendel experimented on hybrids of different varieties of a plant. Mendel investigated the common pea plant (*Pisum sativum*). His methods differed in two essential respects from those of his predecessors. First, instead of trying to describe the appearance of whole plants with all their characteristics, Mendel followed the inheritance of single, easily visible and distinguishable traits, such as round versus wrinkled seed, yellow versus green seed, purple versus white flowers, etc. Second, he made exact counts of the numbers of plants bearing this or that trait; it was from such quantitative data that he deduced the rules governing inheritance.

Experiments with pea plants

Since pea plants reproduce usually by self-pollination of their flowers, the varieties Mendel obtained from seedsmen were "pure"—*i.e.*, descended for several to many generations from plants with similar traits. Mendel crossed them by deliberately transferring the pollen of one variety to the pistils of another; the resulting first-generation hybrids, denoted by the symbol F_1, usually showed the traits of only one parent. For example, the

Table 1: Pea Plants with Dominant and Recessive Characters Obtained by Mendel in the Second Generation of Hybrids

number dominant		number recessive		ratio
Round seed	5,474	Wrinkled seed	1,350	2.96 : 1
Yellow seed	6,022	Green seed	2,001	3.01 : 1
Purple flowers	705	White flowers	224	3.15 : 1
Tall plants	787	Short plants	277	2.84 : 1

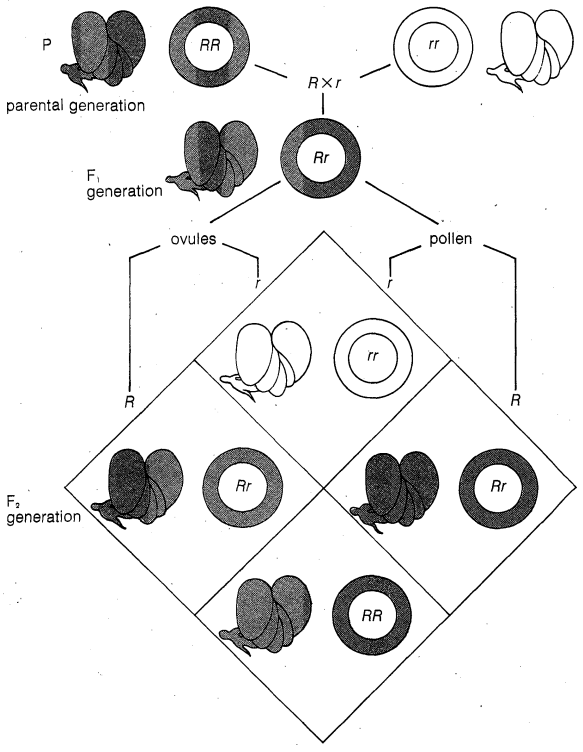


Figure 1: *Mendel's law of segregation.*
Cross of a purple-flowered and a white-flowered strain of peas. *R* stands for the gene for purple flowers and *r* for the gene for white flowers. Dark rings indicate the presence of a dominant gene for purple flowers.
From T. Dobzhansky, *Evolution, Genetics and Man*, (1955); John Wiley & Sons, Inc.

crossing of yellow-seeded plants with green-seeded ones gave yellow seeds; the crossing of purple-flowered plants with white-flowered ones gave purple-flowered plants, etc. Traits such as the yellow-seed colour and the purple-flower colour Mendel called dominant; the green-seed colour and the white-flower colour he called recessive. It looked as if the yellow and purple "bloods" overcame or consumed the green and white "bloods." That this was not so became evident when Mendel allowed the F_1 hybrid plants to self-pollinate and produce the second hybrid generation, F_2. Here both the dominant and the recessive traits reappeared, as pure and uncontaminated as they were in the original parents (generation P). Moreover, these traits appeared in constant proportions, namely about ¾ of the plants in the second generation showed the dominant trait and ¼ showed the recessive, a 3 to 1 ratio. It can be seen in Table 1 that Mendel's actual counts were as close to the ideal ratio as one could expect allowing for the sampling deviations present in all statistical data.

Mendel concluded that the sex cells, the gametes, of the purple-flowered plants carried some factor that caused the progeny to develop purple flowers, and the gametes of the white-flowered variety had a variant factor that induced the development of white flowers. W. Johannsen, the Danish geneticist, proposed in 1909 to call these factors genes.

An example of one of Mendel's experiments will illustrate how the genes are transmitted and in what particular ratios. Let *R* stand for the gene for purple flowers and *r* for the gene for white flowers (dominant genes are conventionally symbolized by capital letters and recessive genes by small letters). Since each pea plant contains a gene endowment half of whose set is derived from the mother and half from the father, each plant has two genes for flower colour. If the two genes are alike, for instance, both having come from white-flowered parents (*rr*), the plant is termed a homozygote (Figure 1). The union of gametes with different genes give a hybrid plant termed a heterozygote (*Rr*). Since the gene *R*, for purple, is dominant over *r*, for white, the F_1 generation hybrids will show purple flowers. They are phenotypically purple, but their genotype contains both *R* and *r* genes, and these alternative (allelic or allelomorphic) genes do not blend or contaminate each other. Mendel inferred that when a heterozygote forms its sex cells, the genes segregate and pass to different gametes. This is expressed in the first law of Mendel, the law of segregation of unit genes. Equal numbers of gametes, ovules, or pollen grains are formed that contain the genes *R* and *r*. Now, if the gametes unite at random, then the F_2 generation should contain about ¼ white-flowered and ¾ purple-flowered plants. The white-flowered plants, which must be recessive homozygotes, bear the genotype *rr*. About ⅓ of the plants exhibiting the dominant trait of purple flowers must be homozygotes, *RR*, and ⅔ heterozygotes, *Rr*. The prediction is tested by obtaining a third generation, F_3, from the purple-flowered plants; though phenotypically all purple-flowered, ⅔ of this group of plants reveal the presence of the recessive gene allele, *r*, in their genotype by producing about ¼ of white-flowered plants in the F_3 generation.

First and second laws of Mendel

Mendel also crossbred varieties of peas that differed in two or more easily distinguishable traits. When a variety with yellow round seed was crossed to a green wrinkled seed variety (fig. 2), the F_1 generation hybrids produced yellow round seed. Evidently yellow (*A*) and round (*B*) are dominant traits, green (*a*) and wrinkled (*b*) are recessive. In the F_2 generation, Mendel found 315 yellow round, 101 yellow wrinkled, 108 green round, and 32 green wrinkled seeds, a ratio approximately 9 : 3 : 3 : 1. The important point here is that the segregation of the colour (*A–a*) is independent of the segregation of the trait of seed surface (*B–b*). This is expected if four kinds of gametes are produced in equal numbers, carrying the four possible combinations of the parental genes: *AB*, *Ab*,

From T. Dobzhansky, *Evolution, Genetics and Man*, (1955); John Wiley & Sons, Inc.

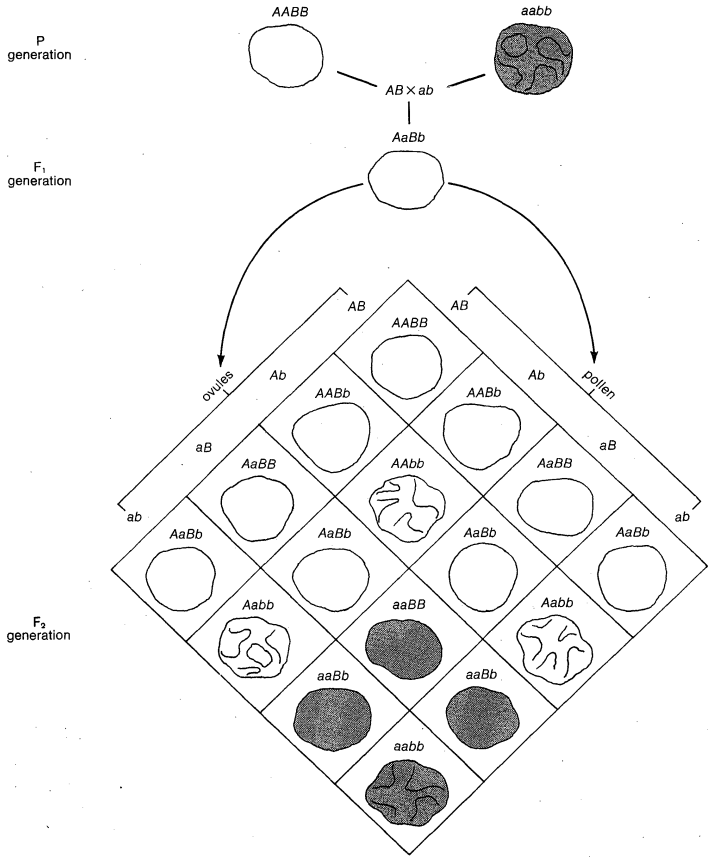

Figure 2: *Mendel's law of independent assortment.*
Cross of peas having yellow and smooth seeds with peas having green and wrinkled seeds. *A* stands for the gene for yellow and *a* for the gene for green; *B* stands for the gene for a smooth surface and *b* for the gene for a wrinkled surface.

aB, and *ab*. Random union of these gametes gives, then, the four phenotypes in a ratio 9 dominant–dominant : 3 recessive–dominant : 3 dominant–recessive : 1 recessive–recessive. Among these four phenotypic classes there must be nine different genotypes, a supposition that can be tested experimentally by raising a third hybrid generation. The predicted genotypes are actually found. Another test is by means of a backcross (or testcross)—the F_1 hybrid (phenotype yellow round seed; genotype *AaBb*) is crossed to a double recessive plant (phenotype green wrinkled seed; genotype *aabb*). If the hybrid gives four kinds of gametes in equal numbers and if all the gametes of the double recessive are alike (*ab*), the predicted progeny of the backcross are yellow round, yellow wrinkled, green round, and green wrinkled seed in a ratio 1 : 1 : 1 : 1. This prediction is realized in experiments. When the varieties crossed differ in three genes, the F_1 hybrid forms 2^3 or eight kinds of gametes (2^n = kinds of gametes, n being the number of genes). The second generation of hybrids, the F_2, has 27 (3^3) genotypically distinct kinds of individuals but only eight different phenotypes. From these results and others Mendel derived his second law, the law of recombination or independent assortment of genes.

UNIVERSALITY OF MENDEL'S LAWS

Although Mendel experimented with varieties of peas, his laws have been shown to apply to the inheritance of many kinds of characters in almost all organisms. In 1902 Mendelian inheritance was demonstrated in poultry and in mice. Albinism was the first trait in man shown, in 1903, to be a Mendelian recessive, with pigmented skin the corresponding dominant.

In 1902 and 1909 A.E. Garrod initiated the analysis of inborn errors of metabolism in man in terms of biochemical genetics. Alkaptonuria, inherited as a recessive, is characterized by excretion in the urine of large amounts of the substance called alkapton or homogentisic acid, which renders the urine black on exposure to air. In normal (*i.e.*, nonalkaptonuric) persons the homogentisic acid is changed to acetoacetic acid, the reaction being facilitated by a certain enzyme. Garrod advanced the hypothesis that this enzyme is absent or inactive in homozygous carriers of the defective recessive alkaptonuria gene; hence the homogentisic acid accumulates and is excreted in the urine. Mendelian inheritance of numerous traits in man has been studied since then (see GENETICS, HUMAN).

Forms of Mendelian inheritance

Mendelian inheritance takes a variety of forms. In the first place, clear-cut dominance and recessiveness are by no means always found. When red- and white-flowered varieties of four-o'clock plants or snapdragons are crossed, the first generation of hybrids have flowers of intermediate pink or rose colour. The F_2 generation shows a segregation in a ratio 1 red : 2 pink : 1 white. Suppose, then, that a gene allele R_1 is responsible for red and R_2 for white flowers; the homozygotes R_1R_1 and R_2R_2 are red and white respectively, and the heterozygotes R_1R_2 have pink flowers. A similar pattern of lack of dominance is found in shorthorn cattle. In diverse organisms, dominance ranges from complete (a heterozygote indistinguishable from one of the homozygotes) through incomplete (heterozygotes exactly intermediate) to excessive or over-dominance (a heterozygote more extreme than either homozygote).

An organism should not be thought of as an aggregate of independent traits, each determined by one gene. A "trait" is really an abstraction, a term of convenience in description. One gene may affect many traits (a condition termed pleiotropic), and many traits are affected by many genes. The gene white in *Drosophila* flies is pleiotropic; it affects the colour of the eyes and of the testicular envelope in the males, the fecundity and the shape of the spermatheca in the females, and the longevity of both sexes. In man many hereditary diseases are pleiotropic in origin, syndromes or complexes of diversified characters, inherited all together and determined by a single gene. On the other hand, the coat colour in many mammals is determined by numerous genes interacting to produce the result. Thus, in domestic cats there is a gene with three variants (alleles): one is dominant and allows for pigmentation, the other is recessive and in homozygous condition causes albinism, or complete lack of pigmentation; the third is intermediate, producing the so-called Siamese colour pattern. Moreover, the difference between yellow and black cats is due to a gene that in heterozygous females gives the tortoiseshell pattern; a dominant gene adds the tabby pattern; a recessive gene is responsible for the Maltese dilution ("smoky"); a dominant gene produces irregular white spotting. The great variety of colour patterns in cats, dogs, and other domesticated animals is the result of different combinations of complexly interacting genes. The gradual unravelling of their modes of inheritance was one of the active fields of research in the early years of genetics.

Two or more genes may produce similar and cumulative effects on the same trait. The skin colour difference between Negroes and so-called whites is due to several (probably four or more) interacting pairs of genes, each of which increases or decreases the skin pigmentation by a relatively small amount. The gene for albinism (lack of pigment) is not a part of this system; its dominant allele is necessary for the development of any skin pigment, and its recessive homozygous state results in the albino condition regardless of how many other pigment genes may be present. Albinism occurs in some individuals among people who belong to the dark- or intermediate-pigmented races, such as Negroes and American Indians, as well as among the Caucasians. The gene that determines whether albinism or pigmentation will express itself is called epistatic, and the genes whose expressions depend on the epistatic gene are called hypostatic.

APPARENT EXCEPTIONS TO MENDELIAN INHERITANCE

Polygenic inheritance. The greatest difficulties of analysis and interpretation are presented by the inheritance of many quantitative or continuously varying traits. The yield of grain in different varieties of corn (maize) and of milk in different breeds of cattle; egg-laying capacity in poultry; body size and proportions in breeds of sheep or dogs; and also stature, shape of the head, intelligence, and temperament in man range in continuous series from one extreme to the other and are in addition dependent on environmental conditions. Crosses of two varieties differing in such characters usually give F_1 hybrids intermediate between the parents, and the F_2 hybrids continue to be more or less intermediate on the average. At first sight, this situation suggests a blending inheritance through "blood" rather than Mendelian inheritance; in fact, it was probably observations of this kind of inheritance that suggested the folk idea of "blood theory." It has, however, been shown that these characters are polygenic—*i.e.*, determined by several or many genes, each taken separately producing only a slight effect on the phenotype, as small as or smaller than that caused by environmental fluctuations in the same characters. That Mendelian segregation does take place with polygenes, as with the genes having major effects (sometimes called oligogenes), is shown by the variation among F_2 and further generation hybrids being usually much greater than that in the F_1 generation. By selecting among the segregating progenies the desired variants, for example, individuals or families with greatest yield, best size, or a desirable behaviour, one can produce new breeds or varieties sometimes exceeding the parental forms. Hybridization and selection are consequently potent methods used for improvement of agricultural plants and animals (see ANIMAL BREEDING; PLANT BREEDING).

Mendelian segregation in polygenes

Higher animals and plants are mostly diploid; *i.e.*, they have two sets of genes (and chromosomes); one set received from the female parent and the other from the male parent. Some simpler forms of life, including most micro-organisms, are haploid, having a single set of genes and chromosomes during most of their life cycle. The sexual process in such organisms involves fertilization and emergence of a diploid state, which reverts more or

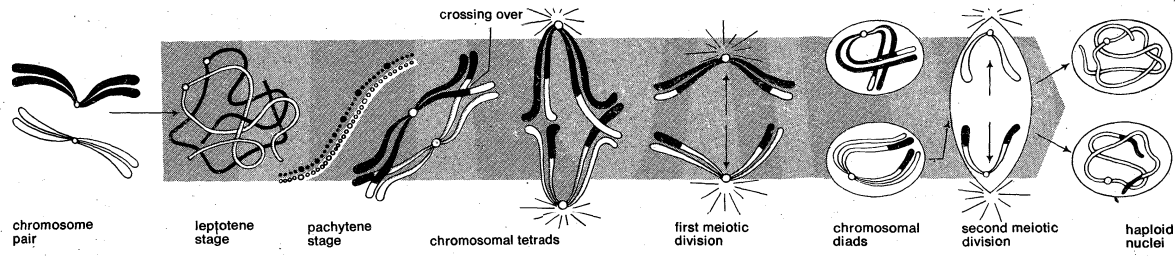

Figure 3: Behaviour of chromosomes at meiosis (see text).
From T. Dobzhansky, *Evolution, Genetics and Man*, (1955); John Wiley & Sons, Inc.

less rapidly to the haploid by means of meiosis, a special form of cell division. Haploid organisms display a much simpler Mendelian inheritance than that observed by Mendel in his pea crosses. When two strains of a haploid unicellular alga or of a bread mold, which differ in n genes, are crossed, sexual union results in a diploid heterozygote, which goes through meiosis; Mendelian segregation and recombination give rise to 2^n kinds of cells or spores with different combinations of the parental genes. Gene inheritance can be observed even in bacteria, where at least some strains undergo a sexual process and Mendelian segregation.

Cytoplasmic inheritance. It appears that all inheritance transmitted through the chromosomes of the nuclei of the sex cells is basically Mendelian inheritance. There are, however, cases of non-Mendelian, or cytoplasmic, inheritance. The classical example is the four-o'clock plant (*Mirabilis jalapa*) studied by C.E. Correns in 1909. Some garden varieties of this normally green plant have leaves streaked with white. Such variegated plants have some branches with only white, others with only green, and still others with mixtures of white, green, and variegated leaves. The seeds coming from the flowers borne on white branches give rise only to white-leaved seedlings, while those from variegated branches give white-, green-, and variegated-leaved plants. The colour of the progeny is clearly independent of the source of the pollen used to pollinate the flowers. The explanation is that the chlorophyll, the green pigment of the leaves, is carried in the cytoplasm of plant cells in special structures called chloroplasts and that the primordia from which the chloroplasts develop are transmitted usually through the female line (ovules) and not through the male line (pollen).

Inheritance in the four-o'clock plant

The cytoplasmic inheritance of the so-called killer trait in certain strains of the protozoan *Paramecium aurelia* is a curious example. These strains produce a substance that poisons and kills individuals of normal "sensitive" strains of the same species. The killer trait depends upon particles called "Kappa" in the cytoplasm of the killer strains. Kappa particles, the size of small bacteria or large viruses, reproduce themselves by division and are transmitted only through the cytoplasm. Yet their maintenance requires also the presence of a Mendelian (nuclear) gene called *K;* experiments can be contrived to obtain individuals with Kappa cytoplasm but without the dominant gene *K;* in the progeny of such individuals the Kappa particles gradually disappear and the killer character is lost.

III. Physical basis of heredity

CHROMOSOMES AND GENES

Chromosomes as carriers of heredity. The human body starts with the union of two sex cells. The body of a newborn infant consists of some 200,000,000,000 (2×10^{11}) cells. Cells arise only through division of other cells; when cells divide, their nuclei also divide by means of a remarkable manoeuvre called mitosis (see CELL AND CELL DIVISION). As early as 1848 cell nuclei were observed to resolve themselves during mitosis into smaller structures; later these structures were found to absorb certain dyes and so came to be called chromosomes (coloured bodies). The number of the chromosomes in a nucleus is usually constant in all individuals of a species but often different in different species—for example, 46 in man, 40 in the house mouse, 8 in the vinegar fly, or fruit fly (*Drosophila*), 20 in corn (maize), 24 in the tomato, 48 in the potato. During a mitotic division each chromosome duplicates itself and splits lengthwise, each duplicant passing to one of the two daughter cells formed during division. The mechanism of mitosis insures that all body cells have true copies of all chromosomes that were present in the fertilized egg from which the body developed.

Fertilization involves fusion of the nuclei of two sex cells or gametes. These nuclei contain haploid sets of chromosomes—23 in man, 4 in *Drosophila*, 10 in corn, etc. A fertilized egg cell, or zygote, contains, then, the diploid chromosome number, given above, $23 + 23 = 46$ in man, $4 + 4 = 8$ in *Drosophila*, etc. Sooner or later, however, the diploid zygotes must produce another crop of haploid gametes. This occurs by means of a process called meiosis; its essential features are shown in Figure 3. For the sake of simplicity, the diploid cell is shown to contain a single pair of chromosomes, one member of which is represented black (from the father) and the other white (from the mother). At the leptotene stage the chromosomes appear as long thin threads. At pachytene they pair, the corresponding portions of the two chromosomes lying side by side. The chromosomes then duplicate and contract; at this stage the chromosomes are usually held together by chiasmata, which are believed to be caused by crossing-over (exchanges of sections of the chromosomes). The first meiotic division separates the chromosomal tetrads into diads. The second meiotic division then gives haploid nuclei.

Behaviour of chromosomes during division

Female gametes, egg cells, are often much larger and quite different in structure from male gametes. Yet, as pointed out above, the mother and the father transmit heredity equally. Female and male gametes are, however, similar in one respect; they contain similar sets of chromosomes. This fact and the orderly precision of the processes of mitosis and meiosis led biologists to infer that the chromosomes must be the carriers of the hereditary materials.

Chromosomes as carriers of genes. When Mendel's work was rediscovered, the question of the relationship between the genes and chromosomes inevitably arose. It was felt that the chromosomes must be the carriers of the genes. Indeed, suppose that the white chromosomes shown in Figure 3 carries the gene for albinism and the black chromosome carries the gene for dark pigmentation. It is evident that the two gene alleles will undergo segregation at meiosis and that one-half of the gametes formed will contain the albino gene and the other half the pigmentation gene. Following the scheme in Figure 1, random combination of the gametes with the albino and the pigmentation gene will give two kinds of homozygotes and one kind of heterozygote in a ratio 1 : 1 : 2. Mendel's law of segregation is, thus, the outcome of chromosome behaviour at meiosis. The same is true of the second law, that of the independent assortment.

Consider the inheritance of two pairs of genes, such as Mendel's factors for seed coloration and seed surface in peas; these genes are located on different pairs of chromosomes. Since maternal and paternal members of different chromosome pairs are assorted independently, so are the genes they contain. This explains, in part, the genetic variety seen among the progeny of the same pair of parents. As stated above, man has 46 chromosomes in his body cells and in the cells (oogonia and spermatogonia) from which the sex cells arise. At meiosis these 46

chromosomes form 23 pairs, one of the chromosomes of each pair being of maternal and the other of paternal origin. Independent assortment is, then, capable of producing 2^{23}, or 8,388,608, kinds of sex cells with different combinations of the grandmaternal and grandpaternal chromosomes. Since each parent has the potentiality of producing 2^{23} kinds of sex cells, the total number of possible combinations of the grand-parental chromosomes is $2^{23} \times 2^{23} = 2^{46}$. The population of the world is now between 3,000,000,000 and 4,000,000,000 persons, or between 2^{31} and 2^{32} persons. It is, therefore, certain that only a tiny fraction of the potentially possible chromosome and gene combinations can ever be realized. Yet even 2^{46} is an underestimate of the variety potentially possible. The grandmaternal and grandpaternal members of the chromosome pairs are not indivisible units. Each chromosome carries many genes, and the chromosome pairs exchange segments at meiosis. This is evidence that the genes rather than the chromosomes are the units of Mendelian segregation.

LINKAGE OF TRAITS

Simple linkage. As pointed out above, the random assortment of the maternal and paternal chromosomes at meiosis is the physical basis of the independent assortment of genes and of the traits they control. This is the basis of the second law of Mendel. The number of the genes in a sex cell is, however, much greater than that of the chromosomes. When two or more genes are borne on the same chromosome these genes may not be assorted independently (some purists consequently prefer to speak of a second "rule" rather than "law" of Mendel). When the parental combinations of traits are more frequent than new combinations, the genes are said to be linked.

Linked genes in Drosophila

When a *Drosophila* fly homozygous (pure breeding) for a normal grey body and long wings is crossed with one having a black body and vestigial wings the F_1 consists of hybrid gray, long-winged flies (Figure 4). Gray body (*B*) is evidently dominant over black body (*b*), and long wing (*V*) is dominant over vestigial wing (*v*). Now consider a backcross of the heterozygous F_1 males to double recessive black-vestigial females (*bbvv*). Independent assortment would be expected to give in the progeny of the backcross the following: 1 gray-long : 1 gray-vestigial : 1 black-long : 1 black-vestigial. In reality only gray-long and black-vestigial flies are produced, in approximately equal numbers; the genes remain linked in the same combinations in which they were found in the parents. The backcross of the heterozygous F_1 females to double recessive males gives a somewhat different result: 42 percent each of gray-long and black-vestigial flies and about 8 percent each of black-long and grey-vestigial classes. In sum, 84 percent of the progeny have the parental combinations of traits, and 16 percent have the traits recombined. The interpretation of these results given in 1911 by the U.S. geneticist T.H. Morgan laid the foundations of the theory of linear arrangement of genes in the chromosomes.

Traits that exhibit linkage in experimental crosses (such as black body and vestigial wings) are determined by genes located in the same chromosome. As more and more genes became known in *Drosophila melanogaster*, they fell neatly in four linkage groups corresponding to the four pairs of the chromosomes this species possesses. One linkage group consists of sex-linked genes, located in the X chromosome (see below); of the three remaining linkage groups, two have many more genes than the remaining one; this corresponds to the presence of two pairs of large chromosomes and one pair of tiny dotlike chromosomes. The numbers of linkage groups in other organisms are equal to or smaller than the numbers of the chromosomes in the sex cells; *e.g.*, 10 linkage groups and 10 chromosomes in corn (maize), 19 linkage groups and 20 chromosomes in the house mouse, at least 4 linkage groups and 23 chromosomes in man.

We have seen above that the linkage of the genes black and vestigial in *Drosophila* is complete in heterozygous males, while in the progeny of females there appear

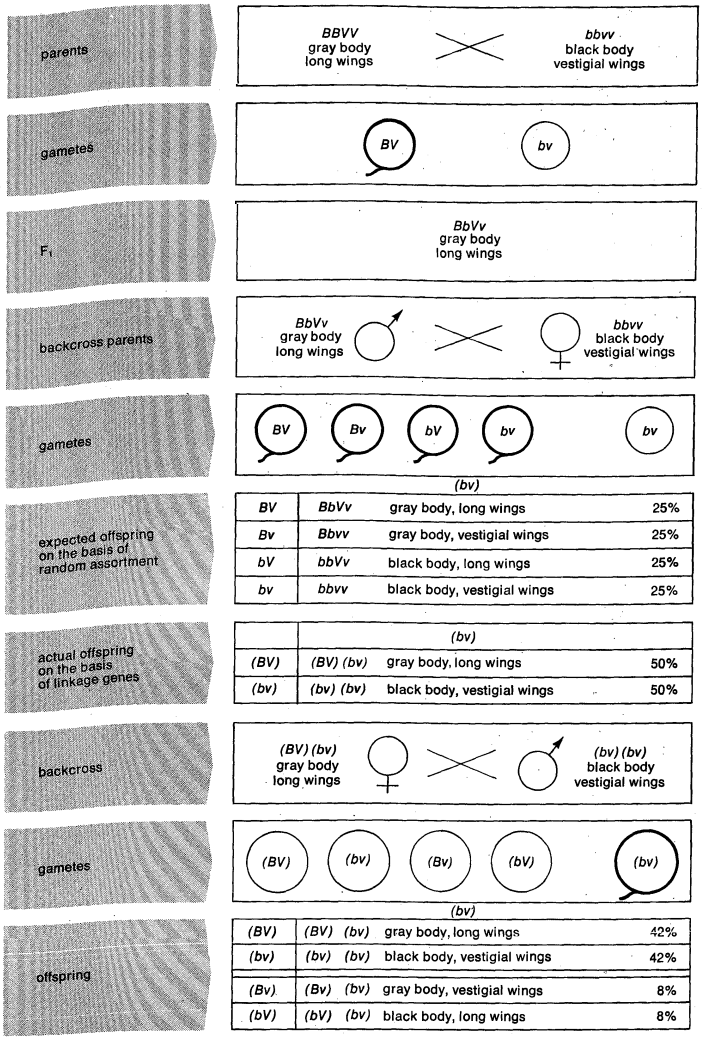

Figure 4: Linkage of genes as illustrated by body colour and wing length in *Drosophila* flies (see text).
Reprinted by permission of the publisher, from L.H. Snyder and P.R. David, *The Principles of Heredity* (Lexington, Mass.: D.C. Heath and Company, 1957)

about 17 percent of recombination classes. With very rare exceptions, the linkage of all genes belonging to the same linkage group is complete in *Drosophila* males, while in the females different pairs of genes exhibit all degrees of linkage from complete (no recombination) to 50 percent (random assortment). Morgan's inference was that the degree of linkage depends on physical distance between the genes in the chromosome: the closer the genes the tighter the linkage, and vice versa. Furthermore, Morgan perceived that the chiasmata, crosses that occur in meiotic chromosomes, indicate the mechanism underlying the phenomenon of linkage. As shown schematically in Figure 3, the maternal and paternal chromosomes (represented black and white) cross over and exchange segments, so that a chromosome emerging from the process of meiosis may consist of some maternal (grandmaternal) and some paternal (grandpaternal) sections. If the probability of crossing-over taking place is uniform along the length of a chromosome (which was later shown to be not quite true), then genes close together will be recombined less frequently than those far apart. This realization opened a hitherto scarcely imagined opportunity to prepare "maps" showing the arrangement of the genes and the estimated distances between them in the chromosome by studying the frequencies of recombination of various traits in the progenies of hybrids. In other words, the linkage maps of the chromosomes are really summaries of many statistical observations on the outcomes of hybridization experiments. In principle at least, such maps could be prepared even if the chromosomes, not to speak of the chiasmata at meiosis, were unknown. But here is

Chromosome maps

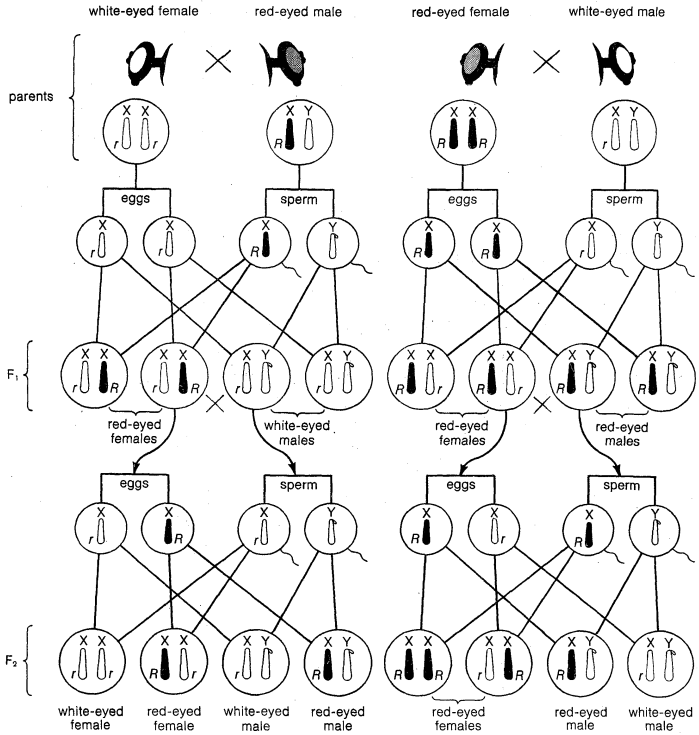

Figure 5: Sex-linked inheritance of white eyes in *Drosophila* flies (see text).

an interesting and relevant fact: in *Drosophila* males the linkage of the genes in the same chromosome is complete, and observations under the microscope show that no chiasmata are formed in the chromosomes at meiosis. In most organisms, including man, chiasmata are seen in the meiotic chromosomes in both sexes, and observations on hybrid progenies show that recombination of linked genes occurs also in both sexes.

The most detailed chromosome maps have been constructed for Morgan's classical material—*Drosophila melanogaster*. Less detailed chromosome maps exist for some other species of *Drosophila* flies, for corn, the house mouse, the bread mold *Neurospora crassa*, and for some bacteria and bacteriophages. The mapping of human chromosomes is a most arduous task, because no experimental crosses can be arranged and because the investigator has to rely on observation in families in which linked traits happen to be segregating.

Sex linkage. The male of many animals has one chromosome pair, the sex chromosomes, consisting of unequal members called X and Y. At meiosis the X and Y chromosomes first pair, then disjoin and pass to different cells. One-half of the gametes (spermatozoa) formed contain the X and the other the Y chromosome. The female has two X chromosomes, and all egg cells normally carry a single X. The eggs fertilized by X-bearing spermatozoa give females (XX), and those fertilized by Y-bearing spermatozoa give males (XY).

Sex-linked genes

The genes located in the X chromosomes exhibit what is known as sex-linkage or crisscross inheritance. The classic case, described by T.H. Morgan in 1910, is that of the white eyes in *Drosophila* (Figure 5). White-eyed females crossed to males with the normal red eye colour produce red-eyed daughters and white-eyed sons in the F_1 generation, and equal numbers of white-eyed and red-eyed females and males in the F_2 generation. The cross of red-eyed females to white-eyed males gives a different result: both sexes are red eyed in F_1, the females in the F_2 generation are red eyed, half of the males are red eyed and the other half white eyed. As interpreted by Morgan, the gene that determines the red or white eyes is borne on the X chromosome, and the allele for red eye is dominant over that for white eye. Since a male receives its single X chromosome from his mother, all sons of white-eyed females also have white eyes. A female inherits one X chromosome from her mother and the other X from her father. Red-eyed females may have genes for red eyes in both of their X chromosomes (homozygotes) or may have one X with the gene for red and the other for white (heterozygotes). In the progeny of heterozygous females one-half of the sons will receive the X chromosome with the gene for white and will have white eyes, and the other half will receive the X with the gene for red eyes. The daughters of the heterozygous females crossed with white-eyed males will have either two X chromosomes with the gene for white and hence white eyes or will have one X with white and the other X with the gene for red eyes and will be red-eyed heterozygotes.

In man, the red-green colour blindness and hemophilia are among traits showing sex-linked inheritance and consequently due to genes borne in the X chromosome.

In some animals—birds, butterflies and moths, some fish, and at least some amphibians and reptiles—the chromosomal mechanism of sex determination is, as it were, a mirror image of that described above. The male has two X chromosomes and the female an X and Y chromosome. Here the spermatozoa are all alike in having an X chromosome; the eggs are of two kinds, some with X and others with Y chromosomes, usually in equal numbers. The sex of the offspring is, then, determined by the egg rather than by the spermatozoon. Sex-linked inheritance is altered correspondingly. A male homozygous for a sex-linked recessive trait, crossed to a female with the dominant one, gives in the F_1 generation daughters with the recessive trait and heterozygous sons with the corresponding dominant trait. The F_2 generation has recessive and dominant females and males in equal numbers. A male with a dominant trait crossed to a female with a recessive trait gives uniformly dominant F_1, and a segregation in a ratio of 2 dominant males : 1 dominant female : 1 recessive female.

Observations on pedigrees or experimental crosses show that certain traits exhibit sex-linked inheritance; the behaviour of the X chromosomes at meiosis is such that the genes they carry may be expected to exhibit sex-linkage. This evidence still failed to convince some skeptics that the genes for the sex-linked traits were in fact borne in certain chromosomes seen under the microscope. An elegant experimental proof was furnished in 1916 by the U.S. geneticist C.B. Bridges. As stated above, white-eyed *Drosophila* females crossed to red-eyed males usually produce red-eyed female and white-eyed male progeny. Among thousands of such "regular" offspring there are occasionally found exceptional white-eyed females and red-eyed males. Bridges constructed the following working hypothesis. Suppose that during meiosis in the female, gametogenesis occasionally goes wrong, and the two X chromosomes fail to disjoin (Figure 6). Exceptional eggs

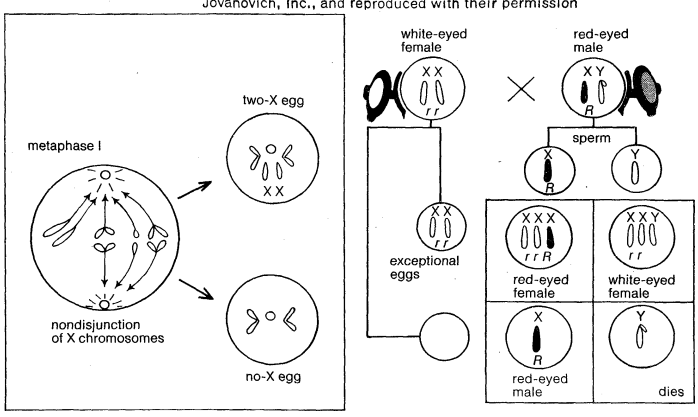

Figure 6: Nondisjunction of the X chromosomes in Drosophila flies, an explanation for the appearance of unexpected types of offspring. Abnormal meiosis in the female (left) is responsible for the exceptional eggs (right).

Verification of sex-linked inheritance

will then be produced carrying two X chromosomes and eggs carrying none. An egg with two X chromosomes coming from a white-eyed female fertilized by a spermatozoon with a Y chromosome will give an exceptional white-eyed female. An egg with no X chromosome fertilized by a spermatozoon with an X chromosome derived from a red-eyed father will yield an exceptional red-eyed male. This hypothesis can be rigorously tested. The exceptional white-eyed females should have not only the two X chromosomes but also a Y chromosome, which normal females do not have. The exceptional males should, on the other hand, lack a Y chromosome, which normal males do have. Both predictions were verified by examination under a microscope of the chromosomes of exceptional females and males. The hypothesis also predicts that exceptional eggs with two X chromosomes fertilized by X-bearing spermatozoa must give individuals with three X chromosomes; such individuals were later identified by Bridges as poorly viable "superfemales." Exceptional eggs with no Xs, fertilized by Y-bearing spermatozoa, will gives zygotes without X chromosomes; such zygotes die in early stages of development.

HEREDITY AND NUCLEIC ACIDS

In 1869 a substance containing nitrogen and phosphorus, was extracted from cell nuclei. It was originally called nuclein, but is now known as deoxyribonucleic acid (DNA). DNA is the chemical component of the chromosomes that is chiefly responsible for their staining properties in microscopic preparations. In addition to DNA, chromosomes contain a variety of proteins, mostly histones but sometimes protamines. The question naturally arises whether the nucleic acids or the proteins, or both together, are the carriers of the genetic information, which makes the genes of the same organism and of different organisms specifically different. Until the early 1950s most biologists were inclined to believe that the proteins were the chief carriers of heredity; at present the weight of the evidence is overwhelmingly in favour of ascribing this role to the nucleic acids. Nucleic acids are not only chemically simpler substances than the proteins but they do not differ greatly in composition in quite different organisms. By contrast, proteins are large, some of them gigantic molecules, and the possible variety of chemically different proteins is virtually unlimited. The diversity of the genes, therefore, seemed likely to rest on the diversity of the proteins.

The weight of evidence for DNA and against protein as the genetic material directed the attention of biologists to the nucleic acids. For details of the determining experiments see GENE.

HEREDITY AND DEVELOPMENT

It has been shown that the sex cells contain in the chromosomes of their nuclei material particles called genes. Variations in the quality or the dosage of the genes produce visible or phenotypic changes in the organism. When parents carry different genes, their hybrid offspring show a distribution of the phenotype traits as described by Mendel's laws. Between the genes in the sex cells and the traits, such as seed colours and shapes in peas or eye and skin colours in man, there intervene, however, very complex processes of the individual's development. The genes determine an organism's potentialities, some of which are gradually realized in a body growing and developing in a certain sequence of environments. The question naturally arises: how does the realization of the genetic potentialities take place? A fertilized egg cell carries a certain complement of genes; by repeated divisions these cells give rise to numerous cells of different kinds (*e.g.*, epidermal, glandular, muscle, skeletal, nerve cells, etc.). What makes these cells different if they carry the same genes? Developmental genetics (also called phenogenetics) attempts to find answers to this question.

Problems of developmental genetics may be approached, generally, in two ways. First, one may attempt to retrace the pathways leading from a gene to a phenotypic trait, starting from the latter and going backward toward the beginning of the development. Second, the action of the genes in the nuclei and the cells that carry them may be studied. Both approaches have in fact been utilized. The first approach usually discloses that the visible expressions of gene differences are brought about by divergence of metabolic processes controlled by the genes. Garden varieties of sweet peas, primroses, dahlias, and verbenas present a great diversity of flower colours. Many investigators made crosses between colour varieties of several species and analyzed the results in terms of the Mendelian genes responsible for the often striking differences observed. Biochemical studies correlated with the genetic ones can be illustrated in a group of water-soluble pigments: anthoxanthins (yellow colours) and anthocyanins (blues, pinks, purples, reds, etc.). These pigments are all chemically related, having in their molecules three rings derived from the condensation of sugars. The differences are due to substitution of hydrogen atoms by hydroxyl (OH) groups at specified positions in the molecules, attachment of extra sugars, and changes in the acidity (pH) of the cell sap. Each of these substitutions and changes is due to a particular gene that modifies or blocks a certain chemical reaction involving usually the colourless precursor of the pigments.

Approaches to developmental genetics

Using the bread mold *Neurospora crassa* as their experimental object, G.W. Beadle and E.L. Tatum initiated in the late 1930s their classical studies on gene control of individual steps in the chains of biochemical reactions. This body of work earned for them a Nobel Prize in 1958. Most strains of *N. crassa* can grow on a "minimal" medium, having a suitable carbohydrate (sugar), certain inorganic salts, and the vitamin biotin. From these sources *N. crassa* can synthesize all the amino acids, vitamins, and other substances necessary for all its vital activities. Now suppose that a gene controlling one of the synthetic reactions is so altered by a mutation that it no longer yields the enzyme necessary for that reaction. The strain with the altered gene cannot, therefore, grow on the minimal medium unless the necessary substance is added to the medium. Let a metabolic pathway consist of a chain of reactions $A \rightarrow B \rightarrow C$ (for example, ornithine → citrulline → arginine). Each step is mediated by a different enzyme controlled usually by a single gene. A change in the gene that mediates, for example, the step $A \rightarrow B$ may eliminate this reaction. The products B and C then fail to be formed; the compound A, which is normally transformed into B and C, accumulates in abnormally high quantities. However, since the enzyme that normally facilitates the reaction $B \rightarrow C$ is available, the organism is able to form D if C is added to the "minimal" medium.

Gene control in bread mold

The control of the successive chemical steps in the metabolic pathways by a single gene for each step appears to be a general phenomenon in the living world. This is what is involved in many inborn errors of metabolism in man. Much important work published in recent years is concerned with analysis of metabolic pathways in a variety of organisms. One of the striking results of this work has been the demonstration that these pathways are frequently similar in quite diverse organisms, which suggests the presence in them of similar genes or at least of genes with similar functions.

The properties that distinguish one gene from another are specified by the sequence of the "letters" of the DNA "alphabet"—A (adenine), C (cytosine), G (guanine), and T (thymine). The protein "alphabet" has 20 "letters," the 20 amino acids, and the properties of the proteins are specified by the sequences of these letters. The "messages" inscribed in the genes by means of the 4-letter alphabet are translated into the 20-letter alphabet of the proteins through the mediation of ribonucleic acids (RNA). How the "letters" in RNA specify the sequence in which amino acids will follow each other is discussed in the article GENE.

IV. Heredity and environment

PREFORMISM AND EPIGENESIS

A notion that was widespread among pioneer biologists in the 18th century was that the fetus, and hence the adult

The homunculus of early microscopists

organism that develops from it, is preformed in the sex cells. Some early microscopists even imagined that they saw a tiny "homunculus," a diminutive human figure, encased in the human spermatozoon. The development of the individual from the sex cells appeared deceptively simple—it was merely increase in size and growth of what was already present in the sex cells. The antithesis of the early preformation theories were theories of epigenesis, which claimed that the sex cells were structureless jelly and contained nothing at all in the way of rudiments of future organisms. The naïve early versions of preformation and epigenesis had to be given up when embryologists showed that the embryo develops by a series of complex but orderly and gradual transformations (see DEVELOPMENT, ANIMAL). Darwin's "Provisional Hypothesis of Pangenesis" was distinctly preformistic; A. Weismann's theory of determinants in the germ plasm as well as the early ideas about the relations between genes and traits also tended toward preformism.

Heredity was defined at the beginning of this article as a process that results in the progeny resembling their parents. This definition is valid as far as it goes, but what about characteristics subject to environmental modification? It would be convenient if some characters were hereditary and others environmental, but in reality such a dichotomy does not exist. As mentioned above, the genotype determines not the characters but the norm of reaction of the developing organism to its environments. The development results in a sequence of phenotypes; "characters" or "traits" are really abstractions used in talking or writing about the phenotype, the appearance the organism presents to us. The "norm" of reaction is perhaps not a felicitous phrase, although it seems to have established itself as a term in genetics; the "norm" does not imply that certain manifestations of the genotype are normal and others abnormal but subsumes the entire repertory of the phenotypes that a carrier of a given genotype can develop in all environments in which it can live.

A trait that is hereditary (*e.g.*, skin colour in man) may be modified by environmental influences (suntanning). And conversely, a trait sensitive to environmental modifications (*e.g.*, weight in man) may well be genetically conditioned. In a sense then, all traits have both a genetic and an environmental component. Organic development is preformistic insofar as a fertilized egg cell contains a genotype that conditions the events that may occur and epigenetic insofar as a given genotype allows a variety of possible outcomes. These considerations should dispel the reluctance felt by many people to accept the fact that mental as well as physiological and physical traits in man are genetically conditioned. Genetic conditioning does not mean that heredity is the "dice of destiny." At least in principle, but not invariably in practice, the development of a trait may be manipulated by environmental changes.

Hygiene, medicine, education, even social and political systems may from this point of view be regarded as environmental engineering devices by means of which organic development may be controlled. Whether man will be the slave or the master of his inherited genes will depend on the degree of understanding of human nature that may be achieved.

HEREDITY IN HEALTH AND DISEASE

Extent of genetic diseases

That the difference between health and disease is sometimes due to heredity has been known for a long time. The authors of the Talmud were aware of the fact that hemophilia was transmitted from mothers to some of their sons; the male progeny of mothers who lost two boy infants because of excessive bleeding were exempt from the rite of circumcision. How great is the sum total of ill health due to defective heredity is nevertheless still very imperfectly known. In the 1950s A.C. Stevenson estimated for the population of Northern Ireland that about 26 percent of the hospital beds were occupied by genetically handicapped patients; some 6 percent of the consultations with medical practitioners and 8 percent of those with specialists involved such persons. At least 4 percent of the infants born had more or less seriously incapacitating genetic defects. This last figure was an underestimate because it did not include some quite serious conditions, such as schizophrenia, in which genetic factors play an important role, nor did it include approximately 14 percent of the recordable pregnancies that resulted in abortions or stillbirths, some of which are also genetically conditioned. There is no reason to believe that the population of Northern Ireland during those years was genetically handicapped either especially severely or exceptionally lightly. It is representative of what may prevail widely.

Diseases due to simple recessive genes are generally more difficult to study genetically because the affected children are usually born to parents, neither of whom is affected. For example, juvenile amaurotic idiocy, a grave neurological disorder that causes death of the afflicted children long before sexual maturity, cannot for that reason be present in a parent. Both parents may, however, be heterozygous and carry one dose of the defective gene; although they themselves enjoy good health, one out of four of their children on the average may develop the disease.

The penetrance level of genes

In some cases the dichotomy of hereditary versus environmental defect or disease cannot always be sustained. The genes for brachydactyly, albinism, juvenile amaurotic idiocy, hemophilia, and other conditions that are classic examples of Mendelian inheritance in man have what is called complete penetrance; that is, individuals carrying them exhibit certain traits regardless, so far as is known, of the environments in which they occur. On the other hand, at least some forms of sugar diabetes (diabetes mellitus) are genetic, but the disease may appear at different ages; and when it does appear, its expression may be more or less severe. Such variable penetrance and expressivity depend presumably on the environment, both external and genetic (*i.e.*, on the other genes the individual carries).

There has been considerable dispute about the hereditary basis of schizophrenia. There are apparently several genes the defective alleles of which may combine to cause, under suitable environmental conditions, a clinically diagnosable schizophrenia. Still stronger environmental components are found in diseases in which a "susceptibility" is inherited. Tuberculosis is caused by infection from a pathogenic bacterium; it is, therefore, basically an "environmental" disease. There is, nevertheless, good evidence that the carriers of certain genotypes contract the disease more easily than do the carriers of other genotypes. An even clearer relationship is that between falciparum malaria and sickle-cell anemia. One gene causes, in the homozygous condition, sickle-cell anemia, a disease usually fatal before adolescence. The same gene in the heterozygous condition gives at most only a mild anemia and in addition confers a relative immunity to falciparum malaria. Malaria is caused, of course, by a blood parasite; however, in populations in which practically everybody is infected, the genotype of a person may be the decisive variable. Evidence is rapidly accumulating that the susceptibility to widespread degenerative diseases, such as hypertension and coronary artery disease, is also genetically conditioned.

To "cure" schizophrenia or any other hereditary disease obviously does not mean removal of the responsible gene or genes. Health and disease, however, are conditions of the phenotype. The curative treatment places the carriers of the undesirable genes in environments in which the disease does not assert itself in the phenotype, and the persons concerned are enabled to lead reasonably normal and happy lives. The symptoms of the disease, not the cause of the disease, are treated, but even this is a great accomplishment.

HERITABILITY

Although hereditary diseases and malformations are, unfortunately, by no means uncommon in the aggregate, no one of them occurs very frequently. The characteristics by which one person is distinguished from another, such

as facial features, stature, shape of the head, skin, eye and hair colours, and voice, are not usually inherited in a clear-cut Mendelian manner, as are some hereditary malformations and diseases. This is not as strange as it may seem. Gene changes, or mutations, that produce morphological or physiological effects drastic enough to be clearly set apart from the more usual phenotypes are likely to cause diseases or malformations just because they are so drastic. The variations that occur among healthy persons are, as a general rule, caused by polygenes with individually small effects. The same is true of individual differences among members of various animal and plant species. Even brown-blue eye colour in man, which in many families behaves as if caused by two forms of a single gene (brown being dominant and blue recessive), is often blurred by minor gene modifiers of the pigmentation. Some apparently blue-eyed persons actually carry the gene for the brown eye colour, but several additional modifier genes decrease the amount of brown pigment in the iris.

The nature-nurture problem in man

The question geneticists must often attempt to answer is how much of the observed diversity between persons, or between individuals of any species, is due to hereditary, or genotypic variations, and how much of it is due to environmental influences. Applied to man, this is sometimes referred to as the nature-nurture problem. With animals or plants the problem is evidently more easily soluble than it is with man. Two complementary approaches are possible. First, individuals, or their progenies, are raised in environments as uniform as can be provided, with food, temperature, light, humidity, etc., carefully controlled. The differences that persist between such individuals or progenies probably reflect genotypic differences. Second, individuals with similar or identical genotypes are placed in different environments. The phenotypic differences then may be ascribed to environmental induction. Experiments combining both approaches have been carried out on several species of plants that grow naturally at different altitudes, from sea level to the alpine zone of the Sierra Nevada of California. Young yarrow plants (*Achillea*) were cut in three parts and the cuttings replanted in experimental gardens at sea level, at midaltitude (4,800 feet [1,460 metres]), and at a high altitude (10,000 feet [3,050 metres]) (Figure 7). The

From T. Dobzhansky, *Heredity and the Nature of Man*, (1964); Harcourt Brace Jovanovich, Inc.

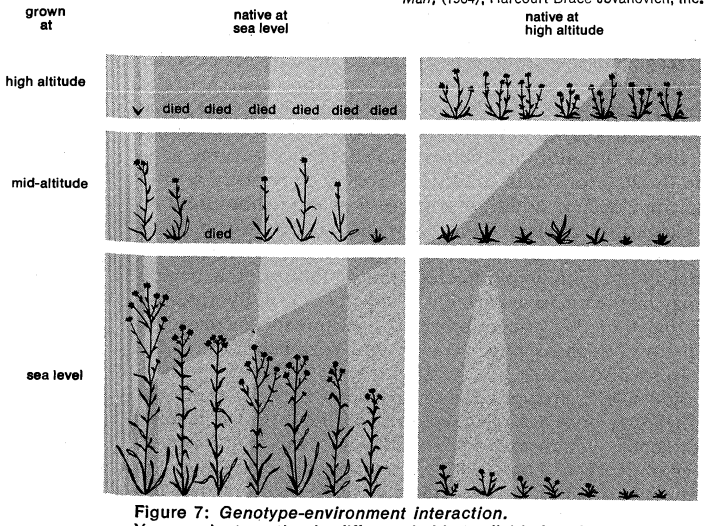

Figure 7: *Genotype-environment interaction.* Yarrow plants native in different habitats divided and replanted at different elevations.

plants native at sea level grow best in their native habitat, less well at midaltitudes, and die at high altitudes. On the other hand, the alpine race survives and develops better at the high-altitude transplant station than at lower altitudes.

With organisms that cannot survive being cut in pieces and placed in controlled environments, a partitioning of the observed variability into genetic and environmental components may be attempted by other methods. Suppose that in a certain population individuals vary in stature, weight, or some other trait. These characters can be measured in many pairs of parents and in their progenies. If the variation is due entirely to environment and not at all to heredity, then the expression of the character in the parents and in the offspring will show no correlation at all (heritability = zero). On the other hand, if the environment is unimportant and the character is uncomplicated by dominance, then the means of this character in the progenies will be the same as the means of the parents; with differences in the expression in females and in males taken into account, the heritability will equal unity. In reality, the heritabilities are found to lie mostly between zero and one. (One formal definition of heritability is the ratio between the additive genotypic variance and the phenotypic variance.) Some examples of heritabilities of traits in different animals are given in Table 2.

Table 2: Some Heritability Estimates

trait	correlation
Cattle	
Butterfat percentage	0.6
Milk yield	0.3
Pigs	
Body length	0.5
Weight at 180 days	0.3
Litter size	0.15
Poultry	
Egg weight	0.6
Annual egg production	0.3
Body weight	0.2
Viability	0.1
Drosophila melanogaster	
Abdominal bristle number	0.5
Body size	0.4
Ovary size	0.3
Egg production	0.2

Heritability estimates

It is important to understand clearly the meaning of heritability estimates. They show that, given the range of the environments in which the experimental animals lived, one could predict the average body sizes in the progenies of pigs better than one could predict the average numbers of piglets in a litter. The heritability is, however, not an inherent or unchangeable property of each character. If one could make the environments more uniform, the heritabilities would rise, and with more diversified environments they would decrease. Similarly, in populations that are more variable genetically the heritabilities increase, and in genetically uniform ones they decrease. In man the situation is even more complex because the environments of the parents and of their children are in many ways interdependent. Suppose, for example, that one wishes to study the heritability of stature, weight, or susceptibility to tuberculosis. The stature, weight, and liability to contract tuberculosis depend to some extent on the quality of nutrition and generally on the economic well-being of the family. If no allowance is made for this fact, the heritability estimates arrived at may be spurious; such heritabilities have indeed been claimed for such things as administrative, legal, or military talents and for social eminence in general. It is evident that having socially eminent parents makes it easier for the children to achieve such eminence also; biological heredity may have little or nothing to do with this.

A general conclusion from the evidence now available may be stated as follows: diversity in almost any trait, physical, physiological, or behavioral, is due in part to genetic and in part to environmental variables. In any array of environments, individuals with more nearly similar genetic endowments are likely to show a greater average resemblance than the carriers of more diverse genetic endowments. It is, however, also true that in different environments the carriers of similar genetic endowments may grow, develop, and behave in different ways.

V. Changing heredity

HEREDITY AS A SOURCE OF CONSTANCY AND CHANGE

The essence of heredity is reproduction of the carriers of the genetic information, the genes. A very remarkable property of the chromosomal deoxyribonucleic acids, DNA, is precisely that these substances have a structure that permits the "messages" they contain, spelled in the "genetic alphabet," to be transcribed exactly in their copies. A dynamic stability, due to the repeated copying of the genetic information, is obviously essential in the hereditary materials. Without it, the complex machinery of the body, developed in the evolutionary history, could not be maintained. On the other hand, if the stability were complete and the self-reproduction of the genes always faultless, evolution could not occur; and life would still be like its primordial source, the first living substance that arose from the inorganic world. Although heredity is a conservative principle, its conservatism is balanced by occasional deviations from the precision of the copying mechanism of the hereditary materials. Such deviations result in mutations (*q.v.*).

USEFUL AND HARMFUL CHANGES

The significance of mutants

Newly arisen mutants are usually detrimental to their carriers. The classical *Drosophila* mutants are, in a sense, a collection of unfit types, most of them unable to survive in nature. Some mutations give rise to serious, or even fatal, hereditary diseases and malformations. Other mutations, studied chiefly in *Drosophila* flies, produce only slight changes in the appearance or physiology of their carriers; they act usually as subvital conditions, which in human genetics are best described as constitutional weaknesses or frail health. Minor mutations seem to be more frequent than the drastic ones; in *Drosophila,* subvitals are certainly more frequent than lethals. There is, however, no doubt—and on this point all competent geneticists are agreed no matter how divergent their opinions may be on other matters—that any increase of the mutation rates in human populations must be injurious to public health. This applies to the mutations induced by high-energy radiations as well as to the spontaneous mutations that arise without known exposures to mutagenic agents.

The fact that most mutations are deleterious may seem to contradict the fairly generally accepted view that the mutation process is the mainspring of evolutionary changes. It should, however, be kept in mind that every species faces not just one standard environment but environments diversified in time and in space. The different variants of a gene arising by mutation may, then, be favourable in some environments and unfavourable in others. The statement that a given mutation is favourable or unfavourable is, therefore, really meaningless if the environment is not specified. Consider the mutation that confers resistance to streptomycin in the colon bacteria. This mutation is useful indeed in an environment that includes streptomycin, for the nonmutants cannot survive at all. On a medium without streptomycin the resistant mutants not only have no advantage but some also are at a severe disadvantage because they cannot live without streptomycin in the medium. What was a poison to the original strain became a necessity to the mutant.

To find useful mutants, experiments must be arranged in one of two ways—either the organisms are placed in unusual environments or one starts with material already carrying a deleterious genetic condition (some sort of a hereditary weakness or malformation). With microorganisms, extensively studied classes of mutants are those that change the nutritional requirements. By placing bacteria or yeasts on culture media with food substances that the original genotype is unable to metabolize, one may select mutants that confer on their possessors such ability. With *Drosophila,* mutants that had originally a poor viability are often observed to improve when kept in laboratory cultures for many generations. It is possible to demonstrate that the improvement is due to selection of favourable mutants modifying the effects of the original mutant in a favourable direction.

The fact remains, nevertheless, that most mutations are harmful, some of them harmful perhaps under all conditions and in all environments. Uncontrolled accumulation of mutations would spell biological disaster—extinction of a species or population. It is basically a consequence of the fact mentioned above, that most mutations are accidents, "misspellings" of the genetic "messages." The mutation process does not, however, constitute evolution; it only supplies the raw materials from which evolutionary changes may be compounded. The compounding agent is natural (or artificial) selection.

VI. Heredity and evolution

Influences on heredity

In the study of heredity the first question that arises is how the genotype of an individual is formed from the constituents of the genotypes of his parents. This is the genetics of individuals or basic genetics. One may also inquire how the genotype in a fertilized egg cell influences the developmental pattern of the organism and thus realizes its potentialities. This is developmental genetics. An individual, at least an individual of a sexually reproducing species, is not, however, biologically complete in itself. Its biological role is actualized through its membership in a reproductive community, a Mendelian population. A Mendelian population consists of individuals among whom matings may or do occur. An individual is mortal and temporary; a Mendelian population has a continuity through time. The genetic processes in Mendelian populations are the subject matter of population genetics.

A Mendelian population is said to have a gene pool. The gene pool is the sum total of the genes carried by the individual members of the population. The gene pool also continues through time. The genes of the individuals of the generation now living come from a sample of the genes of the previous generation; if these individuals reproduce, their genes will pass into the gene pool of the following generations. The Mendelian population and its gene pool in man have a very complex structure. Individuals born and living close together are more likely to meet and to mate than those living far apart. In a widely distributed species such as mankind, the likelihood of mating of individuals born on different continents was, until the development of modern means of travel, very small. The gene pool of the human species is, accordingly, divided into the smaller gene pools of races and populations living in different regions. Aside from the geographic divisions, there are also linguistic, religious, social, economic, and educational barriers that break the gene pools into further, often overlapping, subdivisions. The smallest subdivision is referred to as an isolate or panmictic unit; it consists of a relatively limited number of persons (or animals or plants) that may be regarded as potential mates. Few of these divisions may be sharp enough to decide where one gene pool subdivision ends and the other begins, and yet these subdivisions are biologically meaningful.

A biological species, in sexually reproducing organisms, is defined as the most inclusive Mendelian population. The gene pool of mankind is an entity, the limits of which are not in doubt, since no gene exchange between the human and any other related species takes place. Nor does the intraspecific differentiation impair the unity. There may never have been a marriage of, for example, an Eskimo and a Melanesian, but genetic communications between the Eskimo and Melanesian gene pools occur through the chains of geographically intermediate populations. A genetic change arising anywhere in the world, if favourable, may spread throughout mankind. This is how genetic changes may have transformed the ancestral prehuman species into the present one. The genetic unity of mankind makes any genetic damage (*e.g.*, that caused by exposure to high-energy radiation) a common concern of all mankind, regardless of whether the damage is inflicted more heavily on one portion of the human population than on another.

G.H. Hardy and W. Weinberg independently formulated a theorem that became the foundation of popula-

The basis for population genetics

tion genetics. Two or more gene alleles will have the same frequency in the gene pool generation after generation, until some agent acts to change that frequency. Consider a population that is, as most human populations actually are, a mixture of individuals with M, N, and MN blood types. An individual with M blood is a homozygote with two M genes (MM), and N individual has two N genes (NN), and an MN individual is a heterozygote (MN). Suppose that a population consists of 49 percent of individuals with M, 42 percent with MN, and 9 percent with N bloods. What will be the frequencies of the blood types in the next and the following generations? Assume for simplicity that (1) marriages are at random with respect to the blood groups, (2) people with different blood groups have neither advantages nor disadvantages in survival or in reproduction, (3) the genes M and N do not change frequently by mutation, and (4) the population is large enough so that chance fluctuations may be ignored. Also assume that all individuals produce equal numbers of sex cells with each of the pair of alleles they carry and that the sex cells of the parents combine at random in fertilization. Persons with M blood produce sex cells with the allele M, and these sex cells will amount to 49 percent of the total. Persons with MN blood produce equal numbers of M- and of N-bearing sex cells—*i.e.*, 21 percent of each. Finally, persons with N blood will give N-bearing sex cells, 9 percent of the total. The gene pool will, therefore, contain 49 + 21 = 70 percent of M and 21 + 9 = 30 percent of N-type sex cells, or, using decimals, 0.7 M and 0.3 N, respectively. These sex cells will combine to produce the following blood types in individuals: 0.7 × 0.7 = 0.49, or 49 percent of M; 0.3 × 0.3, or 9 percent of N; and 2 × 0.7 × 0.3, or 42 percent of MN. Generalizing, if the proportions of M and N genes in the gene pool are p and q respectively, the frequencies of the blood groups will be, generation after generation:

$$p^2MM + 2pqMN + q^2M = 1$$

This is the Hardy–Weinberg formula, which describes the genetic equilibrium status in populations. The genetic composition of a population can meaningfully be described in terms of the frequencies of various alleles of the genes in the gene pool. Different populations of the same species are likely to differ in the frequencies of some, probably of many, genes. If the gene frequencies are different, the populations are racially distinct; if the differences are large, one may decide to give these populations different racial (or subspecific) names.

NATURAL SELECTION AND DARWINIAN FITNESS

If all gene frequencies remained constant in populations indefinitely, evolution could not take place. Evolution is, in the last analysis, change of gene frequencies (see EVOLUTION). The four assumptions made above in the discussion of the Hardy–Weinberg equilibrium are, of course, oversimplifications. The mating may be selective rather than random with respect to a given gene. Suppose that persons with M, MN, and N bloods prefer to marry individuals with a blood group the same as themselves. Selective mating will not, by itself, change the gene frequencies, but it will disturb the Hardy–Weinberg equilibrium in another way. The relative frequencies of the homozygotes (MM and NN) will increase from generation to generation, while those of the heterozygotes (MN) will decrease. Eventually the population will consist of homozygotes only. Preferential mating of unlike genotypes will, on the contrary, increase the incidence of the heterozygotes, but it will not, no matter how long continued, eliminate the homozygotes.

The carriers of some genes may survive more often or be more fecund or both than the carriers of other genes. When the carriers of different genes are not equally efficient in transmitting these genes to the succeeding generations, the result is natural selection. When the inequality of the transmission rates of the genes is imposed by man's will, the result is artificial selection. In general, the genes that confer on their possessors a superior reproductive efficiency will increase in frequencies from generation to generation, and the reproductively inferior genes will become less frequent. Let a gene allele A_1 have a frequency p and its alternative gene A_2 the frequency q in the gene pool. The values p and q are fractions, and $p + q = 1$. The formula is then:

Gene frequency

$$(1) \qquad p^2A_1A_1 + 2pqA_1A_2 + q^2A_2A_2 = 1.$$

Suppose that the relative numbers of the surviving progeny left by the carriers of the genotypes A_1A_1 and A_2A_2 are in the ratio 1 : 1 − s (the value s is called the selection coefficient). If for every 100 offspring of A_1A_1 parents only 90 surviving offspring are left by A_2A_2 parents, then s = 1/10 or 0.1. The heterozygotes, A_1A_2, may leave as many progeny as A_1A_1 (if A_1 is dominant) or as many as A_2A_2 (if A_2 is dominant) or an intermediate number (if neither is dominant). The Hardy–Weinberg formula is then modified thus:

$$(2) \qquad p^2A_1A_1 + 2pqA_1A_2 + q^2(1 - s)A_2A_2 = 1;$$
$$(3) \qquad p^2(1 - s)A_1A_1 + 2pqA_1A_2 + q^2A_2A_2 = 1;$$
$$(4) \qquad p^2A_1A_1 + 2pq(1 - hs)A_1A_2 + q^2(1 - s)A_2A_2 = 1.$$

The value h is the coefficient of dominance. The heterozygotes may exhibit the quality of hybrid vigour (heterosis) and be reproductively superior to both homozygotes A_1A_1 and A_2A_2. The expression is then:

$$(5) \qquad p^2(1 - s_1)A_1A_1 + 2pqA_1A_2 + q^2(1 - s_2)A_2A_2 = 1.$$

And finally (though this is rare except in species hybrids) the heterozygotes may be at a disadvantage compared to both homozygotes. The situation is simplest if the heterozygotes (A_1A_2) are equal in reproductive efficiency to one of the homozygotes or intermediate between the two (formulas 2–4 above). Whichever gene, A_1 or A_2, confers a superior reproductive efficiency on its possessors will increase in frequency in the population. The increase will continue generation after generation; given enough time (*i.e.*, enough generations) the more efficient gene will eliminate and supplant the less efficient one entirely. How rapid or slow the gene frequency changes will be depends on the magnitude of the selection coefficients. Table 3 gives some examples for a dominant allele, a recessive allele, and for no dominance—*i.e.*, for the case when the fitness of the heterozygote is intermediate between the two homozygotes. The two alleles in the population with which the selection starts are assumed to be equally frequent, $p = q = 0.5$. The selection coefficients of 1 (lethal), 0.5, 0.1, and 0.01 are considered, and the gene fre-

quencies after 1, 2, 5, 10, 20, 50, and 100 generations of such selection are given.

The homozygotes for a recessive gene allele may not reproduce at all. With natural selection this may happen because they are inviable (lethal) or sterile; with artificial selection the same result is accomplished if the breeder kills them or does not use them as parents. The recessive allele is then opposed by a selection s = 1. Table 3 shows that a gene with an initial frequency of 0.5 will decrease to 0.33 after one generation, to 0.25 after two, and to 0.01 after 100 generations. With weaker selection (s smaller than unity) the decrease of the recessive allele will, of course, be slower. Note, however, that in all cases the frequency change is more rapid when the gene is common than when it is rare. A dominant allele opposed by a selection s = 1 (a dominant lethal) disappears in a single generation, and even weaker selections against dominants are more efficient than similar selections against recessives. A selection in favour of a recessive is, of course, just the reverse of that against a dominant, and vice versa. The frequencies can be read from Table 3 by subtracting the frequencies given from unity. When the dominance is absent, the efficiency of selection is, as shown in Table 3, intermediate between those for recessives and for dominants.

The attainment of balanced polymorphism

A most interesting, and at first sight paradoxical, outcome of selection would arise if the heterozygote is superior to both homozygotes, as shown in equation 5. Neither the gene A_1 nor A_2 is allowed to crowd the other out or to disappear entirely. Instead, a genetic equilibrium is reached, and the population attains the state of the so-called balanced polymorphism. All three genotypes continue to occur in the population, with frequencies dependent on the relative magnitudes of the selection coefficients s_1 and s_2. This will be true even if one of the homozygotes is seriously incapacitated, inviable, or sterile. The possible importance of this in human populations is considered below.

Darwin's description of the process of natural selection as the survival of the fittest in the struggle for life is a metaphor. "Struggle" does not necessarily mean contention, strife, or combat; "survival" does not mean that ravages of death are needed to make the selection effective; and "fittest" is virtually never a single optimal genotype but rather an array of genotypes that collectively enhance population survival rather than extinction. All these considerations are most apposite to consideration of natural selection in man. Decreasing infant and childhood mortality rates do not necessarily mean that natural selection in the human species no longer operates. Theoretically, natural selection could be very effective if all the children born reached maturity. Two conditions are needed to make this theoretical possibility realized: first, variation in the number of children per family and, second, variation correlated with the genetic properties of the parents. Neither of these conditions is farfetched.

Darwinian fitness is sometimes referred to also as the adaptive value or the selective value; these terms are best treated as synonyms, although they may have somewhat different connotations. The Darwinian fitness of a genotype, or of a group of genotypes, is measured as the contribution of their carriers to the gene pool of the succeeding generation, relative to the contributions of other genotypes present in the same population. In the example given above, the Darwinian fitness of the genotype A_1A_1 was taken to be unity and the fitness of A_2A_2 as $1 - s$ or less than unity. The fitness is, of course, subject to change in different environments; the carriers of a genotype A_1A_1 may leave more surviving progeny than A_2A_2 in a certain environment, but the reverse may be the case in another environment. Darwinian fitness is reproductive fitness; bodily or mental vigour, health, and energy obviously contribute to this fitness but only insofar as they result in a superior reproductive capacity. Mules, no matter how strong and resistant, must be ranked zero in Darwinian fitness because they are sterile. The emphasis on reproductive success rather than on survival is characteristic of the modern concept of natural selection, as distinguished from the classical one. The difference is not, however, so great as it may seem at first glance; the carriers of a genotype evidently must survive in order to reproduce, and they must reproduce in order to survive in the next generation.

VARIETIES OF NATURAL SELECTION

There are several kinds of natural selection, rather different in their biological consequences and in their importance to man. The simplest of them is the normalizing selection, which was already known before Darwin but, of course, not under this name. Normalizing selection counteracts the accumulation in populations of hereditary diseases, malformations, and weaknesses. Suppose that a gene allele A_1, the carriers of which have a high Darwinian fitness, mutates to a state A_2, which lowers the fitness. If A_2 is a dominant lethal or a gene that renders its carriers sterile, then (as shown in Table 3 column s = 1.0) all the A_2 mutants will be eliminated in the same generation in which they arise. A new crop of mutants will, of course, appear in the next generation. If, however, the selection is not so completely efficient, some mutant genes will escape its dragnet and will be transmitted to the next generation. That generation will contain all the newly arisen mutants, a part of the mutants that arose in the preceding generation, a smaller part of those having arisen two generations ago, etc. How great a "genetic load" of uneliminated mutants a population can accumulate will depend principally on two factors—how often the mutation arises and how much it lowers the Darwinian fitness.

Normalizing selection

Simple formulas have been worked out to describe the situations that arise. Suppose that a deleterious mutation from $A_1 \rightarrow A_2$ occurs at a rate u per generation. Suppose further that the mutant is discriminated against by a selection coefficient s. If, then, the mutant A_2 is dominant to the original state, A_1, the frequency of A_2 in the gene pool will be u/s. If A_2 is recessive to A_1, its accumulated frequency will be much higher, namely $\sqrt{u/s}$. The reason deleterious recessive mutants are allowed to attain higher frequencies than equally deleterious dominants is simple: a recessive mutant may be carried in many heterozygotes, in which it does not express itself, and is consequently protected, or sheltered, from the weeding-out action of natural selection. With mutants that are neither dominant nor recessive, the accumulation will be between u/s and $\sqrt{u/s}$.

All human populations doubtless carry genetic loads consisting of harmful mutant genes. This cannot be blamed entirely on culture, civilization, or on any other specifically human attributes. Populations of *Drosophila* flies and of other sexually reproducing organisms also carry genetic loads. The accumulation of the genetic loads is a necessary consequence of the occurrence of mutations, most of which are harmful but not always harmful enough to be eliminated immediately after they are produced. Harmful mutations are accumulated until the numbers of the respective mutant genes become equal to the numbers eliminated by natural selection in the same population. The population is then said to be in the state of "genetic equilibrium." H.J. Muller has termed the elimination of harmful mutants "genetic death." Genetic "death" is sometimes cruel, sometimes rather benign. The death of a child from a severe hereditary disease and the genetically conditioned failure to have one more child are both genetic "deaths." The higher the mutation rates, the more harmful the mutants produced and the more frequent the genetic deaths. In populations that have reached genetic equilibrium, the total number of genetic deaths will be equal to the total number of the mutations subject to normalizing natural selection.

Heterotic balancing selection

A very different form of natural selection is heterotic balancing selection. It occurs when the Darwinian fitness of a heterozygote exceeds the fitness of both homozygotes, a situation mentioned above in equation 5. Heterotic balancing selection also leads to genetic equilibrium but not to an equilibrium between mutation and the normalizing selection. The balanced polymorphism that is es-

tablished is due to the selection favouring the heterozygotes against the homozygotes. In a sexually reproducing population the heterozygotes tend, however, to produce a fresh crop of homozygotes in every generation. The maintenance in human populations of such grave hereditary diseases as thalassemia and sickle-cell anemia is apparently due to this form of selection. The homozygotes for the sickle-cell and thalassemia genes are lethal; their Darwinian fitness is zero, and they are discriminated against by selection coefficients $s_2 = 1$. But while the homozygotes are lethal, the heterozygote for the sickle-cell gene has a higher fitness than the "normal" homozygote in countries in which falciparum malaria is endemic, apparently because of its relatively greater resistance to that disease.

In malarial environments, populations that contain some thalassemia and sickle-cell anemia genes, therefore, have advantages over populations free of these genes. The former populations are in less danger from the ravages of malaria, although they "pay" for this advantage by sacrificing in every generation some individuals who die of anemia. This advantage, of course, does not hold in countries in which falciparum malaria is rare or absent. Populations native in these countries have, as expected, few or no thalassemia or sickle-cell genes. The lethal diseases caused by homozygosity for these genes certainly bring about some "genetic deaths"; they are a part of the genetic load of the populations. But this genetic load, due to a disadvantage of being homozygous for certain genes, is very different from the mutational load controlled by the normalizing selection. The former is maintained by the heterotic balancing selection, while the latter is maintained by recurrent mutation.

Diversifying selection

Another form of natural selection is diversifying, or disruptive, selection. In many discussions and mathematical analyses of selection this simplifying assumption is adopted: that the environment in which a population lives is uniform and that the selection advantages and disadvantages of different genotypes are independent of their frequencies in the population. This simplification, however, flies in the face of reality. Many animals can subsist on a variety of foods; many plants grow on different soils; humans have to fill many different employments, functions, professions, and social roles. It is most likely that some genotypes will be fitter in some environments than they are in other environments. Diversifying selection will then favour different genotypes in different subenvironments, or ecological niches, that occur in the population.

A special form of selection occurs in mammals due to the incompatibility of certain maternal genotypes with those of their unborn children. The best studied case in man is that of a Rhesus-positive fetus in a Rhesus-negative mother (see BLOOD GROUPS). This selection should, theoretically, make the entire population either Rhesus positive or Rhesus negative. It does not appear to be doing this for reasons that have not been clarified. Another special kind of selection is that due to so-called meiotic drives, disturbances of the Mendelian segregation mechanisms, which result in sex cells carrying certain gene alleles being more or less frequent than expected on a random basis. The last to be mentioned, but in the long run possibly the most important form of selection, is directional selection. Suppose that the climate becomes warmer or cooler, that there appears a new source of food or a new predator or disease, or that there occur some other prominent environmental changes. Some genotypes will, then, become more favourable and others less favourable. Directional natural selection will operate to reconstruct the gene pool of the population in accord with the demands of the new environment.

NATURAL SELECTION IN OPERATION

When the antibiotic streptomycin is added in a sufficient concentration to a culture of colon bacteria, only the streptomycin-resistant mutants are able to reproduce, while the streptomycin-sensitive cells are eliminated. If an experimenter adds the streptomycin to a culture in order to obtain resistant strains of the bacteria, he is effecting artificial selection. Natural selection acts, however, very much in the same fashion. Widespread and often rather indiscriminate utilization of antibiotics against various infectious micro-organisms led to quite unintended consequences—the appearance of numerous "drug-fast" infections. In some instances (as with gonorrhea in some countries) the treatment with penicillin, originally very effectual, became less reliable or even useless as selection brought about a drug-resistant strain of gonococci.

Genetic resistance to DDT

Essentially the same process took place with considerably more complex organisms, various insect pests, in response to the introduction of certain highly potent insecticides. The first such insecticide, DDT, was used on a large scale during and after World War II. The discovery of DDT, followed by invention of many other insecticides of similar or even greater potency (see PEST CONTROL), led to widespread hope of eradication of all insect pests. This enthusiasm was short lived, since by 1947 DDT-resistant populations of the housefly were recorded in Italy and soon thereafter in other countries. It apparently takes the fly only two to three years to evolve a genetically conditioned resistance to DDT, and similar resistances arise against other insecticides as well. During the Korean conflict DDT-resistant lice emerged. Attempts to eradicate malaria-bearing mosquitoes by DDT sprays resulted in DDT-resistant mosquito populations. Laboratory experiments with *Drosophila* and with houseflies have shown that one can artificially select for insecticide resistance. Moreover, there are apparently genetically different resistant strains, some differing from the sensitive ones by a single gene with a strong effect and others by accumulation of several genetic changes, each taken separately increasing the resistance only slightly but giving strong resistance in the aggregate.

A black mutant of the peppered moth (*Biston betularia*) was found at Manchester, England, in 1848. Until that time the prevalent form of this species was light gray with dark speckles. The frequency of the black variant rapidly increased in the immediate area and reached about 99 percent by 1898. Dark coloration, melanism, has arisen and spread in many species of British moths belonging to different genera and families. The spread of the melanic forms was most rapid in and near industrial areas, where the foliage and the tree trunks are blackened with soot and other atmospheric pollutants. The spread of the dark forms is consequently known as industrial melanism. The light form of *Biston betularia* is protectively coloured when resting on tree trunks covered with lichens but conspicuous on blackened trunks on which the lichens have been largely destroyed by pollution. The selective agents are the insectivorous birds that feed on the moths; they find the light moths easily on dark tree bark and the black moths easily on light tree trunks. H.B.D. Kettlewell has verified the hypothesis by exposing known numbers of light and of melanic moths in localities with blackened and with unpolluted vegetation. A greater proportion of the blacks than of the whites remained alive and were recaptured on dark vegetation, and the opposite was observed on the unpolluted vegetation. Genetically, the difference between the light and the melanic forms has been shown to be due to a single gene, the allele for melanism being dominant to that for the light coloration.

Plant genes modified by man

Plants that grow in man-made or man-modified habitats are often different from their wild relatives and different in ways that adapt them to survive and reproduce in their respective habitats. *Camelina sativa*, a plant of the mustard family, is a common weed in fields of cultivated flax in Europe. The *Camelina* that contaminates the flax fields is, however, genetically different in several ways from that growing outside the fields. *Camelina* outside flax fields is a low-growing, branched plant with small seeds; that growing in flax fields is much taller, unbranched, and with larger seeds that resemble those of the flax in size and in specific gravity. The characteristics of *Camelina* growing in flax fields are such that it is harvested together with the flax, and its seeds remain with

those of flax during the winnowing process. The variety in the flax fields is doubtless derived from the original form now found growing freely; the remarkable adaptations that are found in the former have, then, developed since man started to plant flax on fairly large scales. Genetically, the varieties of *Camelina* differ from each other in several, probably in many genes. The process of natural selection—incidentally abetted by man—has, thus, created a new adaptive genetic system.

The examples of drug resistance in bacteria, pesticide resistance in insects, and industrial melanism in moths all involve directional natural selection, which, if continued long enough, leads to replacement of old gene alleles by new ones. Balancing natural selection has a different biological function—it maintains genetic diversity, or polymorphism, in populations. Selection pressures involved in balancing selection in nature are sometimes quite high. This is very useful to those engaged in research on selection, since it is evidently easier to detect strong selection than weak selection.

Striking examples of heterotic balancing selection have been found in nature in populations of some *Drosophila*. Many species of *Drosophila* are polymorphic for gene arrangements in their chromosomes; two or more kinds of chromosomes differing in inversions of blocks of genes occur in the same population. The carriers of the different chromosomes interbreed freely, and both homokaryotypes (two chromosomes of a pair with the same gene arrangement) and heterokaryotypes (the chromosomes of a pair with different arrangements) occur in different individuals. Some populations of *Drosophila pseudoobscura* in the western United States undergo cyclic seasonal changes in the frequencies of the chromosomal variants. The kinds of chromosomes denoted *ST* are relatively common in spring and autumn and rare in June; the chromosomes with the gene arrangement *CH* are, on the contrary, common in midsummer and relatively rare in spring and in autumn. The changes observed in nature can be reproduced in laboratory experiments. Experimental populations can be created with any desired frequencies of the chromosomal variants and can be left breeding freely for many generations. Samples are taken from time to time to determine the frequencies of the different kinds of chromosomes by microscopic examination, and the selection coefficients and the Darwinian fitnesses of the karyotypes can be calculated. As a rule, the heterokaryotypes show heterosis, fitness greater than in the homokaryotypes; selection coefficients of the order of 0.5 and even higher are often encountered.

GENETICS OF RACE AND SPECIES DIFFERENCES

The nature and origin of races and species are dealt with in other articles (see EVOLUTION; and SPECIES AND SPECIATION). Here it is necessary to consider only the genetic composition of the race and species differences in sexually reproducing and outbreeding organisms. In naturally occurring populations a species may split into races because of a gradual geographical separation and eventual rift between formerly interbreeding groups. Such races, which inhabit different territories, are called allopatric. If these races are brought together, they assume a sympatric status, interbreed, exchange genes, and fuse into a single genetically variable population. Races of man and of certain parasites are exceptional because they can coexist, at least for a time, sympatrically. In man social rather than geographical or biological factors slow down interbreeding and race fusion. Distinct species may, on the other hand, be either allopatric or sympatric. The exchange of genes between species populations is prevented not only by geographic distance (as with races) but also by genetically based reproductive isolating mechanisms. Reproductive isolation is achieved by a variety of means: differences in preferred habitats, in breeding seasons, in sexual attraction and courtship rites, in sexual structures (flowers in plants and genitalia in animal); incompatibility of sex cells; inviability of the hybrid progenies; sterility of the hybrids; and weakness of the gene recombination products of the gene complements of the species.

Types of races

Race differences are more often quantitative than qualitative; racially distinct populations of a species differ usually in the frequency of certain genes rather than the presence or absence of certain genes. Studies on blood groups in man have revealed some most instructive situations. The four "classical" blood groups O, A, B, and AB are due to three alleles of a gene. Most human populations have individuals of all four types, and even parents and children, as well as brothers and sisters, may belong to different blood groups. However, some blood groups, and hence the gene alleles that produce them, are more frequent in some countries than in others. The gene for A blood, for example, increases in frequency from east to west in Europe; B blood is most frequent in some populations of India, Tibet, Mongolia, and Siberia. A majority of American Indians apparently had, before the arrival of Europeans and Africans, the O blood group only; however, the tribes of the Blackfoot and Bloods had the highest known frequencies of A blood, which is also very frequent among the Lapps in northern Europe (see also BLOOD GROUPS).

Human races differ certainly in many genetic traits, not in blood groups alone. Many genetic differences are the rule also between races of animals and plants (races are often referred to as subspecies in wild and as breeds or varieties in domesticated forms). The blood groups are, however, useful as a model to elucidate the genetic nature of race differences in general. Races are genetically open systems, and gene exchange between races does take place. Species, by contrast, are genetically closed systems in which gene exchange is rare or absent. Race differentiation is reversible; hybridization or intermarriage may cause races to merge into a single population. It is an error to think that in a population resulting from race hybridization everybody will be alike; in point of fact, such hybrid populations show a remarkable diversity of individuals. Species differentiation is irreversible. Races are populations, and an individual may have a genetic endowment that can occur in two or more different races or that is not common in any race. An individual belongs, however, to only one species, unless he is a species hybrid. Mules, hybrids between the horse and donkey, are sterile because of abnormalities in the processes of sex-cell formation in their gonads. Sterility of hybrids between species, if viable hybrids between them can be obtained at all, is observed very frequently, though some experimentally obtained species hybrids have proved to be fertile.

The origin of racially distinct populations

What causes the development of the gene-frequency differences between populations that live in different territories; in other words, what makes these populations racially distinct? The probable explanation is that genetic differences between populations arise in most cases through natural selection in response to the local environments that prevail in the territories they inhabit. It is, however, very difficult to verify this explanation in many concrete instances of race differentiation. For example, it is probable that the dark skin pigmentation of many human populations that live, or have until recently lived, in tropical and subtropical countries protects them from sunburns. It is probable also that the light skin colours of the natives of Europe facilitate the acquisition of vitamin D in regions with deficient sunshine. The evidence for even these hypotheses is not as complete and conclusive as might be desired. But when it comes to such racial traits as hair form (straight, wavy, curly, or frizzly), shapes of the nose, of the lips, of the cheekbones, etc., no acceptable evidence of their adaptive significance is available. The situation is no better with races of animals and plants: while some differences are certainly, or at least probably, adaptive, for most of them the adaptive significance is unknown.

Attempts have been made to envisage factors other than natural selection that could be responsible for genetic differentiation of populations. Appeals are frequently made to pleiotropism of the gene action; a visible race difference may in itself be neither adaptive nor unadaptive, yet it may be only an outward sign of an underlying physiological difference that is adaptively important. An elegant

example is the coloration of onions—red and purple bulbs are resistant to the attacks of a smudge fungus, while white bulbs are highly susceptible. A race trait may also be important as a sexual recognition mark, or it may play a role in the courtship ritual.

A most interesting possibility that should be seriously considered is that some differences between populations may be due to random genetic drift. One of the assumptions made in deducing the Hardy–Weinberg equilibrium theorem was that the population is infinitely large, or at least large enough so that chance events will not be seriously disturbing. Suppose, however, that a species lives in many isolated colonies, some of them consisting of only tens or perhaps hundreds of individuals. In such small colonies the number of individuals that inherit the gene allele *A* rather than *a* may, owing to chance alone, be in some generation relatively higher or lower than in a preceding generation. Gene frequencies in the different colonies will drift apart; in some colonies the allele *A* may become rare or may be lost altogether, while in other colonies it will be the allele *a* that will diminish in frequency or be eliminated. How important this random genetic drift may be in race differentiation is controversial. That genetic drift does occur is certain; a simple example is that in small villages a sizable fraction of the inhabitants sometimes have the same surname, and different surnames are frequent in different villages. Increasing or decreasing frequencies of the surnames evidently go together with increases or decreases of the frequencies of certain genes that the ancestors of the people with these surnames carried. Another situation in which genetic drift is likely to take place is when just one pregnant female or a small group of individuals colonizes a hitherto uninhabited island or an isolated mountain or lake area. The genes brought by the founders of new colonies will often be small, atypical, and often unbalanced samples of the gene pools of the populations whence they came. When the populations of the new colonies expand, they will be found to differ genetically from each other and from the ancestral population. Natural selection will then come into operation, giving rise to new balanced gene pools. This "founder principle" was probably important in the development of some human populations. Many tribes and local races may be the descendants of small numbers of original migrants and settlers. Whether the random genetic drift alone can explain the origin of the gene complexes that differentiate races or species is very doubtful. The point is, however, that genetic drift and natural selection are not mutually exclusive alternatives; it is not one or the other but the interaction of both that brings about race differentiation. The founder principle is a special case of random genetic drift. The gene pool of a colony derived from a single immigrant or several pairs of immigrants may need a restructuring by natural selection to become properly adapted to the new environment.

THE SUDDEN ORIGIN OF NEW SPECIES

The question is sometimes asked whether a new biological species has ever been observed to arise or whether all experimentally observed evolutionary changes have been only on intraspecific levels. There are at least two types of species formation, and one of them is rapid enough to be experimentally observable. Races (subspecies) of the same species differ in frequencies not of one but of several or many genes. Distinct species differ doubtless in still more genes, although in just how many cannot be determined exactly. The complexity of the species differentials is, however, demonstrable in those rather exceptional cases when fertile hybrids between species can be obtained in experiments and a second hybrid generation raised in large enough numbers and carefully studied. In such interspecific hybrid progenies an extraordinary diversity is often found; no two individuals are quite alike, and some specimens exhibit peculiar combinations of traits that render them sometimes strikingly different from both parental species and from the first generation hybrids. All this indicates that distinct species carry different, harmoniously balanced systems of genes.

Complexity of species differences

Mixtures and recombinations of the components of these balanced systems give rise to genotypes, most of which are poorly adapted, but a few of which result in satisfactory or even superior fitness. The gene exchange between species is impeded or excluded altogether by reproductive isolating barriers. The biological function of these barriers is limitation or prevention of the appearance of ill-adapted gene combinations.

The process of race (subspecies) formation consists, then, of accumulation of genetic differences, most of them adaptive to the environments these races inhabit. The process of species formation (speciation) consists, in addition, of building reproductive isolating barriers, which takes many generations. It is not surprising, therefore, that this kind of speciation is not fully reproducible in laboratory experiments, although some beginning steps in this direction have been made. New species may, however, arise suddenly, in a single leap, by doubling the chromosome complement in hybrids between two other pre-existing species. This form of speciation is fairly common in many families of plants, much less so in animals (see SPECIES AND SPECIATION).

VII. Heredity and applied science

MEDICO-LEGAL APPLICATIONS AND GENETIC COUNSELLING

Heredity and variation are basic functions of living organisms, and they can be studied regardless of any prospects of technological or other practical applications of the knowledge thus gained. And yet the relevance and applicability of genetics to human affairs is expanding rapidly. It is within the realm of possibility that genetics will become the most important of all applied sciences if it comes to be used to improve man and to direct the evolution of mankind. Genetic engineering may, conceivably, become the pre-eminent form of engineering. These grand and imposing developments are, however, mostly in the future, but some relatively modest applications are even now being used.

Disputed paternity is one of the forensic problems that may sometimes be elucidated by genetic deductions. A man being sued in court for support of a child of whom he does not consider himself the father may seek a "paternity exclusion." In a notorious case in which justice obviously was not done, a well-known actor, whose blood was group O, was forced to pay the attorney's fees and support a child with group B blood, whose mother had A blood. Excepting the extremely unlikely possibility of mutation, an O father (*OO* genotype) and an A mother (either *AA* or *AO*) could not produce a B child because neither of them has a *B* gene to contribute. More recently courts have accepted blood tests as evidence in disputed paternity cases. Note should, however, be taken that while exclusion of paternity can be established, no known tests can affirm that a man X is the father of a child Y, because there may always be more than a single person who carries the same testable genes as X.

The importance of genetic counselling

A geneticist is often asked for an assessment of the chances of birth of genetically handicapped children to prospective parents. The variety of problems that come up in such inquiries is endless, and no geneticist in the world is competent enough to solve all of them. There are hundreds of diseases and malformations in the production of which genetic variables play a part, but all too often the mode of inheritance of these defects (*i.e.*, dominance, recessivity, sex linkage, penetrance, etc.) is not precisely known. The demand for genetic counselling is, however, so widespread and frequently so urgent that more and more so-called heredity clinics and counselling centres are appearing, attached usually to universities and medical schools. In some instances reasonably clear-cut answers can, of course, be given. Suppose, for instance, that a prospective parent is himself healthy but has one or more siblings with a defect or a disease known to be inherited as a simple dominant Mendelian trait. Provided that the dominant gene in question has complete penetrance, the parent can be assured that he is just as unlikely to transmit the respective defects to his children as are persons with no known relatives with these defects.

The prognosis is less reassuring if the parent himself is a carrier of a dominant genetic defect, for in this case the chances are even that any child of his will or will not inherit that defect. The genetic risks are less with recessive defects, such as albinism or phenylketonuria or infantile amaurotic idiocy. A couple that has already produced one affected child stands one chance in four of conceiving another child similarly affected (of course, three out of four chances are that the next child will be unaffected, but in cases of this sort the dire consequence is the pressing one). Whether the counsellor should recommend to a couple that they refrain from having more children is another question; perhaps the wisest course is to explain the situation as clearly as possible and leave the decision to the prospective parents themselves. If they do have more children, they will at least be aware of the risk and be prepared for what may be in store. If recessive defects are found in the relatives of one or both prospective parents, the advice has to be even less confident but more optimistic, since the likelihood of both prospective parents being heterozygous carriers may be quite small. The matter can be clarified better with those recessive diseases that (as is the case with phenylketonuria) render the heterozygous carriers recognizable by certain biochemical tests. If at least one of the parents to be is a noncarrier, the risk is reassuringly small. The predicament of a genetic counsellor is greatest with several widespread and grave diseases, which rather certainly have a genetic basis but the inheritance of which has not been sufficiently clarified. Here belong such genetic puzzles as schizophrenia, various allergies, and predispositions to heart disease and to cancer.

OUTBREEDING AND INBREEDING

Man is an outbreeding species. Marriages between close relatives are forbidden by custom and by law in most human societies. Whether the prohibition was introduced because people knew that incest or inbreeding is detrimental is questionable (see CONSANGUINITY). The prohibition may seem reasonable, however, in view of the evidence accumulated by practical breeders and geneticists. In normally outbreeding species, the progenies of matings in which the parents are close relatives tend to be less vigorous than the offspring of unrelated parents. This is a consequence of the genetic loads of deleterious recessive genes carried in populations. A recessive gene is more or less innocuous in the heterozygous condition, but its chances of becoming homozygous are greater in the offspring of parents who are close relatives (and therefore have more similar genotypes) than in families where the parents are not closely related.

The effects of outbreeding and inbreeding

It is worthwhile to stress at this point that the effects of outbreeding and inbreeding on the vigour, viability, and fertility of the offspring depend upon the reproductive biology of the species or the population in which they occur. Outbreeding is not invariably or necessarily invigorating, nor is inbreeding invariably or necessarily debilitating. Wheat is an example of a plant that is predominantly self-pollinating. Self-pollination is, of course, the closest possible form of inbreeding, but this inbreeding does not progressively weaken the vigour of a wheat strain. The converse, however, is observed with corn (maize). Inbreeding decreases the yield, and the intercrossing of inbred lines restores hybrid vigour in the progeny. One may say that hybrid vigour (heterosis) is the normal state of a corn population, while inbreeding and a prevalance of homozygosis is the normal state in wheat. In species and populations in which the reproductive biology is adjusted to outbreeding, consanguinity leads to a decline in the average vigour and to the appearance of relatively many individuals with hereditary diseases and malformations. Just what kind of a malformation or ill health, if any, will appear in a given progeny depends on what deleterious recessive genes were carried by the common ancestor of the relatives who mate. This will certainly be different in different families. The histories of the reigning houses of Egypt and the Peruvian Incas, where the monarchs allegedly married their sisters, are not sufficiently well documented to conclude that in these instances the incestuous marriages resulted in no weakening of the progeny. High childhood mortality may have gone unrecorded; furthermore, "sister" may have been, in some instances, a title bestowed upon a person rather than indicative of an actual relationship.

It is important to study how much inbreeding depression will occur in a given species or population, and a great deal of information in this direction is being accumulated. With rare exceptions, the highest degree of consanguinity that occurs in mankind with appreciable frequency is marriage of first cousins, resulting in homozygosis of 6.25 percent of the genes in the progeny. A genetic counsellor would hardly be justified in discouraging all marriages of people known to be relatives, and yet he may point out that the chance of genetic weaknesses in the progeny of such marriages is measurably greater than when unrelated persons marry.

GENETIC LOAD AND HYBRID VIGOUR

How hereditary variability is maintained in populations of sexually reproducing species is an unsettled and controversial question. The classical theory assumes that the pressure of mutation generating detrimental genetic variants is the main factor. The balance theory, while not denying that some variability is maintained by recurrent mutation, considers that a far from negligible portion of the variability is preserved by natural selection. These two theories, though they are not incompatible alternatives, have interestingly different theoretical and even philosophical implications.

According to the classical theory, a majority of the genes a species has are fixed, uniform, and homozygous in most, or even in all, individuals. The minority of the genes that are not fixed are represented by two or more variant alleles. One allele of each gene is "normal," and it confers a high fitness on its possessors; the others are mutant, abnormal, and more or less deleterious. This view is logically connected with the conception of the "optimal" genotype. The optimal genotype is the one that contains only normal genes. Any deviation from the optimum genotype will be detrimental. Nevertheless, the process of mutation unrelentingly generates detrimental mutant genes, lowers fitness, and creates a genetic load. A genetic load can, in this view, be defined as the deviation of the observed fitness from that produced by the optimum genotype. The weakness of this definition is obvious: the optimum genotype is operationally elusive; it cannot be located and its fitness cannot be measured.

The balance theory of population structure

The balance theory of population structure takes a somewhat more optimistic view. Not all genetic variability present in populations is a regrettable departure from the optimal genotype. Some of this variability is, on the contrary, an adaptive device that permits the population to secure a firmer hold on its environment. The environment is never uniform; it has a greater or lesser variety of ecological niches, opportunities for living that members of the population can exploit. A living species or population faces many diverse environments, not a single environment. Two genetic strategies are possible to cope with environmental complexity. First, there may be genotypes that react favourably in several environments. Second, there may be a variety of more or less specialized genotypes to match the variety of environments. Nature has used both strategies in the evolutionary process. A sexually reproducing population contains a variety of hereditary endowments. Most, and perhaps all, individuals may be heterozygous for many genes. Any gene that is rare will be carried in heterozygotes much more frequently than in homozygotes (except in highly inbred or self-fertilizing species). Natural selection operates in sexual populations chiefly with heterozygotes. It will tend to make the heterozygotes highly fit, even if the corresponding homozygotes are low in fitness. In other words, natural selection promotes hybrid vigour or heterosis and maintains the variant genes in a state of balanced polymorphism. It takes a variety of genetic endowments to make a world worth living in.

Natural selection cannot prevent the appearance of some individuals of inferior fitness. In a population in which no two individuals carry the same genes, it is not possible to describe the genetic load as the deviation from the optimal genotype. This latter will be represented by a single individual or not at all. An operationally meaningful measure of fitness is that of the average or norm for a given population. The pronounced negative deviants from this average may be considered as constituents of the genetic load and the positive deviants as the genetic elite. Between the genetic load and the genetic elite there is the adaptive norm comprising a majority of the genotypes that are formed. The division lines between the load, the adaptive norm, and the elite can only be established by a convention. For most purposes, the load and the elite should probably refer to fairly extreme negative or positive deviations from the population mean. One may, however, foresee that some genetic processes will cause these deviations to become more or less frequent. For example, a genetic radiation damage or a greater incidence of marriages between relatives would increase the expressed genetic load compared to what it is at present. Positive eugenics may attempt to expand the genetic elite in mankind.

The most impressive success scored to date, in attempts to utilize the genetic elite of an agricultural plant for increasing yields of a useful product, is represented by hybrid corn. Hybrid corn is obtained by artificially crossing inbred corn (maize) strains in order to exploit the phenomenon of hybrid vigour or heterosis.

GENETIC IMPROVEMENTS OF ANIMALS AND PLANTS

Hybrid corn is the most impressive but by no means the only achievement of genetics applied to agriculture. General accounts of ANIMAL BREEDING and PLANT BREEDING can be found in the articles under these titles. This section is concerned only with the genetic basis of the methods used in breeding programs. Attempts to emulate the methods that proved so successful with corn are being made in several species of crop plants as well as in domestic animals. The results look promising, especially with poultry and swine. It should be kept in mind that the inbreeding-heterosis technique is most likely to succeed with species that are normally cross-fertilizing and outbred and less so in habitually inbreeding or self-pollinating forms (like wheat, barley, and some other crop plants).

Artificial selection

The basic method of improvement is artificial selection. The genotypes that are selected are those that, when placed in suitable and economically feasible environments, induce in their carriers the qualities desired by the breeder. The improvement methods used in the breeding work must evidently be appropriate to the reproductive biology, the genetic population structure, and the economic value of the form to be improved. It is evidently impossible, for example, with large domestic animals such as cattle or horses to raise numbers of individuals from which selection is made comparable to that practicable with field crops. Collections of pedigrees, published in stud books for horses and in herd books for some breeds of cattle, are still regarded by commercial breeders as important in the choice of most prized animals. Progeny and sib testing are now being used more and more often as aids for evaluation of the breeding worth of individual animals. A quite different situation is encountered with some useful plants in which cross-pollination happens only rarely, and the normal method of propagation is self-pollination (as in most cereals, peas, beans, tomatoes, etc.) or parthenogenesis or asexual reproduction (sugar cane, bluegrass, bananas, many citrus fruits, etc.). Here the problem is to identify the individual, or a small group of individuals, with a desired combination of traits and to propagate them to form pure lines (progenies obtained by self-pollination) or clones (progenies obtained asexually). Some of the most valuable varieties of wheats are descended from a single seed progenitor.

Selection, artificial as well as natural, can operate only if genetic diversity exists among the materials available. In a genetically uniform pure line or a clone, selection is without effect. Provision of genetic variability is the prime concern for a breeder. A powerful means of inducing genetic variability is hybridization and Mendelian segregation in the hybrid progenies. Two lines, neither of which is particularly good, may produce valuable genotypes in segregating hybrid progenies. This is the reason that modern breeders frequently endeavour to collect primitive varieties from far-off lands and use them as materials for hybridization followed by selection. Many, if not most breeds and varieties, from thoroughbred horses to cultivated strawberries, are descended from hybrids of two or more ancient breeds or even of distinct species. The cultivated roses have genes from at least four wild ancestral species in their gene pool.

A promising new technique to speed up the improvement of useful plants and animals is induction of mutations that increase the amount of genetic variability available for selection. Although a decided majority of mutants are harmful, some exceptional ones may be useful.

IMPROVING MANKIND

Man has been remarkably successful in improving, for his benefit, the genetic endowments of his domesticated animals, cultivated plants, and even micro-organisms. The question inevitably presents itself whether man can succeed equally well in directing the evolution of his own species toward goals he regards as good and desirable. Man is the only organism on earth who is aware that he is a product and even the crowning achievement so far of the evolutionary process. The past evolution was a product of natural selection, a certain pattern of blind forces of nature. Can man gather enough knowledge and enough wisdom to substitute for these blind forces a conscious control of the ongoing evolution of mankind? The central idea of eugenics (*q.v.*) is that such a control is feasible. Ironically enough, thus far the progress of eugenical thought and public acceptance has been impeded more by its overzealous partisans than by its opponents. For decades it was held captive by race and class bigots, and its greatest perversion was its use as a sham justification of the genocidal policies of Nazi Germany. From time to time some fanatics predict mankind's degeneration and even extinction unless their pet eugenical schemes are put in practice without delay. It should, however, be evident that utmost care must be exercised in any attempts to tamper with the genetic endowment of mankind; for example, the implementation of some of the more bizarre eugenic recommendations of several decades ago would have been the worst sort of folly. And yet it is arguable that man will not be able to let his evolution drift uncontrolled much longer.

Negative and positive eugenics

Although there are not sharp dividing lines between them, negative and positive measures of genetic improvement can be distinguished. Negative eugenics is primarily directed toward elimination or, at any rate, reduction of the incidence of hereditary defects and diseases—in other words, toward control of the genetic load of mankind. Positive eugenics favours increasing the frequencies of superior hereditary endowments. Mankind, like any other biological species, has carried a genetic load since the dawn of time. It is claimed, however, that civilized living, technology, medicine, maintenance of the genetically handicapped, etc., increase man's genetic load. The total frequency of mutation in man is conservatively estimated as 10 percent; *i.e.*, at least 10 percent of the sex cells produced carry a newly arisen mutant in every generation. Since, in addition, the mutation rates of human genes are probably increasing as a result of exposure to high-energy radiations and other mutagens, some authorities have expressed alarm concerning the genetic prospect of the human species.

A variety of proposals have been advanced to decrease the genetic load or at any rate to check its increase. It is evident that one way to decrease the frequency of mutation is by avoiding all unnecessary exposure to high-energy radiations and other mutagens. Genetic counsel-

ling could be quite important if it were to become widespread or universal. If known or probable carriers of defective genes were informed of the probable consequences of their begetting children, perhaps some of them would draw the practical conclusions from the information made available to them. More radical proposals would have the carriers of defective genes sterilized or otherwise prevented from reproducing. The effectiveness of such a measure is in doubt because recessive defects are carried mainly in heterozygotes and would escape detection and sterilization, while the dominant hereditary diseases are due mostly to new mutations.

The basic difficulty is, however, that it may not always be easy to decide what artificial selection should select. Does anyone know what will be the best genotype for mankind centuries or millennia hence? In general, dominant defects give rise to the fewest doubts. One can hardly imagine circumstances in which such hereditary disorders as dominant muscular dystrophy, aniridia, multiple polyposis of the colon, or neurofibromatosis may be useful. With recessive defects the thorny question has to be faced whether they are maintained in populations only by the mutation pressure or also by increased fitness of the heterozygous carriers—*i.e.*, by attendant hybrid vigour or heterosis. Mankind free of a genetic load may be not only unattainable but also unacceptable. It may turn out to be a uniformly dull population none of whose members exhibit either great physical or mental vigour.

The claims made by some authorities that selection does not and cannot operate in modern mankind or that decreasing infant and childhood mortalities have done away with selection cannot be accepted without critical examination. The Darwinian fitness of a genotype is defined as its contribution to the gene pool of the following generation relative to the contributions of other genotypes. Differential mortality and differential fertility are, in principle, equivalent as far as selection is concerned. Natural selection can occur either because the carriers of different genotypes produce unequal average numbers of children or because different proportions of the children produced survive or because of any combination of these differences (except, of course, for the possibility that an advantage in fertility is exactly counterbalanced by a disadvantage in survival or vice versa). Decreasing birthrates and childhood mortalities have not necessarily abolished selection, but the direction of the selection in human populations may be undergoing radical changes. Whether selection is at present moving in a beneficial or a detrimental direction is a different issue. Some authorities viewed with alarm the fact that, at least in Western societies, persons with higher intelligence (as measured by intelligence, IQ, tests) have on the average fewer children than persons of lower intelligence. Predictions were made of inevitable decline of the average intelligence with time. Actual surveys have failed to bear out these predictions.

Euthenics and euphenics

Eugenical measures leading to genetic improvements must be accompanied by improvement of the environment in both physical and cultural aspects (euthenics) and by management of the developmental patterns of individual humans (euphenics). No genetic endowment can produce optimal results regardless of the environments in which its carriers are placed. The spectacular advances of the biological sciences have produced optimistic expectations of even more splendid advances to come. Several possibilities can be mentioned, although it is impossible to predict when, if at all, they will be realized. One has been labelled algeny, or "genetic surgery"—*i.e.*, deliberate modification of specific genes or implantation of desired new genes into chromosomes. Transformation and transduction have, indeed, been realized in some micro-organisms; and it is possible, at least in principle, that this kind of directed genetic change may someday be practicable in higher organisms, including man. The potency of genetic surgery for genetic improvement of mankind may, indeed, permit achievements far beyond the reach of the genetic techniques presently available. A variety of instruments for euphenic betterment (developmental engineering) may conceivably become available in the near future. Suppression of the action of undesirable genes and stimulation of that of desirable genes may be a most powerful means for controlling phenotypes that develop from genetically defective genotypes or for stimulating genotypes whose potentialities are hidden. Transplantation of organs to replace those injured by accidents or worn out is another possibility. Such organs may be taken either from people who die accidentally or because of faults in other organs or conceivably from animals bred especially for that purpose. Mechanical aids or prostheses (substitutes) for human organs or limbs may be improved. All this may increase human longevity and decrease the deterioration now unavoidable with aging. Last but not least and probably the most urgent is management and regulation of population growth by reliable, as well as emotionally and aesthetically acceptable, family-planning techniques. It is arguable that the avoidance of a disastrous "population explosion" is the prime necessity to make any genetic improvement of mankind really beneficial.

Herod I the Great

Herod I the Great, king of Judaea under the Romans and founder of the Herodian house, played a major role in Near Eastern affairs in the 1st century BC, but is probably best known as the tyrant portrayed in the New Testament.

Herod was born in 73 BC in southern Palestine; his father, Antipater, was an Edomite (an Arab from the region between the Dead Sea and the Gulf of Aqaba). Antipater was a man of great influence and wealth, who increased both by marrying the daughter of a noble from Petra (in southwest Jordan), at that time the capital of the rising Nabataean kingdom. Thus Herod was, although a practicing Jew, of Arab origin on both sides.

When Pompey (106–48 BC) invaded Palestine in 63 BC, Antipater supported his campaign and began a long association with Rome, from which both he and Herod were to benefit. Six years later Herod met Mark Antony, whose lifelong friend he was to remain. Julius Caesar also favoured the family; he appointed Antipater procurator of Judaea in 47 BC and conferred on him Roman citizenship, an honour that descended to Herod and his children. Herod made his political debut in the same year, when his father appointed him governor of Galilee. Six years later Mark Antony made him tetrarch of Galilee. In 40 BC the Parthians invaded Palestine, civil war broke out, and Herod was forced to flee to Rome. The senate there nominated him king of Judaea and equipped him with an army to make good his claim. In the year 37 BC, at the age of 36, Herod became unchallenged ruler of Judaea, a position he was to maintain for 32 years. To further solidify his power, he divorced his first wife Doris, sent her and his son away from court, and married Mariame, a Hasmonean princess. Although the union was directed at ending his feud with the Hasmoneans, a priestly family of Jewish leaders, he was deeply in love with Mariame.

King of Judaea

During the conflict between the two triumvirs Octavian

and Antony, the heirs to Caesar's power, Herod supported his friend Antony. He continued to do so even when Antony's mistress, Cleopatra, the queen of Egypt, used her influence with Antony to gain much of Herod's best land. After Antony's final defeat at Actium in 31 BC, he frankly confessed to the victorious Octavian which side he had taken. Octavian, who had met Herod in Rome, knew that he was the one man to rule Palestine as Rome wanted it ruled and confirmed him king. He also restored to Herod the land Cleopatra had taken. Herod became the close friend of Augustus' great minister Marcus Vipsanius Agrippa, after whom one of his grandsons and one of his great-grandsons were named. Both Emperor and Minister paid him state visits, and Herod twice again visited Italy. Augustus gave him the oversight of the Cyprus copper mines, with a half share in the profits. He twice increased Herod's territory, in the years 22 and 20 BC, so that it came to include not only Palestine but parts of what are now the kingdom of Jordan to the east of the river and southern Lebanon and Syria. He had intended to bestow the Nabataean kingdom on Herod as well, but by the time that throne fell vacant. Herod's mental and physical deterioration made it impossible.

Herod endowed his realm with massive fortresses and splendid cities, of which the two greatest were new, and largely pagan, foundations: the port of Caesarea Palaestinae on the coast between Joppa (Jaffa) and Haifa, which was afterward to become the capital of Roman Palestine; and Sebaste on the long-desolate site of ancient Samaria. In Jerusalem he built the fortress of Antonia, portions of which may still be seen beneath the convents on the Via Dolorosa, and a magnificent palace (of which part survives in the citadel). His most grandiose creation was the Temple, which he wholly rebuilt. The great outer court, 35 acres (14 hectares) in extent, is still visible as Al-Ḥaram ash-Sharīf. He also embellished foreign cities: Beirut, Damascus, Antioch, Rhodes, and other towns. Herod patronized the Olympic Games, whose president he became. In his own kingdom he could not give full rein to his love of magnificence, for fear of offending the Pharisees, the leading faction of Judaism, with whom he was always in conflict because they regarded him as a foreigner. Herod undoubtedly saw himself not merely as the patron of grateful pagans but also as the protector of Jewry outside of Palestine, whose Gentile hosts he did all in his power to conciliate.

Mental disorder

Unfortunately, there was a dark and cruel streak in Herod's character that showed itself increasingly as he grew older. His mental instability, moreover, was fed by the intrigue and deception that went on within his own family. Deeply in love with Mariame, he was prone to violent attacks of jealousy; his sister Salome (not to be confused with her great-niece, Herodias' daughter) made good use of his natural suspicions and poisoned his mind against his wife in order to wreck the union. In the end Herod murdered Mariame, her two sons, her brother, her grandfather, and her mother, a woman of the vilest stamp who had often aided Salome's schemes. Besides Doris and Mariame, Herod had eight other wives and had children by six of them. He had 14 children.

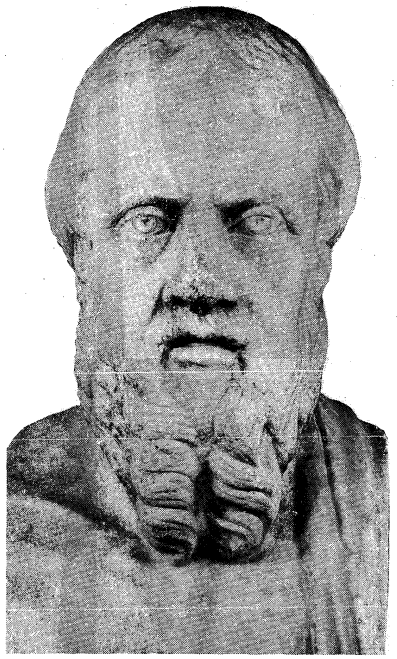
In his last years Herod suffered from arteriosclerosis. He had to repress a revolt, became involved in a quarrel with his Nabataean neighbours, and finally lost the favour of Augustus. He was in great pain and in mental and physical disorder. He altered his will three times and finally disinherited and killed his firstborn, Antipater. The slaying, shortly before his death, of the infants of Bethlehem was wholly consistent with the disarray into which he had fallen. After an unsuccessful attempt at suicide, Herod died at Jericho at the end of March or beginning of April in 4 BC. His final testament provided that, subject to Augustus' sanction, his realm would be divided among his sons: Archelaus should be king of Judaea and Samaria, with Philip and Antipas sharing the remainder as tetrarchs.

BIBLIOGRAPHY. FLAVIUS JOSEPHUS, the Jewish historian who was of priestly descent, wrote a detailed and vivid account of Herod and his times in his *Antiquities*, XV, XVI, XVII, 1–8. *Josephus*, available in many English editions, of which the Loeb, 9 vol. (1926–65), is the latest and best, is the foundation for all later work on Herod. A.H.M. JONES, *The Herods of Judaea* (1938), is a scholar's appreciation. The article "Herodes" in *Pauly-Wissowa Real-Encyclopädie*, suppl. vol. 2, pp. 1–199 (1913), is particularly valuable for its complete family tree. STEWART PEROWNE, *The Life and Times of Herod the Great* (1956), is the work of one who knew intimately the topography of all of Herod's many architectural creations. MICHAEL GRANT, *Herod the Great* (1971), is a beautifully illustrated book by a scholar of international standing.

(S.H.P.)

Herodotus

A Greek historian living in the 5th century BC, Herodotus wrote a history of the Greco-Persian Wars that stands as the first great narrative and critical history in the ancient world. No biography of Herodotus has come down from antiquity, nor is it likely that any was written until long after his death. Scattered references have survived from later classical authors, and a short article has survived in a 10th-century Byzantine lexicon called the *Suda*. The most important source on Herodotus' life is the *History* itself.



Herodotus, Roman herm probably copied from a Greek original of the first half of the 4th century BC. In the Museo Archeologico Nazionale, Naples.

It is believed that Herodotus was born (perhaps in 484 BC) of a prominent family in Halicarnassus, in Asia Minor. He was exiled from that city by the tyrant Lygdamis but returned later to help overthrow the tyranny and restore constitutional government. Also, it is said that Herodotus was related to the epic poet Panyasis, that he spent a considerable time on the island of Samos, and that eventually, despite his services to his native city, he became so unpopular that he decided to leave Halicarnassus—this time permanently. Later, he joined the new colony sponsored by Athens in Thurii, in south Italy, where he finally died and was buried in the market place. Not all these details are certain, but the general outlines are generally accepted.

It is significant that Herodotus should have been an Asiatic Greek by birth and upbringing and equally significant that he left Asia behind him for Athens and the West, because both parts of his experience contributed to his intellectual development. From Asia and the tradition of the Ionian philosophers, he learned to make use of *historiē*, the new method of scientific inquiry that

consisted first in asking a question, then in looking for information relevant to that question, and, finally, in drawing a conclusion from the data collected. Without his sojourn in Athens and, in general, without the breadth of view he acquired by life as an exile, Herodotus might never have come to ask himself the questions that made him a historian: "Why did the Persian Wars come about, and what deeds were accomplished on both sides that are worthy of being remembered?" The historical work of Herodotus, therefore, is intimately connected with the facts of his personal life, while many of those facts must be deduced from the *History*.

Interest in geography

When he began collecting information, he had not decided to write about the Persian Wars, but he probably had in mind a geographical work something like that of Hecataeus of Miletus. Hecataeus had written a book known as the *Periegesis*, enough of which remains to show that he described the different lands around the Mediterranean sea in clockwise order, beginning with Spain and ending with the north coast of Africa. Even before Hecataeus, the philosopher Anaximander had shown an interest in physical geography, constructing the first Greek world map. No doubt Hecataeus hoped to improve on Anaximander, just as Herodotus set out to improve on the results obtained by Hecataeus. There are a number of passages in the text of the *History* indicating that when Herodotus began to collect his information, he was not thinking about the Persian Wars. For example, he undertook a journey in the Black Sea region without making any effort to cover the ground traversed by Darius in his Scythian campaign—a campaign he was later to describe in great detail; then again, his trips to Tyre and to the island of Thasos were both motivated by his curiosity about the legendary Heracles (Hercules), a theological rather than a historical question.

Best known of all his journeys is the one he made to Egypt. Later on, when he had made up his mind to write about the Persian Wars, he could not bear to leave out the account of his investigations in Egypt, which fill the entire second book of the *History*. He probably went there with a copy of Hecataeus' *Periegesis* in his portmanteau along with an improved version of Anaximander's map. A French scholar, Camille Sourdille, writing in 1910, worked out the generally accepted version of Herodotus' itinerary in Egypt. Herodotus entered Egypt in the western delta at Canopus sometime in August, departing from Pelusium in the eastern delta before December. In between, he visited quite a number of famous places, including Memphis and the site of the great pyramids. He travelled up the Nile all the way to the first cataract, stopping briefly in Thebes. Unfortunately, it is not known what year this occurred, though his reference to the skulls of the Egyptian and Persian dead still lying on the battlefield at Papremis shows he was there some time after 460 BC, when the battle had been fought.

Scientific imagination

More important are the inferences drawn from his remarks, for they show that his primary interest was in the geography and monuments rather than in the history of Egypt. A good example of how his mind worked is his discussion of the causes for the annual Nile flood, in which he criticizes earlier explanations and offers one of his own. But he was more interested in the long-term effects of the annual inundation. Others had noted marine fossils (not only in Egypt) far inland and concluded that land can be created by the silt of rivers; the Egyptian Delta had already been recognized as the work of the Nile. But Herodotus went further. Using such information as he had about the height to which the Nile rose in earlier times when it flooded the land, as compared with the greater height needed to accomplish this purpose in his own day, he tried to calculate how long it took for the silt brought down by the river to build up, not merely the delta but the rest of Egypt as well. Thus, he speculated that if the Nile changed course slightly and emptied into the Red Sea, which was about the size of Egypt, it would create a new land there within 5,000 years. His data were unsatisfactory, but his method was scientific. He did not stop there. In summarizing the political history of Egypt, he put the pyramid kings, who belong back in the Old Kingdom, at a very late date. This has been explained in various ways, but the answer may well be a simple one. His calculations had persuaded him that the pyramids could not have been built so early because the area north of Memphis would still have been under water. He was quite wrong, of course, but magnificently wrong, because he formulated for the first time the relationship existing between man and his environment during the historical period.

Herodotus, however, is not always and completely a rationalist, as is shown in the respect he paid to the oracle of Delphi despite the many indications of rather fallible behaviour to be found in his pages. Somehow, Herodotus manages to reconcile belief in a divinely controlled universe with an equally strong belief in natural causes. To understand the kind of man he was, one must consider his attitude toward the supernatural, for G. De Sanctis, a 20th-century Italian historian, and others found him less skeptical toward the religious views of his day than his predecessor Hecataeus of Miletus. Perhaps the historian's comparatively long stay in Athens modified the radical philosophical views to which he had been exposed earlier in life. Be that as it may, Herodotus often seems to anticipate the efforts of later writers in attempting to reconcile the contradictions between faith and reason. A good example is his account of Croesus of Lydia. Croesus is doomed by the fact that the founder of his line, Gyges, usurped the throne; the Delphic oracle had predicted the overthrow of Gyges' succession after five generations, but this prediction had been forgotten by Croesus' time. Then there is another irrational element in the story. The acropolis of Sardis was to be made impregnable by having a lion cub carried around the perimeter. This was done except for a small section, where access was so difficult that no enemy could be imagined foolhardy enough to try that side. And that, of course, is how the Persians got in. Croesus, then, is in a hopeless situation, his fate has been decreed. But while Herodotus preserves these supernatural explanations, he is not satisfied. He offers a rational explanation side by side with the irrational. After fighting a drawn battle with Cyrus, Croesus withdraws to Sardis and dismisses his allies on the mistaken assumption that Cyrus also will retire. But Cyrus did no such thing, and when he suddenly appeared before the walls of Sardis, it was too late for Croesus to recall his allies. Did Sardis fall as the result of divine vengeance for the sins of Gyges or because Croesus made a mistake in judging his opponent?

Ambivalence of reason and faith

Another illustration of Herodotus' ambivalence is his use of dreams. Many of the dreams cited in the *History* have a prophetic character, such as Astyages' dream about his daughter Mandane or Cyrus' dream presaging the future greatness of Darius. Both prophecies are fulfilled despite determined efforts to thwart them. But the dream of Xerxes is somewhat different. The king is accosted by a figure who appears to him as he sleeps and threatens him with dire consequences if he persists in calling off the invasion of Greece. Xerxes promptly consults his uncle Artabanus, who sets his mind at ease. He tells his nephew that dreams can have natural causes, that men tend to dream at night about matters that have been occupying their minds during waking hours, and that there is nothing supernatural in such nocturnal manifestations. But, in the end, Artabanus is forced to withdraw his opposition to the war *by a dream*. Herodotus leaves it to the reader to decide whether the gods have determined on the defeat of Xerxes or whether Xerxes was a fool to allow his good sense to be overruled by a phantom.

Debt to Periclean Athens

It may well have been in Athens that Herodotus decided to write about the Persian Wars. Having made up his mind, he worked up the ethnographic, geographic, and mythological materials he had collected into a new framework, in which all past history leads up to a struggle between East and West, culminating with the invasion of Xerxes in 480 BC. In the process he also makes a clear distinction between history and prehistory, the dividing line for Greece coming at about 600 BC. Rules

of evidence for legendary figures, such as Minos of Crete or the heroes at Troy, are different than those applied to historical personages, such as Croesus or Peisistratus. Herodotus' intellectual development owed much to Periclean Athens, where he was able to read parts of his unpublished *History* to appreciative audiences. Sophocles is said to have been one of his friends, the plays of Aeschylus seem to have influenced him, and among his listeners—perhaps—was the young Thucydides.

Herodotus was unique in the ancient world. Other famous historians, such as Thucydides, Xenophon, and Polybius, great though they were, lacked his qualities of cynicism without despair and humour without bitterness. Above all, he alone was a truly Greek historian, not an Athenian or an Achaean but a Greek, whose birthplace was soon forgotten and had to be redetermined by later scholars. The first historian set an example of universality that few if any of his successors have been able to match.

Hero Worship

Hero worship is the cult of real or imaginary persons of the past at their tombs or relics or at other cult places. This narrow and strict definition has, however, often been broadened to include such phenomena as honour and veneration, as well as worship proper.

Heroes and heroic literature. The term hero—derived from the Greek noun *hērōs*, the etymology of which is uncertain—has, in the course of time, acquired a variety of meanings: the main figure in a literary work; one who accomplishes remarkable deeds or whose life exhibits the qualities of extraordinary courage, valour, and fortitude; the main character in a tale or epic of the kind usually known as heroic literature; or a person worthy of veneration and honour. Because the use of the noun hero and the adjective heroic have been determined by their Greek origins, it may be useful to survey the terms briefly before considering their application by extension to other cultures and cultural phenomena.

Homer and Hesiod

In the Homeric poems the term hero signifies any freeman of that early age described in the *Iliad* and the *Odyssey*. It is applied more specifically to the outstanding characters in those epics: superior beings who excelled in war and adventure and who prized virtues and values such as courage and loyalty. It is difficult to generalize about heroes and the heroic even in Greek culture because there is considerable variety in the treatment of the subject. The Homeric heroes are frequently in touch with the gods who intervene in their affairs and determine their destinies. This is not the case with most of the heroes of the Greek tragedians. Some heroes are of divine parenthood on one side; this semidivine origin serves to account for the supernatural powers of many heroes. Altogether the supernatural plays a prominent role in many heroic tales (*e.g.*, magic weapons, oracles, encounters with powerful sorcerers or witches, battles with dragons and monsters). Furthermore, the hero's exploits are not necessarily confined to this world; his adventures may lead him to the underworld (the realm of the dead) or to the realm of the gods.

The idea that heroes lived in a bygone period, to which the teller of the heroic stories is looking back, gave rise to the notion of a heroic age. This notion is found in Hesiod's *Works and Days*, in which a race of heroes intervenes between the third and the fourth of the four periods into which the history of the world is divided. Very possibly Hesiod's account is an attempt to harmonize an ancient mythological tradition regarding four cosmic ages with the epic tradition of the poets that dealt with the heroic exploits of heroic beings in a heroic age. Something like a heroic age is also assumed by the epics and tales of other cultures.

The stories or cycles of stories describing the exploits of the heroes and great figures of the heroic age are usually subsumed under the heading heroic literature. This type of literature poses a great many problems, both as regards form (poetry, prose, epic) and literary and social history. Among the many questions that are still being discussed are the relation of heroic written literature to earlier oral traditions; the relation of the longer compositions to shorter units; the social background of this literary genre; and the historical realities reflected by the heroic traditions. Some specimens of heroic literature are demonstrably late or are deliberate imitations of earlier models: Virgil's *Aeneid* uses the Homeric example to give an imaginary account of the origin of Rome, in keeping with the new Roman ideology that emerged during the reign of Augustus (27 BC–AD 14). According to some scholars, the heroic poem reflects a phase of culture and a social order dominated by a powerful warrior class of a feudal type. The warrior's heroic exploits were celebrated in songs and lays (ballads) transmitted orally by wandering bards. According to this view, the heroic lay is the literary successor to the religious hymns and myths whose subjects were gods rather than human heroes; it can claim some basis of historical truth, even if this historical nucleus was transformed by and overlaid with imaginative and legendary elements.

Two preliminary questions should be mentioned briefly. The one concerns the possibility and the limitations of a large-scale comparative analysis of the heroic literatures of diverse cultures. Whether, for example, Greek and Roman epic or Old High German (*e.g.*, *Hildebrandslied*) and Middle High German (*e.g.*, *Nibelungenlied*) heroic sagas can be usefully compared and to what purpose is a moot point. The other concerns the fact that heroic literature exists at different levels, referred to by a variety of technical terms (myth, saga, legend, folktale), but there is no unanimity in the use of this terminology.

Nature and sacral status of the hero. The superhuman qualities of many heroes poses the question of their relationship to the gods, especially as the distinction between *Göttermythologie* (myths of gods) and *Heldensage* (heroic saga) is not so neat and rigid as suggested by some scholars. The Greek mythographer Euhemerus of Messina, who lived about 300 BC, maintained that the gods that were the objects of popular worship had originally been great conquerors, heroes, or sages subsequently venerated by posterity. Euhemerus' theory, although inadequate as an explanation of the myths and worship of all gods, has at least the merit of drawing attention to the fact of the veneration or even deification of the illustrious departed. This links hero worship with ancestor worship on the one hand and such phenomena as the deification (Greek *apotheōsis*) and cult of the emperors at Rome on the other. The cult of many lesser or minor gods, unlike that of the great deities, has often been accounted for on lines similar to Euhemerus' theory; even here, however, the problem is more complicated. Many scholars, although agreeing that the cult of ancestors and that of heroes were somehow related, have differed as to the nature of the connection. Ancestors—*i.e.*, powerful departed souls whose hostility could be dangerous, whose favour could be beneficial, and who should therefore be propitiated—enjoyed a cult in the narrow circle of their family and descendants. A hero would be honoured by a wider circle than the family—*e.g.*, by a city that he had founded or in which his remains had been buried. Some scholars have believed that the cult of the dead derived from that of heroes, whereas others have thought that the cult of kings led to that of illustrious ancestors, thence to that of the illustrious dead in general, and, finally, to the worship of

Relationship of heroes and gods

purely legendary figures. The question became one of the divine or human origin of heroes; of whether they were the product of historic reality or of the imagination. Frequently the problem has been posed in terms of a clear-cut dichotomy: heroes are deified (or semideified) men, and their cult is that of the dead elevated to divine rank; or, conversely, they are "faded" gods, and their cult is what was left after their demotion from the status of full divinity.

Another approach, relating the hero to cult and ritual, views heroes not as degraded gods but as personifications of ancient and at times forgotten rituals. This theory, popularized in its more extreme form by Lord Raglan in his *Hero* in 1936, holds that all traditional narratives, including myths and heroic legends, originate in ritual. Tales such as those of Troy or King Arthur are connected with ancient rites that have fallen out of use although the narrative has survived. This explanation of heroes in terms of ritual drama is the very opposite of hero worship as understood by the definition given at the beginning of this article.

Varieties of cultic forms. *Ancient Greece.* Hero worship is well attested in ancient Greece, though the actual facts may not always accord with the accounts and interpretations offered by the later Greek authors. The association of hero worship with the cult of the dead is confirmed by a number of technical ritual details. Thus, cults connected with heroes have a funerary and chthonic, or "underworld," character, unlike the rites offered to the heavenly gods. The manner of slaughtering the sacrificial animal is different, and so is the word itself for sacrificing (*thuein* for the gods and *enagizein* for hero cults). The sacrifice for heroes and for the dead is not offered on a "high altar"; the low, round, and hollow altar is constructed so that the blood flows away into the earth. The whole carcass is burned, whereas a sacrifice to the gods is shared between them and the humans. On the other hand, these differences must not be pressed too much. Some Greek hero cults have no funerary character. There are gods with surnames of heroes. A temple precinct is defiled by the presence of a tomb but not by the tomb of a hero, and many traditions speak of the burial of heroes in sanctuaries. Many heroes prove their divine origin by the rituals or virtues associated with them. The patrons of rain, fertility, and healing cults are, more often than not, archaic spirits with traditional cults that were subsequently personified, given an individual biography, or attached to the names and biographies of existing (legendary or historical) heroes. Heroic legends are often deliberately etiological in intent; *i.e.*, they account for the origin and details of cultic centres, practices, and liturgies. Personification may also lead to identification in the course of literary traditions: Iphigeneia of Brauron, who protects women in labour, and the Iphigeneia sacrificed at Aulis by her father, Agamemnon, leader of the Greeks in the Trojan War, were surely not the same originally, though they were later identified.

Types of Greek heroes

It appears that heroes are as heterogeneous in their origins as in their developed qualities, and thus it is impossible to generalize about their cults. The English scholar L.R. Farnell—in his work *Greek Hero Cults and Ideas of Immortality*, published in 1920—distinguished seven types of hero: priestly hero-gods of cultic origin (*e.g.*, Trophonius, an architect in Greek legend whose oracle—which was consulted only by a means of peculiar ceremonies—was at the spot where he was swallowed up by the earth); sacral heroes or heroines associated with a god (*e.g.*, Iphigeneia); secular figures who became fully divinized (*e.g.*, Heracles); epic heroes like Hector and Achilles in Homer's *Iliad;* fictitious genealogical heroes like Ion, who was constructed to account for the origin of the Ionian people of ancient Greece; functional and cultural demons—often anonymous and generally of local importance only; and, occasionally, real men who were subsequently granted cults. The classification is far from satisfactory, yet it helps to show the variety of types even within one culture and to emphasize the fact that not all heroic types are connected with worship. Thus, the heroes of Homer, although sufficiently close to the gods to have the latter intervene in their affairs, are not described as objects of a cult. On the other hand, the Greeks themselves developed ideas and legends associating heroic tales with cultic data. This pattern easily converged with the habit of considering the illustrious dead as a source of power and a potent force to be used for the benefit of the community. Hence, the relationship to the tomb, interred body, or relics as a centre from which radiated a certain power also developed. During the war between Sparta and Arcadia in the middle of the 6th century BC, the Spartans were told that they would be victorious if they could possess themselves of the body of Orestes, the hero who avenged the death of his father Agamemnon by killing his mother and her lover. Founders and colonizers of cities receive heroic honours in approved Greek fashion (*i.e.*, animal sacrifices, athletic games, paeans). Pausanias, a Greek traveller in the 2nd century AD, still saw the tomb of Leonidas, the king of Sparta, as the site of a cult. Then, as now, popular sports champions would also be "idolized." Euthymus of Locri won a boxing contest in Olympia in 484 BC; six centuries later Pausanias still saw his statue and could even relate a heroic legend to the effect that Euthymus had freed the city of Temesa from a dreadful ghost and ultimately gained "a shrine and a cult."

The concept of the hero and, thus also, that of hero worship was developed and transformed by the Greek poets, who increasingly moralized it. In the tragedies of Euripides, heroic honours are the reward of moral excellence; and these honours are mainly the institution of a cult. In fact, the heroic life epitomizes certain values without which life is not worth living. The hero prefers death to an unworthy life and accepts suffering, trials, and tribulations as long as these are compatible with his conception of fortitude and virtue. According to Plato, the struggles and sufferings of the heroic life are due to man's desire for immortal glory. The ideal hero fears disgrace only. Because the heroic life usually ends with a heroic death, the hero is, almost by definition, a tragic hero. It is this tragic quality that, among other things, distinguishes the heroes of the great epics from those of folktales.

Non-Greek traditions

Primitive religions. The use of the terms hero and hero worship in cultural contexts other than the Greek tradition is somewhat problematic. The chief characters in many primitive myths cannot be described as heroes. Sometimes they are mythical figures (divine, semidivine, human, or animal) whose activities account for the origins of certain cosmic facts or cultural achievements or social institutions; they are often described as culture heroes, but neither are they heroes in the classical Greek sense nor do they enjoy cults and worship. In some instances the mythical ancestors are deemed to return on certain ritual occasions, but it may be doubted whether the term hero worship is applicable here. Even when the myth tells of the origin of things and institutions through the death of a primordial mythical being, the terms hero and hero worship are, strictly speaking, inappropriate.

Shamanism and Chinese and Japanese religions. In some forms of religion, illustrious or powerful individuals may be identified after their death with powerful spirits or promoted to divine rank. Thus, many of the mighty spirits in some forms of Asian shamanism (a religion characterized by belief in a world of unseen gods, demons, and ancestral spirits responsive only to the priests, called shamans) are identified with departed generals and warlords. In Chinese and Japanese religions, the differences between men, spirit powers, and gods are a matter of degree only; and thus worship of the ancestors and the illustrious departed easily merges with spirit cults and regular divine worship. Among the thousands of gods or divine beings, some are the personifications of natural forces, others are mythological deities, and others again are deified kings, heroes, scholars, and benefactors. Because the celestial hierarchy is similar to that on earth, deserving individuals could be elevated to divine rank by imperial decree. One of the best known examples

is the Chinese hero Kuan Ti, also known as Kuan Yü or Wu Ti, who after his death in the 3rd century AD advanced successively—throughout the T'ang, Sung, Ming, and Ch'ing dynasties—to ever higher honours. Thus, in 1594 he received the title "Faithful and Loyal Great Ti, God of War." He is said to have had 1,600 state temples and thousands of local shrines in modern (pre-Communist) China. The 9th-century statesman and scholar Sugawara Michizane (also known as Kanko) may be cited as a Japanese example.

Christianity, Islām, and Buddhism. The Christian cult of saints, though shaped by a specifically Christian ideal of holiness, owes much to Greek forms of hero worship. The original Christian hero is the martyr, and his cult is centred on his tomb and his relics. On the more popular level, saints are considered to be a source radiating power and blessing; in more strictly Christian terms, they are an inspiring reminder of Christian life and a concrete point of contact with the person of the martyr who—somehow still connected with his tomb or relic, yet at the same time in heaven—can act as an intercessor with God. Later, the place of martyrs was taken by confessors (*i.e.*, those who professed their faith but were not required to die a martyr's death) and by saints whose lives exhibited heroic virtue in acts of penance, ascetic mortification, and charity. Whereas the souls of the ordinary departed are prayed for, those of the saints are prayed to. The cult of saints, and especially of tombs of holy men, is also known in popular Islām, though the orthodox disapprove of the practice as heartily as Protestants disapprove of the Catholic attitudes toward saints. The saint as a hero meriting worship is known also in Eastern religions. In Buddhism the ascetic and renouncer is the real victor and hero, for it is he that has overcome the world; the Buddha is the real *cakravartin* (world conqueror).

Modern forms. In addition to the narrow definition of hero worship given at the beginning of this article, the term is also used in a wider sense to refer to attitudes of reverence, honour, and admiration—at times enthusiastic—toward individuals who have excelled in the virtues applauded in a given society. These may range from the most barbarous to the most refined or spiritualized. Heroes can be warriors, rulers, prodigies of sexual prowess, world redeemers, and saints. The study of heroes and of later interpretations of traditional heroic figures can provide a clue to the dominant values—and the changes in the values—of a group. Hiawatha, a legendary chief of the Onondaga tribe of North American Indians, functioned as the Iroquois symbol of civilization and human progress. Perhaps the most striking recent example of a hero cult is that which formed around "Che" Guevara—the Cuban guerrilla leader—who became a kind of mythical symbol with which the revolutionary youth of the radical left wished to identify in ideal as well as in action.

Significance. Some writers, analyzing and comparing the types of heroes described in the various heroic traditions of the world, celebrated in legends, or venerated in cults, claim to find certain regularities or structures characteristic of the hero. These are said to exhibit a basic pattern of the heroes' biographies (*e.g.*, supernatural or marvellous birth, endangered childhood, prodigious feats in manhood, successful overcoming of dangers and trials, acquisition of a hidden treasure, winning a bride or liberating a captive damsel, heroic death) and to express something essential to man's understanding of himself. If all important truths present themselves under the guise of the figures of religion and mythology, then the figure of the hero signifies man's aspiration toward a fuller development of his spirit and transcendence of his incomplete state. The hero, according to this view, symbolizes man's urge and struggle to transcend the limitations of his existence and to conquer a fuller and more total life. The heroic adventures are thus seen as symbolic representations of an essentially spiritual quest.

BIBLIOGRAPHY. THOMAS CARLYLE, *On Heroes, Hero-Worship, and the Heroic in History* (1841, reprinted 1966), popularized the notion of hero worship and contributed to the modern interest in the subject. LORD RAGLAN, *The Hero* (1936), argues the thesis that the heroes of legend and myth are not historical figures but personifications of ancient rituals. JOSEPH CAMPBELL, *The Hero with a Thousand Faces*, 2nd ed. (1968), attempts to bring out the basic problem underlying the many forms of the heroic and to interpret these as a symbol of man's spiritual quest. The classical discussions of hero worship in ancient Greece are F. DENEKEN's article "Heros" in W.H. ROSCHER (ed.), *Ausführliches Lexicon der griechischen und römischen Mythologie* (1886–90); ERWIN ROHDE, *Psyche*, 8th ed. (1921; Eng. trans., 1925); EDUARD MEYER, *Geschichte der Alterthums*, vol. 2 (1893); and FRIEDRICH PFISTER, *Der Reliquienkult im Altertum*, 2 vol. (1909–12), who also discusses the work of his predecessors. The best known English work on the subject is L.R. FARNELL, *Greek Hero Cults and Ideas of Immortality* (1921, reprinted 1970). MARIE DELCOURT, *Légendes et cultes de héros en Grèce* (1942), is an excellent brief survey of the question. The transition from Greek to Christian hero worship is discussed by HIPPOLYTE DELEHAYE, *Les Origines du culte des martyrs*, 2nd ed. rev. (1933); and A.J. FESTUGIERE, *La Sainteté* (1942), which also has a good chapter on the moral aspects of the Greek hero. Problems of heroic literature are discussed in C.M. BOWRA, *Heroic Poetry* (1952).

(R.J.Z.W.)

Herschel Family

Members of the Herschel family transformed the science of astronomy by their indefatigable studies of the stars and nebulae. Sir William, who became famous for the discovery of Uranus, built the largest telescopes of his day and, in collaboration with his sister, Caroline Lucretia, developed pioneer theories of cosmology. His son, Sir John, revised and completed his father's work and became a prominent figure in British science. The Herschels applied the bold concept that vast changes occurred in the universe in the course of time, explaining in this way the differences to be observed among stars and nebulae.

WILLIAM AND CAROLINE HERSCHEL

Frederick William (Friedrich Wilhelm) Herschel was born on November 15, 1738, in Hanover, Germany, where his father was an army musician. Following the same profession, the boy William played in the band of the Hanoverian Guards. After the French occupation of Hanover in 1757, he escaped to England, where at first he earned a living by copying music. But he steadily improved his position by becoming a music teacher, performer, and composer, until in 1766 he was appointed organist of a fashionable chapel in Bath, the well-known spa.

Telescope construction. By this time, the intellectual curiosity he had acquired from his father led him from the practice to the theory of music, which he studied in Robert Smith's *Harmonics*. From this book he turned to Smith's *A Compleat System of Opticks*, which introduced him to the techniques of telescope construction and whetted his appetite for viewing the night sky. Combining obstinacy with boundless energy, William was not content to observe the nearby Sun, Moon, and planets, as did nearly all astronomers of his day, but was determined to study the distant celestial bodies as well, and he realized he would need telescopes with large mirrors to collect enough light, larger, in fact, than opticians could supply at reasonable cost. He was soon forced to grind his own mirrors. They were ground from metal disks of copper, tin, and antimony in various proportions. In 1781 his ambitions outran the capacities of the local foundries, and so he prepared to cast molten metal into disks in the basement of his own home; but the first mirror cracked on cooling, and on the second attempt the metal ran out onto the flagstones, after which even he accepted temporary defeat. His later and more successful attempts produced ever-larger mirrors of superb quality—his telescopes proved far superior even to those used at the Greenwich Observatory. He also made his own eyepieces, the strongest with a magnifying power of 6,450 times.

At Bath, he was helped in his researches by his brother Alexander, who had come from Hanover, and his sister, Caroline, who was his faithful assistant through much

of his career and an excellent astronomer in her own right. News of this extraordinary household began to spread in scientific circles. He made two preliminary telescopic surveys of the heavens. Then, in 1781, during his third and most complete survey of the night sky, William came upon an object that he realized was not an ordinary star.

Discovery of Uranus. It proved to be the planet Uranus, the first planet to be discovered since prehistoric times. William became famous almost overnight. His friend Dr. William Watson, Jr., introduced him to the Royal Society of London, which awarded him the Copley Medal for the discovery of Uranus, and elected him a Fellow. Watson also helped him to secure in 1782 an annual pension of £200 from George III; Sir Joseph Banks, in 1787, helped to secure an annual pension of £50 for Caroline. He could thus give up music and devote himself exclusively to astronomy. At this time William was appointed as an astronomer to George III, and the Herschels moved to Datchet, near Windsor Castle.

Although he was 43 years old when he became a professional astronomer, William worked night after night to develop a "natural history" of the heavens. A fundamental problem for which Herschel's big telescopes were ideally suited concerned the nature of nebulae, which appear as luminous patches in the sky. Some astronomers thought they were nothing more than clusters of innumerable stars the light of which blends to form a milky appearance. Others held that some nebulae were composed of a luminous fluid. When William's interest in nebulae developed in the winter of 1781–82, he quickly found that his most powerful telescope could resolve into stars several nebulae that appeared "milky" to less well equipped observers. He was convinced that other nebulae would eventually be resolved into individual stars with more powerful instruments. This encouraged him to argue in 1784 and 1785 that all nebulae were formed of stars and that there was no need to postulate the existence of a mysterious luminous fluid to explain the observed facts. Nebulae that could not yet be resolved must be very distant systems, he maintained; and, since they seem large to the observer, their true size must indeed be vast—possibly larger even than the star system of which the Sun is a member. By this reasoning, William was led to postulate the existence of what later were called "island universes" of stars.

William's early work on nebulae

Theory of the evolution of stars. In order to interpret the differences between these star clusters, it was natural for William to emphasize their relative densities, which he did by contrasting a cluster of tightly packed stars with others in which the stars were widely scattered. These formations showed that attractive forces were at work: with the passage of time, he maintained, widely scattered stars would no doubt condense into one or more tightly packed clusters. In other words, a group of widely scattered stars was at an earlier stage of its development than one whose stars were tightly packed. Thus, William made change in time, or evolution, a fundamental explanatory concept in astronomy. In 1785 he developed a cosmogony—a theory concerning the origin of the universe: the stars originally were scattered throughout infinite space, in which attractive forces gradually organized them into even more fragmented and tightly packed clusters. Turning then to the system of stars of which the Sun is part, he sought to determine its shape on the basis of two assumptions: (1) that with his telescope he could see all the stars in our system, and (2) that within the system the stars are regularly spread out. Both of these assumptions he subsequently had to abandon. But in his studies he gave the first major example of the usefulness of stellar statistics in that he could count the stars and interpret this data in terms of the extent in space of the Galaxy's star system. Other astronomers, cut off from the evidence by the modest size of their telescopes and unwilling to follow William in his bold theorizing, could only look on with varying degrees of sympathy or skepticism.

In 1787 the Herschels moved to Old Windsor, and the following year to nearby Slough, where William spent the rest of his life. Night after night, whenever the Moon and weather permitted, he observed the sky in the company of Caroline, who recorded his observations. Caroline, on her own, discovered eight comets in the years 1786 to 1797. On overcast nights, William would post a watchman to summon him if the clouds should break. Often in the daytime, Caroline would summarize the results of their work while he directed the construction of telescopes, many of which he sold to supplement their income. His largest instrument, too cumbersome for regular use, had a mirror made of speculum metal, with a diameter of 48 inches and a focal length of 40 feet. Completed in 1789, it became one of the technical wonders of the 18th century.

William's achievement, in a field in which he became a professional only in middle life, was made possible by his own total dedication and the selfless support of Caroline. He seems not to have considered the possibility of marriage until after the death in 1786 of a friend and neighbour, John Pitt, whose widow, Mary, was a charming and pleasant woman. Before long, William proposed marriage; he and Mary would live in the Pitt house, while Caroline would remain at Observatory House in Slough. But Mrs. Pitt was shrewd enough to realize that William's commitment would be to Observatory House, which they made their principal home after their marriage on May 8, 1788. William and Caroline continued their labour in astronomy, but as the rigours of observing took their toll of William's health, he came to appreciate more and more the comforts that Mary's

sensible management brought to his home. It was some time before Caroline was reconciled to being displaced in William's affections, after so many years as his constant companion and assistant.

Theory of the structure of nebulae. William's grand concept of stellar organization received a jolt on November 13, 1790, when he observed a remarkable nebula, which he was forced to interpret as a central star surrounded by a cloud of "luminous fluid." This discovery contradicted his earlier views. Hitherto William had reasoned that many nebulae that he was unable to resolve (separate into distinct stars), even with his best telescopes, might be distant "island universes" (such objects are now known as galaxies). He was able, however, to adapt his earlier theory to this new evidence by concluding that the central star he had observed was condensing out of the surrounding cloud under the forces of gravity. In 1811 he extended his cosmogony backward in time to the stage when stars had not yet begun to form out of the fluid.

This example of William's theorizing is typical of his thinking: an unrivalled wealth of observations interpreted by means of bold though vulnerable assumptions. For example, in dealing with the structural organization of the heavens, he assumed that all stars were equally bright, so that differences in apparent brightness are an index only of differences in distances. Throughout his career he stubbornly refused to acknowledge the accumulating evidence that contradicted this assumption.

William's star catalogs

Herschel's labours through 20 years of systematic sweeps for nebulae (1783–1802) resulted in three catalogs listing 2,500 nebulae and star clusters that he substituted for the 100 or so milky patches previously known. He also cataloged 848 double stars—pairs of stars that appear close together in space, and measurements of the comparative brightness of stars. He observed that double stars did not occur by chance as a result of random scattering of stars in space but that they actually revolved about each other. His 70 published papers include not only studies of the motion of the solar system through space and the announcement in 1800 of the discovery of infrared rays but also a succession of detailed investigations of the planets and other members of the solar system. He was knighted in 1816 for his outstanding contributions to British science.

JOHN HERSCHEL

John Frederick William, the only child of William and Mary Herschel, was born on March 7, 1792. John, a frail child, who struggled against ill health all his life, was to become another object of Caroline's love. When he was eight, he was sent to school at nearby Eton, but his mother, seeing him involved in a fight, took him away to be educated privately in less robust surroundings.

In 1809 John entered Cambridge University, where he gained all the advantages of education and friendship that his father had missed in his youth. He joined with Charles Babbage, the mathematician and inventor of the computer, and George Peacock, also a mathematician and later a theologian, in resolving "to do their best to leave the world wiser than they found it." In 1812 they founded the Analytical Society of Cambridge in order to introduce continental methods of doing the mathematical calculus into English practice. They did so by replacing the cumbersome symbolism of Newton with the more efficient type invented by the German philosopher and mathematician Gottfried Wilhelm Leibniz. John's exceptional abilities were quickly recognized: in 1812 he submitted his first mathematical paper to the Royal Society, for which he was elected a fellow in the following year. In 1813 he earned first place in the university mathematical examinations.

Later that year he asked his father's advice about a career. William recommended the church, for "a clergyman is in possession of dignified leisure" to cultivate his mind. But John was attracted to the law and began to study for the bar in London. He soon realized that he had made a wrong choice. Taking advantage of his residence in London, he established contact with his friends in the scientific community, including the astronomer James South. In 1815 he applied for the professorship of chemistry at Cambridge but lost the election by only one vote. His final break with the legal profession occurred that summer when he became seriously ill; after convalescence he returned to Cambridge as a mathematics teacher. But, because his famous father, in spite of failing health, stubbornly continued his research, John felt a filial duty to join him as his assistant. "My heart dies within me," John wrote Babbage in 1816 when he left Cambridge.

In later years, John's apprenticeship in astronomy did not prevent him from making important contributions to chemistry and the physics of light and particularly to mathematics, for which he was awarded the Copley Medal of the Royal Society in 1821. But, through his work with his father, he gained the full benefit of the aged astronomer's unrivalled experience in the construction and use of large telescopes. This apprenticeship laid the foundation of John's subsequent achievements. In 1820 he was among the founders of the Royal Astronomical Society.

Observation of double stars. John Herschel's first major task in astronomy was the re-observation of the double stars that were cataloged by his father. The movements of these pairs of stars about each other offered the best hope of investigating the gravitational forces operating in the universe. John was fortunate to find in James South a collaborator who was able to afford the refined instruments best suited for this work. The catalog that they compiled between 1821 and 1823 and that they published in the *Philosophical Transactions* in 1824 earned them the Gold Medal of the Royal Astronomical Society and the Lalande Prize in 1825 from the Paris Academy of Sciences. This publication was their only joint undertaking.

In the 1820s John also travelled extensively in Europe, visiting foreign scientists; he was abroad when William's life came peacefully to a close in Slough, on August 25, 1822. John was secretary of the Royal Society in 1824–27. In 1825 he turned his attention to the nebulae his father had studied so closely, writing to Caroline that "The curious objects . . . I shall now take into my especial charge—nobody else can see them." His studies of double stars led him in 1826 to the very important problem of measuring the "parallax of the fixed stars," which is the apparent shift in angular position of a given star as viewed together with its neighbour or against the background of the sky; a shift caused by the Earth's revolution around the Sun. Stellar parallax is therefore empirical proof that the Earth does revolve. John's estimation of annual variations of position angles for many stars was an important step in the resolution of this problem.

Caroline's last years

After William's death, Caroline moved back to Hanover for the last 25 years of her life. During her retirement she prepared a catalog of the 2,500 nebulae and star clusters her brother had discovered. For this accomplishment she was awarded in 1828 the Gold Medal of the Royal Astronomical Society.

On March 3, 1829, John married Margaret Brodie, the daughter of a Presbyterian minister; all who knew them agreed that theirs was an idyllic union. In 1831 he was knighted.

Voyage to the Southern Hemisphere. His sense of obligation to complete his father's work in astronomy led him to consider a journey to the Southern Hemisphere to survey the skies not visible in England, but an extended stay would be necessary, and he was reluctant to leave his aging mother for so long. When she died in January 1832, John quickly began planning his expedition. The revision and extension of his father's catalogs, which he carried out at Observatory House, beginning in 1825, was brought to completion and published in 1833. In November of that year, John and his family set sail for the Cape of Good Hope with a large reflecting telescope for observing faint nebulae, similar in size to William's favourite instrument. It had three interchangeable mirrors, one made by William, one by John under William's

directions, and the third by John alone, all with 20-foot (six-metre) focal lengths. He also had a refracting telescope of seven-foot (two-metre) focal length for observing double stars.

The family established their home at Feldhausen, a Dutch farmhouse six miles southeast of Cape Town. John spent four years of intense scientific activity, the clear southern skies allowing much more rapid progress in observing than was possible in England. When the family embarked for home in March of 1838, John had recorded the locations of 68,948 stars, amassed long catalogs of nebulae and double stars, described many details of the Great Nebula in the constellation Orion, as well as the Magellanic Clouds—actually two galaxies visible only in the Southern Hemisphere—and observed Halley's Comet and the satellites of Saturn. In addition, his descriptions of sunspot activities and his measuring of solar radiation by means of a device he had invented contributed to the development of systematic studies of the Sun as an important part of astrophysics. But preparing his results for publication took longer; on his return he was made a baronet, was lionized by the scientific world, and was obliged to accept time-consuming official duties. The year after returning from Africa, he heard about the remarkable invention of the French photographer Louis-Jacques-Mandé Daguerre to produce pictures on light-sensitive paper. Seeing at once the technical possibilities of photochemistry, he published important studies of his own on this new subject and succeeded in preparing a photograph of a solar spectrum in colour.

In 1840 the Herschels bought a spacious house in Collingwood, Kent, and there John laboured at his desk, taxing his health with additional commitments, which included the composing of the *Outlines of Astronomy* for educated laymen (1849). Growing from an earlier book, this highly successful science text went through many editions, including Arabic and Chinese. He maintained his wide scientific interests, especially in the chemistry of photography in which he conducted many experiments. But the bulk of his time was occupied with the *Results of Astronomical Observations, Made during the Years 1834–38 at the Cape of Good Hope,* which he published in 1847. His aunt Caroline died in Hanover on January 9, 1848.

John's public career

Inherited wealth and a serene family life contributed to his success in his life's work. But suddenly he began to seek appointment to public office. Whatever the reasons, the change cost him dear. At the end of 1850 he was appointed master of the Mint, and, although his integrity, humanity, and intelligence made him an obvious choice for the post, he was not sufficiently robust to cope with the strain of administering a large organization. Furthermore, he continued to undertake even more burdensome tasks, especially the plans for the scientific and technical sections for the Great Exhibition of 1851. He was forced to live in London away from his family and to work all hours of the day and night. His health deteriorated, he became depressed, and in 1854 he suffered a nervous breakdown.

The following year he was incapacitated for several weeks, and in 1856 he resigned his post at the Mint. He spent his remaining years with his family at home in Kent, working on the catalogs of double stars and of nebulae and star clusters, but in the face of ever-deteriorating health. He died at Collingwood on May 11, 1871.

BIBLIOGRAPHY. Two surveys of William Herschel's life and work are J.B. SIDGWICK'S highly readable *William Herschel: Explorer of the Heavens* (1953); and A. ARMITAGE'S more systematic *William Herschel* (1962). A charming picture of his personality, with extensive quotations from manuscripts, is given in *The Herschel Chronicle: The Life-Story of William Herschel and His Sister Caroline Herschel* (1933), ed. by his granddaughter, CONSTANCE A. LUBBOCK. His complete published papers are reprinted in *The Scientific Papers of Sir William Herschel*, ed. by J.L.E. DREYER, 2 vol. (1912); and the most significant are reprinted and critically analyzed by M.A. HOSKIN in *William Herschel and the Construction of the Heavens* (1963). The standard biography of John Herschel is *The Shadow of the Telescope* by GUNTHER BUTTMANN (1970), which includes a bibliography. *Herschel at the Cape* (1969), is a pedantic edition of his diaries and letters, 1834–38.

Herzen, Aleksandr

Aleksandr Ivanovich Herzen (also spelled Gertsen), a social philosopher, political journalist, and memorialist, was one of the founders of the radical tradition of the 19th-century Russian intelligentsia. He originated the theory of a unique Russian path to Socialism, or peasant Populism; he established abroad the first uncensored Russian periodical, *Kolokol* (*The Bell*); and he chronicled his career in one of the great works of Russian prose, *My Past and Thoughts.*

Heritage and early influences

Born in Moscow on April 6 (March 25, old style), 1812, Herzen was the illegitimate son of a wealthy nobleman, Ivan Alekseyevich Yakovlev, and a German girl of humble origins. Reared in his father's house, he received an elite and far-ranging education from French, German, and Russian tutors. Still, the "taint" of his birth, as he regarded it, made him resentful of authority and, ultimately, of the autocratic, serf-based Russian social order. This resentment bred a cult of the Decembrists, a revolutionary group that staged an uprising in 1825. Herzen and his friend, Nikolay Ogaryov, who, like Herzen, was influenced by the dramas of the German playwright Friedrich Schiller, took a solemn oath to devote their lives to continuing the Decembrists' struggle for Russian freedom.

Attending the University of Moscow between 1829 and 1833, Herzen evolved from "romanticism for the heart to idealism for the head" and became an adept of the German philosopher Friedrich Schelling's *Naturphilosophie.*

Eventually Herzen and Ogaryov and their circle fused the pantheistic idealism of Schelling with the Utopian Socialism of the French social philosopher Henri de Saint-Simon to produce a philosophy of history in which the "World Spirit" evolved ineluctably toward the realization of freedom and justice.

This metaphysical politics was enough, however, to lead to the arrest of the entire circle in 1834. Herzen was exiled for six years to work in the provincial bureaucracy in Vyatka (now Kirov) and Vladimir; then, for an indiscreet remark about the police, he spent two more years in Novgorod. The misery of this period was relieved by an extravagantly romantic courtship and an exceptionally happy marriage with his cousin, Natalya Zakharina, in 1838.

Herzen's eight-year experience with injustice and the acquaintance it afforded with the workings of Russian government hardened his radicalism. He abandoned the nebulous idealism of Schelling for the thought of two

other contemporary German philosophies—the "realistic logic" of G.W.F. Hegel and the materialism of L.A. Feuerbach. He thus became a "Left-Hegelian," holding that the dialectic (development through the reconciliation of conflicting ideas) was the "algebra of revolution" and that the disembodied truths of "science" (*i.e.*, German idealism) must culminate in the "philosophy of the deed," or the struggle for justice as proclaimed by French Socialism. In later life Herzen explained that this metaphysical approach to politics was inevitable for his generation, since the despotism of Nicholas I made action impossible and thus left pure thought as the only free realm of expression.

Armed with these philosophical weapons, Herzen returned to Moscow in 1842 and immediately joined the camp of the Westernizers, who held that Russia must progress by assimilating European rationalism and civic freedom, in their dispute with the Slavophiles, who argued that Russian development must be founded on the Orthodox religion and the fraternal peasant commune. Herzen contributed to this polemic two able and successful popularizations of Left-Hegelianism, *Diletantizm v nauke* ("Dilettantism in Science") and *Pisma ob izuchenii prirody* ("Letters on the Study of Nature"), and a novel of social criticism, *Kto vinovat?* ("Who Is to Blame?"), in the new "naturalistic" manner of Russian fiction.

Soon, however, Herzen fell out with the other Westernizers because the majority of the group were reformist liberals, whereas Herzen had by now embraced the anarchist Socialism of the French social theorist Pierre-Joseph Proudhon. At this point, in 1846, Herzen's father died, leaving him a considerable fortune; and the following year Herzen left Russia for western Europe—as it turned out, for good.

Years in Paris

Herzen went immediately to the capital of European radicalism, Paris, hoping for the imminent triumph of social revolution. The revolutionary upheavals of 1848 that he witnessed in Paris and Italy soon disabused him: he became convinced that the Western "matadors of rhetoric" were too imbued with the values of the past to level the existing social order, that Europe's role as a progressive historical force was finished, that Western institutions were in fact "dead." He concluded further that, contrary to the teachings of the Hegelians, there was no "rational" inevitability in history and that society's fate was decided instead by chance and human will. He developed these themes in two brilliant but rather confused works, *Pisma iz Frantsii i Italii* ("Letters from France and Italy") and *Stogo berega* (*From the Other Shore*). His disillusionment was vastly increased by his wife's liaison with the radical German poet Georg Herwegh and by her death in 1852.

Loss of faith in the West, however, provoked a spiritual return to Russia: though "old" Europe, "fettered by the richness of her past," had proved incapable of realizing the ideal of Socialism, "young" Russia, precisely because its past offered nothing worth conserving, now seemed to Herzen to possess the resources for a radical new departure. And Herzen (borrowing an idea from his old foes, the Slavophiles) found these resources above all in the collectivist peasant commune, which he viewed as the basis for a future Socialist order. This new faith in Russia's revolutionary potential was expressed in letters to the French historian Jules Michelet and the Italian revolutionist Giuseppe Mazzini in 1850 and 1851.

Move to London

In 1852, Herzen moved to London and the following year, with the aid of Polish exiles, he founded the "Free Russian Press in London," the first uncensored printing enterprise in Russian history. In 1855, Nicholas I died, and soon thereafter Alexander II proclaimed his intention of emancipating the serfs. Responding to this unprecedented "thaw," Herzen rapidly launched a series of periodicals designed to be smuggled back to Russia: "The Polar Star" in 1855, "Voices from Russia" in 1856, and a newspaper, *Kolokol* (*The Bell*), created in 1857 with the aid of his old friend Ogaryov, now also an émigré. Herzen's aim was to influence both the government and the public toward emancipation of the peasants, with generous allotments of land and the liberalization of Russian society. To this end, he moderated his political pronouncements, speaking less of Socialist revolution and more of the concrete issues involved in Alexander's reforms. For a time he even believed in enlightened autocracy, hailing Alexander II in 1856 (in words that echoed the famous dying tribute of Julian the Apostate to Christ) with: "you have conquered, oh Galilean!" *The Bell* soon became a major force in public life, read by the Tsar's ministers and the revolutionary opposition.

Soon, however, the ambiguity of Herzen's position between reform and revolution began to cost him support. After 1858, moderate liberals, such as the author Ivan Turgenev, attacked Herzen for his Utopian recklessness; and after 1859 he quarrelled with the political writer N.G. Chernyshevsky and the younger generation of radicals, whose intransigent manner appeared to him as very dangerous to reform. He also lost faith in the government; when the Emancipation Act was finally enacted in 1861, he denounced it as a betrayal of the peasants.

He therefore veered again to the left, and called on the student youth to "go to the people" directly with the message of Russian Socialism. Furthermore, on the urging of the anarchist Mikhail Bakunin, he threw the support of *Kolokol* behind the unsuccessful Polish revolt of 1863. He immediately regretted this rashness, for it cost him the support of all moderate elements in Russia without restoring his credit among the revolutionaries. *Kolokol's* influence declined sharply. In 1865 Herzen moved his headquarters to Geneva to be near the young generation of Russian exiles, but in 1867 public indifference forced *Kolokol* to cease publication.

Decline of *The Bell*

Amidst these political reverses, Herzen turned his energies increasingly to his memoirs, *My Past and Thoughts*, which were designed to enshrine both his own legend and that of Russian radicalism. A loosely constructed personal narrative, interspersed with sharp vignettes of both Russian and Western political figures and with philosophical and historical digressions, it provides a masterful fresco of contemporary European radicalism. At times witty, irreverent, and playful in style, and at other times lyrical, passionate, and rhapsodical, it is one of the most original and powerful examples of Russian prose. Published principally between 1861 and 1867, its scope and quality have placed it alongside the great Russian novels of the 19th century in artistic stature.

In 1869 Herzen wrote letters *K staromu tovarishchy* ("To an Old Comrade"; Bakunin), in which he expressed new reservations about the costs of revolution. Still, he was unable to accept liberal reformism completely, and he expressed interest in the new force of the First International, Marx's federation of working-class organizations. This wavering position between Socialism and liberalism, which characterized so much of his career, proved to be his political testament. He died a few months later, on January 21 (January 9, O.S.), 1870, in Paris. The ambiguities of his position have made it possible ever since for both Russian liberals and Socialists to claim his legacy with equal plausibility.

BIBLIOGRAPHY. Works on Herzen include MARTIN MALIA, *Alexander Herzen and the Birth of Russian Socialism, 1812–1855* (1961), for his ideology and politics; E.H. CARR, *The Romantic Exiles: A Nineteenth-Century Portrait Gallery* (1933), for his personal life; *My Past and Thoughts: The Memoirs of Alexander Herzen*, 5 vol., trans. by CONSTANCE GARNETT (1924–26; rev. by HUMPHREY HIGGENS, 4 vol., 1968); and the introduction by ISAIAH BERLIN to Herzen's *From the Other Shore* (1956). Collected editions of his works (in Russian) have been edited by M. LEMKE, 22 vol. (1915–25); and by the SOVIET ACADEMY OF SCIENCES, 30 vol. (1954–66).

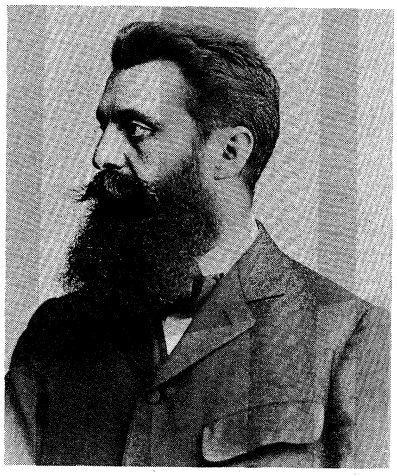
Herzl, Theodor

Theodor Herzl was the founder of the so-called Zionist movement to establish a Jewish homeland. Although he died more than 40 years before the establishment of the State of Israel, he was an indefatigable organizer, propagandist, and diplomat who had much to do with making Zionism into a political movement of worldwide significance.



Herzl, 1904.
By courtesy of the Zionist Archives and Library, New York

Herzl was born in Budapest, Hungary, on May 2, 1860, of well-to-do middle class parents. He first studied in a scientific secondary school, but to escape from its anti-Semitic atmosphere he transferred in 1875 to a school where most of the students were Jews. In 1878 the family moved from Budapest to Vienna, where he entered the University of Vienna to study law. He received his license to practice law in 1884 but chose to devote himself to literature. For a number of years he was a journalist and a moderately successful playwright.

In 1889 he married Julie Naschauer, daughter of a wealthy Jewish businessman in Vienna. The marriage was unhappy, although three children were born to it. Herzl had a strong attachment to his mother, who was unable to get along with his wife. These difficulties were increased by the political activities of his later years, in which his wife took little interest.

Conversion to Zionism

A profound change began in Herzl's life soon after a sketch he had published in the leading Viennese newspaper, *Neue Freie Presse*, led to his appointment as the paper's Paris correspondent. He arrived in Paris with his wife in the fall of 1891 and was shocked to find in the homeland of the French Revolution the same anti-Semitism with which he had become so familiar in Austria. Hitherto he had regarded anti-Semitism as a social problem that the Jews could overcome only by abandoning their distinctive ways and assimilating to the people among whom they lived. At the same time, his work as a newspaperman heightened his interest in, and knowledge of, social and political affairs and led him to the conviction that the answer to anti-Semitism was not assimilation but organized countereffforts by the Jews. The Dreyfus affair in France also helped crystallize this belief. French military documents had been given to German agents, and a Jewish officer named Alfred Dreyfus had been falsely charged with the crime. The ensuing political controversy produced an outburst of anti-Semitism among the French public. Herzl said in later years that it was the Dreyfus affair that had made a Zionist out of him. So long as anti-Semitism existed, assimilation would be impossible, and the only solution for the majority of Jews would be organized emigration to a state of their own.

Herzl was not the first to conceive of a Jewish state. Orthodox Jews had traditionally invoked the return to Zion in their daily prayers. In 1799 Napoleon had thought of establishing a Jewish state in the ancient lands of Israel. The English statesman Benjamin Disraeli, a Jew, had written a Zionist novel, *Tancred*. Moses Hess, a friend and coworker of Karl Marx, had published an important book, *Rom und Jerusalem* (1862), in which he declared the restoration of a Jewish state a necessity both for the Jews and for the rest of humanity. Among the Jews of Russia and eastern Europe, a number of groups were engaged in trying to settle emigrants in agricultural colonies in Palestine. After the Russian pogroms of 1881, Dr. Leo Pinsker had written a pamphlet, "Auto-Emanzipation," an appeal to western European Jews to assist in the establishment of colonies in Palestine. When Herzl read it some years later, he commented in his diary that if he had known of it, he might never have written *The Jewish State*.

Herzl's first important Zionist effort was an interview with Baron Maurice de Hirsch, one of the wealthiest men of his time. De Hirsch had founded the Jewish Colonization Association with the aim of settling Jews from Russia and Romania in Argentina and other parts of the Americas. The 35-year-old journalist arrived at the Baron's mansion in Paris with 22 pages of notes, in which he argued the need for a political organization to rally the Jews under a flag of their own, rather than leaving everything to the philanthropic endeavours of individuals like the Baron. The conversation was notable for its effect on Herzl rather than on the Baron de Hirsch, who refused to hear him out. It led to Herzl's famous pamphlet *The Jewish State*, published in February 1896 in Vienna. The Jewish question, he wrote, was not a social or religious question but a national question that could be solved only by making it "a political world question to be discussed and settled by the civilized nations of the world in council." Some of Herzl's friends thought it a mad idea, but the pamphlet won favourable response from eastern European Zionist societies. In June 1896, when Herzl was en route to Constantinople (Istanbul) in the hope of talking to the Ottoman Sultan about obtaining the grant of Palestine as an independent country, his train stopped in Sofia, Bulgaria; hundreds of Jews were present at the station to greet Herzl and to hail him as a leader.

Although he remained in Constantinople for 11 days, he failed to reach the Sultan. But he had begun the career as organizer and propagandist that would end only with his death eight years later. He went to London in an effort to organize the Jews there in support of his program. Not all the Jewish leaders in England were happy to see him because his political approach was not in tune with their ideas, but at public meetings in the East End he was loudly cheered. He was a tall, impressive figure with a long black beard and the mien of a prophet. Despite his personal magnetism, he found that his efforts to influence Jewish leaders in England were of little avail and therefore decided to organize a world congress of Zionists in the hope of winning support from the masses of Jews in all countries. He proposed to hold the congress in Munich, but as the Jews there—who were mostly assimilated—opposed it, he settled upon Basel, Switzerland. The congress met at the end of August 1897, attended by about 200 delegates, mostly from central and eastern Europe and Russia along with a few from western Europe and even the United States. They represented all social strata and every variety of Jewish thought—from Orthodox Jews to atheists and from businessmen to students. There were also several hundred onlookers, including some sympathetic Christians and reporters for the international press. When Herzl's imposing figure came to the podium, there was tumultuous applause. "We want to lay the foundation stone," he declared, "for the house which will become the refuge of the Jewish nation. Zionism is the return to Judaism even before the return to the land of Israel." One of Herzl's most faithful supporters was the writer Max Nordau, who gave a brilliant address in which he described the plight of the Jews in the East and in the West. The three-day congress agreed upon a program, henceforth to be known as the Basel Program, declaring that "Zionism aspires to create a publicly guaranteed homeland for the Jewish people in the land of Israel." It also set up the Zionist Organization with Herzl as president.

The First Zionist Congress

The seven remaining years of his life were devoted to the furtherance of the Zionist cause, although he remained literary editor of the *Neue Freie Presse* in order to earn a living. He established a Zionist newspaper, *Die Welt*, published as a German-language weekly in Vienna. He negotiated unsuccessfully with the Sultan of Turkey for the grant of a charter that would allow Jewish mass

The Sinai and Uganda projects

settlement in Palestine on an autonomous basis. He then turned to Great Britain, which seemed favourable to the establishment of a Jewish settlement in British territory in the Sinai Peninsula. When this project failed, the British proposed Uganda in East Africa. This offer, which he and some other Zionists were willing to accept, aroused violent opposition at the Zionist congress of 1903, particularly among the Russians. Herzl was unable to resolve the conflict. He died of a heart ailment at Edlach, near Vienna, on July 3, 1904, at the age of 44. He was buried in Vienna, but, in accordance with his wish, his remains were removed to Jerusalem in 1949 after the creation of the Jewish state and entombed on a hill west of the city now known as Mt. Herzl.

After the First Zionist Congress in Basel, Herzl had written in his diary:

> If I had to sum up the Basel Congress in one word—which I shall not do openly—it would be this: At Basel I founded the Jewish state. If I were to say this today, I would be greeted by universal laughter. In five years, perhaps, and certainly in 50, everyone will see it.

While the Jewish state was the product of many complex historic forces, including two world wars and the labours of Herzl's many followers, it was he who organized the political force of Jewry that was able to take advantage of the accidents of history. Through the strength of his personality, he aroused the enthusiasm of the Jewish masses and gained the respect of many statesmen of his time, in spite of the opposition of some Jewish leaders to his plans.

BIBLIOGRAPHY. ALEX BEIN, *Theodore Herzl* (1940; orig. pub. in Hebrew; Eng. trans. from the German of 1934), is the best biography available in English.

(D.B.-G.)

Hesiod

One of the earliest Greek epic poets and the first man in Western civilization to embody precepts or instructions in poetry, Hesiod, through his works, serves as a useful corrective to Homer's more glamorous portrayal of the world. Hesiod has an essentially serious outlook on life and is an artist who deals with the gloomier side of existence, relating, in his *Theogony* (the title not being by Hesiod himself and meaning a history of the generation or birth of the gods), the bloody power struggle among the divine dynasts Uranus, Cronus, and Zeus, while his *Works and Days* demonstrates that, in Hesiod's immediate circle at any rate, mankind's situation on earth was equally deplorable during what he calls the "age of iron."

By courtesy of the Landesmuseum, Trier

Hesiod, detail of a mosaic by Monnus, 3rd century AD. In the Rheinisches Landesmuseum, Trier.

Not a great deal is known about the details of Hesiod's life. A native of Boeotia, a district of central Greece, he flourished around 700 BC. Hesiod himself provides information about his life in his *Works and Days*, in which he vehemently criticizes a covetous brother who has taken the lion's share of their inheritance and who has bribed the rulers of the community to support him. In an attempt to remind them of their duty, Hesiod urges reverential awe of Justice, whom he regards as a goddess. To placate her is to attain happiness, the only possible solution, he thinks, to the miseries man currently suffers.

On one occasion Hesiod participated in a song contest at some funeral games, contests held in honour of one Amphidamas, and was awarded a tripod (a common prize at the time and, like the modern cup, prestigious rather than valuable). This occasion, Hesiod says, was his only overseas trip; the festival took place at Chalcis, which is situated on the island of Euboea some 800 or 900 yards (700 or 800 metres) off mainland Greece. Otherwise, he spent most of his life in his home village of Ascra, near Mt. Helicon, originally as a shepherd, until the Muses (companions of Apollo and inspirers of poetry) appeared, endowing him with a poet's voice and bidding him "sing of the race of the blessed gods immortal."

Genuine works. Of Hesiod's two extant epics, the *Theogony* is clearly the earlier. In it, following the Muses' instructions, Hesiod recounts the history of the gods, beginning with the emergence of Chaos, Gaea (Earth), and Eros. Gaea gives birth to Uranus (Heaven), the Mountains, and Pontus (the Sea); and later, after uniting herself to Uranus, she bears many other deities. One of them is the Titan Cronus, who rebels against Uranus, emasculates him, and afterward rules until he in turn is overpowered by Zeus. This story of crime and revolt is interrupted by many additional pedigrees of gods, including the progeny of Night, a deity sprung directly from the original primordial Chaos; here Hesiod has brought together the forces of evil (Death, Strife, Hunger, and Woe) that beset the life of man. Elsewhere, in addition to mythical family relations, Hesiod presents new ones that are the product of his own speculation. Thus, the names of the 50 sea-maidens (the Nereids) fathered by the sea-god Nereus indicate various qualities of the Sea. In a different way, the story describing the first woman, Pandora, sent by Zeus to bedevil man, brings out Hesiod's firm belief in the supreme and irresistible power of Zeus, This power is most majestically displayed in the Titanomachia, the battle between the Olympian gods, led by Zeus, and the Titans, who support Cronus. After his victory Zeus organizes his kingdom.

Content of the *Theogony*

Hesiod's authorship of the *Theogony* has been questioned but is no longer doubted, though the work does include sections inserted by poets and rhapsodes (professional reciters of poetry) before the degeneration of the epic as an art form in the late 6th century BC. The story of Typhoeus' rebellion against Zeus has almost certainly been added by someone else, while the somewhat overlapping accounts of Tartarus, the hymn on Hecate, and the progeny of the sea monster Keto are highly suspect. The discovery of a Hurrian theogony similar to Hesiod's seems to establish a link with the Near East. But with Hesiod the succession Uranus–Cronus–Zeus resembles a classical Greek tragic trilogy. Thus, the Erinyes (the deities of vengeance) are born when Uranus is overthrown by Cronus, while their own hour for action comes when Cronus is about to be overthrown by Zeus. These and other similar features plausibly represent Hesiod's own contributions to the inherited story.

Personal character of the *Works and Days*

Hesiod's other epic poem, the *Works and Days*, has a more personal character. It is addressed to his grasping brother Perses in an attempt to make him stop his evil practices. In the first part, Hesiod recounts two myths illustrating the necessity for honest, hard work in man's wretched life. One takes up and continues the story of Pandora, who out of curiosity opens a jar, loosing multifarious evils on humanity; the other traces man's decline since the Golden Age, down through the Silver, Bronze, and Heroic to Hesiod's own miserable era of iron.

Hesiod also speaks to Perses directly, urging him to abandon his schemes and thenceforth to gain his livelihood through strenuous and persistent work: "Before success the immortal gods have placed the sweat of our brows." Hard work is for Hesiod the only way to prosperity and distinction.

In the second half of the poem, Hesiod describes with much practical detail the kind of work appropriate to

each part of the calendar and how to set about it. The description of the rural year is enlivened by a vivid feeling for the rhythm of human life and the forces of nature, such as the overpowering winter storm, which drives man back into his home, and the parching heat of summer, during which he must rest.

The poem ends with a series of primitive taboos and superstitions, followed by a section explaining which days of the month are auspicious for sowing, threshing, shearing, and the begetting of children. It is difficult to believe that either of these sections could have been composed by Hesiod.

Spurious works. Such was the power of Hesiod's name that epics by other poets were soon attributed to him; these are often included in editions of his works. The *Precepts of Chiron*, the *Astronomy*, the *Ornithomanteia* (Divination by Birds), the *Melampodeia*, which described a contest between two seers, and the *Aigimios* are today little more than names. There are numerous extant fragments of the *Catalogues of Women*, which deals primarily with women who through union with gods become mothers of heroes and ancestresses of noble families. Papyruses deciphered since the 1890s, and especially in the 1950s and 1960s, have added much to knowledge of its content and have made it possible to arrive at a clearer idea of its organization. There is no evidence for the theory that the oldest parts are by Hesiod. The story of Alcmene, Heracles' mother, is extant in an expanded form as the *Shield of Heracles*, probably dating from the early or middle 6th century. In its present form the *Contest Between Homer and Hesiod*, ending in Hesiod's victory, postdates the emperor Hadrian (2nd century).

BIBLIOGRAPHY

Works: *The Works and Days, Theogony*, and *The Shield of Herakles*, trans. by R. LATTIMORE (1959), a brisk, modern translation, perhaps appreciated best when sampled along with *Hesiod, the Homeric Hymns, and Homerica*, trans. by H.G. EVELYN-WHITE, rev. ed. (1959), an antique but accurate translation, with parallel text. More exotic translations include *Fable of the Hawk and the Nightingale*, trans. by ROBERT GRAVES (1959); and *The Georgicks of Hesiod*, trans. by G. CHAPMAN (1618 and 1858). The most recent edition of the original Greek text of Hesiod's epics and a selection of "fragments" (*i.e.*, passages preserved from the *Catalogues of Women* . . .), ed. by R. MERKELBACH, F. SOLMSEN, and M.L. WEST was published in 1970.

Biography and criticism: Scholarly analyses of Hesiod's poems and discussions of various facets of these works are provided by F. SOLMSEN, *Hesiod and Aeschylus* (1949); and M.L. WEST in the "Prolegomena" of *Hesiod Theogony* (1966). The best appreciation of his poetic individuality is in HERMANN FRANKEL, *Dichtung und Philosophie des frühen Griechentums* (1951). Important for Hesiod's place in the history of Greek thought is WERNER JAEGER, *Paideia: The Ideals of Greek Culture*, trans. from the German by GILBERT HIGHET, 2nd ed., vol. 1 (1945, reprinted 1970). Near-Eastern theologies comparable with Hesiod's *Theogony* are summarized by West; for suggestions about the relationship, see P. WALCOT, *Hesiod and the Near East* (1966).

(F.So.)

Hessen

A *Land* (state) of Germany, that, following partition of the nation after World War II, became part of the Federal Republic of Germany, Hessen (Hesse) had an area of 8,151 square miles (21,111 square kilometres) and a population of some 5,400,000 in the early 1970s. The state lies between the Upper Rhine Plateau and the Thüringer Wald (Thuringian Forest) and was formed in 1945 through the amalgamation of former Prussian provincial units. Its capital is Wiesbaden.

Landscape and people. Hessen consists mainly of richly wooded hill land cut by two fault troughs, the west and east Hessen depressions, which have been important corridors since earliest times. Along these troughs most of the state's main towns were founded in the Middle Ages. The area is dominated to the south by the Vogelsberg, a great basaltic mass, and the Rhön, a mountainous mass rising to the Wasserkuppe (3,117 feet [950 metres]), Hessen's highest mountain. The Spessart and the Odenwald regions both belong in part to Hessian territory.

The Vogelsberg and the Rhön

Hessen is drained by the Rhine and its tributaries the Main and the Lahn, by the Weser, and by the Werra and Fulda. The greater part of the *Land* lies in the country of hills and lowlands that is drained north by the Fulda and Eder rivers above their confluence to form the Weser River. Beechwoods and conifers cover the highlands, and cultivated land lies on the limestone uplands and on the loess soils of the lowlands proper. This is a predominantly unspoiled agricultural countryside with small historic towns.

In the early 1970s, according to the available figures, there were five towns with populations of over 100,000: Frankfurt am Main (669,000), Wiesbaden (250,100), Kassel (214,200), Darmstadt (142,100), and Offenbach am Main (117,300). About 61 percent of the population is Protestant and 33 percent Roman Catholic.

The economy. The state is well wooded, and small-scale farming is still widespread; of over 2,400,000 persons who were employed at the 1970 census, more than 150,000 were engaged in agriculture and forestry. Nearly 1,200,000 were involved in power supply, mining, manufacturing, and building. Potatoes and sugar beets are the chief crops produced in quantity, more than 1,200,000 and 880,000 metric tons respectively in the early 1970s. Wheat is the most widely grown crop, covering more than 320,000 acres (130,000 hectares)—more than double the space devoted to potatoes, which, in turn, have almost two and a half times the acreage accorded to sugar beets.

Poultry outnumbers humans by nearly a million, numbering almost 6,225,000. Pigs total nearly 1,400,000, while cattle number about 900,000. The southwest of Hessen is primarily industrial but is also an area of intensive agriculture (which occupies about one-fifth of its workers). The plains along the Rhine and Main rivers are a mosaic of vineyards, orchards, and fields of grain, potatoes, and tobacco. This lowland has an early spring and a warm summer, and the total rainfall is only about 20 inches (500 millimetres) a year. Market gardening is especially important near the cities. The surrounding hills have a three-year rotation of rye, oats, and potatoes, and livestock farms concentrate on the production of butter and cheese.

Natural resources

Natural resources are small; there are some low-grade iron ores in the Tanus Mountains, which are of little economic significance; salt mines near Fulda; and small, brown-coal deposits near Frankfurt am Main and Kassel. The industries depend on the Rhine waterway and its extensions up the Main and Neckar. The Rhine–Main area, centred on Frankfurt am Main, Mainz, and Wiesbaden, is one of the great industrial regions of Germany. Kassel, Offenbach, Wiesbaden, and Darmstadt are other big manufacturing centres. Vehicles, machinery, chemicals (especially at Höchst, a western quarter of Frankfurt am Main), electrical goods, scientific instruments, and textiles are among the products of these and other towns. New industries have developed since World War II, stimulated by the arrival of refugees; these manufactures include the making of glass, toys, and musical instruments. Book publishing is a prominent economic activity.

Transportation. In the early 1970s, there were nearly 9,900 miles (16,000 kilometres) of classified roads, about 450 miles of *Autobahn*, more than 2,150 miles of federal highway and more than 4,400 miles of first-class highway. Motor vehicles numbered more than 1,700,000. A symbol of progress in transportation is the cloverleaf interchange on the "Frankfurt Cross" *Autobahn*. The Post Office, Federal Railway, and private companies all run bus services. The Rhine provides the chief waterway, and its economic importance cannot be overestimated. In air traffic Hessen is paramount, Frankfurt's Rhine–Main Airport being western Europe's busiest after Heathrow (London) and Orly (Paris). In the early 1970s, it was handling more than 9,300,000 passengers a year. Rail travel in Hessen, as throughout the Federal Republic of Germany, is largely electrified and has international European links.

Administration. Hessen is divided into two administrative districts (*Regierungsbezirke*)—Kassel and Darmstadt—which are subdivided into municipal and rural dis-

tricts (*Stadtkreise* and *Landkreise*). Education is free and widely organized. There are part-time, full-time, and advanced vocational schools and schools for public-health occupations. In addition, 23 institutes for training technicians and 19 colleges of engineering exist.

There are three universities, Frankfurt am Main, Giessen, and Marburg, the latter boasting the largest student hostel in the Federal Republic. These are supplemented by a technical university at Darmstadt, one Protestant and three Roman Catholic theological colleges, eight teacher-training colleges, one college of music, and two colleges of fine arts.

There are nearly 350 hospitals with over 60,000 beds. The social-welfare public assistance includes aid to tuberculars and war victims.

Justice is administered by a constitutional court (*Staatsgerichtshof*), a court of appeal, and various other courts dealing with regional jurisdiction, labour, finance, administrative matters, and cases coming under social headings.

Cultural life. Old traditions remain very much alive in Hessen, especially in the thriving city of Frankfurt am Main. Hessen provided the chief source for the brothers Grimm when they collected their fairy tales—particularly in the Weser Gebirge (hills), on either side of the Weser River and around Kassel. On the Weser's banks are many ruined castles, old churches, and palaces, and there are also burgher houses and town halls throughout the state.

Frankfurt am Main has the Cathedral of St. Bartholomew, the Goethe Museum (1961) standing beside the Goethehaus, the 18th-century poet's birthplace, a town hall (Römer), a picture gallery, and an opera house. Kassel, where an international modern art exhibition is held every four years, boasts a wallpaper museum (Wilhelmshöhe Castle), a museum and gallery with a large collection of works by the 17th-century Dutch painter Rembrandt, and the Brothers Grimm Museum. Wiesbaden and Darmstadt also have very respectable art galleries. Interesting half-timbered buildings and houses in later styles are prolific throughout the state.

BIBLIOGRAPHY. Little material specifically on Hessen is in English. An exhaustive bibliography of ancient to contemporary works is in *Schrifttum zur Geschichte und geschichtlichen Landeskunde von Hessen*, ed. by KARL E. DEMANDT, 3 vol. (1965–68); see also the same author's *Geschichte des Landes Hessen* (1959). A more elementary but useful history of the postwar *Land* and its predecessor states is KURT FINKE, *Hessen: Vergangenheit und Gegenwart* (1970). A firsthand account of the early post-war period appears in DEXTER L. FREEMAN, *Hesse: A New German State* (1948). The standard geography series *Harms Landeskunde* devotes vol. 1, ed. by JULIUS WAGNER, to *Hessen* (1961). Detailed information on Hessen's population, economy, political structure, judiciary, education, and modern historical development are given in a series of volumes of the Hessisches Statistisches Landesamt, Wiesbaden. For a handy ready-reference with abundant information, see the *Hessenlexikon* (1965). A well-illustrated, informative treatment of the Hessian economy appears in *Hessen um Rhein und Main*, 2nd ed. by KLAUS ERHR. VON VERSCHUER (1966). Hessen's lead in reform of primary and secondary education is covered in ROBERT GEIPEL, *Bildungsplanung und Raumordnung* (1968); health and social care are discussed in the HESSISCHES SOZIALMINISTERIUM, *Heute für Morgen: Hessens Gesundheits- und Sozialwesen* (1970). Aspects of Hessian ethnology are dealt with in INGEBORG WEBER-KELLERMANN, *Volksleben in Hessen* (1970). For works in English reflecting portions specifically devoted to Hessen, see the bibliography of the article GERMANY, FEDERAL REPUBLIC OF.

Heterocyclic Compounds

Heterocyclic compounds are a major class of organic (carbon-containing) chemical compounds, characterized by the fact that the atoms in their molecules are joined into rings, or circles, containing at least one atom of an element other than carbon. These compounds are of great importance because many of the biochemical materials essential to life belong to the class. Nucleic acids, for example, the chemical substances that carry the genetic information controlling inheritance, consist of long chains of heterocyclic units held together by other types of materials. Many naturally occurring pigments, vitamins, and antibiotics are heterocyclic compounds, as are most hallucinogens, substances that produce hallucinations. Modern society is dependent on synthetic heterocycles for use as pharmaceuticals, pesticides, and herbicides, as well as dyes and plastics.

The most common heterocycles are those with five- or six-membered rings, containing atoms of nitrogen, oxygen, or sulfur. The best known of the simple heterocyclic compounds are pyridine, pyrrole, furan, and thiophene. Pyridine and pyrrole are both nitrogen heterocycles; that is, their molecules contain nitrogen atoms in the rings with carbon. Because the molecules of many biological materials consist in part of pyridine and pyrrole rings, strong heating of such materials produces small amounts of pyridine and pyrrole. In fact, both of these substances were discovered in the 1850s in an oily mixture of substances formed by strong heating of bones. Today, however, pyridine and pyrrole are generally obtained from coal tar or are prepared by synthetic reactions. The chief commercial interest in both compounds lies in their conversion to other substances, chiefly dyestuffs and drugs. Pyridine is used also as a solvent, a waterproofing agent, a rubber additive, an alcohol denaturant, and a dyeing adjunct. Furan is an oxygen-containing heterocycle, used primarily for conversion to other substances (including pyrrole). Furfural, a close chemical relative of furan, is obtained from oat hulls and corncobs and is used in the production of ingredients of nylon. Thiophene, a sulfur heterocycle, resembles benzene in its chemical and physical properties. It is a frequent contaminant of benzene from natural sources and was first discovered during purification of benzene. Like the other compounds, it is used primarily for conversion to other substances. Furan and thiophene both were discovered in the latter part of the 19th century.

The common simple heterocyclic compounds

Each of the molecules of pyridine contains a ring of six atoms, five of which are carbon atoms and one of which is a nitrogen atom. Pyrrole, furan, and thiophene molecules contain five-membered rings, composed of four atoms of carbon and one atom of nitrogen, oxygen, or sulfur, respectively.

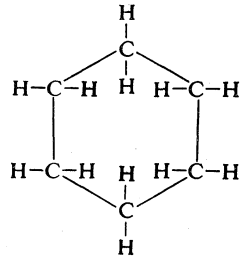
In general, the physical and chemical properties of heterocyclic compounds are best understood by comparing them with ordinary organic compounds that do not contain hetero-atoms (noncarbon atoms). In this article, the comparative aspects of heterocyclic compounds will be considered first, followed by a brief survey of the different classes of heterocyclic compounds, arranged according to the size and nature of the ring.

GENERAL ASPECTS OF HETEROCYCLIC SYSTEMS

Comparison with carbocyclic compounds. The molecules of organic chemical compounds are built up from a framework or backbone of carbon (C) atoms to which are attached hydrogen (H), oxygen (O), or other heteroatoms. Carbon atoms have the unique property of being able to join with one another to form chains of atoms. When the ends of the chains are joined together, ring—that is, cyclic—compounds result; such substances often are referred to as alicyclic or carbocyclic compounds. Substitution of one or more of the ring carbon atoms in the molecules of a carbocyclic compound with a heteroatom gives a heterocyclic compound.

Carbocyclic compounds

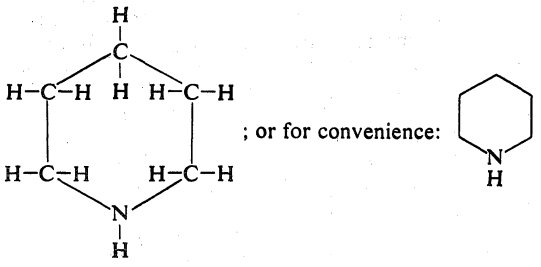
A typical carbocyclic compound is cyclohexane (C_6H_{12}), the molecular structure of which is indicated by the following formula



in which the letters represent atoms of the elements of which they are symbols and the lines represent bonds (linkages) between the atoms. For convenience such formulas are often written in the simplified polygonal form, such as

for cyclohexane, in which each angle of the polygon represents a carbon atom (it being understood that hydrogen atoms are joined to the carbon atoms as required).

When one of the carbon atoms of cyclohexane is replaced with an atom of nitrogen, the compound piperidine (a chemical relative of pyridine, above) is produced. The structural formula of piperidine is written as follows:

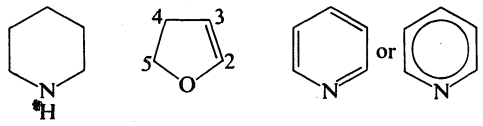


Other heterocyclic compounds can be envisioned as having been produced (similarly) from cyclohexane by substitution with other hetero-atoms or from other carbocyclic compounds by substitution with nitrogen or other hetero-atoms.

Paraffinic, olefinic, and aromatic compounds

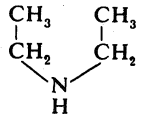
The simplest organic compounds are the hydrocarbons, compounds of carbon and hydrogen only. Hydrocarbons are classed as paraffinic if all the potential bonds of the carbon atoms are saturated—that is, if the four possible bonds of each carbon atom are joined singly to another carbon atom or to a hydrogen atom. They are classified as olefinic if they contain a double bond (also called an unsaturated linkage) between any two of the carbon atoms; and they are classed as aromatic if they contain a ring of alternating single and double bonds. Compounds with unsaturation are highly reactive—that is, they readily undergo additions of atoms or groups of atoms to the carbon atoms of their double bonds, giving each carbon four groups joined to it. Aromatic compounds, though unsaturated, are extremely stable and do not undergo the addition reactions characteristic of other unsaturated compounds. The stability and unreactivity of the aromatic system are associated with presence of three pairs of electrons, the so-called pi electrons, associated with the three double bonds of the ring. Together these electrons, comprising the so-called aromatic sextet, form an unusually stable structure, associated with the aromatic ring as a whole rather than with the individual atoms.

Heterocycles, too, may be classified as paraffinic, olefinic, and aromatic. Thus, piperidine is a heteroparaffinic compound containing no double bond, whereas 4,5-dihydrofuran is a hetero-olefinic compound, and pyridine is a typical hetero-aromatic substance, as shown in the following structural formulas, in the first of which the double bonds are shown and in the second of which the aromatic sextet is indicated by a circle.

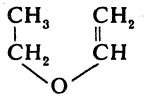


piperidine 4,5-dihydrofuran pyridine

This classification relates the chemistry of heterocycles directly with that of nonheterocyclic derivatives, which are usually better known. In general, synthetic methods and physical and chemical properties of the saturated heteroparaffinic and the partly unsaturated hetero-olefinic compounds closely resemble those for their acyclic (noncyclic) analogues. Thus, piperidine may be considered as a cyclic secondary amine (organic nitrogen compound) and has much in common with the acyclic amine, diethylamine, which is represented as follows:



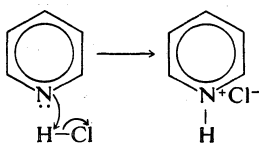
Similarly, 4,5-dihydrofuran mirrors many of the properties of the unsaturated ether, ethyl vinyl ether, written as follows:



It is within the area of hetero-aromatic compounds that most of the novel chemistry of the class is to be found, and for that reason hetero-aromatics will be emphasized in this article.

Chemical reactions. Every chemical reaction involves the forming or breaking of a chemical bond: for heterocycles the bonds in question are generally covalent bonds—linkages consisting of a pair of electrons shared by two atoms. Reactions generally can be placed in one of several categories, depending upon the origin, or disposition, of the electron pair of the bond that is formed or broken. The first of these categories is heterolytic reactions, in which the electron pair is supplied by one of the reactants (known as the nucleophile) to the other reactant (known as the electrophile). In the formation of pyridinium chloride, for example, which occurs as shown in the following equation:

Heterolytic reactions



in which, as is customary, the structure of the starting material is written at the left, the product is written at the right, and an arrow in between the two indicates the reaction. In these structural formulas the presence of a free electron pair on the nitrogen atom is indicated by two dots, the movements of electrons are shown by curved arrows, and plus and minus signs indicate positive and negative charges. In this reaction, the pyridine molecule behaves as a nucleophile, the electron pair that initially resided on the nitrogen atom finally being shared between that atom and the hydrogen atom of the hydrogen chloride (which acts, therefore, as an electrophile). In homolytic reactions, an electron-pair bond is formed (or broken) and in this process each of the reagents donates (or receives) a single electron. In some reactions, cyclic transition states are involved, which must be classified separately.

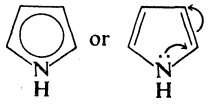
In a heterolytic bond-forming reaction the reagent that accepts the electrons is known as an electrophilic reagent; for instance, in the coordination reaction with hydrogen chloride (above), the nitrogen atom of pyridine acts as a nucleophilic reagent. This behaviour is characteristic of pyridine. The nitrogen atom in pyrrole, by contrast, does not act as a nucleophilic centre, a distinction that can be rationalized by the different type of electronic interaction present in these two hetero-aromatic molecules (as explained below).

The nature of hetero-aromaticity. Aromaticity denotes the significant stabilization of a ring compound by cyclic conjugation in which six pi electrons generally participate. A nitrogen atom in a ring can carry a positive or negative charge, or it can be in the neutral form. Ring oxygen and sulfur atoms can occur either in the neutral form or with a positive charge. A fundamental distinc-

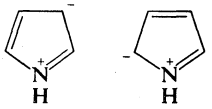
tion is usually made between: (1) those hetero-atoms that enter into aromatic conjugation by means of a lone electron pair in an orbital perpendicular to the plane of the ring, and (2) those hetero-atoms that enter into conjugation because they are connected to another atom by means of a double bond.

Pyrrole- and pyridine-type hetero-atoms

An example of an atom of the first type is the nitrogen atom in pyrrole. In pyrrole, the aromatic electron sextet is made up by the participation of two electrons from each carbon–carbon double bond, as well as the two electrons that comprise the unshared pair of the nitrogen atom. As a consequence, there tends to be a net flow of electron density from the nitrogen to the carbon atoms as the nitrogen electrons are drawn into the aromatic sextet; this movement may be indicated as follows,

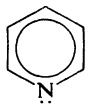


in which the curved arrows depict the movement, or tendency toward movement, of the electron pair. Alternatively, the pyrrole molecule may be described as a resonance hybrid—that is, a molecule whose true structure can only be approximated by two or more different forms, called resonance forms. With pyrrole, resonance forms such as the following make important contributions to the overall structure.

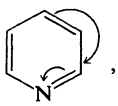


In these forms the nitrogen atom is depleted of electrons, as indicated by the positive charge.

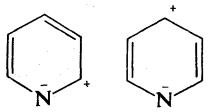
An example of a hetero-atom of the second type is the nitrogen atom in pyridine. Pyridine also has a pi electron sextet; but the nitrogen atom contributes only one electron to it, one further electron being contributed by each of the five carbon atoms. In particular, the lone electron pair on the nitrogen atom is not involved, as indicated in the following formulation.



Moreover, because of the greater attraction for electrons (electronegativity) of the nitrogen atom as compared to carbon atoms, there is a tendency for an electron flow toward the nitrogen atom, rather than away from it, as in pyrrole. This movement of electrons is shown as below

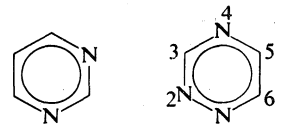


or it can be expressed in terms of contributions of the resonance forms as follows:



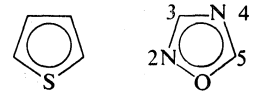
Quite generally, hetero-atoms may be referred to as pyrrole-like or pyridine-like, depending upon whether they fall into the first or second class, respectively, above. The pyrrole-like hetero-atoms $-NR-$ (R being a hydrocarbon group), $-N^{-}-$, $-O-$, and $-S-$ tend to donate electrons into the pi electron system, whereas the pyridine-like hetero-atoms $-N=$, $-N^{+}R=$, $-O^{+}=$, and $-S^{+}=$ tend to attract the pi electrons of a double bond.

A six-membered hetero-aromatic ring contains one or more pyridine-like hetero-atoms (usually nitrogen), as is the case with the compounds pyrimidine and 1,2,4-triazine.



pyrimidine 1,2,4-triazine

A six-membered hetero-aromatic compound cannot normally contain any pyrrole-like hetero-atoms. A five-membered hetero-aromatic ring, however, always contains one pyrrole-like nitrogen, oxygen, or sulfur atom, and it may also contain up to four pyridine-like hetero-atoms, as shown by the compounds below.



thiophene 1,2,4-oxadiazole

The quantitative measurement, or even the precise definition, of aromaticity is difficult; two methods have been widely used to measure the aromaticity of carbocyclic compounds. The first method depends on the determination of the heat given off on complete combustion of the aromatic compound—say, benzene—compared with that expected for the corresponding carbocyclic compound containing three conventional double bonds—say, a cyclohexatriene. Because the heat of combustion is related to the energy content of the molecule, comparisons of the above kind reveal the reduction of energy associated with the aromatic system. The second method depends on measurement of magnetic ring currents set up in aromatic systems by external magnetic fields. The measurement is made with a nuclear magnetic resonance spectrometer, and the degree of observed magnetic effect is related to the degree of aromaticity. Both methods are difficult to apply to hetero-aromatic systems because of complications arising from the presence of the hetero-atoms. Table 1 gives some values for aromatic stabiliza-

Measurements of aromaticity

Table 1: Aromatic Stabilization Energies for Benzene and Some Hetero-aromatic Rings
(kcal/mol)

benzene	pyridine	pyrazine
36	32	24
pyrrole	thiophene	furan
14–31	24–31	17–23
pyrazole	imidazole	1,2,4-triazole
27–41	12–32	20–49

tion determined by combustion or related methods. Unfortunately, high errors are involved, as indicated by the wide variations in some of the values.

With regard to its chemical reactivity, an aromatic compound is characterized by extra stability of the conjugated system it contains; this characteristic, in turn, is denoted by the tendency of the compound to react by substitution (replacement of a hydrogen atom) rather than by addition to the double bonds. From a reactivity

*Melting points above 30°C are indicated by a dagger†; those below 30°C are not included.
A dash indicates the compound is unstable, unknown, or that the data are not readily available.
‡Indicates that the compound melts with decomposition.

standpoint, therefore, the degree of aromaticity is measured by the relative tendency toward substitution rather than addition. Judging by this criterion, pyridine is more aromatic than furan, but it is difficult to say how much more aromatic it is.

Physical properties. Physical properties are important as criteria for judging the purity of heterocycles, just as for other organic compounds. The melting point was once the criterion most widely used, but now the optical spectra (based on light absorption), mass spectra (based on relative masses), and magnetic-resonance spectra (based on nuclear properties) have been increasingly used. Nevertheless, knowledge of the boiling point or melting point is still helpful in following purification of a compound. Organic compounds generally show great regularity regarding their physical properties, and heterocycles are no exception.

Melting and boiling points. The boiling points of certain saturated heterocycles compared with the corresponding cycloalkanes are listed in Table 2. The melting or boiling points of common hetero-aromatic ring compounds and their substituted derivatives are compared with those for benzene and its derivatives in Table 3. It can be seen from the table that replacement of a two-carbon unit (with molecule weight equal to 26) by a sulfur atom (atomic weight 32) has little effect on the melting or boiling point (compare corresponding benzene and thiophene compounds). On the other hand, replacement of a two-carbon unit by an oxygen atom (atomic weight 16) lowers the boiling point by about 40° C (compare corresponding benzene and furan compounds), which is to be expected because of the decreased molecular weight (lighter compounds being more volatile). The introduction of nitrogen atoms into the benzene ring is accompanied by less regular changes. Replacement of a two-carbon unit by an imino (NH) group, or of a single carbon by a nitrogen atom, increases the boiling point. Furthermore, if these two changes are made simultaneously, the boiling point is increased by an especially large amount, probably the result of association by hydrogen bonding (a weak form of attachment through certain types of hydrogen atoms) between the nitrogen atom and the imino group.

Effects of substituents

The effects of substituent groups in hetero-aromatic rings show considerable regularity. Thus, methyl and ethyl groups attached to ring carbon atoms usually increase the boiling point by about 20–30° C and 50–60° C, respectively, whereas conversion of an imino (NH) group into an amino (NR, in which R is a hydrocarbon chain) group (*e.g.*, pyrazole → 1-methylpyrazole) significantly decreases the boiling point because of decreased ease of association by hydrogen bonding (the active hydrogen having been replaced by a hydrocarbon group). Carboxylic acids and amides are all solids; carboxy derivatives of compounds containing a ring nitrogen atom usually melt at higher temperatures than those containing ring oxygen or sulfur atoms because of hydrogen bonding. Compounds containing both a ring nitrogen atom and a hydroxyl or amino group are usually relatively high melting solids. Chloro compounds usually have boiling points similar to those of the corresponding ethyl compounds.

Ultraviolet, infrared, nuclear magnetic resonance and mass spectra. Spectroscopic studies of heterocyclic

compounds, as have those of other organic compounds, have become of great importance as means of identification of unknown materials, as criteria of purity, and as probes for investigating the electronic structures of molecules, thereby explaining and helping to predict their reactions. The pattern of light absorption in the ultraviolet region of the spectrum (the so-called ultraviolet spectrum) of a compound is characteristic of the pi electron system of the molecule; *i.e.*, of the arrangement of double bonds within the structure. The ultraviolet spectra of hetero-aromatic compounds (given in Table 4) show general similarity to those of benzenoid compounds, and the effects of substituents can usually be rationalized in a similar way. The infrared spectrum of an organic compound, with its complexity of bands, provides an excellent "fingerprint" of the compound (far more characteristic than the melting point), and it can also be used to identify certain common groups, such as carbonyl (C = O) and imino (N — H) groups, as well as various of the heterocyclic ring systems (Table 5). Although magnetic resonance spectra were not widely used until about 1955, they have since become indispensable to any serious study of heterocyclic chemistry. Proton resonance spectra (the most common type), for example, yield information regarding the number of hydrogen atoms present in the molecule, as well as their chemical environment and their relative orientations in space (Table 6). Still later, mass spectra have been used to determine not only the complete molecular formula of the heterocyclic compound but also, from the way the molecule is fragmented, the arrangement of many of the atoms.

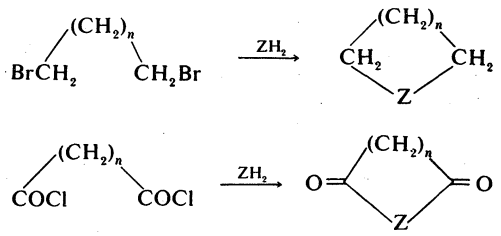
Synthesis and modification of heterocyclic rings. The important methods for synthesizing heterocyclic compounds may be classified under five headings, of which the first three are ways of forming new heterocyclic rings from precursors containing one less ring, the fourth covers the formation of a heterocyclic ring either from another heterocycle or from a carbocyclic ring, and the fifth includes the modification of substituents on a pre-existing heterocyclic ring. The key step in the formation of rings from noncyclic precursors (the first instance above) often is the formation of the carbon hetero-atom linkage (C — Z, in which Z represents an atom of nitrogen, oxygen, or sulfur). The actual ring closure, or cyclization, however, may involve the formation of a carbon–carbon bond. In any case, ring formation reactions are subdivided into three categories according to whether the cyclization reaction occurs primarily as a result of (1) nucleophilic or (2) electrophilic attack, or (3) by way of a cyclic transition state.

Classification by methods of ring closure

Nucleophilic ring closure. To prepare compounds containing one hetero-atom, a compound containing two halides (chloride [Cl], bromide [Br], or iodide [I]) or acyl halides (that is, halide derivatives of carboxylic acids) will react with the dihydro form of the hetero-atom, ZH_2 (or an equivalent reagent such as sodium hydroxide or sodium sulfide), to give nonaromatic heterocycles, as shown in the two examples below:



in which *n* equals only an integer

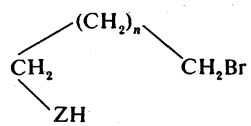
Diketones (ketones being compounds with oxygen atoms joined to carbon by double bonds) also can react with dihydro-Z compounds to give heterocycles. Diketones with the keto groups separated by two carbon atoms, for example, can be cyclized to form aromatic pyrroles, furans, and thiophenes as shown:

in which R is a hydrocarbon chain

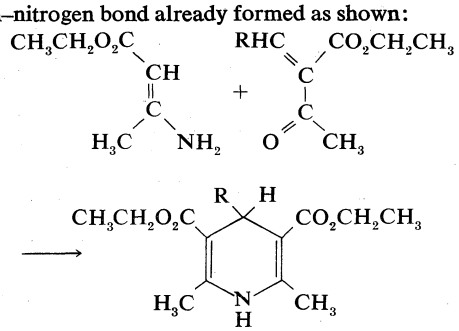
With diketones separated by three carbons, such as the unsaturated compound below, six-membered rings may be formed:

In each of these reactions the hetero-atom Z acts as a nucleophile in attacking the positively charged carbon atom produced by electron withdrawal due to the halogen atom (in the first instance above) or to the oxygen atom (in the second).

Usually, reactions like these proceed by means of intermediates in which only one of the C — Z bonds has been formed. In reactions of the first type in this section, for instance, compounds like the one shown below may be formed first.

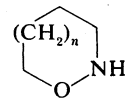


It is frequently possible to synthesize such intermediate compounds by other routes, and they then cyclize readily. One form of pyridine synthesis, for example, involves the condensation of an intermediate with the carbon–nitrogen bond already formed as shown:

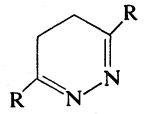


Heterocycles containing two adjacent nitrogen atoms and oxygen atoms, or both, also may be prepared from precursors of the type shown in the first example of this

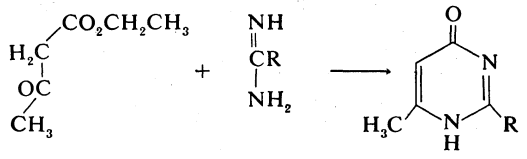
section by using hydrazine (N_2H_4), hydroxylamine (NH_2OH), or hydrogen peroxide (H_2O_2) in place of the dihydro-Z compound (ZH_2). With hydroxylamine, for example, the compound shown below is formed.



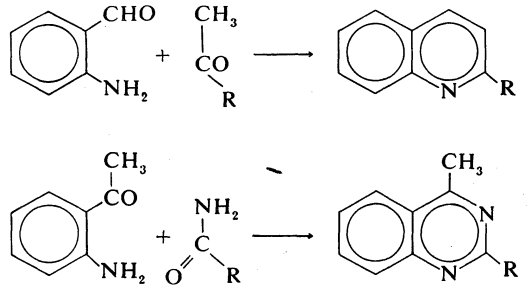
Similarly, two adjacent hetero-atoms can be introduced by reactions with diketones (the second reaction here), producing such compounds as the following:



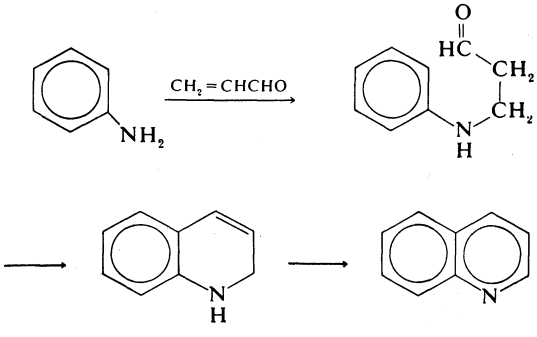
When it is desired to prepare a compound containing two nonadjacent hetero-atoms, appropriate components can be put together as illustrated in the following synthesis of pyrimidines:



Ring synthesis reactions, in which the hetero-atom acts as a nucleophile, also involve orthodisubstituted benzenes (ortho substituents being on adjacent carbon atoms in the benzene ring), as in the preparation of many heterocycles fused to benzene rings. The formation of quinoline and quinazoline rings are examples of this type:

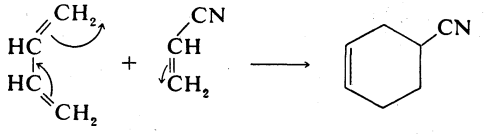


Electrophilic ring closure. Formation of heterocyclic rings by reactions in which the hetero-atom acts as an electrophilic (electron-seeking) reagent are rare, because the nitrogen, oxygen, and sulfur atoms are themselves electron-rich centres that react generally as nucleophiles. Electrophilic ring-closure reactions are known, however, in which a heterocyclic ring is formed by a reaction in which a carbon atom of the ring acts as an electrophile. Usually such reactions involve ring closure onto a benzene ring (or other aromatic system), an electron-rich system that is generally subject to attack by electrophilic reagents. An example of ring closures of this type is the formation of quinoline from aniline and acrolein, a dehydration product of glycerol. As shown below, the initial product of the reaction is a dihydroquinoline, which must be dehydrogenated to the fully aromatic product, quinoline itself:

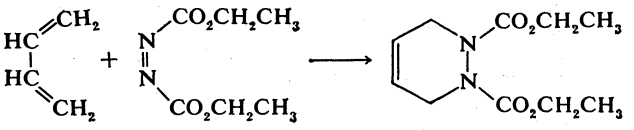


Ring closure by way of cyclic transition states. A most important method for the synthesis of carbocyclic six-membered rings is the so-called Diels–Alder diene reaction (named for its discoverers, two German Nobel Prize winning chemists, Otto Diels and Kurt Alder). In this reaction, as illustrated below, a diene (a compound with two double bonds) reacts with a dienophile (a diene-seeking reagent) to yield a cyclohexene:

The Diels–Alder reaction



In this reaction, it is not possible to determine whether the electrons move clockwise (as shown by the curved arrows) or whether they move in the reverse, counterclockwise fashion. For this reason, in reactions of this type the movements of electrons are thought to be synchronous rather than sequential, and the reactions are said to possess cyclic transition states. Heterocycles can also be prepared by the diene synthesis, as illustrated by this preparation of a tetrahydropyridazine:



Of far greater use, however, is the related method referred to as the Huisgen cyclic dipolar addition reaction; it is an important method for the preparation of many types of five-membered rings, especially those containing several hetero-atoms. Pyrazoles and isoxazoles, and many less common heterocycles, also are prepared by this method.

Conversion of one heterocyclic ring into another. There are many reactions of theoretical, and a few of practical, importance in which one heterocyclic ring is converted into another. The ring-atom exchange reactions of pyridine derivatives (see below, *Six-membered rings with one hetero-atom*) are good examples. In addition, ring-atom rearrangement or "shuffling" can be brought about with light (photochemically) in five- and six-membered hetero-aromatic compounds, and ring contraction by extrusion of an atom or group can occur under certain conditions.

Modification of an existing ring. Dehydrogenation of saturated or partially saturated rings to hetero-aromatic compounds by heating with sulfur or treatment with a palladium catalyst is analogous to similar reactions with carbocyclic compounds. The hydrogenation of hetero-aromatic rings is, by contrast, usually more difficult, for the hetero-atoms tend to poison the catalyst. Finally, the modification of substituents on heterocyclic rings is of highest importance in synthesis; reactions by which substituents may be altered are among the most useful in heterocyclic chemistry.

Nomenclature. Naming heterocyclic compounds is complicated because of the existence of many common names, in addition to the internationally agreed systematic nomenclature. A brief account of systematic nomenclature is given here, but for common names the reader is referred to the systematic survey in the next section.

Common and systematic nomenclature

The types of hetero-atoms present in a ring are indicated by prefixes; in particular "oxa," "thia," and "aza" denote oxygen, sulfur, and nitrogen atoms, respectively. The number of hetero-atoms of each kind are indicated by number prefixes joined to the hetero-atom prefixes as "dioxa" and "triaza." The presence of different hetero-atoms is indicated by combining the above prefixes, using the following order of preference: oxa first, followed by thia, then aza. Ring size and the number of double bonds are indicated by suffixes as shown in Table 7. In

Table 7: Suffixes Used in Naming Monocyclic Heterocycles

ring size	rings with nitrogen			rings without nitrogen		
	maximum unsaturated	one double bond	saturated	maximum unsaturated	one double bond	saturated
3	-irine	—	-iridine	-irene	—	-irane
4	-ete	-etine	-etidine	-ete	-etene	-etane
5	-ole	-oline	-olidine	-ole	-olene	-olane
6	-ine	—	—	-ine	—	-ane
7	-epine	—	—	-epine	—	-epane

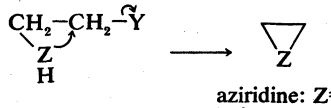
this table, "maximum unsaturation" refers to rings possessing the largest possible number of noncumulative (that is, with no atom in common) double bonds but with oxygen and sulfur atoms in their normal, divalent forms. In addition, partially saturated rings are indicated by the prefixes "dihydro," "tetrahydro," and so on, according to the number of excess hydrogen atoms. The positions of hetero-atoms, extra hydrogen atoms, and substituents are indicated by arabic numerals, for which the numbering starts at an oxygen atom, if one is present, or at a sulfur or nitrogen atom, and continues in such a way that the hetero-atoms are assigned the lowest possible numbers. Other things being equal, numbering starts at a nitrogen atom that carries a substituent rather than at a multiply bonded nitrogen. In compounds with maximum unsaturation, if the double bonds can be arranged in more than one way, their positions are defined by indicating the nitrogen or carbon atoms that are not multiply bonded, and consequently carry an "extra" hydrogen atom (or substituent), as follows: 1H —, 2H —, and so on.

Numbering systems

MAJOR CLASSES OF HETEROCYCLIC COMPOUNDS

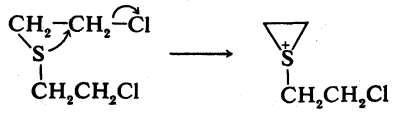
The major classes of heterocycles containing the common hetero-atoms (nitrogen, oxygen, sulfur) are reviewed first, in order of ring size (from smallest to largest), leaving compounds with other hetero-atoms to a final section. The classification by ring size is convenient because heterocyclic rings of a given size have many common features. For heterocyclic (as for carbocyclic) rings, the following broad generalizations can be made: 3- and 4-membered rings are strained and thus readily opened; they are also readily formed: such heterocycles are well-known reactive intermediates. Five- and six-membered rings are readily formed and are very stable: these sizes of ring also allow the development of aromatic character. Seven- and larger-membered rings are stable but not readily formed and are therefore relatively little investigated.

Three-membered rings. The three-membered-ring heterocycles containing single atoms of nitrogen, oxygen, and sulfur—aziridine, oxirane (or ethylene oxide), and thiirane, respectively—and their derivatives can all be prepared by nucleophilic reactions, of the type shown below.



aziridine: Z=NH
oxirane: Z=O
thiirane: Z=S
(Y equals a group displaced by the heteroatom Z)

Thus, aziridine itself is formed by heating β-aminoethyl hydrogen sulfate with base (in which case Y is $-OSO_3H$). A reaction of this type is involved in the action of mustard gas, or dichlorodiethyl sulfide, a poison gas used in World War I. The mustard gas itself ring-closes to give a thiirane derivative, the biologically active agent, according to the reaction below.



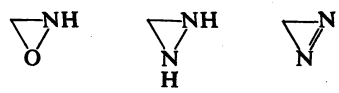
Commercially, oxirane and aziridine (to a lesser extent) are important bulk industrial chemicals; oxirane is prepared on a large scale by the direct reaction of ethylene with oxygen.

The chemical reaction characteristic of these three-membered rings is susceptibility to attack by nucleophilic reagents to open the ring as shown below:

The first step shown is the reverse of the formation reaction above. As indicated, a second molecule of the three-membered ring may react with the first product. Further reaction leads to long, chainlike molecules (polymers) of the type $C_2H_5O(CH_2CH_2Z)_nCH_2CH_2ZH$. Polymers and copolymers of oxirane and aziridine are useful plastics. Although aziridine, oxirane, and thiirane are heteroparaffinic, they are much more reactive than the corresponding normal amines, ethers, or sulfides because of the strain inherent in the three-membered ring. This behaviour reflects the comparable enhanced reactivity of the related carbocyclic compound cyclopropane.

Since 1950, three different classes of three-membered-ring compounds with two hetero-atoms have been discovered. They are derivatives of the parent ring systems oxaziridine, diaziridine, and diazirine, the chemical structures of which are shown below:

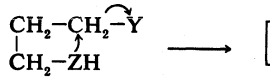
Three-membered rings with two hetero-atoms



oxaziridine diaziridine diazirine

These compounds have no practical importance, but they are stable enough for easy handling and offer interesting possibilities for future use.

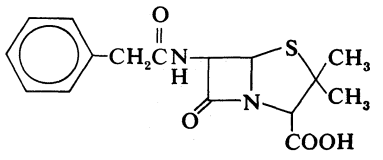
Four-membered rings. Azetidine, oxetane, and thietane—the four-membered rings containing, respectively, nitrogen, oxygen, and sulfur atoms—are prepared by nucleophilic displacement reactions such as those used to prepare the corresponding three-membered rings, as shown:



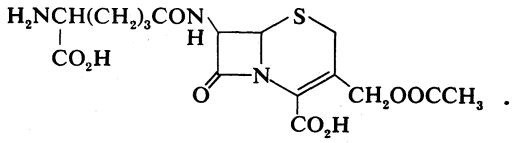
azetidine: Z=NH
oxetane: Z=O
thietane: Z=S

With the four-membered rings, however, the reactions proceed less readily than do the analogous reactions for the formation of the three-membered rings. Similarly, the ring-opening reactions of the four-membered heterocycles qualitatively resemble those of the corresponding three-membered rings, but they occur rather less readily. The most important heterocycles with four-membered rings are two related series of antibiotics, the penicillins and cephalosporins, both of which contain the azetidinone ring:

The chemistry of azetidinones, or β-lactams, as they are also called, was explored thoroughly during the intensive research into penicillin structure and synthesis that took place during World War II, a practical synthesis of penicillin not being achieved, however, until 1959. The complete chemical structures of a representative penicillin and a cephalosporin are shown below:

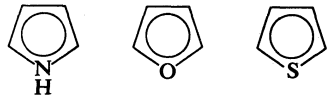


benzylpenicillin



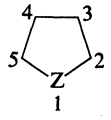
cephalosporin C

Five-membered rings with one hetero-atom. The parent aromatic compounds of the family—pyrrole, furan, and thiophene—have the structures shown:

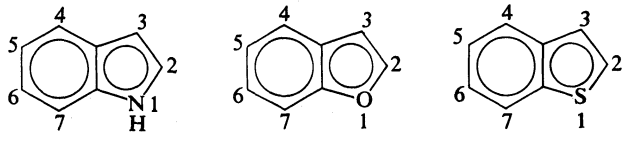


pyrrole furan thiophene

Five-membered heterocycles with one hetero-atom conform to the general structure:



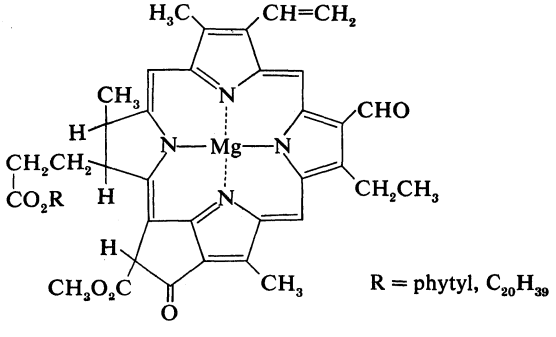
with numbering to indicate substituents as shown. The saturated analogues are called pyrrolidine, tetrahydrofuran, and thiophane, respectively. The bicyclic compounds containing a benzene ring fused to a pyrrole, furan, or thiophene ring are known, respectively, as indole, benzofuran, and thionaphthene; their structures are as shown:



indole benzofuran thionaphthene

The common numbering system is shown only for indole.

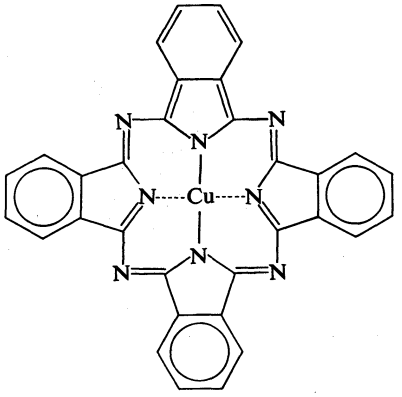
As mentioned earlier, pyrrole occurs in bone oil, in which it is formed by the pyrolytic decomposition of proteins (induced by strong heating). Reduced pyrrole rings are found in the essential amino acids proline and hydroxyproline, which are components of most proteins. Pyrrole derivatives are of widespread natural occurrence: the blood pigment hemoglobin and related compounds, the chlorophylls, and also vitamin B_{12} all are formed from four pyrrole nuclei arranged in a large ring, such as that of chlorophyll b, shown below:



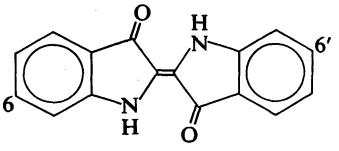
R = phytyl, $C_{20}H_{39}$

chlorophyll b
(plant pigment)

The phthalocyanins are a group of synthetic pigments that contain four benzopyrrole rings linked together in a large ring; a typical member of the family is Monastral blue with the structure shown:



The important vat dye indigo was formerly obtained from natural sources but is now synthesized on a large scale.

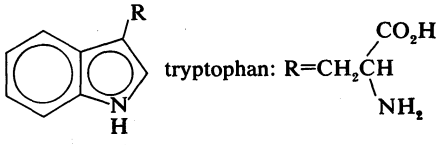


indigo

Tyrian purple, a dye used in classical times, is 6,6′-dibromoindigo (with bromine atoms at the numbered carbons).

Indole compounds

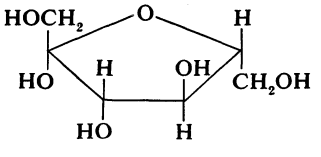
Other indole derivatives occur in nature. Tryptophan is an essential amino acid found in most proteins, and one of its degradation products is skatole, found in feces. Indole-3-acetic acid is a plant growth hormone, and many plant alkaloids contain indole rings. The structures of these compounds are:



tryptophan: R=$CH_2CH(CO_2H)NH_2$

skatole: R=CH_3
indole-3-acetic acid: R=CH_2CO_2H

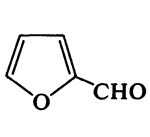
All carbohydrates, the biochemical family that includes the sugars and starches, are composed of one or more sugar (monosaccharide) units. These sugars are polyhydroxyaldehydes or -ketones (carbonyl compounds), which frequently exist as furanosides, that is, as a cyclized form with a five-membered, furanose, ring—*e.g.*, fructose, or fruit sugar—as the fructofuranose shown below:



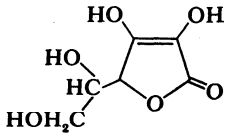
fructofuranose

Dehydration (removal of water) of certain carbohydrates yields furan derivatives; of great commercial importance is the conversion of a carbohydrate in corncobs into fu-

ran-2-aldehyde, or furfural, which is extensively used as a solvent in the manufacture of plastics and in the preparation of other furan derivatives. Many other reduced furans occur naturally, including vitamin C. The structures of furfural and vitamin C are as follows:

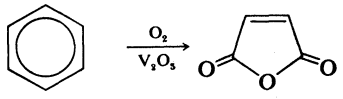


furfural

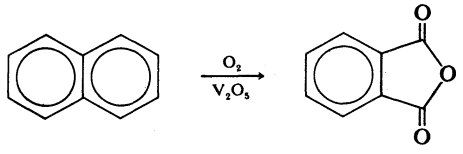


ascorbic acid (vitamin C)

Other derivatives of furan of industrial importance are the solvent tetrahydrofuran prepared from furfural, and maleic and phthalic anhydrides, important constituents of resins and plastics. These compounds are prepared in quantity by the oxidation of benzene and naphthalene, respectively, as shown:

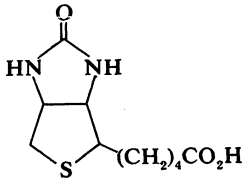


benzene maleic anhydride



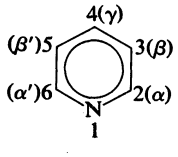
naphthalene phthalic anhydride

Thiophene and related compounds are found in coal tar and crude petroleum. The most important biologically occurring derivative is the vitamin biotin, with the structure:

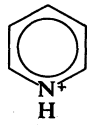


biotin (vitamin H)

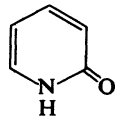
Six-membered rings with one hetero-atom. The nomenclature used for the various monocyclic nitrogen-containing six-membered ring compounds is as shown below, with numbering as shown for pyridine, Arabic numerals being preferred to Greek letters (though both systems are used).



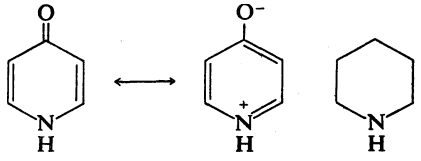
pyridine



pyridinium ion



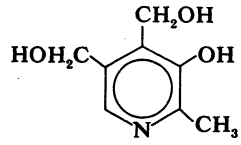
2-pyridone, 2(1H)-pyridone, or 1,2-dihydro-2-oxopyridine



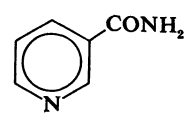
4-pyridone piperidine

The pyridones are aromatic compounds because of contributions to the resonance hybrid from charged canonical forms such as that shown for 4-pyridone. Mono-, di-, and trimethylpyridines are called picolines, lutidines, and collidines, respectively, with the position of the methyl groups denoted by the appropriate numbers; *e.g.*, 2, 4, 6-collidine. Pyridine-2-, -3-, and -4- carboxylic acids also have widely used trivial names; picolinic, nicotinic (derived from nicotine, of which it is an oxidation product), and isonicotinic acid, respectively. Pyridine and the picolines, lutidines, and collidines occur in coal tar and bone oil. Pyridine derivatives are also of great biological importance: vitamin B_6 is pyridoxine, and another B-group vitamin is nicotinamide. Their structures are as follows:

Pyridine and derivatives

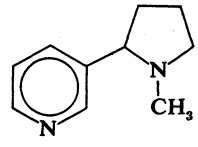


pyridoxine (vitamin B_6)

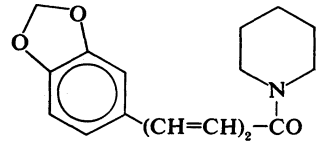


nicotinamide

Coenzymes I and II are derived from nicotinamide, and codecarboxylase from pyridoxine. Many alkaloids are derived from pyridine or piperidine, among them nicotine (in tobacco) and piperine (in pepper), with the structures shown.

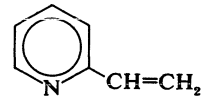


nicotine

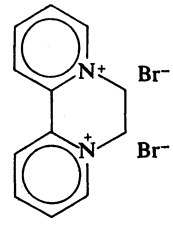


piperine

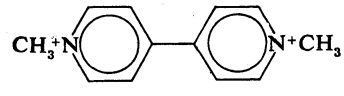
Pyridine, which is now prepared catalytically on a large scale from tetrahydrofurfuryl alcohol and ammonia, is an important solvent and intermediate used to make other compounds. Vinyl-pyridines, such as



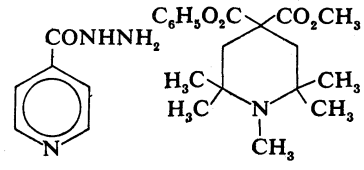
are important monomers used to make plastics. Diquat and paraquat are important herbicides, which selectively kill grassy plants. Pharmaceutically important pyridines include the tuberculostat isoniazid, the local anesthetic α-eucaine, the sulfa drug sulfapyridine, and the respiratory stimulant coramine. The chemical structures of these compounds are as follows:



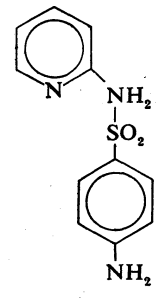
diquat



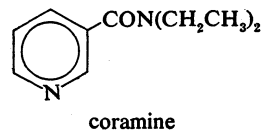
paraquat (herbicide)



isoniazid α-eucaine

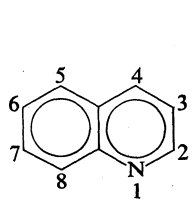


sulfapyridine

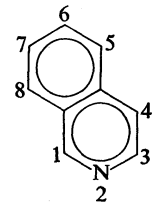


coramine

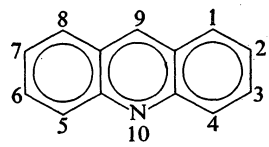
The structures of two isomeric benzopyridines and of two isomeric dibenzopyridines, with their common names and accepted numberings, are shown in the diagrams below:



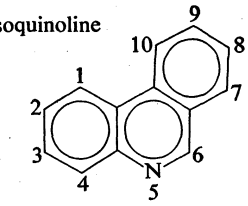
quinoline



isoquinoline

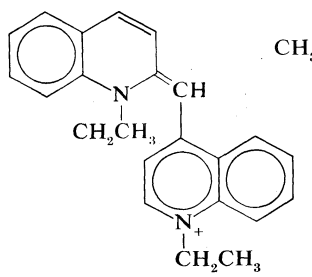


acridine

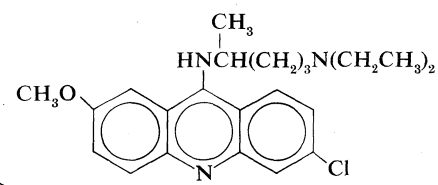


phenanthridine

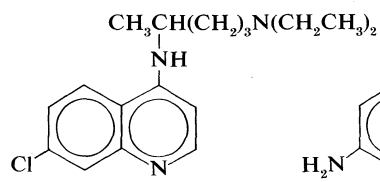
All four of these compounds and some of their alkyl derivatives have been obtained from coal tar. Each of them also is the parent substance of a class of alkaloids; of these, the quinoline (*e.g.*, quinine) and the isoquinoline (*e.g.*, morphine) groups are particularly well known. (For detailed coverage of this family of compounds, see the article ALKALOIDS.) Important synthetic derivatives of the benzo- and dibenzopyridines include members of the family of cyanine dyes, some of which—*e.g.*, ethyl red—are photographic sensitizing agents and others are useful antiseptics for staphylococcal organisms; antimalarials such as mepacrine (also called quinacrine or Atabrine) and chloroquine; antibacterials such as acriflavine (Trypaflavine); trypanocides such as phenidium chloride; and the reagent oxine (8-hydroxyquinoline or 8-quinolinol), used in analytical chemistry. The structures of these compounds are as follows:



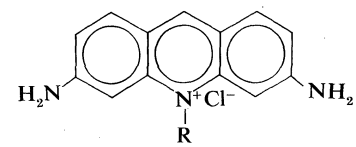
ethyl red



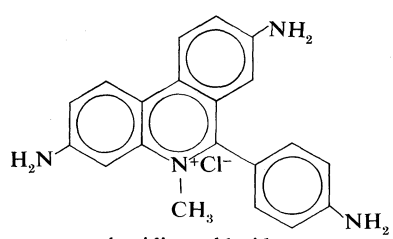
mepacrine



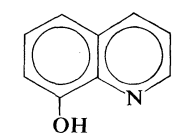
chloroquine



acriflavine (R = H or CH_3)

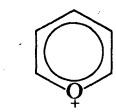


phenidium chloride

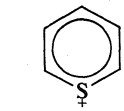


oxine

The parent six-membered, aromatic, monocyclic, oxygen and sulfur compounds are the pyrylium and thiopyrylium compounds bearing positive charges (cations) with the following structures:

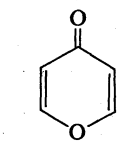


pyrylium cation

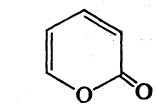


thiopyrylium cation

An uncharged aromatic (completely conjugated) six-membered ring containing an oxygen or sulfur atom is possible only if the ring contains a carbonyl group as in the pyrones:

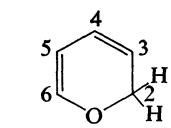


4-pyrone



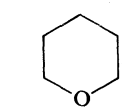
2-pyrone

The pyrans contain extra hydrogen atoms, the position of which is indicated by a number followed by an *H*, as shown:



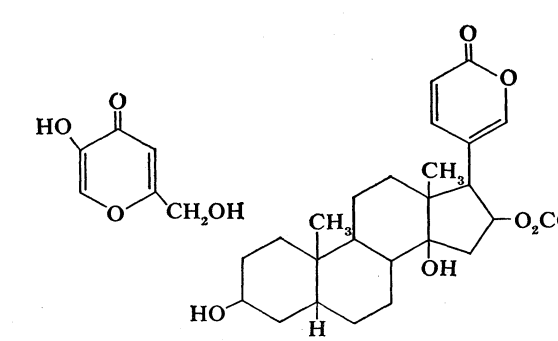
2[*H*]-pyran

Certain sugars are called pyranoses because they contain six-membered tetrahydropyran rings, with the structure:



tetrahydropyran

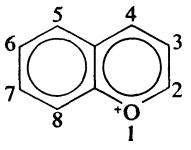
Pyrone derivatives are present in natural products; *e.g.*, kojic acid, an antibiotic derived by the action of certain molds on starches or sugars, and bufotoxin—a poisonous ester of the steroid bufotalin—obtainable from the skin glands of toads. The structures of kojic acid and bufotalin are shown below:



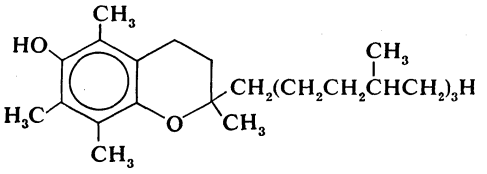
kojic acid

bufotalin

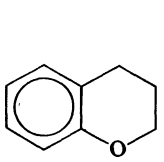
The benzopyrylium cation is the parent of a large number of natural products. Vitamin E is a substituted chroman, whereas dicoumarol, a blood anticoagulant, is a derivative of coumarin. The structures of these compounds are given below.



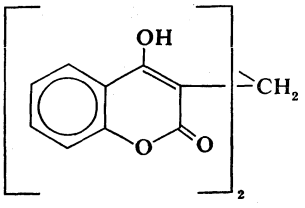
benzopyrylium ion



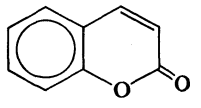
vitamin E



chroman

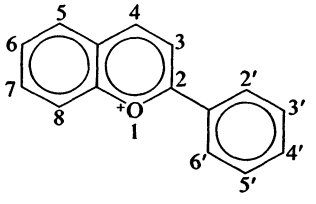


dicoumarol



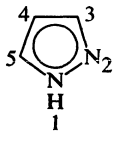
coumarin

The flavylium cation is the parent of the anthocyanidines, substances that are combined with sugars to form the anthocyanin pigments, the common red and blue colouring matters of flowers and fruits. The flavylium ion has the following structure:

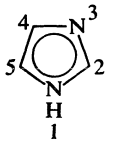


flavylium ion

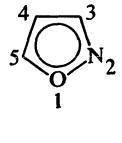
Five- and six-membered rings with two or more hetero-atoms. The names and numbering systems for the five-membered hetero-aromatic rings with two hetero-atoms are shown below:



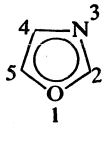
pyrazole



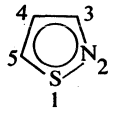
imidazole



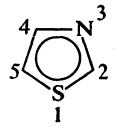
isoxazole



oxazole

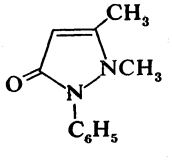


isothiazole

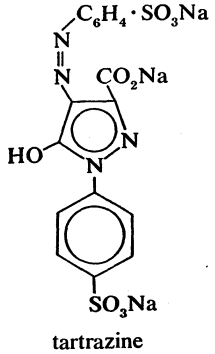


thiazole

Few pyrazoles occur naturally; the antipyretic (fever-reducing) and analgesic (pain-killing) antipyrine and the food and photographic dye tartrazine are important synthetic pyrazoles, with the following structures:



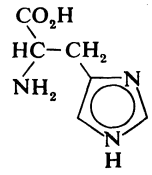
antipyrine



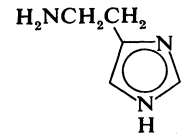
tartrazine

Imidazoles

Imidazoles are most important biologically; histidine, for example, is an essential amino acid, known to be of particular importance in enzyme reactions. A breakdown product of histidine, called histamine, is thought to be responsible for the development of allergies, hence the importance of antihistamine drugs. Histidine and histamine have the structures:

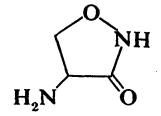


histidine



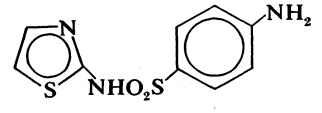
histamine

The antibiotic cycloserine, with structure shown, is one of the few naturally occurring isoxazoles:



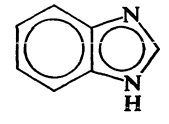
cycloserine

Thiazoles are of great biological importance. This ring system occurs in thiamine (vitamin B_1) and penicillin (see above). Sulfathiazole, an important sulfa drug, has the structure:



sulfathiazole

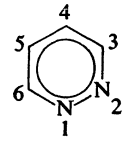
Most bicyclic systems derived from these five-membered rings are named systematically; *i.e.*, by use of the prefix "benz-" to indicate the presence of the benzene ring. Benzimidazole, for example, is the name for the compound:



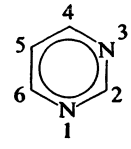
benzimidazole

A benzimidazole unit occurs in vitamin B_{12}.

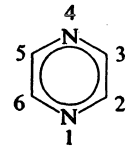
The three monocyclic diazines (six-membered-ring compounds with two nitrogen atoms) are named and numbered as follows:



pyridazine

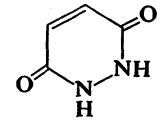


pyrimidine

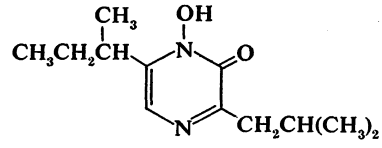


pyrazine

The pyridazine derivative maleic hydrazide is a herbicide, and some pyrazines occur naturally; *e.g.*, the antibiotic aspergillic acid. The structures of these compounds are:

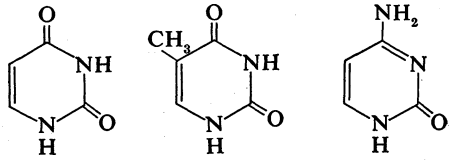


maleic hydrazide



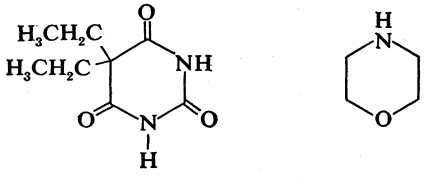
aspergillic acid

The pyrimidines, however, are the compounds of this group that are most important. Uracil, thymine, and cytosine, for example, with the structures shown, are constituents of nucleic acids.



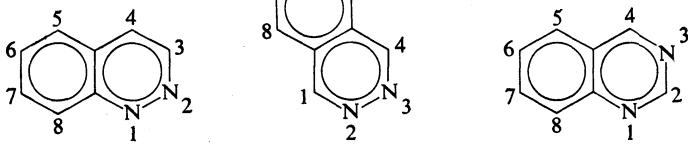
uracil thymine cytosine

Vitamin B_1 contains a pyrimidine ring, and synthetic barbiturates, such as veronal, with the structure given here, are widely used drugs. Various oxazines and thiazines are known but are of little importance, except for the solvent morpholine.

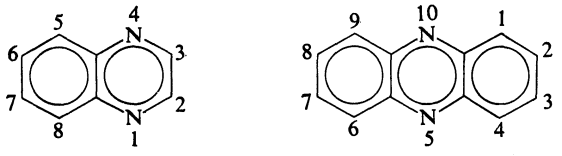


veronal morpholine

Many of the benzodiazines have common names; the structures and numbering of these compounds are as follows:

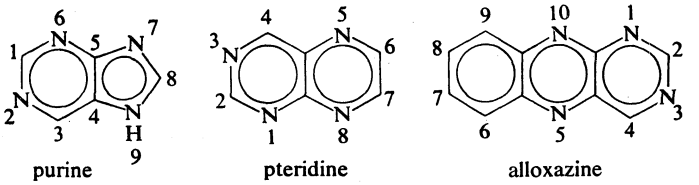


cinnoline phthalazine quinazoline

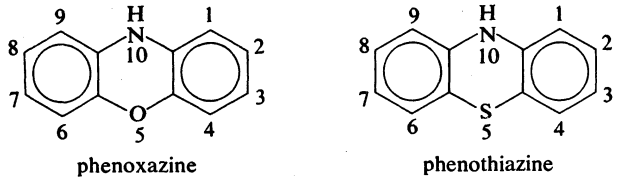


quinoxaline phenazine

Five other polycyclic systems in this general family are of some significance; their structures and numbering system also are given:

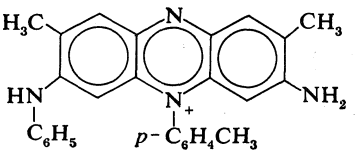


purine pteridine alloxazine



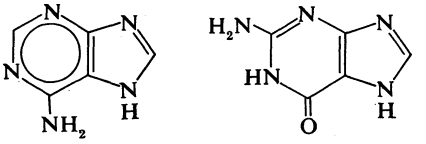
phenoxazine phenothiazine

A few quinoxaline alkaloids exist; there are some phenazine natural products, and phenazine dyes are used for fabrics, the first synthetic dyestuff, Mauve, being historically important—its structure is as follows:



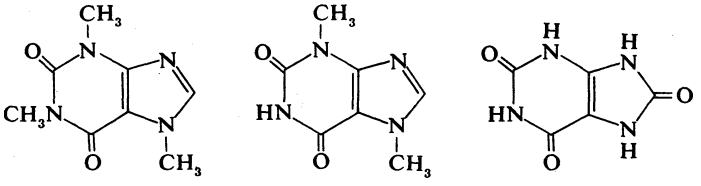
mauve

Biologically, however, the purines and pteridines are of more importance. Two purines, adenine and guanine, occur, together with the pyrimidine bases mentioned previously, in all nucleic acids. Purines and pteridines



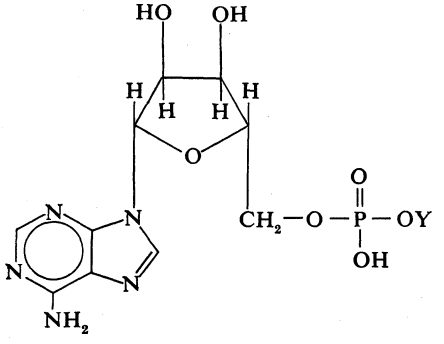
adenine guanine

Other natural purines include caffeine (found in tea and coffee), theobromine (found in cocoa), and uric acid (a metabolic product). The structures of these compounds are as follows:



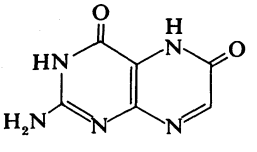
caffeine theobromine uric acid

Adenosine mono-, di-, and tri-phosphate (AMP, ADP, ATP, respectively) with the structures shown, are important in biological energy processes.



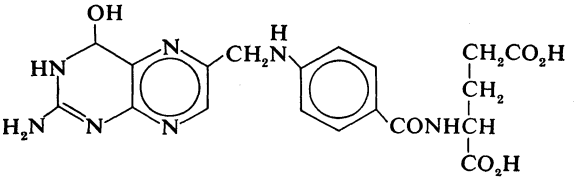
adenosine monophosphate: Y = H
adenosine diphosphate: $Y = PO_3H_2$
adenosine triphosphate: $Y = P_2O_6H_3$

The biological significance of pteridine compounds has become apparent. The first pteridines were discovered as pigments of butterfly wings; *e.g.*, one with the structure:



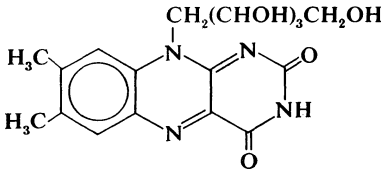
2-amino-4,6-pteridinedione

Folic acid, also a pteridine, is an important growth factor.



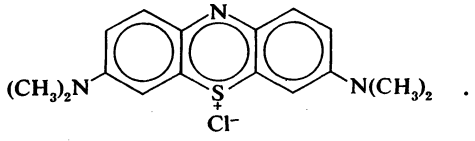
folic acid

Riboflavin, a derivative of alloxazine, is a B-vitamin:



riboflavin

Phenothiazine is an anthelmintic (worm-killing agent) as well as the parent of a family of dyes, such as methylene blue, a substance widely used as a biological stain and as an oxidation-reduction indicator. The structure of methylene blue is:

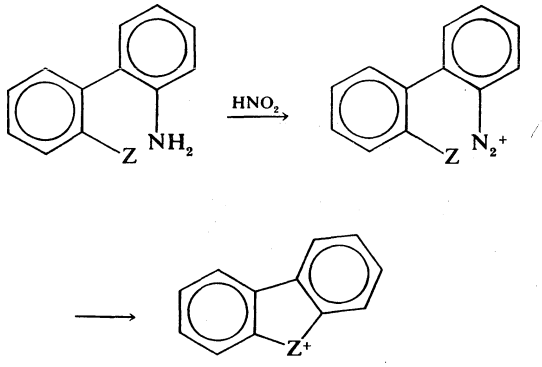


methylene blue

Rings with seven or more members. As the size of the ring increases, the range of compounds obtainable by variation of the number, type, and location of the hetero-atoms increases enormously. Nevertheless, the chemistry of heterocyclic compounds with seven-membered rings, or larger, is still relatively undeveloped, chiefly because the formation of such rings is generally difficult, just as is the formation of large carbocyclic rings. These larger rings, however, can be very stable, once they are formed, and knowledge of their chemistry is likely to increase rapidly in the near future. Some larger ring heterocycles exist in natural products; the porphyrins are widely distributed as pigments; *e.g.*, the chlorophylls and hemoglobins mentioned above.

Rings with uncommon hetero-atoms. Although nitrogen, oxygen, and sulfur are the common atoms found together with carbon in heterocyclic rings, a large number of other elements also form such rings—of greater or lesser stability. Such compounds are as yet of little practical importance. The principal ones known to date contain elements of the classes described below.

Halogens. Certain cyclic chloronium, bromonium, and iodonium ions have been prepared by the following reaction:



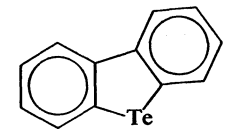
Z = Cl, Br, or I

Of these, only the iodine derivative has much stability.

Selenium and tellurium. Many selenium heterocycles are known. Selenium shows much similarity in its behaviour to sulfur; hence selenophene, with the structure shown,

selenophene

resembles thiophene quite closely. Tellurium heterocycles are more rare, and less stable; an example is dibenzotellurophene:

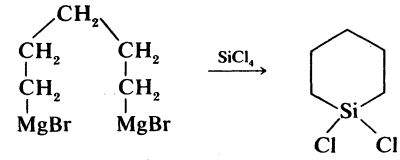


dibenzotellurophene

Phosphorus, arsenic, and antimony. Phosphorus, arsenic, and antimony, all members of Group V of the periodic table of elements, form a closely related group of heterocycles. There is, however, little similarity between their properties and those of the corresponding derivatives of nitrogen, a member of the same group. With few exceptions, no hetero-aromatic compounds are formed by these elements, and the cyclic derivatives resemble their open-chain analogues.

Silicon, germanium, and tin. Although silicon, germanium, and tin fall in the same periodic group as carbon, their atoms form neither stable chains nor double bonds; hence no hetero-aromatic derivatives of these compounds are known. Many saturated heterocyclic derivatives are known, however, including cyclic silanes, which may be prepared as shown by the following example:

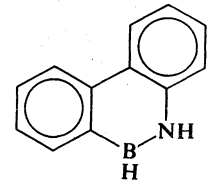
Silanes



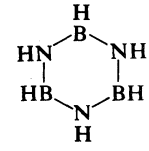
1,1-dichlorosilacyclohexane

All these elements, particularly silicon, readily form rings in which the atoms of these elements alternate with oxygen atoms. Considering this fact, many silicates are, strictly speaking, heterocyclic compounds, but their chemistry is always considered with that of other inorganic compounds, which they closely resemble.

Boron. Although boron heterocyclic chemistry is not yet extensively developed, it has a large potential. A boron and a nitrogen atom together contain the same number of electrons as two carbon atoms. Not surprisingly, it has been found that a boron-nitrogen unit can replace a carbon-carbon unit in benzenoid compounds to give stable hetero-aromatics; a good example is 9-aza-10-boraphenanthrene; its structure is as follows:



Borazine, or borazole, which has been referred to as inorganic benzene, has the following structure:



BIBLIOGRAPHY. Modern textbooks of heterocyclic chemistry include: A.R. KATRITZKY and J.M. LAGOWSKI, *The Principles of Heterocyclic Chemistry* (1967), also available in French, German, Spanish, Italian, Japanese, Russian, and Polish translation, which offers a concise comparative account; R.M. ACHESON, *An Introduction to the Chemistry of Heterocyclic Compounds*, 2nd ed. (1967), which places more emphasis on the division of the subject into compound classes; and A. ALBERT, *Heterocyclic Chemistry*, 2nd ed. (1968), a more detailed treatment. Of the numerous more specialized works available, K. SCHOFIELD, *Hetero-Aromatic Nitrogen Compounds: Pyrroles and Pyridines* (1967), treats the fundamental chemistry of two parent classes of compounds; *Advances in Heterocyclic Chemistry*, 16 vol., ed. by A.R. KATRITZKY and A.J. BOULTON (1963–73); and the *Chemistry of Heterocyclic Compounds*, ed. by A. WEISSBERGER and E.C. TAYLOR (1950–73), are continuing series of reviews.

(A.R.K.)

Heteroptera

Heteropterans, the "bugs" in the strictest sense, are considered a suborder of the Hemiptera by some entomologists, but an order (known either as Hemiptera or Heteroptera) by others. This large group of insects (about 30,000 species) can be recognized by an X-shaped design on the back, formed by the wings at rest. A combination of features—sucking mouthparts adapted to pierce plant or animal tissues and a hardened gula (underside of the head)—separate the heteropterans from all other insect orders. Although most species are terrestrial, a few are aquatic. Some species, which feed on plant juices, are serious pests of cultivated crops; other species are predacious and benefit man by destroying pests. There also are heteropterans that act as carriers of disease.

Heteropterans can be divided into three large groups on the basis of general habitat: the water-dwelling Hydrocorisae (water boatmen, back swimmers, water scorpions, giant water bugs, and creeping water bugs); the surface-swimming and shore-dwelling Amphibicorisae (water striders, marsh and water treaders, shore bugs, and velvet water bugs); and the Geocorisae, a large group of land bugs (plant bugs, bedbugs, assassin bugs, anthocorid bugs, lace bugs, ambush bugs, stinkbugs, burrower bugs, stilt bugs, and fire bugs).

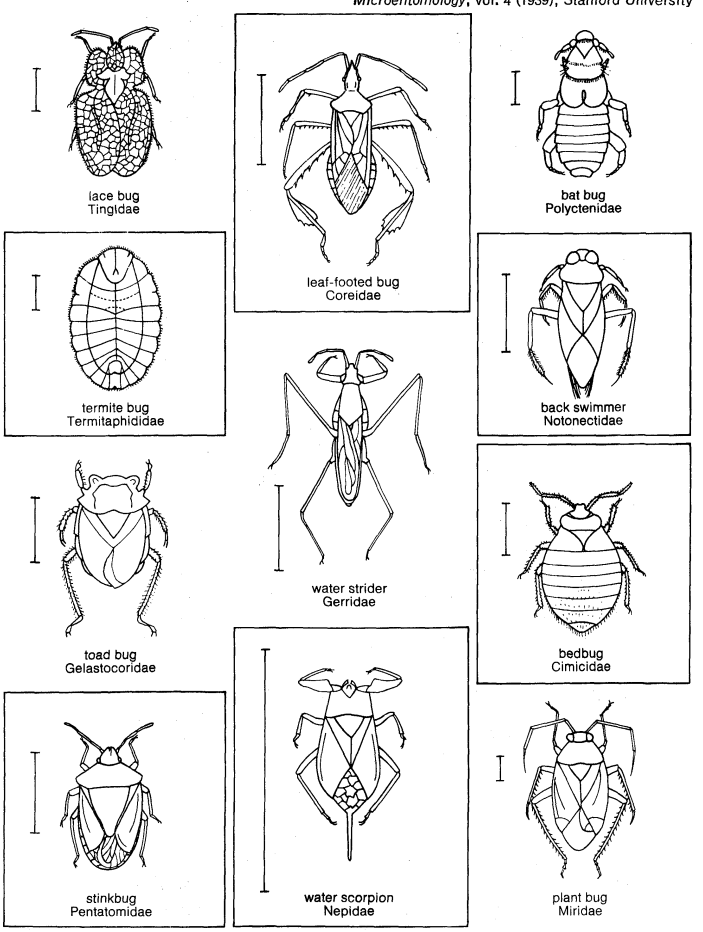

Figure 1: Diversity among heteropterans. Line scales indicate the approximate size of each insect.

GENERAL FEATURES

Size range and diversity. Like any other biologically successful group of organisms, the heteropterans are prolific and diverse and have adapted to a variety of habitats. They range in length from more than 100 millimetres to less than 1 millimetre and have invaded habitats from dry land to water. One of the few insect groups with aquatic adults capable of obtaining adequate oxygen from the water, heteropterans include the only insect species that spend their lives on oceans far from land. Some heteropterans are nourished by blood of animals ranging from mites to man; others feed from the sap of plants as diverse as giant redwoods and algae. Some suck surface fluids (*e.g.*, nectar); others pierce tissues to suck sap, blood, or even to obtain the nourishment provided by dried seeds. Many forms live on open surfaces and escape enemies by running, flying, or remaining inconspicuously motionless. Some seek food and shelter in natural crevices; other actively burrow into the soil or seek out the nests of animals.

Distribution and abundance. The number of individuals in a species depends in part on the availability of food. Growing crops provide concentrated food sources, but large populations, which often occur in areas of no apparent economic importance to man, may result from normal fluctuations in the balance of nature.

Heteropterans are most abundant in the tropics, decreasing in both individuals and species to limits northward beyond the Arctic Circle and southward almost to the Antarctic Circle. Every major land mass harbours different species; migrations to new habitats may be aided by natural agents (*e.g.*, wind, birds, floating debris) or by man. Although heteropterans have been carried throughout the world, only a few species have become established in many lands. Unique among insects are some water striders (Gerridae), which are at home on the open ocean between approximately 40° north latitude and 40° south latitude and may not approach land for several generations.

Approximately 30,000 species of heteropterans are known. Depending upon the availability of favourable habitats, the number of species on a major land mass is directly proportional to its size; the number of species inhabiting small islands is inversely proportional to their distance from large land masses. Age and origin of islands also influence the number of species. Most families containing 150 or more species are represented in every zoogeographic region; two exceptions are the Phymatidae (ambush bugs), with no species known in Australia or the Pacific Islands, and the Plataspidae, with no New World species. Families with the fewest species have the most restricted ranges: Aphylidae, Hyocephalidae, and Lestoniidae are restricted to Australia and contain among them only five species. The Velocipedidae of the Orient and the Vianaididae of the American tropics number four species each. In general, zoogeographic restriction is most evident at the subfamily, tribal, and generic levels.

IMPORTANCE

Heteropterans have complex and important roles in the balance of nature. The majority of them occupy an intermediate position in the ecological food chain; they use food producers (plants) and serve as food sources for parasites and other animals. A few species utilize plant-feeding insects as food.

Beneficial aspects. Heteropterans often serve as food for man and other animals. In some Latin American countries eggs of certain aquatic bugs are collected by providing submerged mats as egg laying sites; the eggs are then dried and made into cakes. Chickens, turkeys, hogs, and other domestic stock consume available heteropterans. Aquatic bugs are an important food source for fish. Wild birds and mammals, from the wrens and shrews to the turkey and grizzly bear, utilize available insects in their diets.

Species that attack unwanted plants and feed on the eggs, immature stages, and adults of injurious insects include most assassin bugs, nabid bugs, anthocorid bugs, stinkbugs, and plant bugs. These heteropterans are used in biological control of noxious weeds and injurious insects (see WEED CONTROL; PEST CONTROL).

Harmful aspects. In contrast, some heteropterans (*e.g.*, plant bugs, chinch bug, lace bugs, stinkbugs) damage both wild and domestic plants by sucking sap or injecting tissue-killing fluids. Insertion of a beak or eggs into a plant tissue harms the protective layers and allows bacteria and other disease-causing organisms to infect the

plant. Although heteropterans are not the major agents for transmission of plant viral diseases, a few species (Piesmatidae) can carry viral diseases of sugar beets and related crops in North America and Europe.

Role in disease

Heteropterans can affect man in several ways. They are common household pests and can spoil the taste of some fruits, (*e.g.*, raspberries contaminated by stinkbugs). But more importantly, some can attack man directly and inflict painful bites as well as introduce disease-causing organisms. The injection of saliva or poison may cause allergic reactions in susceptible persons. Sometimes when they cannot find plants, phytophagous insects probe moist surfaces (*e.g.*, perspiring skin) in search of appropriate food fluids. Transmission of trypanosomes, which cause Chagas' disease in the American tropics, occurs through cone nose bugs (Reduviidae), so-called because of the shape of their head. The insect receives trypanosomes when it feeds on the blood of an infected human. The trypanosome passes part of its life cycle in the insect and again becomes infective to man. Instead of injecting them into a new victim, however, the insect deposits trypanosomes (in its excrement) on the skin of a potential victim. The trypanosomes can enter the bloodstream only through mucous membranes or breaks in the skin (*e.g.*, those that may result from scratching the site of the bite).

NATURAL HISTORY

Life cycle. *General features.* Heteropterans are influenced by seasonal temperature fluctuations in temperate regions. Although the tropical regions, in which they are most abundant, impose no seasonal pattern, heteropterans are influenced by other factors—rainfall, host plant development, internal rhythms.

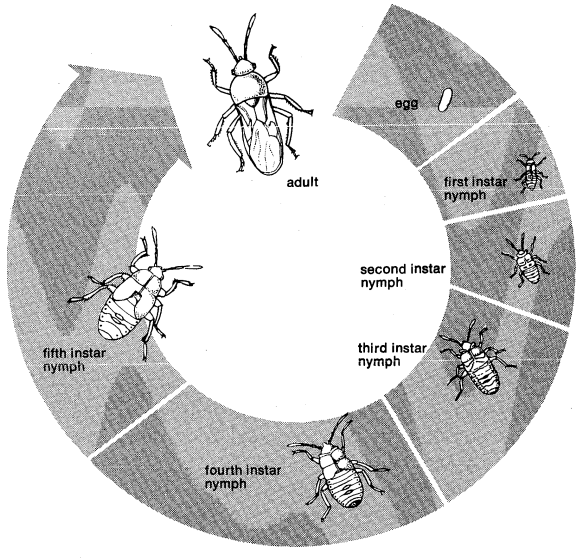

Figure 2: Life cycle of chinch bug.

Dormant stage

Heteropterans generally produce one or two generations a year in temperate regions. The dormant stage, which varies from species to species, is dependent in part on the food source of the species; for example, a heteropteran that feeds on perennial plants often lays eggs that remain dormant through the winter in or on the host plant. The nymphs, which hatch in the spring, then have appropriate leaves and succulent stems to furnish the sap necessary for growth. In contrast, heteropterans that feed on annual plants have a dormant winter adult stage that flies to a new host plant each spring after seeds germinate. Species that have short nymphal and adult stages, which coincide with certain plant characteristics (*e.g.*, short-lived flowers), may pass 10 or 11 months as eggs. Among predatory heteropterans, those whose prey is found on plants or in flowers winter as adults; those whose prey is found on the ground may be dormant as nymphs or adults. Aquatic heteropterans may spend the winter as adults, nymphs, or both; semiaquatic forms are dormant as adults.

Metamorphosis. Heteropterans undergo gradual metamorphosis (hemimetabola). Primary feeding and energy storage, as well as development of adult structures, take place in the nymphal stages. The adults seek mates and potential food sources and are responsible for initiating future generations. These functional specializations are reflected in morphology. The developing embryo, incapable of obtaining food or defending itself, is encapsulated within a protective egg shell that contains adequate food. The nymph, which lacks the locomotor and reproductive ability of the adult, also lacks the hard and rigid extensive exoskeleton necessary for strong muscle action. As a result, however, its body can distend to accommodate large quantities of food. In addition, loss of moisture through the thinner, more membranous body cover is offset by the high water content of the nymph's food.

Reproduction. *Eggs.* Reproduction occurs when eggs are fertilized as they pass through the female ducts by spermatozoa stored in special receptacles in the female. A notable exception to this method occurs in the bat bugs (Polyctenidae). In this case shell-less, yolkless eggs are fertilized in the female ovariole where they remain; the developing embryo is nourished by special maternal cells through a placenta-like structure consisting of tissues from both parent and offspring. The bat bug nymph leaves the mother's body only after reaching an advanced stage of development. Heteropteran eggs generally are moderate to large in size relative to adults and have a smooth to finely sculptured surface, sometimes with a colour pattern and often with slender projections. Eggs contain sufficient nutrients to permit the embryo to develop into a free-living, sexually immature, wingless nymph. Just before an egg hatches, the shell becomes translucent and reveals the segmentation and strongly coloured structures (*e.g.*, eyes) of the nymph inside.

Egg-laying sites

Eggs may be laid singly or in clusters. Eggs of plant-eating species generally are glued to a surface or inserted into the tissues of a selected host plant. Eggs of predatory forms often are laid near prey. Aquatic bugs may lay their eggs above or below the water's surface. Some bugs have special habits; for example, eggs may be glued in a large cluster to the back of a heteropteran male (Belostomatidae) or to the body of a crayfish as in Corixidae.

Nymphs. A newly developed nymph uses one or both of the following mechanisms to escape the egg: a cuticular spine on the head, sometimes known as an egg burster; or internal hydrostatic pressure created by forcing fluids (sometimes in the head) against the site of egg rupture. The pattern of rupture may be controlled by a line of weakness in the egg; in some cases a flaplike operculum lifts back to allow the nymph to escape. After withdrawing itself from the egg, the newly hatched nymph seeks the organic food essential for its development. Some nymphs leave the egg with a sufficient store of nutrients to allow them to pass through their first molt (or ecdysis). This is especially important to predatory species whose newly hatched nymphs might have to spend considerable time searching for prey.

The wingless nymph must rely on mimicry or disguise to prevent detection by enemies. Relatively inactive nymphs often assume colours and shapes of objects in their immediate environment; others disguise their bodies with a layer of small particles collected on a coat of sticky body hairs; and still others exhibit contrasting colours that break up the body outline. Some active nymphs confuse predators by alternating short quick dashes with periods of no motion; others deceive predators by simulating body shape, colour, or erratic gait of ants, with which nymphs sometimes are associated (see COLORATION, BIOLOGICAL; MIMICRY).

Lacking a pupal stage in which to change into an adult, the flightless nymph must sustain itself while it gradually transforms into an adult. As the nymph feeds and grows, it discards through five successive molts (ecdyses) the growth-restricting outer layers of its exoskeleton. Wings

Transformation to adults

appear first as slight outpocketings at posterior regions of the mesothorax and metathorax during the third instar (interval between molts) and enlarge during the fourth and fifth instars; however, the wings are not fully functional until the last ecdysis, when the nymph becomes an adult. At the time of the last molt, other changes occur: the head and thorax assume new shapes; the number of segments in antennae and tarsi may change; scent glands on the top of the abdomen cease functioning and are replaced by metathoracic scent glands; and the external genitalia and the internal reproductive organs become functional.

Adults. Flight is common among adult heteropterans; although they are capable fliers, no species has developed the aerial efficiency of some other insect groups (*e.g.*, dragonflies, flies). Predatory heteropterans lie in wait for a potential victim to wander close enough to be captured, instead of overtaking their prey in flight. Winged adults may rely on flight or inaction and the optical deceptions of colour arrangement and body form utilized by the nymphs to escape enemies. Flight also enables the two sexes to come together and provides an effective means for seeking favourable egg-laying sites.

Behaviour. *Sound production and reception.* Heteropterans cannot produce the conspicuous sounds typical of katydids, crickets, and cicadas. The whirring or buzzing noise common to heteropteran flight is caused by the rapidly moving flight mechanism. Sound production by specialized body parts (also called sonification or stridulation) is common among heteropterans but seldom loud enough to attract human attention. Heteropterans produce sounds by moving one roughened member over a roughened area of body surface. Sometimes both roughened parts consist of a series of minute, closely-set, parallel furrows or ridges called a strigose area, strigil, file, or rasp. Sometimes the second part of the mechanism consists of a series (called a plectrum) of minute pegs, setigerous tubercles, or an upturned edge of a sclerite (hard body plate). The plectrum may be on the movable body member or on the fixed body part. One or both sexes, and sometimes even the nymphs, of a species may stridulate. Some sounds appear to have courtship significance. The presence and form of sound-producing mechanisms are useful in the classification of Heteroptera.

Mechanisms for detecting airborne and possibly waterborne vibrations (or sounds) are known in Heteroptera: auditory organs known as Johnston's organs are found in the antennae of all species, and the tympanal (stretched membrane) organs are known in several families of aquatic bugs. A variety of receptors, especially for detecting substrate vibrations, have been described for members of this order.

Feeding. Heteropterans are essentially nonsocial insects. Newly hatched nymphs occasionally remain together for a short time, clinging to the shells of the eggs from which they have hatched; for example, plant feeding (phytophagous) nymphs may remain together because they hatch on their food source and need not search for it. In contrast, however, most predatory heteropterans encounter their prey by chance; in this case, dispersion increases individual opportunities for finding prey and for escaping other predatory heteropterans. Apparent coordinated migrations reported for chinch bugs generally result from a sudden disappearance or failure of a food source.

Ecology. Heteropteran behaviour, governed by natural instincts, includes patterns that enable individual species to live within specific environments. The patterns are so similar for all members of a family that each family can be characterized as essentially phytophagous or predatory, and terrestrial, semiaquatic, or aquatic. Most heteropterans rely on atmospheric oxygen for respiration.

Habitats. Aquatic Heteroptera vary in their independence of atmospheric oxygen. Members of one of the nonswimming families (Nepidae) submerge just below the water's surface and obtain oxygen through a slender, terminal breathing tube that breaks the surface film. Some swimming families (Corixidae, Notonectidae) dive deeply; however, they must surface periodically to replenish air supplies either stored in chambers formed against body surfaces by the folded wings or entrapped by rows of dense hairs folded against the body. These insects swim to overcome the buoyancy of the renewed air supply, grasping underwater objects to anchor themselves. Heteropterans with air storage chambers are independent of oxygen dissolved in the water; therefore, they survive in warm springs or polluted waters almost devoid of oxygen. Another family (Naucoridae) contains species that spend their entire lives below the water's surface; these heteropterans can obtain oxygen from that dissolved in the surrounding water. Water insulates its inhabitants from cold temperature extremes; thus aquatic species exhibit considerable activity the year around. Chilled water holds more dissolved oxygen than warm water, and air is available also between the water's surface and the ice layer during winter months in temperate regions.

Aquatic species

Semiaquatic bugs literally walk on water; they are supported solely by the water's surface film. Their small, slender bodies have little bulk to support. Long, thin middle and hind legs spread the points of contact with the water; the tarsus of each leg causes only a slight dent in the surface film. The shorter front legs may rest on the water or capture and hold prey. Wetting of the body during submersion is prevented by a thin layer of air trapped by the fine, dense, water-repellent (hydrofuge) pile that covers the insect. Many surface dwellers live in quiet water; others prefer flowing water, even rapids, where considerable strength is needed to overcome the current. In some cases, a bug may anchor the legs on one side of its body to some fixed object in a stream and wait for food carried to it by the rushing water. Adults survive the winter beneath objects on land either close to or some distance removed from a body of water.

Although shore bugs normally frequent shore lines, they occasionally make short forays onto the surface of adjacent bodies of water. Shore bugs generally are heavier bodied than surface dwellers; the strong, and often long, legs of some shore bugs enable them to run quickly across ground, rocks, and other exposed surfaces. Short rapid flights are not uncommon. All shore bug families are predatory. Their front legs often are thickened distinctly and sometimes spined for grasping prey. Adults generally overwinter beneath convenient objects.

Terrestrial species

Terrestrial heteropteran species are more abundant than either aquatic or semiaquatic forms and have a variety of habits and life histories. Some species wander over leaves, flowers, and other surfaces exposed to sunlight; others prefer the shadows (*e.g.*, underside of foliage). Many forms hide under rocks, logs, loose bark, or in crevices. Some species, which are active during the night, hide only during the day; other groups (*e.g.*, Aradidae) live in obscure habitats and leave only if the environmental conditions become unsatisfactory. Members of one family (Cydnidae) burrow by cutting soil in front of them and shoving it behind; these insects live in moving underground chambers. Species in at least two families (Nabidae, Reduviidae) live in spider webs and skillfully avoid entanglement as they eat trapped insects or, in some cases, the spider itself.

Relationships of heteropterans to plants vary. Plants may serve simply as a site on which to stand or move, or as a lure for plant feeding insects on which predatory bugs feed; plants are most important as a source of nourishing sap for phytophagous heteropterans. A few species can cause modifications in plant growth; for example, a feeding insect may cause leaves to roll up around it. In Europe certain lace bugs (Tingidae) insert their eggs into flower buds, which enlarge and house developing lace bug nymphs. A new adult lace bug needs no jaws to gnaw its way out; it leaves when the bud begins to open.

Food habits. Predation is common throughout the Heteroptera, sometimes as a family-wide feeding pattern, sometimes as a deviation within an otherwise phytopha-

gous family. In the suborder Hydrocorisae all families except one (Corixidae) are predatory on small aquatic animals, including small fish, tadpoles, and frogs; the exception has been known to add mosquito larvae to its usual algal diet. The suborder Amphibicorisae, without reported exception, contains forms that prey on plankton, small arthropods, or worms. In the suborder Geocorisae, many families of the series Cimicomorpha (*e.g.*, Reduviidae, Nabidae, Phymatidae), are predatory, generally on other insects; however, a few assassin bugs (Reduviidae), bedbugs (Cimicidae), and bat bugs (Polyctenidae) seek the warm blood of birds and mammals. In addition, some members of plant feeding families (including the Miridae) attack other arthropods; a few families (Pentatomidae, Lygaeidae) of the series Pentatomomorpha, fundamentally plant feeders, contain insect-eating species. The original food habit of this order is not yet clear, but even in some avidly predatory species, the first and second nymphal instars may be plant feeders. In capturing its prey, a heteropteran may use front legs modified for grasping or insert feeding stylets. In either case the victim is paralyzed quickly by an injected salivary secretion.

Predators

Any insectan stage may fall to the hungry predator. Insect eggs are a favourite food for many small (Anthocoridae) or very young heteropteran predators. Caterpillars and other larvae commonly are attacked by predatory Heteroptera, and it is estimated that one stinkbug (Pentatomidae) may destroy more than 200 caterpillars during its lifetime. One stinkbug, long known to feed upon bedbugs, was recommended for use in control as early as 1776.

Other arthropods also may be attacked. One anthocorid bug (Anthocoridae) may destroy an average of 33 mites per day. In some instances size of prey is no barrier. In Sri Lanka a small assassin bug (Reduviidae) only 4 millimetres long can paralyze a giant millipede 150 millimetres long.

Associations. Individual heteropterans may associate accidently on a food source. On quiet pools of water, water striders (Gerridae, Veliidae) often assemble in milling "schools" of a few to hundreds of individuals; they quickly reassemble if dispersed. Sometimes a female will reassemble disturbed batches of eggs. In cases where the female lays her eggs on the back of a male, the parental responsibility is his.

Members of one family (Termitaphididae), unable to live alone, share the nests of certain termites and feed on the fluids of the fungi growing there. In exchange, a substance secreted from pores on the backs of these bugs is eaten by the termites. Reports of heteropteran associations are difficult to assess and may reflect coincidental use of the same environment.

FORM AND FUNCTION

General features. Heteropterans have features typical of all insects and special adaptations that differentiate them from other insect groups. The head tests new environments through light perceptions by compound eyes and simple eyes (ocelli) and through both scent and sound perceptions by the antennae. The mouthparts are located conveniently for quick exploitation of newly discovered food sources. The thorax bears support and transportation mechanisms, legs, and wings. An important function for the third body region, the abdomen, is reproduction. Sutures divide the body surface into sclerites (hard plates), which may be fused or separated by flexible membranes. Hairs, scales, or a variety of glandular secretions may adorn at least some areas of the body. The body surface may be raised into spines of a variety of shapes, knobs, or tubercles; tubercles often are setigerous; *i.e.*, glandular with a straight or curved filament or bristle at the tip. Some of these projecting structures, which have bases associated with specialized cells, probably have a sensory function and respond to vibrations of air, substrate, or touch. Certain long hairs, each arising from a ringed socket, are called trichobothria, and their presence and arrangement on various parts of the body have taxonomic significance.

Special adaptations

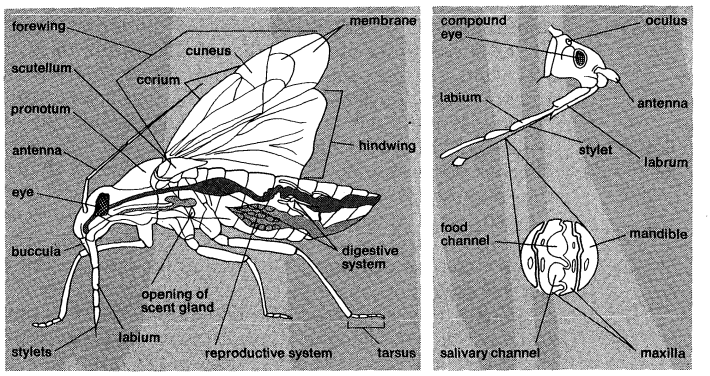

Figure 3: (Left) Heteropteran body plan. (Right) Section through stylet showing relationships of mandibles and maxillae.

Adapted from (left) H. Weber, *Grundriss der Insektenkunde*, Gustav Fischer Verlag, Stuttgart; (right) *Introduction to Comparative Entomology* by R. Fox and J. Fox.

Distinguishing features. The covering of the head is a sclerotized ring tapering from the flexible neck forward or downward and ending in three lobes: a jugum on each side and a central clypeus (or tylus). The area above and between the eyes (called the vertex) may bear a transverse pair of simple eyes (a median one is never present in Heteroptera). The hard lower surface of the head is called the gula (hypostomal bridge).

Mouthparts. The piercing-sucking mouthparts are composed of a troughlike, four-segmented labium in which lie four stylets; these are modified mandibles and maxillae. Each of the hairlike maxillae has two major grooves plus minor grooves and ridges along its median surface. When brought together and locked by the minor grooves and ridges, the two major grooves form the left and right halves of two separate tubular canals that extend the length of the maxillae. The anterior canal is the food tube through which fluids are drawn by a sucking pump (described below); the posterior tube is the salivary canal through which digestive and certain other fluids may pass into a food source. These fluids stun or kill the prey, prevent coagulation of blood, and initiate the process of digestion. Along the sides of the maxillary stylets are slender mandibles with serrated tips. The mandibles and maxillae alternately advance into the food tissue until the appropriate fluid is reached by the maxillae; then ingestion begins. Since the labium does not penetrate the food tissue, the stylets must extend beyond the protection of the labial groove. This extension may be accomplished in one of two ways. The labium may be shortened by jackknifing some of its segments, leaving only the apical and sometimes the basal segments to guide the exposed stylets. In some species the extensible stylets are much longer than the labium; when not extended, the stylets either are coiled or looped in a chamber located in the labium or the head, or are found in a long sheath that extends backward into the heteropteran's body cavity.

Sucking pump

The sucking pump is a chamber whose front wall is folded lengthwise into the mouth cavity; the fold is pulled out and springs back to change the size of the cavity. Contraction of certain muscles increases the size of the cavity, decreases the pressure in it, and allows the liquids to flow through the food canal into the pump. When the muscles relax, the size of the chamber decreases gradually and pushes the food toward the true mouth, which opens into the esophagus.

Thoracic features. Each of the three somites of the thorax bears a pair of legs; both meso- and metathorax bear a pair of wings. The large conspicuous part of the thorax between the head and the wings is called the pronotum (*i.e.*, the expanded top part of the prothorax). Projecting from beneath the hind margin of the pronotum is the triangular, sometimes U-shaped, scutellum. Along the side margins of the scutellum may be a groove or fold (the frenum). In repose, the inner edges of the front wings hook onto the frenum. On each side of the

metathorax may be a pore (ostiole) that provides an outlet for a highly volatile, repellent fluid secreted by internal scent glands. The ostiole may be surrounded by an elevated ridge (peritreme), and then by an extensive, roughened, evaporative area.

Legs. The legs may be modified in various ways to serve specific functions. Legs may be lengthened or expanded to aid in camouflage. Sometimes the hind femurs and their accompanying leg muscles are adapted for jumping. The middle and hind legs may be flattened for swimming, or their effective width increased by a marginal fringe of long hairs that spread during a power stroke and flatten against the leg on the recovery stroke. The front legs, when specialized for grasping prey, have tibia and tarsus adapted to fold tightly against a thickened femur; stout hairs or spines along one or both of the opposing surfaces of this grasping leg prevent a victim from slipping free. The males of many species have hind legs that are thickened or spined to hold females during mating. Lacking mandibulate mouthparts with which to clean their antennae, many Heteroptera have a comblike series of hairs on the end of the front tibia, across which the antennae may be dragged. Certain genera (Nabidae, Reduviidae) that live suspended slothlike from the underside of spider webs have long, foldable claws.

Wings. The texture of each of the two pairs of wings is distinct in heteropterans. The mesothoracic or forewings (called hemelytra, elytra, or tegmina) are stiff and have an oblique line that abruptly separates the leathery basal half from the membranous apical half; the metathoracic or hindwings are thin, delicate membranes. At rest the forewings are folded over the hindwings; the membranous tips of the forewings overlap, so that the fragile hindwings lie beneath them. In macropterous individuals with wings of normal size, the wings approach or extend beyond the apex of the abdomen; some species have wings that are brachypterous (slightly to moderately reduced), micropterous (very small), or absent. Both pairs of wings are absent in one family (Termitaphididae), apparently an adaptation to the termite tunnels in which they live. In the bat parasite family (Polyctenidae) the budlike character of the nymphal wings is carried into the adult stage with no further development; in effect these insects also are wingless. The front pair of wings of the bedbug family (Cimicidae) are reduced to short, nonfunctioning pads; the hind pair is lost completely. Although these heteropteran families are the only examples of a general pattern of wing loss or reduction, some individual species show a variety of wing developments (alary polymorphism) or aptery (winglessness) in one or both sexes. Species with sexual dimorphism in wing length have females with reduced wings or none at all; apparently the retention of flight in the male assures his ability to move to the female.

Diversity of wings

Heteropteran wings, especially the front pair, may be modified for specific functions. Their presence above the abdomen provides protection for the soft parts beneath. More effective protection is provided in forms with fused forewings. Some forms can couple their wings by means of a fingerlike projection (jugum) on each forewing, thus enhancing their flying ability. The colour and texture of the forewings may be modified so that an insect resembles bark; bright or contrasting wing colours announce unpalatability to an enemy. The lace bugs (Tingidae), so-called because they have a lacelike pattern of many fine, interconnecting wing veins, resemble the fine veins on the undersides of the leaves on which they feed.

Wing modifications

Abdomen. The abdomen contains 11 segments; the tenth and eleventh, and sometimes others, are fused. Sensory appendages (cerci) are never present in this order; the sensory function may be performed in part, however, by several apparently tactile hairs along the underside of the abdomen. The terminal abdominal segments of the male are adapted primarily for transfer of sperm, those of the female for reception of sperm and egg laying. Females that insert eggs into plant tissue have an ovipositor under the tip of the abdomen; the ovipositor consists of blades that slice plant tissue and guide the eggs into the slit. In females that glue eggs to a surface, the ovipositor usually is reduced to a noncutting egg guide.

Internal features. *Digestive system.* The three embryological regions of the alimentary canal become modified by constrictions, dilations, and outpocketings. The stomodaeum becomes a short esophagus that connects to the midgut. The midgut frequently differentiates into four distinct regions, two dilations connected by a short, narrow tube and a second tubular section that gives rise to slender, terminally closed, tubular outpocketings, called mycetomes. The cavities of the mycetomes are filled with bacteria, whose role may be either to supply essential nutrients or to inhibit development of other bacteria. The bacteria, hereditarily transferred from mother to offspring, migrate to the ovarian follicle of the female and invade the eggs. As soon as an embryo begins to develop a gut, the bacteria appear in it.

Role of bacteria in mycetomes

Respiratory system. The respiratory system consists of longitudinal tracheal trunks that branch internally and commnunicate with the external air through ten pairs of holes called spiracles. Respiration under water presents special problems. Young aquatic nymphs may respire exclusively through the thin body wall. Adult aquatic insects, with their hard body walls, must rely on tracheal respiration; modifications of the spiracles and external skeleton surrounding them serve to exclude water while admitting oxygen. In some species the spiracles are sunken and protected by a circlet of hydrofuge (water repellent) hairs or by a fine-pored membrane; in other aquatic heteropterans the spiracles are closed and only one or two pairs function in association with either diving air storage chambers or the base of a snorkel-like breathing tube that breaks the surface film of the water. Although air storage chambers absorb some dissolved oxygen from the surrounding water, they gradually diminish in size as the nitrogen contained in them dissolves outward into the surrounding water. Unless they are replaced by frequent trips to the surface, air supplies may be lost completely, thus allowing water to reach and enter the spiracle; drowning would result. A few forms (Naucoridae) have "plastron" respiration. The plastron is actually a modified air storage chamber that consists of air in a series of cuticular grooves radiating from a spiracle. This air, continuous with tracheal air, is held in each groove by hydrofuge hairs, so that its volume does not change. Sustained absorption of dissolved oxygen by the plastron eliminates the need for contact with atmospheric air as long as the surrounding water is well oxygenated.

Other systems. The skeletal, muscular, circulatory, and excretory systems are structurally and functionally typical of a winged insect with the exception of some adaptive variations. The piercing-sucking mouthparts require protractor and retractor muscles for insertion and withdrawal of each stylet, and dilator muscles to enlarge the sucking pump cavity. General blood flow throughout the body is provided by the four- or five-chambered heart, but circulation in legs and wings requires special devices (*e.g.*, the pulsating membranes located within the base of each tibia and sometimes in the tarsus). Rhythmical waving of pulsating membranes causes a pattern of blood flow to the tip of the limb and back. The number of excretory tubes (*i.e.*, malpighian tubules) generally is four.

The nervous system consists of three interconnected parts known as central, visceral (sympathetic), and peripheral parts. The ventral nerve cord exhibits considerable concentration near the head end (cephalization) of the ganglia; in all species the abdominal ganglia have migrated into the thorax. Most members of the order have three ganglia on the ventral nerve cord; the subesophageal, the first thoracic, and a mass that results from fusion of the second and third thoracic ganglia with all the abdominal ganglia. Complete cephalization of the ventral nerve cord occurs in a few Heteroptera where all the ventral ganglia, including the subesophageal, unite into a single ganglionic centre.

The heteropteran reproductive system consists of a pair of gonads whose ducts unite to form a single tube leading to the exterior near the posterior end of the abdomen. In

Reproductive system

most species spermatozoa are transferred directly into the female reproductive tract and stored in a spermatheca (outpocketing of female tract) until fertilization occurs (as the egg is laid). In two families (Cimicidae, Anthocoridae) the female has an organ separate from the reproductive tract to receive the spermatozoa. This organ is a rounded internal pouch associated with a slit on the underside of the abdomen and is called the organ of Ribaga. During mating the spermatozoa are deposited in this pouch. They then penetrate the pouch wall, travel through the body cavity, and burrow into the spermatheca, remaining there until needed to fertilize the eggs. Excess spermatozoa are absorbed as nutrients by special cells in the female.

EVOLUTION AND PALEONTOLOGY

The fossil record is too poor to offer significant help in reconstructing the phylogeny of the Heteroptera; their small size, the fragile nature of dead individuals, and a preference for habitats that seldom are conducive to fossilization have resulted in few fossils. Often only wings or parts of wings are represented. Known fossils do reveal, however, that during the Permian Period (more than 225,000,000 years ago), two major lines existed. The order Protohemiptera, which revealed a number of features common to homopterans and heteropterans, including stylet-like mouthparts assumed to be piercing-sucking, actually represents an unrelated parallel development.

The appearance of the Heteroptera as a line distinct from the Homoptera also is represented in Permian fossils. The oldest known member of the order Heteroptera (from the Permian in Australia) represents the only family (Paraknightiidae) with no living species. Fossils from the next geological period, the Triassic, reveal that the major forking of the heteropterans into aquatic and terrestrial branches had already occurred near the beginning of the Mesozoic Era. Several modern aquatic family types are recognizable in the Mesozoic. The bulk of modern terrestrial heteropterans appears in the fossil record by the Tertiary Period of the Cenozoic Era.

CLASSIFICATION

Distinguishing taxonomic features. Modifications of mouthparts and wings are generally accepted as important characteristics by which to divide the class Insecta into orders. One peculiar type of mouthpart, possessed by more than 50,000 insect species, is the piercing-sucking type in which the labium forms a trough containing two pairs of threadlike stylets (highly modified mandibles and maxillae). All modern insects with mouthparts of this type are closely related to each other but not to other insects, none of which possess truly comparable modifications. Some entomologists consider all insects with piercing-sucking mouthparts as members of a single order, the Hemiptera (sometimes called Rhyngota or Rhynchota), with two suborders Homoptera and Heteroptera separated traditionally by texture and resting position of the forewings and by the apparent origin of the beak; other entomologists, while recognizing the proximity of relationship between these two groups, consider that the relationship is of superorder value and that features separating the two groups are of sufficient magnitude to warrant full ordinal status for each group.

Separation of the two groups is reflected by differences in several important functioning body parts. The gula of the Heteroptera is a hard bridge that separates the mouthparts from the prothorax. In the homopterans the gula is small and membranous or absent, allowing the base of the mouthparts to abut or fuse to the prothorax. The forewings of heteropterans are generally divided into basal and apical halves of different texture. Homopteran forewings, on the other hand, are generally of similar texture for their full length. Scent glands are present in all terrestrial and some aquatic nymphs and adults of the Heteroptera. Homopterans lack scent glands.

Reduction and loss of the gula in homopterans, coupled with the migration of the mouthparts to the prothorax, were significant changes in functional specialization. In some homopteran families of the suborder Sternorrhyncha, the mouthparts have fused to the prothorax and remain attached to it if the cranium is removed. These and other basic characters that began to differentiate in the geologically remote Permian time (when many other insect orders were evolving) indicate an important branching of the phylogenetic line of homopterans and heteropterans and substantiate their separation at the ordinal level.

The heteropterans are divided into suborders on the basis of habitat, antennal structure, ability to produce sound (stridulate), and presence and arrangement of long hairs (called trichobothria) on various parts of the body. Division into families is based on structural differences and adaptations for specialized ways of life.

Annotated classification.

ORDER HETEROPTERA (true bugs)

Wings, when present, usually number four that may vary in size; basal portion of forewings thick and leathery, apical portion membranous; hindwings membranous, slightly shorter than forewings; wings at rest held flat over abdomen; piercing-sucking mouthparts arise from front part of head; compound eyes usually well developed; two simple eyes, or ocelli, present or absent; scent glands usually present; gradual metamorphosis; widely distributed, terrestrial and aquatic species number about 30,000.

Suborder Hydrocorisae (or Cryptocerata)

Neither cephalic nor abdominal trichobothria; antennae 4-segmented, shorter than head, usually in grooves on underside of head; semiaquatic (Gelastocoridae, Ochteridae) or aquatic (all other families); swimming members with fringe of swimming hairs on hind legs; aquatic members lay eggs in or on submerged exposed objects, are relatively active under water during winter; probably all males, and some females, stridulate; important food for fish, some water birds.

Family Corixidae (water boatmen). Head overlaps front of prothorax; scutellum small, usually concealed by pronotum; front legs short, 1-segmented tarsus with fringe of long hairs beneath for gathering food; middle legs long, slender, for submerged anchoring; males with stridular pegs on front femurs and tibiae of legs, a polished black strigil above on asymmetrical abdomen; females nonstridulatory, abdomen symmetrical; colour pattern commonly alternating light and dark transverse stripes; inhabit fresh, brackish, or salt (Great Salt Lake) waters; use diving air stores; phytophagous on algae and diatoms, but may eat insect larvae; more than 300 species; in all major faunal regions.

Family Notonectidae (back swimmers). Head not overlapping prothorax; scutellum large, exposed; all legs long and slender, hind pair longest; male stridulating mechanism involving front legs and labium; inhabits fresh and mineral waters; diving air stores trapped under hairs on underside of abdomen, hence inverted position in swimming; bite painful to man; predatory on insects, small crustaceans, fish, and tadpoles; almost 200 species; in all zoogeographical regions.

Family Pleidae. Very small, stout, convex above; scutellum large, exposed; hindwings reduced or absent; head and pronotum partially or wholly fused; inhabit fresh waters; about 20 species; in all zoogeographic regions.

Family Helotrephidae. Like Pleidae; about 15 species; only in Asia, Africa, and South America.

Family Nepidae (water scorpions). Body stout to very slender; legs long, generally slender, front pair adapted for grasping; abdomen of most nymphs and adults with snorkel-like breathing tube at tip; nymphs and adults stridulate by opposable files on anterior coxae and coxal cavity plates; inhabit fresh water; swim poorly or not at all; predatory; principal food, other insects; nearly 200 species; in all zoogeographical regions.

Family Belostomatidae (giant water bugs and toe biters). Large, some species exceeding 109 millimetres (4 inches) in length; broad, flattened body; middle and hind legs markedly flattened, with swimming hairs; inhabits fresh water; may lie in mud or debris on bottom; can inflict severe bites; predatory; aggressive, strong swimmers; grasping front legs capture insects, fishes, frogs; approximately 100 species; in New World, Asia, and Africa (including Madagascar).

Family Naucoridae (creeping water bugs). Head large, inserted into thorax; scutellum large, exposed; front femurs enlarged, tibiae opposable; middle and hind legs slender, sometimes with fringing hairs; inhabit fresh water, often warm

springs; generally use diving air storage chambers or "plastron" respiration; predatory mostly on mollusks and insects; about 150 species; most common in tropical continents, ranging north into Europe and North America; subfamily Aphelocheirinae uses plastron respiration, sometimes elevated to family rank.

Family Gelastocoridae (toad bugs). Broadly oval in shape, roughened surface, elevated protuberant eyes; resemble tiny toads; beak reaching only to coxae of front legs; broadened front femurs and opposable tibiae form effective grasping organ; middle and hind legs slender for running, lack fringing hairs; inhabit shores, burrows into mud or sand to lay eggs; predatory principally on small insects; about 100 species; in all zoogeographic regions.

Family Ochteridae (velvety shore bugs). Similar to Gelastocoridae in general appearance; body surface smooth, with velvety pile; beak reaches abdomen; found among plants growing along margins of ponds and streams; predatory upon other insects; about 25 species; in all zoogeographic regions.

Suborder Amphibicorisae

Trichobothria on head but not on abdomen; members generally live on the water's surface film or on mud or sand; predatory on tiny animals, including injured or freshly-killed insects; nonstridulating except for both sexes of genus *Stridulovelia* (Veliidae); within one species individuals may vary from winged to wingless.

Family Gerridae (water striders; pond skaters). Slender bodied; legs long, slender, front pair short, used for support or grasping prey; middle pair longest, used for propulsion over water surface; hind femurs extends beyond tip of abdomen; tips of tarsi project beyond insertion of claws; body covered below with hydrofuge hairs; on quiet or flowing fresh or marine water; *Halobates* occurs on open oceans hundreds of miles from land; predatory generally on insects; oceanic forms feed on plankton and floating jellyfishes; about 350 species; in all zoogeographic regions and intervening oceans between 40° north and 40° south latitudes.

Family Veliidae (smaller water striders). Habits and structures similar to Gerridae, but generally smaller, stouter bodied, and with hind femurs not reaching beyond tip of abdomen; two genera with last segment of middle tarsus split and with collapsible, fan-shaped tuft of long hairs used for propulsion over water surface; about 300 species; in all zoographic regions, genus *Trochopus* marine, but not in open sea.

Family Hydrometridae (marsh treaders). Body, head, and legs long and slender; claws arise at tip of tarsus; wings present or absent; crawl weakly and clumsily among emergent plants in fresh water; predatory; more than 100 species; mostly tropical, a few species in North America and Eurasia.

Family Mesoveliidae (water treaders). Small; body and legs slender; live on fresh water, especially among emergent plants or on saturated mud; one New Guinea species lives on the forest floor away from water; about 30 species; in all zoogeographical regions.

Family Saldidae (shore bugs). Head large; eyes prominent; labium apparently 3-segmented, long, first segment very short and stout, second very long; legs long and slender for running or leaping; generally inhabit land surfaces near fresh or salt water; some species live on rocks in the intertidal zone, hide in air trapped in crevices when rocks are covered at high tide; predatory on small or crippled insects; over 200 species, in all zoogeographic regions.

Family Leptopodidae. Like Saldidae; all 24 species native to Old World, one Mediterranean species established in New World (California).

Family Hebridae (velvet water bugs). Tiny, covered with hydrofuge hairs suitable to habitat on surface or along edges of bodies of still, fresh water; sometimes crawl into the water; food habits not known; about 120 species; in all zoogeographic regions; some widely distributed species may have been carried in drinking water on early sailing ships.

Family Leotichiidae. Structure suggestive of Saldidae but distinguished by strong median ridge on pronotum; habits unlike Hebridae; one of the two known species (both from southeastern Asia) occurs in caves.

Suborder Geocorisae

Trichobothria either present on abdomen or absent from both abdomen and head; antennae longer than head; difficult suborder to define; perhaps a convenient ecological (rather than a taxonomic) category better replaced by elevation of the two series to suborders; terrestrial; habits and foods varied.

Series Cimicomorpha

Trichobothria absent from head and abdomen; front wings with or without a cuneus (special region on hardened basal portion known as the corium).

Family Miridae (plant bugs). Small, fragile; ocelli absent; labium 4-segmented; front wing with cuneus, membranous area with 1 or 2 closed cells; legs slender to stout, for walking, running, or jumping; predatory, phytophagous, or both; often host specific; includes major crop pests (*e.g.*, "lygus bugs" of the Northern Hemisphere, the "tea blight" [*Helopeltis*] in southeastern Asia), also several important predators of small insects; about 8,000 species; in all zoogeographic regions; found north of the Arctic Circle.

Family Cimicidae (bedbugs). Oval to elongate oval, very flat; eyes small; forewings reduced to small, transversely oval pads exposing most of abdomen; hindwings absent; blood-sucking parasites of mammals and birds, usually present on host only while feeding, otherwise hiding in crevices in nest or lair; eggs glued to walls of crevices; contains the two species of bedbugs that attack man, *Cimex lectularius*, (originally in Europe and North America, now in all parts of the world) and *Cimex hemipterus* (common in southern Asia and Africa); *C. lectularius* probably encountered cave-dwelling men; not yet conclusively proved as carriers of any human diseases even though the bug can be successfully infected with some human parasites; about 75 species; found throughout the world but show marked parallels with ranges of their hosts.

Family Reduviidae (assassin bugs). Head usually protruding; beak short, 3-segmented, strongly curved away from underside of head, with tip in deep stridular groove between front coxae; front legs adapted for grasping; prey on insects and other small animals; genus *Triatoma* and some close relatives suck blood of mammals (including man) and are carriers of the tropical American Chagas' disease; can inflict painful bites; nearly 4,000 species; on all significant land masses.

Family Anthocoridae (anthocorid bugs). Ocelli and cuneus present; membrane of wing with or without veins; male external genitalia asymmetrical; predatory, mostly on small arthropods, including their eggs; some eat ants; others inhabit bird nests; may bite man; about 400 species; in all zoogeographic regions.

Family Polyctenidae (bat bugs). Oval; flattened; eyeless; front forewings, rudimentary, unhinged; hindwings absent; head and certain other parts with transverse rows of spines forming ctenidia (combs); eggs hatch within female, young nymphs retained in body and nourished by mother through a pseudoplacenta; blood suckers live entire life in fur of certain bats; 18 species; found from southern North America to South America, in Africa, and from southern Asia to Java.

Family Aradidae (flat bugs). Extremely flat; surface usually rough; head horizontal; clypeus prominently convex; ocelli absent; legs short; tarsi two-segmented; abdomen much wider than wings when present; found in crevices, as under loose bark or debris on the ground; feed on molds or fungi; nearly 1,000 species in all zoogeographic regions; sometimes part of group separated as family Dysodiidae.

Family Tingidae (lace bugs). Head small, without ocelli; antennae slender to stout, generally with first two segments very short, third long; pronotum and forewings often finely to coarsely reticulate (lacy); tarsi two-segmented; phytophagous, on anything from mosses to flowering plants, often host specific; several species are common pests on maize, cotton, cacao, and other cultivated plants; almost 2,000 species; in all zoogeographic regions.

Family Nabidae (nabid bugs). Ocelli present; beak four-segmented, long, generally curved away from underside of head; no striated groove between front coxae of legs; front legs more or less thickened for grasping; forewings without a cuneus; predatory on softbodied insects; frequently investigated as a possible biological control agent for insect pests of field crops; about 300 species; in all regions of the world.

Family Phymatidae (ambush bugs). Stout; surface roughened by tubercles; beak short, three-segmented, curved away from underside of head, tip resting in stridular groove between front coxae and legs; fourth antennal segment conspicuously thickened; front femurs of legs strongly thickened; scutellum small and triangular or large, broad, and reaching tip of abdomen; predatory, generally, lying among flower petals awaiting prey; more than 200 species; found on all major continents, except Australia, not found on oceanic islands.

Family Enicocephalidae (unique-headed bugs). Predatory; about 130 species; in all zoogeographic regions.

Family Dipsocoridae (or Cryptostemmatidae or Ceratocombidae). Biology poorly known; about 200 species; in all zoogeographic regions, more than half of species found in tropical America.

Family Isometopidae. Phytophagous; less than 50 species; sometimes reduced to a subfamily in the Miridae.

Family Ioppeicidae. The sole species occurs in the eastern Mediterranean region.

Family Microphysidae. Predatory; about 25 species; found in Eurasia and North America; one African genus questionably placed here.

Family Schizopteridae. About 100 species; sometimes united with the Dipsocoridae (see above).

Family Termitaphididae. Lives with termites; includes 9 species; found in tropical America, Africa, India, and Australia.

Family Thaumastocoridae (or Thaumastotheriidae). Phytophagous; about 12 species; found in Australia, India, North and South America, and the Greater Antilles.

Family Velocipedidae. Predatory; four species; found in Orient.

Family Vianaididae. Lives with ants (myrmecophilous); four species; found in tropical America.

Series Pentatomomorpha (or Trichophora)

Trichobothria on abdomen; cuneus always absent; terrestrial; various habits and foods.

Family Pentatomidae (stinkbugs). Head with side margins generally expanded over bases of antennae; ocelli usually present; antennae usually five-segmented; scutellum large to very large, triangular or U-shaped; without claval commissure; tibiae without rows of spines; phytophagous or predatory, sometimes within same species; several important pests, the "southern green stinkbug" (*Nezara viridula*), a serious pest of fruit and vegetable crops throughout the world, the "harlequin cabbage bug" (*Murgantia histrionica*) on North American cruciferous crops, the senn bugs (*Eurygaster* species) on small grains in the Old World; several genera (*Podisus, Zicrona*) feed on caterpillars and other larvae; about 5,000 species; in all zoogeographic regions; taxonomy unsettled, especially assignment of taxonomic levels; definition and relationships of subgroups not in dispute.

Family Plataspidae. Oval to transversely oval; head small, inserted deeply into prothorax; scutellum large, broadly U-shaped, reaching apex of abdomen; forewings much longer than body; wing membrane transversely folded at base and inserted under scutellum; tibiae not spined; phytophagous; about 500 species; found only in Old World.

Family Cydnidae (burrower bugs). Scutellum triangular or broadly U-shaped; forewings without claval commissure (except genus *Amnestus*); tibiae with rows of spines; colour generally brown or black, sometimes with creamy markings; phytophagous, most species in soil feed on roots of host; more than 600 species; in all zoogeographic regions; subfamily Corimelaeninae (or Thyreocorinae) sometimes given family status.

Family Coreidae. Antennae four-segmented, inserted on or above imaginary line connecting middle of eye to front end of buccula (cheek plates); ocelli present; forewings with claval commissure; wing membrane with numerous interconnected veins; appendages often with leaflike expansions; phytophagous, some as pests of cultivated plants, for example, the "squash bug" (*Anasa tristis*) on cucurbit crops in North America, a rice bug (*Leptocorisa varicornis*) in the Orient; over 2,000 species; in all zoogeographic regions; subfamilies Alydinae and Rhopalinae (or Corizinae) sometimes given family status.

Family Berytidae, or Neididae (stilt bugs). Body slender, narrowly elongate; legs extremely long, linear; labium four-segmented; usually phytophagous, sometimes attack soft-bodied plant-feeding insects; more than 100 species; in all zoogeographic regions.

Family Piesmatidae. Juga (two outer lobes of head) extend as a pair of horizontal, hornlike projections; prothorax with a deep pit below expanded sides; forewings, except apical part of membrane, with numerous coarse punctures; phytophagous, most frequently on plants of the goosefoot family (Chenopodiaceae); proven vectors of viral diseases of sugar beets in Europe and North America; about 20 species; in all zoogeographic regions.

Family Lygaeidae. Antennae four-segmented, inserted on side of head below an imaginary line connecting middle of eye to front end of buccula; ocelli present except in brachypterous forms; forewings with a claval commissure; wing membrane with four or five simple, longitudinal veins; phytophagous (on sap or seeds) or predatory (on mites and small insects); pests include the "chinch bug" (*Blissus leucopterus*) of North America, the Old World "cotton stainer" (*Oxycarenus hyalinipennis*), and several species of "false chinch bugs" in the widely distributed genus *Nysius;* in North America *Geocoris*, considered beneficial, feed upon mites and small insects attacking crop plants; almost 3,000 species found in all parts of the world, including many small islands.

Family Largidae. Head triangular, without ocelli; forewings with claval commissure; female with sixth visible abdominal segment below cleft medially; phytophagous; habits not well known; of no economic importance; about 100 special; in all zoogeographic regions.

Family Pyrrhocoridae (fire bugs or cotton stainers). Head triangular, without ocelli; forewings with long claval commissure; female with sixth visible abdominal segment below entire; phytophagous or predatory; "cotton stainers" (*Dysdercus*), serious pests of cotton crops; some species (*e.g.*, genus *Dindymus*) feed on flies as adults, nymphs prefer termites; more than 300 species; in all zoogeographic regions.

Family Aphylidae. Two species in Australia.

Family Colobathristidae. Phytophagous; about 90 species; inhabit Neotropical, Oriental, and Australian regions; unknow in North America, Europe, and Africa.

Family Hyocephalidae. One species in Australia.

Family Lestoniidae. Two species in Australia.

Family Phloeidae. Three species in tropical America, one in Borneo.

Family Stenocephalidae. About 40 species; except for one species on the Galapagos Islands, all known species live in Eurasia and Africa.

Family Urostylidae. Approximately 50 species confined to Asia and Australia.

Critical appraisal. The classification of the Heteroptera is in a state of flux due to continuous investigations in ontogeny, genetics, ecology, and morphology. Not all results are in agreement; therefore, important changes probably will occur. Wide disparity in superfamily concepts has resulted in dropping them from the above classification of the heteropterans.

The division of the order into three suborders is generally accepted, even if only for convenience; the prefixes reflect the broad ecological habits of the families included. Hydrocorisae reflects the adaptation of most of its families (Gelastocoridae and Ochteridae excepted) for life under water. Amphibicorisae suggests the land and water habits of these insects that live on the surface of the water or along shores. Geocorisae reflects the preferred terrestrial habitats of members of this group.

BIBLIOGRAPHY. Heteroptera literature is voluminous but scattered. Recent comprehensive works are too few and too limited in scope to supersede all the older works. The reader will find additional important, useful, and interesting information on this order in textbooks on insects listed in the article INSECTA.

(R.C.F.)

Hieroglyphic Writing

Hieroglyphic writing is a system that employs characters in the form of pictures. These individual signs, called hieroglyphs, may be read either as pictures, as symbols for pictures, or as symbols for sounds. The name hieroglyphic (from the Greek word for "sacred carving") is first encountered in the writings of Diodorus Siculus (1st century BC). Earlier, other Greeks had spoken of sacred signs when referring to Egyptian writing. Among the Egyptian scripts, the Greeks labelled as hieroglyphic the script that they found on temple walls and public monuments, in which the characters were pictures sculptured in stone. The Greeks distinguished this script from two other forms of Egyptian writing that were written with ink on papyrus or on other smooth surfaces. These were known as the hieratic, which was still employed during the time of the ancient Greeks for religious texts, and the demotic, the cursive script used for ordinary documents.

Non-Egyptian hieroglyphic scripts

Hieroglyphic, in the strict meaning of the word, designates only the writing on Egyptian monuments. The word has, however, been applied for about 100 years to the writing of other peoples, insofar as it consists of picture signs used as writing characters. The name hieroglyphics is, for example, always used to designate the scripts of the Indus civilization and of the Hittites, who also possessed other scripts, in addition to the Mayan, the Incan, and Easter Island writing forms, and also the signs on the Phaistos Disk on Crete. Colloquially, the word hieroglyphics has been extended to mean any sort of illegible or barely legible writing.

Because of their pictorial form, hieroglyphs were difficult to write and were used only for monument inscriptions. They were usually supplemented in the writing of a people by other, more convenient scripts. Among living writing systems, hieroglyphic scripts are no longer used.

The rest of this article is concerned only with Egyptian hieroglyphic writing.

Development of Egyptian hieroglyphic writing. The most ancient hieroglyphs date from the end of the 4th millennium BC and comprise annotations to the scenes cut in relief—found on slabs of slate in chapels or tombs—that had been donated as votive offerings. Although by no means all of these earliest signs can be read today, it is nonetheless probable that these forms are based on the same system as the later classical hieroglyphs. In individual cases, it can be said with certainty that it is not the copied object that is designated but rather another word phonetically similar to it. This circumstance means that hieroglyphs were from the very beginning phonetic symbols. An earlier stage consisting exclusively of picture writing using actual illustrations of the intended words cannot be shown to have existed in Egypt; indeed, such a stage can with great probability be ruled out. No development from pictures to letters took place; hieroglyphic writing was never solely a system of picture writing. It can also be said with certainty that the jar marks (signs on the bottom of clay vessels) that occur at roughly the same period do not represent a primitive form of the script. Rather, these designs developed in parallel fashion to hieroglyphic writing and were influenced by it.

Improbability of relationship to cuneiform

It is not possible to prove the connection of hieroglyphs to the slightly older cuneiform characters used by the Sumerians in southern Mesopotamia. Such a relationship is improbable because the two scripts are based on entirely different systems. What is conceivable is a general tendency toward words being fixed by the use of signs, without transmission of particular systems.

Invention and uses of hieroglyphic writing. The need to identify a pictorial representation with a specific, unique event, such as a hunt or a particular battle, led to the invention of hieroglyphic writing. Hieroglyphs added to a scene signified that this illustration represented a particular war rather than an unspecified one or war in general. This new attitude toward time and toward history as unique events in time led to the invention of hieroglyphic writing. The system first appeared only in connection with relief depictions, which they explained by means of place names. Beginning in the 1st dynasty (3100 BC), images of persons were also annotated with their names or titles, a further step toward expressing individuality and uniqueness. The so-called annalistic tablets of the first two dynasties were pictorial representations of the events of a year with specifically designated personal names, places, and incidents. For example, accompanying a scene of the pharaoh's triumph over his enemies is the annotation "the first occasion of the defeat of the Libyans." Simultaneously, the writing of the Egyptians began to appear unaccompanied by pictorial representations, especially on cylindrical seals. These roller-shaped incised stones were rolled over the moist clay of jar stoppers. Their inscription prevented the sealed jar from being covertly opened and at the same time described its contents and designated the official responsible for it. In the case of wine, its origin from a specific vineyard and often also the destination of the shipment were designated, and, as a rule, so was the name of the reigning king.

From the stone inscriptions of the 1st dynasty, only individual names are known, these being mainly the names of kings. In the 2nd dynasty, titles and names of offerings appear, and, at the end of this dynasty, sentences occur for the first time. The discovery of a blank papyrus scroll in the grave of a high official, however, shows that longer texts could have been written much earlier; *i.e.*, since the early part of the 1st dynasty.

Relationship of writing and art. The form of these hieroglyphs of the archaic period (the 1st to 2nd dynasty) corresponds exactly to the art style of this age. Although definite traditions or conventions were quickly formed with respect to the choice of perspective—*e.g.*, a hand was depicted only as a palm, an eye or a mouth inscribed only in front view—the proportions remained flexible. The prerequisite of every writing system is a basic standardization, but such a standardization is not equivalent to a canon (an established body of rules and principles) in the degree of stylistic conformity that it requires. A recognized canon of Egyptian hieroglyphic writing arose in the 3rd dynasty and was maintained until the end of the use of the script.

Formation of the standard and canon of Egyptian writing

In that hieroglyphic signs represented pictures of living beings or inanimate objects, they retained a close connection to the fine arts. The same models formed the basis of both writing and art, and the style of the writing symbols usually changed with the art style. This correspondence occurred above all because the same craftsmen painted or incised both the writing symbols and the pictures. Deviations from the fine arts occurred when the writing, which was more closely bound to convention, retained patterns that the fine arts had eliminated. The face in front view is an example of this. This representation, apart from very special instances, was eventually rejected as an artistic form, the human face being shown only in profile. The front view of the face was, however, retained as a hieroglyph from the archaic period to the end of the use of hieroglyphic writing. Similar cases involve the depiction of various tools and implements. Although the objects themselves fell out of use in the course of history—*e.g.*, clubs used as weapons—their representations, mainly misunderstood, were preserved in the hieroglyphic script. The hieroglyphs corresponding to such objects that had disappeared from daily life were therefore no longer well known and were often distorted beyond recognition. But the style of representation in the hieroglyphs still remained closely bound to the art of the respective epoch. Thus there appeared taut, slender forms or sensuous, fleshy ones, or even completely bloated characters, according to the art style of the period.

Media for hieroglyphic writing. In historical times (2800 BC–AD 300), hieroglyphic writing was used for inscribing stone monuments and appeared in Egyptian relief techniques, both high relief and bas-relief; in painted form;

on metal, sometimes in cast form and sometimes incised; and on wood. In addition, hieroglyphs appear in the most varied kinds of metal and wood inlay work. All of these applications correspond exactly with the techniques used in fine art, and the same craftsmen who produced the works of art painted or incised the hieroglyphic inscriptions.

Subject matter of inscriptions

Hieroglyphic texts are found primarily on the walls of temples and tombs, but they also appear on memorials and gravestones, on statues, on coffins, and on all sorts of vessels and implements. Hieroglyphic writing was used as much for secular texts—historical inscriptions, songs, legal documents, scientific documents—as for religious subject matter—cult rituals, myths, hymns, grave inscriptions of all kinds, and prayers. These inscriptions were, of course, only a decorative monumental writing, unsuitable for everyday purposes. For popular use, hieratic script was developed, an abbreviated form of the picture symbols such as would naturally develop in writing with brush and ink on smooth surfaces like papyrus, wood, and limestone.

Writing and religion. The influence of religious concepts upon hieroglyphic writing was confined to two cases. In the 3rd millennium, certain signs were avoided or used in garbled form in grave inscriptions for fear that the living beings represented by these signs could harm the deceased who lay helpless in the grave. Among these taboo symbols were human figures and dangerous animals, such as scorpions and snakes. Secondly, in all periods and for all uses of the writing, symbols to which a positive religious significance was attached were regularly placed in front of other signs, even if they were to be read after them. Among these were hieroglyphs for God or individual gods, as well as those for the king or the palace. Thus, for example, the two signs,  denoting the word combination "servant of God" (priest), are written so that the symbol for God, , stands in front of that for servant,  , although the former is to be read last. Moreover, theology traced the invention of hieroglyphic writing back to the god Thoth, although this myth of its divine origin did not have an effect on the development of the script. In the late period, Egyptian texts referred to hieroglyphic inscriptions as "writing of God's words"; earlier, in contrast, they were simply called pictures.

Literacy and knowledge of hieroglyphic writing. At all periods only a limited circle understood the script. Only those who needed the knowledge in their professions acquired the arts of writing and reading. These people were, for example, officials, doctors, and priests (insofar as they had to be able to read rituals and other sacred texts), as well as craftsmen whose work included the making of inscriptions. Under Greek and especially under Roman rule, the knowledge declined and was entirely confined to temples, where priests instructed their pupils in the study of hieroglyphic writing.

Decline of hieroglyphic writing

From the time of the rule of the Ptolemies (305 to 30 BC), national consciousness became more and more narrowly bound up with religion, and for both the national consciousness and religion alike the tradition-filled hieroglyphic writing was an outward sign—in the fullest sense, a symbol. There was no lack of attempts to replace the hieroglyphic writing, cumbersome and ever more divergent from the spoken language, with the simpler and more convenient Greek script. Such experiments, however, remained ineffective precisely because of the emotional value that the old writing system had when the country was under the foreign domination of the Macedonian Greeks and the Romans.

Christianity and the Greek alphabet. The situation was altered with the conversion of the country to Christianity in the 2nd and 3rd centuries AD. The new religion fought against the Egyptian polytheism and traditions, and with its victory, the Greek script triumphed. From the beginning, Egyptian Christians used the Greek alphabet for writing their spoken Egyptian language. This practice involved enlarging the Greek alphabet with five supplementary letters for Egyptian sounds not present in Greek. As a consequence, the knowledge of hieroglyphic writing quickly declined. The last evidence of the writing system is a rock inscription from the island of Philae, dating from August 24, 394, from the reign of the emperor Theodosius I. The language as well as the writing system of the Egyptian Christians is called Coptic.

Characteristics of hieroglyphic writing. The system of hieroglyphic writing has two basic features: first, representable objects are portrayed as pictures (ideograms), and second, the picture signs are given the phonetic value of the words for these represented objects (phonograms). At the same time, these signs are also written to designate homonyms, similar-sounding words. The writing disregards vowels, and, also, in earlier times, the semivowels *i*, *y*, and *w*, thus offering more possibilities for the transference of signs to words with identical consonant combinations. For example, the sign for "wood" is written as a branch,  , which is pronounced with the consonants *ḫ* and *t*, which occur in the Egyptian word for wood. Other words with the same series of consonants can also be written with the same basic sign; *e.g.*, *ḫt* "after," *ḫtì* "to retreat," or *ḫtì* "to carve." Words that consisted of only one consonant, plus one or more vowels, supplied single consonant signs. The Egyptians, however, never reduced their writing to an alphabet by discarding the multiconsonant signs; rather, they retained clearly the form of the original words. When doubts occurred, as in the case of the three signs for the frequent consonant series *m* + *r* (the hoe,  , the chisel,  , and the pyramid,), the plurality was used to make clear distinctions between words: all derivations from the stem *mr* "to love" were written with the hoe; those from the stem *mr* "to be ill," with the chisel; and those words related to pyramids with the sign for pyramid. Thus, two or more existing signs for the same sound or combination of sounds were retained and used in conscious distinction to promote easier readability. Although each sign originally had only one reading, occasional ambiguities did develop through the convergence of two symbols of similar form, such as those for the thighbone and the shankbone of an animal. A few signs, therefore, had two or, less commonly, three readings in classical Egyptian writing.

Ideograms and phonograms

Reading aids: spelling, phonetic complements, determinatives. By means of this rebus system in which letters and pictures were combined the Egyptians could write a large number of the words of their language. But there remained a residue for which no drawable word with the same consonant framework presented itself; *e.g.*, *nḫt* "strong." Here the Egyptians spelled out the word: for *n*, they had a sign, the water symbol (from the word *nwy* "flood"), and for *ḫt* they had the above-mentioned sign for wood, , so that they could now write *nḫt* as .

Two additional reading aids that were quickly added to this system promoted distinctness and readability. For multiconsonant signs, one or more consonants, or in some cases all of them, were also written to serve as a phonetic complement. Thus there is for *mr* "to be ill," in which the owl (top, left) possesses the phonetic value *m* and the mouth ( ) that of an *r*. In cases like this, the consonants, according to the conception of modern scholars, were written twice but read only once. For the Egyptians, the single consonant signs were there simply as reading aids for clarification of the word sign, the logogram. Accordingly, they wrote , inwhich is complemented by the two signs , *ḫ*, and , *t*, which appear after it.

Phonetic complements

In addition, determinatives—signs that do not represent a phonetic value but serve only to inform the reader as to the family of meanings to which the designated word belongs—were quickly formed out of these. The consonant combination *ḫtì* "to engrave" has a knife written after it; on the other hand, *ḫti* "to retreat" has legs striding backward. Thus, these two words, otherwise written identically, are differentiated graphically as and . In this

manner, each Egyptian word possessed its own writing picture with which it was strictly associated. Grammatical endings were attached to this word picture and stood after the determinative. From the outset, therefore, Egyptian writing was a complete script; that is, it could unequivocally fix any word, including all derivations and all grammatical forms.

Summary of the types of signs. In summation, hieroglyphs can be separated into three groups, of which the first two render a phonetic value, and the third represents mute reading aids: (1) ideograms, or signs that should be read as the word they represent—*e.g.*,  , "branch"; (2) phonograms, or signs that do not refer back to the objects they represent but stand simply for one or more consonants—*e.g.*,  as *n* and as *ḫt* in , *nḫt* "strong"; and (3) determinatives, which possess no phonetic value but which aid the reader by leading him to the correct interpretation of the meaning—*e.g.*,  in  , *ḥtì* "to retreat." Egyptian writing lacked punctuation in our meaning of the term. Line and stanza signs appeared only in certain literary texts.

Number of symbols. In the classical period, the number of hieroglyphs totalled approximately 700. Their number multiplied considerably in the late period (about 600 BC), because scholars constantly invented new forms or signs. The additions were, however, always in accordance with the principles that had governed Egyptian writing from its beginnings. The hieroglyphic system remained flexible throughout all periods, always open to innovation, even though, as with every writing system, convention played a preponderant role.

Invention of new signs

Direction of the writing. The lines were written from right to left or, less frequently, from left to right. Vertical rows could be placed next to horizontal rows, according to the demands of the architectural setting. The direction of the writing is immediately ascertainable because the signs always face the beginning of the row. Occasionally, some signs are turned around in the row, presumably so that two human figures can face one another, to avoid standing with their backs toward each other. These rotations are infrequent, however, and are found almost exclusively in the names of kings. Royal names were enclosed in a ring, the so-called cartouche; *e.g.*,  "Khufu," in Egyptian *Ḫwfw*. This ring, originally a rope, was supposed to protect the bearer of the enclosed name from injury and, in particular, from harmful magic.

Egyptian pedagogical traditions. To understand hieroglyphic writing, one must know about its tradition within Egypt. The Egyptian student of writing, who brought with him a knowledge of the spoken language as his mother tongue, began by learning the script picture corresponding to each word without having isolated its elements; *i.e.*, its individual signs. Through centuries this pedagogical tradition in the schools helped Egyptian words retain the original established spelling, with only minor—usually stylistic—changes, even when the phonetic form had radically changed. Hieroglyphic writing thus conceals historical sound changes.

Sound changes shown by misspellings

The mistakes in hearing made by pupils in the writing schools have helped scholars to understand the phonetic changes that occurred in the development of the Egyptian language. When the pupil who was learning to write the hieroglyphic script did not recognize a word dictated to him, he wrote it badly—that is, just as he heard it. Because he had not yet learned to spell in the orthodox manner, what appeared on his papyrus was usually a word that sounded similar to the dictated but misunderstood term and whose word picture was familiar. Thus, although Egyptian writing was originally composed of symbols that represented a phonetic value, the system was transmitted in the form of word pictures; that is, closed or indivisible groups, generally of several signs per word.

Cryptographic hieroglyphic writing. That knowledge of the hieroglyphic system and the principles upon which it was devised had not become lost is attested by two phenomena: cryptography and the development of the hieroglyphic writing during the last millennium of its existence. From the middle of the 3rd millennium but more frequently in the New Kingdom (from 1500 BC), hieroglyphic texts are encountered that have a very strange appearance. The absence of familiar word groups and the presence of many signs not found in the canon characterize these texts at first glance as cryptographic, or secret, writing. This kind of hieroglyphic writing was probably intended as an eye-catcher, to entice people to seek the pleasure of deciphering it. Composed according to the original principles of the script, these inscriptions differed only in that certain features excluded when the original canon was formulated were now exploited. The new possibilities involved not only the forms of the signs but also their selection. For example, the mouth was not drawn in front view (), as in the classical script, but in profile (), although it had the same phonetic value. An example of a change in the choice of signs is the case in which a man carrying a basket on his head (), a determinative without phonetic value in the classical script, was later to be read as *f* and was used in lieu of the familiar sign having this phonetic value, that of the horned viper. In the new selection of the sign, the phonetic value is obtained from the word *f3ì* "to carry" (neglecting its two weak consonants), in accordance with a principle that the inventors of the writing had applied in 3000 BC. These cryptographic inscriptions prove that alongside the method of instruction in the schools, which was based on memorization or recognition, not upon analytical understanding, there was another tradition that transmitted knowledge of the basic principles of the hieroglyphic script. A command of the principles of hieroglyphics similar to that which the composers of the cryptic inscriptions had was presupposed for the puzzle-happy decipherers. Because the encoded texts often consisted of a petition by the inventor of the text to say a prayer on his behalf, the number of these decipherers must surely not have been small.

Transmission of the hieroglyphic principles

Growth of hieroglyphic writing during the last millennium BC. At about the middle of the last millennium BC, Egyptian writing experienced new developments and a revival of interest. Again the inscriptions abounded with new signs and sign groups unknown in the classical period, all generated according to the same principles as the classical Egyptian script and the cryptographic texts. The writing of this late period was distinguished from the cryptograms in that this script, like every normal system of writing, developed a fixed tradition, being intended not to conceal but to be read easily, whereas the cryptography strove for originality.

Stages of hieroglyphic writing. The development of hieroglyphic writing thus proceeded approximately as follows: at first only the absolutely necessary symbols were invented, without a canonization of their artistic form. In a second stage, easier readability (*i.e.*, increased rapidity of reading) was achieved by increasing the number of signs (thereby eliminating some doubts) and by employing determinatives. Finally, after the second stage had endured, essentially unaltered, for about 2,000 years, the number of symbols increased to several thousand in about 500 BC. This rampant growth process occurred through the application of hitherto unused possibilities of the system. With the triumph of Christianity, the knowledge of hieroglyphic writing was extinguished along with the ancient Egyptian religion.

Tools. The tools used by the craftsmen for writing hieroglyphic symbols consisted of chisels and hammers for stone inscriptions and brushes and colours for wood and other smooth surfaces. Only for the cursive scripts, hieratic and demotic, were special materials developed. Leather and papyrus became writing surfaces, and the stems of rushes in lengths of 16–32 centimetres, cut obliquely at the writing end and chewed to separate the fibres into a brushlike tip, functioned as writing implements. The split calamus reed was introduced into Egypt by the Greeks in the 3rd century BC.

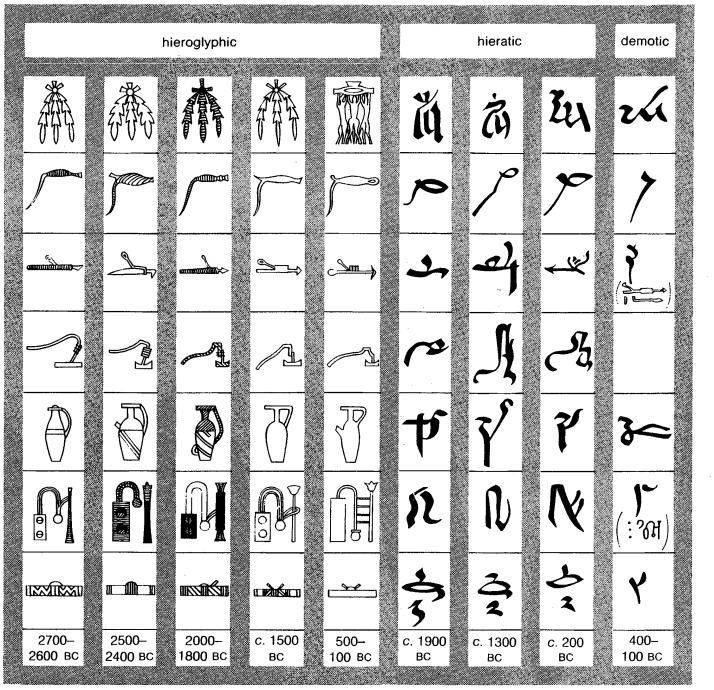
Development of special writing materials

Hieratic script. The Egyptian cursive script, called hieratic writing,. received its name from the Greek *hieratikos* (meaning priestly) at a time when the script was used only

for sacred texts. Everyday secular documents were written in another style, the demotic (Greek *dēmotikos* "for the people" or "in common use") script.

Relation of hieratic to hieroglyphic script. The structure of the hieratic script corresponds with that of hieroglyphic writing. Changes occurred in the characters of hieratic simply because they could be written rapidly with brush or rush and ink on papyrus. In general, the picture form is not, or not easily, recognizable. Because their models were well known and in current use throughout Egyptian history, the hieratic symbols never strayed too far from them. Nevertheless, the system differs from the hieroglyphic script in some important respects:

1. Hieratic was written in one direction only, from right to left. In earlier times, the lines had run vertically, and later, about 2000 BC, horizontally. Subsequently, the papyrus scrolls were written in columns of changing widths.
2. There were ligatures in hieratic, so that two, but no more than two, signs could be written in one stroke.
3. As a consequence of its decreased legibility, the spelling of the hieratic script was more rigid than that of hieroglyphic writing. Variations from uniformity at a given time were minor; but, during the course of the various periods, the spelling developed and changed. As a result, hieratic texts do not correspond exactly to contemporary hieroglyphic texts, either in the placing of signs or in the spelling of words.
4. Hieratic used diacritical additions to distinguish between two signs that had grown similar to one another because of cursive writing. For example, the cow's leg received a supplementary distinguishing cross, because in hieratic it had come to resemble the sign for the leg of a man. Certain hieratic signs were taken into the hieroglyphic script.



Egyptian hieroglyphs and their cursive equivalents. **The hieroglyphs depict (top to bottom): three fox skins tied together; a whip; a single-barbed harpoon; an adz at work on a block of wood; a stone jug with handle; a scribe's outfit; a roll of papyrus tied with a cord.**

Role of hieratic in Egypt

All commonplace documents—*e.g.*, letters, catalogues, and official writs—were written in hieratic script, as were literary and religious texts. In the life of the Egyptians, hieratic script played a larger role than hieroglyphic writing and was also taught earlier in the schools. In offices, hieratic was replaced by demotic in the 7th century BC, but it remained in fashion until much later for religious texts of all sorts. The latest hieratic texts stem from the end of the 1st century or the beginning of the 2nd century AD.

Demotic script. Demotic script is first encountered at the beginning of the 26th dynasty, in about 660 BC. The writing signs plainly demonstrate its connection with the hieratic script, although the exact relationship is not yet clear. The demotic characters are more cursive (flowing and joined), and thus more similar to one another, with the result that they are more difficult to read than are the hieratic forms. Countering this difficulty, there is less freedom for the writer's individual variations. It appears that demotic was originally developed expressly for government office use; that is, for documents in which the language was extensively formalized and thus well suited for the use of a standardized cursive script. Only some time after its introduction was it used for literary texts in addition to documents and letters; much later it was employed for religious texts also. The latest dated demotic text, from December 2, AD 425, consists of a rock inscription at Philae. In contrast to hieratic, which is, almost without exception, written in ink on papyrus or other flat surfaces, demotic inscriptions are not infrequently found engraved in stone or carved in wood.

Alternative demotic spelling. The demotic system corresponds to the hieratic and hence also to the hieroglyphic system. Alongside the traditional spelling, however, there was another spelling that took account of the markedly altered phonetic form of the words by appropriate respelling. This characteristic applied especially to a large number of words that did not occur in the older language and for which no written form had consequently been passed down. The nontraditional spelling could also be used for old, familiar words.

Decipherment of hieroglyphic writing. With the possible exception of Pythagoras, no Greek understood the nature of hieroglyphic writing. The Greeks did not obtain guidance from their Egyptian contemporaries, some of whom even lived on Italian soil and wrote proper hieroglyphic inscriptions on Roman obelisks. Rather, the Greek tradition taught that hieroglyphs were symbolic signs or allegories. The Egyptian-born Greek philosopher Plotinus interpreted hieroglyphic writing entirely from the viewpoint of his esoteric philosophy. Only one of the numerous works on the hieroglyphic script written in late antiquity has been preserved: the *Hieroglyphica* of Horapollon, a Greek Egyptian who probably lived in the 5th century AD. Horapollon made use of a good source, but he himself certainly could not read hieroglyphic writing and began with the false hypothesis of the Greek tradition, namely, that hieroglyphs were symbols and allegories, not phonetic signs.

Greek beliefs concerning hieroglyphic writing

The Middle Ages neither possessed any knowledge of hieroglyphic writing nor took any interest in it. But a manuscript of Horapollon brought to Florence in 1422 stirred great interest among the Humanists. Without giving a thought to thepossibility that ancient Egyptian originals might be available in Rome, Renaissance artists designed hieroglyphs after Horapollon's descriptions, as well as from their own imaginations. They used hieroglyphs as wisdom-laden symbols in architecture and also in drawings and paintings.

Kircher's attempts at decipherment. The great German scholar Athanasius Kircher (1602–80) began his attempts at decipherment with the Coptic language and with the correct hypothesis that the hieroglyphs recorded an earlier stage of this language. He also believed, again correctly, that the signs recorded phonetic values. In spite of this, he did not arrive at correct results—with the exception of a single character. This failure can be attributed not only to Kircher's erroneous assumption that the hieroglyphs must correspond phonetically to an alphabet but primarily to the fact that he was most interested in the Renaissance conception of a supposed symbolic meaning constituting the deeper significance of hieroglyphs. In his view, the phonetic value of the hieroglyphs was merely the commonplace, superficial part of the sign.

Discovery of the Rosetta Stone. Both the intellectual and the physical prerequisites for the deciphering of the hieroglyphic script first presented themselves at the end of the

18th century. By accident, a stone that exhibited three different scripts—hieroglyphic, demotic, and Greek—was discovered by members of Napoleon's expedition to Egypt in 1799 near Rashid (French Rosette; English Rosetta) on the Mediterranean coast. The Greek text stated clearly that the document set forth the same text in the sacred script, the folk or popular script, and Greek. The stone was promptly made known to all interested scholars. Important partial successes in the effort of deciphering the scripts were achieved by the Swede Johan David Åkerblad and by the great English physicist Thomas Young, who mainly studied the demotic text, again beginning with the false hypothesis that the hieroglyphs were symbols. Young succeeded in proving that they were not symbols—at least that the proper names were not—and that the demotic and hieratic signs had come from the hieroglyphs. (He first published this result in the supplement to the 4th, 5th, and 6th editions of the *Encyclopædia Britannica*.) He was the first to isolate correctly some single consonant hieroglyphic signs. But a wrong turn in the course of his investigations then prevented him from fully deciphering the writing.

Thomas Young's work

Champollion's decipherment. This task of complete decipherment was first accomplished by the Frenchman Jean-Francois Champollion (1790–1832) in 1822, after long years of intensive work and many setbacks. His success was due to the recognition that hieroglyphic writing, exactly like the hieratic and demotic scripts derived from it, did not constitute a writing system of symbols but rather a phonetic script. He arrived at this breakthrough by an exact comparison of the three Egyptian forms of writing, as well as by reference to Coptic, the late phase of the Egyptian language that was written with the Greek alphabet and was thus directly readable. The Coptic language was also understood at that time. Starting, as had his predecessors, from Ptolemy and Cleopatra, both ring-enclosed royal names, and adding the hieroglyphic spelling of Ramses' name, Champollion determined, essentially correctly, the phonetic values of the signs. Soon after, he also learned to read and translate a large number of Egyptian words. Since then, precise research has confirmed and refined Champollion's approach and most of his results.

BIBLIOGRAPHY. Books in English on hieroglyphic writing include: A.H. GARDINER, *Egyptian Grammar*, 3rd ed., rev. (1957), with a list of hieroglyphs from the Middle Kingdom; H. PETRIE, *Egyptian Hieroglyphs of the First and Second Dynasties* (1927); F.L. GRIFFITH, *A Collection of Hieroglyphs* (1898); and N.M. DAVIES, *Picture Writing in Ancient Egypt* (1958), a collection of artistically valuable hieroglyphs.

For those with a knowledge of German, the following texts may be consulted: H. BRUNNER in the *Handbuch der Orientalistik*, pt. 1, vol. 1, ch. 1 (1959), and "Die Schrift der Ägypter," *Handbuch der Archäologie: Allgemeine Grundlagen der Archäologie* (1969); S. SCHOTT, *Hieroglyphen* (1951), the origin and early development of hieroglyphic writing; P. KAPLONY, *Die Inschriften der Ägyptischen Frühzeit*, 3 vol. (1963, suppl. 1964), a collection of inscriptions of the archaic period; G. MOLLER, *Hieratische Paläographie*, 3 vol. (1909–12); W. ERICHSEN, *Demotische Lesestücke I. Literarische Texte*, pt. 3 (1937), and *Auswahl frühdemotischer Texte*, pt. 3 (1950). The last two sources concern demotic texts.

Higher Education

The best short definition of higher education may be the one devised and accepted in 1962 by 44 nations participating in a UNESCO conference on higher education in Africa:

> Higher education is defined as all types of education (academic, professional, technological, or teacher education) provided in institutions such as universities, liberal arts colleges, technological institutes and teachers' colleges for which: (a) the basic entrance requirement is completion of secondary education . . . ; (b) the usual entrance age is about 18 years; and (c) in which the courses lead to the giving of a named award (degree, diploma, or certificate of higher studies).

The definition has unavoidable limitations since each nation uses its own nomencature for its various educational institutions and programs. Many countries, for example, use the term school to describe an institution of higher education, particularly a professional institution such as medical school or law school, and the word college, on the other hand, is frequently used to describe an institution of secondary education. Moreover, although all institutions of higher education provide courses concluded by the giving of a named award, many also offer some courses that do not conclude in this way.

In addition to setting up institutions of higher education, all countries provide in different ways for the education of those who, at 18 years of age, are described as adults and who do not wish to proceed to an institution of higher education, but who do wish to continue their education. Courses of study in such cases are generally shorter and less rigorous than those pursued in institutions of higher education and rarely lead to a named award. They are best described as courses in "adult" education. It is not always easy, however, to draw the line between institutions of higher and adult education.

The article is divided into the following sections:

I. Major models of higher education

The essential characteristics of higher education in western Europe may be said to have been firmly established in its institutions between the 11th and 16th centuries; after that, new historical forces worked to produce different modifications of the medieval pattern in different countries. It is possible to recognize five major models of higher education that developed in the five countries of France, Germany, England, the United States, and the Soviet Union; these, more than others, have powerfully influenced the development of higher education elsewhere in the modern period.

CHARACTERISTICS OF EDUCATION IN MAJOR COUNTRIES

France. The medieval universities of France, abolished during the Revolution in 1793, were re-established by Napoleon in 1808, and because by that time he had made France supreme in Europe, their influence was powerful over a very large area of Europe and for a very long time. The Napoleonic pattern of government was a metropolitan one, and the centralization of political power was reflected in a system of higher education characterized by the primacy of a single university, the University of Paris. Only in very recent years has a policy of decentralization been initiated to offset the weakness of provincial universities due to a drain of superior talent to the capital. Even so, today, a third of all French students go to Paris for their higher education.

Centralization in the French system

The clarity of the organization of French education is shown in the geographical division of all France and its overseas possessions into a number of *académies*, each composed of from three to eight civil *départements*. The academic head of each *académie* is the rector of its major university, who is not only the head of the university but also the head of the whole educational system in the *académie* and the representative there of the central Ministry of National Education. The rector is appointed by the president of the Republic himself and is both chairman of his own university council and president of a regional council for higher education.

Central control over higher education is exercised by a Directorate acting on the advice of a Council of Higher Education, which is responsible for policy in matters of curriculum, examinations, awards, and administration. Parallel with the council is a Universities Consultative Committee organized in five divisions corresponding to the fivefold Faculty organization that is typical of the French pattern of higher education: law, science, letters,

medicine, and pharmacy. (At the University of Strasbourg there is also a faculty of theology.) The consultative committee deals with faculty matters and is responsible for the nomination and promotion of professors. Each faculty is under the charge of a dean, an officer appointed for three years by the Minister of National Education on the joint recommendation of faculty and the university council. The Dean is in charge of faculty finance and administration and is provided with a secretariat. The office of dean symbolizes the degree to which university teachers are saved from many of the burdens of administration, but in a way that also relieves them of some of the advantages of self-government.

Higher education in France is free and open to all students who have passed the *baccalauréat* examination with which the cycle of secondary studies is concluded. The first year of studies in a university is called the preparatory, or *propédeutique*, year. It is terminated by an examination the severity of which may be judged from the fact that only 30 to 40 percent of the students are selected to continue their degree studies. Those excluded can, however, proceed with a further year of higher studies, and many of them do so in a two-year *collège universitaire*, where certificates or diplomas of higher studies are awarded at the end of the two-year period. Those who are successful in the *propédeutique* examination embark on a course lasting for further three or four years and leading to the first university degree of *licence*.

Grandes écoles

In France there are important institutions of higher education that have grown up outside the universities. Called the *grandes écoles*, they are concerned with advanced professional and technological training. Though some of these schools are affiliated with universities, the majority are not. Their students, whose number is limited, are recruited by competitive examinations held all over France for candidates who already possess the *baccalauréat* and who, customarily, have followed it by a year or two of special coaching. In these schools the work of students is closely supervised so that their diplomas have a standing in France that is higher than that of most *licences*. These high standards have ensured a supply of intelligent, well-educated men into all branches of applied science and technology in France, and their organization has been copied wherever the French model has had influence.

The degree of financial aid given to French students is less than might be expected in a state system. Only some 30 percent of students receive state grants, and the average value of these is no more than £100 a year. In addition, there are subsidized meals, welfare facilities, and student loans, repayment of which need not begin until ten years after graduation.

Following the example of Paris, many universities have built a *cité universitaire*, or group of residence halls, but these are mainly for the benefit of foreign students or, to a lesser degree, students from distant parts of France, since most students are obliged, for financial reasons, to live at home. The effect of this is to give to universities outside Paris a strongly regional character. There is therefore nothing like the movement between universities that is common in Germany.

An aspect of higher education that follows different lines of development in different countries is that of institutions concerned with the training of teachers. In France, as in a number of other countries, training institutions for teachers in primary schools are not regarded as part of the system of higher education. Graduates who wish to teach may study for their *agrégation* either at an institute of education attached to the faculty of letters or science at a university of at one of the four *écoles normales supérieures*. If less ambitious, a *licencié* may undertake a short period of study for the professional qualification of the *certificat d'aptitude* and then follow this by a longer period of practical training at one of the regional centres set up by the Ministry of Education under a decree of 1957.

After the student disturbances of 1968, the Ministry of Education initiated far-reaching reforms that were expected eventually to bring French universities much closer to the American and English models. In place of central control there was to be institutional autonomy. The rigid faculty structure was to be replaced by a flexible grouping of Unités d'Anseignement et de Recherche (UAR). One-third of the places on the elected UAR councils were to go to students. Formal lectures and infrequent examinations were to be replaced by work in small groups with continuous assessment. A new award, the *maîtrise*, was to follow the *licence*. New university construction was to be modelled more nearly on the campus pattern. Twenty new university Institutes of Technology began to invade the monopoly of the *grandes écoles*.

Germany. As in France, the institutions of higher education established in Germany in the 19th century were, from the outset, operated as agencies of the state. But the separate German principalities aimed at strong federal unity, and so the control of universities in a federal Germany came from the separate *Länder*, and there developed no single centre of power, as in the French model. There did, however, develop a view of the university as the embodiment of the national mind, and this was combined with the ideal of a university as primarily a research institute. These two seminal ideas soon influenced both European and American institutions of higher education.

Federalism and centralization in the German system

The relations between universities and the state are close in both the French and German models of higher education, but a sharp difference results from the status of two officials in the German university—the *Rektor* and the *Kurator*. The *Rektor*, the curricular and faculty chairman, is elected by secret ballot from among the titular professors and holds office for one year only. The *Kurator* is appointed by the state minister of education as a permanent officer to be the head of the university's administrative staff and to control its finances. The internal organization of universities has developed in relation to the nature of these two offices. Because of the annual change of the *Rektor*, the university senate—which includes not only the titular professors but also representatives of all grades of the academic staff and also student members elected by a student parliament—becomes the main initiator of policy.

A feature of staffing in German institutions of higher education is the method of recruiting most teachers from among the large groups of assistants who have found professors willing to recommend them to the faculty for a period of study beyond the first degree (which is a doctorate), leading to the postgraduate award of *Habilitation*, which can confer on its possessor the rank of *Privatdozent* (corresponding roughly to the English reader or American assistant or associate professor). The *Habilitation* award requires the student to present a research thesis to the faculty and to conduct a colloquium and lecture before the faculty board. The *Privatdozenten* are by far the largest group among university teachers, and titular professors are drawn from them. Titular professors holding chairs in established departments and "extraordinary professors" holding chairs in new or very specialized disciplines are civil servants for life. In recent years a new grade of teacher has been established—that of academic councillor, conferred upon *Privatdozenten* who, at the recommendation of the university, are appointed civil servants for life. Another group are the *Lektoren* or lecturers appointed to teach a special subject, some of whom come from outside the institutions of higher education.

Admission to German universities follows the same general plan as admission to the French, but in matters of curriculum, examinations, and degree awards there are marked differences, springing from the fact that in Germany both students and teachers are traditionally compulsive wanderers. It is the custom for students to attend two, three, or even four different universities in the course of their undergraduate studies; and the majority of professors at a particular university may have taught in four or five others. As a result, the personal loyalty to his university that marks a Harvard man in the United States or an Oxford man in England is almost absent in Germany. Able students go where their subject is best taught or where research is of repute. This inevitably

German scholastic wandering

means that schemes of study and examination are marked by a freedom unknown in France. Minimum requirements are laid down, after which students are free to choose the component parts and the lengths of their degree courses. There are no annual examinations, but, as a course proceeds, written papers are prepared, test essays are set, and the quality of these must be adequate before authorization to the final examinations is given. This movement and freedom in undergraduate studies means that universities have to respond to a nationwide competition, and the enfeebling effect of metropolitan institutions upon the more provincial is thus avoided.

The first degree award in Germany is called the doctorate, and afterward, as in France, students can sit for further examinations for awards, some of which are set by the university and some by the state.

One of the results of the tradition of drawing academic staff from the large group of candidates for the *Habilitation* is that postgraduate courses rarely have a formal organization; a period of service as an assistant to a professor, combined with research and postgraduate study, is seen as serving the same purpose.

The academic year in Germany is divided into two semesters, rather than three as in the English model, and for the early semesters of a degree course a large majority of students receive state grants that meet about two-thirds of the cost of fees and living expenses. For the final two semesters of the course, this grant is supplemented by an interest-free loan. The custom of student wandering has led to the provision of residential accommodation on a much wider scale than in France. Some of this takes the form of buildings on the university campus where 30 to 40 members of a student corporation live together; there are also larger halls of residence built by religious bodies or by the welfare service of a student parliament or by the university itself. Many halls of residence attempt to be more than simply hotels and develop educational, social, and cultural activities.

England. The pattern of higher education in England is different from that in either France or Germany mainly because until 1969, when the Open University was constituted by royal charter, the state had never founded a university; universities were responsible to no ministry; no government representatives sat on their governing bodies; and universities themselves appointed their own staff. Universities are also independent of any control by local education authorities that control elementary and secondary education in a region. English universities, despite the fact that they receive 90 percent of their capital and recurrent finance from the state, enjoy almost complete autonomy. In addition to rich endowments, about £100 million have been contributed by private individuals or corporations for the purchase of land, the erection of buildings, the endowment of chairs and scholarships, and the building of halls of residence.

Self-government and autonomy in the English system

In recent years, as the size of the state subvention has increased, an administrative invention called the University Grants Committee has been used to associate the Department of Education and Science with the work and expansion of universities while yet allowing them to retain all their ancient freedoms. The members of this committee are appointed by the government, but the majority are individuals actively engaged in university teaching or research and the minority are drawn from industry or nonuniversity research establishments. Universities prepare their budgets on a five-year basis, and once every five years the grants committee visits each university to discuss the present and future needs of the university with its council, senate, academic staff, administrative staff, and students. The committee then advises the government of the total grant needed by the universities, and by tradition the government accepts the advice of the committee without question. Once a block grant for a quinquennium has been given to a university, it is free to use it in any way it thinks best.

The existence of the University Grants Committee has placed upon the academic members of universities the burdens of their own administration, but it has also produced a firmer and more elaborate organization of self-government than in other models. This self-government takes one form in the ancient universities of Oxford and Cambridge and a different form in almost all the others. Oxford and Cambridge are federations of colleges, and the centre of teaching and research is in each of the separate colleges and only to a minor degree in the university itself. The university is the creature of the colleges and possesses only such powers as the colleges have delegated to it. The head of the university is a vice chancellor, who is elected from among the heads of colleges for a period of three years, but who nevertheless retains all his powers and duties as head of a college during his term of office. Colleges are autonomous, each governed by a group of fellows engaged in teaching or research, many of whom live in rooms in college. Fellows are elected by the college in most cases for life, and they are presided over by a master, whom they elect also for life. Fellows teach only the undergraduates of their own college, except when two or more colleges combine to provide teaching in subjects that draw few students. This college teaching is supplemented by the university, which appoints its own professors, readers, lecturers, and research fellows, and maintains libraries, laboratories, institutes, museums, and other facilities open to the students of all colleges.

In other universities in England the pattern is quite different. The main organs of self-government are the senate and council—the senate being an exclusively academic body and the council a mixed lay and academic body. The majority of the senate membership is composed of professors or nonprofessional heads of academic departments, together with a minority representation of the nonprofessorial staff. Under the chairmanship of a vice chancellor (the administrative and academic head of the university, who is appointed by the council for life), the senate is the central governing body of the university in all academic matters. The council exercises control in matters of finance and in matters in which university policy involves issues of regional or national importance; by tradition, it also confirms without amendment the academic decisions of senate. The academic members of the council are elected by the senate, and the lay members by an electorate composed of all the interests in the region concerned with higher education.

The conditions of entry into English institutions of higher education are more complicated than those in France or Germany. The school-leaving examination that secures the General Certificate of Education corresponding to the *baccalauréat* in France or the *Hochschulreife* in Germany is a subject examination, in which each subject may be passed separately either at "advanced" or at "ordinary" level. Possession of a General Certificate does not, as in France or Germany, automatically entitle a school leaver to university entrance, however. Although the minimum standards of entrance to universities are generally the possession of at least two advanced level passes with appropriate supporting passes at ordinary level, faculties and departments require higher qualifications than these, and entry is very competitive. University-entrance procedures have been simplified by the organization of a central admissions bureau, to which candidates for admission are able to give their choice of universities in an order of preference. Minimum standards of admission to colleges of technology or colleges of education are generally the possession of five ordinary level passes, but for these institutions the entry is also competitive, and higher standards than the minimum are necessary to secure a place.

Selective admission and the tutorial system

The selective admission to universities, combined with the close supervision of students through a tutorial system of teaching, makes it possible for most English undergraduates to complete a first degree course in a period shorter than the normal period in France and Germany. For 85 percent of students the length of course is three years.

Although becoming less so, courses in English universities are in general more highly specialized than those in France and Germany. About 80 percent of undergradu-

ates choose to follow an "honours" course in a single subject or, at most, two allied subjects. The remaining minority of students take "pass" courses that include the study of three, four, or five subjects. (Some pass courses may result in an honours degree, however, if the student achieves distinction in the final examination.) Most degree courses in England are examined at the end of the first year of studies and then not again until the "finals" examination at the conclusion of the course.

A unique feature of the English examination system is the use made of "external examiners." Tests are set and marked by the staff of a particular institution, and the results are passed on to a member or group of members of the staff of a different institution who have been appointed as external examiners for a fixed period of years. The external examiners review the assessments given, propose changes, and finally reach agreements with their colleagues in the examining institution on what the final assessments should be. This pragmatic device for securing some uniformity of degree standards among universities has been followed in colleges of technology and education and also in those countries that have borrowed from the English model.

Colleges of education in England are closer to universities than they are in most other countries because they are all now constituent colleges of Institutes of Education, administered and controlled by universities. These Institutes of Education are peculiarly English in their mode of operation. They supervise and coordinate the work of a group of colleges, conduct examinations, and make recommendations to the Minister of Education and Science for the award of "qualified teacher status" to those who are successful in their examinations. They also engage in research and provide extensive series of courses of inservice training for serving teachers both in the university and at regional centres.

Colleges of technology, architecture, commerce, music, and art provide both full-time and part-time courses, to meet professional and technical needs; and an increasing proportion of their students study for "external" degrees awarded by the University of London, for degrees and diplomas awarded by the Council for National Academic Awards, or for "higher certificates" awarded by national professional examining bodies.

In 1971 the Open University began a program of teaching by radio and television for students wishing to study while remaining at home or in employment. The teaching is supplemented by correspondence courses sent by post, by assistance given at a network of study centres by tutors and counsellors, and by required attendance at summer schools. In 1971 only foundation courses were taught, but faculties of arts, science, social sciences, mathematics, technology, and educational studies were to be established in succeeding years.

English inresidence tradition

In all institutions of higher education in England there is a high priority given to expenditure on halls of residence for students. At Oxford and Cambridge almost all students spend a period of residence in their college and another period in "recognized lodgings." At all other universities, halls of residence, generally four or five in number, provide study-bedrooms for students who are not living at home; and some universities also provide special accommodations for married students. In the halls of residence there are rooms for members of the academic staff, as well as common rooms, dining rooms, and facilities for social and athletic activities.

In England, students are extensively assisted from public funds. A standard grant adequate to cover the cost of fees, equipment, and living expenses is available to all students. The grant is reduced if parental income exceeds a given sum, but a minimum of £50 is available to all regardless of parents' income. More generous grants are available for postgraduates' studies, although, unlike undergraduate grants, these are limited in number.

United States. The Laws, Liberties, and Orders of Harvard College, drawn up in 1636, are a fairly faithful copy of the Elizabethan Statute for the English University of Cambridge. Nevertheless, the New England colleges, of which Harvard was simply the first, soon began to adapt old traditions to a new way of life. There were two early adaptations that influenced the whole pattern of university development: the first was the transfer of the government of a university from faculty members to a lay board of trustees; the second was the democratization of the curriculum.

Democratization in the American system

The first adaptation did not live on in its original form. Over the years there has been a gradual and sometimes painful redistribution of power between boards of trustees, faculty members, and university administrations. The democratization of the curriculum began in the 19th century when farmers believed that they needed less of the education suitable for a scholarly elite and more of a broad, liberal, and practical education for an expanding and changing rural population. Social pressures produced a new type of "land-grant college," in which agriculture and veterinary science were taught alongside some traditional subjects and in which there were also such subjects as home economics (or domestic science), journalism, and engineering. The land-grant colleges also developed another idea that has remained as a permanent feature of American higher education—the idea of the university as a service agency for the whole community. Hence, university teachers carried lectures, specimens, books, and demonstrations to the farms and homesteads within range; and university bureaus of welfare answered thousands of questions about everything from sanitation to the testing of milk. Today, American universities feel themselves under an obligation to develop a whole range of services for the general public, including television programs and highly organized home-study courses that may earn a person credits toward a degree.

At the present time, a high proportion of youth in America complete a full cycle of secondary school studies with sufficient high school work to their credit to admit them to a university. As a result there appears to have emerged a nationwide assumption that American children should enjoy at least two years of university education. This has led to an increasing provision of two years of initial undergraduate study at a "junior college" or "community college" rather than at a university, where a majority of students intend to complete four years of study for a degree and where substantial numbers go on for one to three years of postgraduate study in a "graduate school."

Universities that provide four-year degree courses are either private foundations receiving little state or federal assistance or state or city foundations depending heavily or almost completely on public financial support. Because of the freedom enjoyed by private foundations, the publicly supported also enjoy great freedom from public control; and their boards of trustees, on which there is generally a minority of representatives from the state or city, carry large responsibilities. In both private and public schools, it is the board of trustees that appoints the university president, and it is to him that they delegate large powers. He is the main agent in securing funds for a private institution or in securing appropriations in a public one. He is responsible for maintaining good relations between the university and leaders in commerce, administration, and industry and between the university and its alumni, who are generally better organized than alumni in other countries. Above all he is the head of a powerful administrative machine.

In Europe, academic standards do not vary much from university to university, but this is not the case in America, where there is also a much greater proliferation of courses than in European universities. The way to a first degree does not lie through the passing of a single "finals" examination as in England, but through the accumulation of course "credits" or hours of classroom study. The quality of work done in each classroom course is assessed periodically and a student's continuous record of credits and grades is recorded in a course transcript. When a student's progress is finally assessed, his transcript is scrutinized for a possible degree award.

Variety in the American curricula

During the first two years of a student's studies, either in a junior college or a university, three-quarters of his studies generally will be made up of prescribed courses

in the humanities, the natural sciences, the social sciences, and the fine arts. The remaining quarter will be "elective" courses selected by the student himself from a very wide range of options. In the third and fourth years, a student will specialize in one or perhaps two subject fields, with the equivalent of a full year of study in a major field (and sometimes half a year in a minor field) and a full year (or half a year) in a number of supporting studies.

Postgraduate students who wish to pursue either advanced studies or research, or both, do so in one of the many graduate schools. At these schools some students are engaged in working for "master" or "doctor" degrees, while others, who already have their doctorates, will be engaged in their own research or in contract research.

University schools or departments of education have made contributions to higher education that are more notable than those made by similar institutions elsewhere. Most of these schools also have graduate schools.

Financial aid to students is not as uniform as it is in England or Germany, but the number of scholarships sponsored by private individuals, foundations, religious bodies, and industry is increasing rapidly. The federal government grants a large number of scholarships to the more able students, particularly in the fields of science, engineering, and health. Student loans are available, with little or no interest and liberal repayment privileges. Many students pay their fees with earnings gained from working in college cafeterias or student centres or working as student assistants in a library or laboratory.

Most American universities provide housing in dormitories, in houses provided by student societies, or in officially approved off-campus housing.

Soviet Union. No university arose in Russia until 1755, when the empress Elizabeth set up the University of Moscow. Vilna, Kharkov, Karan, and St. Petersburg followed in the next half century. From the outset, all were developed as agencies of the state with no memory of a medieval life as autonomous institutions devoted to the search for truth. German influences, however, brought a growing number of Russian institutions into the main stream of European higher education, until the abrupt reversals of policy that followed in the wake of the Revolution of 1917.

A striking feature of higher education in all the republics of the U.S.S.R. today is the high proportion, (nearly 60 percent) of students who are reading for degrees by part-time study while still engaged in productive enterprise. Such students follow very carefully prepared correspondence courses, are aided by radio broadcasts and television, and meet regularly at centres of study scattered all over the U.S.S.R. Worker-students, they are given leave to attend the study centre, to attend for examinations, and to carry out laboratory work. It is a measure of the efficiency of these part-time studies that the majority of such students require only one more year of study for a degree than do students working in institutions for full-time study. The close relation between the economic needs of the people and their higher education is seen not simply in the system of part-time study; it is also seen in the strong encouragement given to all aspirants for university education to complete two years of productive work before beginning any full-time studies in an institution of higher education.

Institutions of higher education can be grouped under three headings: universities, institutes, and polytechnical institutes. Universities are concerned with the teaching of the humanities and the pure sciences, although in the smaller republics, universities often add the study of agriculture, technology, and medicine. Numerically, the largest group is comprised of the institutes, which train specialists in some single field, such as agriculture, economics, law, medicine, education, technology, art, drama, or music. The polytechnics offer the same subjects as the institutes but with the difference that several studies will be grouped together on a broader scientific base.

Higher education is financed and controlled by the Ministry of Higher and Specialized Secondary Education, and its policy is formulated in association with the State Institute of Planning for Higher Education. The large majority of the institutions of higher education have been set up by the government, and a minority by trade unions, cooperatives, and the Communist Party.

Centralization in the Soviet system

The head of each institution is a rector, appointed by the state for life. He is assisted by three prorectors responsible respectively for teaching, research, and administration. The rector is chairman of an academic board composed of the prorectors, the faculty deans, heads of departments, representatives of the academic staff elected by faculty boards, representatives of public bodies, and specialists appointed by economic or cultural organizations whose interests are involved with the education of specialists in institutions of higher education.

All candidates wishing to enroll in an institution must sit for a competitive examination. Industrial firms, collective farms, and state enterprises are entitled to send forward their best workers for admission; and the workers most successful in the entrance examination are entitled to a financial grant that is supplementary to the grants available to all entrants. In granting admission, the state gives a degree of preference to these worker candidates and to others who have completed two years of productive work after leaving school.

The duration of studies for a first degree varies from four to six years, the average being five years. The curriculum consists of compulsory, alternative, and optional subjects. A student chooses his specialist subject, and the compulsory courses will be in the basic and theoretical areas of that subject. To these are added alternative courses consisting of related disciplines or narrower aspects of the major specialty. To these two divisions a student must add courses chosen from a wide range of options, in which the emphasis is on recent scientific and technological research.

Examinations are the special responsibility of a state examinations commission, and the examinations at the end of a course include those in two or three basic disciplines related to a chosen specialty, one of which must be a social science. Candidates for a degree must also defend a thesis embodying the results of individual research or group research or a practical project. The scientific societies that exist in all institutions organize student research, which, under the guidance of professors or senior research workers, is regarded as an important aspect of undergraduate training.

At the conclusion of a first degree course, all students receive the same diploma—an award conferring identical rights as a specialist—but students with the best results are awarded a "distinction." Universities, institutes, and state research establishments all organize graduate schools with three-year courses for full-time students and four-year courses for part-time students. Postgraduate studies are concluded by a set of examinations for the degree of *kandidat nauk*, which include three written examinations and the defense of an original research thesis. The highest degree, the doctorate, is awarded for a thesis that records the solution to a major scientific problem on original lines.

Virtually all students are supported by government grants, a special feature of which is that the amount of grant is related to progress in studies. Students who achieve a "distinction" standard in their work receive a bonus award of as much as 25 percent of the basic grant. Students who are unable to live at home find accommodation in hostels at costs that they are able to meet from their grants.

OVERSEAS INFLUENCE OF THE MAJOR MODELS

The French model overseas. The various avenues of influence offered by a well-established model of higher education can be seen in the example of Tunisia. Even before the French went to Tunis, Muslim missionaries had established a religious university at El-Zitouna, which has persisted to modern times (its programs of philosophy, theology, law, language, and literature were recognized and incorporated as a Faculty of Theology and Religious Science in the modern University of Tunis). The agricultural and vinicultural potential of Tuni-

sia attracted French settlers, and it was for their sons and the able sons of natives that a French colonial government set up the École Coloniale d'Agriculture in 1898. Later in the colonial period, an Institut des Hautes Études was founded in Tunis to provide the early years of studies required by the University of Paris. Just prior to the grant of political independence this institute had grown to the point of providing full degree courses for a limited student body in science, letters, and law. Finally, in order to strengthen the force of French administrators and teachers, the government in Paris set up an École Nationale d'Administration, École Normale Supérieure, and Institut Bourguiba des Langues Vivantes in Tunis. At first, and for a number of years, all these institutions prepared students for the *licences* of the University of Paris, but by 1958 a new *licence èn lettres arabes tunisiennes* had been established, and by 1960 all existing institutions had been combined in a single University of Tunis awarding its own degrees. Even so, today after years of independence, higher education in Tunisia follows the French pattern very faithfully.

French missionary influences

The number of *instituts des hautes études* or even universities on the French model that had been established overseas by the middle of the 19th century was large, partly because even in such ex-colonial territories as Quebec, French institutions had survived, and partly because in the early years of the century the religious orders were restricted in France but were able to establish strong educational movements in Indochina, China, Japan, the islands of the Pacific, and Latin America. At that time, for example, 4,000 members of a single teaching order, the Christian Brothers, went to Latin America and with the Jesuits influenced first secondary and then higher education. The Federal University of Rio de Janeiro, when it was created out of a union of schools of law and medicine and a large polytechnic, emerged as an institution of French design. Later still, as the University of Brazil, it was taken as the model for all the universities of Brazil. In the case of Japan, in 1872, by a stroke of the imperial writing brush, all Japanese universities were remodelled on the pattern of the University of Paris. (In the following decade, though, Japan's Germanophile minister of education tried to incorporate German organizational and pedagogical patterns.) French influence remains strong in the former colonial territories of France, because, when such territories were part of France, their institutions were governed by French law, which included a detailed decree governing every aspect of higher education. During this period the academic staffs of overseas institutions were part of the cadre of French universities and were eligible for all their privileges—each faculty of every institution having its own administrative autonomy within the overriding governance of the Ministry of Education in Paris.

Germanic educational hegemony in the 19th century

The German model overseas. As French cultural influences declined in Europe, German influences grew strong. In the second half of the 19th century, Prussia, in particular, produced educational philosophers whose works were widely read. Even earlier, the German tradition of the wandering scholar had taken German ideas northward into Scandinavia, where their influence has remained strong ever since, and eastward up the Baltic coast into Russia. The Russian University of Dorpat (Tartu), for example, founded in 1802, used German as the language of teaching for most of the 19th century, and most of its professors were either Germans or had been educated in German universities.

In the second half of the 19th century emigrants from Germany to America, and American students returning from study in Germany, carried with them German ideas of higher education, particularly the emphasis on research and postgraduate studies. These indeed were the most important educational influences of that era. The Ph.D. degree, the first degree in a German university, from that time forward became the criterion of ability for the serious university student in America, and in the 20th century the popularity of this degree has influenced even countries that in the 19th century were not greatly influenced by German thought.

The English model overseas. The large groups of migrants from the British Isles who settled in Canada, Australia, New Zealand, and South Africa established universities almost as soon as they had solved their pressing economic problems. In Canada, colleges on the English model received royal charters as early as 1802 in Nova Scotia and 1828 in New Brunswick. In 1849 in Australia, a select committee appointed to report on the best means of instituting a university advised that the University of London should be taken as the model to be followed. When the University of Sydney was founded as the first of the Australian universities and the University of Otago as the first university of New Zealand, the English model was copied very closely.

In the 19th century and the first half of the 20th century, wherever the English sent military and trade missions, colonial administrators fostered the development of universities on the English model. The first plans for setting up universities in India grew out of the work of the secretary to the Bengal Council of Education in 1842. As in Australia, the University of London was taken to be the appropriate model to copy. As a mainly examining university, testing the standards of external students or affiliated colleges and free from religious bias, it seemed best suited to the needs of a subcontinent of wide distances and several creeds. In spite of this early start, 15 years of persuasion were required before the government in Westminster would agree to the incorporation of three universities in Calcutta, Bombay, and Madras. From India's point of view these universities and those that followed proved to suffer from the disadvantage that they were designed to implement two aims of the colonial administration, neither of which was proper for a university. The first of these was to transmit an alien culture (namely, English), and the second was to provide a way of measuring eligibility for government employment. It was not until political independence had been achieved and Indian graduates had taken over the control of higher education that Indian institutions began to be more responsive to Indian needs. Fortunately, the mistakes made in India in the 19th century were not repeated in Africa, the Pacific, Malaya, and the Near and Far East, where the story of university development as a cooperative enterprise is a happier one.

Anglicization of colonial schools

In the 20th century the University of London continued to play an important and growing role in the development of higher education overseas, in nurturing potential institutions toward the goal of complete independence. It did so because by a statute of 1858 it was authorized to examine for degrees any students who presented themselves, regardless of how or where they had studied, and to affiliate suitable institutions as colleges of the university with privileges similar to those afforded to its associated group of colleges in England. Over the years, the visits of external examiners overseas, the interchange of academic staff, and the award of scholarships to enable overseas students to study in England have all strengthened the influence of the English model overseas. These links have remained even as, one after the other, the territories in question have secured political independence. And they are kept strong today chiefly through the work of a body called the Inter-University Council for Higher Education Overseas, which is composed mainly of the vice chancellors of English universities. Cohesion and interchange is similarly promoted among the countries of the British Commonwealth by the Association of Universities of the Commonwealth.

The American model overseas. The United States, like France and England, has had charge of the development of colonial territories and has thus influenced their institutions of higher education. The story of this process is not, in principal, different in character from the similar story of change in French and English institutions overseas. To this colonial story must be added that of the influence of American missionaries who, in the 19th century, often went deliberately to territories in the Near and Far East, where they would not be in competition with French or English educational missions. To North Africa, Lebanon, Iraq, the Middle East, and above all

American missionary influences

to China, men and money for the development of education were sent in large amounts. The American University of Beirut and the medical school in Peking were typical examples of energetic developments of this kind. When Americans went to the Philippines, they found there several universities that had been built in the 17th century by the Spanish; today all Philippine universities and colleges broadly follow the American pattern. Military or economic intervention in such countries as Japan and Formosa led to the modification of indigenous institutions of higher education in directions that brought them closer to the American pattern. More recently in Africa, joint Anglo-American advisory missions or American missions alone have influenced higher education in Nigeria and Zambia.

The Soviet pattern abroad. All countries that have adopted a political system based on Marxist ideas have looked to the U.S.S.R. when seeking inspiration for the development of their institutions of higher education, and this applies particularly to the group of countries that lie between western Europe and the U.S.S.R. To this influence must be added the influence of the many specialist and advisory groups invited abroad from the U.S.S.R. for their higher education. Since 1960 three organizations have been particularly concerned with fostering closer relations between the U.S.S.R. and other countries in the field of higher education: the Soviet Committee of Solidarity, the Union of Soviet Societies for Friendship and Cultural Relations with Foreign Countries, and the large Patrice Lumumba People's Friendship University for foreigners in Moscow.

Organized Soviet cultural relations

Mixed influences. In many parts of the world, where institutions of higher education are of relatively recent growth, it is possible to trace the influence of several models of higher education. When a second university was founded in Nigeria, for example, it did not follow the English pattern of the University of Lagos but borrowed much more from the ideas of the American land-grant colleges. New universities in Zambia and Malawi have actually been planned by joint Anglo-American teams drawing freely upon their knowledge of two models of higher education. The developing countries could, in fact, learn much from multiple models: the English and French commitment to high standards of scholarship is needed wherever standards are in danger of erosion; the German emphasis on research is needed in situations in which educational miming is too easy; American flexibility and social relevance could be vital to countries that need more middle-level than high-level specialists; and Soviet methods of planning and part-time study are particularly relevant where financial resources are limited.

In contrast to the broad influence of several models today, there is sometimes a more direct influence as a result of the link between a single institution in one country and a single institution in another. There are many examples of this twinning in the modern world, such as the universities of Rabat and Bordeaux, of Rhodesia and Birmingham, and of Cornell and Djakarta. In this work, the influence may be stronger because it is based on personal links.

II. Organization of higher education

CURRICULUM IN HIGHER EDUCATION

Preparation for higher education. In most countries students rely on the secondary schools to prepare them for the next stage in their education, so that the pattern of higher education in a country is necessarily reflected in the organization and standards of its secondary education. In this matter there are great similarities between France and Germany. The *baccalauréat* and the *Hochschulreife*, which admit students to higher education, are both examinations that require a pass in nine or ten subjects at a high standard. The position is quite different in England, where a secondary school curriculum of increasing specialization has grown up in relation to university requirements for the "honours" degree. In the United States the position is closer to that of Europe since admission to an institution of higher education depends on the possession of about nine good high school credits. The advantages of the European and American patterns are that the first year of higher studies can be wide in scope, leaving the choice of a major subject of study until the student's inclinations and abilities have been disclosed. As against these advantages the English pattern avoids any considerable dropout of students at the end of the first year of higher education, and the wasteful repetition of some elements of secondary school work in the first year of higher studies is also avoided.

Subject patterns. The curricular patterns of higher education vary greatly from country to country, and in countries in which institutions have great autonomy they vary from institution to institution. The greatest contrast is to be seen between the array of optional subjects open to students of a junior college in America and the single "honours" subject in an English university. Between these two extremes there is great variety, and the situation in most countries is also one of great change and experimentation. Only in the traditional professional studies (where there is a need to relate the curriculum to a single vocational purpose) is there reasonable stability, although even in medical schools, for example, revolutionary changes are being tested at such institutions as Northwestern University in the United States and the international medical school on the Greek island of Kos. Because the present period is one of experiment, change is also accompanied by the desire for stability in the production of structured courses and for the return of unity into the untidy proliferation of subjects to which modern research has given birth.

Traditional departmentalization

Despite the pragmatic means taken in a few countries to bring coherence into the curriculum, the calendars of most universities still show subject disciplines organized as departments, in which new courses have been added to old mainly by a process of accretion. Ancient languages and their literature are still there, and to them have been added modern languages and their literatures. Philosophy remains from the distant past, and history from the 18th century. To these basic "humanist" studies others such as geography, music, fine arts, and architecture have been added. A new group of disciplines called the social sciences reflect the interest of scholars of this century in the study of society. They include anthropology, sociology, economics, and psychology. The older professional studies of law, medicine, pharmacy, and theology remain and to these have been added, many new ones, such as agriculture, veterinary science, and commerce. The older sciences of physics, chemistry, botany, zoology, and geology have been so enlarged by research that it has been convenient to break them up into smaller units like nuclear physics or organic chemistry, physical chemistry or geological spectroscopy. And perhaps the largest proliferation of courses has taken place in the rapidly growing areas of applied science and technology. Much thought is therefore being given in every country to the problem of combining depth of study with the need for coherence in the curriculum.

Teaching methods. The problems created by rapid advances in knowledge have led not only to structural reforms of the curriculum but also to new methods of teaching that emphasize principles rather than factual knowledge, and conceptual thought rather than mechanical skills.

Lectures, which still have their old merits in the teaching of large groups, are being supported or even replaced by seminars and tutorials. The seminar is generally a group of no more than 20 students meeting relatively informally under the chairmanship of a teacher to discuss a prescribed text or a paper presented by a student. In the seminar it is easy for a teacher to detect the difficulties of some students, and there is an impact of mind on mind that it is both remedial and stimulating. The tutorial is a meeting of one to six students, frequently based on reading or writing assigned by the tutor.

Audio-visual aids

Audiovisual aids are now widely used in lectures, seminars, tutorials, and small working groups involved in practical activities. Closed-circuit television may be the most flexible of such aids. In some large institutions this enables a lecture or demonstration to be made available

simultaneously to several different groups of students meeting in different places. The production of relatively inexpensive video-type recordings has made it possible to store illustrated lectures and demonstrations for future use. Some institutions not only have closed-circuit television equipment but also operate open-circuit systems to bring university teaching to groups some distance away, or to students following part-time courses of study at home. Open-circuit television can be combined with well-tried methods of teaching by correspondence course; it is already used in this way in the U.S. and the U.S.S.R. and in the recently organized Open University of Great Britain.

Examinations. In many countries examinations in higher education are given at the end of a period of study and determine what kind of award or degree that the student should receive. They also act, however, as an incentive to work, particularly if they take place from time to time during the course of studies rather than only at its conclusion. In some countries the examination at the end of the first year of studies is largely a selective one, to determine those fitted to proceed to a further period of study of two or four years, but in others it is used to determine the kind of specialization that will be best for succeeding years. England is typical of countries in which the final examination at the end of the course provides the main evidence for a degree award; the United States is typical of those in which the final examination carries much less weight and the main emphasis is on continuous assessment.

In professional schools it is almost universal practice for students to sit for examinations as and when sections of the course are successively completed. In science and the applied sciences, practical and laboratory exercises are used widely for examination purposes. A thesis and the defense of a thesis, which to some degree embodies original work or participation in research, form an essential part of the examination process for a first degree in Germany and Russia. The only generalization that can be made about examinations is that there is a general movement toward continuous assessment.

SOCIAL AND ADMINISTRATIVE PATTERNS OF HIGHER EDUCATION

Relations with governments. Everywhere in the world the cost of higher education has increasingly been met from governmental sources. When governments supply funds they must hold the recipients to a standard of public accountability; no government can fail to be interested in the degree to which its educational institutions supply it with the high-level manpower it needs; and some feel that their control must be absolute. If universities are to retain their freedoms, they must pursue them within a framework that brings a number of different and sometimes conflicting principles into the most fruitful balance.

Scholarly responsibilities of higher education

A measure of critical dissent emanating from universities can help to keep national institutions flexible and growing, but if this reaches the point at which university discipline or social order is threatened the fruitful balance will have been broken. The pursuit of truth is usually held to require a certain detachment from immediate political and social problems; yet if institutions are not deeply involved with the life of the region and the nation, they will fail to produce the well-trained talent that both need. Institutions of higher education are involved in the transmission of a cultural heritage, or perhaps in the revival of a failing national culture, and yet they are drawn by other loyalties into an international community of scholarship transcending national and regional differences. If a balance is not held, nationalism easily deteriorates from a desirable dynamic of political unity into the isolation of group hatred. By the same token, when a university teacher uses his position as a base from which to exert pressures toward purely political objectives, or when a government official uses his power to prevent a university from achieving its intrinsic aims, the desirable framework of balance is weakened.

Internal Relations. The charter granted in 1200 to the University of Paris secured for it a large measure of autonomy and the basis of a faculty organization of self-government, and this faculty organization has persisted almost unchanged in European universities until the present century—except curiously enough, at the University of Paris itself. In this type of organization, the teachers in a group of related disciplines meet regularly to organize their business under an elected dean. Deans and all senior teachers in all disciplines meet as a senate to regulate university business. In many universities, the head of the faculty of arts was at first appointed to be the chairman of the senate as well as the rector or academic head of the university. Later the senate more often elected its own rector, or he came to be appointed by an external authority.

Lay influence in academia

A modification of the faculty pattern of internal organization occurred as universities became increasingly involved in public affairs. At first a university chancellor was appointed by the authorities of church or state. With the growth of representative government the universities came increasingly to elect an officer called a vice chancellor or rector, and he came in time to be both the academic and administrative head of the university. As the vice chancellor took over the power and duties of his chancellor, the latter became the chairman of a mixed lay and academic body, generally called the council, which has remained as a most useful link between the activities of a university and the social, political, and economic life by which it is surrounded.

This European model of organization has undergone further modifications elsewhere. In the American approach, the president of a university combines some of the functions of a chancellor and a vice chancellor in the European model. His administrative role is stronger than that of a vice chancellor and his board of control (which approximates to the European council) has greater power over the appointment, dismissal, and conditions of service of university staff than is the case in Europe, where such matters are dealt with either by the university senate or by the officers of a government ministry.

In countries where institutions have been influenced by the Soviet model of higher education the modifications are more pervasive. Institutions of higher education are closely linked with a ministry of higher education and planning, and this gives a more hierarchical structure to their internal organization. Such a structure might easily develop some of the defects of bureaucracy were it not for the fact that individual institutions are increasingly seen as socialist collectivities with intrinsic traditions and objectives that need to be fostered and strengthened by external authorities.

Student initiative

The great expansion of numbers in higher education, coming at a time of acute housing shortage, has led students to organize in support of their welfare needs. In France, for example, nearly all students belong to the National Union of Students of France, which assists students' societies and presses their claims and needs upon all who are likely to listen and help. The Centre Nationale des Oeuvres en faveur de la Jeunesse Scolaire et Universitaire operates low-cost restaurants for students, gives assistance in finding lodgings, and tries to meet other welfare needs.

In West Germany the general movement of students from one institution to another has made the building of halls of residence one of the priority fields for the expenditure of public funds. The ultimate goal is to provide residential accommodation for about half of the student body at all institutes. Most halls of residence are maintained by students' welfare organizations, which also administer grants and loans, operate student restaurants, and provide health and counselling services and vocational guidance. They receive considerable government financial support.

In England there is a National Students Union resembling the French one. In addition, each institution has its own students union; these have become particularly powerful agencies for the furtherance of social life and welfare.

In the United States the concentration of university buildings facilitates the development of a vigorous stu-

dent's social life. A large campus may have student societies and organizations by the hundred, as well as student advisory and governing councils. A peculiarly American feature is the provision of many grants-in-aid to students willing to perform duties about the campus—serving as student assistants in libraries, laboratories, or administrative offices, or working in cafeterias and student centres.

In the U.S.S.R., participation in a wide variety of cultural activities in clubs and hostels is regarded as an integral part of higher education. A particularly Soviet characteristic is the degree to which famous writers, poets, scientists, actors, musicians, and artists actively direct these student activities. There is much emphasis upon the positive development of health, and all students are required to attend classes in physical education.

In 1968 a wave of student protest arose in most countries of the world. Its strongest manifestations were in France, Japan, and the United States, where large-scale clashes with the police took place. One of a number of student demands was for representation on the self-governing bodies of the universities. Student protestors were also critical of the content of courses of study, methods of teaching, examinations, and the ways in which subjects were grouped into courses; but many demonstrations had to do with broader political and national issues, involving armaments or wars or minority rights. In many countries some degree of representation has since been given to students, although the prevailing view is that in academic situations, in which individuals meet as teacher and learner, superior authority should remain with the teacher.

RESEARCH AND POSTGRADUATE STUDIES

Research and teaching. Teaching rises to a high level when it is shot through with the thread of discovery, and in institutions of higher education teachers are most successful when then can convey to their students something of the excitement that has come to them personally as they have worked at the frontiers of knowledge. But not all university teachers are equally good at teaching and research. Thus most institutions maintain some posts wholly for teaching or for research, though these are generally in a small minority of appointments.

Role of research in higher education

In highly industrialized countries most scientific and technological research is now carried on outside of the universities. Consequently there is an increasing degree of cooperation between governmental or industrial research bodies and the institutions of higher education; there are exchanges of students and staff and even common research projects. Sometimes a distinction is drawn between fundamental research and applied research, often with the implication that the main concern of teaching institutions is with fundamental research. But modern scientific work cannot be divided that way. Very little fundamental research is without practical application or social relevance, and often applied research forces its workers back into areas of fundamental research.

Much research is nowadays carried out by teams, sometimes large ones, in which the combined intelligence of a large body of workers is brought to bear on the solution of a problem. Along with this there is an increasing specialization of knowledge and skills. This situation has created a need for the wide and rapid dissemination of research plans and results, leading to a growth of coordinating bodies and their publications.

Postgraduate studies. Postgraduate schools in most countries (other than those in the French system) award a master's degree and a doctor's degree or their equivalent. In the shorter course leading to a master's degree the main element is acquisition of skills or knowledge at a more advanced level than required for a first degree. Work for the doctor's degree also involves participation in research and requires some account to be given of a piece of original research at its conclusion. The research frontier of most subjects advances so swiftly that only in two or three years of postgraduate study can a student be brought to the point at which he is capable of undertaking research himself. During these years he can continue to advance in knowledge and skill while undertaking a minor research project under guidance. Opportunities will also be opened to him by senior research workers who need the help of juniors in team research.

Not all students have the inventive gifts that make good researchers, nor need this be their aim in following a postgraduate course. As society grows more complex, many enterprises call for more specialized knowledge than can be acquired in a first degree course. Some students who proceed directly into employment return later for advanced study, and these now form an important element in postgraduate schools. Thus one finds, all over the world, postgraduate education provided in increasing measure to produce research workers and university teachers, to give refresher courses for older graduates, or to train those who require a greater degree of specialized knowledge than is given in undergraduate studies. Because postgraduate schools draw upon so many sources of recruitment and meet so many pressing needs, they are expanding in some countries at a rate faster than that of higher education in general.

Postgraduate schools always include among their students some who come from countries where higher education is only beginning to develop. Just as, in earlier years, these countries sent secondary school graduates to countries more advanced in the provision of higher education, so now they send graduates from their new universities for higher study abroad.

III. General trends of change

RECENT CHANGES

The world enrollment in higher education doubled during the 1950s. In those countries where a steadily rising standard of life may make possible an ultimate provision of higher studies for all who wish to follow them, growth is likely to continue. The more rapid growth of higher education in developing nations was expected to level off as the needs for trained manpower were increasingly met. At the same time there was an increase in unemployment among graduates. In 1950 unemployment was practically nil in nearly every country, but by 1970 the world percentage had risen to 10 percent, an average that concealed much higher figures in some of the developing nations. This figure did not include a rising degree of unemployment among graduates in such countries.

Differing national requirements

In many developing countries, particularly India and the Latin American countries, higher education has been oriented too much to the needs of the modern sector of the economy. It may be that until it is reoriented to the manpower needs of a mainly rural economy, and until that economy itself is transformed, higher education will not have a social function in such countries. The position is quite otherwise in countries where a balanced rural and industrial economy produces a steady rise in the national product. In these countries the continual emergence of new industries and the expansion of established enterprises call for new skills, more and more specialists, and for new and more extensive courses for graduates employed in industry.

A trend in higher education found everywhere is the steadily increasing number of women students. This has been particularly noticeable in the U.S.S.R., where between 1960 and 1970 the proportion of women in full-time and part-time education rose from 40 percent to 50 percent, and, in the nonscientific and nontechnological institutions, to as high as 80 percent. By comparison, statistics published by the United Arab Republic show that the percentage of women enrolled in institutions of higher education increased from 7 percent in 1950 to 14 percent in 1960. The increase in France over the same period was from 34 to 38 percent, a slower but still significant pace of advance. This trend must be expected to continue as the social, political, and economic disabilities under which women continue to suffer in many parts of the world are removed.

REGIONAL TRENDS OF CHANGE

North America. In spite of the already high proportion of North American youth who attend institutions

of higher education, enrollments in both Canada and the United States continue to rise year by year, and this trend has a compounding effect since all researches show that the educational attainments of parents influence the educational aspirations of their children. Not only are enrollments increasing but an increasing proportion of students now tend to go on to postgraduate studies. Overall, the institutional response has been the expansion of facilities in existing colleges and universities and the multiplication of newly established institutions of higher learning. In California, for example, all the existing branches of the state university in various cities are envisaging satellite campuses geographically and organically related to the branches.

The lack of a powerful central ministry responsible for higher education in either the United States or Canada has meant a diversity of academic standings has been difficult to avoid. There is now a trend for groups of institutions to develop coordinating organizations of various kinds, which are delegated powers to accredit institutions meeting agreed standards and which in different ways work to bring about more cooperation between institutions that previously had worked in isolation.

In Canada, two specific trends are caused by the demand for more specialized degree courses and for more postgraduate schools. In the past the reputation of neighbouring U.S. postgraduate schools was so high that there were always more Canadian graduates studying abroad than at home; this balance is now changing. There are also an increasing number of institutions organizing work-study programs in which a student alternates periods of study with periods of work in industry, government, or the professions.

Latin America. The main trends in Latin America reflect the prevailing desire to raise academic standards while at the same time relating courses of study and the choices of students to the economic development of the country and the region. A past imbalance between the overenrollment in courses in literary, legal, or sociological studies and the underenrollment in departments of science, technology, medicine, and agriculture has led to graduate unemployment. This picture is now changing and many institutions are making use of differential admission standards between departments in order to adjust the balance. This imbalance is also reflected in the shortage of university teachers in departments in which expansion is greatly to be desired. These shortages have often been met by the appointment of part-time teachers whose major employment and interests might be elsewhere than in the university.

Imbalance between humanistic and scientific enrollments

Western Europe. The institutions of higher education in Europe are engaged in the difficult process of transition from providing higher education for a selected elite to doing so for much larger numbers drawn from a wide spectrum of home backgrounds. As the economic and political ties between countries grow closer, there is a tendency to look more closely at different practices over the whole field of higher education and to seek for explanations of the degree of difference. This is beginning to lead to changes even of deeply rooted models like the English, French, and German, thus bringing them into a closer approximation of each other.

Increases in size and the pressure of student opinion are leading to a re-examination of historic forms of self-government and often to change. At the Sorbonne, for example, the senate and titular professors, which governed for so many centuries without change, has reformed its membership so that only 50 percent is now composed of titular professors, the other 50 percent being made up of students and junior teaching staff. In most institutions a democratization of committee procedures, even if less startling, is taking place.

Eastern Europe and the Soviet Union. There is an increasing trend in the countries of eastern Europe for separate countries to ratify bilateral cultural agreements with Western neighbours. These agreements make provision for joint educational conferences, in some cases for joint staff appointments, and for intervisiting by students and staff.

In the U.S.S.R. the effort to make higher education available to all who want it by 1980, is powering a major expansion movement. This has led to the steady development of facilities for students to continue in full-time employment, with periods of release for special study purposes. An increasingly sophisticated system of personal tuition has tended to improve the quality in this large sector of part-time higher education.

Re-emphases on work-study

Asia. The largest territory and the largest student population in Asia is that of the People's Republic of China, but because of the relative political isolation of that great land mass, development there has proceeded in unique ways. The only striking similarity is between the developments in the U.S.S.R. and China, despite their growing political antagonisms. The influence of the Soviet model on higher education in China has been profound and has now quite replaced the earlier work of foreign missionaries, other models, and influences coming across merely geographical barriers. As in the U.S.S.R., institutions have been developing into the three groups of universities, specialized institutes, and polytechnical universities. New universities and institutes have been founded in large numbers, but mainly in the coastal or near-coastal belt of the large cities. In Peking, for example, no less than 50 institutions of higher education have been set up. As in the U.S.S.R., nearly all these institutions promote correspondence and evening classes for students who wish to study for a degree while remaining in productive work. In addition, there are "spare time" universities as well as "work-study" universities on the American model.

All this development in China went on steadily until 1965, when political relations with the U.S.S.R. began to deteriorate. At the same time a "cultural revolution," with the Red Guard and students at its spearhead, began to disrupt all institutions of higher education. There followed a protracted period of violence and disorder in higher education in which thousands of lives were lost, the economy was disrupted, and education brought almost to a standstill. By 1968 the extremes of disorder had produced a reaction, and in July the army began to intervene to suppress the cultural revolution. The army was successful and by 1970 professors and teachers driven out by the young Red Guard were reinstated, and normal academic life was slowly resumed in institution after institution.

Across the Yellow Sea, in Japan, a period of rapid expansion in higher education has also been retarded by episodes of student violence, but the violence has not seriously held back the speed of progress, particularly in the field of technology education.

In the subcontinent of India and over the numerous and widely spread countries of Southeast Asia, the main concern has been to combine expansion with a process of decolonization in higher education. In all these countries the fundamental feature of higher education had been that it was imported from the West with ready-made value systems crystallized in institutions and techniques. Criteria for admission, curricula, teaching methods, and constitutional structure were better related to conditions in Western industrial nations than to the financially poor countries of Asia. Even late reports of visiting commissions recommended development along foreign lines. The Carr-Saunders Commission for Malaya and the Darwin Commission for Thailand recommended British practices, and the Allen Report recommended American practices for higher education in Indonesia. Now the trend is all the other way, and innovations are striking roots deep in native soil. One result of all this has been to destroy the image of a university as a place where students learn to pass examinations in a foreign language and make it instead, one of a place where attitudes are changed, values created, and national traditions made strong and relevant.

Nativism and nationalism

A second trend in all Asian countries arises from linguistic nationalism—that is, from the desire to make the medium of instruction in higher education a native and not a foreign language. Unfortunately, some new universities have tried to use a native language even though it

has led to such seeming absurdities as training Javanese chemists through the medium of Malay, although Malay is neither a language native to the Javanese nor a language with any technical vocabulary or technical literature. In some Asian institutions there is parallel teaching in a native and an international language. In others an international language has been selected (generally English) to be taught in the secondary schools so that university students will have acquired a sufficient reading ability (if not verbal ability) to avoid the need for an expensive translation service. This policy has been followed in Thailand with growing success. The Japanese have shown that it is possible to learn to read a European language very quickly without speaking it at all.

The emphasis upon a regional language does create formidable problems, but it has one advantage in that it may lead to the development of genuine regional research. Thus have Indian and Indonesian institutions conducted village surveys that have provided valuable information to their respective governments.

Africa. The trends of development in Africa differ considerably as one moves from countries north of the Sahara to countries of tropical Africa and then further south to the Republic of South Africa.

In the countries north of the Sahara political independence came relatively early so that the expansion of higher education that so largely determines development in European countries has also begun to affect the countries just south of the Mediterranean in the same way. These countries, like those of the subcontinent of India, have begun to deal with the problem of decolonization and are tackling the problem of the language of instruction in higher education relating higher education more closely to the nation's need of specialists, replacing foreign cultural aims by those of an indigenous culture, and replacing foreign academic staffs by graduates from their own universities.

In the countries of tropical Africa the most important stimulus to development came from a Conference of representatives from 31 African nations and 14 non-African nations (including both the U.S. and the U.S.S.R.), which was held in the Malagasy Republic in 1962. The Conference produced a detailed and comprehensive plan of development for higher education in Africa over a 20-year period. Expansion targets were proposed and the financial implications of the plan worked out by some of the best economists in the world.

Since 1962 tropical Africa has seen the development of new postgraduate schools, the setting up of regional centres for the training of laboratory technicians, the development of library interchange, and the standardization of degrees and diplomas. To carry such work forward, a new permanent body, the Association of African Universities, has been set up.

South of the Limpopo River, the Republic of South Africa pursues a political policy of "separate development" for different racial groups, which has led to a pattern of educational advance different from that of any other part of Africa. In the general expansion, separate, new, ethnic universities have been created for the Bantu and Coloured populations of the Republic. The effects of racial discrimination in higher education, like those of religious discrimination in earlier centuries or of political discrimination in the 20th century, can lead inevitably to a debasing of the academic currency. A nation's university degrees, like its money, must be acceptable in other nations, and racial, religious, or political discrimination inevitably leads to the loss of independent-minded teachers so that first the quality of its research, and then that of its teaching, declines. Institutions of higher education are unlike institutions in other sectors of education in their essential need to maintain bonds of loyalty not only with their country of origin but also with the international company of universities.

Necessity for racial, religious, and political tolerance

(B.F.)

High-Pressure Phenomena

High-pressure phenomena are those changes that occur in ordinary matter when subjected to pressures that may range from ten to millions of times greater than normal atmospheric pressure. Under such conditions, matter is compressed, and chemical and physical properties are altered; the material may even become unrecognizable. Laboratory studies conducted at these pressures may also involve temperatures that range from near absolute zero (−273° C [0° K]) to far beyond the melting point of any element under normal conditions.

Definitions. Pressure is measured as a force per unit area. The unit of pressure is the bar, which is approxi-

mately equal to the sea-level pressure of the atmosphere on an average day. More precisely, it is equivalent to 0.98692 atmosphere (standard). Specifically, one bar equals 1×10^6 dynes per square centimetre (one dyne is the force that gives a mass of one gram an acceleration of one centimetre per second). It is also equal to 1.01972×10^3 grams per square centimetre (14.504 pounds per square inch). The range of pressure in nature is extreme: at the deepest ocean depths (about 11 kilometres [seven miles]), the pressure is about one kilobar (1,000 bars); at the base of the earth's crust (about 40 kilometres' [25 miles'] depth), the pressure is approximately ten kilobars; at the base of the earth's mantle (about 2,900 kilometres [1,800 miles]), the pressure is about 1.3 megabars (1,300,000 bars); and at the earth's centre, it is at 3.4 megabars. Pressures at the centre of Saturn and Jupiter are estimated to be 20 and 100 megabars, respectively, and those of some stellar interiors are thought to be 10^{10} bars or greater. While it is exceedingly difficult to understand those laws of physics and chemistry that apply to material properties over the wide range of pressure that occurs in the universe, present technology does make it possible to study materials at all pressures found in the earth. A few studies using explosive techniques have even attained pressures greater than those at the centre of Saturn.

Range of pressures

History. The amount of pressure necessary to create similar effects on different materials is highly dependent on the materials involved. Whereas a pressure change of 0.2 bar on a gas, for example, causes the volume of the gas to change by 20 percent, a similar volume change requires 10,000 bars in a liquid and 200,000 bars in a solid. Hence the selection of materials and effects to be studied has been strongly influenced by the historical development of high-pressure apparatus.

Before the 20th century, when research was concerned primarily with the effects of pressure on gases and liquids because of apparatus limitations, considerable work was done at pressures of three kilobars and over a temperature range of 200° C. Typical of such investigations were those concerned with the volume behaviour of liquids and with the existence of gas–liquid critical points (the combination of temperature and pressure at which the specific volumes of a gas and liquid become identical, thus forming one phase). At the critical point the temperature and pressure are such that the transition from a gas to a liquid takes place with zero change in volume and energy. This transition involves two factors: (1) the critical temperature, which is the highest temperature at which a gas can be liquefied by pressure; and (2) the critical pressure, which is the pressure of a gas at its critical point. The important question of a critical point between liquid and solid matter was also raised during the 19th century, but the pressures available for research at that time were far too small to settle the matter.

Modern approach to research

Modern high-pressure research was made possible primarily by the work of Percy Williams Bridgman, a physicist in the United States who received the Nobel Prize in 1946 for his investigation of high-pressure phenomena. Except for those techniques that involve the use of explosives, all current high-pressure apparatus is derived from equipment that Bridgman designed and used (see below *Principles of apparatus design*).

PHYSICAL AND CHEMICAL EFFECTS OF HIGH PRESSURE

In order to describe high-pressure phenomena over extremely wide ranges of variables, it is necessary to use mathematical statements that relate small increments of the various changes taking place simultaneously during the overall transformation of conditions and reveal graphically what is occurring.

On typical single-component systems. The three classical phases, or states, of matter consisting of atoms and molecules are solid, liquid, and gas. (There is a fourth, plasma, consisting of atoms stripped of their electrons, and several others are recognized.) Most phase changes are familiar phenomena: a gas condensing into a liquid, a liquid evaporating to a gas, a solid melting to a liquid, and a liquid freezing into a solid. Modern high-pressure research in phase changes, particularly the work of Bridgman, has revealed that a myriad of transformations occur as a result of atomic rearrangements, many of which involve gross changes in the physical properties of a substance.

Gibbs free energy and high pressure. Two or more phases can exist in equilibrium, a balanced coexistence that is governed by thermodynamic (heat) relationships. These relationships are formulated into a concept called Gibbs free energy, which is the difference between the heat content of a substance (called enthalpy) and the product of its temperature and entropy. (Entropy, the energy of disorder, is a measure of the unavailable energy in a thermodynamic system; if left to itself, the entropy of any closed system increases, while the available energy decreases.) The equation for this thermodynamic relationship is written in symbols: $G = H - TS$, in which G is the Gibbs free energy of the phases in equilibrium, H is the enthalpy, T is the absolute temperature, and S is the entropy of the phase mixture. As the equation indicates, at any constant pressure and temperature, when the phases are in equilibrium, the mixture has the lowest Gibbs free energy, relative to the energy of the mixture at any other configuration.

By differentiating this equation it may be seen that there is a simple relationship between Gibbs free energy and the volume and entropy of the phase. The partial derivative of the free energy with respect to the pressure (P), the temperature (T) being held constant, is equal to the volume (V). This is written $(\partial G/\partial P)_T = V$. The partial derivative of the free energy with respect to the temperature (T)—the pressure (P) being held constant—is equal to minus the entropy (S). It is written $(\partial G/\partial T)_P = -S$.

If entropy and volume are known as a function of the pressure and temperature for two phases, these equations may be integrated and an equilibrium-phase boundary thus calculated, separating the regions in P–T space (a phase plot of pressure versus temperature) in which the two differing states are stable. Stability does not imply that a phase transformation will take place, however; for example, with care, most liquids may be preserved as liquids for lengthy periods of time below their freezing points, at temperatures where the solid is the normal stable phase. Such supercooling (or any other such sluggish transformation) is known as metastable behaviour, marked by only a slight margin of stability for that phase, because any disturbance will bring about a transformation to the stable phase. A supercooled liquid, for example, becomes solid rapidly if a minute crystal is dropped into it.

Supercooling

Effects on melting. Melting phenomena are best discussed with reference to the above equations. Most melting curves have been studied only up to less than 100 kilobars by static apparatus; melting has been detected, however, at higher pressures in some dynamic shock-wave experiments on copper and on lead. The tangent to the melting curve that results when pressure is plotted against temperature, $\partial P/\partial T$, is given by the ratio of the change in entropy (ΔS) and the change in volume (ΔV) between solid and liquid, or $\partial P/\partial T = \Delta S/\Delta V$. Thermodynamics shows that the liquid, being the high-temperature phase, has the greater entropy. Usually, because the liquid has the larger volume, both the change in entropy and the change in volume are positive. This is not true for water, bismuth, and a few other substances.

In most cases, pressure raises the melting point, and, most frequently, the liquid is more compressible. Therefore, as pressure is increased, the change in volume decreases, and the rate of temperature increase of the melting curve is slowed. In a few cases, however, such as cesium and potassium nitrates, a maximum temperature is reached at which the liquid becomes denser than the solid. Thereupon, any further application of pressure decreases the melting point. If a transition in crystal structure takes place, thereby transforming one type of solid into another (*i.e.*, if there is a solid–solid transition in a solid), then a triple point occurs on the melting curve at which solid (1), solid (2), and liquid are all in equilibrium at one pressure and temperature. After continuing past

this break in the melting curve, the process may be repeated.

Both cesium and potassium nitrates actually have two maximums in their melting curves before a third solid phase intervenes. To illustrate further the occasional complex behaviour of matter, the melting temperature of cesium decreases with pressure until a minimum is reached, after which the melting temperature increases. In this case, even though the solid is less dense than the liquid, it has a lower initial compressibility, hence the volume of solid and liquid approach each other and become equal at the minimum point.

Effects on polymorphism. Polymorphism is the phenomenon in which a substance can exist in more than one form. Diamond and graphite, which are radically different forms of carbon, and calcite and aragonite, two forms of calcium carbonate ($CaCO_3$), are examples of polymorphic substances. Although this aspect of solids had been known for over 200 years, it was not until Bridgman extended the range of pressure studies that it was realized how universal this behaviour of matter is. In polymorphic substances, a thermodynamic rule states that for two-phase equilibrium, at constant temperature, the high-pressure phase must be denser. In a crystalline solid, one obvious way of obtaining a denser phase without chemical change is to increase its coordination number (the number of neighbour atoms surrounding a given atom). The common form of iron (alpha iron, or α-iron), for example, is a body-centred cubic crystal at room temperature; and, hence, it is eight coordinated (each atom has eight atoms around it positioned as though at the eight corners of a cube). One might anticipate, therefore, that, at some unspecified elevated pressure, a closer packed form of iron might become stable. Such a form of iron, which is 12 coordinated, has been found at 130 kilobars in shock-wave studies. X-ray crystallography has shown it to be hexagonal close-packed, not cubic close-packed, as the gamma iron already known to occur at elevated temperatures. It is paramagnetic (a weak form of magnetism), unlike normal ferromagnetic α-iron.

Coordination number. The statement that an increase in a substance's coordination number results in a higher density, however, is true only if the atoms in the higher coordinated phase do not have drastically larger radii. For some elements—*e.g.*, titanium, zirconium, and ytterbium—the converse is true. In these cases, application of pressure to an initially close-packed 12-coordinated element changes it to a more open-body eight-coordinated cubic, the atomic radii of which are smaller. The tetrahedrally coordinated elements germanium and silicon are semiconductors (materials differing from metals in that their electrical conductivity increases with temperature), the electrical conductivity of which becomes metallic when they adopt the structure of metallic white tin at high pressure, which is 20 percent denser. Other atomic arrangements are known for these elements. Indeed, white tin itself changes to a tetragonal form.

Phase diagram. To illustrate further, the complexity of polymorphism, the phase diagram for water is shown in Figure 1. On this scale the gas phase cannot be shown, but ice under different conditions is identified by roman numerals. Ordinary ice (I) is less dense than the liquid; hence pressure lowers the melting point until a triple point is reached for liquid ice (I) and ice (III). Because ice (III) is denser than liquid, its melting point is raised by pressure until a further triple point is reached. Ice (V) is also denser than its liquid, so that "normal" melting behaviour is achieved. From Figure 1 it may be seen that an application of 6.5 kilobars to water at 0° C is sufficient to freeze it to a different form of ice, ice (VI). A phase diagram such as Figure 1 represents only equilibrium behaviour; in the case of water, as in most other systems, reaction does not necessarily occur, because as conditions are changed, metastability may result. Diamond is an example of a metastable form of carbon. With water, ice (II) may be chilled to the temperature of liquid nitrogen, after which the pressure may be released, because metastable ice (II) does not transform to ordinary ice until its temperature is raised.

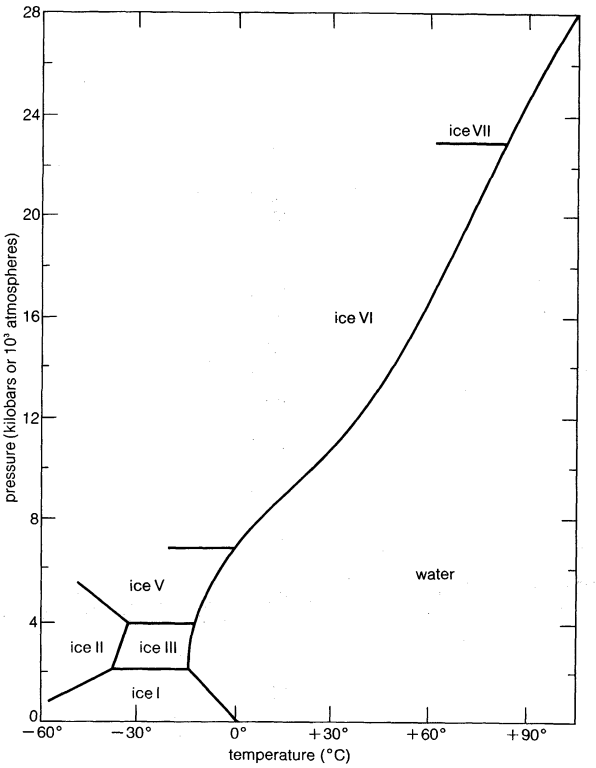

Figure 1: Phase diagram of water (see text).

Shock-wave techniques have provided considerable insight into the volume behaviour of matter. They reveal how cations (positive ions), much more than anions (negative ions), influence the pressure at which the coordination structure changes. Sodium chloride (NaCl), for example, in its normal six-coordinated structure has a density of 2.165 grams per millilitre at one bar, 2.248 at ten kilobars, 2.731 at 100 kilobars, and finally 3.349 at 300 kilobars, at which it transforms to the eight-coordinated modification. In potassium chloride (KCl) the same transition as that in sodium chloride occurs at 18 kilobars, in rubidium chloride (RbCl) at four kilobars, whereas cesium chloride (CsCl) is in this form at one bar. The effect of the chlorine anion on these transformations is trivial by comparison with the cation (*e.g.*, sodium, potassium, or other). Shock-wave techniques have also been used to study the volume behaviour of many elements at a pressure of two megabars. At this pressure the densities of most metals have been increased by 60–100 percent, temperatures of 2,000° C are attained, and all thermodynamic properties of the materials may be obtained for use in calculating chemical equilibrium. By using the Rankine-Hugoniot relations (see below *Principles of apparatus design*) the internal energy (E) and the enthalpy (H), with $H = E + PV$, are obtained directly from the shock-wave data. The entropy (S) may be obtained from an equation relating change in energy to pressure, change in volume, temperature, and change in entropy, as follows: $dE = -PdV + TdS$, but not directly; an approximation has to be made, as must also be done for temperature. From these expressions, Gibbs free energy is derivable. Further thermodynamic considerations permit reduction of the data to an isotherm (constant temperature), so that thermodynamic functions covering a large rectangle in P–T space become known. In liquid oxygen, for example, the upper corner in P–T space is 10,000° C and 1.4 megabars.

Effects on minerals. Although the necessary apparatus had been in existence for some time before World War II, it was not until afterward that there was a major effort to solve high-pressure mineralogical problems in the laboratory. Because the entire range of geological conditions that exist in the earth's crust (namely, pressures up to ten kilobars and temperatures up to 1,500° C) may be duplicated in the laboratory, it is possible to investigate natu-

ral reactions in which pressure is a factor. Moreover, by using such fluids as water and carbon dioxide as pressure mediums, physical properties as well as chemical reactions can be studied. Among the geological conditions that can be measured are the effect of pressure on the electrical conductivity of minerals and on various Curie temperatures (a critical temperature above which a ferromagnetic substance becomes paramagnetic). Much laboratory effort has also been expended on measuring the effect of pressure on the propagation of longitudinal and transverse elastic waves through the earth. It has been found that such measurements, to be meaningful, must be made under pressure; this is because, at a pressure as low as one bar, the initial porosity and lack of compactness of rocks make it impossible to determine values of wave velocity between different samples of nominally the same rock type. In those cases in which the deformation (under confining pressure) of at least a few rock types has been studied in detail in the laboratory, pressure enhances rock flow and helps to explain the tortuous nature of certain folded rocks in nature.

Duplicating nature in geological research

With the development in the mid-1950s of the apparatus illustrated in Figure 2, conditions duplicating those in the earth's upper mantle could be achieved. There then followed a major change in geophysical concepts, such as the previously unrealized importance of polymorphic changes induced by high pressure. An indication of what was to come was the discovery of a denser (2.91 grams per cubic centimetre versus 2.65 grams per cubic centimetre) form of quartz (coesite), first in the laboratory and subsequently at meteorite craters. Later, a still denser (4.29 grams per cubic centimetre) modification, now called stishovite, was found. Thus it was seen that a common constituent (quartz) of surficial rocks could exist in a form that was 62 percent denser at depths of about 400 kilometres. Similar pressure studies have revealed modifications of olivines, pyroxenes, iron oxides, and feldspar in which density increases of 25–50 percent are not uncommon. As a result of such studies, it is safe to say that the mineral components of the earth at a depth of 1,000 kilometres—corresponding to a pressure of 400 kilobars—will contain completely different crystal structures than their chemical counterparts found in the crust. There may be a few exceptions, however, such as magnesium oxide (MgO) and carbon in the form of diamond.

Laboratory studies also destroyed the belief that the rise time of a shock wave is too rapid to allow a polymorphic transition to occur. Many mineral transitions are found to take place—even diamonds have been made—when explosives are used. Stishovite has also been recovered from explosive studies, and its occurrence at meteorite craters is thought to have been caused by natural explosive events when the meteors struck the earth.

Effects on magnetic and electrical properties. Solids are classified as insulators, semiconductors, or metals, depending on the magnitude of their electrical resistivity and its temperature coefficient (*i.e.*, the change of resistivity with temperature). Although such insulators as magnesium oxide and certain alkali halides have been studied while under explosive shock, comparatively few studies have been made of the effect of pressure on the

Electrical effects

electrical resistance of insulators because of experimental difficulties. A common method of estimating temperatures in the earth is to compare the earth's known electrical conductivity, which varies as a function of depth, with the conductivity at various temperatures of those minerals thought to exist there. Although olivine, which has a wide distribution in the earth, has been studied extensively in the laboratory, no definitive statement concerning the effect of pressure on electrical conductivity can be made. In general, however, one can say that, if the electrical conductivity in a substance is the result of ionic motion, pressure should inhibit the motion and thus increase the resistivity. Similarly, diffusion rates should decrease. If, on the other hand, the process is electronic —*i.e.*, the result of motion of an electron or a hole (a positive charge caused by the absence of an electron in a conductive band)—pressure may either increase or decrease the electrical resistance.

Semiconductors are much more sensitive to pressure than other metals, because pressure can have gross effects on carrier density or mobilities or both through an alteration of the conductive-band structure. Changes of several orders of magnitude in resistivity can occur; for instance, 30 kilobars at room temperature changes the resistivity of the semiconductor germanium by a factor of 100. Even more startling changes in resistivity happen when a phase change occurs, as, for example, when at about 120 kilobars germanium adopts the white-tin structure and becomes a metallic conductor. Even in metals, the high density of charge carriers, the free electrons, can react in a complicated manner with the nuclear potentials, causing great variability in behaviour when pressure is increased. Strontium, for example, has maximum resistivity at about 40 kilobars, whereas calcium has a maximum at over 300 kilobars. Barium's electrical resistance is at a minimum near ten kilobars and at a maximum near 130 kilobars. Similarly, antimony has a maximum near 25 kilobars, whereas arsenic has a minimum near that pressure but a maximum near 60 kilobars. Phosphorus (the black form), which has the same number of electrons as arsenic in its outer atomic shell, adopts the arsenic structure at an elevated pressure and then is transformed to a simple cubic structure around 110 kilobars. Presumably, both latter forms of phosphorus are metals, although at a pressure of one bar phosphorus is a semiconductor.

Magnetic effects

Few studies have been made of the effect of pressure on the magnetic properties of matter. In the range below 30 kilobars, where hydrostatic mediums may be used, the effect of pressure is slight. In the range above 30 kilobars, where solid mediums must be used, experimental design and interpretation of data are difficult. Nevertheless, the Curie point of iron has been found to be unaffected by pressure up to the point at which paramagnetic γ-iron forms from ferromagnetic α-iron. In a few other elements, pressure causes moderate fluctuations in Curie points.

APPLICATIONS OF HIGH PRESSURE

The most important economic use of "high" pressure, namely in refining and plastic industries, will not be discussed here, because the pressures employed are lower than those with which this article is concerned. The primary industrial application of truly high pressure is in the manufacture of diamonds from other forms of carbon. In the belt apparatus (Figure 2A), carbon can be transformed to the diamond modification at about 55 kilobars and 1,500° C in the presence of a transition metal (one with an incomplete inner shell) such as nickel. The small diamonds made this way are of industrial grade. Although the same technique can be used to manufacture gem-quality diamonds, the time involved makes this process uneconomical at present. A denser form of boron nitride, with diamond-like hardness, has also been manufactured under pressure.

Another use of high pressure is to alter the mechanical properties of materials, such as increasing the ductility of a metal. In one such application, a new high-speed wire-drawing system has been developed in which external hydrostatic pressure is used to reduce the size of the wire in one die, thereby replacing a whole series of reduction dies that had formerly been needed. Attempts are also being made to compress hydrogen or its compounds in order to create a stable form of hydrogen metal in the solid crystalline state.

The comparative paucity of major applications of ultrapressure technology is probably not because of any lack of phenomena but rather because of the newness of the field and the magnitude of the area to be surveyed. To map out the temperature properties of a hypothetical alloy at normal temperature and pressure, for example, might require 20 samples that differ in composition and, thus, 20 experiments. To make the same temperature study for the 20 samples at intervals between ten kilobars and 200 kilobars, 400 experiments would be necessary.

Principles of apparatus design. *Use of hydrostatic pressure.* In 1909 Percy Williams Bridgman published a

description of a leakproof packing that would extend high-pressure research from three kilobars to 30. Although there had been no problem previously in finding theoretical ways to obtain high pressures by hydrostatic means, no one had discovered how to keep a fluid at such pressures from seeping out of the system. To circumvent this problem, Bridgman used the principle of unsupported area in his packing, which is annular; *i.e.*, shaped like a ring. The pressure of fluid is against one side of the disk, which in turn presses on the annulus. Because the annulus has no material in its centre, its area is less than that of the disk. Hence the pressure per unit area on the annulus is greater than on the disk. Thus the fluid, which is confined behind the disk, cannot escape past it. With this packing arrangement, the sealing of gases and liquids was no longer a problem, but then the strength of containers and plungers became an important factor. The problem with plungers was solved by the use of cemented tungsten carbide, which rarely fails for pressures under 50 kilobars.

Containers. As for containers, such as heavy-walled steel cylinders that may not burst until 40 kilobars of internal pressure, they suffer plastic deformation starting at 15–20 kilobars. Therefore, they are inefficient for repeated use. Bridgman devised a scheme for overcoming this weakness, by fashioning a conical container. As pressure is increased in the interior of the container, the conical vessel is forced into a conical sleeve, because this creates a stress on the exterior of the interior vessel that is approximately equal to the pressure on the inside; thus, deformation is avoided. Bridgman modified this principle of external support by immersing an entire small pressure vessel in a fluid at 30 kilobars. This enabled him to perform at pressures as high as 100 kilobars. More recently, by using the same modification principle, pressure generators have been developed, as illustrated in Figure 2. Figure 2A is a diagram of the belt, an apparatus

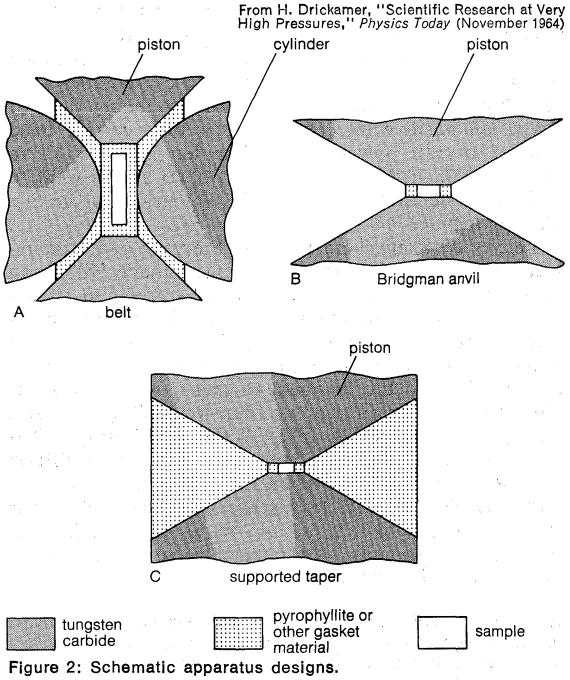

Figure 2: Schematic apparatus designs.

developed in the United States by the General Electric Company for manufacturing the first man-made diamonds. Devices of this general type have been used to achieve pressures of about 200 kilobars and a temperature of about 3,000° C (but not concurrently). Bridgman anvils, which are shown in Figure 2B, were developed to study the electrical resistance of materials up to 100 kilobars. Their chief use has been by geologists in studying mineral reactions in the laboratory; generally, a furnace is added externally to provide elevated temperatures. Figure 2C shows a modification of Bridgman anvils. By supporting the tapered faces, it has been possible to achieve the greatest static (nonexplosive) pressure to date, about 500 kilobars. These and similar designs are successful for two reasons. One is termed "massive support"; that is, a high pressure is exerted on only a small region of a massive object, as in all three designs of Figure 2. The second reason is that a comparatively soft gasket, such as that filling the space between piston and cylinder in Figure 2A, seals against high pressure by its own internal friction as well as by friction against the walls, but only as long as the piston–cylinder gap is not too great.

Shock-wave technique. The greatest extension of pressure and temperature studies began after World War II with the development of controlled explosive events. Even higher pressures and temperatures are now being achieved with nuclear devices. Studies with explosives, termed shock-wave research, are excellent illustrations of how an experiment may be designed to yield valuable information that can be interpreted without mathematical complexity. The basic tool for such studies; displayed in Figure 3, is called a plane-wave generator. When detonated, the velocities of the two explosive charges in the device are such that, due to the conical angle, the velocity at the edge of the slower central explosive wave is exactly matched by the faster wave of the outer explosive. Thus the inner wave is kept exactly plane, and any waves it induces in another pad of explosive and the sample assembly are also plane, at least for a known distance.

Plane-wave generator

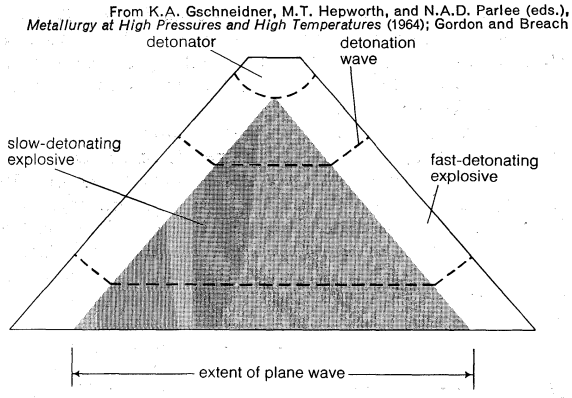

Figure 3: Plane-wave generator.

The three governing equations for a shock wave under the above conditions are called the Rankine-Hugoniot relations. These equations, which are based on the conservation of mass, momentum, and energy, show the relationship between the energy, pressure, and specific volumes (reciprocal of the density) as well as the shock velocity and the partial velocity (the velocity at which the shock material is moving after the shock has passed). When the shock velocity and the partial velocity are measured, the volume behaviour of a substance, which is a function of pressure, can be computed.

The Rankine-Hugoniot equations also apply to projectile impact when it is more convenient to impel a projectile at a high velocity and allow it to impact a sample than it is to use explosives. Whereas explosive research is limited to pressures of about two megabars, high-velocity studies with a gas gun may reach several megabars. Workers in the Soviet Union have reported experimentation at 34 megabars, but they have not specified the technique they employed to reach such pressures.

Hilbert, David

The German mathematician David Hilbert was a towering figure in world mathematics for an entire generation. He fully grasped the major problems that since his time have occupied the attention of 20th-century research in many branches of mathematics.

Hilbert was born on January 23, 1862, at Königsberg, Germany (now Kaliningrad, Russian Soviet Federated Socialist Republic). Partly because he was able to earn his living by the mathematical work he chose to do—as was seldom the case for his predecessors—his life was reasonably placid. The first steps of his career occurred at the University of Königsberg, at which, in 1884, he finished his *Inaugurel-dissertation* (Ph.D.) and remained at Königsberg as a *Privatdozent* (lecturer, or assistant professor) in 1886–92, as an *Extraordinarius* (associate professor) in 1892–93, and as an *Ordinarius* in 1893–95. In 1892 he married Käthe Jerosch, and they had one child, Franz. In 1895 Hilbert accepted a professorship in mathematics at the University of Göttingen, at which he remained for the rest of his life.

Association with the University of Göttingen

The University of Göttingen had a flourishing tradition in mathematics, primarily as the result of the contributions of Carl Friedrich Gauss, Peter Gustav Lejeune Dirichlet, and Bernhard Riemann in the 19th century. During the first three decades of the 20th century this mathematical tradition achieved even greater eminence, largely because of Hilbert. The Mathematical Institute at Göttingen drew students and visitors from all over the world.

Hilbert's intense interest in mathematical physics also contributed to the university's reputation in physics. His colleague and friend, the mathematician Hermann Minkowski, aided in the new application of mathematics to physics until his untimely death in 1909. Three winners of the Nobel Prize for Physics—Max von Laue in 1914, James Franck in 1925, Werner Heisenberg in 1932—spent significant parts of their careers at the University of Göttingen during Hilbert's lifetime.

In a highly original way, Hilbert extensively modified the mathematics of invariants—the entities that are not altered during such geometric changes as rotation, dilation, and reflection. Hilbert proved the theorem of invariants—that all invariants can be expressed in terms of a finite number. In his *Zahlbericht*, a report on algebraic number theory published in 1897, he consolidated what was known in this subject and pointed the way to the developments that followed. In 1899 he published the *Grundlagen der Geometrie* (*The Foundations of Geometry*, 1902), which contained his definitive set of axioms for Euclidean geometry and a keen analysis of their significance (see GEOMETRY, EUCLIDEAN). This popular book, which appeared in 10 editions, marked a turning point in the axiomatic treatment of geometry.

Hilbert.

A substantial part of Hilbert's fame rests on a list of 23 research problems he enunciated in 1900 at the International Mathematical Congress in Paris. In his address, "The Problems of Mathematics," he surveyed nearly all the mathematics of his day and endeavoured to set forth the problems he thought would be significant for mathematicians in the 20th century. Many of the problems have since been solved, and each solution was a noted event. Of those that remain, however, one, in part, requires a solution to the Riemann hypothesis, which is usually considered to be the most important unsolved problem in mathematics (see NUMBER THEORY).

Hilbert's 23 problems

In 1905 the first award of the Wolfgang Bolyai prize of the Hungarian Academy of Sciences went to Henri Poincaré, but it was accompanied by a special citation for Hilbert.

In 1905 (and again from 1918) Hilbert attempted to lay a firm foundation for mathematics by proving consistency—that is, that finite steps of reasoning in logic could not lead to a contradiction. But in 1931 the Austrian–U.S. mathematician Kurt Gödel showed this goal to be unattainable: propositions may be formulated that are undecidable; thus, it cannot be known with certainty that mathematical axioms do not lead to contradictions. Nevertheless, the development of logic after Hilbert was different, for he established the formalistic foundations of mathematics (see MATHEMATICS, FOUNDATIONS OF).

Hilbert's work in integral equations about 1909 led directly to 20th-century research in functional analysis (the branch of mathematics in which functions are studied collectively). His work also established the basis for his work on infinite-dimensional space, later called Hilbert space, a concept that is useful in mathematical analysis and quantum mechanics. Making use of his results on integral equations, Hilbert contributed to the development of mathematical physics by his important memoirs on kinetic gas theory and the theory of radiations. In 1909 he proved the conjecture in number theory that for any n, all positive integers are sums of a certain fixed number of nth powers; for example, $5 = 2^2 + 1^2$, in which $n = 2$. In 1910 the second Bolyai award went to Hilbert alone and, appropriately, Poincaré wrote the glowing tribute.

Hilbert space

The city of Königsberg in 1930, the year of his retirement from the University of Göttingen, made Hilbert an honorary citizen. For this occasion he prepared an address entitled "Naturerkennen und Logik" ("The Understanding of Nature and Logic"). The last six words of Hilbert's address sum up his enthusiasm for mathematics and the devoted life he spent raising it to a new level: "Wir müssen wissen, wir werden wissen" ("We must know, we shall know"). In 1939 the first Mittag-Leffler prize of the Swedish Academy went jointly to Hilbert and the French mathematician Émile Picard.

The last decade of Hilbert's life was darkened by the tragedy brought to himself and to so many of his students and colleagues by the Nazi regime. He died at Göttingen on February 14, 1943.

BIBLIOGRAPHY. Hilbert's collected works, *Gesammelte Abhandlungen*, 3 vol. (1932–35, reprinted 1965; 2nd ed., 1971), contain almost all of Hilbert's papers, including the *Zahlbericht;* there are also assessments of his work by other mathematicians. Four of his six books have been translated into English, but the *Zahlbericht* is available only in German and French. CONSTANCE REID, *Hilbert* (1970), is a full-length biography. OTTO BLUMENTHAL, Hilbert's first Ph.D. student and lifelong colleague, wrote two biographical sketches; the first appeared in the 1922 *Naturwissenschaften* and the second at the end of the collected works. HERMANN WEYL's obituary notice in the *Bull. Am. Math. Soc.*, 50:612–654 (1944), is a definitive assessment by Hilbert's leading student. KURT REIDEMEISTER (ed.), *Gedenkband* (1971), contains some previously unpublished papers of Hilbert and also the recording of his 1930 speech.

(I.K.)

Hillel

In his time—the last half of the 1st century BC and approximately the first quarter of the 1st century AD—the Jewish sage Hillel was the foremost master of biblical commentary and interpreter of Jewish tradition.

Hillel was born in Babylonia, where he received both his early and secondary education. As a young man he went to Palestine in order to continue advanced studies under the leading teachers of Scripture and the Oral Law who belonged to the group or party called Pharisees. Although a strictly biographical account of Hillel's life cannot be set forth, for virtually every narrative about him is encrusted with legend, the literary sources do combine coherently to summon up what may be called the first distinct personality of Talmudic Judaism, the branch of Jewish thought and tradition that created the Talmud, a commentative work on the Oral Law. Put another way, it can be said that the life of Hillel is more than a vague recollection of anecdotes or a name with a saying or two attached.

The first distinct Talmudic personality

More than one story underscores his whole-hearted devotion to study; for example, on one occasion when he lacked the necessary funds for admission to the academy, he is said to have climbed to the roof of the study house, and so attentive was he to the discussions he heard through the "skylight" that he once failed to notice that snow had begun to fall and almost froze to death. It is impossible to separate fact from fancy in such narratives, but such stories are illustrative of the character Hillel projected.

As with most of the Talmudic sages, no miracles or supernatural performances are ascribed to Hillel, but he is represented as a person of exemplary, even superlative virtues. He is, in the traditional accounts, the model of patience, and even when repeated attempts are made by some to insult him, his equanimity and civility remain unaffected. He appears as a fervent advocate of peaceful conduct, a lover of all men, a diligent student, a persuasive and ready teacher, a man of thorough and cheerful trust in God, and the most considerate of hosts. In this last quality he influenced his wife as hostess. In short, he appears in all accounts as the model of the ideal Jewish sage.

This idealization is not entirely storyteller's praises. Critical analysis of Hillel's sayings, of his two legal enactments to relieve economic hardships in society, and even of the motifs the legends seek to emphasize leave little doubt that Hillel did indeed affect the texture of Jewish life profoundly.

While he is nowhere described as the originator of rules to guide the student in the legitimate interpretation of Holy Scriptures, Hillel is unquestionably one of the most influential Talmudic sponsors and practitioners of a conscious, carefully applied exegetical discipline necessary for the proper explanation of the contents of the Bible. The "Seven Rules" he employed—some of which are reminiscent of rules prevailing in Hellenistic schools where Homer was studied and interpreted—were to serve as the basis for more elaborate rules in the 2nd century. Homilies or parables ascribed to Hillel reveal him as a superb pedagogue. For example, there is a story of a heathen who, having been dismissed by Shammai, a sage who was Hillel's chief opponent, came to Hillel and asked to be converted so that he might be appointed high priest. Instead of saying to him that his request was preposterous, Hillel said, "If one wishes to greet a king of flesh and blood, is it not right that he learn how to make his entrances and exits?" The heathen agreed. Hillel continued: "You wish to greet the King over kings of kings, the Holy One, blessed be He. Is it not all the more right that you learn how to enter into the Holy of Holies, how to fix the lights, how to approach the altar, how to set the table, how to prepare the row of wood?" To this too the heathen agreed and thereupon began to study. The heathen's biblical studies finally disclosed to him "of his own accord" why his request could not have been granted.

Mastery of parable and epigram

Along with his other gifts, Hillel had an epigrammatic felicity that is apparent in his sayings, in Aramaic no less than in Hebrew ("A name made great is a name destroyed"; "If I am not in my own behalf, who will be in my behalf? And if I am for myself only, what am I? And if not in the present, when?"), and that inevitably contributed to their being long remembered and very likely taught to schoolchildren as examples of good style. Significantly, in the unique treatise of the Mishna (the authoritative collection of Oral Law), *Pirqe Avot* ("Chapters of the Fathers"), Hillel is quoted more than any other Talmudic sage. As head of a school known as the House of Hillel, he succeeded in winning wide acceptance for his approach, which liberated texts and law from slavishly literal and strict interpretation; indeed, without him an uncompromising rigidity and severity might have developed in the inherited traditions.

Hillel's appreciation of the socioeconomic needs of his age, and of the large possibilities that are inherent in both biblical statements and values, plus his preference for persuasiveness to get across his point of view led to the adoption, with few exceptions, of the Hillelite view of Talmudic teaching and to its establishment as the legal norm.

Talmudic sources speak of Hillel's promotion to patriarchal leadership after he had proved his intellectual superiority to the incumbents then in office. In any event, the Jewish patriarchs—the Roman term for the official leaders of the Palestinian Jews—down to about the 5th century, when the patriarchate came to an end, were descendants of Hillel.

Many of the stories about Hillel, especially those in which he is contrasted with his countercolleague Shammai, are among the most popular Talmudic tales in Jewish literature and folklore.

BIBLIOGRAPHY. In addition to the summary description in the general Jewish histories, see W. BACHER, *Die Agada der Tannaiten*, vol. 1, pp. 4–24 (1890); A. BUCHLER, *Types of Jewish-Palestinian Piety* (1922); L. FINKELSTEIN, *Ha-Perushim ve-Anshe Keneset Ha-Gedolah*, pp. 1–16 (1950), English summary, pp. vi–viii; L. GINZBERG, *On Jewish Law and Lore*, pp. 77–124 (1955); N.N. GLATZER, *Hillel the Elder: The Emergence of Classical Judaism* (1956); and J. GOLDIN, "Hillel the Elder," *Journal of Religion*, 26:263–277 (1946). The nature of the material on Hillel is such as to make impossible a solid reconstruction of his life along the lines of scholarship. The better studies on him, listed in this bibliography, are ultimately speculative. The most useful presentation, therefore, remains the chapter in *Die Agada der Tannaiten* (cited above), for it assembles conveniently all that the sources have on Hillel, and Bacher also provides useful notes for the reader.

(J.Gol.)

Hillslopes

Few landscapes are completely flat. Most plains contain isolated hills rising from the main land surface, and most plateaus have been dissected by streams to produce valley-side slopes. The form of hillslopes, using the term to cover the sloping surface of both hills and valleys, imposes a distinctive mark on the scenery of a landscape. The chalk downs of southern England are, for instance, renowned for their gently rolling profiles; the limestone massifs of Europe for their spectacular gorges; and the semi-arid Colorado Plateau area for its steep-sided scarps and hills that rise abruptly from the desert floor. It is not surprising that scientists have long been fascinated by hillslopes and their change in form through geological time.

Concepts and historical background

The history of concepts of hillslope development is a colourful one. A particularly prominent figure in the early days of earth science was Maj. J.W. Powell (1834–1902), a veteran of the American Civil War and pioneer explorer of the Grand Canyon of the Colorado River. Powell was one of the first to accept the idea that the landscape is molded not only by internal earth movements but also by erosion associated with the action of rain and streams. He recognized that steep, narrow valleys cut in upland massifs, and low-lying plains broken only by occasional small hills, are often merely extreme stages in a gradual process of earth sculpture in which

highlands become plains. Many of his ideas were expanded by another American geomorphologist, W.M. Davis (1850–1934), who set forth the concept of the erosion cycle.

According to Davis, the landscape, and its component parts such as hillslopes, undergo a systematic evolution through geologic time. Landmasses are uplifted from beneath the sea, and once uplift is halted, a gradual process of destruction through erosion takes place. The early stages of the cycle presumably are characterized by steep hillside slopes undergoing rapid undercutting by streams. As the cycle progresses, erosion flattens hillslopes, and the gentler slopes result in slower rates of erosion. Eventually very gentle slopes are formed, and these constitute the supposed ultimate planar surface, a peneplain. Davis was clearly influenced by the evolutionary ideas of Charles Darwin a few years earlier and, indeed, in outlining the cycle he compared the various stages of landscape dissection to organic life cycles and gave his stages the anthropomorphic designations "youth," "maturity," and "old age."

Although Davis attracted many disciples in North America, his ideas were strongly challenged in Europe, particularly by Walther Penck (1888–1923), a German geologist. Penck argued that insufficient attention had been paid to the basic premise underlying the whole concept. He maintained that the notion of rapid uplift of the earth's surface followed by stable conditions, during which erosion destroyed the landmass, was a great oversimplification of actual continental events and histories. It completely ignored the possibility of concurrent uplift and erosion and the emergence of time-independent, equilibrium landforms associated with this. Notwithstanding the theoretical significance of Penck's views, evidence accumulated during this century tends to support Davis. Modern rates of mountain upheaval, averaging 7.5 metres per thousand years (24.6 feet per thousand years), are about ten times greater than maximum rates of erosion found in drainage basins today. Uplift, when it occurs, takes place at rates much greater than erosion rates, whereas in stable areas, erosion appears to be the dominant process at work.

It should be emphasized that Penck did recognize that many continental areas of the earth's surface have been tectonically stable for long periods of time, and that, in these areas, a cycle of erosion not unlike that suggested by Davis would occur. For many years this was not realized, and it was thought that Penck's scheme of landscape development during stable conditions was radically different from the Davisian cycle. According to the popular view of the Penckian scheme, hillslopes retreat parallel to themselves, leaving behind a very gently sloping surface at the foot of the slope. The real founders of the school of parallel slope retreat, however, were Kirk Bryan, an American geomorphologist, and Lester King, a South African geomorphologist, who worked in semi-arid areas in the United States and southern Africa, respectively.

Modern focus on processes

Much of the early work in hillslope studies was speculative. It was often based on visual impression rather than field survey; little attention was directed to the mechanics of the processes held responsible for hillslope erosion; and many ideas, usually expressed in words rather than mathematically, were in fact illogical. More recently, however, hillslopes have attracted the attention of engineers concerned with erosional problems from a practical viewpoint. Landslides pose problems in hilly urban areas; clearing of forests on valley slopes has increased flood frequency; and exposure of the soil surface on hillside slopes has resulted in washing away of valuable topsoil and rapid silting of expensive reservoirs. Detailed research by engineers tackling these problems has provided considerable information that may also help to solve the more academic problem of how hillslopes develop through time.

This article treats the basic aspects of hillslope form, processes, and development. (For further information on concepts of landscape development in general, see LANDFORM EVOLUTION; for more detail on the relevant processes involved, see EARTH MOVEMENTS ON SLOPES; FLUVIAL PROCESSES; and SEDIMENT YIELD OF DRAINAGE SYSTEMS.)

HILLSLOPE FORM

Description of slope profiles. One of the basic problems in hillslope studies is to define quantitatively the form or geometry of hillslopes. If slopes were simply tilted planar surfaces of bare rock or soil-mantled rock, this would be fairly easy; two parameters, slope angle and slope length, would be sufficient to describe the slope form. Even if hillside slopes were not planar, but curved like part of the surface of a cone, it would be relatively simple to add an extra parameter to describe the contour curvature, provided that the slope profiles were straight in section.

Few hillslopes are, however, entirely straight. Many, in fact, are predominantly curved, either convex (steepening from hillcrest to slope base) or concave. In such cases, other parameters are required to describe slope profiles quantitatively. At this point it is simplest to assume that contour curvature (the aspect of hillslope form as viewed from above) is zero; later this will be built into slope description. Slopes that are entirely curved in profile may be described in terms of vertical and horizontal distances by a general curve of the form:

$$H = cL^f, \text{ or}$$
$$\log H = \log c + f \log L \qquad (1a)$$

in which H is the vertical fall from the hilltop, L is the horizontal distance from the hilltop, and c and f are constants for a particular hillslope. The constant c is a measure of average steepness, and f is a measure of the amount of curvature—that is, the rate of change of steepness along the slope profile. Whereas a straight slope is defined by the two parameters of slope angle and length, three parameters are needed for curved hillslope profiles. Studies of hillslope profiles in the Appalachian Mountains of the eastern United States have shown that convex hillslope profiles are properly expressed by curves of this type. Typical values of c and f vary between 0.001 and one, and one to two, respectively. These values vary for slopes on different rock types. For concave profiles f would be less than unity but greater than zero. This type of power function is often called a logarithmic curve; if a graphic plot of H against L were made with logarithmic values along the axes, a straight line would result. An alternative form of curved profile, in which the symbols have the same meaning, is the exponential relation:

$$H = f \log L + C. \qquad (1b)$$

If values of L were plotted on a logarithmic axis and values of H on an arithmetic axis, a straight line would result. Such curves have been applied to the longitudinal profiles of rivers, which are often regularly concave. In areas where most of the lowering of hillslope profiles is the result of erosion by water flowing downslope, stream profiles could be regarded as merely an extreme form of hillslope profile.

Few hillslope profiles, however, conform to a single, regular curve. Most profiles combine one or more convex, concave, and straight parts, and this inevitably makes the study of slope profiles rather more difficult. Three distinct responses to this problem can be detected in the work of the last two or three decades. Some authorities have maintained that hillslope profiles are so complex that studies must use very detailed procedures for delineating, describing, and classifying the various hillslope elements. A second approach has ignored the complex geometry of profiles and attempted merely to pick out salient geometric properties such as maximum angle of slope, average slope steepness, and slope length. Third, some workers, while recognizing that the detailed form of slope profiles is complex, have argued that the basic form is fairly simple, and, without any concern for microscale features, have attempted to describe and explain the large-scale geometric properties of profiles.

Much work on the detailed form of hillslopes has been

Slope segments and elements

done by investigators in England. Hillslope profiles are usually surveyed in the field by measuring the steepness and lengths of successive sections of slope along the line of steepest gradient (that is, perpendicular to contours); the problem is then to separate the profile into its various components. A lengthy nomenclature has been provided. The term segment is used for straight sections, and element for curved parts of slopes and slope profiles. Unfortunately, such classifications sometimes pose more problems than they solve. Terms such as approximately rectilinear and approximately smoothly curved must be defined quantitatively, unless they are to be interpreted in different ways by different workers. Moreover, it is doubtful if any single method of subdividing slope profiles would prove suitable for all of the areas; techniques that are satisfactory for small slopes may be meaningless for longer slope profiles. It is questionable whether very detailed methods of slope-profile description are more useful than generalized delineation of slopes into straight, convex, and concave sections. The ultimate test of any classification is the extent to which it enables improved comprehension of the system. Notwithstanding the painstaking thoroughness of this morphometric approach, the amount of light thrown on slope-profile development has been rather limited.

Major characteristics of slope profiles. The second approach, limited to quantitative description of a few basic parameters of slope profiles, has yielded a number of rather interesting points. A.N. Strahler, an American geomorphologist, examined the relationship between the maximum steepness of hillside slopes and the steepness of the stream gradient at the slope base for a large number of hillslopes. A strong correlation was found between the two variables: hillsides with steep maximum-slope sections were undercut by streams with steep gradients, whereas gentler hillsides were associated with gentler streams. Subsequently, other workers have detected additional correlations between maximum hillside slope and such factors as rock type, infiltration capacity of the soil mantle, vegetation cover on the hillside, and related attributes. Maximum hillside slope, thus, appears to be a useful property of slope profiles inasmuch as it seems to reflect processes operating on and at the base of hillslopes. Early hillslope studies were also directed to average hillslope steepness, but this is a less useful parameter because it is essentially dictated by the drainage pattern. It is easily shown that average hillside slope can be expressed as:

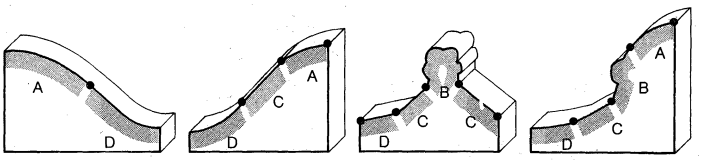
$$\bar{\theta} = 2HD_d \qquad (2)$$

in which $\bar{\theta}$ is average hillslope angle; H is the vertical height of the slope; and D_d is the drainage density (ratio of total stream channel length in a drainage basin to the drainage area) of the area. Studies restricted to basic properties such as length and average and maximum steepness are, however, inevitably rather limited in their approach to slope form, even though they have produced certain interesting data.

The four-section profile

The most successful of the three approaches has been that directed at describing and explaining the generalized form of hillslope profiles. Descriptions of profiles by many workers in different geologic and climatic environments have shown that certain types of profile occur repeatedly in the landscape. It has been noted, for example, that profiles of hillslopes cut in highly fractured rocks, such as granites, shales, and some limestones, typically show a four-section form in a wide variety of climates. This standard profile is convex at the top, exhibits a steep rock cliff below, and then, in succession, a straight slope mantled by debris from the cliff above, which merges into a concave basal slope. Although not all hillslopes contain all of the four components, many profiles (Figure 1) are essentially variants on the basic form. Along with this recognition of the overall form of hillslope profiles, recent work has offered explanations for the basic features of these profiles in terms of the various erosion processes occurring on the slopes.

Before turning to the topic of hillslope processes, mention must be made of the plan form (as viewed from above) of hillslopes. Clearly, the major aspects of the plan geometry of hills are determined by the pattern of the drainage network. Parallel streams produce similar ridges, and tributary streams that cut into those ridges will produce alternate hollows and noses or spurs. Rounded hills in plan are simply the extreme case of a nose. These features are easily explained in terms of the drainage pattern and have important implications for slope profiles. Profiles in hollows and on noses may be expected to differ from those on true valley-side slopes or hillslope ridges. In hollows, for instance, water flow converges as it moves downslope, and, therefore, discharge per unit of surface area will tend to increase downslope; on noses, in contrast, water flow diverges, and discharge will increase more slowly in moving downslope from the divide.



A Upper convex hilltop
B Outcrop of bare rock as cliff
C Straight, debris-mantled slope
D Lower concave basal slope

Figure 1: Variants on the basic hillslope profile.

Similar statements may be made about the downslope movement of soil on slopes. Observations suggest that the hillcrest convexity is more strongly developed on noses, and the concave basal slope is more prominent in hollows than for comparable profiles where hills are straight in plan view. The long profiles of streams are dominantly concave and, in a sense, stream profiles can thus be considered slope profiles in extremely pronounced hollows.

HILLSLOPE PROCESSES

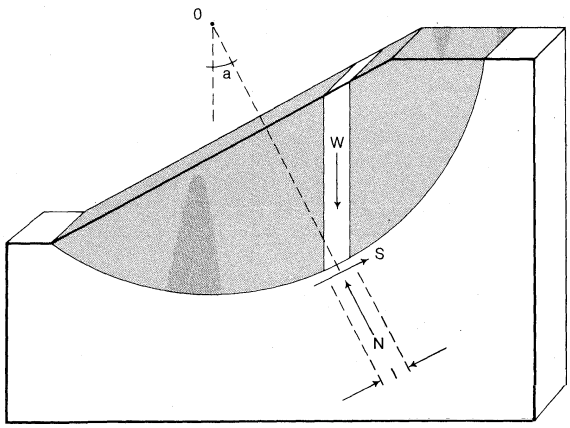
The various processes that act to move material down, and eventually off, hillside slopes may be conveniently grouped into two categories; namely, fluvial processes and mass movements. The former processes occur on all slopes irrespective of the steepness of the hillside. The latter, with the exception of certain very slow mass movements, are most frequent on slopes that are being undercut rapidly; in the absence of undercutting, they occur only on slopes that are greater than a critical angle of stability. This limiting or threshold slope angle depends on the type of material forming the slope. Slopes subject to slow undercutting are, thus, molded primarily by fluvial processes and slow mass movements; slopes subject to rapid undercutting are lowered essentially by instability processes—that is, by rapid mass movement.

Shear force and strength of materials

Mass movements. There are many types of instability processes, but all of them obey the same physical laws. Any point in a mass beneath a sloping surface supports a vertical force due to the weight above. The component of this force acting along any potential slip surface is called the shear force; this increases with depth and with slope angle. The component acting perpendicular to the surface, and, hence, at right angles to the shear force, is called the normal force. These relations are shown in Figure 2. At any depth beneath the surface the shear force is attempting to move the material above that depth downslope, and eventually, to reduce the slope to a level surface. Whether or not movement of the material actually occurs depends on the strength of the material to withstand the shear force. Water, for instance, has no strength and, if it is subjected only to the force of gravity, will always move to produce a level surface. Slopes cut in soil or rock, in contrast, do have strength to withstand shear forces; if they did not, the landscape would be flat. Nonetheless, there are limits to the vertical height of canyon walls and to the steepness of debris slopes; these

limits depend on the amount of shear strength of the material in which the hillslopes are formed.

The strength of earth materials is usually separated into two components. One is frictional resistance between



W weight of slice
S shear resistance along potential slip surface
N force normal to potential slip surface
l thickness of hypothetical slice
a slope angle

Figure 2: Section through a circular landslip (see text).

mineral particles. This includes not only true friction between flat surfaces but also interlocking of particles. It is termed internal friction and is designated by either the angle, *phi* (ϕ), or the coefficient, mu (μ), of internal friction. The total frictional force along a potential failure surface, at limiting equilibrium, can be expressed as:

$$F = N\mu = N \tan \phi \qquad (3a)$$

in which F is the frictional force; N is the normal force that is pushing the particles together; and μ, or the tangent of the angle ϕ, represents the internal friction. Sometimes friction is expressed in terms of a stress—that is, the frictional force per unit area. In addition to frictional strength, particles may be cemented together or drawn together by physicochemical forces, providing another source of strength termed cohesion. This is the major source of strength in intact rocks, but it is lost when the rock mass is broken down into individual fragments. Cohesion is usually regarded as independent of the normal stress; total shear strength is, thus, conventionally expressed as cohesion plus the stress acting on the internal rock resistance, namely:

$$s = c + \sigma \tan \phi \qquad (3b)$$

in which s and c are, respectively, shear strength and cohesion expressed as stresses, *sigma* (σ) also is a stress, and ϕ is again internal friction.

Instability and critical height

Instability processes may be classified in many ways. The following approach is unconventional but very useful in understanding hillslope forms; it is based on the rate of undercutting of hillslopes relative to the rate at which the rock breaks down under the action of weathering (*q.v.*). At high rates (rapid undercutting or resistant rock), little of the cohesive bonding in the rock mass is destroyed and the rock may be considered intact. At medium rates, weathering destroys the cohesive strength of the rock mass near the surface of the valley slopes, but not at depth. At slower rates (slow undercutting or easily weathered rock), cohesion is lost throughout and the shear strength of the hillside material is entirely frictional.

Streams cutting down vertically into a solid, intact, rock mass will produce stable vertical slopes until a critical valley depth is reached. It can be shown that this depth is related to the physical properties of the rock and the stresses that are operative upon it, namely:

$$H = \frac{kc}{\gamma} \tan (45 + \phi/2) = \frac{kq_u}{2\gamma} \qquad (4)$$

in which H is the critical height of slope (valley depth); *gamma* (γ) is the unit weight (density) of the rock; k is a constant approximately equal to four, varying slightly with the shape of the potential failure surface; and c and ϕ are cohesive and frictional components of rock strength, respectively. The parameter q_u is the unconfined compressive strength of the rock (see ROCKS, PHYSICAL PROPERTIES OF). The critical height of a rock cliff with $q_u = 500$ kilograms per square centimetre (7,100 pounds per square inch) and $\gamma = 2{,}500$ kilograms per cubic metre (150 pounds per cubic foot), typical values for a medium-strength sandstone, would be 4,000 metres (13,000 feet). The critical height of a vertical rock slope is rarely attained in nature. The reason is that the process of valley cutting itself produces extensive weakening of the rock mass. If the rock mass is thought of as a set of vertical columns of rock packed together tightly, then this claim can be appreciated. Each column exerts a lateral thrust on adjacent columns; if a column is removed, there is a sudden drop in the lateral pressure on adjacent columns. This pressure release, or stress relaxation, results in a slight expansion of the rock mass toward the gap. The effect is a weakening of the rock and eventual destruction of cohesion in the vicinity of the gap. Analogous processes occur on the sidewalls of valleys as streams cut down creating canyons in rock masses.

The destruction of the cohesive strength in a rock mass by pressure release may take many forms, depending on the type of rock. Massive rock formations (rocks with few fractures) tend to produce vertical tension cracks at some distance from the canyon wall. This reduces the critical height of the wall by an amount equal to the depth of the tension crack. Instability thus takes the form of slabs of rock peeling off the valley wall. In highly fractured rocks, pressure release weakening takes a different form. As the lateral stress is relaxed, some cracks begin to open; the shear strength along these cracks is accordingly reduced and an extra part of the shear force must be taken up by other cracks. This increase in shear force opens up other cracks, and a chain reaction occurs until the slope material becomes completely cohesionless. Substitution of $c = 0$ in Equation 4 (above) yields zero, indicating that vertical slopes cannot exist in cohesionless material. If cohesion is lost throughout the rock mass, rock avalanches will lower the valley slope to an angle θ, at which the slope is just stable. It can be shown that θ should be identical to ϕ. Highly fractured material in a dense state of packing has ϕ values in the range 45° to 75°; clay usually has ϕ values in the range 5° to 25°, and as a result, slopes cut in clay tend to be gentler.

If a rock mass is sufficiently strong, or if undercutting is sufficiently rapid, cohesion may be destroyed only in the near-surface parts of the rock mass, and slope angles will be steeper than ϕ. The actual value will be restricted by the depth of the valley, as indicated by the expression relating slope angle, critical height, and rock properties; namely:

$$\frac{\sin \theta \cos \phi}{1 - \cos (\theta - \phi)} = \frac{H\gamma}{kc} \qquad (5)$$

in which θ is the angle at which the slope is just stable, ϕ represents internal friction, H is slope height, γ is rock density, k is a constant, and c represents rock cohesion. Examination of this equation shows that θ increases as the left-hand side decreases and, therefore, as H decreases and c increases. Note that Equation 4 is simply a special case of Equation 5, solved for H rather than θ, with $\theta = 90°$. As an example, consider a stream downcutting into a clay mass characterized by $\gamma = 2{,}500$ kilograms per cubic metre (150 pounds per cubic foot), $\phi = 20°$, and $c = 1$ kilogram per square centimetre (14 pounds per square inch), with valley-side slopes at 45°. The critical height would be 104 metres (341 feet).

Once the valley depth exceeded this value, instability would occur. On steep slopes, instability takes the form of a wedge sliding on a planar, failure surface. On gentler slopes, such as in clay masses, the failure surface

is usually curved, and instability takes the form of a rotational slip. This is illustrated in Figure 2; at limiting equilibrium, the shear force and strength along the failure arc are just equal.

Threshold slope angles

Under slower conditions of undercutting, widespread destruction of cohesion allows slope angles to become independent of slope height. The actual angle depends on the extent of weathering because this affects not only the cohesive strength but also the frictional strength of the rock material. With little weathering, so that in effect the rock mass is a densely packed, cohesionless aggregate, the angle $\phi = 45°–75°$, as noted previously. Further weathering, particularly loosening of the surface material by frost action, would produce a less densely packed aggregate. Such loose rock debris is often called talus or scree; the reduction of interlocking strength during weathering into scree results in a decrease in ϕ to about 32°–38°. The ϕ value of talus is often referred to as the angle of repose. Further weathering would break down rock fragments into earth. Deposits of earth and talus, termed taluvium, have ϕ values between 40° and 45°; fully weathered material may have values of ϕ between 4° and 35°, depending on the mineralogical composition and grain size of the soil.

The limiting angle of slope (threshold slope) for material containing fine earth debris, however, is no longer determined simply by ϕ. The angles are equal only for materials in which the voids, or pores, between particles are occupied by air. When water fills these voids, the pore pressures are greater than atmospheric pressure. This pore pressure tends to reduce the interparticle contact force imposed by the normal force and, therefore, it also reduces the amount of friction developed. In regoliths containing appreciable earthy material, the small voids allow saturation at times of prolonged rainstorms; and when the pore pressure is greater than zero, the threshold slope is less than the angle ϕ. Pore pressure increases with depth below the water table, but the exact relationship depends on the pattern of groundwater flow. Several studies have shown that the threshold slope of hillslopes mantled by weathered debris may often be given by the equation:

$$\tan \theta = \tfrac{1}{2} \tan \phi \qquad (6)$$

where θ is the threshold slope angle. Taluvium would, therefore, be expected to be stable only at angles near to 25° and colluvial mantles at angles from 2° to 20°, depending on the type of soil. This last expression may not hold for mantles that weather into clay, however; cohesion may develop in regoliths of fine earth and the angle of limiting stability in this case would depend on slope height.

Soil creep

Under very slow conditions of undercutting, instability processes are infrequent, but slower mass movements, commonly called soil creep, may, under suitable conditions, become very important. There are at least two mechanisms of soil creep. One is a rheological effect, long studied by engineers, and sometimes referred to as shear creep. It occurs at depth as well as in the near-surface zone, but only on slopes greater than a critical steepness, which varies with the soil type. The other, called seasonal soil creep, is confined to surface layers (usually within the upper 50 centimetres [or 20 inches]) but does not depend upon a minimum slope steepness. Seasonal soil creep is probably more universal than shear creep, and more is known about it.

This slow downslope movement of the surface layers is primarily the result of alternate expansion and contraction of the soil. It may stem from either wetting-drying or freeze-thaw of the surface soil. Expansion of the soil mass is along paths perpendicular to the ground slope, but during contraction the soil moves back in a direction between these expansion directions and the vertical. The effect of an expansion-contraction cycle, therefore, is to move material slightly downslope. The rate of soil creep on a hillside slope depends on slope angle, the amount of expansion-contraction per cycle, and the frequency of cycles. Creep is important in humid areas, where alternate wetting and drying of the soil mantle is fairly frequent; field measurements indicate rates of one to ten cubic centimetres per centimetre per year (the volume moving past a line one centimetre wide, along the contour, in a year) in these environments. Creep rates appear to be even higher in Arctic and Alpine areas, where the magnitude of the annual freeze-thaw cycle is at a maximum; in these areas creep probably merges imperceptibly into solifluction (earth flowage). Creep is probably at a minimum in tropical deserts, where neither of the two mechanisms of expansion-contraction can be very effective.

Evidence and theory suggest that, on straight hillside slopes, creep rate is independent of distance downslope from the divide. This has important implications for slope-profile development. If, during a unit of time, the volume of soil moving past a point downslope is equal to the volume moving down from an upslope point, clearly there is no net removal of soil, and, therefore, no lowering of the hillside along that stretch of slope. All of the net loss of material must occur at the hillcrest; as a result, crests are rounded convexly. Continued creep will tend to extend the convexity downslope.

Fluvial processes. Three main types of fluvial processes of erosion act on hillslopes: rain-splash, surface-soil wash, and solution. In terms of the effect on slope-profile geometry, rain-splash should be grouped with soil creep rather than with other fluvial processes. The term rain-splash is applied to the splashing of soil particles off the ground surface by the impact of falling raindrops. On hillside slopes this tends to produce a net movement of material downslope because particles are splashed further downslope than upslope from any point. Experiments have shown that the movement of soil downslope due to rain-splash increases with slope angle. Whether or not rain-splash attains any real importance, however, depends on the effectiveness of the vegetation cover in sheltering the ground surface from raindrop impact. Field data show that bare soil surfaces may erode at rates that are many times greater than rates on grass-covered plots. Much of the accelerated soil erosion on watersheds cleared for farming can be attributed to rain-splash. On natural slopes, with unaltered vegetation cover, rain-splash erosion is much greater on the bare surfaces of semi-arid areas than in humid areas; this is accentuated by the high intensity of rainstorms in the former areas. Data suggest that volumetric rates of rain-splash erosion in semi-arid areas may approach creep rates in humid areas, although generally they are probably lower. The layer of moving debris is much thinner and the velocity much greater in the case of rain-splash. As in the case of soil creep, the downslope movement of material that is due to rain-splash appears to be independent of distance downslope on straight slopes except at the hillcrest. Net loss, therefore, is concentrated near the summit of the slope, producing, and extending downslope, a convex slope element.

Rain-splash erosion

Soil wash and overland flow

Surface-soil wash, the transport of soil debris downslope by water flowing over the ground surface, may take many forms. At one extreme there are isolated rivulets or rills and, at the other extreme, a continuous sheet of water. Early workers maintained that rill erosion and unconcentrated wash had radically different effects on slope-profile geometry, but there is little evidence to support this view. The hydraulics of overland flow in all of its various forms on hillslopes seem to be similar to open channel flow modified by the thinness of the moving fluid. Although the detailed mechanics of debris transport by moving water, in both channels and on slopes, are poorly understood, certain relationships are well established. First, the tractive force acting to move debris along, or suspended above, the bed of a flowing fluid increases with the depth of flow and the slope of the water surface. Second, the threshold tractive force necessary to initiate movement along the bed increases as the particle size increases. For a given particle size there is, therefore, a critical combination of depth and slope that must be attained before movement will occur. If it is assumed that there is a definite limit to the depth of flow that will occur at any point, it is evident that, at that

point, there is a threshold gradient below which no movement will occur. Neither channel slope nor hillside slope can be flattened to angles below that corresponding to the threshold traction condition. This threshold gradient is not the same at all of the points along a hillside slope. Average particle size decreases downslope owing to various processes, including abrasive action during movement, and as a result, the threshold tractive force necessary for debris transport is smaller at increasing distances from the divide. Moreover, because the water discharge of overland flow, and therefore depth, increases with distance from divide, there is a still more pronounced decrease in threshold gradient downslope.

The ultimate slope profile developed by surface wash processes should, therefore, be concave upward. But this threshold slope profile is not necessarily static; at any point on the profile weathering may reduce particle size over time. This fact means that the equilibrium concave slope will depend on the extent of weathering of the surface.

The importance of surface-soil wash depends on two factors: the frequency of occurrence and depth of overland flow, and the resistance offered by soil particles to movement by the flow. In very dry areas, soil wash is small because overland flow is rare; in very wet areas, soil wash is also relatively minor because of the dense vegetal cover, which not only intercepts much of the rainfall but also protects the ground surface against the force of overland flow. Data on the sediment yield of drainage systems (*q.v.*) indicate that maximum erosion rates occur in semi-arid areas with an annual effective precipitation of about 40 centimetres (16 inches). Direct measurement of surface-soil wash in these areas shows rates of 200–500 cubic centimetres per centimetre per year (30–79 cubic inches per inch per year) and, sometimes, even higher (1,000 cubic centimetres per centimetre per year has been measured in the Sangre de Cristo Mountains, New Mexico), in contrast to rates less than 0.3 cubic centimetres per centimetre per year (0.05 cubic inches per inch per year) on grass-covered slopes in humid areas.

Subsurface solution

One of the main reasons why surface-soil wash is so ineffectual in humid areas is that the combination of lower rainfall intensities and denser vegetal cover on hillslopes increases infiltration of rainwater into the soil mantle and allows little overland flow. In these areas, water moves to stream channels primarily through subsurface routes; it is to be expected, therefore, that subsurface erosion is more important than surface-soil wash. Some of this erosion is direct mechanical movement of fine material through pores in the soil. A much more important process, however, is transport of elements in solution. This affects particularly calcium, sodium, magnesium, and potassium cations (positively charged ions). Direct evidence of the importance of solution in humid areas is afforded by studies of solute and sediment concentration in stream water; except for infrequent storms, the dissolved load is usually appreciably higher than the sediment load. Some of this dissolved load originates from the chemical weathering of bedrock at depth beneath the ground surface and has no direct effect on slope profiles. Solution is also responsible, however, for movement of material out of the soil mantle; this is indicated by the development of distinct soil profiles (vertical layering or zoning) on flatland. On hillside slopes, subsurface movement of water is downslope rather than vertical, particularly above impermeable layers, so that soil profiles are poorly developed. Studies show that much of this subsurface seepage occurs just above the interface between the soil mantle and the underlying bedrock, and it is probable that much of the solution process is concentrated here. In this way the interface is directly lowered, and, indirectly, the ground surface is also lowered, although by a smaller amount depending on the fraction of residual material undissolved. This residual fraction is very low in limestones, which typically produce very shallow soils. In other rocks, much of the solution process is taken up by thickening of the soil mantle rather than lowering of the ground surface. The thickness of weathered material on tropical hillsides testifies to the high rate of solution under hot, moist conditions. Solution is possibly the major erosion process operative on stable slopes in humid areas. Little is known about the effect solution has on slope profiles. Uniform lowering of the soil-rock interface would produce parallel retreat of hillside slopes. Precipitation of salts on the downslope parts of hillsides, the result of the evaporation of water as it seeps downslope, would, however, result in a gradual decrease in the net loss of material with increasing distance from the divide, and hence, to slope decline.

HILLSLOPE DEVELOPMENT

The equilibrium slope. Each process or combination of erosional processes acting on hillsides will produce an equilibrium slope form that is lowered at the same rate as undercutting of the hillside, assuming that undercutting continues at a constant rate for a sufficiently long period of time. Under conditions of rapid undercutting, instability processes control the equilibrium slope form; hillsides will be straight and inclined at angles of limiting stability. Under very slow conditions of undercutting, slower mass movements and fluvial processes determine slope geometry; equilibrium slopes are rounded, being dominantly convex where creep or rain-splash prevails, and dominantly concave where surface-soil wash is most important.

It is unlikely, however, that undercutting rates will remain constant over long periods of geologic time; as a result, it must be expected that slope forms also will change through time as one equilibrium form is replaced by another. According to W.M. Davis, as discussed at the outset of this article, undercutting of slopes by streams decreases through geologic time, and slope forms evolve accordingly. The Davisian system is not entirely satisfactory because, as emphasized by Walther Penck and others, it focusses attention on only one of an infinite number of possible courses of stream behaviour and landscape evolution. There is no single course of hillslope evolution even for a given rock type in a given climatic setting; the actual sequence depends upon changes in the rate at which slopes are undercut over time. Any general framework of hillslope evolution can present only the equilibrium slope forms for different rates of undercutting for different rock type-climatic environments. These forms may then be arranged in any permutation to accommodate different courses of stream erosional behaviour.

Classification of equilibrium slope forms

A convenient classification of equilibrium slope forms, on the basis of the rate of undercutting (in relation to the rate of weakening of the rock mass), follows directly from the previous discussion of erosional processes on hillsides. Four general classes may be distinguished in order of decreasing rates of undercutting:

1. Slopes produced by downcutting in fully cohesive rock masses will be vertical provided that valley depth is less than the critical value given by Equation 4; subject to this proviso, these vertical walls may be regarded as equilibrium–or time-independent forms. Such slopes do exist in nature, but only in very strong rock masses. Moreover, such massive formations are limited in thickness and probably always are thinner than the critical depth for the canyon walls that can be cut in them. These equilibrium forms, therefore, are short-lived in terms of geological time; as soon as streams cut through these massive formations into weaker rock underneath, nonvertical equilibrium slopes, discussed below, will be formed. Vertical cliffs, thus, tend to form parts of valley slope profiles in deep valleys, but they rarely form the entire rock wall. Many hills in the Colorado Plateau of the southwestern United States, for instance, show vertical slopes of sandstone that cap gentler slopes in weaker shales.

2. Slopes produced by downcutting at slower rates, which allow partial weathering of the rock mass and destruction of cohesive bonds in the near-surface zones, are nonvertical, as noted previously. Actual slope angles depend upon the extent of penetration of the cohesion-destroying forces and also on the valley depth, as indi-

cated by Equation 5. In areas where valleys are widely spaced and separated by broad, flat divides, the concept of equilibrium slope forms is inapplicable because valley depth increases with time, and slope steepness, therefore, is also a time-dependent phenomenon. Valley depths cannot increase indefinitely, however, because as they get deeper, the divides between them become narrower; eventually, divides become narrow ridges formed by the intersection of the valley slopes themselves. In this situation divides are lowered at the same rate as slopes are undercut; valley depth and slope now become time-invariant features. Because the initial valley spacing influences the depths to which valleys may develop before equilibrium is attained, the drainage density has a direct influence on slope form as indicated previously by Equation 2.

3. Slopes cut sufficiently slowly to allow complete loss of cohesion in the rock, in the vicinity of valleys, stand at an angle dictated by the internal friction angle ϕ, itself dependent on the stage of rock weakening and the characteristic pore-pressure pattern. Theoretically, straight equilibrium slopes may occur at any value between 90° and 0°, depending on these two parameters. Certain ϕ values are characteristic of different materials, and certain pore-pressure patterns are probably more common than others. It is, therefore, not surprising that some slope angles occur repeatedly in nature, whereas others are rare. Some common equilibrium slope angles reported by various authorities are as follows: clay, 10° to 15°; sandy soil, 20° to 21°; earthy rubble (taluvium), 25° to 27°; scree, 32° to 38°; and densely packed, fractured rock, 43° to 48°. The steepness of these straight threshold slopes depends not only on the type of rock mass but also on the rate of undercutting of the rock mass in relation to the rate of weakening of it.

4. Under conditions of downcutting, which are slower than those just necessary to produce fully weathered threshold slopes, instability processes become more infrequent and other processes—slow mass movements and fluvial processes—begin to mold the equilibrium slope forms. Soil creep and rainsplash produce convex hilltops, and equilibrium profiles may be either convex–straight or entirely convex, depending on the rate of the process relative to the rate of undercutting. Surface-soil wash produces concave forms beginning at the slope base and extending upslope. In areas where both soil wash and creep are significant and undercutting is slow, the typical slope form will be convex–concave. The effect of solution on the equilibrium slope form is still not fully understood and is probably dependent on the environment.

Influence of rock type and climate. The influence of rock type on the equilibrium slope form is immediately evident from this classification. The rate at which the rock mass weakens affects the class of slope form that is developed. Within any single class it may also affect the equilibrium profile. Highly fractured rock masses, for instance, may produce at least four different threshold slopes depending on the stage of rock disintegration, whereas a rock that weathers directly into a fine earth debris is restricted to much fewer possibilities. Because of its influence on the type of residual mantle that is produced by weathering, the rock type may indirectly influence the balance of processes that yield convex and concave forms. Impermeable clays encourage overland flow and surface-soil wash, whereas more permeable soil allows infiltration of rainfall and produces creep; this was neatly demonstrated in a study of slope forms in the Badlands National Monument, South Dakota.

Climate, runoff, and vegetation

Climate exerts a major influence on the form of equilibrium slopes in two main ways. First, it may allow fluvial processes and slow mass movements to assume a significant role well before weathering of the hillside material has been completed. In semi-arid areas, *in situ* debris mantles derived from the weathering of highly fractured rock frequently do not pass beyond the scree stage. Soil-size particles tend to be washed downslope by overland flow as soon as they are produced, and the hillside material remains as scree. More fully weathered threshold slopes, therefore, should not be as common as in humid temperate areas where surface-soil wash is a minor process. This may also be true for some parts of Arctic and Alpine areas that, in terms of vegetation, may be regarded as semi-arid. Second, climate exerts a strong control on the relative importance of slow mass movements and the various fluvial processes, and, thus, on the form of equilibrium slopes developed under conditions of very slow downcutting. In semi-arid areas the dominance of surface-soil wash is associated with very long, shallow concave profiles. Where this is developed on *in situ* rock material it is termed a pediment. Many pediment-like slope forms, however, are produced in semi-arid areas by extensive deposition of colluvium in valley bottoms, after it has been washed off the main hillsides. In humid temperate areas, surface wash and rainsplash are minor processes, but soil creep is relatively important. Slope profiles produced under conditions of slow undercutting are, therefore, largely, or sometimes wholly, convex. Concavities do occur at the slope base on many profiles, but whether they are caused by contemporary solution, surface wash in Pleistocene times (from 10,000 to 2,500,000 years ago), or some other process, is uncertain. Cold areas and hot, moist areas appear to be intermediate between semi-arid and humid temperate conditions in terms of the relative importance of convex- and concave-producing processes, but very little research has been undertaken in these areas so far.

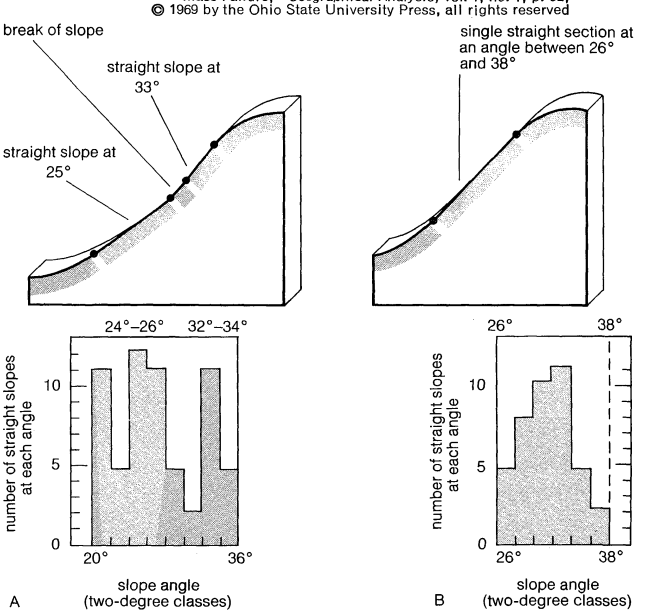


Figure 3: Differences between hillslopes attributable to (A) parallel slope retreat and (B) slope decline. Both hillslopes occur in jointed rocks in humid temperate climate, but the (top) actual hillslope profiles and (bottom) corresponding frequency histograms contrast (see text).

Slope retreat. In the Davisian system of landscape evolution, hillside slopes supposedly change through time, from equilibrium forms associated with high rates of undercutting to forms associated with slower rates. The main problem involved in the construction of such an evolutionary sequence, once the various equilibrium forms are known (at the time Davis proposed the cycle of erosion, very little was known about these forms), is to determine how, geometrically, the change from one equilibrium profile to another is achieved. There are two possible ways in which steeper hillslopes may be replaced by gentler slopes: hillsides may retreat from the initial position of the slope base and produce a new, gentler slope at its foot until continued retreat eventually results in complete replacement of the steeper slope by the gentler one; or steep slopes may gradually flatten to gentler slopes as though they were hinged at the slope base. Both views have their adherents, and the argument

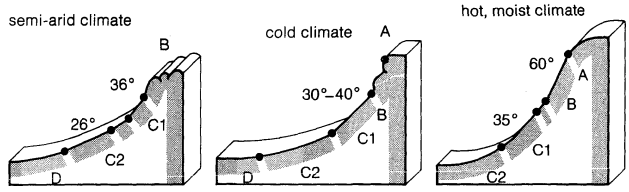
between the parallel-retreat school and the slope-decline school was the central issue in slope studies.

There is little doubt that both modes of change may occur—indeed, possibly even on the same hillside. This may be illustrated by some work on highly fractured rocks (shales, shaly gritstones, quartzitic gritstones, and limestones) in central and southwestern England, as shown in Figure 3. Most of the hillslopes in these two areas are mantled by scree or taluvium; a few are cloaked by a colluvial mantle. Equilibrium slope forms are dominated by straight sections at 32°–37° (scree slopes), where undercutting is rapid, and by straight sections at 25°–26° (taluvial slopes), where undercutting is slower. On slopes cut in shales and shale-grit, the change from one angle to another appears to be the result of the retreat of the scree slope and upslope extension of the taluvial replacement. This is indicated by two observations. Many slope profiles are multisegmented, with upper scree slopes at 32° and lower taluvial slopes at 25°—26°; upper slopes are very unstable and landslides appear to strip material off of these slopes resulting in retreat. This is supported by the histogram (Figure 3) of straight-slope angles, which shows peaks at 32° and 25° and a gap between these peaks. If slopes were to decline gradually from 32° to 25°, straight slopes would be expected at all angles between the two limits. On slopes cut in quartzitic gritstone and limestone, in contrast, the change from a scree-mantled slope to a taluvium-mantled slope appears to be caused by a gradual hinge decline; slopes occur at all angles between 37° and 26°, and no double-segment slope profiles occur.

Multi-segment slope profiles

Two lines of evidence do suggest, however, that retreat of slopes is a common mode of adjustment from one equilibrium form to another. The first is that multisegment slope profiles are very frequent even in relatively homogeneous rock material. The second is that similar angles of straight slopes occur repeatedly in different areas, whereas others are relatively infrequent. Figure 4 shows typical slope profiles on highly fractured rock

From (centre) based on photo from A. Jahn, *Zeitschrift fur Geomorphologie, Suppl. Bd. 1, Morphologie des Versants* (1960), Gebruder Borntraeger Verlagsbuchhandlung; and A. Rapp, *Geographiska Annaler* (1960), Generalstabens Litografiska Anstalt; (right) C.K. Wentworth, *Journal of Geology* (copyright 1928) The University of Chicago Press



A Convex, soil-mantled upper slope
B Fairly straight rock cliff
C1 Straight, dry, talus slope near to angle of repose of debris
C2 Moist taluvial slope; sometimes straight, sometimes concave merging with valley floor
D Very gentle concave slope mantled by very fine colluvial material

Figure 4: Slope profiles on jointed rock (see text).

in three climate settings: semi-arid, cold, and hot, wet conditions. All of them show distinct segments, as they steepen from slope base to hillcrest, hinting that the steeper segments are in the process of retreat, producing gentler slopes beneath them. In addition, all of the three profiles contain talus slopes at 30°–40° and taluvial-mantled slopes. Slope retreat does appear to be a common mode of adjustment from one equilibrium form to another. Moreover, judging by the abundance of multisegment slope profiles, this adjustment is rather a slow one. In an evolutionary system, then, it seems probable that many, perhaps most, of the slopes are not equilibrium forms but are in transition states from one equilibrium condition to another. In view of this, it is not surprising that slope studies have produced many conflicting ideas.

This framework of discussion of slope form and slope development is inevitably a much more simplified picture than actually exists in nature. Most of it relates to a uniform rock mass, whereas many natural slopes are carved in materials of mixed lithology. This may result in complex slope forms. Moreover, it has been assumed that constant climatic conditions prevail, and this, in the long term, is a purely hypothetical situation; climatic zones have fluctuated in position over the earth, especially during the last two to three million years of geologic time. Slope forms in humid temperate areas may have been affected by colder conditions; slope forms in semi-arid areas have probably been modified by former moist conditions. Indeed, some workers believe that it is impossible to explain present-day slope forms in terms of present-day processes, for this reason. Finally, any model is only as good as the "tools" with which it is built. The tools involved here are the concepts of fluid mechanics, soil mechanics, rock mechanics, hydrology, geochemistry, and related disciplines. Advances in these subjects will inevitably lead to refinements in current models of slope development.

BIBLIOGRAPHY. The three classic works by W.M. DAVIS, *Geographical Essays* (1909); W. PENCK, *Die morphologischen Analyse* (1924; Eng. trans., *Morphological Analysis of Landforms*, 1953); and L.C. KING, *The Morphology of the Earth* (1962), all discuss the development of hillslopes. The articles by A.N. STRAHLER, "Equilibrium Theory of Erosional Slopes Approached by Frequency Distribution Analysis, *Am. J. Sci.*, 248:673–696, 800–814 (1950); and S.A. SCHUMM, "The Role of Creep and Rainwash on the Retreat of Badland Slopes," *Am. J. Sci.*, 254:693–706 (1956), are two of the first attempts to measure slope form and process quantitatively. M.A. CARSON and M.J. KIRKBY, *Hillslope Form and Process* (1972); A. YOUNG, *Slopes* (1972); and S.A. SCHUMM and M.P. MOSLEY, *Slope Morphology* (1973) are devoted to this topic.

Himachal Pradesh

Occupying a region of scenic splendour in the western Himalayas, Himachal Pradesh is a state of the Indian Union at the extreme north of the Indian subcontinent. It is bounded on the north by Jammu and Kashmir, on the east by China (Tibet), on the southeast by Uttar Pradesh, on the south by Haryana, and on the west by Punjab. Towering snow-clad mountains are divided by deep valleys with thick woods, green fields, and cascading streams, as well as lakes and waterfalls. Himachal means Snowy Mountain (*hima*, "snow"; *acal*, "mountain"), the state (*pradesh*) taking its name from the Himalayas.

The physical setting

The area of the state is 21,490 square miles (55,658 square kilometres). Its population in 1971 was more than 3,400,000. The capital is Simla, at an elevation of 7,262 feet above sea level, the largest and most popular hill resort in India and the summer headquarters of pre-independence British viceroys.

Formerly a union territory, Himachal Pradesh emerged as a full state of the Indian Union on January 26, 1971.

History. The history of the area dates back to the Vedic period, the earliest known tribal group being Dāsas, who had a reputation in the arts of warfare. Later the Aryans assimilated the tribes. The area was exposed to successive invasions through the centuries, ending with the British dominion over the native princes of the hill states.

Himachal Pradesh was constituted as an administrative unit comprising 30 hill states in 1948. This event was preceded by a movement for the end of feudalism and the introduction of responsible government. One of the princely states, Suket, virtually surrendered to the peaceful demonstrators, hastening the process of change.

Achievement of statehood

Between 1948 and the achievement of statehood in 1971, Himachal Pradesh went through various changes in size and administrative setup. First a substate and then a union territory directly administered by the central government, Himachal Pradesh was enlarged in 1954 by the merger of Bilāspur (a former Indian state and then a chief commissioner's province), and again in 1966 by the merger of Punjab hill areas including Simla, Kāngra, Kulu, and Lahaul and Spiti. Y.S. Parmar, who since the 1940s had led the hill people of Himachal Pradesh in the quest for responsible government, became the first chief minister of the new state.

Physical geography. The terrain varies with hills of

low and high altitudes, wooded valleys, flowing rivers, and rocky soils. The mountains rise to about 22,000 feet and include the Himalayan ranges of the Pīr Panjāl, Hathi Dhār, and Dhaula Dhār. The mountain valleys are known locally as *dūns* (*e.g.*, the Kiarda Dūn in the Sirmūr district); the hill stations of Kulu, Manāli, and Dharmsāla are in the Kulu and Kāngra valleys. The major rivers are the Chenāb (Chandra Bhāga), Rāvi, and Beās in the west and the Sutlej and Yamuna (Jumna) in the east.

The climate ranges from mild to cold. Icy winds sweep the state, and the hills and valleys remain covered with snow for months. In the valleys flowers and fruits grow in abundance, and their rivers abound in fish. The forests harbour wildlife, including the ibex, goral, bear, and snow leopard.

Population. The population of the state in 1971 was approximately 3,400,000, and its population density was about 159 per square mile. The population presents a mixture of hill tribes, including Gaddis, Gūjars, Kinners, Lahaulis, and Pangwalas. The vast majority of the people are Hindus, who worship in temples dotted throughout the state, but there are also Buddhists, Sikhs, Muslims, and Christians. About 60 dialects are spoken, the main language being Western Pahari. Pahari is derived from Sanskrit and Prākrit. Caste distinctions and outdated social customs are slowly fading under the impact of influences from outside, the spread of education, and the growing consciousness of changes taking place throughout the country.

Himachal Pradesh is the least urbanized state in India, the urban population accounting for just 7 percent of the total. There are few towns, of which only the capital, Simla, has a population exceeding 50,000. The population of Sundarnagar is 21,000. The populations of Mandi, Nāhan, Chamba, Solon, and Dharmsāla are between 10,000 and 17,000; those of Bilāspur, Kāngra, Dalhousie, Una, and Kulu are between 5,000 and 9,000; Palampur and Kasauli range down to less than 4,000. Over 90 percent of the people depend for their livelihood on farming, horticulture, and livestock raising.

Administration. The head of the state is the governor, appointed by the president of India. The council of ministers, headed by a chief minister, is responsible to the 68-member legislative assembly that is elected directly on the basis of adult suffrage. The state has four representatives in the lower house (Lok Sabha) of India's Parliament and three in the upper house (Rajya Sabha). The state is divided into ten districts—Chamba, Mandi, Bilāspur, Mahāsu, Sirmūr, Kinnaur, Simla, Kāngra, Kulu, and Lahaul and Spiti.

Social conditions. In the second half of the 20th century, there has been expansion of education and public health facilities and an improvement of communications. The people, however, remain at the subsistence level, and the state's vast natural resources have yet to be tapped systematically. Development plans lay emphasis on road building, power generation, and exploitation of forest products for industrialization.

Growth of educational institutions

In the years since 1948, education has made rapid strides. The state now has 18 degree-granting colleges connected with Punjab University as compared with one in 1950. There is a medical college at Simla and an agricultural college at Solon, and research is carried on at the Indian Institute of Advanced Study (Simla) and the Central Research Institute (Kasauli). School enrollment has gone up in the wake of a phenomenal rise in the number of primary, middle, and higher schools. In addition to some 500 hospital-dispensaries and over 70 primary health centres, there are more than 70 family-planning centres engaged in the campaign to check the birth rate. More than 3,000 out of 13,000 inhabited villages had been electrified by 1971, and a substantial beginning had been made in providing drinking water to the people in the remote areas.

Economy. Himachal Pradesh, with its perennially snow-fed rivers, has a hydroelectric power potential of 8,500,000,000 watts. There is immense scope for the development of forests and setting up of forest-based industries, including newsprint. Hydroelectric development has only begun with installations in Mandi district on the Uhl River, a tributary of the Beās, and in Bilāspur district at the Bhākra Dam across the Sutlej.

Economy based on the land

The state's economy is still almost entirely based on the products of the land. The chief crops are wheat, maize (corn), barley, rice, and potatoes. Excellent varieties of plums, peaches, apricots, pomegranates, and other fruits are produced. The state's high-quality apples are exported to neighbouring states and abroad. Sheep and goat rearing are widespread, and wool and pashm (the fleece of the Tibetan goat) are important exports. The coniferous forests have also been a source of revenue.

There is very little industry. A foundry was established at Nāhan in 1872; taken over by the Indian government in 1952, it manufactures agricultural implements. There are also a turpentine factory at Nāhan and a brewery at Solon. Some woolen goods are made on handlooms and small machines, and several small plants process foods, notably fruits.

Concentrated efforts have been made to improve the state's economy through a series of development plans. The outlook for the economy is regarded as hopeful in view of the prospects of exploitation of the abundant power potential, mineral deposits, and forests and the promotion of tourism.

Transportation and communication. Except for the rail line from Kālka (in Haryana) to Simla, the capital, and the narrow-gauge track connecting Pathānkot (Punjab) and Jogindarnagar (H.P.) through the Kāngra valley, there are no railways or waterways in the state. Roads are the communications lifeline of Himachal Pradesh, and the state spends 30 percent of the development plan outlay to expand the road system. There are now over 4,500 miles of roads compared with less than 300 miles in 1950. The nationalized transport system operates more than 140 routes in the state.

Cultural life. The fairs and festivals of the hill people are occasions of joyful song and dance. Besides folk dances, there are folk songs with romantic themes and folktales woven around mythological figures. Both men and women partake in the dance and music and in the folk dramas.

Kāngra is a famous centre of paintings of delicate beauty with love as their central theme. In addition to this 18th-century school of painting, Himachal can boast of beautiful and useful crafts, such as the exquisitely designed shawls of Kinnaur and the embroidered handkerchiefs of Chamba.

The Simla hills, Kulu and Manāli valleys, and Dalhousie are tourist attractions. Skiing, golfing, fishing, trekking, and mountaineering are activities for which Himachal Pradesh is ideally suited.

Pilgrims journey to the Kulu and Kāngra valleys to worship at shrines of legendary antiquity. From Kāngra, one can proceed to Dharmsāla, a pleasant hill station that is the home of the Dalai Lama, who fled from Tibet in 1959 in the wake of Chinese occupation of Lhasa. The Kulu Valley is known as the Valley of the Gods; its pine and deodar forests, flower-spangled meadows, and fruit orchards provide the setting for the colourful Dussehra fair held every autumn. The temple gods are taken in caparisoned palanquins from the hilltops, and through singing and dancing the hill people give vent to their joy.

BIBLIOGRAPHY. Y.S. PARMAR, *Himachal Pradesh: Its Proper Shape and Status* (1965) and *Himachal Pradesh: Case for Statehood* (1968), present the historical perspective of the movement for a separate state of Himachal Pradesh, by the first chief minister of the state. R.K. KAUSHAL, *Himachal Pradesh* (1965), is a historical study that deals with developments leading to the formation of the state. H.C. SARASWAT, *Himachal Pradesh* (1970), provides a synoptical account of the state, its people, social customs, and economy. The *Census of India*, Paper 1 of 1971 (1971), gives the population and other vital statistics. The *Himachal Pradesh: Fourth Five Year Plan* (1969), embodies the programs formulated by the state government for development in agriculture, power and irrigation, transport and communications, social services, and other fields.

(C.Ra.)

Himalayan Mountain Ranges

The Himalayas, of Asia, include the highest mountains in the world, with more than 30 peaks rising to heights of 24,000 feet (7,300 metres) above sea level. One of these peaks is Mt. Everest, the world's highest, which reaches a height of 29,028 feet. The great heights of the mountains rise above the line of perpetual snow. The vast permanent snowfields attracted the attention of the pilgrim mountaineers of ancient India, who coined the Sanskrit name Himalaya—from *hima*, "snow," and *ālaya*, "abode"—for this great mountain system. In modern times, the Himalayas have constituted the greatest attraction and the greatest challenge to mountaineers throughout the world.

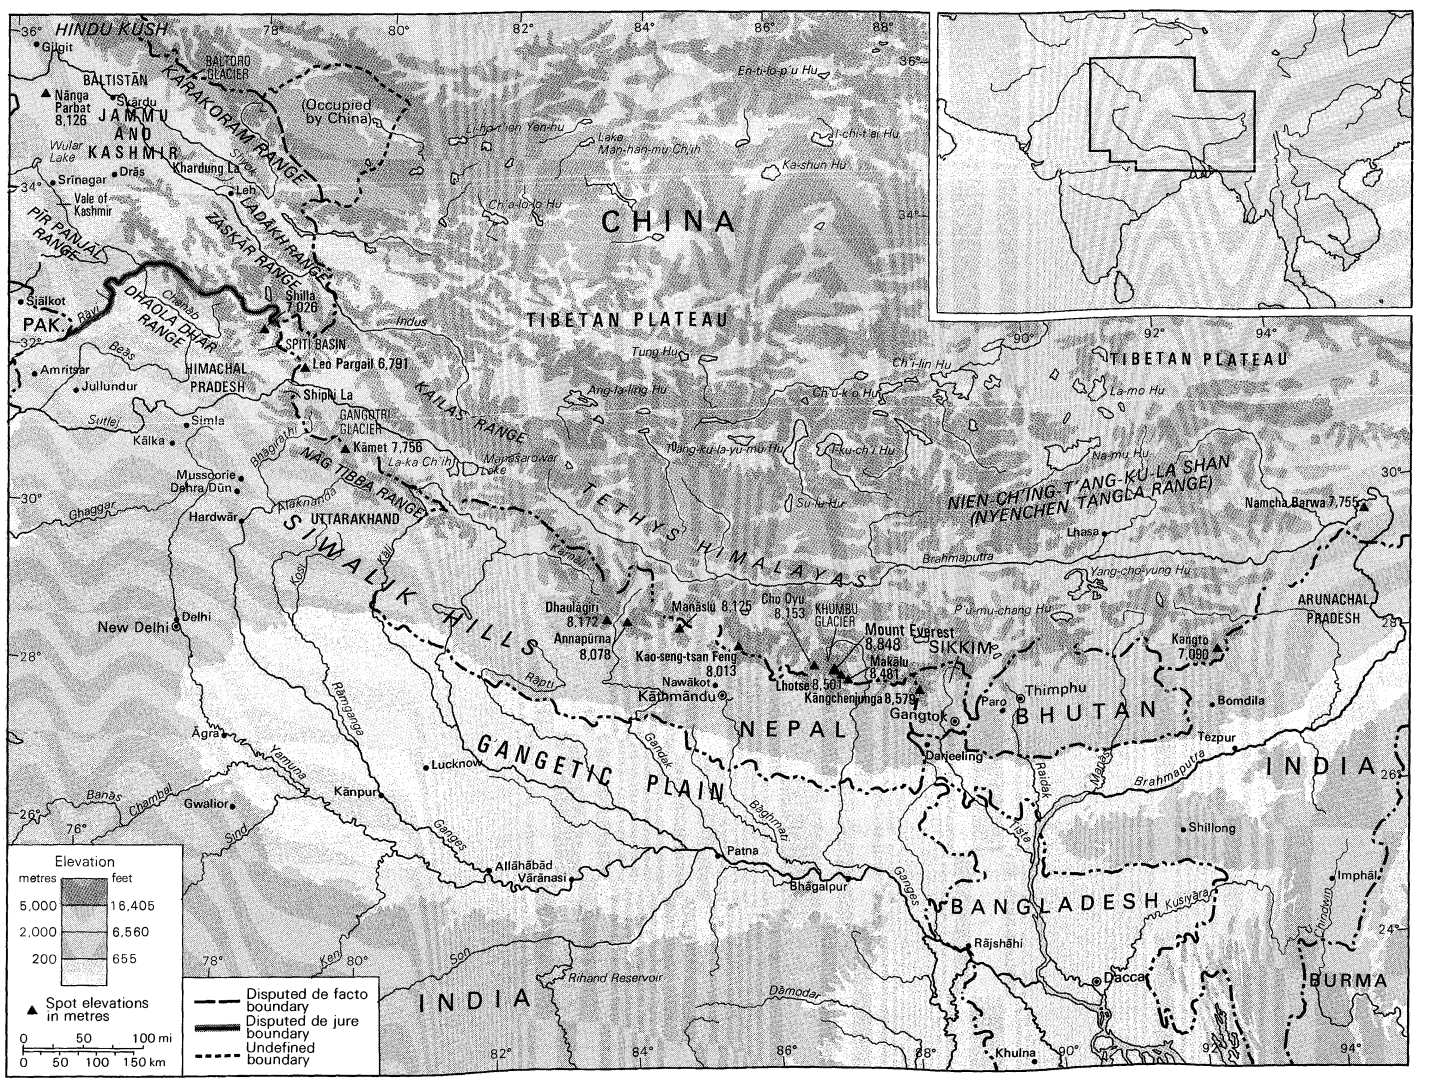
Forming the northern border of the Indian subcontinent and an almost impassable barrier between it and the lands to the north, the ranges form part of the great mountain belt stretching halfway around the world from northern Africa to the east coast of Asia. The Himalayas themselves stretch uninterruptedly for about 1,550 miles (2,500 kilometres) from west to east between Nānga Parbat (26,660 feet), in the disputed state of Jammu and Kashmir, and Namcha Barwa (25,445 feet), in Tibet. Between these eastern and western extremities lie the three Himalayan kingdoms of Nepal, Sikkim, and Bhutan. The Himalayas are bordered to the northwest by the mountain ranges of the Hindu Kush (*q.v.*) and Karakoram (*q.v.*) and to the north by the high Plateau of Tibet. The width of the Himalayas from south to north varies between 125 and 250 miles. Their total area amounts to about 229,500 square miles (594,400 square kilometres).

Though India has sovereignty over most of the Himalayas, Pakistan and China occupy parts of them. In the state of Jammu and Kashmir, Pakistan has administrative control of 32,362 square miles of the range lying north and west of a cease-fire line established between India and Pakistan in 1948. China's occupation of 14,000 square miles in the Ladākh district of Kashmir, as well as Chinese incursions to the south of the McMahon Line (a 1914 boundary line limiting Tibetan sovereignty in the Assam Himalayas of northeast India) in the North East Frontier Agency (now Arunachal Pradesh) in 1962, have accentuated further the boundary problems faced by India in the Himalayan region. (For an associated physical feature, see EVEREST, MOUNT.)

Physical geography. The Himalayas' most characteristic features are their soaring heights, snowcapped and steep-sided jagged peaks, valley glaciers often of stupendous size, topography deeply cut by erosion, seemingly unfathomable river gorges, complex geological structure, and a rich temperate and alpine vegetation. Viewed from the south, the Himalayas appear as a gigantic crescent, with its main axis rising above the snow line, where snowfields feed the valley glaciers and constitute the sources of most of the Himalayan rivers. The greater part of the Himalayas, however, lies below the snow line. The mountain-building process that created the range is still active and is accompanied by erosion by rivers and landslides of great dimension.

From south to north, the Himalayan ranges can be grouped into four parallel, longitudinal mountain belts of varying width, each having distinct physiographic features and its own geological history. They are designated

Principal divisions



The Himalayan region of the Indian subcontinent.

as the Outer, or Sub-Himalayas; the Lesser, or Lower Himalayas; the Great, or Higher, Himalayas; and the Tethys, or Tibetan Himalayas. Farther north lie the Trans-Himalayas in Tibet proper, eastward continuations of some of the most northerly Himalayan ranges. From west to east the Himalayas are divided broadly into three mountainous regions: Western, Central, and Eastern.

Physiography. The Outer Himalayas comprise flat-floored structural valleys and the Siwalik Hills, which border the Himalayan mountain system to the south. Except for small gaps in the east, the Siwalik run for the entire length of the Himalayas with a maximum width of 62 miles in the Indian state of Himachal Pradesh. In general, the 900-foot contour line marks their southern boundary; they rise to another 2,500 feet to the north. The main Siwalik range has steeper southern slopes facing the Indian plains and descends gently northward to flat-floored basins, called *dūns.* The best known of these is the Dehra Dūn, in Uttarakhand, which is in the mountainous parts of Uttar Pradesh.

Northward, the Siwalik Range abuts against a 50-mile-wide massive mountainous tract, the Lesser Himalayas, where mountains rising to 15,000 feet and valleys with altitudes of 3,000 feet run in different directions. There is a general conformity of altitude among neighbouring summits, which creates the appearance of a highly dissected plateau. The three principal ranges of the Lesser Himalayas, the Nāg Tibba, the Dhaola Dhār, and the Pīr Panjāl, have branched off from the Great Himalayan Range lying farther north. The Nāg Tibba, the most easterly of the three ranges, is 26,795 feet high near its eastern end, in Nepal, and forms the watershed between the Ganges (*q.v.*) and the Yamuna, in the Uttarakhand.

To the west, the picturesque Vale of Kashmir, a structural basin (*i.e.*, an elliptical basin in which the rock strata are inclined toward a central point), forms an important section of the Lesser Himalayas. It extends from southeast to northwest for 100 miles, with an average elevation of 5,100 feet, having a width of 50 miles; it is traversed by the meandering Jhelum River, which runs through the Wular Lake, the largest freshwater lake in India.

The backbone of the Himalayan system is formed by the Great Himalayas, a single high range rising above the line of perpetual snow.

Highest peaks of Himalayas

The Great Himalayan Range rises to its maximum height in Nepal, having in that section nine of the 14 highest peaks of the world. From west to east they are: Dhaulāgiri (26,810 feet), Annapūrna 1 (26,504 feet), Manāslu (26,760 feet), Kao-seng-tsan Feng (Gosainthan; 26,291 feet), Cho Oyu (26,750 feet), Mt. Everest (29,028 feet), Makālu (27,824 feet), Lhotse (27,923 feet), and Kāngchenjunga (28,208 feet).

Farther east the range changes from a southeasterly to an easterly direction as it enters Sikkim. After this, it runs eastward for another 260 miles through Bhutan and the eastern part of Arunachal Pradesh as far as the peak of Kangto (23,260 feet) and finally turns northeast, terminating in Namcha Barwa.

There is no sharp boundary between the Great Himalayas and the ranges, plateaus, and basins lying to the north of the Great Himalayan Range, generally grouped together under the name of the Tethys Himalayas and extending far northward into Tibet. In Kashmir the Tethys are at their widest, forming the Spiti Basin and the Zāskār Mountains, the highest peaks of which, to the southeast, are Leo Pargail (22,280 feet), rising north of the Sutlej River opposite Shipki La (pass), and Shilla (23,050 feet).

Geology. A study of the geological history of the Himalayas reveals that marine sediments of Paleozoic and Mesozoic eras (between about 65,000,000 and 570,000,000 years ago) deposited on the floor of the ancient Tethys Sea; the frontal part of the crystalline massif (mountain mass) of peninsular India; estuarine deposits along the flanks of the embryonic mountains; and finally products of surface erosion of the rising mountains—all contributed to the formation of the present-day range. The uplift of the Himalayas took place in at least three distinct and widely separated phases. The first phase of the major mountain-building movement took place at the close of the Eocene Epoch (about 38,000,000 years ago), although the beginning of the main Himalayan uplift started in Middle and Upper Cretaceous times (from about 100,000,000 to 65,000,000 years ago), with the advancement of the crystalline massif of peninsular India toward the Plateau of Tibet. This movement caused the rise of the Tethys Himalayas, along with the greater part of the Great Himalayas. In the second phase of upheaval, which occurred in the Miocene Epoch (7,000,000 to 26,000,000 years ago), the estuarine deposits and the Indian Massif formed the ranges of the Lesser Himalayas. The final mountain-building phase started at the end of the Tertiary Period (about 7,000,000 years ago), lifting the detrital deposits accumulating at the base of the Himalayas to form the Siwalik Range, the foothills of the Outer Himalayas. Since the middle Pleistocene Epoch (about 1,500,000 years ago), the Himalayas have risen at least 4,500 feet, an occurrence witnessed by early man. That the Himalayas still continue to rise is evidenced by the upheaval of the younger river terraces.

Formation of the ranges

Precambrian metamorphic rocks (rocks formed by heat and pressure from 570,000,000 to 4,600,000,000 years ago) form the bulk of the Himalayas. These rocks represent the frontal part of the Indian Shield, which, according to the theory of continental drift (see CONTINENTAL DRIFT), pushed northward, uplifting the Himalayas as it pressed against the Asian landmass. Only in the Spiti Basin and in a few other localities can large outcrops of marine sediments from Paleozoic and Mesozoic times be seen.

Plutonic rocks (formed deep down from a molten state), such as granites and granodiorites of pre-Miocene age (*i.e.*, more than 26,000,000 years old), outcrop in extensive areas in north Kashmir, forming the whole of the Ladākh Range and the greater part of the area of Baltistān to the west of the Drās River and to the south of the Karakoram Range (*q.v.*). The intrusion during post-Miocene times (*i.e.*, within the last 7,000,000 years) of tourmaline granite into an older series of gneisses (rocks formed by heat and pressure and made of bands that differ in colour and composition) and schists (crystalline rocks, the constituent minerals of which are usually arranged in a foliated or parallel pattern), aided by upthrusts in many areas, has given rise to many of the high peaks of the Himalayas, such as Makālu, Manāslu, and Nānga Parbat, which are typical examples. Mt. Everest and its two associated peaks, Lhotse and Cho Oyu, are, however, formed of limestones and pelitic (clay and mudstone) rocks, the latter dipping toward the north. It is possible that the entire formation of Mt. Everest is thrust up over a foundation of gneiss, as nappes or overturned folds.

The nappe structure of the Himalayas can also be seen elsewhere in the ranges. The Krol Nappes of the Simla region, in Himachal Pradesh, and the Garhwal Nappes, of Uttarakhand, are typical. These nappes are also evident in Nepal in the Nawākot and Kāthmāndu areas, which were formed along the line of the main central thrusts. This thrust zone borders the Great Himalayas to the south, rising abruptly in height and showing changes in the sequence of geological beds. The Pīr Panjāl Range, for example, owes its origin to thrust faulting; in the Simla region Krol limestones of Carboniferous Period (*i.e.*, from 280,000,000 to 345,000,000 years old) are overthrust onto much younger deposits of Pliocene Epoch (from 7,000,000 to 2,500,000 years old).

The geological structure is much simpler in the Outer Himalayas, where the foothills are mainly composed of Tertiary formations (from 2,500,000 to 65,000,000 years old), grouped under the Lower, Middle, and Upper Siwaliks. These consist mostly of freshwater deposits, such as sandstones, shales, and conglomerates. The Lower Siwaliks are from 1,800 to 6,000 feet thick, the Middle Siwaliks from 3,000 to 4,500 feet thick, and the Upper Siwaliks from 4,500 to 6,000 feet thick. At the same time that the Siwalik deposits were occurring, lacustrine (lake) deposits known as Karewas (flat-topped terraces) were

being formed in the Vale of Kashmir. Both the Karewas and Siwaliks show evidence of glaciation during Pleistocene times (from 10,000 to 2,500,000 years ago).

Major Tibetan rivers

Drainage system. The Himalayas are drained by 19 major rivers, of which the Indus (*q.v.*) and Brahmaputra (*q.v.*) are the largest, each having catchment basins about 100,000 square miles in extent in the mountains. Of the other 17 rivers, five belong to the Indus system—the Jhelum, Chenāb, Rāvi, Beās, and Sutlej, with a total catchment area of 50,958 square miles; nine belong to the Ganges system—the Ganges (*q.v.*), Yamuna, Rāmganga, Kāli (Sarda), Karnāli, Rāpti, Gandak, Bāghmati, and Kosi, draining another 84,098 square miles; and three belong to the Brahmaputra system—the Tista, Raidak, and Manās, draining another 70,769 square miles.

Most of the Himalayan rivers flow in troughs, the trends of which are generally determined by the branching ranges of the Great Himalayas. The rivers of the Indus system as a rule follow northwesterly courses, whereas most of the rivers of the Ganges–Brahmaputra systems take easterly courses while in the mountain region.

To the north of India, the Karakoram Range, with the Hindu Kush (Mountains) (*q.v.*) on the right and the Ladākh Range on the left, forms the great water divide, shutting off the Indus system from the rivers of Central Asia. The counterpart of this divide on the east is formed by the Kailas Range and its eastward continuation, the Nien-ch'ing-t'ang-ku-la Shan (Nyenchen Tangla Range), which prevent the Brahmaputra from flowing northward. South of this divide, the Brahmaputra flows eastward for about 900 miles before cutting across the Great Himalayan Range in a transverse gorge, although many of its Tibetan tributaries flow in an opposite direction, as the Brahmaputra may once have done.

The Great Himalayan Range, which normally would form the main water divide throughout its entire length, functions as such only in limited areas. This situation exists because the major Himalayan rivers, such as the Indus, Brahmaputra, Sutlej, and at least two headwaters of the Ganges—the Alaknanda and Bhāgirathi—are older than the mountains they traverse. It is believed that the Himalayas were uplifted so slowly that the old rivers had no difficulty in continuing to flow through their channels and, with the rise of the Himalayas, even acquired a greater momentum, which enabled them to deepen their valleys more rapidly. The elevation of the Himalayas and the deepening of the valleys thus proceeded simultaneously, with the result that the mountain ranges emerged with a completely developed river system cut into deep transverse gorges, ranging in depth from 5,000 feet to 16,000 feet and in width from six to 30 miles. The earlier origin of the drainage system explains the peculiarity that the major rivers drain not only the southern slopes of the Great Himalayan Range but to a large extent its northern slopes as well, the water divide being north of the crest line.

The role of the Great Himalayan Range as a watershed can, nevertheless, be seen between the Sutlej and Indus valleys for 360 miles; the drainage of the northern slopes is carried by the north-flowing Zāskār and Drās rivers, which drain into the Indus. Glaciers also play an important role in draining the higher altitudes and in feeding the Himalayan rivers. Several glaciers occur in Uttarakhand, of which the largest, Gangotri, is 20 miles long. The Mahalangur *himāl* ("snowfield"), with its Khumbu Glacier, drains the Everest region in Nepal. The rate of movement of the Himalayan region glaciers varies considerably; in the neighbouring Karakoram ranges, for example, the Baltoro Glacier moves about six feet a day, while others, such as the Khumbu, move only about a foot daily. Most of the Himalayan glaciers are in retreat.

Glaciers

Soils. Not much is known about the Himalayan soils. The north-facing slopes generally have a fairly thick soil cover, supporting dense forests at lower altitudes and grasses higher up. The forest soils are dark brown in colour and silt loam in texture and occur mainly in Uttarakhand; they are ideally suited for growing fruit trees. The mountain-meadow soils are well-developed but vary in thickness and in their chemical properties. Some of the wet, deep, upland soils of this type in the Eastern Himalayas—for example in the Darjeeling Hills and in the Assam Valley—have a high humus content that is good for growing tea. Podzolic soils (infertile, acidic forest soils) occur in a 400-mile-long belt along the valley of the Indus and of its tributary the Shyok, to the north of the Great Himalayan Range, and are also found in patches in Himachal Pradesh. Farther east, saline soils occur in the dry Ladākh Plateau. Of the soils that are not restricted to any particular area, alluvial soils (deposited by running water) are the most productive, though they occur in limited areas, such as the Vale of Kashmir, the Dehra Dūn and on the high terraces flanking the Himalayan valleys. Lithosols consisting of imperfectly weathered rock fragments deficient in humus content cover many large areas at high altitudes and are the least productive soils.

Climate. The Himalayas, as a great climatic divide affecting air- and water-circulation systems, exercise a dominating influence upon meteorological conditions in the Indian subcontinent, to the south, and in the Central Asian highland, to the north. By its situation and stupendous height, the Great Himalayan Range obstructs the passage of cold continental air from the north into India in winter and also forces the southwest monsoonal (rain-bearing) winds to give up most of their moisture before crossing the range northward, thus causing a heavy precipitation of rain and snow on the Indian side but arid conditions in Tibet. The average annual rainfall on the south varies between 60 inches at Simla and Mussoorie in the Western Himalayas and 120 inches at Darjeeling in the Eastern Himalayas. At places such as Skārdu, Gilgit, and Leh, in the Indus Valley, to the north of the Great Himalayan Range, only three to six inches of rainfall occur.

The precipitation pattern

Local relief and situation determine the meteorological variations experienced not only in different parts of the Himalayas but even on different slopes of the same range. Because of its favourable location on top of the Mussoorie Range facing the Dehra Dūn, the town of Mussoorie, at a height of about 6,100 feet, receives 92 inches of rainfall annually, as against 62 inches recorded in the town of Simla, which lies behind a series of ridges at a height of 6,600 feet. The Eastern Himalayas, being at a lower latitude than the Western Himalayas, are relatively warmer; the lowest minimum temperature so far recorded was at Simla, in the Western Himalaya, −13° F (−25° C). The average minimum temperature for the month of May, recorded in Darjeeling at 6,380 feet elevation, is 52° F (11° C). In the same month, at an altitude of 16,500 feet in the neighbourhood of Mt. Everest, the minimum temperature is about 17° F (−8° C); at 19,500 feet it falls to −8° F (−22° C), the lowest minimum being −21° F (−29° C). At this time during the day, in areas sheltered from strong winds that blow at more than 100 miles an hour, the sun is often pleasantly warm, even at that altitude.

There are two periods of wet weather—the winter rains and the rains brought by the southwest monsoon winds. Winter precipitation is due to the depressions advancing into India from the west, causing heavy falls of snow. Within the regions where western disturbances are felt, condensation takes place in upper air levels at a height of 10,000 feet from the surface; as a result, precipitation is much greater over the high mountains. It is at this season that snow accumulates around the Himalayan high peaks and that the Western Himalayas receive more rain than the Eastern Himalayas. In January, for example, Mussoorie in the west receives almost three inches, while Darjeeling to the east receives less than an inch. By the end of May, meteorological conditions are reversed. Southwest monsoon currents passing over the Eastern Himalayas reach heights of 18,000 feet; in June, therefore, Darjeeling receives about 24 inches, and Mussoorie less than eight inches. The rains cease in September, after which the finest weather in the Himalayas prevails until the beginning of winter in December.

Plant and animal life. *Plant life.* Himalayan vegetation can be broadly classified into four groups: tropical,

Types of vegetation

subtropical, temperate, and alpine. This division is based mainly on altitude and rainfall. Local variations in relief and climate, as well as exposure to sun and winds, cause considerable variation in the composition of the vegetation within each group. Tropical evergreen rain forest is confined to the humid foothills of the Eastern and Central Himalayas. The evergreen dipterocarps—a group of timber- and resin-producing trees—are common; their different species grow on different soils and on hill slopes of varying steepness. *Mesua ferrea* (rose chestnut) occurs on porous soils at altitudes between 600 and 2,400 feet; bamboos grow on very steep slopes; oaks and chestnuts grow on the lithosol, covering sandstones from Arunachal Pradesh westward to central Nepal at altitudes of from 3,600 to 5,700 feet. Alder trees grow along the watercourses on the steeper slopes. At higher elevations they are succeeded by mountain forests in which the typical evergreen is *Pandanus furcatus*, a type of screw pine. Besides these trees, some 4,000 species of flowering plants, of which 20 are palm, are estimated to occur in the Eastern Himalayas.

With the decrease of rainfall and the increase of altitude westward, the rain forests give place to tropical deciduous forests, where the timber tree, sal, is the dominant species, thriving best on high plateaus at 3,000 feet (wet sal), as well as higher up, at 4,500 feet (dry sal). Westward, steppe forest (*i.e.*, forest on an extensive plain), steppe, subtropical thorn steppe, and subtropical, semidesert vegetation occur successively. Temperate forests extend from about 4,500 to about 11,000 feet and contain conifers and broad-leaved temperate trees. Evergreen forests of oaks and conifers have their westernmost outpost on the hills above Murree, some 30 miles northwest of Rāwalpindi, in Pakistan; these are typical of the Lesser Himalayas, being conspicuous on the outer slopes of the Pīr Panjāl, in Kashmir, India. *Pinus roxburghi* (chir pine) is the dominant species at altitudes of from 2,700 to 5,400 feet. In the inner valleys this species may occur even at an altitude of 6,300 feet. Deodar cedar, a highly valued timber tree, is another species particular to the Himalayas, occurring mainly in the western part of the range. Stands of this species occur between 6,300 and 9,000 feet and also tend to grow at still higher altitudes in the upper valleys of the Sutlej and the Ganges. Of the other conifers, blue pine and spruce make their appearance between about 7,300 and 10,000 feet.

Alpine plants

The alpine zone begins above the tree line between 10,500 and 11,700 feet and extends as far as 13,700 feet in the Western Himalayas and 14,600 feet in the Eastern Himalayas. In this zone all the wet and moist alpine vegetation is to be found. Juniper is widely distributed, preferring sunny sites, steep and rocky slopes, and drier areas; on Nānga Parbat they are found even at an altitude of 12,750 feet. Rhododendron occurs everywhere but more abundantly in the wetter parts of the Eastern Himalayas, where it grows in all sizes from trees to low scrub. Mosses and lichens grow in shaded areas at lower levels where the humidity is high; flowering plants occur at high altitudes, especially on Nānga Parbat and Mt. Everest.

Animal life. The animal life of the Eastern Himalayas is derived mainly from that of the South Chinese and Indo-Chinese region. It is primarily the type of animal life found in the tropical forest and is only secondarily adapted to the subtropical, mountain, and temperate conditions prevailing at higher altitudes and in the drier western areas. The animal life of the Western Himalayas, however, has more affinities with that of the Mediterranean, Ethiopian, and Turkmenian regions. The past presence in the region of some African animals, such as the giraffe and the hippopotamus, can be inferred from fossil remains in the Siwalik deposits of the Outer Himalayas. The animal life at higher altitudes above the tree line consists almost exclusively of species, adapted to the cold, that have originated in the area, having evolved from the wild life of the steppes (extensive plains) after the Himalayan uplift. Elephants, bison, and rhinoceroses are restricted to certain areas of the forested *terai* (moist or marshy lands, now largely drained) at the base of the low hills in the Outer Himalayas. The Indian rhinoceros was once abundant all over the foothill zone of the Himalayas but is now becoming extinct; the musk deer and the Kashmir stag, or hangul, are also on the point of extinction. The Himalayan black bear, the clouded leopard, the langur monkey (a long-tailed Asian monkey), and the cat are some of the other denizens of the Himalayan forests. Himalayan goat antelopes are also found.

Exotic game animals

In higher altitudes above the tree line, the snow leopard, the brown bear, the red panda, and the Tibetan yak can occasionally be seen. The yak has been domesticated and is used as a beast of burden in Ladākh. The typical inhabitants of higher altitudes above the tree line are, however, diverse types of insects, spiders, and mites, which form the only animal life that can live as high up as 20,700 feet.

Catfish of the genus *Glyptothorax* live in most of the Himalayan streams, on the banks of which is found the Himalayan water shrew. Lizards of the genus *Japalura* are widely distributed. *Typhlops*, a genus of blind snake, is common in the Eastern Himalayas. The butterflies of the Himalayas are extremely varied and beautiful, especially the genus *Troides*.

The bird life is equally rich but is more in evidence in the east than in the west. Among some of the common Himalayan birds are different species of magpie—the black-rumped, the blue, and the racket-tailed; titmouse; chough (related to the jackdaw); whistling thrush; and redstart. A few strong fliers, such as the lammergeier (bearded vulture), the black-eared kite, and the Himalayan griffon (an Old World vulture), can also be seen in Sikkim. The snow partridge and the Cornish chough are found at elevations of 18,600 feet.

The people. Of the three principal ethnic types in the Indian subcontinent—the Indo-Aryan, the Mongolian, and the Dravidian—the first two are well represented in the Himalayas, although mixed in varying proportions in different areas. Waves of immigration into the mountains have occurred from all directions in the past and have caused intermingling of peoples. Generally speaking, the Great Himalayas and the Tethys Himalayas are inhabited by Tibetan and other Mongoloid people; the Lesser Himalayas are the home of the tall, fair Indo-Aryans. In the Outer Himalayan region of Jammu and Kashmir the Indo-Aryans are called Dogras and are divided into two main castes, Brahmins and Rājputs. In the Kashmir Valley the same type is represented by the Kashmīrī people. The Gaddis and Gūjars, who live in the hilly areas of the Lesser Himalayas, also belong to the Aryan type. The Gaddis are essentially a hill people; they possess large flocks of sheep and herds of goats and come down with them from their snowy abode in the Outer Himalayas only in winter, returning again to the highest pastures in June. The Gūjars are a migrating, pastoral people living from their herds of sheep, goats, and a few cattle, for which they seek pasture at various altitudes.

The Champa, Ladākhī, Balti, and Dard peoples live to the north of the Great Himalayan Range in the Kashmir Himalayas; the Dard are Aryan, the others Mongoloid. The Champa lead a nomadic pastoral life in the Upper Indus Valley. The Ladākhī have settled on terraces and alluvial fans flanking the Indus in Kashmir. The Balti have spread farther down the Indus Valley and have adopted Islām.

The Aryan racial type is represented by the Kanets in Himachal Pradesh and the Khāsas in Utturakhand. In Himachal Pradesh the majority of the inhabitants of Kinnaur and Lāhul-Spiti districts are Mongoloid, having immigrated from Tibet.

In Nepal, the Tibeto-Nepalese and Indo-Nepalese form the two main ethnic divisions, which are further subdivided into a large number of ethnic groups, including the Newārs, the Tamangs, the Gurungs, the Magars, the Sherpas, and the Kirāts. The Kirāts were the earliest inhabitants of the Nepal Valley. The Newārs are also one of the earliest Nepalese groups. The Tamangs inhabit the high valleys of Ganesh Himal (Nepal, southwest of Himachal Pradesh). The Gurungs live on the southern slopes of the Annapūrna Massif (mountain mass), pastur-

ing their cattle as high as 12,000 feet. The Magars inhabit western Nepal but migrate seasonally to other parts of the country. The Sherpas, who live to the south of Mt. Everest, are famed mountaineers.

The people of Sikkim belong to three distinct ethnic groups—the Lepchās, the Bhotiyas (Bhutias), and the Nepalese. Generally speaking, Nepalese and Lepchās live in western Bhutan and Bhotiyas of Tibetan origin in eastern Bhutan. Arunachal Pradesh is the homeland of several groups—the Abors or Adis, Akas, Apa Tanis, Daflas, Khamptis, Khowas, Mishmis, Mombas, Miris, and Singpho. Ethnically, all these groups are Indo-Mongoloid; linguistically, they are Tibeto-Burman. Each group lives in a distinct river valley, practicing shifting cultivation (*i.e.*, constantly changing the land on which they raise crops).

Early explorations

Mapping. The first Himalayan sketch map of some accuracy was drawn up by Father Antonio Monserrate, a Spanish missionary to Akbar's court in 1590. In 1733 a French geographer, Jean-Baptiste Bourguignon d'Arville, compiled the first map of Tibet and the Himalayan range based on systematic exploration. In the middle of the 19th century, the Survey of India organized a systematic program to measure correctly the heights of the Himalayan peaks. The Nepal and Uttarakhand peaks were observed and mapped between 1849 and 1855. Nānga Parbat, as well as the peaks of the Karakoram to the north, were surveyed between 1855 and 1859. The surveyors did not allot individual names to the innumerable peaks observed but designated them by figures and roman numerals. Thus, at first Mt. Everest was simply labelled as "h"; this was later changed to Peak XV in 1849–50. Not until 1856 were the computations sufficiently advanced for it to be realized that Peak XV was higher than any other peak in the world. By 1862 more than 40 peaks of 18,288 feet and above had been climbed for surveying purposes.

In the early 1970s the Survey of India was preparing large-scale maps of the Himalayas from aerial photographs. Parts of the Himalayas have also been mapped by German geographers and cartographers with the help of ground photogrammetry.

Transport. The difficulty of transport in the Himalayas has always constituted a barrier to economic growth. Only in recent years have new highways been built, making the Himalayan region accessible from both the north and the south. Of these, the 75-mile, all-weather Tribhuvan Rajpath road connecting Kāthmāndu, capital of Nepal, with India and the 65-mile road connecting Kāthmāndu with Kodari, on the Tibetan border, deserve special mention. The Hindustān–Tibet road—Indian National Highway No. 22—which passes through Himachal Pradesh has also been considerably improved by the government of India; this 300-mile highway, which runs through Simla, once the summer capital of India, connects the Punjab plains with the Indo-Tibetan border near the Shipki La (pass). There are only two main railroads, both of narrow gauge, penetrating into the Lesser Himalayas from the plains of India—one in the Western Himalayas, between Kālka and Simla, and the other in the Eastern Himalayas, between Silīguri and Darjeeling. There is another narrow-gauge line in Nepal, running 29 miles from Raxaul to Amlekhganj and connected with Kāthmāndu by an electrically operated aerial cableway, which transports cargo in baskets. Two other short railroads run to the Outer Himalayas—one, the railroad of the Kulu Valley, from Pathānkot to Jogindarnagar; the other from Hardwār to Dehra Dūn. A short railway, formerly running between Wazīrābād and Jammu through Siālkot, is now permanently closed.

There are two major airstrips in the Himalayas—one at Gaucher, Kāthmāndu, capital of Nepal, and the other in Srīnagar, capital of Kashmir—which are served by national and (except Srīnagar) international airways. Besides these, there are also many airstrips of local importance in the hills and in the *terai* district of Nepal. In Nepal there are 650 miles of dirt road, 200 miles of paved road, 50 miles of railroads, and 42 miles of aerial ropeway.

From the Punjab plains the only direct approach to the Vale of Kashmir is by the National Highway No. 1A from Jullundur to Uri through Jammu, Banihāl, Srīnagar, and Bāramūla. It crosses the Pīr Panjāl Mountains through a tunnel at Banihāl. The old road from Rāwalpindi to Srīnagar through Pakistan has lost much of its former importance. Within the Kashmir Himalayas, the 235-mile Srīnagar to Leh road is the longest. It was built in 1960 and connects Leh in Ladākh with the Nubra Valley, passing over the 17,730-foot-high Khardung La —the first of the high passes on the historic caravan trail to Central Asia from India. Many other new roads have been built in recent years.

Sikkim commands the historic Kālimpong to Lhasa caravan trade route, which passes through Gangtok. Before 1956, there was only one (30-mile) motorable highway running between Gangtok and Rongphu, on the Tista River near the Sikkim–West Bengal border, which then continued southward to Silīguri for another 70 miles. Since then, several roads passable by jeep have been built in the southern part of Sikkim, and some 95 miles of highway have been built in northern Sikkim, connecting Gangtok with Lachen (Lachung). A ropeway from Gangtok to Sherathang, south of the Nathu La Pass, is also in operation.

Bhutan has a 120-mile road, constructed in 1962, connecting Phuntsoling on the West Bengal–Bhutan border to Paro in western Bhutan; a 20-mile bifurcated extension runs northward to Thimphu, the capital. There are also aircraft-landing facilities at Paro and Thimphu.

Arunachal Pradesh is connected with the Brahmaputra Valley by roads running from Namsai to Chowkham, Sadiya to Roing, Pāsighāt to Dibrugarh, Along to Sonarighat, North Lakhimpur to Hapoli, and Tezpur to Bomdila.

Arable lands, minerals, and water resources

Economic resources. The Himalayas abound in economic resources. These include rich arable land, extensive grassland and forest, workable mineral deposits, and easily harnessable waterpower. The most productive arable lands in the Western Himalayas are in the Vale of Kashmir, the Kāngra Valley, the Sutlej Basin, and the terraces flanking the Ganges and Yamuna in Utterakhand; these produce 1,600,000 tons of cereals—rice, corn (maize), wheat, and millet—each year. In the Central Himalayas in Nepal most of the arable land is in the foothills and on the adjacent plains; this land produces four-fifths of the total rice production of the country, amounting to 1 percent of world production. The region also produces large crops of corn and wheat. In addition to cereals, most of the cash crops of the country—jute, sugarcane, and oilseeds—are grown in this region.

Most of the fruit orchards of the Himalayas lie in the Vale of Kashmir and in the Kulu Valley of Himachal Pradesh. Such fruit as apples, peaches, pears, and cherries, for which there is a great demand in the cities of India, are grown extensively. There are rich vineyards on the shores of Dal Lake in Kashmir, which produce grapes of good quality from which wine and brandy are made. On the hills surrounding the Vale of Kashmir grow walnut and almond trees, the nuts of which are exported to India where oil is extracted from them. Bhutan also has fruit orchards and exports oranges to India.

Of the plantation crops, tea is grown mainly on the hills and on the plain at the foot of the mountains in the Darjeeling district. Tea in limited quantity is also grown in the Kāngra Valley. Plantations of cardamom, a spice used in curry, are to be found in Sikkim, Bhutan, and the Darjeeling Hills. Medicinal herbs are grown in plantations in the Uttarkāshi and Pithorāgarh districts of Uttarakhand.

Transhumance (the seasonal migration of livestock) is widely practiced during the summer months in the Himalayas pastures, called *margs*, in Kashmir. Sheep, goats, and yak are raised on the rough grazing lands available.

Woodlands occupy at least one-third of the Himalayas, covering more than two-thirds of the total area of Bhutan and Sikkim. They constitute the greatest asset of the

mountains, although their fuller use is hampered because of inaccessibility. Logs of timber are floated down the Himalayan streams to sawmills located at the foot of the mountains. Forest-based industries, to manufacture matches, rayon, and paper pulp, are being established in Bhutan.

The Himalayas are rich in minerals, although their exploitation is restricted to the more accessible areas. Jammu and Kashmir state is the most mineralized region. Sapphires are found in the Zāskār Mountains, and alluvial gold in the nearby bed of the Indus. There are deposits of copper ore in Baltistān, and iron ores are found in the Vale of Kashmir. Ladākh contains borax and sulfur deposits.

The coal deposits of the Jammu Hills have an estimated reserve of 100,000,000 tons. Bauxite occurs in Jammu and Kashmir. Nepal, Bhutan, and Sikkim have extensive deposits of coal, mica, gypsum, and graphite and ores of iron, copper, lead, and zinc.

The Himalayan rivers have a tremendous hydroelectric potential, which has been harnessed more intensively since the five-year plans were introduced in the 1950s in India. The biggest multipurpose river-valley project is located at Bhākra-Nāngal on the Sutlej River in the Outer Himalayas; completed in 1963, it has a storage capacity of 348,218,000,000 cubic feet of water and a total installed capacity of 1,050 megawatts. Three other Himalayan rivers, the Kosi, Gandak, and Jaldhāka, have been harnessed by India, which then supplies the power to Nepal and Bhutan.

Hindenburg, Paul von

Paul von Hindenburg, a German field marshal in World War I, later became the second president of Germany's postwar Weimar Republic. Without special military or political qualifications, Hindenburg is usually said to have attained these posts largely because of his impressive bearing, suggesting great inner strength and calmness of mind. He thus met an apparently deeply felt need for a father figure during the crisis-ridden war and postwar years from 1914 to 1933.

Culver Pictures

Hindenburg

Paul Ludwig Hans Anton von Beneckendorff und von Hindenburg was born in the Prussian town of Posen (Poznán, Poland) on October 2, 1847. On his father's side he came from old Prussian Junker (aristocratic) stock; on his mother's, from a middle-class family—a fact he preferred to ignore but that may help account for his cautious, adaptable ways. A cadet at the age of 11, he served in the Austro-Prussian (Seven Weeks') War of 1866 and in the Franco-German War of 1870–71. In due time he was promoted to general, retiring in 1911 after an honourable but not especially distinguished career.

Hindenburg was called back into service in August 1914 to be the nominal superior of Maj. Gen. Erich Ludendorff. Acclaimed as one of the army's best strategists, Ludendorff was to drive a Russian invasion force from East Prussia. For this achievement, the rocklike Hindenburg, rather than Ludendorff, received the nation's applause. Soon Hindenburg's standing overshadowed that of Emperor William II; he was promoted to the rank of field marshal general, and in 1916 the Emperor was pressured into giving him command of all German land forces, with Ludendorff his coresponsible chief aide. Unable to win the war on land, they tried starving Britain into surrender by unrestricted submarine warfare, thus drawing the United States into the war and causing Germany's ultimate defeat. When they conceded defeat, Hindenburg let Ludendorff take the blame.

World War I commander

After the overthrow of William II, Hindenburg collaborated briefly with the new republican government. He directed the withdrawal of German forces from France and Belgium and had his staff organize the suppression of left-radical risings in Germany. With both tasks accomplished (and the old officer corps preserved in the process), he retired once more in June 1919. Living quietly in Hanover, he occasionally expressed antirepublican

views, but, on the whole, cultivated his image of nonpartisan national stature.

In April 1925, after the death of Friedrich Ebert, Hindenburg was elected the republic's second president, despite his professed monarchism. He adhered, if not to the spirit, then at least to the letter of the republican constitution. Yet his personal confidants, among them especially Maj. Gen. Kurt von Schleicher, longed for a new authoritarian regime and urged him to use his prestige and render the government more independent of parliamentary controls. Though tired of the frequent Cabinet crises, Hindenburg, fearful of any unconstitutional action and of added responsibilities, procrastinated.

When the depression set in and the government again broke up, he did appoint a Cabinet resting on his, rather than on the Reichstag's (parliament's) confidence. He authorized Chancellor Heinrich Brüning to dissolve the Reichstag should it prove uncooperative and promised to issue emergency decrees in lieu of Reichstag-enacted laws. The Reichstag was dissolved in July 1930; new elections produced an even less cooperative successor in which the antiparliamentarian National Socialists emerged as the second largest party. Brüning now governed almost exclusively by decree. Since the president's signature was required on each decree, however, Hindenburg could veto any governmental decision. Increasingly feeble, moody, and influenced by his military and landowning friends, the Marshal forced the government to spend huge amounts on the army and navy and hopelessly indebted estates at the expense of unemployment relief and other imperative needs. At the same time, Brüning's deflationist policies aggravated the economic difficulties. Unrest, sparked above all by the Nazis, kept mounting.

When Hindenburg's presidential term expired in April 1932, he ran again for the presidency as the only candidate who could defeat Hitler. He was re-elected, but mainly by the support of Brüning's Catholic Center Party and the Social Democrats, rather than the conservative nationalist circles, to whom he felt closest and who now supported Hitler. Those who did vote for him clung to him as a bulwark against Nazi lawlessness and brutality. Yet the President's confidants considered the Nazis a useful, if unpleasant, movement with whom they were sure they could come to terms. They saw in Brüning an obstacle to such an accommodation and persuaded the Marshal to dismiss the Chancellor, who had just helped to re-elect him.

Two governments, one headed by Franz von Papen, a former cavalry officer, the other by Schleicher, failed to win the support of the Nazis. Hitler insisted on becoming chancellor in any government in which his party participated, but, despite a deluge of petitions and letters, Hindenburg, who distrusted the Führer's noisy aggressiveness, would not concede him that post. In November 1932, however, when the Nazis lost 10 percent of their vote in new Reichstag elections, Papen and Hitler agreed on forming a government with Hitler as chancellor, Papen as vice chancellor, and non-Nazis in most other posts. Hindenburg was assured by Papen that Hitler could easily be controlled. When Schleicher failed in his efforts to obtain parliamentary support for his government, Hindenburg, frustrated and tired, asked for his resignation. On January 30, 1933, Hindenburg appointed Hitler chancellor of a new Cabinet in which only two other Nazis, Wilhelm Frick and Hermann Göring, held offices.

Hindenburg and Hitler

Papen's safeguards proved ineffective. Hitler quickly secured almost unlimited political power through terror, manipulations, and false promises. Hindenburg on his part accommodated himself to the new situation and, in effect, became a warm supporter of Hitler, although making an occasional innocuous gesture that seemed to set him apart from the Führer and the Nazi Party. He died on August 2, 1934, still a revered, though by then rather remote, national figure.

Hinduism

Hinduism consists of the beliefs, practices, and socio-religious institutions of the South Asian peoples known as Hindus, principally the peoples of India and parts of Pakistan, Ceylon, Nepal, and Sikkim. Hinduism also has a following among overseas Hindu communities that are situated in parts of Southeast Asia, East and South Africa, Surinam, and in islands such as Fiji, Mauritius, and Trinidad.

This article is divided into the following topics:

I. General nature and characteristic features

The name Hinduism means the civilization of the Hindus (originally, the inhabitants of the land of the Indus River). Introduced *c.* 1830 by English writers, it properly denotes the Indian civilization of approximately the last 2,000 years, which gradually evolved from Vedism, the religion of the ancient Indo-European peoples who settled in India in the last centuries of the 2nd millennium BC. Because it integrates a large variety of heterogeneous elements, Hinduism constitutes a very complex but largely continuous whole, and since it covers the whole of life, it has religious, social, economic, literary, and artistic aspects. As a religion, Hinduism is an utterly diverse conglomerate of doctrines, cults, and ways of life.

The distinction between the level of popular belief and that of elaborate ritual technique and philosophical speculation is very marked and attended by many stages of transition and varieties of coexistence. Primitive magic and fetishism, animal worship, and belief in demons occur beside, and often combined with, the worship of more or less personal gods, as do mysticism, asceticism, and abstract and profound theological systems or esoteric doctrines. For example, worship of female local deities does not, in the same milieu, exclude the belief in pan-Indian higher gods or even in a single High God. Such deities are also frequently looked upon as manifestations of a High God.

Religious tolerance

In principle, Hinduism incorporates all forms of belief and worship without necessitating the selection or elimination of any. The Hindu is inclined to revere the divine in every manifestation, whatever it may be, and is doctrinally tolerant, leaving others—including both Hindus and non-Hindus—whatever creed and worship practices

suit them best. A Hindu may embrace a non-Hindu religion without ceasing to be a Hindu, and since the Hindu is disposed to think synthetically and to regard other forms of worship, strange gods, and divergent doctrines as inadequate rather than wrong or objectionable, he tends to believe that the highest divine powers complement each other for the well-being of the world and mankind. Few religious ideas are considered to be finally irreconcilable. The core of religion does not even depend on the existence or nonexistence of God or on whether there is one god or many. Since religious truth is said to transcend all verbal definition, it is not conceived in dogmatic terms. Hinduism is, then, both a civilization and a conglomerate of religions, with neither a beginning, a founder, nor a central authority, hierarchy, or organization. Every attempt at a specific definition of Hinduism has proved unsatisfactory in one way or another, the more so because the finest Indian scholars of Hinduism, including Hindus themselves, have emphasized different aspects of the whole.

COMMON CHARACTERISTICS OF HINDU BELIEF

There are, however, some—noncumulative and not even universally applicable—characteristics by which, it is said, a Hindu may be recognized.

Doctrine of Atman-Brahman. First, there is the belief in an uncreated, eternal, infinite, transcendent, and all-embracing principle, which, "comprising in itself being and non-being," is the sole reality, the ultimate cause and foundation, source, and goal of all existence. This ultimate reality is called Brahman. As the All, Brahman causes the universe and all beings to emanate from itself, transforms itself into the universe, or assumes its appearance. Brahman is in all things and is the Self (Ātman) of all living beings. Brahman is the creator, preserver, or transformer and reabsorber of everything. Though it is Being in itself, without attributes and qualities and hence impersonal, it may also be conceived of as a personal High God, usually as Viṣṇu (Vishnu) or Śiva (Shiva), who is characterized by sublime and adorable qualities. This fundamental belief in, and the essentially religious search for, ultimate reality, thus conceived—*i.e.*, for the One that is the All—have continued almost unaltered for over 30 centuries and have been the central focus of India's spiritual life.

Identity of individual self and the sacred

Concepts of iṣṭadevatā and Trimūrti. Although those Hindus who particularly worship either Viṣṇu or Śiva generally consider one or the other as their "favourite god" (*iṣṭadevatā*) and as the Lord (Īśāna) and Brahman in its personal aspect, Viṣṇu is often regarded as a special manifestation of the preservative aspect of the Supreme and Śiva as that of the "destructive" function. Another deity, Brahmā, the personification of the impersonal Brahman, remains in the background as a demiurge. These three great figures (Brahmā, Viṣṇu, and Śiva) constitute the so-called Hindu Trinity (Trimūrti, "the One or Whole with three forms"). This conception attempts to synthesize and harmonize the conviction that the Supreme Power is singular with the plurality of gods in daily religious worship. Although the concept of the Trimūrti assigns a position of increasing importance to some great gods, it never has become a living element in the religion of the masses. Moreover, Brahmā since ancient times has had no cult worth mentioning, and many Hindus worship neither Śiva nor Viṣṇu but one or another of the innumerable other Hindu gods.

Authority of the Veda and the Brahmin class. Another characteristic of Hindu belief is recognition of the Veda, the most ancient body of religious literature, as an absolute authority revealing fundamental and unassailable truth. At the same time, however, its content—*i.e.*, the Eternal Reality as Word—has long been practically unknown, so that even though it is venerated from a distance by every traditional Hindu and even though those Indians who reject its authority (such as Buddhists and Jains) are regarded as unfaithful to their tradition, it is, in fact, hardly drawn upon at all, not even for edification.

Also characteristic of Hinduism is the belief in the sacrosanctity of the Brahmins, a noble class possessing spiritual supremacy by birth. As special manifestations of Brahman and "bearers" and teachers of the Veda, Brahmins are considered to represent an ideal norm of ritual purity and social prestige. This characteristic of Hinduism is, however, losing its importance in modern times, especially in north India.

Ahiṃsā: respect for life. Further characteristics include vegetarianism and the application of the *ahiṃsā* idea to animal life. *Ahiṃsā*, consisting in respect of and consideration for life and fellow feeling with all living beings, is based on belief in the unity of all life. One of the cardinal virtues of Indian humanity, *ahiṃsā* is, according to Indian thinkers, the keystone of their ethics. Thus the protection and veneration of the cow are deemed especially important. On the other hand, about a quarter of the population do not hold eating of beef in abomination, and the double doctrine of *ahiṃsā* and vegetarianism has never found full acceptance.

Doctrines of transmigration and karman. Rarely disputed and thus generally accepted by Hindus are the doctrine of transmigration and rebirth and its complement, the belief in *karman*—that is, of previous acts, as the factor that determines the condition into which a being, after a stay in heaven or hell, is reborn. The whole process of rebirths is called *saṃsāra*, and the beings entrapped in it wander through a restless and unending stream of periodic returns to life in one form or another. Any earthly process is viewed as cyclic, and all worldly existence is subject to the cycle. *Saṃsāra* has no beginning and, in most cases, no end; it is not a cycle of progress or a process of purification but a matter of perpetual enslavement. The *karman*, acting like a clockwork that, while running down, always winds itself up, binds the *ātmans* (selves) of beings to the world, compelling them to go, in unremitting restlessness, through an endless series of births and deaths. This belief is indissolubly connected with the traditional Indian views of society and earthly life. It has given rise to an acquiescence that may verge upon fatalism—the belief that any misfortune is the effect of *karman*, of one's deeds, and so one's own doing—and to the conviction that the course of world history is conditioned by the collective *karman*.

Saṃsāra liberation

Such doctrines also encourage the view that mundane life is not true existence (the so-called Indian pessimism) and that human endeavour ought to be directed toward a permanent interruption of the mechanism of *karman* and transmigration—that is, toward final emancipation (*mokṣa*), toward escaping forever from the impermanence that, clouding all joy of living, is an inescapable feature of mundane existence. In this view there can be no other goal of this effort than the only permanent and eternal principle, the Holy, the One, God, Brahman, which is totally opposite to any phenomenal existence. Anyone who has not fully realized that his being is identical with Brahman is thus seen as afflicted, wretched. The only possible solution consists in the sudden realization that the kernel of human personality (*ātman*) really is Brahman and that it is man's very attachment to worldly objects that prevents him from reaching salvation and eternal peace. (Hindus sometimes use the largely Buddhist term Nirvāṇa to describe this state.)

THREE MARGAS: PATHS TO SALVATION

There is much difference of opinion among Hindus about the way (*mārga*) to final emancipation (*mokṣa*). Three paths to salvation (variously valued but nonexclusive) are presented in an extremely influential religious text, the *Bhagavadgītā* ("The Lord's Song"; *c.* 200 BC), according to which it is not acts themselves but the desire for their results that produces *karman* and thus enslavement. These three ways to salvation are (1) the *karma-mārga* ("the path of duties"), the disinterested discharge of ritual and social obligations; (2) the *jñāna-mārga* ("the path of knowledge"), the use of meditative concentration preceded by a long and systematic ethical and contemplative training—*yoga*—to gain a supra-intellectual insight into one's identity with Brahman; and (3)

the *bhakti-mārga* ("the path of devotion")—*i.e.*, devotion to a personal God. These ways are regarded as adapted to various types of men.

Although the search for *mokṣa* has never been the ideal of more than a small minority of Hindus, liberation has been for all a religious norm by which their lives were affected. For *mokṣa* has determined not only the hierarchical values of Indian social institutions and religious doctrines and practices but also the function of Indian philosophy, which is to discuss what man ought to do in order to find true happiness and what he has to realize, in direct experience, in order to escape from *saṃsāra* (bondage) and obtain spiritual freedom. While those who have not been reached by Brahmin thought have only vague ideas about the doctrines of *karman* and *mokṣa*, in semipopular milieus these doctrines gave rise to much speculation.

For the ordinary Hindu, the main aim of worldly life lies in conforming to social and ritual duties, to the traditional rules of conduct for his caste, family, and profession. Such requirements comprise an individual's *dharma* (law and duties); *i.e.*, that stability, law, order, and fundamental equilibrium in the cosmos, nature, and society that should not be infringed for fear of undesirable results. *Sanātana* (traditional) *dharma*—a term used by Hindus to denote their own religion—is a close approximation to "religious practices" in the West. Religion for Hindus is thus mainly a tradition and a heritage, a way of life and a mode of thought. In practice, it is the right application of methods of securing welfare in this life and a good condition in the hereafter.

Dharma: comprehensive system of duties, morals, and religious law

II. Forms of Hinduism

The several forms of Hinduism may be conveniently grouped into the following categories: (1) Vedism, the religion of the earliest Indo-European peoples who settled in India in the last quarter of the 2nd millennium BC and named after their sacred texts known collectively as the Veda; (2) Brahmanism, the religion into which Vedism gradually grew, deriving its name from both its ancient Brahmin priestly elite and the Supreme God Brahman, whom they worshipped; (3) Vaiṣṇavism (Vaiṣṇava), later sectarian cult forms that regard Viṣṇu or his earthly incarnations as the Supreme Being; (4) Śaivism (Śaiva), rival religious forms that regard Śiva as supreme; (5) Tantrism (Tantra) and Śāktism (Śākta), esoteric, magical, and devotional developments within various religious forms; and (6) folk Hinduism, an amalgam of numerous local folk beliefs and practices that have notable continuities with and differences from the other forms of Hinduism. Modern developments require separate treatment, not only because of new religious forms but also because of new amalgams of earlier forms.

VEDISM AND BRAHMANISM

Vedism, or the Vedic religion, is the earliest known form of religious practice of the ancient Indo-Aryan settlers of India. What is known of Vedism is derived from surviving texts of the Veda and certain ritual practices still performed by India's Brahmin elite. Vedic religion consisted principally of two categories of ritual practice: (1) domestic rites, known as *gṛhya*, and (2) great sacrifices and other communal rites, known as *śrauta*. Much of Vedism has died out, and whatever of it has survived has become so integral a part of Hinduism that it is no longer distinguishable as a separate element. Many features of Hinduism, however, have their roots in the Vedic past; and some characteristic ideas inherited from that past and developed in a few main currents—primarily theories of salvation—have up to the present time largely determined the character of the Indian view of life and the world.

The Veda is considered to be eternal, not even created or revealed by a god or gods, whose only task has been to promote the inspiration of gifted men (*ṛṣi*, or *rishi*, "seers") of archaic times who were able to "see" this eternal truth directly, without the intermediary of normal sense perception, and to express it in a human language, Sanskrit. Because of this origin and their character as bearers of supranormal power, the metrical portions (*mantra*) of the Vedic corpus are regarded, when solemnly recited and accompanied, as an infallible means of coming into contact with the unseen.

The sacred: nature, man, and God. The contact with the unseen or sacred also included man's contributions by ritual acts to the maintenance of the universe—of which Vedic man felt he was an indissoluble part—and to the periodic regeneration, through sacrificial practices, of both the powers for good and the cosmic processes that make earthly life and welfare possible. Vedic man was deeply convinced that the world is an actually existing organized cosmos (*sat*) governed by order and truth (*ṛta*) and that it is always in danger of being damaged or destroyed by the powers of chaos (*asat*). This conviction found mythological expression in the continual conflict between gods (*devas*) and demoniac antigods (*asuras*).

Ṛta: cosmic order

Gods were conceived as presiding over certain provinces of the universe or as responsible for important cosmic or social phenomena. Their deeds are timeless and exemplary presentations of mythic events replete with power and universal, eternal significance. To reproduce themselves in time and thus retain their vitality and efficacy, mythical events need repeating—that is, celebration and confirmation by means of the spoken word and ritual acts. Since the Vedic gods were not fully anthropomorphic—many minor deities are hardly distinguishable from impersonal powers—they were often representatives of natural functions, and not individuals, and the functions were liable to various applications and interpretations. Thus Indra, the greatest and most anthropomorphic god of the early Veda, was, in the view of the noble patrons of the Vedic poets, primarily a fighter and a warrior god invoked to bring booty and victory. Agriculturalists, however, emphasized Indra's fecundity, celebrating until recent times his very ancient festivals to produce fertility, welfare, and happiness. Indra, however, was essentially a representative of useful force in the cosmos and nature and the great champion of an ordered and habitable world. He won repeated victories over the snake-demon Vṛtra, the representative of obstruction and chaos, and these resulted in the separation of heaven and earth (the support of the former and the stabilization of the latter), the rise of the sun, and the release of the waters: in short, in the organization of the universe.

Vedic and Brahmanic theological principles and rites. Vedic religion—as it is now known—is primarily a liturgy differentiated in various types of ritual designed for almost any conceivable purpose. These rites are described in ritual handbooks (*sūtra*) in the minutest detail—no operation, no gesture, no formula is meaningless or left to an officiant's discretion. On the basis of a complicated speculative system, all are explained and shown to be effective in later prose works called *Brāhmaṇas*. The often very complicated ritual technique was devised mainly to safeguard man's life and survival, to enable him to face the many risks and dangers of existence, to thwart the designs of human and superhuman enemies that cannot be counteracted by ordinary means, to control the unseen powers, and to establish and maintain beneficial relations with the supramundane sacred order. Belief in the efficacy of the rites was the natural consequence of the belief that all things and events are connected with or participate in one another. Hence it was also believed that a close correspondence exists between a sacred place—for instance, the sacrificial place of many Vedic rites or a place of pilgrimage or consecrated area (*maṇḍala*, "circle")—and a province of the universe or even the universe itself. Such places represent, within the reach of the officiants, the universe or as much of it as was relevant. In such places, direct communication with other cosmic regions (heaven, underworld) is possible because they are said to be at the point of contact between this world and the "pillar of the universal," "the navel of the earth." The sacred place is (by virtue of a system of connections) identical with the universe in its various states of emanation from, reabsorption into, integration with, and disin-

Cosmic role of sacred places

tegration from the sacred. This idea has as its corollary the possibility of ritually enacting the cosmic drama and, thus, of influencing, through the same system of connections, those events in the cosmos that continuously affect man's weal and woe.

In the major *śrauta* rites, requiring three fires and up to 16 priests or more, "the man who knows"—he who has an insight into the correspondences (*bandhu*) between the mundane and cosmic phenomena and the eternal transcendent reality beyond them and who knows the meaning of the ritual words and acts—may set great cosmic processes in motion for the sake of human interests. In these rites, Brahmin officiants repeat the mythic drama for the benefit of their patron, the "sacrificer," who, temporarily, becomes its centre and realizes through ritual "symbolism" his identity with the universe. Whatever magical elements may be involved in this ritual technique, its aim in establishing an efficacious contact with a transcendental order that is the source of all life and power is based on an essentially religious conception.

Such officiants are firmly convinced of the efficacy of their rites: "the sun would not rise, were he [the officiant] not to make that offering; this is why he performs it" (*Satapatha Brāhmaṇa* 2. 3. 1. 5). The oblations might not be used to propitiate the gods, even less thank them for favours bestowed. The efficacy of the rites—some of which are sporadically performed up to the present day—did not depend on the will of the gods, who were regents presiding over definite phenomena and were, according to later exegesis, only indispensable, hypothetical entities required as addresses of the oblations to make the acts effective. The offerings do not require the postulation of any High God to whose beneficence the merit earned from performing the ritual should be regarded as due.

The origin of the world is of special interest to the authors of the Ṛgveda, the oldest document. Among its many incomplete and often unsystematic speculations, one came into prominence. In Ṛgveda 10, 90, the phenomenally evolved universe is described as having issued from a primeval Person, Puruṣa, whose origin is not explained. In Puruṣa, God and matter are one; he is the All. Everything existing in the world is only one-quarter of his being; three-quarters of him is immortal and in heaven. It was from this Person, the ultimate reality, who is the universe and transcends it, that the "goddess" Virāj (literally, the one "extending and ruling far and wide") was born. From Virāj (actually the hypostatization of the conception of the universe as an evolving, expanding, and creative whole) Puruṣa arose again in an evolved state. Puruṣa then became the victim in a primeval and exemplary sacrifice performed by the gods, and from his dissected body there arose the particular elements of the phenomenal creation. The poem in the Ṛgveda in which this is dealt with is the first expression of the fundamental Indian idea that creation is the self-limitation of the transcendent—in this instance conceived as a Person—manifesting itself in the realm of human experience.

Puruṣa: primeval cosmic man

In the course of the Vedic period Puruṣa fused with the figure Nārāyaṇa ("Scion of man") and with Prajāpati ("the Lord of Beings"), the patron of procreation in popular belief. In the speculative thought of the ritualists, Prajāpati came to the fore as the creator god and in many respects as the highest divinity, the immortal father even of the gods, whom he transcends and encompasses while molding them into one complex. As the One, the concentrated All, or Totality, Prajāpati was identified with the highest and most general categories. By a process of emanation and self-differentiation (by dividing up himself), he created all beings and the universe. After this "creation," Prajāpati became the disintegrated and differentiated All of the phenomenal world and was exhausted. He then reintegrated himself to prepare for a new phase of creativity by means of a rite. Since the sacred act aims at the restitution of the organic structural norm, which ensures the ordered functioning of the universe, Prajāpati was identified with the rite; by identifying himself with Prajāpati, a sacrificer may temporarily reintegrate within himself what has been disintegrated, and thus restore oneness and totality in himself and the universe.

In the course of the *Brāhmaṇa* period, the fear of the impermanence of religious merit and its loss in the hereafter, as well as the fear-provoking anticipation of the transience of any form of existence after death, culminating in the much-feared repeated death (*punarmṛtyu*), assumed the character of an obsession. The means of escaping and conquering death and of attaining integral life devised in the *Brāhmaṇas* were of a ritual nature, but in one of the oldest *Upaniṣads* (early religio-philosophic texts), the *Bṛhadāraṇyaka Upaniṣad* (6th century BC), more emphasis was laid upon the knowledge of the cosmic connection underlying ritual. When the doctrine of the identity of Ātman and Brahman was established in the *Upaniṣads*, the true knowledge of the "Self" and the realization of this identity was (by those who were inclined to speculative and meditative thought) substituted for the ritual method.

Development of Ātman-Brahman doctrine from ritual speculation

In the following centuries, the main theories connected with the divine essence underlying the world were harmonized and synthetized, and the tendency to extol one god as the supreme Lord and Originator (Īśvara), who at the same time is Puruṣa and Prajāpati and Brahman and the inner Self (Ātman) of all beings, gained ground. For those who worshipped him, he became the goal of identificatory meditation, which leads to complete cessation of phenomenal existence and becomes the refuge of those who seek eternal peace.

Ethical and social doctrines. In Vedic times, "sin" (*enas*) or evil (*pāpman*) was put on a par with illness, enmity, distress, or malediction to the extent that it was conceived of as a sort of pollution that might be neutralized by ritual or devices for averting evil. A man might incur "sin" by any incorrect or improper behaviour, in particular improper speech, and be thus guilty of *anṛta* (*i.e.*, any infidelity to fact or nonconformity with what is true, real, and constitutes the established order) without regard to whether he wittingly or unwittingly had committed a crime. Other transgressions included making mistakes in sacrificing or coming into contact with corpses, ritually impure persons, or persons belonging to the lower classes of society. Such acts were only rarely considered to be misdeeds against a god or violations of moral principles of divine origin, and consciousness of guilt was much more rare than fear of the evil consequences (disease, untimely death, and any other form of mishap). Sometimes, however, a god (Agni, the evil-devouring fire, or Varuṇa, the god of order supposed to punish and fetter the "sinner") was invoked to forgive the neglect or transgression or to release a man from their concrete results. More usually, however, these results were done away with by means of purifications, such as the ceremonial use of water, and a variety of expiatory rites.

To the pure who earned ritual merits, the prospect of a safe "world" (*loka*) or condition was held out. The meticulous effort to purify oneself from every kind of evil also involved the observation of various customs with regard to the avoidance or expiation of inauspicious occurrences (this endeavour is called *śānti*). Ritual purity was the principal concern of the compilers of the manuals of *dharma* (religious law) that, belonging to the sacred tradition (*smṛti; i.e.*, remembered by human teachers), have contributed much to the special character of Hinduism. According to the authorities on *dharma*, ritual purity is the first approach to *dharma*, the resting place of the Veda (Brahman), the abode of prosperity (*śrī*), the favourite of the gods, and the means of clearing (soothing) the mind and of seeing (realizing) the *ātman* in the body.

Importance of ritual purity

VAISNAVISM

Vaiṣṇavism is the worship of Viṣṇu (Vishnu) and his various incarnations (usually said to number ten). During a long and complex development from Vedic times, there arose many Vaiṣṇava groups with differing beliefs and aims. Some of the major Vaiṣṇava groups are the Śrī-

vaiṣṇavas and Dvaitins ("philosophical or religious dualists") of south India, the followers of the teachings of Vallabha in western India, and several Vaiṣṇava groups of Bengal in eastern India who follow teachings derived from those of the saint Caitanya (1485–1533). The majority of Vaiṣṇava believers, however, take what they like from the various traditions (described below) and blend it with various local practices (described under *Folk Hinduism* below).

Views of nature, man, and the sacred. In the Veda, Viṣṇu is the god of far-extending motion and pervasiveness who, for man in distress, penetrates and traverses the spaces to make his existence possible. All beings are said to dwell in his three strides or footsteps (*tri-vikrama*): his highest step, or abode, is beyond mortal ken in his dear and highest resort, the realm of heaven. So Viṣṇu is also the god of the pillar of the universe and identified with the sacrifice. He imparts his all-pervading power to the sacrificer who imitates his strides and so identifies himself with him, conquering the universe and attaining "the goal, the safe foundation, the highest light" (*Śatapatha Brāhmaṇa*).

Composite historical nature of Viṣṇu

In the centuries preceding the beginning of our era, Viṣṇu became the Īśvara (immanent deity) of his special worshippers, fusing with the Puruṣa-Prajāpati figure; with Nārāyaṇa, whose cult discloses a prominent influence of ascetics; with Kṛṣṇa (Krishna), who in the *Bhagavadgītā* revealed a religion of wide catholicity, open to everybody desiring to lead a socially normal life while having a prospect of final liberation; and with Vāsudeva, adored by a group known as the Pāñcarātrins.

Whatever justification the different Vaiṣṇava groups (*e.g.*, the Śrīvaiṣṇavas of south India or the worshippers of Viṣṇu Viṭhobā in Mahārashtra) offer for their philosophical position, all Vaiṣṇavas believe in God as a person with distinctively high qualities and worship him through his manifestations and representations. Vaiṣṇava faith is essentially monotheistic, whether the object of adoration be Viṣṇu Nārāyaṇa or one of his incarnations (*avatāra*s), such as Rāma or Kṛṣṇa. Preference for any one of these manifestations is largely a question of tradition. Thus, the south Indian Śrīvaiṣṇavas mostly prefer Viṣṇu, Rāma, or Śrī (Viṣṇu's consort); the north Indian groups, Kṛṣṇa. The *avatāra* doctrine, in accommodating the cults of various divine or heroic figures within a monotheistic framework, proved a powerful integrating force. Whenever the *dharma* declines and evil and general disaster threaten, God, the protector and preserver of the world, emanates himself and assumes an earthly form to guard the good, to destroy the wicked, and to confirm the *dharma* (*Bhagavadgītā* 4, 6 ff.). The benevolence and beneficial activity of these figures (Rāma, Kṛṣṇa, etc.) is rarely in doubt. In many mythical tales, Viṣṇu is depicted as a versatile figure of great adaptability, able, for instance, to disguise himself as a fascinating young woman in order to trick the *asura*s (antigods) out of the possession of the newly-produced draft of immortality. His absorbing many-sided character was a source of inspiration for various stories in which his figure displays sentimentality and exhibits a view of humanity. Moreover, the scene of his great deeds is usually laid in this world, especially India, in places often mentioned by name. The narratives are full of the miraculous, but their central figures give the impression of human, sometimes all too human, characters whose actions and reactions are within the limits of ordinary understanding.

Avatāras: Viṣṇu's incarnations

The theologians had to assume the task of explaining the relation between God, as the unaffected and unchanging cause of all things, and the universe. According to Rāmānuja (*c.* 1050–1137), a great south Indian thinker of Śrīvaiṣṇava persuasion, Brahman (*i.e.*, God) is a Person with high attributes, the object of a higher knowledge that is the only entrance to salvation. Since an absolute creation is denied, God is viewed as the sole cause of his own modifications; viz., the emanation, existence, and absorption of the universe. Although unlimitedly expansive, God is conceived to be essentially different from everything material, the absolute opposite of any evil, free from any imperfection, omniscient, omnipotent, possessed of all positive qualities (such as knowledge, bliss, beauty, and truth), of incomparable majesty, the inner soul of all beings, and the ultimate goal of every religious effort. The universe is considered a real transformation of Brahman, whose "body" consists of the conscious souls and everything unconscious in their subtle states, if Brahman is viewed as the cause, and of the same in their gross states, if he is viewed as the product. The *karman* (see above) doctrine is modified as follows: the Lord, having determined good and bad deeds, provides all individual souls with a body in which they perform deeds, reveals to them the scriptures from which they may learn the *dharma* (duties of life), and enters into them as their internal regulator. The individual acts at his own discretion but needs the Lord's assent. If the devotee wishes to please him, God induces him, with infallible justice and loving regard, to intentions and effort to perform good deeds by which the devotee will attain to him; if not, God keeps him from that goal.

Vaiṣṇava theology of Rāmānuja

The *Bhāgavata-Purāṇa* (written *c.* 10th century in Tamil-speaking south India) teaches a quite representative Vaiṣṇava theology: God is transcendent and beyond human understanding; he is the universal causality, creator and substratum, time and the bearer of all possibilities that are susceptible of actualization; through his incomprehensible creative ability (*māyā*) or specific power (*ātmaśakti*) he expands himself into the universe, which he pervades and which is his outward appearance (his immanence); so he is the All and everything and the inner Self of all beings. When God is conceived of as Brahman, he is immutable and as such the Puruṣa (cosmic Person) who is not the universe; if, however, his creation is thought to be in him, he is the world.

Accepting the *Bhāgavata-Purāṇa* as a high scriptural authority, Bengal Vaiṣṇavism considers God the ground and subsistence of whatever exists, from whom all objects have come, by whom they continue to be, toward whom they move, and into whom they enter at the final dissolution at the end of this world, unless they come to him in the state of emancipation (*mokṣa*). Between God and the world there is a relation of inconceivable difference in identity and identity in difference (*acintyabhedābheda;* literally, "unthinkable difference and nondifference"). The Lord creates the world merely because he wills to do so. Creation, or rather the process of differentiation and integration, is his sport (*līlā*). The world is real, but reality has two aspects; viz., the transcendent and eternally real and that which is progressively realized and, in the process, bound up with the eternal aspect.

Vaiṣṇava theological principles and rites. The day of the faithful Śrīvaiṣṇava Brahmin is usually devoted to five pursuits: purificatory rites, collecting the requisites for worship, acts of worship, study and contemplation of the meaning of the sacred books, and meditative concentration on the Lord's image. The performance of sacrifices and other rites, restraint of the senses, fasting and soberness, worship, recitation of the scriptures, and visits to sacred places are a lifelong obligation. In addition, to those who aspire to liberation, Rāmānuja recommends concentration on God, a virtuous way of living, and insensibility to luck and misfortune. According to Madhva (1199?–1278?), a faithful observance of all regulations of daily conduct—including bathing, breath control, etc.—will contribute to eventual success in the quest for liberation.

Devout Vaiṣṇavas are inclined to emphasize God's omnipotence and the far-reaching effects of his grace and attach much value to the repeated muttering of his name or sacred formulas (*japa*), to his praise and the commemoration of his deeds as potent means of self-realization and of unification with his essence. Special stress is laid on *ahiṃsā* as a virtue of those who are born to the divine estate.

Bhakti

A very pronounced feature of Vaiṣṇavism is the strong tendency to "devotion" (*bhakti*), which is generally considered to be "the heart of worship," the sole true religious attitude toward a personal God, and the very foun-

dation of the realization of man's relationship with him. Characterized by a continual consciousness of participating in God's essence, *bhakti* is the disinterested performance of all deeds for him, a passionate love and adoration of and a complete surrender to him. The widespread *bhakti* movement is a corollary of the Vaiṣṇava ideal of a loving personal God and aversion to a conception of salvation that puts an end to all consciousness or individuality. Attesting to the superiority of a mystic and emotional attitude to the meditative or preponderantly ritualistic means to the highest goal, the practical and theoretical development of the *bhakti* idea constitutes one of the main points of difference among the several Vaiṣṇava schools. The belief already expressed in the *Bhagavadgītā* (18, 62) that those who seek refuge in God with all their being will by his benevolence and grace (*prasāda*) win peace supreme, the eternal abode, was generally accepted: *bhakti* will result in divine intercession with regard to the consequences of one's deeds.

Among many followers of Rāmānuja, however, complete self-surrender (*prapatti*) came to be distinguished from *bhakti* as a superior means of spiritual realization. One of the chief purposes of the *Bhāgavata-Purāṇa* is the glorification of an intensely personal and passionate *bhakti* that gradually develops into a decidedly erotic mysticism, independent of all alternative means of salvation. According to this text, there are nine characteristics of *bhakti:* listening to the sin-destroying sacred histories; praising God's name; recollecting and meditating on his nature and salutary endeavour (resulting in a spiritual fusion of devotee and God); serving his image; adoring him; respectful salutation; servitude; friendship; and self-surrender. Meritorious works are now also an element of *bhakti.*

In later Bengal Vaiṣṇavism, the emphasis shifts from service and surrender to mutual attachment and attraction between God (*i.e.*, Kṛṣṇa) and man: God is said to yearn for man's identification with himself, which is his gift to the wholly purified devotee. All the mystical and devotional possibilities of the Kṛṣṇa legend are made subservient to religious practice; the divine sport and wonderful feats of this youthful hero are interpreted symbolically and allegorically. The highest fruition of *bhakti* is admission to the eternal sport of Kṛṣṇa and his beloved Rādhā, whose sacred love story is explained as the mutual love between God and the human soul. Various gradations of *bhakti* are distinguished, such as awe, subservience, parental affection. These are to be correlated with the persons of the Kṛṣṇa legend; the highest and most intimate emotion is said to be the love of Rādhā and her girl friends for Kṛṣṇa.

The work of Caitanya

These ideas were developed into the practice of devotional ecstasy by Caitanya (1485–1533), who had a profound and continuing effect on the religious sentiments of his Bengali countrymen and propagated the community celebration (*saṃkīrtana*) of Kṛṣṇa as the most powerful means of bringing about the proper *bhakti* attitude. Caitanya also introduced the worship of God, the director of man's senses, through the very activity of man's senses, which must be free from all egoism and completely filled with the intense desire (*preman*) for the satisfaction of the beloved (*i.e.*, Kṛṣṇa).

The influence of the *bhakti* movement had earlier led Rāmānuja to admit a twofold possibility of emancipation: besides the meditative method of the highest insight (*jñāna*) into the oneness of soul and God, which destroys the residues of *karman* and propitiates God to win his grace, there is the way of *bhakti.* Those who prefer the former way will reach a state of isolation, the others an infinitely blissful eternal life in, through, and for God, with whom they are one in nature but not identical. They do not lose their individuality and may even meet Viṣṇu in his Vaikuṇṭha heaven and enjoy delight beyond description.

Vaiṣṇava ethical and social doctrines. The *Bhagavadgītā,* by demanding that God's worshippers fulfill their duties—"better one's own duty ill-done than another's well-performed" (3.35)—and observe the rules of moral conduct, disinterestedly bridged the chasm between ascetic morality and the search for emancipation, on the one hand, and the exigencies of daily life, on the other. For those who must lead a normal life in this world, the *Bhagavadgītā* gave a moral code and a prospect of final liberation. In so doing, the work thus founded, on the basis of the Vaiṣṇava tradition, what may be called a social ethic. Since God is in all beings as their physical and psychical substratum—and collectively in human society—the wise should not see any difference between his fellow creatures and should love God in them equally. Like God himself, the devotee should be impartial—the same to friend as to foe. The serious endeavour to realize God's presence in man requires humility and a complete unconsciousness of oneself as a corollary of the consciousness of the Presence. It demands selfless dedication of all one's actions, duties, and ceremonies to the Lord and obliges one to promote both individual and social uplift and welfare.

Bhagavāt and Bhāgavata

According to the *Bhāgavata-Purāṇa,* the highest Bhāgavata—worshipper of the Bhagavāt (God: literally, "the adorable possessed of all excellences")—sees himself in all beings and all beings in the Bhagavāt; free from hatred and partiality and knowing God to be present in all beings, he loves him also in them. Those who cannot reach this level will in any case have friendly relations with coreligionists, irrespective of their birth or social status, and take compassion upon the infatuated. The true Vaiṣṇava should worship Viṣṇu or one of his *avatāras* (incarnations), construct temples, bathe in holy rivers, study religious texts, serve superiors, and honour cows. In social intercourse with the adherents of other religions he tends to be passively intolerant, avoiding direct contact, without injuring them or prejudicing their rights. He should not neglect other gods but must avoid behaving ritually like their followers. Misuse of the advantages of birth is severely condemned, and those who apply themselves mainly to the acquisition and enjoyment of wealth are hardly supposed to be qualified for *bhakti.* The concept of class divisions is accepted, but the idea that possession of their characteristics is the inevitable result of birth is decidedly rejected. Since sin is antithetical to *bhakti,* a Brahmin who is not free from jealousy, falsehood, hypocrisy, envy, injury, and pride cannot be the highest of men, and many persons of low social status may have some advantage over him in moral attitude and behaviour. The most desirable behaviour is compatible with *bhakti* but independent of class.

In establishing *bhakti* religion against any form of opposition and defending the devout irrespective of birth, the Bhāgavata religion as such did not propagate social reform; but the attempts to make religion an efficient vehicle of new spiritual and social ideas, especially Caitanya's movement, contributed, to a certain extent, to the emancipation of lowborn followers of Viṣṇu.

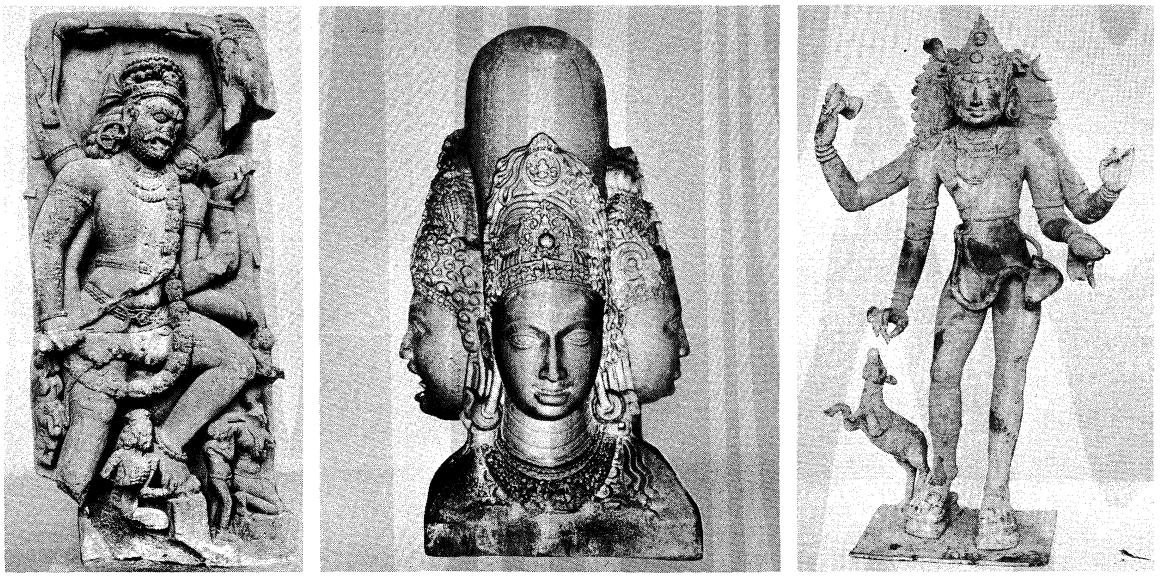
SAIVISM

Śaivism is the worship of Śiva (Shiva) in his various forms and manifestations. During a complex development from ancient, possibly in part from pre-Vedic, times, many different Śaiva groups arose. Despite the fact that major groups such as the Vīraśaivas of southern India and the Kashmir Śaivas contributed the theological principles of Śaivism, most Śaiva worship is not systematic but a complex amalgam of pan-Indian Śaiva philosophy and local or folk worship.

The Vedic god Rudra—called Śiva, "the Mild or Auspicious One," when this aspect of his ambivalent nature is emphasized—had a character and a position of his own, which remain clearly perceptible in some important features of the great god who together with Viṣṇu came to dominate Hinduism.

Composite historical nature of Śiva

In the minds of the ancient Indians Śiva must have been primarily the divine representative of the uncultivated, dangerous, unreliable, and much-to-be-feared aspects of nature. Śiva's character lent itself to being split up into partial manifestations—each said to represent only an aspect of him—as well as to assimilating divine or demoni-



Paradoxical nature of Śiva as indicated by differing representations.

Pramod Chandra

ac powers of a similar nature from other deities. Already in the Ṛgveda, deprecations and a frequent appeal to him for help in case of disaster—of which he might be the originator—were combined with the confirmation of his great power. In the course of the Vedic period, Śiva—originally a ritual and conceptual outsider, yet a mighty god whose benevolent aspects were readily emphasized—gradually gained access to the circle of honourable gods who preside over various spheres of human interest. Many characteristics of the Vedic Prajāpati, or Brahmā, the personification of Brahman, and of the great Vedic god of fire, Agni, have been accreted to the figure of Śiva.

Śaiva views of nature, man, and the sacred. In those circles that left the world the *Śvetāśvatara Upaniṣad* (*c.* 400 BC), Śiva rose to the highest rank. In grandiose terms its author desires both to show a way of escape from *saṃsāra* and to proclaim Śiva the sole eternal Lord but to establish, primarily, Śiva's existence. In the description of Śiva's nature, some of the most salient features of the later Śiva, the Īśvara (immanent deity), are clearly discernible: he is the ultimate foundation of all existence and the source and ruler of all life, who, while emanating and withdrawing the universe, is the goal of that identificatory meditation that leads to complete cessation from phenomenal existence. While Viṣṇu became a friend nearer to man, Rudra-Śiva developed into an ambivalent and many-sided lord and master. His "doubles" or partial manifestations remain to be distinguished: as Paśupati ("Lord of Cattle"), he in a way took over the fetters of the Vedic Varuṇa; as Aghora, he shows the uncanny traits of his nature (evil, death, punishment) but also their opposites.

It is not always clear in particular cases whether Śiva is invoked as a great *deva* (god) of frightful aspect, capable of conquering demoniac power, or as the boon-giving Lord and protector. The Īśvara idea of a Highest Being demonstrably beyond contingency is rather abstract; hence its propagators could not do without the imagery, popular belief, and mythical thought of the masses. Śiva might be the sole Principle above change and variation, yet he did not sever his connections with innumerable local deities and much-feared powers worshipped by the masses, who still continue to invoke him in magical rites. Whereas Viṣṇu champions the cause of the gods, Śiva sometimes sides with the demons.

Śiva is a typical example of polarity within the Highest Being since he reconciles in his person semantically opposite though complementary aspects: he is both terrible and mild, creator and agent of reabsorption, eternal rest and ceaseless activity. These seeming contradictions make him a paradoxical figure, transcending humanity and assuming a mysterious sublimity of his own. His character is so complicated and his interests are so widely divergent as to lead him in mythical narratives into conflicting situations. Yet, although Brahmin philosophers like to emphasize his ascetic aspects and the ritualists of the Tantric tradition (see below) his sexuality, the seemingly opposite strands of his nature are generally accepted as two sides of one character.

Power of chastity and sexuality

Śiva interrupts his austerity and asceticism (*tapas*), which is sometimes described as continuous, to marry Pārvatī—he is even said to perform ascetic acts in order to win her love—and he combines the roles of lover and ascetic to such a degree that his wife must be an ascetic (*yogīnī*) when he devotes himself to austerities and a lustful mistress in the other case. This dual character finds its explanation in the ancient double conviction that unrestrained sexual intercourse is conducive to the fertility of nature and that the chastity and continence of the ascetic produce marvellous events and have an uncommon influence upon the unseen. By his very chastity, an ascetic accumulates (sexual) power that can be discharged suddenly and completely so as to produce marvellous results such as the fecundation of the soil. From various mythical tales it is seen that both chastity and the loss of chastity are necessary for fertility and the intermittent process of regeneration in nature. Ascetics engaging in erotic and creative experiences are a familiar feature in Hinduism. The element of teeming sexuality in mythological thought counterbalances the Hindu bent for asceticism. Such sexuality, while rather idyllic in Kṛṣṇa, assumes a mystical aspect in Śiva, which is why the devotee can see in him the realization of the possibilities of both asceticism and the householder state. His marriage with Pārvatī is, then, a model of conjugal love, the divine prototype of human marriage, sanctifying the forces that carry on the race of men.

Comparison of Śiva and Viṣṇu

Unlike Viṣṇu and his incarnations, there is indeed little about Śiva that is human. His myths—fewer in number than those produced by the Vaiṣṇavas—tend to depict him as the absolutely mighty unique One, who is not responsible to anybody or for anything. Much less active than Viṣṇu, he is a god of poses that express aspects of his nature: as a dancer, he is the originator of the eternal

rhythm of the universe; he also catches the waters of the heavenly Ganges River, which destroy all sin; and he wears in his headdress the crescent moon, which drips the nectar of everlasting life.

Authors of Śaivite *Purāṇas* (sacred encyclopaedic texts) established two ingenious and complementary doctrines to explain the nature and omnipotence of God (the force that rules, absorbs, and reproduces the world and that in performing any one of these acts necessarily performs the other two as well), the existence of the world and the identity of God and the world. A theory of five "faces," or manifestations—each of which is given mythological names and related *mantras*—is of great ritual significance. It associates Śiva's so-called creative function, by which he provokes the evolution of the material cause of the universe, with his first face or aspect; its maintenance and reabsorption with his second and third faces or aspects; his power of obscuration, by which he conceals the souls in the phenomena of *saṃsāra*, with his fourth face or aspect; and his ability to bestow his grace, which leads to final emancipation, with the fifth face or aspect. The five functions are an emanation of the unmanifested Śiva who is the transcendent Brahman.

The faces became central elements of a comprehensive classification system. They were identified with parts of God's body, regions of the universe, various ontological principles, organs of sense and action, and the elements. The system was used to explain how Śiva's being is the All and how the universe is exclusively composed of aspects or manifestations of Śiva. In his fivefold nature, Śiva was shown to be identical with the 25 (five times five) elements or principles assumed by the very prominent Sāṃkhya school of Indian philosophy. The special significance of the number five in Śaivism can be understood as a philosophical elaboration of the time-honoured fourfold organization of the universe. (The four quarters of the sky also play a prominent part in religious practice.) According to this conception, a fifth aspect, when added to the four, is considered the most important aspect of the group because it represents each of the four and collectively unites all their functions in itself. The system finds its complement in the doctrine of the five Sadākhyas (five items that bear the name *sat*, "is" or "being") representing the five aspects of that state, which may be spoken of as the experience of "there is" (*sat*) and which have evolved from God's fivefold creative energy (*śakti*). In these God "dwells" in his aspect called Sadāśiva ("the Eternal Śiva"), which is regarded sometimes as a manifestation of and sometimes as identical with the Supreme Being.

Another Śaiva doctrine posits eight "embodiments" of Śiva as the elements of nature (ether, wind, fire, water, and earth), sun, moon, and the sacrificer or consecrated worshipper (also called *Ātman*). To each of these eight elements corresponds one of Śiva's traditional names or aspects, to the last one, usually Paśupati. The world is a product of these eight forms, consists of them, and can only exist and fulfill its task because the eight embodiments cooperate. Since each individual is also composed of the same eight realities (*e.g.*, the light of man's eyes corresponds to that of the sun), Śiva makes up the corporeal frame and the psychical organism of every living being. The eighth constituent is the indispensable performer of the rites that sustain the gods who preside over the cosmic processes and are really Śiva's faculties.

Regional variations in Śaivism

Although Śaivism is a much more coherent whole than Vaiṣṇavism, there evolved, in different parts of India, some branches with peculiarities of their own. According to the pronouncedly idealist monism of Kashmir Śaivism, an important religio-philosophic school, Śiva manifests himself through a special power as the first cause of creation, and he also manifests himself through a second power as the innumerable individual souls who because of a veil of impurity forget that they are the embodiment of the Highest. This veil can be torn off by intense faith and constant meditation on God, by which the soul transmutes itself into a universal soul and eventually attains liberation through a lightning-like, intuitive insight into its own nature. Those Hindus who adhere to this group consider their doctrine a manifestation of the highest Reality, Knowing Consciousness, neither personal nor impersonal; as Śiva in the form of the transcendent Word, which is his unspoken Thought, the content of which is the universe.

The Śaiva-siddhānta, a prominent religio-philosophic school of Tamil-speaking South India, assumes three eternal principles: God (who is independent existence, unqualified intelligence, and absolute bliss), the universe, and the souls. The world, since it is created by God (efficient cause) through his conscious power (instrumental cause) and *māyā* (material cause), is no illusion. The main purpose of its creation is the liberation of the beginningless souls, which are conceived as "cattle" (*paśu*) bound by the noose (*pāśa*) of impurity (*mala*) or spiritual ignorance, which forces them to produce *karman*. The *karman* process, however, proves to be a benefit; for as soon as the soul has sufficiently ripened and reached a considerable state of purity enabling it to strive after the highest insight, God graciously intervenes, appearing in the shape of a fully qualified and liberated spiritual guide (guru), through whose words God permits himself to be realized by the individual soul.

Śaiva theological principles and rites. Ascetic tendencies were much in evidence among the Pāśupatas, the oldest Śaivite tradition in north India, the last adherents of which now live in Nepal. Pāśupatas often gave offense because of their customs and ritual practices. Their *yoga*, consisting of a constant meditative contact with God in solitude, made them frequent burial places for cremated bodies. More extreme groups carried human skulls (hence the name Kāpālikas, from *kapāla*, "skull") and a bowl of liquor in which they projected and worshipped Śiva as Kapālika, "the Skull Bearer," or Bhairava, "the Frightful One," and by which they had to forget the world in intoxication. Their belief was that an ostentatious indifference to anything worldly was the best method of severing the ties of *saṃsāra*.

Vīraśaivas (Liṅgāyats)

The view and way of life peculiar to the Vīraśaivas, or Liṅgāyats (*liṅga*-bearers), in southwestern India is mainly characterized by a deviation from some common Hindu traditions and institutions, such as sacrificial rites, temple worship, pilgrimages, child marriages, and inequality of the sexes. Initiation (*dīkṣā*) is, on the other hand, an obligation laid on every member of the community. It is bestowed upon the newborn and converts, who receive the spiritual power of the guru, the eightfold shield—which includes the guru, *liṅga* (phallic representation of Śiva), *mantra*, sanctified food—to protect the devotee from nescience (ignorance of the supremacy of God) and to guide him to final beatitude, and the *liṅga* phallic symbol. The miniature *liṅga*, the centre and basis of all their religious practices and observances, which they always bear on their body, is God himself concretely represented. Worship is due it twice or three times a day. When a Liṅgāyat "is absorbed into the *liṅga*" (*i.e.*, dies), his body is not, as is customary in Hinduism, cremated but, like those of the ascetics of other groups, interred. Those Liṅgāyats who have reached a certain level of holiness are supposed to die in the state of emancipation.

Śaivism, though in doctrinal matters it is inclined to adoptive inclusivism, inculcates some fundamental lines of conduct: one should worship one's spiritual preceptor (guru) as God himself, follow his path, consider him to be present in oneself, and dissociate oneself from all opinions and practices that are incompatible with the Śaivite creed. Yet some of Śiva's devotees also worship other gods, and the "Śivaization" of various ancient traditions is sometimes rather superficial. Like many other Indian religions, the Śaiva-siddhānta has developed an elaborate system of ethical philosophy, primarily with a view to preparing the way for those who aspire to liberation. Since *dharma* leads to happiness, there is no divorce between sacred and secular duties. Any deed is to be performed as a service to God and in the conviction that all life is sacred and God-centred. A devout way of living and a non-emotional mysticism are thus much recom-

mended. Kashmir Śaivism developed the practice of a simple but most unusual method of salvation: by the recognition (*pratyabhijñā*)—direct, spontaneous, techniqueless, but full of *bhakti*—of one's identity with God.

Kashmir Śaivism

TANTRISM AND ŚAKTISM

Indian authors have often considered Vedism and Tantrism (Tantra)—a comprehensive term for religious doctrines and practices characterized by a "systematic succession of ceremonies"—complementary concepts. But it is more correct to say that the cult of the Vedic elite was gradually superseded by religious traditions dating from both Aryan and non-Aryan antiquity. Vedic religion, through a long and complicated process of amalgamation, transformation, assimilation, and interpenetration with other traditions, some doubtless pre-Aryan, developed into the extremely variegated complex called Hinduism. Nevertheless, Tantrism, which appears both in Buddhism and in Hinduism, is an important component of religion that, though primarily meant for esoteric circles, also influenced and penetrated, from the 5th century AD, many religious trends and movements.

Nature of Tantric tradition. Opinions of what Tantrism is are quite diverse. Generally speaking, Tantrism claims to show in times of supposed religious decadence a new way to the highest goal and bases itself upon mystic speculations concerning divine creative energy (*śakti*). Tantra is essentially a method of conquering transcendent powers and of realizing oneness with the highest principle by yogic and ritual means—in part magical and orgiastic in character—which are also supposed to achieve other supranormal goals.

Tantrics take for granted that all factors in both the macrocosm and the microcosm are closely connected. The adept (*sādhaka*) has to perform the relevant rites on his own body, transforming its normal, chaotic state into a "cosmos." The macrocosm is conceived as a complex system of powers that by means of ritual-psychological techniques can be activated and organized within the individual body of the adept. Contrary to the ascetic emancipation methods of other groups, the Tantrics emphasize the activation and sublimation of the possibilities of their own body, without which salvation is believed to be beyond reach.

Vāmācāra: left-handed Tantra

The Tantrics of the Vāmācāra ("the left-hand practice") sought to intensify their own sense impressions and so made enjoyment or sensuality (*bhoga*) their principal concern: the adept was to pursue his spiritual objective through his natural functions and inclinations, which were to be sublimated and then gratified in rituals in order to disintegrate his normal personality. This implies that cultic life was also largely interiorized and that the whole world, since it became completely ritualized, was given a new and esoteric meaning.

Tantric worship (*pūjā*) is complicated and in many respects different from the conventional ceremonies that, however, it has often influenced. Tantric devotees distinguish between an "external" and an esoteric meaning of their texts and interpret their texts by means of an ambiguous shadow language. Tantrics describe states of consciousness with erotic terminology and describe physiological processes with cosmological terminology. They proceed from "external" to "internal" worship and adore the goddess mentally, offering their hearts as her throne and their self-renunciation as "flowers."

According to Tantra, concentration is intended to evoke an internal image of the deity and to resuscitate the powers inherent in it so that the symbol changes into mental experience. This "symbolic ambiguity" is also much in evidence in the esoteric interpretation of ritual acts performed in connection with images, flowers, and other cult objects and is intended to bring about a transfiguration in the mind of the adept.

The *mantra*s (one-word spells, such as *hūṃ*, *hrīṃ*, and *klaṃ*) are an indispensable means of entering into contact with the power they bear and of transcending normal mundane existence. Most potent are the monosyllabic, fundamental, so-called *bīja* ("seed") *mantra*s, which constitute the main element of longer formulas and embody the essence of divine power as the eternal, indestructible prototypes from which anything phenomenal derives its existence. Even the cosmos itself owes its very structure and harmony to them. Also important is the introduction, through imposition of a finger (accompanied by a *mantra*), of spiritual qualities or divine power into the body (*nyāsa*).

Those Tantrics who follow the "right-hand path" attach much value to the *yoga* that developed under their influence and to *bhakti* and aspire to union with the Supreme by emotional-dynamic means, their *yoga* being a self-abnegation in order to reach a state of ecstatic blissfulness in which the passive soul is lifted up by the divine grace.

There is also a Tantric Mantra Yoga (discipline through spells), which operates with formulas, and a Haṭha Yoga, "[a method of] reintegration through force." Besides normal yogic practices—abstinences, observances, bodily postures, breath control that requires intensive training, withdrawal of the mind from external objects, concentration, contemplation, and identification that are technically helped by *mudrās* (*i.e.*, ritual intertwining of fingers or gestures expressing the metaphysical aspect of the ceremonies or the transformation effected by the *mantra*s) and muscular contractions—Haṭha Yoga consists of internal purifications (*e.g.*, washing out stomach and bowels), shaking the abdomen, and some forms of self-torture. The whole process is intended to "control the 'gross body' in order to free the 'subtle body.' "

Mudrās

Some Tantrics also employ Laya Yoga ("reintegration by mergence"), in which the female nature-energy (representing the Śakti), which is said to remain dormant and coiled in the form of a serpent (*kuṇḍalinī*) representing the uncreated, is awakened and made to rise through the six centres (*cakra*s) of the body, which are located along the central artery of the subtle body, from the root centre to the lotus of a thousand petals at the top of the head, where it merges into the Puruṣa, the male Supreme Being. As soon as the union of Śakti and Puruṣa has become permanent, according to this doctrine, wonderful visions and powers come to the adept, who then is emancipated. Some of the Tantric texts also pursue worldly objectives verging on magic or pseudo-medicine.

Tantric and Śākta views of nature, man, and the sacred. The Tantric movement is not rarely inextricably interwoven with Śāktism (Shāktism, Śākta). Śāktism consists of doctrines and practices that assume one or more *śakti*s, "creative energies," that are inherent in and proceed from God and are also capable of being imagined as female deities. Śakti is the deciding factor in the salvation of the individuals and in the processes of the universe because God acts only through his energy, which, personified as a goddess, is his spouse. Her role is very different in the various systems: she may be the central figure in a philosophically established doctrine, the dynamic aspect of Brahman, producing the universe through her *māyā* (mysterious power); a capricious demoniac ruler of nature in its destructive aspects; a benign Mother Goddess; or the queen of a celestial court. There is a comprehensive Śāktism that identifies the goddess (usually Durgā) with Brahman and worships her as the ruler of the universe by virtue of whom even Śiva exists. As Mahāyoginī (Great Mistress of Yoga), she produces, maintains, and reabsorbs the world. As the eternal Mother, she is exalted in the *Devīmāhātmya* ("glorification of the goddess") section of the *Mārkaṇḍeya-Purāṇa* (an important medieval Śākta encyclopaedic text). In the Bengal cult of the ogress Kālī, she demands bloody sacrifices lest her creative potency fail her; this cult propounds the belief that birth and death are inseparable, that joy and grief spring from the same source, that the frightening manifestations of the divine should be faced calmly.

Śakti

Whatever non-Aryan roots of Śāktism there may have been, the idea of a bisexual Primeval Being was also well known in the Veda. The goddess Vāc (her name means "Word") was then already the energetic and productive partner of Prajāpati; attention has already been drawn to

Various roles of sakti, the female aspect of the divine.
(Left) Pārvatī, the beneficent mother, bronze statue, south Indian, *c.* 900. Formerly in the collection of Srinivasa Gopalachari. (Centre) Durgā, the destroyer, detail from a Basohli school painting, *c.* 1700. In the Cleveland Museum of Art, Ohio. (Right) Ardhanārīsvara, united with lord Śiva as half-male, half-female, sandstone sculpture from Jhālawār, 6th century. In the Jhālawār Archaeology Museum, Rājasthān, India.

the part played by the goddess Virāj in Puruṣa's becoming the world through a sacrifice. As Ardhanārīśvara (the "Lord Who Is Half Female"), Śiva presides over procreation. The Śāktas—often markedly associated with Śaivism—drew these conclusions: creation is the result of the eternal lust of the divine couple; the man who is blissfully embraced by a beloved woman who is Pārvatī's counterpart assumes Śiva's wonderful personality and, liberated, will continue the joy of amorous sport.

Vaiṣṇava Śāktism

In all of his incarnations Viṣṇu is united with his consort, Lakṣmī (Lakshmī). The sacred tales of his various relations with her manifestations led his worshippers to view human devotion as divine and hence as universal, eternal, and sanctified. In Vaiṣṇava Tantrism, Lakṣmi plays an important part as God's *śakti*—that is, as a central metaphysical principle. In his supreme state, Viṣṇu and his *śakti* are indissolubly associated with one another so as to constitute the personal supreme Brahman, also called Lakṣmī-Nārāyaṇa. In mythical imagery, Lakṣmī never leaves Viṣṇu's bosom. In the first stage of creation, she awakes in her dual aspect of action-and-becoming, in which she is the instrumental and material cause of the universe; Viṣṇu himself is the efficient cause. In the second stage, her "becoming" aspect is manifested in the grosser forms of the souls and the *māyā* power, which is the immaterial source of the universe. In displaying her power she takes into consideration the accumulated *karman* of the beings, judging mundane existence as merit and demerit. Presented in myth as God's wife and the queen of the universe, she is always intent on liberating, by her favour and compassion, the incarnated souls of the devout; that is, she allows them to re-enter into herself because they are really "parts," or rather "contractions," of her own essence. After entering her, the liberated soul takes part in the perfect embrace of the divine couple. Pāñcarātra Vaiṣṇavism emphasizes that Lakṣmī—who in the mythological sphere intercedes with her husband for the preservation of the world—spontaneously and by virtue of her own power differentiates herself from Viṣṇu because she has in view the liberation of the souls. This current of thought complicated its explanation of the relation between God and the universe—which was also at the same time an attempt at assigning to God's manifestations a place in a harmonious theological and cosmological system—by an evolutionist theory of successive creations. God is assumed to manifest himself also in three other figures, mythologically his brothers, who, each with his own responsibility, have not only a creative but also an ethical function, by which they assist those who seek to attain to final emancipation.

Śākta ritual and magical practices. The cult of the Śāktas, though often deteriorated, is based on the principle of the ritual sublimation of natural impulses to maintain and reproduce life. Śākta adepts are trained to direct all their energies toward the conquest of the Eternal. The ritual satisfaction of lust, consumption of consecrated meat or liquor, and sexual intercourse are all esoterically significant means of realizing the unity of flesh and spirit, of the human and the divine. They are not sinful acts but, on the contrary, effective means of salvation. Ritual copulation—which may also be accomplished symbolically—is, for both partners, a form of sacralization, the act being a participation in cosmic and divine processes. The experience of transcending space and time, of surpassing phenomenal duality, of recovering the primeval unity, the realization of the identity of God and his Śakti, and of the manifested and unmanifested aspects of the All, constitute the very mystery of Śāktism. The interpretation—metaphorical or literal—of the doctrines is, however, largely a matter of opinion and practice. Ritual practice is indeed as varied as the doctrines. Extreme Śākta communities perform the secret nocturnal rites of the *Śrīcakra* ("wheel of fortune"), described in the *Kulārṇava Tantra*, a leading text, and avail themselves of the natural and esoteric symbolic properties of colours, sounds, and perfumes to intensify their sexual experiences.

After elaborate purifications, the worshippers—who must be initiated, full of devotion toward the guru and God, have control over themselves, be well prepared and pure of heart, know the mysteries of the scriptures, and look forward to the adoration with eagerness—make the prescribed offerings, worshipping the mighty puissance of the Divine Mother, reciting the relevant *mantra*s, and identifying themselves with their "soul." Once they have become aware of their own state of divinity, they are qualified to commune with the goddess. *Yoga* and worship (*pūjā*), individually and collectively, daily, fortnightly, and monthly, "for the delectation of the deity," are of special importance. If a woman or a girl is, in certain rituals, made the object of worship, the goddess is first invoked into her; the worshipper is not to cohabit with her until his mind is free from impurity and he has risen to divine status. A relationship with a low-caste woman helps to transcend all opposites; that with a woman who

belongs to another man is often preferred because it is harder to obtain, nothing is certain in it, and the longing stemming from the separation of lover and beloved is more intense—it is pure *preman* (agape, or divine love); adoration of a girl of 16 aims at securing the completeness and perfection of which this number is said to be the expression. The texts however reiterate how dangerous these rites are for those who are not initiated; those who fail and perform such ritual acts without merging their minds in the Supreme are likely to go to one of the hells.

Bengali Vaiṣṇava-Sahajīya cult

The esoteric Vaiṣṇava-Sahajīya cult, which arose in Bengal in the 16th century, was another emotional attempt at reconciling the spirit and the flesh. Displaying contempt for social opinion, its adherents, using the natural (*sahaja*) qualities of the senses and stressing the sexual symbolism of Bengal Vaiṣṇavism, reinterpreted the Rādhā–Kṛṣṇa legend and sought for the perpetual experience of divine joy: since Kṛṣṇa's nature is love and the giving of love and man is identical with Kṛṣṇa, the realization of love is, after an arduous training, to be experienced in man's nature. Women, being a ritual necessity as well as the embodiment of a theological principle, could even become spiritual guides, like Rādhā, conducting the worshipper in his search for realization. After reaching this state, he remains in eternal bliss, can dispense with guru and ritual, and be completely indifferent to the world, "steadfast amidst the dance of *māyā*."

Tantric and Śākta ethical and social doctrines. The ethical and social principles, though fundamentally the same as those promulgated in the classical *dharma* works, breathe a spirit of liberality: much value is set upon family life and respect for women (the image of the goddess); no ban is placed on travelling (conventionally regarded as bringing about ritual pollution) or on the remarriage of widows. Although Tantric and Śākta tradition did not oblige its followers to deviate in a socially visible way from the established order, it provided a ritual and a way of life for those who, because of sex or caste, could not participate satisfyingly in the conventional rites.

FOLK HINDUISM

In spite of the impact of the West, the propaganda of modern reform movements, and the spread of education and secularist modernization, the Hinduism of the masses is changing only slowly. For the ordinary Hindu, religion consists primarily in the manual and verbal performance of rites to promote his private interests. To him, the innumerable ceremonies, observances, fasts, feasts, pilgrimages, and visits to nearby temples constitute the essence of religion.

General characteristics of folk traditions. For millions, the main motive of religious practices is still the fear of ambivalent powerful beings, which infuse their minds with vague and primitive "theological" ideas. The lower castes often confine themselves to propitiating the meat-eating, sometimes benevolent but largely malevolent deities concerned with man's daily events, their ancestors or the founder of their community, and those various spirits that, causing evil and misfortune, have no permanent residence. These castes are content to escape the powers of the evil eye; to manipulate those spirits dwelling in wells, trees, stones, water, and ground; to counteract curses, witchcraft, plague, and cholera; and to worship village godlings who may give rain or a bountiful harvest. They believe in astrology, horoscopy, divination, and the reading of omens and auspicious moments. A large variety of purifications and ritual prohibitions, charms, and amulets to ward off any kind of misfortune (including bad luck in lawsuits and examinations) are, in the eyes of the majority, of greater importance than the Ātman-Brahman doctrine. Even the hope of heaven or the fear of hell has little vogue in various regions except among the higher castes.

It is difficult to draw a sharp line of distinction between popular Hinduism, the beliefs and practices of more or less Hinduized "external" groups, and Indian tribal religion. Many elements of tribal culture that in a definite region have not been adopted by those who are recognized as belonging to the Hindu fold are similar to what has been adopted. Tribal people and outcaste groups are, on the other hand, always willing to worship a few more gods or to imitate the rituals of lower caste Hindus if they can expect to gain some social or material advantages from so doing. Age-long processes of interpenetration and fusion have led to an adoption of many local and popular cults into general Hinduism—or, because it expressed itself mainly in Sanskrit, into the Great, or Sanskritic, tradition—and to the identification of regional gods with the great figures of the Hindu pantheon. Popular belief is integrated and refined rather than discounted or discarded. This process is facilitated by a tendency toward assimilation of local beliefs by pan-Indian Hinduism and by an unwillingness to deny the gods and cults of the lower groups (the worship of a local river deity, for instance, may be identified with that of the Ganges). The inheritors of the Little, or regional, traditions—which are essentially popular, pragmatic, and without a philosophical foundation and transcendent ideals—accepted, as a result of continual and complicated Hinduizing influences, vegetarianism, regular fasts, and food restrictions and began to object to the remarriage of widows, to observe Hindu festivals, to sing Hindu religious songs, to perform funeral and other ceremonious worship, and last, but most importantly, to imbibe the ideas embodied in religious and mythological narratives. Thus, various tribal or outcaste groups have a religion "anticipating" Hinduism, with some affinities to a simple Śaivism without sacred books or regular liturgy.

Relation of folk Hinduism to Indian tribal religions

While the higher caste Hindu pursues his approach to the divine individually, corporate worship in families, villages, and "sects" is far more common among the masses. These groups exhibit the utmost variation in beliefs and practices. As a rule, each community selects only a small segment from the whole spectrum of religious behaviour as the expression of its own religious life. As to the relation between religion and social structure, there are in many communities differently structured systems, each with its own religious behaviour, in which their members may be involved. As members of a joint family, they have to take part in the domestic cult and ritually to express family solidarity at such critical points as mourning or marriage; as members of a village community, they are expected to take part in its particular cult, which is a collective action of that community. Different castes, however, establish, also in respect of ritual, their own unity differentiating themselves from others. There is, on the other hand, ritual cooperation between different villages of the same region.

For many communities, spiritual reality is complex: while many women may address local spirits, family ancestors, and disease goddesses, some of the men may adhere to monotheistic ideas. The village's guardian spirit and the saint of a Muslim shrine may also be worshipped, Rāma's name is invoked in prayers, and the major deities are honoured chiefly during their periodic festivals. Marriage and other ceremonies combine ancient "Sanskritic" rites with popular and local features, and even members of the higher classes may accept a range of belief from the lowest to the highest. In many regions, each caste has both general Hindu and "parochial" rituals and beliefs, but the proportions in which the two are found together vary from caste to caste and from locality to locality. The upper castes everywhere, however, have a certain amount of "Sanskritic" ritual in common; but even those who are more or less exclusively devoted to, for instance, Śiva under one of his names do not necessarily constitute a Śaiva community. The *bhakti* movements have long since influenced the religious feelings of their followers. Religious problems are discussed by people of any profession or intellectual level. Divine assistance is implored on every imaginable occasion; ancient Vedic rites were recently used as a defense against atomic danger.

Regional varieties of folk religion. In the hilly and mountainous regions of north India, Śaivism, aligned with Śāktism, is prevalent. The awe and mystery of jungle and mountains are, there and elsewhere, personified as

forest "Mothers" or mountain deities, represented by piles of stones or branches of trees to which every passer-by contributes an offering. Mother Earth is a great goddess whose marriage (with the earth god or the sun) is festively celebrated and whose annual period of impurity is observed by a cessation of all agricultural activities. During the harvest season she is propitiated with wild orgies. In secluded parts of central India she is identified with Devī, the goddess mostly worshipped in North India. Very often, however, she shows herself in her malevolent form—*e.g.*, as Mother Death (Mārī) or as Kālī. There are also many lower caste groups that have adopted a Vaiṣṇava way of life either in order to raise their social status or to have a prospect of salvation.

Folk goddesses

In the east and northeast, where, broadly speaking, Śāktism is dominant, though Vaiṣṇavism is far from absent, popular belief has modified the transmigration doctrine by the assumption that a soul of the deceased reappears in a child born in the same family within a year after the person's death. Among the female deities, there are tutelary goddesses of young children and women in childbed: Ṣaṣṭhī, "the Sixth," worshipped on the sixth day after birth and represented by a compost pile of cow dung or earth that is placed in the birth room; and Caṇḍī, a form of the goddess Durgā, who lives in trees and is propitiated by lumps of earth. The snake goddess Manasā is personified in a plant of the same name or a stone rudely carved into the shape of a female seated on a snake; a day in the rainy season, when reptiles are most dangerous, is especially devoted to her priestless and unpretentious worship. In literary works, she is eulogized as the Great Mother who is expected to give a prosperous journey through life and, to a certain extent, "Sanskritized" by being identified with epic snake demons. Another example of fusion of more general and local Hindu institutions is the conviction that ghosts and demons are warded off by performing a ceremony in honour of the deceased at Gayā in modern Bihār state.

In many regions—*e.g.*, in western India, where Vaiṣṇavism is dominant—people admit that virtue will improve one's lot in a subsequent existence but, except for the Brahmins and the educated, seem to have only vague ideas of final union with the Supreme. Here also there is a workaday religion practiced by the masses to meet the requirements of everyday existence as well as a higher religion understood only by the Brahmins, who are called on to officiate on important occasions. In order to discover the divine will, exorcists and mediums, claiming to be possessed by mother goddesses and submitting themselves to self-torture, are called upon to prophesy about future events. In these regions also the worship of snakes—to which even temples are dedicated—is much in prominence. Practices based on the belief in scapegoats, ritual nudity, and black magic are not yet things of the past; but here also modernization has penetrated, especially into places near railways or industrial areas.

The whole of peninsular India is mainly devoted to Śaivism and devotional forms of Vaiṣṇavism. A very striking feature in the religion of south India is the propitiation of usually local female village deities of varied and ambivalent character, to whom in almost every settlement a simple shrine or other sacred place is dedicated. These deities have no relation to the universe and are only competent to deal with the facts of village life, such as diseases of the inhabitants and their cattle. Although there are special cholera and smallpox goddesses, their functions are not clearly marked in comparatively primitive milieus; but wherever higher civilization has penetrated, they are more differentiated and the subject of elaborate stories. In a few cases—*e.g.*, that of Māriyamma, the smallpox goddess of South India—such a goddess is known to a large region. These mothers, from whom all good and bad luck emanates, are almost universally worshipped with animal sacrifices; the priestly ministrants (*pūjārī*) officiating in their cult belong to the non-Brahmin groups. The goddesses may be represented by various symbols (stone pillars, sticks, clay figures) that need not even be permanent. Most of their shrines are mean little brick buildings or rough stone platforms under a tree. Offerings of rice, fruit, and flowers may be made every day or on fixed days; there often is a fixed annual festival but no uniformity and no calendar of festivals. An exception to this is the male deity Aiyaṉār, who in the countryside of Tamil Nadu state is worshipped as the watchman and patron of the villages but who is also implored to grant children and other blessings. He is a vegetarian and therefore ranks as "socially" superior to the female village goddess with whom he has entered into a complementary relation. Aiyaṉār is worshipped either as a village deity or in a temple dedicated to Śiva, where he is given the rank of a son of that god. In these Śiva temples he is legitimated by higher Hinduism and fulfills the function of a double of Śiva representing "All-India" or general Hinduism in the village, which does not regard him as an outsider. Śiva himself is also worshipped and given a consort, who, though considered a manifestation of Durgā, has various names according to the tradition of temple or village.

Aiyaṉār

The cult of the sacred snakes, especially cobras, is also practiced—partly to avert danger from these reptiles, partly to propitiate them with the aim of obtaining rain, fertility, or children; to that end women worship snake stones (*nāgalkals*) or erect stone figures of cobras. Every joint family of the Coorgs in Mysore state and most other peoples have a snake deity of their own that is said to embody their welfare. Here and there, Brahmins officiate in this cult, which usually takes place in small sanctuaries in private gardens. Though also known in other parts of India, the methods of exorcising evil spirits known as devil-dancing are most fully developed in south India. The notorious hook-swinging festival, Caḍak-pūjā, held for propitiatory purposes in cases of famine or other calamities—a man was suspended by hooks at the end of a long pole and swung around—though strictly prohibited, survived in this century. Greater festivals are, generally speaking, either celebrated at the chief agricultural seasons or connected with the expulsion of malign powers.

MODERN HINDUISM

The beliefs and customs of the masses are much the same in the present century as they were in the past. Contact with the dynamic West, Christianity, modern life, and technology since the early 19th century have, however, resulted in the emergence of a considerable number of movements and spiritual groups as diverse in their principles, ideals, and reactions to foreign influences as the many remarkable men who founded them. Most such movements distinguish themselves from traditional movements of a devotional variety by more pronouncedly ethical, social, and national preoccupations.

Brahmo Samaj and Arya Samaj. The first product of this cultural encounter, the Brahmo Samaj, founded by the Brahmin Rammohan Ray (1772–1833), aimed at a restoration of a monotheistic and Upaniṣadic Hinduism, purged of abuses and idolatry, which, expressing eternal truth in a comparatively undiluted form, might become the foundation of a universal religion. Though its appeal was to an elite, it stimulated many Hindus into a reflection on the postulates of their view of life. Some schisms, resulting mainly from the activities of Keshab Chunder Sen (1838–84)—in whom *bhakti*, mysticism, and asceticism were stronger than rational theism—led to the coexistence of some small groups, mainly in Bengal, whose ideals range from radicalism (abolition of castes and the remodelling of rituals) to the introduction of Christian elements and institutions (welfare work) or to philosophical reformation of points of ancient Hindu belief.

The work of Rammohan Ray and Keshab Chunder Sen

After the Indian Mutiny (1857), anti-Muslim and anti-Occidental ideas began to spread, and a religious nationalism crystallized, mainly in western and northwestern India, either in movements of reformation and modernization or in the propagation of what was considered the core of traditional Hinduism. The Arya Samaj, founded in 1875 by the militant Dayānanda Sarasvati (1824–83), is a typical example of the former tendency: op-

posing foreign religions as well as Hindu sectarianism and claiming to return to the authentic Vedic tradition, it actually propagates a refined nationalist and democratic Hinduism and a worship of God by means of praise, prayer, and meditation, but without symbols and local cults; emphasis is laid upon the importance of the five-fold daily worship and includes the respect for worthy persons and social activity.

Ramakrishna and Vivekananda: the Ramakrishna Mission. The main object of Ramakrishna (1836–86) was the propagation of Śaṅkara's Vedānta as a superior and comprehensive view of life and a philosophy of meditative experience, synthesizing on a higher level of spiritual consciousness, reached by inner realization, the plurality of human faiths. He proposed not only to prepare the individual devotee for eternity but also to translate his religious ideals into useful social activity. The work of Vivekananda (1862–1902), Ramakrishna's chief disciple, sought to include other religions and philosophies and deliberately turned the trend of Vedānta philosophy toward new values. From these beginnings grew the Ramakrishna Mission and its international "missionary" offshoots, known in Europe and North America as Vedānta societies. Internally, this mission has become an important force for regeneration and unification. Strongly inclined to tolerance and reconciliation, the Ramakrishna Mission has prevented many Indians from being converted to foreign religions. It is the first Indian society to promote its ideas abroad.

Roles of Ramana Maharishi and Rabindranath Tagore. Ramana Maharishi (1879–1950), a southerner, is a typical representative of those holy men who, living in retreat, attempt to achieve the realization of the Vedāntic truth by asceticism. He wrote very little, did not found a system, and communicated his ideas to his disciples, inducing them to search for the Self in themselves.

Although the cosmopolitanism of Rabindranath Tagore (1861–1941) was the utopia of a minority, his foundation, the *āśrama* ("abode of retired ascetics") Santiniketan—which developed into the international Visva-Bharati University—has become a centre of study and inspiration for those who accepted his partly traditional, partly innovatory *bhakti* and mystic view of life and belief in the creative power of Brahman and in the unity of all things and all lives in God.

Political teachers. The intimate relations between religion and social life induced the leaders of the nationalist movements to borrow political lines of action from the religious traditions and to transform ancient religious ideals—*e.g.*, Rāma's perfect rule—into expectations of the future. Ancient doctrines such as the *Bhagavadgītā* were reinterpreted in a political sense, the *avatāra* doctrine becoming a political messianism. Combining with the cult of Kālī and Gaṇeśa—who was made the patron of nationalism—these tendencies even developed into popular movements in Bengal and the Deccan.

The politician B.G. Tilak (1856–1920) professed self-realization through higher meditative knowledge, based on the *Bhagavadgītā* and determining social and political activity. In giving a new content to traditional beliefs and customs. Mahatma Gandhi (1869–1948), who characterized himself as a man of religion in the garb of a politician, far surpassed him. The ancient ideals of *ahiṃsā*, chastity, observances, and *satya* (Truth, which he identified with God) were the main principles of his undogmatic doctrine and social and political practice.

Observances (*vrata*) of restrictions help a man find the energy necessary for the realization of his ideals. By practicing *ahiṃsā* one is believed to acquire an incomparable power that causes the good qualities of one's opponents to triumph over their evil inclinations; asserting truth (*satyāgraha*, the name of his practical politics) implies patience, self-denial, and complete confidence in righteousness and morality. Gandhi was also among those who adapted the ancient institution of *āśramas* so as to suit the new circumstances and to become communities of people bound together by common ideals and activities. Whereas Vinoba Bhave (1895–) propagates, in Gandhi's spirit, the donation of fields and money as a means of self-realization by work (*karma-mārga*), the Hindu-Mahasabha advocates, like other groups of the right, a pure and orthodox anti-Occidental and anti-secularist Hinduism.

Aurobindo's idea of Mother India

One of the most striking personalities was Sri Aurobindo (1872–1950), a native of Calcutta. After studying classical philology at Cambridge University and a career as teacher, poet, publicist, and radical politician, he devoted himself, in his *āśrama* in the then French Pondicherry (now union territory), to spiritual realization, introducing mystical *bhakti* into politics, urging the necessity of a spiritual emancipation of Mother India, whom he identified with the divine Mother, and teaching a *yoga* by which to transform ordinary human beings into divine beings possessing love, wisdom, and power for good and so to achieve a transfiguration of material existence.

Patterns of change. Thus, notwithstanding the presence of both secular ideas and an accelerating process of secularization—which is also unintentionally brought about, for instance, by orthodox Hindu vaccinators making the belief in the goddess of smallpox superfluous—in the general change from predominantly rural to predominantly urban patterns of life and thought, Hinduism has remained an utterly varied complex of religious beliefs and practices, assimilative in adopting Western institutions in a familiar form yet clinging to the essence of its old—mainly Vedāntic—traditions. Vaiṣṇavas, Śaivas, and other religious groups apply modern methods of propaganda, publishing texts and periodicals, founding associations, and convening conferences. Through its best exponents, neo-Hinduism is steadily adapting itself to the exigencies of modern life.

III. Rituals, social practices, and institutions

SACRIFICE AND WORSHIP

Image worship and mental adoration have in later Hinduism taken the place of the great Vedic sacrificial rituals (*yajña*). Nevertheless, much of the comparatively uncomplicated Vedic private rites (*gṛhya*) has survived. The Vedic householder was expected to maintain a domestic fire into which he made his offerings. Normally he did this himself, but in many cases he might also employ a Brahmin officiant. In the course of time, the family priest claimed or was given a large part in these ceremonies, so that most Hindus have been dependent on Brahmins for the administration of the "sacraments" (*saṃskāra*), which, accompanying them from their conception to their cremation, are the main constituents of the domestic rites.

Domestic rites. These sacraments as transitional rites are intended to make a person fit for a certain purpose, for the next stage in his life, by removing taints (sins) or by generating fresh qualities. If the blemishes incurred in this or a previous life are not removed, man is impure and will acquire no reward for his ritual acts. The sacraments, while sanctifying critical moments, are therefore deemed necessary for unfolding man's latent capacities for development. Śūdras are mostly allowed to perform some *saṃskāras* without using Vedic *mantras*.

Saṃskāras: passage rites. In antiquity there was a great divergence of opinion about the number of passage rites, but in later times 16 were regarded as the most important. The impregnation rite consecrating the supposed time of conception consists of a ritual meal of pounded rice (mixed "with various other things according as the married man desires a fair, brown or dark son, a learned son or a learned daughter"), an offering of rice boiled in milk, sprinkling of the woman, intercourse; all acts are accompanied by *mantras*. In the third month of pregnancy, the rite called *puṃsavana* (begetting of a son) is to follow. The birth is itself the subject of elaborate ceremonies, the main features of which are an oblation of ghee (clarified butter) cast into the fire; the introduction of a pellet of honey and ghee into the newborn child's mouth, which according to many authorities is an act intended to produce mental and bodily strength; the muttering of *mantras* for the sake of a long life; rites to coun-

Rites associated with the newborn

teract inauspicious influences. There is much divergence of opinion as to the time of the name-giving ceremony; in addition to the personal name, there is often another one that should be kept secret for fear of sinister designs against the child.

In modern times most *saṃskāra*s (except impregnation, initiation, and marriage) have in many areas fallen into disuse or are performed in an abridged or simplified form without Vedic *mantra*s and a priest. This tendency was encouraged by the accommodating spirit of the Brahmins who allowed their clients easy atonements for the nonobservance of rites. The important initiation *upanayana* is held when a boy is between eight and 12 and marks his entry into the community of the three higher classes of society. In this rite he becomes a "twice-born one," or *dvija*. Traditionally, this was also the beginning of a long period of Veda study and education in the house under the guidance of a teacher (guru). Nowadays, the hair-cutting ceremony—formerly performed in a boy's third year—and the initiation are usually performed on the same day, the homecoming ceremony at the end of the period of study being little more than a formality.

A young boy performs his first *pūjā* after initiation into the "twice-born."

Marriage customs

Wedding ceremonies, the most important of all, have not only remained elaborate—and often very expensive—but have also incorporated various elements—among others, propitiations and expiations—which are not indicated in the oldest sources. Already in ancient times there existed great divergences in accordance with local customs or family or caste traditions. Yet a small number of practices is usually considered essential. The date is fixed only after careful astrological calculation; the bridegroom is conducted to the home of his future parents-in-law, who receive him as an honoured guest; there are offerings of roasted grain into the fire; the bridegroom has to take hold of the bride's hand; he conducts her around the sacrificial fire; seven steps taken by bride and bridegroom are to solemnize the irrevocability of the unity; both are in procession conducted to their new home, which the bride enters without touching the threshold.

Of eight forms of marriage recognized by the ancient authorities, two have remained in vogue; viz., the simple gift of a girl and the legalization of the alliance by means of a marriage gift paid to the bride's family. In the Vedic period, girls do not seem to have married before they had reached maturity. Child marriage and the condemnation of the remarriage of widows, especially among the higher classes, became customary later and have gradually, since the mid-19th century, lost their stringency.

The traditional funeral method is cremation (a family affair), burial being reserved for those who have not been sufficiently purified by *saṃskāra*s (*i.e.*, children) and those who no longer need the ritual fire to be conveyed to the hereafter, such as ascetics who have renounced all earthly concerns. An important and meritorious complement of the funeral offices is the *śrāddha* ceremony: offerings of food to Brahmins for the benefit of the deceased. Many people are still solicitous to perform this rite at least once a year even when they no longer engage in any of the five obligatory daily offerings.

Death rites and customs

Daily offerings. There are five obligatory offerings: (1) offerings to the gods (food taken from the meal); (2) a cursory offering (*bali*) made to "all beings"; (3) a libation of water mixed with sesame offered to the spirits of the deceased; (4) hospitality; and (5) recitation of the Veda. The conventional Hindu daily worship of the five protecting deities (Viṣṇu, Śiva, Pārvatī, Gaṇeśa, Sūrya), represented by figurines, continues in the present century.

Other private rites. The morning and evening adorations (*saṃdhyā*), being a very important duty of the traditional householder, though mainly Vedic in character, have, by the addition of Purāṇic and Tantric elements, become lengthy rituals. If not shortened, the morning ceremonies consist of self-purification, bathing, prayers, recitation of *mantra*s, especially the "Gāyatrī" *mantra* (Ṛgveda 3.62.10), a prayer for spiritual stimulation addressed to the sun. The accompanying ritual includes (1) the application of marks on the forehead characterizing the adherents of a particular religious community, (2) presentation of offerings (water, flowers) to the sun, and (3) meditative concentration. There are Śaiva and Vaiṣṇava variants, and some elements are optional. The observance of the daily obligations, including the care of bodily purity and professional duties, leads to mundane reward and helps to preserve the state of sanctity required to enter into contact with the divine.

"Gāyatrī" *mantra*

Temple worship. According to Vaiṣṇava authorities, the regular temple worship of God grants the same results as the ancient fire cult; it even has an advantage over it because temple worship may be continued after the death of the founder.

Temples. The erection of a temple, which belongs to whoever paid for it or to the community that occupies it, is a meritorious deed recommended to anyone desirous of heavenly reward. The choice of site, which should be serene and lovely, is determined by astrology and divination as well as by its situation with respect to the dwellings of men: a sanctuary of a benevolent deity should face the village. The construction of temples is, because of its "symbolic" value, described in great detail. There is much diversity in size and artistic value, ranging from little village shrines with crude statuettes to great temple-cities whose boundary walls, pierced by monumental gates (*gopura*), enclose various buildings, courtyards, pools for ceremonial bathing, and sometimes even schools, hospitals, and monasteries. From the point of view of construction there is no striking difference between Śaivite and Vaiṣṇavite sanctuaries, which are easily recognizable by the image or symbols in the centre, the images on the walls, the symbol fixed on the finial (crowning ornament) of the top, and Śiva's bull, Nandi, or Viṣṇu's bird, Garuḍa—theriomorphic duplicate manifestations of each god's nature—before the entrance. Services, which may be held by any qualified member of the community, are neither collective nor carried out at fixed times. Those present experience, as spectators, the fortifying and beneficial influence radiating from the sacred acts. Sometimes the faithful assemble to meditate, to take part in chanting, or to listen to an exposition of doctrine. The *pūjā* (worship) performed in public "for the well-being of the world" is, though sometimes more elaborate, largely identical with that executed for personal interest. There are, on the other hand, many regional differences, even within the same community.

Pūjā. Hindu worship (*pūjā*) consists essentially of an invocation, reception, and entertainment of God as a royal guest. It normally consists of 16 "attendances" (*upacāra*): invocation by which the omnipresent God is

invited to direct his attention to the particular worship; offering of a seat, of water (for washing the feet, for washing the hands, and for rinsing the mouth), of a bath, a garment, a sacred thread, perfumes, flowers, incense, a lamp, food, and homage; and a circumambulation of the image and dismissal by God.

Photo Atlas-Doumic, Paris

A temple *pūjā* to Krsna.

The Pāñcarātra Vaiṣṇavas in south India introduced the songs of the Dravidian poets into their temple cult and regard these poets and their great teachers as incarnations of God and worship their images also. The Śaivites also have songs of their own but were, generally speaking, more open to Tantric elements and to the admission in their cult of dances executed by dancing girls. In both religious groups, there are communities that cling to the traditional Sanskrit *mantra*s and others that also use other languages.

The significance of the temple door

The first phase of worship is the reverential opening of the temple door and the adoration of the powers presiding over it: according to the Vaikhānasa Vaiṣṇavas, the opening of heaven; and to the Śaivites, an act to secure the building's protection. The divine powers carved in the doorjambs promote the process of transmutation without which man cannot even enter into the presence of God, whose image is established in the cella (*garbhagṛha*). This image is honoured with gifts, notably flowers, fruit, and perfumes. Small portions of the consecrated food (*prasāda*) are given to visiting worshippers. The offering into the fire (*homa*) of Vedic origin has been retained in nearly all extended *pūjā* ceremonies. The main purpose of the rites is the meditative identification of the worshipper with the divine Presence; the enactment, in a gradual process of development, of the realization of the worshipper's soul and God. The Vaikhānasas distinguish between the transcendent and unanalyzable Brahman and its immanent and analyzable aspect and invoke God to descend out of compassion from the immovable image—the permanent "seat" of the former—into a movable cult image in which he converses with the world, represented by the worshipper. Those denominations (both Śrīvaiṣṇavas and Śaivites) that adopted Tantric practices believe that God comes, during these ceremonies, also out of the worshipper's heart or that the latter's soul leaves his body to reach God's feet in heaven, to descend from there in a new body that is meditatively created.

A remarkable rite of yogic-Tantric origin is, also in other ritual contexts, the transmutation of water into the elixir of life and "immortality" (*amṛta*), the essential element of which is drawn from the spot between the worshipper's eyebrows, which is supposed to be the seat of Śiva's highest aspect.

Śaivas have to transform themselves into Śiva by means of complicated preparatory rites, because, they say, "Śiva alone can worship Śiva." Some authorities also enjoin a mental worship and sacrifice, without which "exterior" rites are rendered senseless. The merit of the performances is often said to be entrusted to God's keeping for the sake of the worshipper. Many Vaiṣṇavas emphasize that *pūjā* is to propitiate God disinterestedly.

SACRED TIMES AND PLACES

Festivals. Hindu festivals are complex combinations of religious ceremonies, semi-ritual spectacles, worship, prayer, lustrations, processions (supposed to set something sacred in motion and to extend their powerfulness over a certain region), music, dances (which by the rhythm of their movement have a compelling force), magical acts—the participants throw fertilizing water or, during the Holī festival, red powder (an aphrodisiac) at each other—eating, drinking, lovemaking, licentiousness, feeding the poor, and other activities of a religious or traditional as well as of a recreational character. Their original functions appear clearly from both ancient literature and anthropological research: they are intended to purify, to avert malicious influences, to renew society, to bridge over critical moments, to stimulate or resuscitate the vital powers of nature (hence the term *utsava*, meaning both a generation of power and a festival). Since such festivals relate to the cyclical life of nature, they are supposed to prevent it from stagnating. These cyclic festivals —which may extend for many days—continue to be celebrated.

Such festivals refresh the mood of the participants, further the consciousness of their own power, and thus help to compensate for their sensations of fear and inferiority concerning the unknown forces of nature. Such mixtures of worship and pleasure require the participation of the whole community and create harmony among its members, even if only some of the total number of participants may now be aware of their original character. There are also innumerable festivities in honour of individual gods, relating to particular temples, villages, and religious communities.

Holī: festival of spring

A very important festival, formerly celebrating Kāma, the god of sexual desire, survives in the Holī, a saturnalia connected with the spring equinox and in western India with the wheat harvest and in its boisterous and licentious form observed by the lower classes. There are local variants: among the Marāṭhās, heroes who died on the battlefield are "danced" by their descendants, sword in hand, until they believe themselves possessed by the spirits of the heroes. In Bengal, swings are made for Kṛṣṇa; in other regions, a bonfire is also essential. The mythical tradition that accounts for the festival describes how young Prahlāda, who, in spite of his father's opposition, persisted in worshipping Viṣṇu, was carried into the fire by the female demon Holikā, the embodiment of evil, who herself was believed to be immune to the ravages of fire. Through Viṣṇu's intervention, Prahlāda emerged unharmed, while Holikā was burned to ashes. The bonfires are intended to commemorate this event or rather to reiterate the triumph of virtue and religion over evil and sacrilege. This explains why objects representing the sickness and impurities of the past year—the new year begins immediately after Holī—are thrown into the bonfire, and it is considered inauspicious not to look at it. Moreover, people pay or forgive debts, reconcile quarrels, and try to rid themselves of the evils, conflicts, and impurities that may have accumulated during the preceding months, translating the central conception of the festival into a justification for dealing with continuing situations in their lives. The New Year festival, according to another Indian calendar, Dīwālī, though celebrated by all classes of society, is traditionally believed to have been given by Viṣṇu to the Vaiśyas (traders, etc.); it takes place in September–October, with worship and ceremonial lights in honour of

New Year festivals

Lakṣmī, the goddess of wealth and good fortune; fireworks to chase away the spirits of the deceased; and gambling, an old ritual custom intended to secure luck for the coming year. The nine-day Durgā festival, or Navarātrī, is, especially in Bengal, splendid homage to Śakti, and in south India, a celebration of Rāma's victory over Rāvaṇa.

Pilgrimages and fairs. Like processions, pilgrimages (*tīrthayātrā*) to holy rivers (*tīrtha*) and other places were already known in Vedic and epic times and are, up to the present day, one of the most remarkable aspects of Indian religious life. Many sections of the *Purāṇas* eulogize temples and the sacredness of places situated in beautiful scenery or wild solitude (especially the Himalayas). Although the whole of India, and especially Kurukṣetra (presumed to be the scene of the great war portrayed in the Mahābhārata) in the northwest, is holy ground offering an opportunity to reach emancipation and although the number of places of pilgrimage of regional significance amounts to many hundreds, some of them (Ayodhyā, Mathurā, Hardwār, Kāśī or Vārānasi [Benares], Kāñcī or Kānchipuran, Avantikā or Ujjain, and Dvāravatī or Dwārkā) have for many centuries possessed exceptional holiness. The reason for such sanctity derives from their location on the bank of a holy river, especially of the Ganges, or from their connection with legendary figures of antiquity who are said to have lived there, or

Paul Popper Ltd.

Pilgrims bathing in the Ganges River at Hardwār, India.

from the alleged local manifestation of a god. Many places are sacred to a specific god; the district of Mathurā, for example, is studded with places of pilgrimage connected with the Kṛṣṇa legends. Visits to holy places may bestow special benefits upon pilgrims; temples or ponds dedicated to Sūrya ("the Sun") are visited in order to recover from leprosy, other places to escape from astrological threats. Pilgrimages to Gayā (Bihār state)—where visitors are escorted around the sacred centres by Brahmin temple priests who maintain certain ritual connections with their clients—are undertaken for the sake of the welfare of deceased ancestors. In most cases, however, the devotee hopes for deliverance from sin or pollution, preservation of his religious merit, rebirth in a heaven, or even emancipation. The last prospect is held out to those who, when death is near, travel to Vārānasi to die near the Ganges.

On special occasions, be they auspicious or, like a solar eclipse, inauspicious, the devout crowds increase enormously. Most important shrines also organize gatherings (*melā*), half fairs, half religious demonstrations. These journeys, which are also undertaken, individually or in groups, in order to discharge a vow or to please the devotee's favourite god, confirm the devotees in their faith, providing them with an opportunity for spiritual retreat or to bring their inner life nearer to a state of perfection. They have contributed much to the spread of religious ideas and the cultural unification of India.

RITUALS AND SOCIAL STATUS

The traditional Hindu expresses his religious beliefs also in his social customs and institutions as well as in his relations with his fellow men. Four social classes (*varṇa*) were distinguished in the oldest period. Notwithstanding a certain openness and fluidity, these classes appear to have been a socio-religious reality. Such is evident from the Puruṣa hymn (Ṛgveda 10. 90), in which the statement that the Brahmin (Brāhmaṇa) was the Puruṣa's mouth, the nobleman (Kṣatriya) his arms, the Vaiśya his thighs, the Śūdra being born from his feet, gives us an idea of their functions and mutual relations.

The four social classes

The Brahmins, whatever their worldly avocations, are by virtue of their birth a perpetual incarnation of the *dharma*, guardians and dispensers of divine power, entitled to teach the Veda, sacrificing for others and accepting gifts and subsistence; the term alms is misleading, and the *dakṣiṇā* offered at the end of a rite to a Brahmin officiant is not a fee but an oblation through which the rite is made complete. Brahmins are, on account of their pre-eminence, the superiority of their origin, their sanctification owing to the *saṃskāra*s (rites of passage), and their observance of restrictive rules, held to be the highest of all human beings. The main duty of the nobility (the Kṣatriyas) is to protect the people, that of the third estate (the Vaiśyas) to tend cattle, to trade, and to cultivate land. Even if a king (theoretically of Kṣatriya descent) was not of noble descent, such an upholder of *dharma* was clothed with divine authority in the eyes of the masses. He was consecrated by means of a complex and highly significant ritual; he was Indra and other gods (*deva*) incarnate; the emblems or paraphernalia of his office represent sovereign authority; the white sunshade of state is, for instance, the residence of Śrī-Lakṣmī, the goddess of fortune. All three higher classes, claiming Aryan descent, had to sacrifice and to study the Veda, although the responsibilities of the Vaiśyas in sacred matters were less onerous.

While this tripartition seems, in the main, to have been inherited from prehistoric times, the fourth class (the Śūdras), whose sole duty it was "to serve meekly" (*Mānava Dharmaśāstra* 1, 91) the other classes, are partly descended from the subjugated non-Aryans, a fact which accounts for their many disabilities and exclusion from religious status. According to Hindu tradition, the Veda should not be studied in their presence, but they may listen to the recitation of epics and *Purāṇas*. They might perform the five main acts of worship (without Vedic *mantra*s) and undertake observances, but even now they have various ceremonies of their own, carried out without Brahminic assistance. Yet a distinction is often made between Śūdras of a more and those of a less pure and correct behaviour and way of living, the former tending to assimilate with higher castes, the latter to rank with the lowest in the social scale, who, often called *cāṇḍālas*, were already at an early date sweepers, bearers of corpses, or charged with other impure occupations. Ritual purity was indeed an important criterion; "impure" conduct and neglect of Veda study and the rules regarding forbidden food might suffice to stigmatize a "twice-born man" as a Śūdra. On the other hand, in later times the trend of many communities has been toward integrating all Śūdras into the Brahminic system. The Brahmins, who have far into modern times remained, on the whole, a respected, traditional, and not rarely intellectual upper class, were generally until the 1930s much in demand because of their knowledge of rites and traditions. Although Kṣatriya rank is claimed by many whose title is one of function or creation rather than of inheritance, this class is in many regions nowadays numerically insignificant. Moreover, none of the four *varṇas* represented for a considerable time anything but hierarchically arranged groups of castes.

Castes. The origin of the castes (*jāti*, literally "birth"), the most conspicuous characteristic of Hindu society, cannot be explained from a simple splitting up of the *varṇas;* nor, in accordance with the Indian tradition, from the mixture of these through intermarriage, considered an infraction of the *dharma;* nor, in accordance with some one-sided modern theories, from exclusive commensality deriving from family worship, racial, or ritual differences, occupational differentiation, taboo, and totemism. This is not to deny that some of these factors contributed to the growth and extension of the highly complex division of the Hindu society into nearly 3,000 castes and subcastes—only small parts of which are actually coexistent in the same region—a division that, with the sanction of religion and tradition, survives, especially in South India, though tending to mitigation, up to modern times.

A caste is, in general, an endogamous hereditary group of families, bearing a common name; often claiming a common descent; as a rule professing to follow the same hereditary calling; clinging to the same customs, especially regarding purity, meals, and marriages; and very often further divided into smaller endogamous circles. Moreover, tribes, "guilds," or religious communities characterized by particular customs—for instance, the Vīraśaivas—could easily be regarded as castes. The status of castes is variable in different localities, and social mobility is possible, but their mutual relation is hierarchically determined; local Brahmin groups occupy the highest place, and differences in ritual purity are the main criterion of position in the hierarchy. Most impure are the outcastes, or, to use modern names, the exterior or scheduled castes, which, however, have among themselves numerous divisions, each of which regards itself as superior to others.

Traditional Hindus are inclined to emphasize that the ritual impurity and "untouchability" inherent in these groups does not essentially differ from that temporarily proper to mourners or menstruating women. This, and the fact that some exterior group or other might rise in estimation and become an interior one, or that individual outcastes might be well-to-do, does not alter the fact that the spirit of exclusiveness was in the course of time carried to extremes. The scheduled castes were subjected to various socio-religious disabilities before mitigating tendencies made progress; social discrimination was, after independence, prohibited, and the practice of untouchability made a punishable offense (which does not, however, mean abolition). Scheduled castes were barred from use of temples and other religious institutions and from public utilities such as tanks and schools. These groups also had many disabilities in relations with private persons. From the traditional Hindu point of view, this social system is the necessary complement of the principles of *dharma*, *karman*, and *saṃsāra*. Like hells and heavenly regions in the hereafter, the castes are the mundane, social frame within which *karman* is settled. A low social status is the inevitable result of sins in a former life but can, by virtue and merit, be followed by a better position in the next existence (see CASTE SYSTEMS).

Religious orders and holy men. Those members of the various denominations who are inclined to abandon all worldly attachment assume the character of an "inner circle" or "order" that, seeking a life of devotion, adopts or develops particular vows and observances, a common cult, and some form of initiation.

Initiation. Though Hindus, generally speaking, are free to join an order or inner circle, once they have joined it they must submit to its rites and way of living. The initiation (*dīkṣā*), a sort of purification or consecration involving a transformation of the aspirant's personality, is regarded as a complement to, or even a substitute for, a previous initiation ceremony that it strikingly resembles. Such religious groups integrate ancient, widespread ideas and customs of initiation into the framework of either the Vaiṣṇava or Śaiva patterns of Hinduism. Vaiṣṇavism emphasizes their character as an introduction to a life of devotion, as an entrance into closer contact with God, although happiness, knowledge, a long life, and a prospect of freedom from *karman* are also among the ideals aspired to by them. Śaivism is convinced of the absolute necessity of initiation for anyone desirous of final liberation and requires an initiation in accordance with their rituals. All communities are agreed that the authority to initiate belongs only to a qualified spiritual guide (guru), usually a Brahmin, who has previously received the special *gurū-dīkṣā* (initiation as a teacher) and is often regarded as representing God himself. The postulant is sometimes committed to a probationary period, to training in *yoga* mysticism, or to instruction in the esoteric meaning of the scriptures. The initiate receives a devotional name and is given the distinctive *mantra*s of the community, which, since they are sacred, must never be misused.

Dīkṣā

There are numerous, complicated forms of initiation: the Vaiṣṇavas differentiate between the members of the four classes; the Śaivas and Tantrics take account of the natural aptitude and competency of the recipients and distinguish between first-grade initiates, who obtain access to God, and higher grade initiates, who remain in a state of holiness.

Yoga. The initiate guided by his guru may apply himself to *yoga* (a "methodic exertion" of body and mind) in order to attain, through mortification, concentration, and meditation, a higher state of consciousness in which he may find the supreme knowledge, achieve spiritual autonomy, and realize his oneness with the Highest (or however the ultimate goal is conceived). *Yoga* may be atheistic or combined with various philosophical or religious currents. Every denomination attempted to implement yogic practices on a theoretical basis derived from its own teachings. There are many different forms of *yoga*, the practices vary according to the stage of advancement of the adepts. All serious *yogins*, however, agree in disapproving use of yogic methods for worldly purposes.

Āśramas: the four stages of life. In the West, the so-called life-negating aspects of Hinduism have often been overemphasized. The polarity of asceticism and sensuality, which assumed the form of a conflict between the aspiration to liberation and the heartfelt desire to have descendants and continue earthly life, manifested itself in Hindu social life as the tension between the different goals and stages of life. The relative value of an active life and the performance of meritorious works (*pravṛtti*) as over against renunciation of all worldly interests and activity (*nivṛtti*) was a much-debated issue. While one-sidedly religious and philosophical works such as the *Upaniṣads* place emphasis on renunciation, the *dharma* texts argued that the householder who keeps up his sacral fire, procreates children, and performs his ritual duties well earns religious merit. They also came, nearly 2,000 years ago, to elaborate the social doctrine of the four *āśrama*s ("stages of life"). This concept is a typically Brahmanic and legalizing attempt at harmonizing these conflicting tendencies in one system. A member of the three higher classes should first become a chaste student (*brahmacārin*); then a married householder (*gṛhastha*), discharging his debts to his ancestors by begetting sons and to the gods by sacrificing; then (as a *vānaprastha*) retire, with or without his wife, to the forest to devote himself to spiritual contemplation; and finally, but not mandatorily, become a homeless wandering ascetic (*sannyāsin*). The situation of the married ascetic was always a delicate compromise remaining problematic on the mythological level and often omitted or rejected in practical life.

Although the status of a householder was often extolled, and some authorities, regarding studentship as a mere preparation, went so far as to brand the other stages as inferior, there were always men who became wandering ascetics immediately after studentship. Theorists were inclined to reconcile the divergent views and practices by allowing the latter course of life to those who are, owing to the effects of restrained conduct in former lives, entirely free from worldly desire, even if they had not gone through the traditional prior stages.

Sectarian symbols. The typically Hindu ascetic (*sādhu*) usually wears some distinctive mark (*puṇḍra*) on his forehead and often carries some "symbol" of his religion.

Symbols of Viṣṇu and Śiva

If he is a Vaiṣṇava he may possess a discus (*cakra*) and a conch shell (*saṅkha*), replicas of Viṣṇu's flaming weapon and his instrument of beneficent power and omnipresent protection; a *śālagrāma* stone or a *tulasī* plant, which represent both Viṣṇu's own essence and that of his spouse Lakṣmī. If he is a Śaiva, he will impersonate Śiva himself and carry a trident (*triśūla*), denoting empire and the irresistible force of transcendental reality; wear a small *liṅga;* carry a human skull, showing that he is beyond the terror inspired by the transitoriness of the world; and smear his body with apotropaic (supposed to avert evil) and consecratory ashes. These emblems are sacred because the divine Presence, when invoked by *mantra*s, is felt to be in them, which makes them a means of worship.

The attitude toward asceticism has always been ambivalent. On the one hand, there is a genuine regard for hermits and wandering ascetics and a desire to store up spiritual merit through feeding religious mendicants. On the other hand, the fact that fringe members of society may find a sort of respectable status among Śaiva ascetics often led to a decline in the moral reputation of the latter.

Role of Śaṅkara. In ancient times, religious communities were somewhat isolated and scattered throughout India. However, after Śaṅkara (8th century), as tradition has it, had founded and organized a Śaivite order composed of ten brotherhoods and hence called Daśanāmīs ("Those with Ten Names"), orders became an established institution with wider geographic affiliations. Some of these admitted Brahmins only; others were open to all four classes or even to women; some made a practice of nudity. Śaṅkara is also credited with having founded four great monasteries (*maṭha*), governed by the head of Śṛṅgeri monastery in Mysore, who enjoys great spiritual authority. These Śaiva communities are more inclined to individual asceticism and are less closely organized than the Vaiṣṇava Vairāgins ("the Dispassionate") or Gosvāmins ("the Masters").

IV. Cultural expressions of Hindu values and ideas

The structure of Indian temples, the outward form of images, and indeed the very character of Indian art are largely determined by religion and the traditional view of the world, which penetrated the other provinces of culture and welded them into a homogeneous whole.

SYMBOLS AND IMAGES

Indian art is highly symbolic, a "symbol" being understood as the representation or manifestation of an invisible idea and the relation between a sign and an idea being understood as one of community or unity. The much-developed ritual-religious symbolism presupposes the existence of a spiritual reality that, while being in constant touch with phenomenal reality, may make its presence and influence felt and can also be approached through the symbols that belong to both spheres.

Mental and external fashioning of images

The production of objects of symbolic value is therefore more than a technique. The artisan has to model a cult image after the ideal prototype that, with its canonical forms, appears in his mind only when he has brought himself to a state of supranormal consciousness. Undergoing a process of spiritual transformation himself, he also transforms the material of which the image is to be made into a receptacle of divine power. Like the artisan, the worshipper (*sādhaka*, "the one who wishes to attain his goal") must grasp the esoteric meaning of a statue, picture, or flowerpot and identify himself with the power residing in it. The usual offering, a handful of flowers, is a vehicle to convey his "life-breath" into the external image, which has already been transformed into an adequate internal vision of the same divine power.

Types of symbols. If he knows how to handle the symbols, the worshipper—who must achieve his object himself and cannot come into contact with God unless he insistently invokes him—has the disposition of an instrument for utilizing the possibilities lying in the depths of his own subconsciousness as well as a key to the mysteries of the forces dominating our world.

Yantra and maṇḍala. The general term for such an "instrument [for controlling]" is *yantra*, which, while denoting in a wider sense cult images, pictures, and other such aids to worship, is often especially applied to ritual diagrams. Any *yantra* represents some aspect of the divine and enables the devotee to worship it immediately within his heart while identifying himself with it. Except in its greater linear complication, a *maṇḍala* does not differ from a *yantra*, drawn with a highly complex ritual upon the ground on a purified and ritually consecrated place. The meaning and the use of both are similar, and both may be permanent or provisional. A *maṇḍala*, delineating a consecrated place and protecting it against disintegrating forces represented in demoniac cycles, is the geometric projection of the universe, spatially and temporally reduced to its essential plan. It represents in a schematic form the whole drama of disintegration and reintegration, and the adept standing in its centre identifies himself with the forces governing these. Just as in temple ritual, a vase is employed to bring down the divine power so that it may be projected into the drawing and into the person of the adept. Thus the *maṇḍala* becomes a support for meditation, an instrument to provoke visions of the unseen. A good example of a *maṇḍala* is the *śrīcakra*, "the Wheel of Śrī" (*i.e.*, of God's Śakti) made up of four isosceles triangles with the apices upward symbolizing Śiva and five isosceles triangles with the apices downward symbolizing Śakti; the nine triangles are of various sizes and intersect with one another. In the middle is the power point (*bindu*), visualizing the highest, the invisible, elusive centre from which the entire figure and the cosmos expand. The triangles are enclosed by two rows of (eight and 16) petals, representing the lotus of creation and reproductive vital force. The broken lines of the outer frame make the figure a sanctuary, with four openings to the regions of the universe. A *yantra*, called *maṇḍala*, of the Puruṣa (spirit) of the site, is, as a "spiritual" foundation, also drawn on the site on which a temple is built. This rite is motivated by a replica of the myth of Puruṣa—an immortal primeval being who with his bulk obstructed both worlds until subdued by the gods; the parts of his body becoming site spirits.

Śrīcakra-maṇḍala

Liṅga and yoni. One of the most common objects of worship, whether in temples or in the household cult, is the *liṅga* (phallus). Often much stylized and an austere rather than obscene symbol, erect and representing the cosmic pillar, it emanates its all-producing energy to the four quarters. As the symbol of male creative energy it is frequently combined with its female counterpart (*yoni*), the latter forming the base from which the *liṅga* rises. Although the *liṅga* originally may have had no relation to Śiva, it has from ancient times been regarded as symbolizing Śiva's creative energy and is widely worshipped as his "fundamental form."

Visual theology in icons. The beauty of the cult objects contributes to their force as sacred instruments; their ornamentation facilitates the process of inviting the divine power into them. Statues of gods, however, are not intended to imitate ideal human forms but to express the supernatural. A divine figure is a "likeness" (*pratimā*), a temporary benevolent or terrifying expression of some particular aspect of a god's nature. Iconographic handbooks attach great importance to the ideology behind images and reveal, for instance, that Viṣṇu's eight arms stand for the four cardinal and intermediate points of the compass and that his four faces, illustrating the concept of God's fourfoldness, typify his strength, knowledge, lordship, and potency. The emblems express the qualities of their bearers—*e.g.*, a deadly weapon pointing to destructive force, many-headedness to omniscience. Much use is made of gestures (*mudrā*), conventional devices for denoting activities that express an idea; thus, the raised right hand, in the "fear-not" gesture (*abhaya-mudrā*), bestows protection. Every iconographic detail has its own symbolic value, helping the devotee to direct his energy

Purposes of Hindu iconography

to a deeper understanding of the various aspects of the divine and to proceed from external to internal worship. For many Indians, an installed and consecrated image becomes a container of concentrated divine energy; according to Hindu theists, an instrument for ennobling the worshipper who realizes God's Presence in it.

VISUAL ARTS

Religious principles in sculpture and painting. The dance executed by Śiva as king of dancers (Naṭarāja), the visible symbol of the rhythm of the universe, represents God's five activities: he unfolds the universe out of the drum held in one of his right hands; he preserves it by uplifting his other right hand in *abhaya-mudrā* (a gesture indicating "do not be afraid"); he reabsorbs it by the upper left hand, which bears a tongue of flame; his transcendental essence is hidden behind the garb of apparitions and grace is bestowed and release made visible by the foot that is held aloft and to which the hands are made to point. The other foot, planted on the ground, gives an abode to the tired souls struggling in *saṃsāra*. Another dancing pose adopted by Śiva is the famous *tāṇḍava*, executed in his destructive Bhairava manifestation, usually with ten arms and accompanied by Devī and demons. The related myth is that Śiva conquered a mighty elephant demon whom he forced to dance until he fell down dead; then, wrapped in the blood-dripping skin of his victim, the god executed a horrendous dance of victory.

Images sustain the presence of the god: when Devī is shown advancing against the buffalo demon, seated on her lion, she represents the affirmative forces of the universe and the triumph of divine power over wickedness. Male and female figures in uninterrupted embrace, as in Śaiva iconography, signify the union of opposites and the eternal process of generation. Lovers sculptured on temples are "auspicious symbols" put on a par with foliage, water jars, and other representatives of fertility.

Religious organization of sacred architecture. Temples must be erected on a site that is *śubha* (*i.e.*, suitable, beautiful, and auspicious), in the neighbourhood of water, because the gods will not come to other places. Temples are not, however, designed to be congenial to their surroundings because a manifestation of the sacred is an irruption, a break in phenomenal continuity. Since temples are said to constitute an opening in the upward direction and thus ensure communication with the gods, they are visible representations of a cosmic pillar and their site is said to be a navel of the world. Their outward appearance must raise the expectation of meeting with God. Their erection is considered a reconstruction and reintegration of Puruṣa-Prajāpati, enabling him to continue his creative activity, and the finished monuments are "symbols" of the universe that is the unfolded One. The owner (*i.e.*, an individual or community that paid for its construction, and the descendants) of the temple—also called the "sacrificer"—participates in the process of reintegration and experiences his spiritual rebirth in the small cella, aptly called the "womb room" (*garbhagṛha*), by means of meditative contact with God's presence, symbolized or actualized in his consecrated image. The cella is in the centre of the temple above the "navel"—*i.e.*, the "foundation stone"—a jar filled with the creative power (*śakti*) that is identified with the goddess Earth (who bears and protects the monument) three lotus flowers, and three tortoises (of stone, silver, gold) that represent earth, atmosphere, and heaven. The tortoise is regarded as a manifestation of Viṣṇu bearing the cosmic pillar, and the lotus as a symbol of the expansion of generative possibilities. The vertical axis or tube (coinciding with the cosmic pillar), which connects all parts of the building and is continued in the finial on the top, corresponds with the mystical vertical "vein" in the body of the worshipper through which his soul rises to unite itself with the Highest.

Requirements of temple architecture and planning

THEATRE AND DANCE

Theatrical performances of various types and artistic levels are also events to secure blessings and happiness; the element of recreation is indissolubly blended with edification and spiritual elevation. The structure and character of the classical Indian drama reveal its origin and function; it developed from the last part of a magico-religious ceremony that survives as a ritual introduction and begins and closes with benedictions. Drama is produced on festive occasions with a view to spiritual and religious success (*siddhi*), which must also be prompted by appropriate behaviour from the spectators; there must be a happy ending; the themes are borrowed from epic and legendary history; development and unravelling of the plot are retarded and so the envy of malign influences averted by the almost obligatory buffoon (*vidūṣaka*, "the spoiler"). The less cultured masses still have, in addition to the films, which often use the same religious and mythic themes, their uncomplicated *yātrās*, a combination of stage play and various festivities, which have contributed much to the spread of the "puranic" view of life.

Yātrās

Dancing is not only an aesthetic pursuit but a divine service. Hence there are halls for sacred dances annexed to some temples. The rhythmic movement has a compelling force, generating and concentrating power or releasing superfluous energy. It induces the experience of the divine and transforms the dancer into whatever he impersonates. Thus, many tribal dances consist of symbolic enactments of events (harvest, battles) that are desired to be accomplished successfully. Musicians and dancing girls accompany processions to expel the demons of cholera or cattle plague. Even today, religious themes and the various relations between man and God are "danced" and made visual by the codified symbolic meanings of gestures and movements (see SOUTH ASIAN PEOPLES, ARTS OF).

V. Place of Hinduism in Indian and world religions

HINDUISM AND OTHER RELIGIONS OF INDIAN ORIGIN

Buddhism and Jainism are, essentially, new interpretations rather than repudiations of the common Indian tradition.

Buddhism. Since Buddhism did not interfere with Hindu customs and usages, allowing its adherents to approach Hindu or local supernatural powers for immediate favours, Hindu criticism came mainly from Brahmin philosophers who opposed its adherents because they rejected the authority of the Veda and the Brahmins and the doctrine of the *ātman* (soul) and because they admitted persons of any age and caste to monastic life. The spread of Buddhism was often regarded as an indication of the degeneration of humanity. In the course of time, Buddha was recognized as an incarnation of Viṣṇu, but this recognition was often qualified by the addition that Viṣṇu assumed this form in order to mislead and destroy the enemies of the Veda. Yet this *avatāra* is rarely worshipped. Buddhist emblems also were often ascribed to Viṣṇu or Śiva. Some ancient Buddhist shrines have remained partly under the supervision of Hindu ascetics and are visited by pilgrims notwithstanding their much neglected condition.

After the rise of Buddhological studies in the West and the archaeological discoveries and restorations since the end of the 19th century had made Indians more aware of the Indian origin of Buddhism, the Republic of India adopted the Buddhist emperor Aśoka's lion capital, marking the place of Buddha's first teaching, as its national emblem. The Buddha jubilee in 1956 was an occasion for enthusiastic celebrations. In recent years the number of Indian Buddhists is again increasing, due mainly to the conversion of persons of low social rank for whom, after conversion, the disabilities of their birth no longer remain.

Jainism. With Jainism, which always remained an Indian religion, Hinduism has, especially in social institutions and ritual life, so much in common that nowadays Hindus generally tend to consider it a Hindu sect and many Jainas are much inclined to fraternization. The points of difference—*e.g.*, a stricter *ahiṃsā* practice and the absence of sacrifices for the deceased in Jainism—do not give any offense (see BUDDHISM; JAINISM).

HINDUISM AND ISLAM

Islām, so different from Hinduism in creed and institutions, was, in India, neither absorbed nor powerful enough to make India a Muslim country. The religious situation created by the presence of its numerous adherents always had explosive potentialities: the Muslims do not respect bovine life and regard Hindu cult practices as objectionable idolatry. Although the Indian Muslims, with few exceptions, are of native descent, they are theoretically outcastes with whom dealings must remain restricted by formal rules; but, like Christians, they are less polluting than the Hindu lower castes. The Islāmic way of life meets with opposition; Muslims and Hindus do not ordinarily intermarry or dine together. Up to the present day, this situation has raised acute and even devastating issues, but it does vary somewhat from region to region, from village to village, and from class to class. Very often, however, mutual differences are accepted. Though repudiating caste, Muslims often observe it in practice or have even after their conversion to Islām retained their original caste organization.

Hindus, inclined to worship the holy whatever its manifestations, may revere Muslim saints or take part in Muslim festivities, often to such an extent that the character of these celebrations has been altered. The Muslim faith of ordinary people was constantly exposed to the subtle infection of Hinduism. This led, especially among the mystically minded who speculated whether the sole reality should be called Allāh or Brahman, to various syntheses, such as Sikhism, which are, for the Hindu, Hindu sects, and to communities whose religious practice is partly Muslim, partly Hindu. Those who, like Gandhi, could not understand the intolerance of orthodox Islām sympathized with the moderation and eclecticism of these groups. Most of the educated class, however, always remained aware of the cleavage. To the Muslims—who, as part of an ecumenical community stretching over large parts of Asia and Africa, are concerned about the political and religious crisis of Islām since the late 19th century—the collapse of the Mughals after the Indian Mutiny (1857) was a severe blow that did not contribute to closer and better relations with Hindus. This is particularly true because anti-Muslim tendencies had, since the renascent Hinduism of the Marāṭhā movement and in later times in the Arya Samaj (see above), won ground, and Muslims became self-assertive and determined to maintain their distinctive position. After partition of the subcontinent into India and Pakistan—partly based on religious differences—and independence (1947), the political controversies between India and Pakistan constituted a complication.

HINDUISM AND CHRISTIANITY

For the eclectic and undogmatic educated Hindu, who believes that religion is a matter of personal realization, every religion is true and a path to truth. If the adherents of Christianity sincerely follow it, the Hindu's attitude toward it, notwithstanding what he believes to be the militant and essentially intolerant disposition of the followers of Christianity—which is regretted by Hindus—continues to be one of respect and understanding, of tolerance and even sympathy. The Hindu is ready to accept the ethical teachings of the Gospels, particularly the Sermon on the Mount (whose influence on Gandhi is well known) but rejects the theological superstructure. Many adherents of *bhakti* movements—the Christian influence on which has been grossly exaggerated—feel that the Christian conceptions, which are regarded as a kind of *bhakti*, do not realize in God the multiplicity of human relations of love and service. Educated Hindus, though assimilating some Christian ideas, often regard missionary propaganda as an attack on their national genius and time-honoured institutions and take offense at what they regard as the disrespectful utterances of Christian missionary literature. They are averse to the organization, the reliance on authorities, and the exclusiveness of Islām and Christianity, considering these obstacles to harmonious cooperation. They subscribe to Gandhi's opinion that missionaries should confine their activities to humanitarian service. Since independence, conversion has indeed been viewed with disfavour by many influential Indians, who often also find in Hinduism what might be attractive in Christianity. Movements that, like the Arya Samaj, advocate a Hindu theism designed to rival Islām and Christianity, make serious efforts to reconvert Christians to the Hindu community. The ordinary people tolerate the proximity of Christian converts, even if these transgress Hindu taboos, provided they form a more or less separate community. Thus Christians often form castes or endogamous bodies analogous to castes. They are sometimes admitted to temples to which untouchable Hindus have no entrance. In Malabar, Christians came, on account of their economic position, to be practically equalized with Brahmins. Nationalism has challenged the more serious-minded Indian Christians to express the genius of their faith in Indian modes and patterns. This has led, since 1921, to the emergence of Christian *āśramas* in the south. The dialogue between Hinduism and Christianity is more or less institutionalized at Bangalore in Mysore state where the Christian Institute for the Study of Religion and Society is located. Its bulletin offers an opportunity for discussion between, for example, Christians and supporters of the Ramakrishna Mission.

The Arya Samaj movement

Hinduism, History of

The history of Hinduism, a religion that in the 20th century claims more than 437,000,000 followers, began in India about 1500 BC. From its literature Hinduism can be traced back to before 1000 BC; evidence of its earlier antecedents is derived from archaeology, comparative philology, and comparative religion. This article is concerned only with the history of Hinduism; the manifold doctrines, practices and scriptures of the religion are described in greater detail elsewhere (see also HINDUISM; HINDU SACRED LITERATURE).

This article is divided into the following sections:

SOURCES OF HINDUISM

Indo-European sources. The earliest literary source for the history of Hinduism is the Ṛgveda, the hymns of which were chiefly composed over the last two or three centuries of the 2nd millennium BC. The religious life reflected in this text is not that of Hinduism but of an earlier sacrificial religious system, generally known as Brahmanism or Vedism, which developed in India among the invaders who brought with them the horse and chariot and the Sanskrit language and who are generally known as Aryans, the name by which they referred to themselves. They were a branch of a related group of nomadic and seminomadic tribal peoples originally inhabiting the steppe country of southern Russia and Central Asia. Other branches of these peoples penetrated into Europe, bringing with them Indo-European languages that developed into the chief language groups now spoken there.

The religion of the Ṛgveda

Before they entered the Indian subcontinent (*c.* 1500 BC), the Aryans were in close contact with the ancestors of the Iranians, as evidenced by a near kinship between Sanskrit and the earliest surviving Iranian languages. Thus, the religion of the Ṛgveda contains elements from three evolutionary strata: an early element common to most of the Indo-European tribes; a later element held in common with the early Iranians; and an element acquired in the Indian subcontinent itself, after the main Aryan migrations. Hinduism arose from the continued accretion of further elements derived from the original non-Aryan inhabitants, from outside sources, and from the geniuses of individual reformers at all periods. The accretion was accompanied by an inverse process of dropping elements of beliefs and practices that had outlived their usefulness. This has been going on, often almost imperceptibly, throughout the history of Hinduism.

Indo-European influences. In Hinduism there are few direct survivals of the Indo-European heritage. Some of the rituals of the Hindu wedding ceremony, notably the circumambulation of the sacred fire and the cult of the domestic fire itself, look back to the remote Indo-European past. The same is probably true of the custom of cremation and some aspects of the ancestor cult. The Ṛgveda shows many other Indo-European elements, such as the worship of male sky gods with sacrifices, and the old heaven god Dyaus, whose name is cognate with those of the classical Zeus of Greece and Jupiter of Rome ("Father Jove"). The Vedic heaven, the "World of the fathers," resembled the Germanic Valhalla and seems also to be an Indo-European inheritance.

Cremation and the ancestor cult

Indo-Iranian influences. The Indo-Iranian element in later Hinduism is chiefly to be found in the initiatory ceremony (*upanayana*) performed with boys of the three upper classes, a rite both in Hinduism and in Zoroastrianism that involves the tying of a sacred cord. Vedic religion showed many such elements. The Vedic god Varuṇa, now an unimportant sea god, appears in the Ṛgveda as sharing many features of the Zoroastrian Ahura Mazdā ("Wise Lord"); the narcotic sacred drink *soma* corresponds to the sacred *haoma* of Zoroastrianism.

Indigenous influences. Even in the earlier parts of the Ṛgveda the religion had already acquired numerous specifically Indian features. Some of the chief gods, notably Indra (god of storms and battle), have no clear Indo-European or Indo-Iranian counterparts. Some of the new features may have evolved entirely within the Aryan framework, but it is generally presumed that many of them stem from the influence of the indigenous inhabitants. That the Vedic Aryans were in direct contact with the civilization of the Indus Valley in its prime is doubtful, but the religion of the valley's culture probably had some influence upon the Aryans.

Non-Indo-European sources. *The Dravidian hypothesis.* All features of Hinduism that cannot be traced back to the Ṛgveda are sometimes ascribed to the influence of the original inhabitants, who are often vaguely and incorrectly referred to as "Dravidians." The ruling classes of the Harappā culture (*c.* 2300–1700 BC), or the Indus civilization, may have spoken a Dravidian language, but the presence of Dravidian speakers throughout the whole subcontinent at any time in history is not attested. The Mediterranean racial type, to which most modern higher caste Dravidian speakers belong, is widespread throughout India; but it cannot be proved that all men of this type originally spoke Dravidian languages or that all followed the same culture. Equally or more widely spread in South and Southeast Asia is the Proto-Australoid racial type, the purest members of which in India are the tribal peoples of the centre and the south, many of whom speak languages of the Austric family. Thus, although many aspects of Hinduism are traceable to non-Aryan influence, not all of these aspects are borrowed from "Dravidians." In the 20th century, the term Dravidian is generally used to refer to a family of languages and not to an ethnic group.

Role of the Proto-Australoid racial type

Other influences. Further influences have affected Hinduism in historic times. The Central Asian nomads who entered India in the two centuries before and after the beginning of the Christian Era may have had some effect on the growth of devotional Hinduism out of Vedic religion. There was indirect influence of the classical western world on Hindu religious art, and several features of Hinduism may be traced to Zoroastrianism. The influence of later Taoism from China on Tantric Hinduism (an esoteric system of achieving release from transmigration) has been suggested, though this cannot be finally proved. In more recent centuries, the influence of Islām and Christianity on Hinduism can be seen.

The process of "Sanskritization" and its converse. The development of Hinduism may be interpreted as a constant interaction between the religion of the upper social groups, represented by the Brahmins (priests and teachers), and the cults of the masses. From the time of the Aryan invasion (*c.* 1500 BC) the indigenous inhabitants of the subcontinent have tended to adapt their religious and social life to Brahminic norms. This has developed from a desire of lower class groups to rise on the social ladder by adopting the ways and beliefs of the higher castes. This process, sometimes called "Sanskritization," was going on in Vedic times, when non-Aryan chieftains accepted the ministrations of Brahmins and thus achieved status in the social system for themselves and their subjects. It was probably the main means whereby Hinduism spread through the subcontinent and beyond it into Southeast Asia. Sanskritization still continues in the form of the conversion of tribal groups, and it is reflected in the persistent tendency of low-caste Hindus to try to raise their status by adopting high-caste customs, such as wearing the sacred cord and becoming vegetarians.

If "Sanskritization" has been the main means of spreading Hinduism throughout the subcontinent, its converse process, which has no convenient label, has been one of the means whereby Hinduism has changed and developed over the centuries. The Aryan conquerors had to live side by side with the Aboriginals, and many features of Hinduism, as distinct from Vedic religion, apparently developed from the cults of the non-Aryan lower orders. The doctrine of transmigration, which is the hallmark of Indian religions, may have developed in this kind of process. The phallic emblem of Śaivism, a major form of Hinduism centring on devotion to the god Śiva (originally a storm god), most likely was borrowed from early popular fertility cults. Many features of Hindu mythology and several of the lesser gods—such as Gaṇeśa, an elephant-headed god, and Hanumān, the monkey god—were incorporated into Hinduism by this means. The system of ecstatic devotional religion known as Bhakti seems to have begun in unorthodox circles on the fringes of Brahminic culture. Thus, the history of Hinduism may be interpreted on the one hand as the imposition of orthodox custom upon wider and wider ranges of people and on the other as the survival of features of non-Aryan cults, which gained strength steadily until they were taken over or adapted by the Brahmins.

Accretions from non-Aryan religions

THE PREHISTORIC PERIOD (3RD AND 2ND MILLENNIA BC)

Indigenous prehistoric religion. The prehistoric culture of the Indus Valley arose in the latter centuries of the 3rd millennium BC from the metal-using village cultures of the region. There is considerable evidence for the religious life of the Indus people, but in the absence of intelligible written records its interpretation is speculative. There is enough, however, to show that several features of later Hinduism had prehistoric prototypes.

In most of the village cultures, small terracotta figurines of women, found in large quantities, have been interpreted as icons of a fertility deity whose cult was widespread in the Mediterranean area and in West Asia from Neolithic times onward. This hypothesis is strengthened by the fact that the goddess was apparently in several instances associated with the bull—a feature also found in the ancient religions farther west.

Religion in the Indus Valley civilizations. The Harappā culture (often referred to as the Indus Valley civilization, located in modern Pakistan) has produced much evidence of the cult of the goddess and the bull. Figurines of both occur, the goddess being commoner than the bull. The bull, however, appears more frequently on the many seals. A horned deity, possibly with three faces, occurs on a few of these; in one specimen it is surrounded by animals. A few male figurines in hieratic (sacerdotal) poses and one apparently in a dancing posture suggest deities. No building has been discovered at any Harappan site that can with certainty be interpreted as a temple, but the famous "Great Bath" at Mohenjo-daro (also in Pakistan) was almost certainly used for ritual purposes, as were the *ghāṭs* (bathing steps on riverbanks) attached to later Hindu temples. The presence of bathrooms in most of the houses and the remarkable system of covered drains indicate a strong feeling for cleanliness that was probably connected with concepts of ritual purity and taboo, rather than with ideas of hygiene.

Many of the seals show religious and legendary themes that cannot be interpreted with certainty. There is clear evidence, however, of the worship of sacred trees or of the divinities believed to reside in them. The bull is often depicted standing before a sort of altar, which may be a cult object connected with a fertility ritual. The horned god has been interpreted, perhaps overconfidently, as a prototype of the Hindu god Śiva. Small conical objects appear to be phallic emblems, also connected with Śiva in later Hinduism, although they may have been pieces used in board games. Other interpretations of the remains of the Harappā culture are more speculative and, if accepted, would indicate that many features of later Hinduism were already in existence 4,000 years ago.

The fact that Harappans buried their dead with grave deposits, a practice not followed by the later Hindus, shows that they had some belief in an afterlife. At Lothal, a Harappan site in Gujarāt (in western India), a double grave containing a man and a woman has been found, possibly indicating the occasional sacrifice of a widow upon her husband's death, similar to the later self-sacrifice of the *satī* ("virtuous woman").

Harappan burials

Survival of archaic religious practices in modern folk and primitive religions. However much the more developed forms of Hinduism may owe to the Harappā culture, some elements of the religious life of that civilization may be paralleled in the current and past folk religions of India—notably sacred animals, sacred trees, especially the *pīpal* (*Ficus religiosa*), and the use of small figurines for cult purposes. Such features of primitive religion are found in all parts of India, among tribal peoples as well as among the less sophisticated Hindus.

THE VEDIC PERIOD (2ND MILLENNIUM–7TH CENTURY BC)

The beginning of text and ritual: the Ṛgveda. The Aryans of the early Vedic period left hardly any material remains, but they did leave a very important literary record in the Ṛgveda (see also HINDU SACRED LITERATURE).

The Ṛgveda is not a unitary work, and may have been composed over several centuries. In its form at the time of its final edition it reflects a well-developed religious system and a culture considerably in advance of that depicted in the earlier hymns. The date commonly given for the recension of the Ṛgveda is 900 BC.

The religion reflected in the Ṛgveda is a polytheism mainly concerned with the propitiation of divinities associated with the sky and the atmosphere. Of these, the Indo-European sky father Dyaus, mentioned above, had by then become little regarded. More important were such gods as Indra, Varuṇa (guardian of the cosmic order), Agni (the sacrificial fire), and Sūrya (the sun; see also HINDU MYTHOLOGY).

The main ritual activity referred to in the Ṛgveda is the *soma* sacrifice. *Soma* was a narcotic beverage prepared from a now-unknown plant; recently it has been suggested that the plant was a mushroom. Later another plant was substituted for the agaric fungus, which had become difficult to obtain. The Ṛgveda contains few clear references to animal sacrifice, which probably became more widespread later. There is some doubt whether the priests formed a separate class of society at the beginning of the Ṛgvedic period. If they did so, the prevailingly loose boundaries of class made it possible for a man of nonpriestly parentage to become a priest. By the end of the period, however, they had become a separate class of specialists, the Brahmins (Brāhmaṇas), who claimed superiority over all the other social classes, including the Rājanyas, the tribal aristocrats.

The *soma* sacrifice in the Ṛgveda

The Ṛgveda throws little light on birth rituals, but the rites of marriage and disposal of the dead were basically the same as in later Hinduism. Marriage was an indissoluble bond cemented by a lengthy and solemn ritual

Scenes of a *soma* sacrifice performed in Pune (Poona), India, on behalf of a traditional Brahmin, following the same ritual used in 500 BC, an unusual example of the continuance of the Vedic tradition. (Though Vedic rites are still occasionally performed, photographic documentation of a complete and ritually correct ceremony is rare.) (Top) Group of 16 priests (four of each of the four Vedas) swear to the common interest of the sacrificer prior to the beginning of the ritual, their hands outstretched toward the fire (*āhavanīya*). (Bottom) Priests bring in fire to light the sacrificial fire in the newly constructed altar, taken from the household fire of the sacrificer, shown with his wife in the middle of the group.
C.M. Natu

centring on the domestic hearth. The funeral rites of the rich included cremation, though other funeral forms were also practiced. An interesting reference in one hymn shows that the wife of the dead man lay down beside him on the funeral pyre but was called upon to return to the land of the living before it was lighted. This may have been a survival from an earlier period when the wife was actually cremated with the husband, a custom that was revived in later times.

Among other features of Ṛgvedic religious life that were important for later generations were the groups or fraternities of *munis*. The *muni* was apparently a sort of wizard or shaman (religious personage having healing and psychic transformation powers), trained in various magic arts and believed to be capable of supernatural feats, such as levitation. He was particularly associated with the god Rudra, a deity connected with mountains and storm and more feared than loved. Rudra developed into the Hindu god Śiva, and his prestige increased steadily with time. The same is true of Viṣṇu, a minor solar deity in the Ṛgveda, who later became one of the most important and popular divinities of Hinduism.

Some of the hymns of the tenth book of the Ṛgveda show speculative tendencies, which were the beginnings of the persistent effort of the Indian philosopher to reduce all things to a single basic principle. The favourite myth of the Aryans apparently was one that attributed the origin of the cosmos to the god Indra, after he had slain the great dragon Vṛtra, a myth very similar to that of early Mesopotamia. With time, such tales were given up for speculative theories that are reflected in several hymns of the late tenth book of the Ṛgveda.

Even more important as a landmark in the history of Indian religion is the "Hymn of the Person" ("Puruṣa-sūkta," RV. x, 90), which is one of the latest hymns in the collection (see also HINDUISM). Here the four classes (*varṇa*) of Indian society are referred to: the priest (Brāhmaṇa) emerging from the head, the warrior (Rājanya, later Kṣatriya) from the arms, the peasant (Vaiśya) from the trunk, and the servant (Śūdra) from the legs of the primeval victim of a cosmic sacrifice. The "Puruṣa-sūkta" represents the beginning of a new phase, in which the sacrifice became even more important and elaborate, and the Brahmins even more exalted.

The exaltation of the Brahmins

Elaborations of text and ritual: the later Vedas and Brāhmaṇas. The chronology of later Vedic developments is extremely vague, but they can probably be related to the Painted Grayware strata in the archaeological sites of the western Ganges (Gaṅgā) Valley, dated from about 1000 to 500 BC. These reflect a culture still illiterate but showing considerable advances in civilization. Nothing, however, has yet been discovered from sites of this period that throws much light on the religious situation, and the historian is still chiefly dependent on texts.

The period was one in which the sacrifices were developed to become lengthy series of rituals—sometimes lasting more than a year—in which hundreds of animals were slaughtered. As the world was produced by sacrifice, according to the Vedas, so also a constant performance of sacrifice was required to maintain it, and this demanded numerous highly trained Brahmins to intone the hymns, to utter the ritual phrases, and to perform the ritual actions with scrupulous accuracy. Thus, the influence of the priesthood increased.

The class of Brahmins by then was divided into groups that married exogamously (only to members of other groups, or *gotras*), and the Brahmins formed various schools (*śākhā*) according to the recension of the sacred texts (*Brāhmaṇas*) that were specially studied. The Brahmin claimed supremacy over the ruler, although often he did not obtain it. One might suspect that the great elaboration of the sacrifice at this period and the appearance of long and expensive new sacrifices, especially intended for royal patrons, were deliberately devised to enhance the influence and wealth of the priests by flattering the kings. The lengthy series of rituals of the royal consecration, the *rājasūya*, emphasized the royal power and endowed the king with a divine charisma, raising him, at least for the duration of the ceremony, to the status of a god. Typical of this period is the elaborate *aśvamedha*, the horse sacrifice, in which a consecrated horse was left loose and allowed to wander at will for a year, followed by the king's troops, who defended it from all attack until it was brought back to the royal capital and sacrificed with a very complicated ritual. The ambition to perform an *aśvamedha* was encouraged in later times by the Brahminic traditions and was one of the causes that contributed to the instability of Hindu kingdoms.

The beginnings of philosophy: the "Upaniṣads." The next phase of Indian religious life, roughly between 700 and 500 BC, is the period of the beginnings of philosophy and mysticism marked by the *Upaniṣads* ("sittings near a teacher"). Historically, the most important of these are the two oldest, the *Bṛhadāraṇyaka* ("great forest text") and the *Chāndogya* (pertaining to the "Chandogas," a class of Brahmin specially connected with the intonation of hymns at sacrifices), both of which are compilations recording traditions of certain sages (*ṛṣi*) of the time, notably Yājñavalkya, who was a pioneer of new religious ideas.

The primary motive of the *Upaniṣads* is a desire for

mystical knowledge such as would ensure freedom from "re-death." Throughout the later Vedic period, the idea that the world of the fathers was not the end—and that even in heaven death was inevitable—had been growing. The age of the *Upaniṣads* was one of rapid material progress, and urban civilization was reviving. The geographical horizon was also expanding, as the "other worldly" aspects of Indian religion became prominent. The new developments were connected with the growth of asceticism and the appearance of the doctrine of rebirth, generally called transmigration.

The development of asceticism and belief in rebirth

The Ṛgveda shows little evidence of asceticism, except among the *munis* (shamans). In the Atharvaveda appears another class of religious adepts, or specialists, the *vrātyas*, particularly connected with the region of Magadha (southern Bihār). The *vrātya* was a wandering hierophant (one who manifested the Holy), outside the regular system of Vedic religion. He travelled from place to place in a bullock cart with an apprentice and with a woman who appears to have been used for ritual prostitution. Flagellation and other forms of self-mortification seem to have been part of his routine. Efforts were made by the orthodox to bring the *vrātyas* into the Vedic system by special rituals of conversion, and it may be that these people helped to introduce non-Aryan beliefs and practices into Vedic religion. Meanwhile, the more complex sacrifices of the later Vedic period demanded purificatory rituals such as fasting and vigil as part of the preparations for the ceremony. Thus there was a growing tendency toward the mortification of the flesh.

The origin and the development of the belief in the transmigration of souls are very obscure. A few passages have been found to suggest that this doctrine was known even in the days of the Ṛgveda, but it is first clearly propounded in the earliest *Upaniṣad*—the *Bṛhadāraṇyaka*. Here it is stated that normally the soul returns to Earth and is reborn in human or animal form. This doctrine of *saṃsāra* (reincarnation) is attributed to the sage Uddālaka Āruṇi, who is said to have learned it from a Kṣatriya chief. In the same text, the doctrine of *karma* (works), that the soul achieves a happy or unhappy rebirth according to its works in the previous life, also occurs for the first time, attributed to Yājñavalkya. Both doctrines appear to have been new and strange ones, circulating among small groups of ascetics who were disinclined to make them public, perhaps for fear of the orthodox priests. These doctrines must have spread rapidly, for in the later *Upaniṣads* and in the earliest Buddhist and Jain scriptures they are common knowledge.

Dissatisfaction with the ritualism of Vedic religion and the increasing popularity of the life of the ascetic wanderer or the hermit encouraged mysticism and a search for the ultimate, union with which would bring complete bliss and release (*mokṣa*) from transmigration.

The concept of the Absolute as a neuter entity was not universal even in the earlier *Upaniṣads*. The oldest, the *Bṛhadāraṇyaka*, contains little-noticed passages of theistic import. The later *Upaniṣads* have a much larger theistic content and link up with theistic developments of later times. The *Upaniṣads* represent the beginnings of philosophy in India. Their authors usually make their points by analogical arguments, but the literature of the *Upaniṣads* also contains numerous attempts at logical reasoning and argument from observed facts.

CHALLENGES TO BRAHMINISM (7TH–2ND CENTURIES BC)

Domestic ritualism and reform

The elaboration of expensive and large-scale ritual, which is evident in the later Vedic literature, was accompanied by the first steps in the codification of the rules of Aryan conduct in the literature of the *sūtras* ("threads," or collections of aphoristic statements). From about 600 BC, texts appeared containing terse instructions on the ritual of lesser sacrifices (*Śrauta-sūtras*), on domestic rituals (*Gṛhya-sūtras*), and on the conduct of life (*Dharma-sūtras*). Society was ritually stratified in the four classes, each of which had its own *dharma* (law), or eternal norm of conduct. The ideal life was sacramentalized by numerous ceremonies incumbent upon the upper classes, carrying the individual from the cradle to the grave in a series of complex rites. The *Gṛhya-sūtras* show that in the popular religion of the time there were many minor divinities who are hardly mentioned in the literature of the large-scale sacrifices but who were probably far more influential on the lives of the lower orders than the great gods of Vedism (see also HINDUISM).

The century from about 550 BC onward was a period of great change in the religious life of India, for it saw the rise of breakaway sects of ascetics denying the authority of the Vedas and of the Brahmins and looking up to founders who claimed to have discovered the secret of obtaining release from transmigration. The most important of these were Siddhārtha Gautama, the Buddha, and Nātaputta Vardhamāna, called Mahāvīra ("Great Hero"), the great teacher of Jainism (see also BUDDHISM; JAINISM). There were many other heterodox teachers who organized bands of ascetic followers, each group following a specific code of conduct. They gained considerable support from ruling families and merchants. The latter were growing in wealth and influence, and many of them were in search of forms of religious activity that would give them a more significant part to play than did orthodox Brahminism and would be less expensive to support.

The new religious movements left scriptures behind them that throw some light on the popular religious life of the period. The god Brahmā was widely looked on as the highest god and the creator of the universe, with Indra, known chiefly as Śakra ("the mighty one"), second to him in importance. The Brahmins were very influential, but opposition had developed to their large-scale animal sacrifices—on both humanitarian and economic grounds—and their pretensions to superiority by virtue of their birth were questioned. The doctrine of transmigration was now almost universally accepted, although a group of outright materialists denied the survival of the soul after death. The ancestor cult, part of the Indo-European heritage, was kept up almost universally, at least by the higher castes. Popular religious life largely centred around the worship of local fertility divinities (*yakṣa*, *yakṣī*), snake-spirits (*nāga*), and other minor spirits in sacred places and groves (*caitya*). These sacred places were the main centres of popular religious life. There is no evidence of any buildings or images associated with them, and it appears that neither temples nor large icons existed at the time.

At this time (*c.* 500 BC), asceticism became widespread, and more and more intelligent young men "gave up the world" in search of release from transmigration in a state of psychic security. The orthodox Brahminical teachers reacted to these tendencies by devising the doctrine of the four *āśramas* (abodes), which divided the life of the twice-born after initiation into four stages: the *brahmacārin* (celibate religious student); the *gṛhastha* (married householder); the *vānaprastha* (forest hermit); and the *sannyāsin* (wandering ascetic). This attempt to keep asceticism in check and confine it to men of late middle age was never followed universally, but henceforth Hindu social theory centred round the concept of *varṇāśramadharma*, the duties of the four classes (*varṇa*) and the four stages of life (*āśrama*), which formed the ideal that the Hindu was encouraged to follow.

The doctrine of the four *āśramas*

The 3rd century BC was the period of the Mauryan Empire, the first great empire of India. Its early rulers were heterodox, and Aśoka (reigned *c.* 265–238 BC), third and most famous of the Mauryan rulers, was a professed Buddhist. There is no doubt that Aśoka's patronage of Buddhism did much to spread that religion, though in his inscriptions he recognizes the Brahmins as worthy of respect. Sentiments in favour of nonviolence (*ahiṃsā*) and vegetarianism, much encouraged by the heterodox sects, spread during the Mauryan period and were greatly encouraged by Aśoka, though such sentiments began long before Buddhism. A Brahminic revival appears to have occurred with the fall of the Mauryas. But the orthodox religion was itself undergoing change at this time, with a development of theistic tendencies that centred around the gods Viṣṇu and Śiva.

Inscriptional and iconographic evidence of devotional theism appears in the 2nd century BC, together with literary references. Several brief votive inscriptions refer to the god Vāsudeva, who by this time was widely worshipped in western India. At the end of the 2nd century, Heliodorus, a Greek ambassador from King Antialcidas of Taxila (in Pakistan), erected a large column in honour of Vāsudeva at Besnagar in Madhya Pradesh and recorded that he was a Bhāgavata, a term specially used for the devotees of Viṣṇu. It is possible that Vāsudeva originally may have been a popular god outside the orthodox pantheon, but his identification with the old Vedic god Viṣṇu and, later, with Viṣṇu's incarnation, Kṛṣṇa, was rapidly accepted.

From around the end of the Mauryan period the first surviving stone images of Hinduism appear, not representing any of the great gods but *yakṣa*s, or local chthonic (earth or fertility) divinities, of whom several large, rather crude figures survive. The original locations of these images are uncertain, but they were probably erected in the open air in sacred enclosures. Temples are not clearly attested in this period either by archaeology or literature. A very few fragmentary images of pre-Christian date are thought to be those of Vāsudeva, and Śiva, both in anthropomorphic form and in the form of a *liṅga*, or phallic emblem, is attested on coins of the 2nd and 1st centuries BC.

EARLY HINDUISM (2ND CENTURY BC–4TH CENTURY AD)

Transformations of Brahminism and popular religion. The development of the cult of Viṣṇu was much encouraged by the editors of the *Mahābhārata*, a great Hindu epic. Numerous interpolated episodes were introduced into the epic, among them the *Bhagavadgītā* ("Song of the Lord"). This marks the real beginning of Hinduism as distinct from Brahminism and the culmination of the literature of the *Upaniṣads*. Beside the impersonal, rather intellectual mysticism of the early *Upaniṣads*, a new theism developed, replacing sacrifice (*yajña*) by worship (*pūjā*) and the attitude of self-knowledge and introspection by one of respect and devotion (*bhakti*) to a personal god, who, in the case of the *Bhagavadgītā*, is conceived of as the Vedic god Viṣṇu incarnate as Kṛṣṇa. The *Bhagavadgītā* is significant also for its sturdy defense of the system of the four classes and for its doctrine that selfless action, done in order to carry out the duties of one's class and for the glory of God, is a more effective means of obtaining release from transmigration than sacrifice, asceticism, or meditation. It is chiefly this ethical doctrine that has made the *Bhagavadgītā* so influential in the Hinduism of the 19th and 20th centuries.

First distinction of Hinduism from Brahminism

The rise of the major sects: Vaiṣṇavism, Śaivism, and Śāktism. Alongside the cult of Viṣṇu, that of Śiva developed. The god Rudra gained in importance from the end of the Ṛgvedic period onward. In the *Śvetāśvatara Upaniṣad*, Rudra is for the first time called Śiva and is described as the creator, preserver, and destroyer of the universe. His followers are called on to worship him with the same devotion (*bhakti*) as that accorded to Kṛṣṇa-Viṣṇu in the *Bhagavadgītā*. The tendency for the laity to form themselves into religious guilds, or societies—evident in the case of the *yakṣa* cults, Buddhism, and Jainism—promoted the growth of devotional Vaiṣṇavism and Śaivism. These local associations of worshippers appear to have been among the main means of spreading the new cults. Theistic ascetics are less in evidence at this time; but a society of Śaivite monks, the Pāśupatas, was also in existence by the beginning of the Christian Era.

The period between the fall of the Mauryan Empire (*c.* 184 BC) and the rise of the Gupta Empire (*c.* AD 320) was one of great change, with the conquest of most of the area of Pakistan and parts of western India by a succession of invaders. India was opened to influence from the West as never before, not only by its invaders but by way of the sea through the flourishing trade with the Roman Empire. The most obvious effects of the new contacts were shown in art and architecture. The oldest free-standing stone temple in the subcontinent has been excavated at Taxila, near Rāwalpindi, Pakistan. Early in the Christian Era the Gandhāra school of sculpture grew up in the same region and made use of Hellenistic (Greek cultural) and Roman prototypes, mainly in the service of Buddhism. At that time Hindu temples probably were made of wood because no remains of them are known to exist, but literary evidence shows that they were not unknown.

By the time of the early Gupta Empire the new theism had been harmonized with the old Vedic religion, and two of the main branches of Hinduism were fully recognized. The Vaiṣṇavas had the support of the Gupta emperors, who took the title *paramabhāgavata* ("supreme devotee of Viṣṇu"). Viṣṇu temples were numerous and the doctrine of Viṣṇu's *avatāra*s (incarnations) was widely accepted. Of the ten incarnations of later Vaiṣṇavism, however, only two seem to have been much worshipped in the Gupta period. These were Kṛṣṇa, the hero of the *Mahābhārata*, who begins to appear also in his pastoral aspect as the cowherd and flute player, and the divine boar (Varāha), of whom several impressive images survive from the Gupta period.

The Śaivites were also a growing force in the religious life of India. The sect of Pāśupata ascetics, founded by Lakulīśa (or Nakulīśa), who lived early in the Christian Era, is attested by inscriptions from the 5th century and is among the earliest of the sectarian religious orders of Hinduism. The son of Śiva, Skanda (also called Kārttikeya, the war god), figures already on Kuṣāṇa coins around 100. Śiva's other son, the elephant-headed Gaṇeśa, patron deity of commercial and literary enterprises, does not appear until the 5th century. Very important in this period was Sūrya, the sun god, who had temples built in his honour, though in modern times he is little regarded by most Hindus. The popularity of the solar cult may have come from Iranian influence.

Rising importance of goddesses

Several goddesses began to gain importance in this period. Although goddesses were no doubt always worshipped in local and popular cults, they play comparatively minor roles in Vedic religion. Lakṣmī or Śrī, goddess of fortune and consort of Viṣṇu, was worshipped before the beginning of the Christian Era, and several lesser goddesses are attested from the Gupta period. But the cult of Durgā, the consort of Śiva, was only beginning to gain importance in the 4th century, and the large-scale development of Śāktism (devotion to the active, creative principle, personified as the Mother Goddess) did not take place until medieval times.

Interplay of Indo-European and Dravidian cultures. Aryan influence is already in evidence in the earliest Tamil (a principal Dravidian language) literature, perhaps dating from the 1st century AD. At this time in South India the orthodox cults were aristocratic in character, supported by kings and chiefs who gained in prestige by patronizing Brahmins and adopting Aryan ways. The Tamils were still in the main devoted to the old cults, some of which, however, were taking on an Aryan complexion. The pastoral god Murugaṉ was identified with Skanda and his mother, the fierce war goddess Korravai, with Durgā. Varuṇaṉ, a sea god who had adopted the name of the old Vedic god but otherwise had few Aryan features, and Māyoṉ, a black god who was a rural divinity with many of the characteristics of Kṛṣṇa in his pastoral aspect, also are depicted in Tamil literature. The final "Sanskritization" of the Tamils was brought about through the patronage of the Pallava kings of Kāñcīpuram, who began to rule in the 4th century AD and who financed the making of many temples and fine religious sculpture. Similar processes were taking place in the Deccan, Bengal, and other regions.

Establishment of basic doctrines and practices. The texts on conduct known as *Dharma-śāstra* show that by this time the caste system, as distinct from the four classes, was already in existence. The texts attribute the change to the miscegenation of the four original orders of society, a fallacy that was accepted by many earlier students of the Indian social order (see also CASTE SYSTEMS).

The *Smṛti* ("remembered," or traditional) literature, like the *sūtra* literature that preceded it, stresses the religious

merit of gifts to Brahmins. Kings transferred the revenues of villages or groups of villages to Brahmins, either singly or in corporate groups; and thus the status and wealth of the priestly class rose steadily. In the *agrahāras*, as the settlements of Brahmins were called, they were encouraged to devote themselves to the study of the Vedas and the subsidiary studies associated with them; but many Brahmins also developed the sciences of the period, such as mathematics, astronomy, and medicine, and others cultivated literature.

Family law and the *Smṛti* texts

The *Smṛti* texts are binding to this day on the orthodox Hindu, and until quite recently Hindu family law was based on them. By the Gupta period marriage, solemnized by lengthy sacred rites, was virtually indissoluble, though in earlier times there is evidence of divorce. Intercaste marriage was becoming rarer and more difficult, and the whole social life of India was hardening into a rigid pattern. Some of the less attractive features of Hinduism, such as child marriage and the rite of the *satī*, were already in existence, although less frequent than they later became. The earliest definite record of a *satī* burning herself on her husband's pyre is found in an inscription from Eran, Madhya Pradesh, dated 510, but the custom had been followed sporadically long before this. From the 6th century AD onward, such records become frequent.

The Gupta period (4th–6th centuries) saw the rapid development of temple architecture. Earlier temples had been of wood, but now free-standing stone and brick temples appeared in many parts of India. By the 7th century, stone temples, some of considerable dimensions, were to be found in the Aryanized parts of the country. In its origin, the design of the Hindu temple may have owed something to Buddhist precedent, for in some of the oldest temples the image was placed in the centre of the shrine, with an ambulatory path around it resembling the path surrounding the Buddhist *stūpa* (a religious building containing a relic). Nearly all surviving Gupta temples are comparatively small, and consist of a small cella (central chamber), constructed of very thick and solid masonry, with a verandah either at the entrance or on all sides of the building. The very earliest Gupta temples, such as one of the Buddhist temples at Sānchī, have flat roofs, but the *śikhara* (spire), typical of the north Indian temple, began in this period and with time steadily grew higher. The massive and tall tower of the Buddhist temple of Bodh Gayā, which was in existence in the 7th century, represents the culmination of Gupta temple architecture.

The Buddhists and Jains had made use of artificial caves for religious purposes, and these were adapted by the Hindus. Hindu cave-temples, however, are comparatively rare, and none are earlier than the Gupta period. In the Pallava site of Māmallapuram, to the south of Madras, a number of small temples were carved in the 7th century from outcroppings of rock and represent some of the oldest religious buildings in the Tamil country.

The spread of Hinduism in Southeast Asia and the Pacific. Hinduism and Buddhism made an immense impact on the civilizations of Southeast Asia and were the means whereby the peoples of that area emerged into literate civilization. Around the beginning of the Christian Era, Indian merchants in comparatively large numbers settled there, bringing Brahmins and Buddhist monks with them. These religious men were patronized by local chiefs, who became Hinduized. The earliest material evidence of Hinduism in Southeast Asia comes from Borneo, where late 4th-century inscriptions in good Sanskrit testify to the performance of Vedic sacrifices by Brahmins at the behest of local chiefs. Chinese chronicles attest an Indianized kingdom in Vietnam two centuries earlier. The dominant form of Hinduism exported to Southeast Asia was Śaivism, though some Vaiṣṇavism was also known there. Later, from the 9th century onward, Tantrism, both Hindu and Buddhist, spread in the region.

The civilizations of Southeast Asia developed forms of Hinduism and Buddhism that had distinctive local features and were attuned to the local cultures, but the framework of their religious life was essentially Indian. The *Rāmāyaṇa* (an epic centring on the deeds of Rāma) and the *Mahābhārata* stories became well-known in Southeast Asia and are still popular there in local versions. The people of Bali (in Indonesia) still follow a form of Hinduism much adapted to their own genius. Versions of the *Laws of Manu* (a mythical lawgiver) were taken to Southeast Asia and were translated and adapted to indigenous ways until they lost most of their original content.

Claims for early Hindu contacts farther east are more dubious. There is little evidence of the influence of Hinduism on China and Japan, except through Buddhism.

Indian religious influence in the Mediterranean world. Nearly as dubious as the question of Indian influence on the religious life of the Far East is its influence on that of the ancient Mediterranean world. Pythagoras, a Greek philosopher, may have obtained his doctrine of metempsychosis (transmigration, or passage of the soul from one body to another) from India, mediated by Achaemenian (6th–4th centuries BC) Persia, but similar ideas were known in Egypt and were certainly also present in Greece even before the time of Pythagoras. The Pythagorean doctrine of a cyclic universe may also be derived from India, but the only argument is one of resemblance, and the Indian theory of cosmic cycles is not certainly attested in the 6th century BC. Nevertheless, it is clear that Hindu ascetics did occasionally visit Europe at a later time, and the self-immolation of the ascetic Zarmanochegas in Athens (*c.* 20 BC) may have inspired St. Paul to write, "if I deliver my body to be burned, but have not love, I gain nothing" (I Cor.). The most striking resemblance between Greek and Indian thought is in the system of mystical *gnōsis* (esoteric knowledge) described in the *Enneads* of the Neoplatonic philosopher Plotinus (3rd century AD) and that of the *Yoga-sūtras* attributed to Patañjali, an Indian religious teacher sometimes dated in the 2nd century AD. Of these two texts, that of Patañjali is the older, and one cannot but suspect influence, though the problem of mediation remains difficult because Plotinus gives no direct evidence of having known anything about Indian mysticism. Several Greek (*e.g.*, Clement of Alexandria) and Latin writers show considerable knowledge of the externals of Indian religions, but none gives any intimation of understanding their more recondite aspects.

Resemblances between Hinduism and Greek and Christian thought

Certain Vaiṣṇava legends, especially those referring to the infant Kṛṣṇa, bear some resemblance to those of Christianity, and claims have been made by both Hinduism and Christianity that the one influenced the other. In most instances, however, the Christian legends (for example, the massacre of the innocents, with the divine child carried to safety) are attested earlier than their Hindu counterparts.

THE PURANIC PERIOD (4TH–8TH CENTURIES)

The Purāṇas. The period of the Guptas saw the production of the first of the series of lengthy versified texts known as *Purāṇas* ("ancient stories"). These are sectarian, chiefly devoted to the glory of one god or another. With the epics, with which they are closely linked in origin, they became the scriptures of the common man, since they were available to everybody, including women and members of the lowest order of society (Śūdras), and were not, like the Vedas, restricted to initiated men of the three higher orders. The origin of much of their contents may be non-Brahminic, but they were accepted and adapted by the Brahmins, who thus brought new elements into the orthodox religion.

The scriptures of the common man

Tantric traditions and Śāktism. At about this same time, toward the end of the 5th century, the cult of the mother goddess began to achieve a significant place in religious life. Śāktism, the worship of the Śākti, the active power of the godhead conceived in feminine terms, should be distinguished from Tantrism, or Tantricism, the search for spiritual power and ultimate release by means of the repetition of sacred syllables and phrases (*mantra*) and other secret rites. The latter, in a sense, is as old as the Ṛgveda, but it was given special prominence

by the sects that arose about this period. In Hinduism, Tantrism was chiefly associated with Śāktism, the cult of the Mother Goddess.

A temple was erected in honour of the Mothers, a vague group of goddesses related rather artificially to the gods of the Hindu pantheon by being described as their wives, at Gangdhār, Rājasthān, in AD 423. Here, magical rites of a terrifying kind were practiced, for the temple is described as "loud with the shouts of demonesses, crying in the thick darkness." The playwright Bhavabhūti's drama *Mālatī-Mādhava* (about the adventures of the hero Mādhava and his beloved Mālatī), composed in the early 8th century, contains a scene depicting secret rites with human sacrifice and ritual cannibalism. The goddess cults eventually centred around Durgā, the spouse of Śiva in her fiercer aspect. Surviving Hindu *Tantras*, the texts of the movement, are much later than many of those of Tantric Buddhism, and it may be that the Hindus derived much from the Buddhists in this respect. Although there is early evidence of Tantrism and Śāktism in other parts of India, the chief centre of both was modern Bengal, Bihār, and Assam.

Philosophical sūtras and the rise of the six schools of philosophy. Meanwhile, much religious activity of a more intellectual kind was taking place. From about the beginning of the Christian Era through the period of the Gupta Empire, the systems of the "Six Schools" (Ṣaḍdarśana) of orthodox philosophy were formulated in terse *sūtras*.

Śaṅkara and the Vedānta school

The most important of the Six Schools is the Vedānta ("End of the Vedas"), also called Uttara-mīmāṃsa, or later Mīmāmsā. The most renowned philosopher of this school and, indeed, of all Hinduism was Śaṅkara (traditionally dated *c.* 788–820, but he probably died about 20 years later). He was born at Kāladi in Kerala and is said to have spent most of his life travelling through India disputing with members of other sects. The Śaṅkaran system has sounded the keynote of intellectual Hinduism down to the present, but later teachers founded subschools of Vedānta, which are perhaps equally important.

Śaṅkara was also responsible for the growth of Hindu monasticism, which had been in existence for well over a millennium, in the form of hermit colonies. Also a few inscriptions from Gupta times onward contain references to orders of Śaivite ascetics, apparently living according to distinctive disciplines and with distinguishing garments and emblems. Śaṅkara founded a closely disciplined Śaivite order, perhaps modelled partly on the Buddhist *saṅgha* (order), known as Daśnāmī, which is still the most influential orthodox Hindu ascetic group. The Order is based in four main monasteries (*maṭha*) at the four corners of India, Śṛṅgerī in Mysore, Badrīnāth in the Himalayas, Dvārakā in Saurāshtra, and Purī in Orissa. The abbots of these monasteries control the spiritual lives of many millions of devout Śaivite laymen throughout India, and their establishments strive to maintain the traditional philosophical Hinduism of the strict Vedānta. In modern times, certain Daśnāmī leaders have incurred criticism for their firm opposition to social change (see also INDIAN PHILOSOPHY; MONASTICISM).

THE RISE OF DEVOTIONAL HINDUISM (8TH–11TH CENTURIES)

The medieval period, especially after the Muslim conquest, saw the growth of new devotional religious movements, centring round hymnodists who taught in the popular languages of the time.

The new movements began, as far as can be seen, with the appearance of hymns in Tamil associated with two groups of poets, the Nāyaṉārs, worshippers of Śiva, and the Ālvārs, devoted to Viṣṇu. The oldest of these can be dated in the early 7th century, though passages of devotional character can be found in earlier strata of Tamil literature. By that century also the religious life of the region had been influenced by the Bhāgavatas, the school of Vaiṣṇavism that based its teachings largely on the *Bhagavadgītā*.

This devotional poetry is characterized by a mystical fervour very different from that of the *Upaniṣads* and the *Bhagavadgītā*, in both of which, even when the object of meditation is conceived as a personal God, there is little expression of emotion. The Tamil "saints," however, felt an intense love (*aṉbu*) of a personal kind toward their god. They experienced overwhelming joy in his presence and deep sorrow when he did not reveal himself. Some of them had a profound sense of guilt or inadequacy in the face of the divine. But the dominant emotion in these poems is one of joy, often expressing itself in song and dance. The poems have a strong ethical content and encourage the virtues of love, humility, and brotherhood. Probably the ideas of these poets, spreading northward, were the origin of the growth of devotional *bhakti* in the centuries following the Muslim invasion of northern India.

The new forms of South Indian devotionalism also produced works in Sanskrit, the most important of which was the *Bhāgavata-Purāṇa* that soon was read all over India. Its tenth book is devoted entirely to Kṛṣṇa; and here, for the first time, the adventures of this god as a lovable child and as a youth sporting with the milkmaids are given great emphasis. The *Bhāgavata-Purāṇa* may have been written in the 10th century and is certainly a product of the Dravidian south. The doctrine of the *avatāras* (incarnations) of Viṣṇu was by now in full force, and the *Bhāgavata* recognizes 22 of them.

Antagonism between devotional cults and Buddhism

The devotional cults helped further to weaken Buddhism, which had long been on the decline. From time to time Hindus, especially Śaivites, took aggressive action against Buddhism. At least two Śaivite kings—the Hūṇa invader Mihirakula (early 6th century) and the Bengal King Śaśāṅka (early 7th century)—are reported to have been active persecutors, destroying monasteries and killing monks. The philosophers Kumārila and Śaṅkara were strongly antagonistic to Buddhism. In their journeys all over India they debated with Buddhists with special vehemence and tried to persuade kings and other influential people to withdraw their support from Buddhist monasteries. Thus, opposition from Hinduism must have had some effect in weakening the strength of the already declining Buddhism. Only in Bihār and Bengal, because of the patronage of the Pāla dynasty and some lesser kings and chiefs, did Buddhist monasteries continue to flourish. Buddhism in eastern India, however, was well on the way to reabsorption into Hinduism when the Muslims invaded the Ganges (Gaṅgā) Valley (12th century). Buddha was recognized as the ninth *avatāra* of Viṣṇu, and thus he could be worshipped by orthodox Hindus without compunction. The great Buddhist shrine of Bodh Gayā, the site of the Buddha's enlightenment, became a Hindu temple dedicated to the *Buddhāvatāra* and remained such until recent times.

At the very end of its existence in India Buddhism developed in a way that had some effect on Hinduism. Among the Buddhist Tantrists appeared a new school of preachers, often known as *siddha*s (those who have achieved), who sang their verses in the contemporary languages, early Maithili and Bengali. They taught that "giving up the world" was not necessary for release from transmigration and that by living a life of simplicity in one's own home one could achieve the highest state. This system, known as Sahajayāna ("the vehicle of the natural," or "the easy vehicle"), influenced on the one hand Bengali devotional Vaiṣṇavism, which produced sects called Sahajiyā with similar doctrines, and on the other the Nātha Yogīs (mentioned below), whose teachings influenced Kabīr and other later Bhakti teachers.

THE AGE OF BHAKTI (11TH–19TH CENTURIES)

The challenge of Islām and popular religion. The phase of Indian history marked by the domination of the Muslims in most of northern India saw great changes in Indian religion. The term *bhakti*, in the sense of devotion to a personal god, appears already in the *Bhagavadgītā* and the *śvetāśvātara Upaniṣad*. In these earlier sources, however, it represents a devotion still somewhat restrained and unemotional. The new form of *bhakti*, associated with hymn singing in the languages of the com-

mon people, on the other hand, was highly charged with emotion, and the relation of divinity and worshipper was often described on the analogy of that of lover and beloved. The advent of Islām in the Ganges (Gaṅgā) Basin at the end of the 12th century meant that royal patronage was withdrawn from Hinduism in much of the area. The attitude of the Muslim rulers toward Hinduism varied. Some, like Fīrūz Tughluq (ruled 1351–88) and Aurangzeb (ruled 1659–1707), were strongly anti-Hindu and enforced payment of *jizya*, the poll tax on unbelievers. Others, like the Bengali sultan Ḥusayn Shāh (reigned 1493–1519) and the great Akbar (reigned 1556–1605), were well-disposed toward their Hindu subjects and the Hindu faith. Numerous temples, however, were destroyed by the more fanatical rulers. Conversions to Islām were more numerous in areas where Buddhism had once been strongest—modern Pakistan, Bangladesh, and Kashmir.

Hinduism on the eve of the Muslim occupation

On the eve of the Muslim occupation, the Hindu religion was by no means sterile in northern India, but its vitality was centred in the southern, Dravidian-speaking areas rather than in the north. Over the centuries, the system of class and caste had become more rigid; in each region there was a complex hierarchy of castes strictly forbidden to intermarry and interdine, controlled and regulated by the secular power on the advice of the court Brahmins. The system was looked on as an integral part of religion and seems to have been accepted without question. Child marriage, polygamy, and widow burning were widespread. The large-scale Vedic sacrifices had practically vanished, but new, simple forms of animal, and sometimes human, sacrifice had appeared, especially connected with the cult of the Mother Goddess.

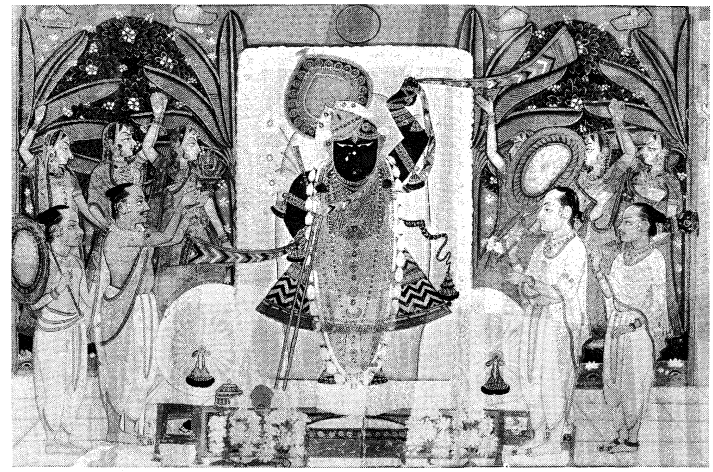
All the divinities of later Hinduism by that time were being worshipped. Rāma, the hero of the epic poem, had become the eighth *avatāra* of Viṣṇu, and his cult was growing, although it was much less prominent than it later became. Similarly, Rāma's monkey helper, Hanumān, now one of the most popular divinities of India and the most ready helper in time of need, was rising in importance. Strange syncretic gods had appeared, such as Harihara, a combination of Viṣṇu and Śiva, and Ardhanārīśvara, a synthesis of Śiva and his *śakti* Pārvatī or Durgā.

From the Gupta period onward temples tended to become larger and more prominent in Hinduism, and their architecture developed in distinctive regional styles. In northern India the finest remaining Hindu temples are to be found in Orissa, as well as at Khajurāho, in northern Madhya Pradesh. The finest example of Orissan temple architecture is the Liṅgarāja temple of Bhubaneswar, built in *c.* 1000. The largest temple of the region, however, is the famous Black Pagoda, the Suntemple of Konārak, built in the mid-13th century. Its 200-foot (60-metre) tower has long since collapsed, and only the assembly hall remains. The most important Khajurāho temples were built during the 11th century. Individual architectural styles also arose in Gujarāt and Rājasthān, but their surviving products are less impressive than those of Orissa and Khajurāho. By the end of the first millennium AD the South Indian style had reached its apogee in the great Rājarājeśvara temple of Thanjāvūr (Tanjore).

Temple design as cosmic symbolism

The designing of Hindu temples, like that of religious images, was codified in the *Śilpa-śāstras* (craft textbooks), and every aspect of the design was believed to be symbolic of some feature of the cosmos. The idea of microcosmic symbolism is very strong in Hinduism and comes from Vedic times; the *Brāhmaṇa* texts are replete with similar cosmic interpretations of the many features of the sacrifice. In this context, the erotic sculptures carved on the outer walls of the towers of some medieval temples, notably at Khajurāho and Konārak, may perhaps be interpreted.

In the temple the god was worshipped by the rites of *pūjā* (reverencing a sacred being or object) on the analogy of serving a great king. In the important temples, a large staff of trained officiants waited on the god. He was awakened in the morning along with his goddess, washed, clothed and fed, placed in his shrine to give audience to his subjects, praised and entertained throughout the day, ceremoniously fed, undressed, and put to bed at night. Worship consisted of hymn singing, burning of lamps, waving of lights before the divine image, and similar acts of homage. The god's dancing girls (*devadāsīs*) would perform before him at regular intervals, watched by the officiants and lay worshippers, who were his courtiers. These women, either the daughters of *devadāsīs* or girls dedicated in childhood, also served as prostitutes. The association of dedicated prostitutes with certain Hindu shrines can be traced back to before the Christian Era and may have existed in the Harappā culture. It became more widespread in post-Gupta times, especially in South India, and aroused the reprobation of 19th-century Europeans. Under the efforts of Hindu reformers the *devadāsīs* disappeared. The role of *devadāsīs* is understandable if the analogy of the temple and the royal court is remembered, for the Hindu king also had his dancing girls, who bestowed their favours on his courtiers.



"Four Priests Doing Puja Before the Image of Śrī Nāthajī," Rajasthani miniature painting from Nāthdwāra, *c.* 1830. In the Fogg Art Museum, Cambridge, Massachusetts.
By courtesy of a private collector, Cambridge, Mass.

The analogy of the royal palace was also in evidence in the *rathayātra*s (shrine processions). As on festival days the king would issue from his palace and parade around his city, escorted by courtiers, troops, and musicians, so also would the god parade around his city in a splendid procession, together with the lesser gods of the minor shrines. The god rode on a tremendous and ornate moving shrine (*ratha*). It was often pulled by large bands of devotees. *Rathayātra*s still take place in many cities of India. The most famous is the annual procession of Jagannātha, a form of Viṣṇu, at Purī, Orissa, which achieved notoriety from the fact that Westerners interpreted the frequent accidental deaths and the occasional sacrificial acts of worshippers, who would throw themselves under the gigantic wheels of his *ratha*, as common occurrences.

The wealth of the great temples

The great temples were (and still are) very wealthy institutions. They were supported by the transfer of the taxes levied by kings on specific areas of the nearby countryside, by donations of the pious, and by the fees of worshippers. Their immense hoarded wealth was one of the factors that encouraged the Ghaznavid and Ghūrid Turks to invade India in the 10th and 11th centuries. They were controlled by self-perpetuating committees—whose membership was usually a hereditary privilege—and by a large staff of priests and temple servants under a high priest who wielded tremendous power and influence. The great walled temple complexes of South India were (and still are) small cities, containing the central and numerous lesser shrines, bathing tanks, administrative offices, homes of the temple employees, workshops, bazaars, and public buildings of many kinds. Directly and indirectly they played an important part in the economy, as they were among the largest employers and greatest landowners in their areas. They performed very

definite social functions because they also served as schools, dispensaries, poorhouses, banks, concert halls, and, very often, even as brothels.

The Muslim occupation brought India into close contact with a different, more aggressive, faith. In such circumstances, the absence of a central religious authority in Hinduism was a source of strength rather than otherwise. The *purohitas*, the family priests who performed the domestic rituals and personal sacraments for the lay people, continued to function, as did the thousands of ascetics. In Muslim-occupied territory the temples were the chief sufferers. In the sacred cities of Vārāṇasī (Banaras) and Mathurā, no large temple remains from any period before the 17th century. The same is true of most of the main religious centres of northern India, but not of the regions where the Muslim hold was less firm, such as Orissa, Rājasthān, and South India.

Philosophical movements. *The qualified Advaita of Rāmānuja.* Before the time the Muslims invaded the subcontinent, the new forms of South Indian Bhakti had begun to flourish and develop and were spreading beyond the bounds of the Dravidian south. Certain Vaiṣṇava theologians of the Pāñcarātra and Bhāgavata schools had long opposed the Advaita Vedānta (nondualism) of Śaṅkara in favour of a more theistic interpretation of the *Upaniṣads* and the *Brahma-sūtras*. The greatest of these philosophers, Rāmānuja, a Tamil Brahmin who was for a time chief priest of the Vaiṣṇava temple of Śrīraṅgam, near Tirucchirāppalli (Trichinopoly), arose in the 11th century. He gave to the growing Vaiṣṇava Bhakti cults a philosophical framework that was developed by other Vaiṣṇava teachers and was not without influence on some Śaivite schools.

Influence of the philosopher Rāmānuja

Dualism and Śaiva philosophies. The most interesting development of Rāmānuja's doctrine of qualified monism is found in the philosophy of Madhva (died *c.* 1276), a Kanarese Brahmin who taught a doctrine of dualism according to which God and the soul are eternally distinct. Between Madhva's system and Christianity the parallels are so striking that it is generally believed that Madhva was in contact with the Syrian Christians of Kerala.

Two other Vaiṣṇava teachers deserve mention. Nimbārka, a Telugu Brahmin of the 12th century, spread the cult of the divine cowherd and his favourite *gopī* (cowherdess, especially associated with the legends of Kṛṣṇa's youth), Rādhā. His sect survives in the vicinity of Mathurā but has made little impact elsewhere. More important was Vallabha (Vallabhācārya; 1479–1531), who took up the Vaiṣṇava doctrine of grace and emphasized its erotic imagery. His sect is noteworthy for the stress it places on absolute obedience to the *guru* (teacher). Early in its existence it was organized with a hierarchy of senior monks (*gosvāmī*), many of whom became very rich. The Vallabhācārya sect was once very influential in the western half of North India, but it declined in the 19th century because of a number of lawsuits against the chief guru, the descendant of Vallabha.

The Śaiva sects also developed from the 10th century onward. In South India there emerged the school of Śaiva-siddhānta, still one of the most significant religious forces in that region, and one which, unlike the school of Śaṅkara, does not admit the full identity of the soul and God. A completely monistic school of Śaivism appeared in Kashmir in the early 9th century. Its doctrines differ from those of Śaṅkara chiefly in attributing personality to the absolute spirit, who is the god Śiva and not the impersonal *Brahman*.

The unorthodoxy of the Liṅgāyats

An important and interesting sect, founded in the 12th century in the Kannada-speaking area of the Deccan, was that of the Liṅgāyats, or Vīraśaivas ("Heroes of the Śaiva faith"). Its traditional founder, Basava, taught doctrines and practices of surprising unorthodoxy—he opposed all forms of image worship and accepted only the *liṅga* of Śiva as a sacred symbol. It rejected the Vedas, the Brahmin priesthood, and all caste distinction. Several Liṅgāyat practices, now largely abandoned, such as the remarriage of widows and the burial of the dead, seem very non-Hindu and indicate a possibility that Islām influenced the doctrines of the sect.

An important development of Śaivism in North India was brought about by Gorakhnāth (Gorakṣanātha), who in the 13th century became leader of a sect of Śaivite ascetics known as Nātha ("Lord") from the title of their chief teachers. The Gorakhnāthīs were particularly important as propagators of the practices of Haṭha Yoga, the form of Yoga that requires complex and difficult physical exercises and which has become well-known in the West. These yogis, who are still numerous, influenced the teaching of several of the Bhakti hymnodists.

Bhakti movements. The hymnodists and "saints" of medieval Bhakti appeared in all parts of India. The origin of the new forms of Hinduism has been attributed to the influence of Islām, but the proposition that the rise of popular emotional Bhakti was a response to Islām is chronologically impossible, for the practice of singing ecstatic hymns in the current local language was well-known in South India even before Muḥammad. All the features of this form of Bhakti are to be found in the *Bhāgavata-Purāṇa* and in the commentaries of Rāmānuja. The earliest Bhakti literature in a living Indo-Aryan language is from Mahārāshtra and was composed before Muslims occupied the area. Thus, emotional Bhakti existed long before the Muslim conquest. The presence of rulers of alien faith and the withdrawal of royal patronage from the temples and Brahminic colleges may have encouraged the spread of new, more popular forms of Hinduism. The psychological effect of the Muslim conquest also may have predisposed the masses to accept the simple teachings of the hymnodists, but Islām was only a contributory factor in the spread of the new movements.

Northern India. In the Hindi-speaking areas the development of the new religious forms was stimulated by Rāmānand (*c.* 1400–70). This teacher, in the line of Rāmānuja, made Vārāṇasī his headquarters, and there established a sect solely devoted to Rāma; the Rāmānandīs rejected caste and image worship. They admitted even untouchables as members and conveyed their message entirely in the contemporary language.

The most important spiritual descendant of Rāmānand was Tulsīdās, considered by many to be the greatest of Hindi poets. Tulsīdās, a Brahmin ascetic who spent most of his life at Vārāṇasī and died there in old age in 1623, produced the *Rāmcaritmānas* (or *Ramacaritmānas*, "The Lake of the Deeds of Rāma"), the most important text of Hinduism in the Hindi-speaking area. Tulsīdās' theology is simple, emphasizing divine love and compassion.

The schools of Nimbārka and Vallabhācārya produced a line of Kṛṣṇaite Bhakti singers in Hindi, the first of whom was the poetess Mīrā Bāī, a Rājput princess living in the earlier half of the 16th century. She composed hymns in honour of Kṛṣṇa in Rajasthani, and these were translated into various dialects of Hindi and Gujarati and are now sung all over western India.

Eastern India. In Bengal, the decline of Buddhism and the coming of the Muslims resulted in developments in folk religion. There seems to have been a certain loss of faith in the great gods in the period after 1200, and several local divinities, no doubt long worshipped by peasants and the poor, became popular with the richer and more educated. Among these are Manasā (the goddess of snakes); a divinity strangely called Dharma ("Law"); and a Śiva who, far from being the exalted ascetic deity of the myths of the *Purāṇas*, is sometimes depicted as a simple peasant farmer with a nagging wife.

Influence of Caitanya in Bengal

The various strands of Bengali Vaiṣṇavism were drawn together by the teacher Viśvambhara Miśra, generally known by his religious name, Caitanya (1485–1533), who established a sect that has given Bengali religious life much of its individual character. Caitanya gave up the world after an intense religious experience at the age of 22, and the band of friends and followers who surrounded him virtually became a religious order. The Caitanya sect is not particularly remarkable for its theology but rather for its practices. The focus of its religious life is the *saṃkīrtana*, a hymn-singing session (often accompanied by ecstatic dancing) conducted by a group of worshippers and sometimes continued in relays

for days on end. The *saṃkīrtana* also may take the form of a procession through the streets (*nagara-kīrtana*). With its discouragement of ritualism, its strong ethical emphasis, and its joyful and expressive method of worship, the Caitanya movement affected the whole life of Bengal and was not without influence on other parts of India.

Although the Caitanya movement may have tended to relax caste barriers, the complex Bengali system of subcastes, known as Kulīnism, persisted, as did the Śākta cults, often involving animal sacrifice and in some cases ritual sexual activity. Widow cremation was particularly prevalent in Bengal in the early 19th century.

Southern and western India. Mahārāshtra, closely in touch with the Dravidian south, was the first region where an Indo-Aryan language was spoken to produce literature inspired by the Bhakti movement. Its first important literary figure is Jñāneśvara (13th century), a teacher who was born in a Brahmin family that had lost status and who early came under the influence of the Nātha Yogīs and became an ascetic. His most important achievement is his long Marathi paraphrase and commentary on the *Bhagavadgītā*, commonly known as *Jñāneśvarī*, after its author. In other parts of India, until the end of the 19th century, the *Bhagavadgītā* was chiefly studied by the learned, with the commentaries of Śaṅkara, Rāmānuja, and others; but among Marathi speakers it was well known to all classes through Jñāneśvara's version.

The greatest medieval Maharashtrian teacher and, according to many critics, the greatest Bhakti poet of all India, was Tukārām (17th century). Tukārām was a Śūdra, the son of a poor village grain dealer, who took to a life of religion after bereavement and failure in business.

Bhakti teachings in all of India's main languages

All the main languages of India are represented among important Bhakti teachers. Much of the life of Caitanya was spent at the sacred city of Purī in Orissa, and for this reason most Oriya Bhakti shows the influence of his teaching. The greatest of the Assamese Bhakti reformers, Śaṅkardeb (Sanskrit, Śaṅkaradeva, traditional dates 1449–1569), spread Vaiṣṇavism of a type similar to that of Caitanya in the Brahmaputra Valley and produced an Assamese paraphrase of the *Bhāgavata-Purāṇa* as well as shorter devotional poems. Kashmir produced an important religious poet in Lallā, or Lāl Ded, a woman ascetic devotee of Śiva whose verses are still very popular among the Kashmir peasantry and are repeated even by Muslims. There is much Bhakti literature in Gujarati, the most famous being the hymns of Narsiṃha Mehtā (1415–81).

In the literature of the Dravidian languages other than Tamil, the Bhakti movement was largely Śaiva. Vīraśaiva devotional literature in Kannada goes back to Basava, the founder of the sect. In Telugu the most interesting figure is Vemana (15th century), a Śaivite teacher of low birth, who attacked the caste system and the Brahmins in particular with a vehemence rare in all Indian literature and who was almost equally antagonistic to iconolatry (worship of images), pilgrimage, and other aspects of ritualism.

The synthesis of Hinduism with Islām and folk religion. Approximately contemporary with Vemana was Kabīr (1440–1518), who was probably born a Muslim. Kabīr rejected many of the external forms and doctrines of both Hinduism and Islām—caste, image worship, asceticism, divine incarnation, sacred texts, and pilgrimages. He believed, however, in transmigration and the doctrine of *karma;* he regularly referred to God as Rāma and to the phenomenal world as *māyā* (illusion); and he admitted the qualified reality of the lesser gods of Hinduism. Kabīr probably knew something about Ṣūfism (Islāmic mysticism), which had itself been influenced by Hinduism, but his teaching is essentially Hindu and it is hard to recognize any specifically Islāmic element in it, except perhaps his opposition to image worship and to strict asceticism, although both had also been part of the teaching of some earlier Hindu reformers. Kabīr's doctrine was not a syncretism of Hinduism and Islām but rather a simplified form of Hinduism, by which he hoped to foster brotherly love between the two communities. His poems are popular all over the Hindi-speaking area, among Hindus and Muslims alike.

A small sect, the Kabīrpanthīs, looks back to Kabīr as its founder, but its importance is less than that of the vigorous new religion (Sikhism) founded by one of Kabīr's disciples, Nānak. In its final form, Sikhism contains elements taken from Islām (equality in the faith, opposition to iconolatry, extreme reverence for the sacred book) and probably also from Christianity (the Sikh Baptism and Communion meal), but its theology is still essentially Hindu.

Much has been said about the synthesis of Hinduism and Islām in the period of Muslim dominance, but, as far as the Hindus were concerned, this was generally in the matter of superficial observances. Thus, *parda,* the strict seclusion of women, became usual among the Hindu upper classes of northern India, and numerous Muslim social customs were adopted, as were Persian and Arabic words in the vocabularies of most Indian languages. The fundamental theology of Hinduism, however, was unaffected by Islām, even in the teachings of such men as Basava and Kabīr, who themselves may have been somewhat influenced by Muslim observances and social customs.

The Hindu influence on Islām

What synthesis did take place came from the Muslims, most of whom were Indian by blood. In Hindi, Bengali, Gujarati, Punjabi, and Marathi there is much poetic literature, written by Muslims and commencing with the Islāmic invocation of Allāh, which nevertheless betrays strong Hindu influence. Thus, there are texts that proclaim Kṛṣṇa as being in the line of the prophets of Islām and as the teacher of the unity of God. Much mystical poetry, though written by authors with Muslim names, uses Hindu imagery and Hindu terminology. The origin of this literature is to be found in the accommodating character of early Indian Ṣūfīsm, which well before Kabīr proclaimed that Muslim, Christian, Jew, Zoroastrian, and Hindu were all striving toward the same goal and that the outward observances that kept them apart were false. Some of the Indian Ṣūfīs were much influenced by Hindu customs. A school of Kashmir Ṣūfīs, whose members call themselves *rishis,* after the legendary Hindu sages (*ṛṣi*), respect and repeat the verses of Lāl Ded and are strict vegetarians.

Syncretic tendencies were encouraged by tolerant Muslim rulers, and these tendencies reached their zenith in the reign of Akbar (1556–1605), who took a great interest in the religion of his Hindu subjects, favoured vegetarianism, and tried to establish a single, all-embracing religion for his empire. Although the efforts of Akbar failed, they influenced India for more than 50 years after his death. But the orthodox Muslim theologians had long been complaining about the growth of heresy, and the emperor Aurangzeb (reigned 1659–1707) did all in his power to discourage it. Popular Muslim preachers throughout the 18th and 19th centuries worked to restore orthodoxy. Thus, syncretic tendencies virtually came to an end before the imposition of British power in the mid-18th century. Furthermore, British rule, emphasizing the distinctions between Hindu and Muslim, was not calculated to encourage the revival of efforts to harmonize the two religions.

THE MODERN PERIOD (19TH–20TH CENTURIES)

Western Christian missionary activities

From their small coastal settlements in southern India, the Portuguese had promoted Catholic missionary activity and had made converts, most of whom were of low caste; the mass of caste Hindus was unaffected. Small Protestant missions operated from the Danish factories of Tranquebar in Tamil nadu and Serampore in Bengal, but they were even less influential. The British East India Company, conscious of the disadvantages of unnecessarily antagonizing its Indian subjects, excluded all Christian missionary activity from its territories. Indeed, the Company continued the patronage accorded by indigenous rulers to many Hindu temples and positively forbade its Indian troops to embrace Christianity. The growing evangelical conscience in England brought this

policy to an end with the renewal of the Company's charter in 1813. The Company's policy then became one of strict impartiality in matters of religion, and missionaries were allowed to work throughout its territory. Thus, Christian ideas began to spread.

Hindu reform movements. *Brahmo Samaj.* The pioneer of reform was Rammohan Ray. His intense belief in strict monotheism and in the evils of image worship began early and was probably derived from Islām, because at this time he had no knowledge of Christianity. He later learned English and in 1814 settled in Calcutta, where he was prominent in the movement for encouraging education of a Western type. His final achievement was the foundation of the Brahma Sabha, later known as Brahmo Samaj ("Society of God"), in 1828.

Rammohan outwardly remained a Hindu, wearing the sacred cord and keeping up most of the taboos of the orthodox Brahmin; but his theology was surprisingly un-Indian. He was chiefly inspired by 18th-century Deism (rational belief in a transcendent creator god) and Unitarianism (belief in God's essential oneness), but some of his writing suggests that he was aware of the religious ideas of the Freemasons (a secret fraternity that espouses some deistic concepts). Several of his friends were members of the active Masonic lodge in Calcutta. His ideas of the future life are obscure, and it is possible that he did not believe in the doctrine of transmigration. Rammohan was one of the first higher class Hindus to visit Europe, where he was much admired by the intelligentsia of Britain and France. He died in Bristol, England.

Debendranath Tagore and Keshab Chunder Sen

After Rammohan Ray's death, Debendranath Tagore became leader of the Brahmo Samaj, and under his guidance a more mystical note was sounded by the society, nearer to the main stream of Indian religious life. The third great leader of the Brahmo Samaj, Keshab Chunder Sen, was a more vigorous reformer and introduced the complete abolition of caste in the *samāj* and the admission of women. As his theology became more and more syncretistic and eclectic, a schism developed, with the more conservative faction remaining under the leadership of Tagore. Keshab's faction, the Brahmo Samaj of India, adopted as its scripture a selection of theistic texts gathered from all the main religions; at the same time, it became more Hindu in its worship, employing the *saṃkīrtana* (hymn-singing session) and *nagara-kīrtana* (street procession) of the Caitanya sect. In 1881 Keshab founded the Church of the New Dispensation (Naba Bidhan) with the purpose of establishing the truth of all the great religions in an institution that, he believed, was to replace them all. When he died in 1884, the Brahmo Samaj began to decline, but it produced the greatest poet of modern India, Rabindranath Tagore, son of the second of its great leaders, Debendranath Tagore.

Arya Samaj. A reformer of different character was Dayanand Sarasvati, who was trained as a yogi but steadily lost faith in yoga and many other aspects of Hinduism. After travelling widely as an itinerant preacher, he founded the Arya Samaj in 1875, and it rapidly gained ground in the west of India. Dayanand rejected image worship, sacrifice, and polytheism and based his doctrines firmly on the four Vedas as the eternal word of God. Later Hindu scriptures were to be judged on their merits, and many of them were believed to be positively evil. The Arya Samaj did much to encourage Hindu nationalism, and among its members was the revolutionary Lala Lajpat Rai. It did not disparage the knowledge to be found in the West, and it established many schools and colleges.

New religious movements. *Ramakrishna Mission.* The most important developments in Hinduism, however, did not arise primarily from the new *Samaj*es. The mystic Ramakrishna, who was a devotee at a temple of Kālī called Dakṣiṇeśvar to the north of Calcutta, attracted a band of educated lay followers who spread his simple doctrines. As a result of his psychological experiments, he came to the conclusion that "all religions are true." Nevertheless, the religion of a man's own time and place was for him the best expression of the truth. Even idolatry met the needs of simple people and was not to be disparaged. Ramakrishna thus gave the educated Hindu a basis on which he could accept the less rational aspects of his religion without believing in them literally.

Influence of the mystic Ramakrishna

Among the followers of Ramakrishna was Narendranath Datta, who became an ascetic after his master's death, assuming the religious name Vivekananda. In 1893 he attended the World's Parliament of Religions at Chicago, where his powerful personality and stirring oratory made a very deep impression. After lecturing in the United States and England, he returned with a small band of Western disciples to India in 1897. There he founded the Ramakrishna Mission, the most important modern organization of reformed Hinduism. Vivekananda, more than any earlier Hindu reformer, encouraged social service and the uplift of the masses. Influenced by progressive Western political ideas, he set himself firmly against all forms of caste distinction and fostered a spirit of self-reliance in his followers. The Ramakrishna Mission has done much to spread a knowledge of Hinduism outside India and now has branches in many parts of the world.

Theosophical Society. Another neo-Hindu movement, which at one time exerted considerable influence, is the Theosophical Society. Founded in New York City in 1875 by Helena Blavatsky of Russia, its original inspiration was Kabbala (Jewish esoteric mysticism), Gnosticism (esoteric salvatory knowledge), and other forms of Western occultism. When Madame Blavatsky came to India in 1879, her doctrines quickly took on an Indian character, and from her headquarters at Adyar she and her followers established branches in many cities of India.

The society survived serious accusations of charlatanry levelled against its founder and certain other leaders, and it reached the peak of its influence under its next important leader, Annie Besant, a reform-minded English woman. Under her guidance, many Theosophical lodges were founded in Europe and the United States, and these helped to acquaint the West with the principles of Hinduism, if in a rather garbled form.

Aurobindo Ashram. Another modern teacher whose doctrines have had some influence outside India was Sri Aurobindo, who began his career as a revolutionary. He withdrew from politics, however, and settled in Pondicherry, then a French possession. There he established an *āśrama* (a retreat) and achieved a high reputation as a sage. His followers looked on him as the first incarnate manifestation of superbeings whose evolution he prophesied, and apparently he did not discourage this belief. After his death, the leadership of the Aurobindo Ashram was taken over by "the Mother," Mme Mira Richard, a Frenchwoman who had been one of his leading disciples.

Other reform movements. Numerous other teachers have affected the religious life of modern India. Among them was the great Bengali poet, Rabindranath Tagore, who was influenced by many currents of earlier religious thought, both Indian and otherwise. Tagore was particularly popular in Europe and America around the time of World War I, and he did much to enlist sympathy for Hindu religious thought in the West.

Less important outside India, but much respected in India itself, especially in the Dravidian south, was Ramana Maharishi, a Tamil mystic (died 1950) who maintained almost complete silence. His personality was powerful and he attracted a large band of devotees.

Swami Sivananda, who had been a doctor, established an *āśrama* and an organization called the Divine Life Society near the sacred site of Rishikesh in the Himalayas. This organization has numerous branches in India and some elsewhere. His movement teaches more or less orthodox Vedānta, combined with both yoga and *bhakti*, but rejects caste and lays stress on social service.

Jiddu Krishnamurti represents the most attenuated form of Hinduism. He rejects all religious organization and makes no claim to special revelations or exceptional spiritual development but teaches self-realization through introspection and the abandonment of personal ambition.

Religion and the growth of nationalism

The struggle for independence. The Hindu revival and reform movements of the 19th and early 20th centuries were closely linked with the growth of Indian nationalism and the struggle for independence. The Arya Samaj strongly encouraged nationalism, and even though Swami

Vivekananda and the Ramakrishna Mission were always uncompromisingly nonpolitical, their effect in promoting the movement for self-government is quite evident.

Religion and politics were joined in the career of B.G. Tilak, an orthodox Maharashtrian Brahmin who realized that the masses of India could only be aroused by appeals couched in religious terms. Tilak used the annual festival of the god Gaṇapati (Gaṇeśa) for nationalist propaganda. His view of the *Bhagavadgītā* as a call to action was also a reflection of his nationalism, and through his mediation the *Bhagavadgītā* became a stimulus to later leaders, including Mahatma Gandhi.

In Bengal, also, Hindu religious concepts were enlisted in the nationalist cause. In his historical novel *Ānandamaṭh*, the Bengali novelist Bankim Chandra Chatterjee described a band of martial ascetics at the time of the decline of the Mughal Empire, who were pledged to free India from Muslim domination. These had as their anthem a stirring devotional song written in simple Sanskrit—"Bande Mātaram" ("I revere the Mother"). The Mother referred to is at once the stern demon-destroying goddess Kālī and a personification of India. This song was soon taken up by the more extreme nationalists. Vivekananda emphasized the need to turn the emotion of *bhakti* toward the suffering poor of India. During his short career as a young revolutionary leader, Sri Aurobindo made much use of "Bande Mātaram," and called on his countrymen to strive for the freedom of India in a spirit of devotion. The *bhakti* of the medieval hymnodists was thus enlisted in the cause of modern independence.

Mahatma Gandhi. Much influenced by the traditional *bhakti* of his native Gujarāt and fortified by Christian and other religious literature that encouraged similar attitudes, Mahatma Gandhi, the most important leader for independence, appeared to his simpler followers as the quintessence of the Hindu tradition. His austere celibate life was one that the Indian layman had learned to respect implicitly. Thus, Gandhi's message reached a wider public than that of any of the earlier reformers.

The Western element in Gandhi's ideology has often been exaggerated. His doctrine of nonviolence can be found in many Hindu sources, although his beliefs were much strengthened by Christian ethical literature and especially by the later writings of Leo Tolstoy. His political technique of passive resistance, *satyāgraha*, also has Indian precedents, although in this he was much influenced by Western writers such as the American Henry David Thoreau. The chief innovations in Gandhi's philosophy were the dignity of manual labour and the equality of women. Precedents for both of these are to be found in the writings of some 19th-century reformers, but they have little basis in earlier Indian thought. In many ways Gandhi was a traditionalist. His respect for the sacred cow—which, as some other educated Indians did, he rationalized as the representative of Mother Earth—was a contributory factor in the failure of his movement to attract large-scale Muslim support. His insistence on strict vegetarianism and celibacy among his disciples, in keeping with the traditions of Vaiṣṇava ascetic ethics, also caused difficulty among some of his followers. Still, the success of Gandhi represented a political culmination of the movement of popular Bhakti begun in South India early in the Christian era.

Gandhi as innovator and traditionalist

The religious situation after independence. The rise of nationalism, after the division of India into India and Pakistan in 1947, led to a widening of the gulf between Hindu and Muslim. In the early 1970s it was fashionable in Indian circles to paint the relations of the two religions in earlier centuries as friendly, blaming alien rule for the division of India. In Pakistan the tendency has been to insist that Hindus and Muslims have always been "two nations," even though the Hindus were happy under their Muslim rulers. Neither position is wholly correct. In earlier times there was much mutual influence. But the conservative and rigid moralistic element in Indian Islām was gaining the upper hand long before British power was consolidated in India, and Islāmic influence on Hinduism was largely in externals.

Among the pioneers of nationalism, Tilak glorified the Maharashtrian hero Śivajī as the liberator of his country from the alien yoke of the Mughals; and Bankim Chandra Chatterjee's militant ascetics, pledged to conquer and expel the Muslims, sang a battle hymn that no orthodox Muslim could repeat. British rulers of India did little or nothing to lessen Hindu–Muslim tension, and their policy of separate electorates for the two communities worsened the situation. Many leaders of the Indian National Congress movement, such as Jawaharlal Nehru, carried their Hinduism lightly and favoured a secular approach to politics. The majority, however, followed the lead of Gandhi, whose insistence on Hindu values discouraged Muslims from joining his movement, despite the fact that he recited passages from the Qur'ān as well as from the Hindu and Christian scriptures at his prayer meetings. To the right of the Congress politically, the Hindu Mahasabha was equally nationalistic, but its explicitly Hindu nationalism was not opposed to nonviolence in its drive to establish a Hindu state in India.

The transfer of power in 1947 was accompanied by slaughter and pillage of huge proportions. Literally millions of Hindus left their homes in Pakistan for India, and as many Muslims migrated in the opposite direction. The tension culminated in the assassination of Gandhi by a Hindu fanatic in January 1948.

India as a secular state

The policy of the Indian government was to establish a secular state, and the successive Congress governments have broadly kept to this policy. The governments of the Indian states, however, have not been so restricted by constitutional niceties. Some state governments have introduced legislation of a specifically Hindu character.

On the other hand, the Congress government has passed legislation offensive to Hindu traditional prejudices such as no British Indian government would have dared to enact. All forms of discrimination against "untouchables" are now forbidden, although it has been impossible to enforce this law in every case. A great blow to conservatism was dealt by legislation of 1955–56 which gave full rights of inheritance to widows and daughters, enforced monogamy, and permitted divorce on quite easy terms. A further enactment that tended to undermine traditional Hinduism was the law forbidding dowries (1961). The dowry has long been a tremendous burden to the parents of daughters, but the strength of social custom is such that this law cannot be fully enforced.

The mantle of Mahatma Gandhi fell on Vinoba Bhave, one of his most devoted Maharashtrian supporters. For some years after independence Vinoba led a campaign of social service that culminated in the *bhūdān* (land-giving) movement, which persuaded many landowners and wealthy peasants to give fields to landless labourers. This movement had some small success in rural areas, but it gradually lost momentum.

Although the memory of Gandhi is revered by most Indians in the latter part of the 20th century, his policies and principles carry little weight. The great bulk of social service is performed by government agencies rather than by voluntary bodies, whether Gandhian or otherwise. The social structure of traditional Hinduism is slowly crumbling in the cities. Intercaste and interreligious marriages are becoming more frequent among the educated, though some aspects of the caste system show remarkable vitality, especially in the matter of appointments and elections. The bonds of the tightly knit Hindu joint family are also weakening, a process helped by recent legislation and the emancipation of women. The professional priests, who perform rituals for laymen in the home or at temples and sacred sites, complain of lack of custom, and their numbers are diminishing. Mythological films, once the most popular form of entertainment, are now less often made.

Nevertheless, Hinduism is far from dying. Organizations such as the Ramakrishna Mission flourish and expand their activities. New teachers appear from time to time and attract considerable followings. The Jan Sangh, a right-wing party devoted to maintaining Hindu values, gains a considerable number of seats in every election, especially in Uttar Pradesh. The adaptability of Hinduism to changing conditions is illustrated by the

The appearance of a new deity: Santoṣī Mātā

appearance in the Hindu pantheon of a new divinity, of special utility in an acquisitive society. This is the goddess Santoṣī Mātā, now worshipped widely by women in many cities of Uttar Pradesh. The new goddess was unheard of a few years ago and has no basis in any Purāṇic myth. Propitiated by comparatively simple and inexpensive rites performed in the home without the intervention of a priest, Santoṣī, it is believed, will grant practical and obvious blessings, such as a promotion for a needy, overworked husband, a new radio, or even a refrigerator. News of Santoṣī's blessings is passed from housewife to housewife, and, against all reason, even moderately well-educated women have become her devotees.

On both the intellectual and the popular level, Hinduism is thus in the process of adapting itself to new values and new conditions that have been brought about by mass education and industrialization and is responding to 20th-century challenges.

Hinduism outside India. During the latter part of the 19th and through the 20th centuries, large colonies of Hindu migrants have been established in East Africa, Malaysia, the islands of the Pacific and the Indian Ocean, and some of the islands of the West Indies. These migrants have taken their religion with them and have adhered to it faithfully over several generations. In recent years they have been aided by Hindu missionaries, chiefly of the Arya Samaj or the Ramakrishna Mission. Since World War II many Hindus have also settled in the United Kingdom. Most of these migrants, however, have been comparatively uneducated. Their religion has made little impression on the people among whom they live, and they themselves have made no serious attempts to gain converts. Yet, one of the most striking aspects of contemporary Western culture is its readiness to accept Eastern religious ideas in a way unprecedented since the days of the Roman Empire. The most recent manifestation of the spread of Indian religious attitudes in the Western world is the Hare Krishna cult, officially known as the International Society of Krishna Consciousness Inc., with its head office in Los Angeles. This is essentially a *bhakti* movement, broadly following the precedents of Caitanya. Since its foundation by a Hindu *sannyāsī*, Swami Prabhupada, in 1965, its growth has been surprising, and *nagar-kīrtans* (devotional singing and dancing) may now be seen in the streets of New York and London, performed by young men and women from Christian or Jewish homes wearing *dhotīs* and *sarīs*. These manifestations of the spreading influence of Hinduism are part of a process that began in 1784 with the first English translation of a Hindu religious text, Charles Wilkins' version of the *Bhagavadgītā*. Even if modern forms of Hinduism have only an ephemeral existence, new manifestations most likely will be seen in the West. Hinduism is now a part of the cultural heritage of the world.

BIBLIOGRAPHY. Among the many general studies of Hinduism treating the subject briefly in historical perspective, perhaps the best is R.C. ZAEHNER, *Hinduism*, 2nd ed. (1966). The monumental R.C. MAJUMDAR (ed.), *The History and Culture of the Indian People*, 10 vol. (1951–), contains sections on religion and philosophy in each volume, giving useful general surveys of the subject at different periods. BENJAMIN WALKER, *The Hindu World*, 2 vol. (1968), is an alphabetically arranged encyclopaedia of Hinduism that pays due attention to its historical aspects. On the archaeology and anthropology of religion in India, B. and R. ALLCHIN, *The Birth of Indian Civilization* (1968), contains a valuable chapter on the subject and useful bibliographical references. D.D. KOSAMBI, *Myth and Reality*, ch. 2–4 (1962), and *The Culture and Civilization of Ancient India in Historical Outline* (1965), are perhaps in places overimaginative but stimulating. The best general survey of Hinduism as practiced by the masses is probably still L.S.S. O'MALLEY, *Popular Hinduism: The Religion of the Masses* (1935). The classical case history of the process of Sanskritization is M.N. SRINIVAS, *Religion and Society Among the Coorgs of South India* (1952). The standard survey of Vedic religion is A.B. KEITH, *The Religion and Philosophy of the Veda and Upanishads*, 2 vol. (1925). More recent are the works of J. GONDA, especially *The Vision of the Vedic Poets* (1963) and *Change and Continuity in Indian Religion* (1965). For the evolution of theistic Hinduism, the classic survey of NICOL MACNICOL, *Indian Theism from the Vedic to the Muhammadan Period* (1915), is still important. For a more recent interpretation, see S. CHATTERJI, *The Evolution of the Theistic Sects in Ancient India* (1962). E.W. HOPKINS, *Epic Mythology* (1915), is still the best general survey of the subject. Recent more specialized historical studies are SUVIRA JAISWAL, *The Origin and Development of Vaiṣṇavism* (1967); and V.S. PATHAK, *History of the Śaiva Cults in Northern India* (1960). On the history of South Indian Śaivism, see C.V. AYYAR, *Origin and Early History of Śaivism in South India* (1936). Many studies of the Hindu temple have been published, but most of these are mainly concerned with its architecture and sculpture, though a few also give accounts of temple ritual. Interesting and important is the article of B. STEIN, "The Economic Function of a Medieval South Indian Temple," *Journal of Asian Studies*, 19:163–175 (1960). On medieval devotional Hinduism, see J.E. CARPENTER, *Theism in Medieval India* (1921); LILIANE SILBURN, *La Bhakti* (1964); and M.B. SINGER (ed.), *Krishna: Myths, Rites and Attitudes* (1966). A remarkable survey by the early 19th-century Catholic missionary J.A. DUBOIS, *Hindu Manners, Customs and Ceremonies*, 3rd ed. (1906, reprinted 1959), though betraying prejudice here and there, is one of the very few detailed and reliable studies of living Hinduism as it existed before it came under any Western or other reforming influence. A good overall survey of the developments in Hinduism in the last 150 years is yet to be written. J.N. FARQUHAR, *Modern Religious Movements in India* (1915), still forms a useful survey of developments down to the date of publication, though written from a missionary viewpoint. See also D.S. SARMA, *Studies in the Renaissance of Hinduism in the Nineteenth and Twentieth Centuries* (1944). On 19th-century Bengali reformers, see N.S. BOSE, *The Indian Awakening and Bengal*, 2nd ed. rev. (1969). The EARL OF RONALDSHAY, *The Heart of Aryâvarta: A Study of the Psychology of Indian Unrest* (1925), is a contemporary study of the religious bases of Hindu nationalism, written with considerable understanding, though by one of the British rulers of India. The short work of C.E.M. JOAD, *Counter Attack from the East: The Philosophy of Radhakrishnan* (1933, reprinted 1951), was perhaps among the first to recognize the extent of the influence of Hinduism on the West. The collection of articles edited by M. SINGER, *Traditional India: Structure and Change* (1958), contains several dealing with the recent religious history of Hinduism. R.W. SCOTT, *Social Ethics in Modern Hinduism* (1953), examines recent trends.

(A.L.B.)

Hindu Kush (Mountains)

The Hindu Kush is one of the great watersheds of Central Asia, forming part of the vast alpine zone that stretches across the continent from east to west. Broadly defined, it is a mountain system nearly 1,000 miles (1,600 kilometres) long and possibly 200 miles (320 kilometres) wide, running northeast to southwest, and dividing the valley of the Amu Darya (the ancient Oxus River) to the north from the Indus River Valley to the south. There is no agreement among geographers as to its precise boundaries. To the east, the Hindu Kush buttresses the Pamir Plateau near the Chinese border, after which it runs southwest through Pakistan and into Afghanistan, finally merging into minor ranges in western Afghanistan. The highest peak is Tirich Mīr, which is 25,263 feet (7,700 metres) high.

Historically, the passes across the Hindu Kush have been of great military significance, providing access to the northern plains of India. Alexander the Great (*q.v.*), king of Macedonia, who passed over the Hindu Kush in the 4th century BC, was among those who invaded India by this route. During the period of British rule in India, the Indian government was keenly concerned with the security of these passes, and more especially with their own control of an associated physical feature to the south, the Khyber Pass. The Hindu Kush range has rarely constituted the frontier between major powers, but has usually formed part of an intermediate buffer zone.

The name Hindu Kush first appears in 1333 in the writings of Ibn Baṭṭūṭah, the medieval Berber traveller, who said that the name meant "Hindu killer," a meaning still given by Afghan mountain dwellers, who are traditional enemies of Indian plainsmen. More likely the name is a corruption of the classical term Hindu-Caucasus, or else Hindu-Koh, meaning "Indian Mountains."

The mountains. The eastern limit of the Hindu Kush is difficult to determine because of a locally complex

topography, although the Karambar Pass (14,225 feet, or 4,345 metres) between the valleys of Chitrāl and Gilgit may be tentatively accepted as marking the boundary. The western limit is still more uncertain, as the mountains lose height and fan out into minor ranges. The Kirmu Pass (10,879 feet, or 3,316 metres) to the west of Kābul may, nevertheless, be regarded as indicating the approximate boundary. Geologists, however, consider the Hindu Kush range to extend much further west not only into Afghanistan but also into Iran.

Three main regions

Three main sections of the Hindu Kush may be defined. These are the eastern Hindu Kush, which runs from the Karambar Pass in the east to the Dorah Pass (14,940 feet, or 4,554 metres) not far from Tirich Mīr; the central Hindu Kush, which then continues to the Khawak Pass (11,640 feet, or 3,548 metres) to the north of Kābul; and the western Hindu Kush, also known as the Koh-i-Bāba, which gradually descends to the Kirmu Pass.

The Eastern Hindu Kush. In its extreme eastern section, between the passes of Karambar and Baroghil (12,480 feet, or 3,804 metres), this region is not very high and has mountains that often take the form of rounded domes. Further to the west the main ridge rises rapidly to Baba Tangi (21,368 feet, or 6,513 metres) and becomes rugged, after which, within the space of about 100 miles, are concentrated the highest mountains of the entire region—about two dozen summits of more than 23,000 feet, or 7,000 metres, in height. A first cluster of high peaks around Urgend (23,094 feet, or 7,039 metres) is followed further south by the massif (principal mountain mass) of Sara Ghar (24,111 feet, or 7,349 metres). Another line of imposing mountains, which includes Koh-i-Langar (23,162 feet, or 7,060 metres), Shachaur (23,346 feet, or 7,116 metres), Udrem Zom (23,376 feet, or 7,125 metres), and Nader Shah (23,376 feet, or 7,125 metres), leads to the three giant mountains of the Hindu Kush, which are Noshaq (24,580 feet), Istor-o-Nal (24,242 feet), and Tirich Mīr (25,263 feet). Most major glaciers of the Hindu Kush—among them Kotgaz, Ushko, Nirogi, Atrak, and Tirich—are in the valleys of this section.

The Central Hindu Kush. The central region lies almost entirely within Afghanistan. According to the report of a British expedition in 1967, this region "has no nice, easily definable east–west ridge but rather a tortuous twisting watershed with massive off-shoots running north towards the Soviet Union and south into Nuristan (a region of Afghanistan)." Maximum heights, which are lower than those in the eastern section, include Koh-i-Bandakor (22,451 feet, or 6,843 metres), Koh-i-Mondi (20,498 feet, or 6,248 metres), and Mīr Samir (19,878 feet, or 6,059 metres). These peaks are surrounded by a host of lesser mountains. Glaciers are poorly developed, but the mountain passes—which include Putsigram (13,450 feet, or 4,100 metres), Weran (15,400 feet, or 4,700 metres), Ramgul (15,400 feet, or 4,700 metres), and Anjuman (13,850 feet, or 4,225 metres)—are high, thus making transmontane communications difficult.

Watershed of the Central Hindu Kush

The Western Hindu Kush. The mountains of the western region fan out gradually toward the Afghan town of Herāt, near the Iranian border, declining into hills of lesser importance. Communication is easier in this region, as the passes, such as the Shebar Pass (9,800 feet, or 2,987 metres), have long since been crossed by roads.

A wider definition of the limits of the Hindu Kush would lead to the inclusion of a fourth region known as Hindu Rāj. This is formed by a long, winding chain of mountains—with some lofty peaks, such as Darkot (22,447 feet, or 6,842 metres), and Būni Zom (21,499 feet, or 6,553 metres)—which strikes southward from the Lupsuk Peak (18,853 feet, or 5,746 metres) in the eastern region, then continues to the Lowarai Pass (12,100 feet, or 3,700 metres) and beyond to the Kābul River. If this chain were to be considered as part of the Hindu Kush, then the outlying mountains of Swāt Kohistān to the south would also form part of the complex. For most purposes of this article, however, the Hindu Rāj and its associated ranges are excluded from consideration.

International boundaries. International boundaries running through the Hindu Kush are primarily those of Pakistan and Afghanistan. The Karambar Pass lies about 40 miles west of the Chinese borders, while to the west the Hindu Kush, strictly considered, approaches the border between Afghanistan and Iran without extending into Iranian territory. Between these extremes the Pakistan–Afghanistan border follows the main watershed of the Hindu Kush throughout its eastern region, from Lupsuk Peak just north of the Karambar Pass to the Dorah Pass just south of Tirich Mīr. Not far from the Dorah Pass the boundary leaves the main watershed and follows minor spurs until it crosses the Kābul River, continuing along the crest of the Safed Koh Range toward the south. The Khyber Pass constitutes an important strategic gateway because it cuts through the Safed Koh range instead of through the Hindu Kush thus offering a comparatively easy route between the valley of the Kābul and the plains of Punjab.

The erratic boundary line is the result of a series of compromises reached at the end of the 19th century between the British and the ruler of Afghanistan; called the Durand Line, after the British negotiator, it has been inherited by the modern states of Pakistan and Afghanistan. Another curious configuration established about the same time and as yet unchanged is the Vākhān corridor, a panhandle of Afghan territory designed to act as a buffer between British India and tsarist Russia.

Geology. In many of its features the Hindu Kush resembles its eastern neighbour, the Karakoram Range that extends from Tibet into Pakistan. The Hindu Kush, which some authorities consider to be a continuation of the Karakoram, has the same core of igneous metamorphic rock (*i.e.*, rock formed by heat and pressure that has solidified from a molten state) flanked, especially toward the north, by sedimentary material. In the Hindu Kush, however, there appears to be a greater prevalence of sedimentary rocks—a fact that may explain the softer and more rounded forms of many of the mountains. In the Afghan section the core of the chain is formed by a complex sequence of metamorphic rocks containing marble, together with intrusions of granodiorites (rocks formed deep down by heat and pressure, and containing a certain admixture of both dark-coloured and light-coloured minerals). In Nūrestān the hills consist mainly of schists (medium- or coarse-grained metamorphic rocks), gneiss (a coarse-grained rock in which bands containing granular materials alternate with bands of schistose materials), and intrusions of granite with zones of migmatite (rock consisting of alternate layers of granite and schist). The Hindu Kush differs markedly from the Karakoram, however, in the winding direction of its strike (*i.e.*, its course, or bearing).

Drainage. The Eastern Hindu Kush appears to be formed of two parallel chains, consisting of a lower one to the north, which acts as a watershed, and a higher southern one that carries the main peaks. Drainage is comparatively simple on the northern side but highly complex on the southern one, where valleys follow two contrasting directions—northeast to southwest and roughly east to west. Most of the rivers, such as the Panjshir, the Alingar, the Kunar, and the Pānjkora, follow the northeast to southwest direction and are then suddenly deflected toward the east–west axis by the Kābul River, into which they flow. The Karumbar and Gizar valleys also take the same east to west direction. The Indus River, however, swerves in its course from one direction to another as it makes its roundabout descent toward the lower plains.

Climate. Since the range separates one important zone of Asia from another, the climate shows great variations. The mountains of Swāt Kohistān are virtually within the area of the rain-bearing monsoon winds, and most of the Eastern Hindu Kush, as well as the Hindu Rāj, rises up at the extreme limit of monsoonal Asia. The Central and Western Hindu Kush, however, border the Mediterranean climatic zone. Thus, moving from the southeast to the northwest and west, one moves from a region of rainy or snowy summer (from July to September) and of dry winters into a region of hot dry summer and cold and rainy or snowy winter (from December to early March).

Climatic contrasts

Climatic variations between these opposites also occur, producing often striking local contrasts.

A graphic image of climatic conditions is presented by the glaciers. The mantle of snow and ice is heaviest at the extreme eastern end of the Hindu Kush, where the Chiāntar Glacier is situated, and is also heavy in the higher section around Tirich Mīr and Saraghrar and in parts of the Hindu Rāj. Toward the west, however, glaciation is more sporadic. In the Central Hindu Kush, mountains 12,000 feet high are often bare almost to the summit. Most of the glaciers of the Hindu Kush appear to be retreating. A striking feature of some glacial regions are the so-called nieves penitentes, which are protruding spikes of frozen snow forming the illusion of kneeling human figures, sometimes two or three feet high, which are especially noticeable in the early morning; they are caused by the alternation of fierce sun and rapid evaporation during the day and of severe cold at night.

Vegetation. Differences in latitude and the variety of climates make it difficult to generalize about vegetation. Compared to the Himalayas of Nepal, and still more to those of Sikkim and Bhutan, the mountains of the Hindu Kush appear bare, stony, and poor in vegetation, although there are local exceptions. Some rich forests and pastures are found in the extreme southeast of the extended Hindu Kush region, as well as in the hills of Swāt Kohistān and in the Pānjkora Valley of the Dīr District. Parts of the valleys of the Gupis and Yasin rivers in the Gilgit area enjoy sufficient summer precipitation to be partially covered with vegetation. In the valleys of the Swāt and Dīr districts, as well as in some parts of the Chitrāl area, rice is cultivated.

The highlands of the eastern extremity of the Hindu Kush with their rolling pastures, bear some resemblance to Tibet, but further south valleys become arid and stony. A typical view in parts of Chitrāl, for example, would include snowy peaks in the distance, dry, barren, brick-red or ochre-coloured mountains all around, and bright emerald-green islands of vegetation near the villages where springs and irrigation furnish abundant water. In such oases, poplar trees are a distinct feature, often being accompanied by old and gigantic plane trees.

Much moisture carried by the monsoon winds penetrates the lower part of Chitrāl across the Lowarai Pass, so that stands of coniferous trees occur in the surrounding districts. The valleys of Nūrestān receive sufficient precipitation to have some pastureland and forests.

To the west of Afghanistan, and to the north of the Hindu Kush, extremely dry summers prevail; much of the country is stony, or sparsely covered with thorny and spiny plants, or with poor grass.

The meagre vegetation of most parts of the Hindu Kush does not favour wild animal life. The snow leopard manages barely to survive in the most remote valleys. Bears formerly roamed Nuristan, but few remain today. The markhor (a kind of wild goat) was once abundant, but hunters have now thinned the stock. Birdlife is rich, however, and eagles are occasionally to be seen.

The inhabitants. A long and tormented history, together with fragmented topography, has produced a veritable mosaic of ethnic units in the region. Kirgiz nomads, about 30,000 in number, graze their herds on the Vākhān uplands. The lower parts of the Vākhān corridor and the higher parts of the Sanglich and Anjuman valleys, all on the northwest slopes of the Hindu Kush, are sparsely inhabited by the so-called Pamir Tadzhiks, most of whom are Shīʿah Muslims. Other Tadzhiks (who are Sunnī Muslims), Uzbeks, and some Ḥazāra (Persian-speaking Mongols) live in the valleys of the central and western parts of the Hindu Kush. Afghans are found in the major towns, in Kābul, and in many districts to the south of the Hindu Kush, with the exception of Nūrestān.

On the southeast (Pakistan) side of the Hindu Kush, most people are Chitrāli, a racially mixed ethnic group that shows a marked cultural unity.

The Kafirs of Nūrestān

The Kafirs of Nūrestān, numbering 60,000 or 70,000, and of Chitrāl, numbering 2,000 or 3,000, are an exceptionally interesting people. Their name means "infidel" or "non-Muslim" and seems to have been used since the 11th century. Traditionally, they are divided into two groups—the *kalash* ("black") Kafirs of Chitrāl, and the *kati* ("red") Kafirs of Nūrestān. In the remote past, the Kafirs possibly inhabited a much larger area. The Kafirs of Nūrestān were forcibly converted to Islām in 1896.

Physically, the Kafirs do not seem to differ much from their neighbours; they speak a language classed by some as Dardic. It is in their religion and culture that their ethnic individuality is most strikingly expressed. In religion they practise a form of polytheism; worship consists mainly in the sacrifice of animals. Dancing is important, and divination through shamans is practiced. The dead are disposed of, unburied, in heavy wooden coffins. Large wooden statues of ancestors, often on horseback, stand near graveyards; many are works of vigorous and elemental beauty. Kafir homes are strong rectangular wooden buildings. Their economy is based on agriculture, hunting, and the raising of goats and oxen.

Exploration. The West took note of the Hindu Kush when Alexander and his armies crossed the mountains, which according to some authorities, he did twice. The Hindu Kush was well known to Arab geographers, as well as to the Chinese, who occupied Chitrāl in the 8th century AD. Marco Polo (*q.v.*), the Venetian traveller, and his group passed along the Hindu Kush through the Vākhān corridor. The mountains were also traversed by Timur (Tamerlane), the Mongol conqueror, in the 14th century and by Bābur, the Turkish conqueror who founded the Mughal empire, in the 15th century, in their expeditions against India. A number of explorers visited the region in the 19th century, and much knowledge was gained by the British during the two wars that they waged against Afghanistan from 1838 to 1842 and from 1878 to 1879. Further detailed knowledge of the area has been gained in the 20th century. Between 1960 and 1970 over 150 mountaineering and exploring expeditions visited the Hindu Kush.

Communications. The Hindu Kush offers a formidable barrier to communication. There are, however, some important passes. The Baroghil Pass (12,480 feet, or 3,804 metres high), at the head of the Chitrāl Valley, is one of the lowest and easiest openings in the 1,500 miles of forbidding mountains that border the north of India and Pakistan. Further west the highest section of the Hindu Kush offers, for about 100 miles, a wall quite unpassable by normal means of communication. In the Central Hindu Kush the passes are also high; only in the western section do more accessible passes occur. In 1964 a tunnel was completed under the Salang Pass (12,008 feet, or 3,660 metres) north of Kābul; consequently, for the first time in history, the great mountain wall has been pierced, making the north of Afghanistan accessible to the south at all seasons.

The Kakal Tunnel

The Hindu Kush can now be approached by motor transport from many directions. Chitrāl in the south is accessible, via the Lowarai Pass from Peshāwar, while the Kakal Tunnel has made Khānābād in the north accessible from Kābul. Lesser roads lead on to Faizābād and, from there, to the Vākhān corridor, or to Zebak, both situated in the heart of the mountain ranges. Many major peaks are now barely three or four days march from the last village accessible to motor transport.

Economic resources. The economic resources of the region remain virtually undeveloped. It is thought that the northern slopes may contain coal and perhaps petroleum or natural gas; the presence of gold, silver, copper, zinc, and lead also is suspected. Quantities of salt are known to exist, and lapis lazuli (a deep blue mineral, used as a gem), rubies, and beryl (a mineral, usually green, one variety of which is emerald) have been reported. There is some antimony (a white metallic element used in alloys of medicine) in Chitrāl. There is a hydroelectric potential, especially in the Daryā-ye Qondūz and Kokcha river basins on the northern side. Forests are still partially standing, but much merciless lumbering is rapidly reducing this resource. While many local peoples, especially the Chitrāli, make ingenious use of springs and rivers by building small aqueducts, agri-

culture would benefit greatly from more modern methods of irrigation. The local economy is at the bare subsistence level. Some dried fruit, a little lumber, mineral salt, charcoal, fodder grass, mats, and ropes are exported, mainly from Chitrāl. Sheep and goats are also raised.

Future prospects. Prospects for future development, as in most remote mountain districts, are not bright; it is even possible that improved communications, combined with the attractions of cities and industries elsewhere, may cause depopulation. While tourism can become an important source of income, tourist facilities—roads, trails, hotels, huts, and camping sites—have yet to be planned and built. Apart from this, however, there appears no reason why the Hindu Kush Mountains, with their wild valleys and rugged peaks, waterfalls and forests, and in some regions the prevailing blue skies and bracing air, should not become one of the playgrounds of the world.

BIBLIOGRAPHY. General geographic descriptions of the region appear in D.N. WILBER (ed.), *Afghanistan* (1956); and J.C. GRIFFITHS, *Afghanistan* (1967). M. KLIMBURG, *Afghanistan* (1966), is an authoritative survey (in German) rich in detailed information. S.G. BURRARD and H.H. HAYDEN, *A Sketch of the Geography and Geology of the Himalaya Mountains and Tibet*, 2nd ed. (1933); and A. GANSSER, *Geology of the Himalayas* (1964), deal briefly and technically with the eastern section of the chain. The results of alpine exploration and climbing up to 1965 are recorded by B. CHWASCINSKI, "The Exploration of the Hindu Kush," *Alpine Journal*, 2:199–214 (1966).

Invaluable material on Kafir culture, previous to its dissolution, is contained in *The Kafirs of the Hindu-Kush* by G.S. ROBERTSON (1896). R.C.F. SCHOMBERG, *Between the Oxus and the Indus* (1935) and *Kafirs and Glaciers* (1938), provide much information on the Hindu Kush and its people. *The Pathans, 550 B.C.–A.D. 1957* by O.K. CAROE (1958); and *Anthropological Research in Chitral* by P. GRAZIOSI (1964), offer further important contributions.

Aspects of Hindu Kush geology are treated in S. MATSUSHITA, *Geology of the Karakoram and Hindu Kush* (1965); vegetation in S. KITAMURA, *Flora of Afghanistan* (1960); and insect life in M. UENO (ed.), *Insect Fauna of Afghanistan and Hindukush* (1963). For early history of the region, see W.W. TARN, *The Greeks in Bactria and India* (1938) and *Alexander the Great* (1948). For later periods, consult *Afghanistan: Highway of Conquest* by A. FLETCHER (1965); and *Afghanistan: A Study of Political Developments in Central and Southern Asia* by W.K. FRASER-TYTLER, 3rd ed. (1967).

Two eminently readable travel accounts are: *Between Oxus and Jumna* by A.L. TOYNBEE (1961); and *A Short Walk in the Hindu Kush* by E. NEWBY (1958).

(F.M.)

Hindu Mysticism

Mysticism is usually defined as union, or desire for union, of the self with something greater than the self, whether that be defined as a principle that pervades the universe or as a personal God. Hindu mysticism includes both these definitions and a great many that lie in between. At one extreme is the realization of the identity of the individual self with the impersonal principle called Brahman, the position of the Vedānta school of Indian philosophy; and at the other is the intensive devotionalism to a personal God, called by a variety of names, which is found in the Bhakti (devotional) sects.

TYPES OF MYSTICISM

It is usual for writers on the subject, following Surendranath Dasgupta, a historian of Indian philosophy, to consider that there are five major varieties of Hindu mysticism, the five having arisen in historical order as follows:

1. The sacrificial, based on the texts called Vedas, the earliest Hindu scriptures, and *Brāhmaṇas*, ritual texts (*c.* 1500–1000 BC); in this variety the sacrifice, a complex ritual involving recitation of sacred formulas and the offering of sacred materials to the fire, recreates the original creation; the forces of nature and the gods are controlled by the sacrificer through his knowledge of the texts and rituals.

2. The *Upaniṣadic*, exemplified by early religio-philosophic texts called *Upaniṣads* (1000–500 BC), which are filled with dense speculations on the relationship of man to the universe, and in which are found the beginnings of both monistic (concerned with a unitary principle of reality, immanent in the world) and theistic (concerned with a personal or suprapersonal God) systems.

3. The Yogic, relating to physical and mental discipline; the earliest known text of this school is the *Yoga-sūtra* of Patañjali, dated variously between the 2nd century BC and the 4th century AD. According to Yogic mysticism, man realizes union by means of physical and mental control of himself, which leads to control of both natural and divine forces.

4. The Buddhistic, in which enlightenment is the realization of the four Truths—the fact of pain, the cause of pain, the cessation of pain, and the means of arriving at these three truths: the Eightfold Path. The ultimate state, the culmination of one path of the Eightfold Path, is Nirvāṇa, "the blowing out," the extinction of desire (see BUDDHIST MYSTICISM).

5. The devotional or Bhakti type of mysticism comprises a range of theistic systems, with a conception of absolute dualism between man and God on the one extreme, and a conception of qualified nondualism on the other. Although there are traces of this devotionalism throughout the history of Indian religion, it began to develop in earnest in South India in the 9th and 10th centuries AD with the hymns of the poet saints called Āḻvārs. Bhakti is the primary characteristic of medieval and modern Hinduism.

Such a historical division as the one just given obscures the fact that several of these five "types" have much in common; for example, the technique of meditation is similar in both Buddhism and Yoga. It may be that a different type of categorical analysis will be more fruitful.

Four elements common to all Hindu mystical thought

There are four things common to all Hindu mystical thought. The first is that it is all based on experience: the state of realization, whatever it is called, is both knowable and communicable, and the systems are all designed to teach men how to reach it. It is not, in other words, pure speculation. Second, it has as its goal the release of the spirit-substance of man from its prison in matter, whether matter be considered real or illusory. Matter is the cause of the pain of which Buddhism speaks. Third, all the systems recognize the importance or the necessity of the control of the mind and body as a means of realization; sometimes this takes the form of extreme asceticism and mortification, and sometimes, at the other extreme, it takes the form of the cultivation of mind and body in order that their energies may be properly channelled. And, finally, at the core of Hindu mystical thought is the functional principle that knowing is being. Thus, knowledge is something more than analytical categorizing; it is total understanding. This understanding can be purely intellectual, and some schools can equate the final goal with omniscience, as does Yoga. Knowing can also mean total transformation: if one truly knows something, he is that thing. Thus, in the devotional schools, the goal of the devotee is to transform himself into a being who, in eternity, is in immediate and loving relationship to the deity. But despite the fact that these are both ways of knowing, the difference between them is significant. In the first instance, the individual has the responsibility to train and use his own intellect. The love relationship of the second, on the other hand, is one of dependence, and the deity assists the devotee through grace. The distinction is generally made by the analogy of the cat and the monkey: the cat carries her young in her mouth, the kitten has no responsibility. But the young monkey must cling by its own strength to its mother's back.

A BRIEF HISTORY

Mysticism of the Vedas and *Brāhmaṇas*

Early mysticism. The earliest books of the Hindus, the Vedas (*c.* 1500 BC), are not deeply concerned with speculative thought. They are, rather, hymns to a series of gods who have control over natural forces and therefore over the fortunes of men. These gods are categorically separate from men, however, and, although they enter into human life, there is no union between men and gods. The attitude of men, hardly loving, was that propitiation

was necessary. Nature, to a wandering people, was often ruthless, sometimes dangerous, and only by sacrifice could natural forces be controlled. As time went on, the sacrifices became more and more elaborate, so elaborate that it took days to complete them. And with increasing complexity came increasing specialization in performance. Thus, around 1000 BC, a series of texts developed, called *Brāhmaṇas*, which were handbooks to these rituals. From these books it is clear that ritual had become an end unto itself. Its propitiatory function had been lost; the rituals had life and meaning all their own. They themselves were the re-enactment of the creation; except in form, they were no longer offerings to deities. They were themselves the deities. The ritual was identified with the cosmos, and by control of the ritual the cosmos was controlled. The gods that had populated the universe during the Vedic period had all but disappeared. The sacrifice was identified with the world process itself: the creation had been through the sacrifice of primordial man. The Vedic god of fire, Agni, had now become the messenger from man to the powers that control the universe. The sacrificer spoke the esoteric formulas that themselves contain awful power as he poured the sacrificial substance into the mouth of the fire; because he knew the words that contain power, the sacrificer was that power. The formulas, called *mantras*, are important in much of later mystical thought and practice. They are used, often in the form of "seed *mantras*" (*bīja-mantra*), both as aids to meditation and as direct means of realization. For, it is said, "the seed is in the tree, and the tree in the seed"; the universe is in the *bīja-mantra*, and knowledge of that *mantra* means that the knower is the universe.

This was the legacy that was carried into the texts called *Upaniṣads*, usually dated between 1000 and 500 BC, though there are very recent books that call themselves by this name. The early *Upaniṣads* are usually cited as the beginnings of Hindu speculative thought, and indeed they are filled with tortuous musings. But in no way do they present a unified system, or even a related series of systems; there are variations, inconsistencies, and contradictions, not only between one text and another, but often internally within a single text. Some of the *Upaniṣads*, such as the *Īśā* and *Kena*, are theistic and are used as authority for later theistic thought. Others, such as the *Bṛhadāraṇyaka* and *Chāndogya*, are largely pantheistic, though even these early texts are woven of various strands. Despite their inconsistencies, the *Upaniṣads* were all considered authoritative, for they are developments of the absolute authority, the Vedas themselves. This provided later thinkers with justification for a variety of positions.

There is, says the *Chāndogya Upaniṣad* (7.25), a spiritual principle called Brahman, which creates the universe, pervades the universe, and is the universe:

> That [*i.e.*, the spiritual principle], indeed, is below. It is above. It is to the west. It is to the east. It is to the south. It is to the north. It, indeed, is this whole world.

The self and the soul (called Ātman) also pervade the universe:

> Next, the instruction with regard to the Ego. I, indeed, am below. I am above, [etc.]. Next, the instruction with regard to the soul. The Soul, indeed, is below: The Soul is above, [etc.].

Mysticism of Śaṅkara

Such pantheistic statements can be interpreted in many ways. The great teacher Śaṅkara (*c.* AD 788–820) chose to have them mean that the soul, the *Ātman*, is identical with the all-pervasive spiritual principle, the Brahman, and that release is the experience of that identity. In his commentaries on the *Upaniṣads* and on the *Brahma-sūtra* of Bādarāyaṇa, Śaṅkara established what came to be called the "End of the Veda," the Vedānta. The *Upaniṣads*, he held, demonstrated that the pure self as pure being, pure intelligence, and pure bliss is itself the ultimate truth, and that the world and all else that is contingent is imperfect and false (*māyā*). *Mokṣa*, or release, to the Vedānta

> meant the dissociation of the self from the subjective psychosis and the world. . . . [The] Vedānta . . . held that the world as such has no real existence at all, but is only an illusory imagination which lasts till the moment when true knowledge is acquired. (From S.N. Dasgupta, A History of Indian Philosophy.)

To attain this knowledge, to separate the contingent from the eternal, to realize oneness with Brahman, no action or worship is necessary. Knowledge is what pierces the veil of ignorance that hides the truth. It is only necessary that a man lead a disciplined life, that he be no longer concerned with the things of this world, that he be able to discern what is transitory and what is permanent, that he be desirous and capable of peace, and that he exercise restraint and faith and be capable of deep concentration (the latter being a stipulated technique in many systems). Śaṅkara and the Vedānta do not deny the concept of a personal God (Īśvara). But since the definition of Brahman must be in terms of negatives ("it is not this, nor is it that"), there are those who are not satisfied by this. Brahman is by them called Īśvara. But when the ultimate state of identity is realized, the necessity for the notion of Īśvara, like other imperfect things, vanishes.

There are other possibilities, said the schools of Yoga. These also do not deny God, but union with God is not the goal of Yoga. God is a particular soul, not essentially different from other particular souls, which are, like God, eternal. The bondage of the soul, say the schools of Yoga, is due to lack of discrimination. Mental activity, which is involved with the things of the world, must be controlled. The means to this control is an eightfold path, of which the three most important elements are fixed attention, contemplation, and concentration (*samādhi*). In *samādhi*, the perfect life of the spirit, the soul is omniscient, self-illumined, and eternal. *Mokṣa* is the soul's realization of itself as an eternal monad.

Neither of these systems, then, has any real place for a personal God. The process of release is initiated by the self, pursued by the self, and attained by the self. And yet, these systems were confronted with such *Upaniṣadic* statements as this one, from *Śvetāśvatara Upaniṣad* 4:11:

> The One who rules over every single source,
> In whom this whole world comes together and dissolves,
> The Lord, the blessing-giver, God adorable—
> By revering him one goes forever to this peace.

Mokṣa, then, to the theistic *Upaniṣads*, is not in becoming one with the One but is in worship and reverence, which results in knowledge of the peace that is in God but that is not the totality of God. By *bhakti*, by devotion and faith, one gains that peace and joy; God is a God of love and grace who, like the god *Kṛṣṇa* (Krishna), hero of the *Bhagavadgītā* ("The Lord's Song"), can be known, at least in part, as a person. Such is the basis for the dualistic systems.

Mysticism of Madhva and Rāmānuja

The philosopher Madhva, born in the 12th century in South India, took a position of absolute dualism, in opposition to the Vedānta. To Madhva and his followers all texts and schools that speak of the unity of the self with the Brahman are false. The world is real, and the essential principle is that of the fivefold difference: difference between the self and God, between selves, between matter and God, between self and matter, and between matter and matter. Reality is of two kinds, independent and dependent; only God is independent reality, matter and souls being dependent on and controlled by God. The self, however, though dependent, is active and is responsible for its own release, that release coming through *bhakti* or devotion. Since it is the individual's responsibility, the ultimate state is gained by comparatively few (only in Madhva, of all Hindu religious and philosophical systems, is there a notion of eternal salvation). That ultimate state, as in other systems, is one in which there is neither pain nor sorrow. But unlike many other systems, in Madhva, since every soul is unique, the ultimate condition varies from individual to individual.

Rāmānuja, who also was born in South India about AD 1050, stopped well short of this absolute dualism and in fact represents a middle ground between the two extremes. To Rāmānuja, God is not the unqualified absolute principle of Śaṅkara but is a personal God who can be known, though imperfectly. God is internally differ-

entiated, and souls and matter are aspects of that differentiation. Though they are contained within God and are attributes of him, souls and matter possess qualities of their own. They are, therefore, both the same as and different from God. Identity means to Rāmānuja only that souls and matter do not exist independently; hence, identity is not the ultimate state. Matter, since it is one of the attributes of God, cannot be unreal. Furthermore, the sacred texts speak of the creation of the world by God, and if the world is a creation of God, it must be real; because matter changes and does not persist in a single form, it cannot be concluded to be unreal. So while for Śaṅkara liberation is the removal of the barrier of *māyā* (illusion), for Rāmānuja it is communion with God through devotion. When the goal is reached, the individual is not obliterated, but, as in Madhva, he retains his identity and enjoys forever the blissful fruits of his faith. He does not become one with God. This is the first of two new ideas that were to have great effect on later developments. The second is that the worshipper proceeds along the path of devotion because of the grace of God, which instills in him a desire to approach the godhead and share in the bliss of nearness. These ideas are vital to the later syncretistic systems, of which that of the Vaiṣṇavas of Bengal might be taken as an example.

Later mystical thought and method. Although the Vedic gods had largely disappeared from the monistic philosophies, they persisted, in changed form, in popular Hinduism, and eventually a select few found their way into the theism of Rāmānuja and Madhva. The most popular were Śiva, "the Auspicious One," and Viṣṇu, or Nārāyaṇa, and his incarnations Rāma and especially Kṛṣṇa. In the later schools, the personal nature of the deity was accepted: these gods had names and qualities. The questions became those of the proper relationship of man to God and the nature of a godhead that allows the simultaneous immanence and transcendence that Rāmānuja proposed.

The answer to the first of these questions seems to have been found—as it was by St. John of the Cross, the 16th-century Christian mystic, and others in very different traditions—in the symbol of human love. The Lord is the lover, the worshipper is the woman whom he loves. The human soul is feminine and yearns for and sometimes attains the Lord. This is clearly poetic expression rather than systematic doctrine. But it is a poetic expression that found voice through many of the languages of India. To the woman poet Mahādevīyakka, who wrote in Kannada in the 12th century, the Lord Śiva (Shiva) is the object of a very real and intensely passionate love. And yet he is beyond passion, attributes, death, and form:

Love mysticism of Mahādevīyakka

I've fallen in love with the splendid one:
death decay form
place and part
has He none,
and no birthmarks.
O mother, I love him.
. . .
I fell for the Handsome One
who is not of this world,
has no fear:
therefore, Arjuna of the Jasmines
is my husband.
Take the rest of them these husbands—
who die, who rot—
and throw them
into kitchen fires.

(Translation by A.K. Ramanujan; used by permission.)

Like St. Catherine of Siena, the 14th-century Christian mystic, who felt herself married to Christ, Mahādevīyakka felt herself married to Śiva, who was to her real and immediate and yet beyond all material qualities. Male devotees also, like the earlier Āḻvars, who wrote in Tamil, felt themselves to be female, and the Lord Kṛṣṇa (Krishna) the sole male of the universe. Nammāḻvār, of the 8th century, wrote such lines as these:

All places, shining like great lotus pools
On a blue mountain broad, to me are but
The beauties of his eye—the lord of earth
Girt by the roaring sea, heaven's lord, the lord
of other good souls, black-hued lord—and mine!

Kṛṣṇa, black in colour, pervades all. The Vaiṣṇavas of Bengal, too, in the 15th and 16th centuries, used the same image to express their passionate love for Kṛṣṇa:

Let the earth of my body be mixed with the earth
my beloved walks on.
Let the fire of my body be the brightness
in the mirror that reflects his face.
Let the water of my body join the waters
of the lotus pool he bathes in.
Let the breath of my body be air
lapping his tired limbs.
Let me be sky, and moving through me
that cloud-dark Shyāma, my beloved.

(Trans. by Edward C. Dimock, Jr., and Denise Levertov, *In Praise of Krishna;* Copyright © 1967 by Asia Society, Inc. Reprinted by permission of Doubleday & Company, Inc., and Jonathan Cape Ltd.)

In such poetry the images are immediate and intimate, but they are not images of union. The longed-for condition of the worshipper is near, not identical with, the divine lover. For love is the ultimate state, and if there were identity, the dynamic process of love could not exist. Yet the intimacy is extreme; Kṛṣṇa's loves are in some way extensions of himself. The relationship, say the Vaiṣṇavas, is both the same and not the same: it is as the flame to the fire, or the flower to its scent.

THE VAISNAVAS OF BENGAL

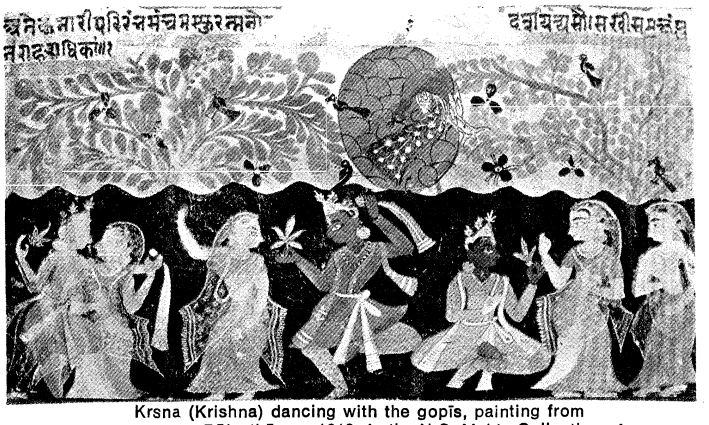
Unlike many other schools, the Vaiṣṇavas tried to explain this relationship systematically. The main text of the doctrine called *acintya-bhedābheda,* "unknowable and simultaneous difference and nondifference" (between the soul and God) is the *Ṣaṭ-saṃdarbha* of the 17th-century philosopher Jīva Gosvāmin. According to this text, the relationships are defined as follows:

Kṛṣṇa mysticism

The deity, Kṛṣṇa, is of three levels of reality. These are described by an analogy also used by Rāmānuja, that of the sun. The sun itself is of course the highest aspect; Brahman, the One of the Vedānta, is merely the undifferentiated radiance of this orb. But knowledge of the sun comes by two of its characteristics: sunbeams, which transmit the qualities of the sun to the earth, and the reflection of the sun in a mirror or a body of water. The three are interdependent: without the solar disk, neither sunbeams nor reflection exist. Without a reflection, the sun does not exist, for what is real is reflected. And the sunbeams are intermediate between the two. But the point of the image is that the reflection of the sun is a function of the sun itself; it represents the reality of Kṛṣṇa in the world. Not only is the world therefore real, but through it Kṛṣṇa can be known.

The text called *Bhāgavata-Purāṇa*, from South India in the 9th or 10th century, is considered to be revelation and truth. It is enigmatic and poetic, telling of the various aspects of the god Kṛṣṇa—as king, mighty God, child, and, most important to the Vaiṣṇavas of Bengal, as lover of the cowherding village girls called *gopīs*. This *Purāṇa* is taken to be the commentary by the legendary sage Vyāsa on the Vedas themselves. It is accepted as the ultimate authority.

The love between Kṛṣṇa and the *gopīs* has all the varied aspects of a fully human love, with anger and satisfaction, separation and union. Yet it is, of course, more than human love, for Kṛṣṇa is the true form of the godhead. Although he walked the earth, as the story is told in the *Purāṇa*, he was untouched by the material qualities of it; he could not in fact be touched by them, for his true form, while a form as if made up of those qualities, is in fact immaterial. The worshipper, therefore, in order to know the pure love that existed between Kṛṣṇa and the *gopīs*, must transform himself; he must also gain a divine, immaterial form; he must in fact become a *gopī*. As with Madhva, there is a difference between matter and spirit, a difference between man and God, and a difference between *gopī* and Kṛṣṇa. There can be union of the *gopīs* with Kṛṣṇa, as in the analogy of human sexual love. But there can never be unity.



Krsna (Krishna) dancing with the gopīs, painting from western Rājasthān, *c.* 1610. In the N.C. Mehta Collection of the Gujarāt Museum Society, Ahmadābād, India.

But there are others in the *Bhāgavata* story besides the *gopīs*. There are Kṛṣṇa's foster-parents, his friends, his servants, and others. All of these love him, in different ways. Each man, say the Vaiṣṇavas, is distinct and individual; therefore paths of devotion will differ, and, as the *Gītā* says, what is gained depends upon the path followed. The common quality of the ultimate experience is that all—*gopīs*, parents, and the others—are near Kṛṣṇa and love him. And not only are there many people in the story whose paths might be followed, but the story itself is a representation, in time, of what is happening eternally in heaven. Thus each moment of each emotion of each of the characters is also eternal. When the worshipper is transformed, he knows love for Kṛṣṇa through one who loves him in the story, and he experiences forever what on earth would be a momentary passion.

Mystical techniques

The mode of transformation involves characteristics that are common to all later schools (and many earlier schools as well) of mysticism. Among these are discipline of the body (though not in the way of Haṭha, or physical, Yoga), the help of the guru (religious teacher), and the use of the name of the deity.

There are said to be 64 acts of devotion, and these are undertaken for several purposes. They concentrate the whole attention on the religious object, the attainment of transformation; they discipline the body so that religious activity becomes normal activity; and they demonstrate purpose, which disposes the deity to grant his grace. The acts themselves include singing the names and praises of Kṛṣṇa, going to the temple, listening to the reading of the *Bhāgavata-Purāṇa*, putting the Vaiṣṇava signs upon the body, associating with holy men, and concentrating on or "remembering" the episodes of the *Bhāgavata-Purāṇa*, especially those appropriate to one's own goals. With constant performance of such acts, if the effort is sufficiently sincere, grace is granted, and the worshipper passes beyond the state in which external acts are necessary. Sometimes while still in this life one attains the state of true and eternal love.

Like the sun, the true form of the deity is knowable on earth only indirectly, until transformation is reached. A guru is one who has already reached the ultimate state but who, like the *bodhisattva* ("Buddha-To-Be") of Mahāyāna Buddhism, remains in the body in order to help others reach the ultimate state. The guru is a channel of the grace of the deity; he is the sunbeam. Unlike the deity himself, the guru is related to the earth, for he retains his material human form, and he has memories of the pain of life on the earth. He knows man and therefore can be sympathetic; he also knows Kṛṣṇa and can demonstrate his love.

There are two types of gurus—the guru who gives the *mantra*, or formula, that the devotee will meditate on and repeat to assist himself on the path of *bhakti;* and the guru who instructs and guides the devotee step by step along the way. The *mantra*—often a name of the deity—is crucial in the process of transformation, and it is said that taking the name of Kṛṣṇa only once will cleanse the heart and dispose Kṛṣṇa to grant his grace. The *mantra* in many ways contains the same power as do the formulas of the sacrifice; the *mantra* is in fact said to be the sacrifice of this, the Kali, age, the last and most degenerate of the traditional Indian ages of the world. The *Viṣṇu-Purāṇa* points out that men, in this age of degradation, are incapable of performing the Vedic sacrifice properly; the gracious deity, therefore, has given his name as an easier means to salvation.

This concept of the power of the word is familiar to many systems of Indian thought. But to the Bhakti systems, and to the *Tantras*, esoteric and magical sacred texts, it is crucial.

THE TANTRAS

The Tantric tradition is a very ancient one but one that has become, through time, so interwoven with more orthodox Hinduism that it is difficult to define precisely. Like the Vedānta, it is monistic; but it differs from the Vedānta in that, while it sees an identity between the soul and the cosmos, it speaks of the internalization of the cosmos rather than of the release of the soul to its natural state of unity. The body is the microcosm, and the ultimate state is not only omniscience but total realization of all universal and eternal forces. The body is real, not because it is the function or creation of a real deity but because it contains the deity, together with the rest of the universe. The individual soul does not unite with the One; it is the One, and the body is its function.

Tantrism, though not always in its full esoteric form, is a feature of much modern mystical thought. In Tantrism, the consciousness is spoken of as moving—driven by repetition of the *mantra* and by other disciplines—from gross awareness of the material world to realization of the ultimate unity. The image is of a serpent, coiled and dormant, awakened and driven upward in the body through various stages of enlightenment until it reaches the brain, the highest awareness. The modern mystic Ramakrishna describes the process, which also describes the experience that all Hindu mystical process seeks:

Mysticism of Ramakrishna

> When [the serpent] is awakened, it passes gradually through [various stages], and comes to rest in the heart. Then the mind moves away from [the gross physical senses]; there is perception, and a great brilliance is seen. The worshiper, when he sees this brilliance, is struck with wonder. The [serpent] moves thus through six stages, and coming to [the highest one], is united with it. Then there is *samādhi* . . . When [the serpent] rises to the sixth stage, the form of God is seen. But a slight veil remains; it is as if one sees a light within a lantern, and thinks that the light itself can be touched, but the glass intervenes. . . . In *samādhi*, nothing external remains. One cannot even take care of his body any more; if milk is put into his mouth, he cannot swallow. If he remains for twenty-one days in this condition, he is dead. The ship puts out to sea, and returns no more.
>

It is axiomatic that no religious idea in India ever dies or is superseded. All of these systems exist still, and are practiced still. As are so many areas of Indian life, Hindu mystical thought is of wondrous complexity and richness, uninhibited by dogma, a laboratory for the understanding of these special strivings of the religious mind.

BIBLIOGRAPHY. In most cases, Hindu mysticism is treated as an integral part of philosophy as a whole; the standard works on mysticism, then, are the standard histories of philosophy. The classic work among these is S.N. DASGUPTA, *A History of Indian Philosophy*, 5 vol. (1922–55). Excerpts of the relevant ideas from Dasgupta's larger study is *Hindu Mysticism* (1927, reprinted 1959). Other standard histories include S. RADHAKRISHNAN, *Indian Philosophy*, 2nd ed., 2 vol. (1956). More recent and more specific is R.C. ZAEHNER, *Hindu and Muslim Mysticism* (1960). In addition there are many sources on specific aspects, such as (for Yoga) MIRCEA ELIADE, *Le Yoga: immortalité et liberté* (1954; Eng. trans., *Yoga: Immortality and Freedom*, 2nd ed., 1969); or for the Bhedābheda school of the Vaiṣṇavas of Bengal, S.K. DE, *The Early History of the Vaisnava Faith and Movement in Bengal*, 2nd ed. (1961).

(E.C.D.)

Hindu Mythology

Hindu mythology consists of the stories of the several varieties of gods, the myths, and the tales of Hinduism, one of the oldest continuous religious traditions in the world and the predominant religion of India. This mythology has inspired a monumental literature, of theatre, song, dance, sculpture, painting, and architecture. In accepting the fearful as well as the benevolent, the sublime as well as the grotesque, it mirrors life, as viewed by the Hindus, to the fullest. Hindu mythology has a continuous documented history dating from *c.* 1400 BC. It is rich and varied, ranging from vague personifications of natural phenomena to an intricate mythical architecture of space and time. It can provide a grand cosmogonic design whereby the Hindu can understand the origin of the universe and man's place in it, or it can tell a simple story to explain the holiness of a river ford.

Myth in Hindu life and worship

Myth constantly enriches the Hindu's life, born as he is with the hereditary deities of his family and his village, to which he also adds a deity that he chooses for his own devotions. A wide variety of festivals, in which he shares with his fellow Hindus dramatizations of cosmic and divine events, punctuate his year. As a caste Hindu he communes with his caste fellows in a common caste myth. He will go on a pilgrimage and at the great centres of pilgrimage share in all-India myths. In the large temples he will visit and he will worship his gods, often represented in each place by a different icon, illustrating the variety of his gods' feasts. At festivals he will listen to the recitations of professionals, which glorify the myth of the day. Artistic performances of dance and music will continually remind him of the myths of which they are expressions and which also provide the themes of devotional songs. There is no aspect of Hindu life that is not entwined in mythology.

SOURCES AND VARIETIES OF MYTHS

Distinction must be made between the so-called Vedic mythology and classical Hindu mythology, though they are in part continuous. Classical mythology in turn can be contrasted with folk myth, though it is not easy to distinguish the differences. This difficulty is due to historical processes. The oldest sources for Hindu mythology are the Vedic texts composed in Vedic, an early form of Sanskrit. These texts are the literature of an Aryan people who were in fact the last to arrive in India. These Aryans, who spoke an Indo-European language akin to the languages of Europe and Persia, began their invasions prior to 1500 BC. They found in the Indian subcontinent peoples of different stock, and the ruins of a culture in the Indus Valley (in what is now Pakistan), known as the Harappan civilization. At first the Aryans were slow to assimilate the indigenous, non-Aryan inhabitants, who were styled *dasyus* (people to be tamed) and were profoundly hated. Vedic literature is thus mostly conservative, the expression of the ruling Aryan warrior and priest classes. It is not until 500 BC that there is found in the Hindu literature impressive evidence of a body of beliefs that incorporates, side by side with the Vedic one, myths that were non-Vedic as well as non-Aryan. But the degree of assimilation is so great that it is hard, if not impossible, to isolate satisfactorily the Aryan elements from the non-Aryan ones. Yet assimilation was by no means complete, and today there are still folk mythologies that have not been absorbed into official Hindu mythology.

The great works of Vedic literature

Vedic. The Vedic literature, which is the earliest source of Hindu mythology, ranges from the Ṛgveda (Rigveda) (*c.* 1400 BC) to the *Upaniṣads* (*c.* 500 BC). This literature provides the sole documentation for all Indian mythology before Buddhism and the early texts of classical Hinduism. Since it is the literature of a ruling class, it does not represent all the myths and cults of the early Indo-Aryans, let alone those of the non-Aryans.

The most important texts are the four collections (saṃhitā) known as the Veda or Vedas (*i.e.*, "Book[s] of knowledge"): the Ṛgveda (Wisdom of the Verses), the Yajurveda (Wisdom of the Sacrificial Formulas), the Sāmaveda (Wisdom of the Chants) and the Atharvaveda (Wisdom of the Atharvan Priests). Of these, the Ṛgveda, the oldest, is also the richest in myth. The text consists essentially of hymns in praise of certain gods as powers of nature and has become correlated with the Vedic liturgy. The gods celebrated are mostly the more important gods, and the text presents the official pantheon of the ritual. The Yajurveda mainly contains the formulas spoken by certain priests at the ritual. The Sāmaveda is an anthology of Ṛgvedic verses and thus adds nothing to the Ṛgveda. Different is the Atharvaveda, which is concerned with magic, and mentions spirits and demons of the lower cults.

In the Vedic texts following these earliest compilations, viz., the *Brāhmaṇas* (discussions of the ritual) *Āraṇyakas* (books studied in the forest) and *Upaniṣads* (secret teachings concerning cosmic equations), the interest in the early Ṛgvedic gods wanes and they become little more than accessories to the Vedic rite. Polytheism begins to make way for a sacrificial pantheism of a "god sacrifice," Prajāpati (lord of creatures), who is the "All." In the *Upaniṣads* Prajāpati merges with the concept of Brahman, the supreme reality and substance of the universe (not to be confused with the Hindu god Brahmā), replacing any specific personification, and mythology is transformed into rudimentary philosophy (see also HINDU SACRED LITERATURE).

Classical. Classical Hindu mythology is documented by the Sanskrit texts of the classical period (*c.* 500 BC–*c.* AD 1000), art and architecture, and by the vernacular, largely epigonic, literature after AD 1000. The earliest sources of the classical period are the texts of the two colossal epics, the *Mahābhārata* (Great Epic of the Bharata Dynasty) and *Rāmāyaṇa* (Romance of Rāma), and the no less voluminous encyclopaedias of Hinduism, the *Purāṇas* (sacred lore). At first sight the discontinuity between Vedic and classical mythology appears to be so sharp that one might wish to consider them as being of altogether different traditions. Yet it soon becomes clear that they are in part continuous, and that what appears to be discrepancy is but a difference between the narrow, liturgically minded emphasis of the Vedas, and the wide, catholic acceptance of the epics and *Purāṇas*. For example, the great god of the Ṛgveda is Indra, god of war and monsoon, prototype of the warrior; but for the population as a whole he was more important as the rain god than the war god, and it is as such that he survives in early classical mythology. Little is learned in the Veda of goddesses, yet they must have existed for they rose steadily in recognition in classical mythology.

The literature of classical Hinduism

While in these works some of the Vedic gods have an afterlife in which their importance is reduced, other gods, previously of less official significance, arise. The two principal gods of classical Hinduism are Viṣṇu (Vishnu) and Rudra-Śiva. Both are known in the Vedas, Viṣṇu as the strider who with his three strides establishes the three worlds of heaven, atmosphere, and earth, and thus is present in all three orders; Rudra-Śiva as a mysterious god who is to be propitiated.

The classical literature documents the stages of the rise of the two gods, who become as it were god-types, attracting to themselves the identities of other popular gods and heroes: Viṣṇu those gods who protect the world and its order, Śiva (Shiva) the powers that are outside and beyond them. To these two is often added Brahmā, personification of the Brahman of the *Upaniṣads*, creator of the world and teacher of the gods. Though still somewhat important in the *Mahābhārata*, Brahmā later dwindles away.

In the Purānic literature (*c.* AD 500–1000) sectarianism creeps into mythology and one god is extolled above the others. Of prime interest are cosmology, myths of the great ascetics (who in some respects eclipse the old gods), and myths of sacred places, usually rivers and fords, whose powers to reward the pilgrim are often cited and related to a local legend.

Folk and tribal. The sources of folk and tribal mythology are vernacular literature, oral tradition, folklore, and folk and tribal arts. Folk mythology derives from the most ancient times and has influenced both Vedic

and classical mythology. Classical mythology became what it is by continuously assimilating myths not previously known or accepted, so that the line between classical and folk (and tribal) mythology is apt to be arbitrary. The great (Sanskrit) tradition of classical mythology (as contrasted with the local or little traditions of folk mythology) may include within its own scheme a god who continues an independent existence on a folk level. Conversely, an incident of the great tradition may be adopted and adapted on the folk level. For example, the local Mahārāstrian god Viṭhobā is identified with a manifestation of Viṣṇu and thus assured a place in the great tradition; on the other hand, the widely celebrated festival of Navarātrī (nine nights) is associated in northern India with a village goddess, Naurthā.

The concepts of *avatāra* and *vāhana*

Certain concepts that evolved in classical mythology have facilitated the absorption of folk elements; two of these should be singled out: *avatāra* (incarnation), and *vāhana* (vehicle).

The concept of *avatāra* (lit. descent) issues from the belief that in times of trouble a god, notably Viṣṇu, descends and incarnates himself as a man or hero to set matters aright. Such a concept provides the opportunity of identifying a local deity (like Viṭhobā, above) with an all-Indian god like Viṣṇu. The concept may also extend to the worship of very local hierophanies (manifestations of the sacred; *e.g.*, South Indian Vaiṣṇavism accepts "icon-incarnation" [*arcāvatāra*], in which Viṣṇu "descends" in a local icon).

According to the concept of a *vāhana* (lit. mount), every god has an entourage of his own, which includes a favourite riding animal; this facilitates many folk associations. Viṣṇu's mount is the bird Garuḍa, an old solar symbol; Śiva's is the bull Nandi, whose worship may go back to the ancient Harappan civilization. There are other mythological patterns, *e.g.*, adoption in a family; thus the folk god Gaṇeśa, an elephant-headed god, is made the son of Śiva, as is Kumāra Kārttikeya, the war god, who arose from the South Indian war god Murugaṇ. Hanumān, the monkey god, becomes an all-Indian god as a helper of Rāma, who is an *avatāra* of Viṣṇu.

Other spirits and godlings of folk provenance are not absorbed to the same degree and so retain their folk character. Important are the snakes (*nāgaṣ*), objects of folk cults to which great power is attributed; the *yakṣa*s, kobold-like keepers of wealth, with a king, Kubera; *vetāla*s, ghoulish pranksters who haunt corpses; and spirits of the restless dead (*bhūta*s, *preta*s), who must be warded off. Though the existence of these spirits is fully recognized in the classical mythology, they remain on a folk level.

Thus, it is often impossible to draw a precise line between gods of the great (Sanskrit) tradition and those of numerous local or little traditions, since the same god may be universally honoured as a great all-powerful god and still participate in a local tradition as a god of limited function and cult. Conversely, sacred manifestations of purely local interest are associated with the higher mythology by becoming a little manifestation of a great god, *e.g.*, the footstep of Rāma and the bathing place of Sītā (Rāma's spouse).

It is therefore hard to find folk myths and cults that are not in one form or another elevated into the Sanskrit tradition by a specific association with a major god. Only where there has been no appreciable cultural contact between Indian tribal people and Hindus (or "hinduized" folk groups) can a significant distinction be drawn between classical Hindu mythology and "folk" mythology. The latter has been little studied, but the myths of the tribes of Chota Nāgpur (Bihār state), the Santāls (West Bengal, Bihār state), the Todas in the Nīlgiri Hills (Tamil Nadu state), and others are examples of such mythology. Much material lies hidden in folktales, which have been investigated only sporadically.

MODES OF REPRESENTATION

Recitation. Little relevance attaches to a distinction between "written" and "oral" traditions, since both have been in constant interplay. A myth is essentially *told*. Sanskrit uses words like *purāṇa* (ancient story) and *ākhyāna* (illustrative narrative). In the oldest source, the Ṛgveda, myths are not so much told as alluded to; it is in the later Vedic literature of the *Brāhmaṇas* that narratives are found, and these are often prejudiced by the authors' liturgical concerns.

The many forms of Hindu myths

The recitation of certain myths was prescribed for specific rituals. The epic *Mahābhārata* has it that Vedic stories were narrated "in the pauses of the ritual," probably by Brahmins (priests). The warrior class (Kṣatriyas) had their own mythographers in their *sūta*s (charioteers and panegyrists), who celebrated the feats of great rulers. These *sūta*s, who became popular narrators of myth and legend, had their own bardic repertoire, which was extended soon to higher mythology. They and their likes—often wanderers who found a ready audience at a sacrifice or a place of pilgrimage—disseminated the lore.

Such narrators still continue to repeat and embroider their ancient stories of gods, sages, and kings. At an early stage their narratives were dramatized and gave rise to the Sanskrit theatre, where epic mythic themes preponderate, and to the closely related dance, surviving in the now largely South Indian schools of bhārata-nāṭya (traditional dance) and the kathakali (narrative dance) of Kerala.

Depiction in the visual arts. Like literature and the performing arts, the visual arts also contributed to the perpetuation of myths. Hindu sculpture tends to be less narrative than Buddhist, which delights in scenes from the Buddha's lives. In Hindu sculpture the tendency is toward hieratic poses of a god in a particular conventional stance (*mūrti*), which, once fixed, perpetuates itself. An icon is a frozen incident of a myth (*e.g.*, *mūrti* [image] of Śiva is the "destruction of the elephant," in which Śiva appears dancing before and below a bloody elephant skin that he holds up with eight arms before the image of his horrified consort; the stance is the summary and reminder of his triumph over a certain demon). A god may also appear in a characteristic pose while holding in his multitudinous hands his various emblems, by each of which hangs a story. Carvings such as those that appear on temple chariots tend to be more narrative; even more so are the miniature paintings of the Middle Ages. A favourite theme in the latter is the myth of the herd god Kṛṣṇa (Krishna) and his loves for the cowherd wives (*gopīs*), narrated in a series of paintings.

RECURRENT MYTHIC THEMES

Myths of origin. *Cosmogony.* In the Vedic literature there are different but not exclusive accounts of the origin of the universe. The simplest is that the creator built the universe with timber, as a carpenter does a house. Hence there are many references to gods measuring out the different worlds as parts of one edifice, atmosphere upon earth, heaven upon atmosphere. Creation may be viewed as procreation: the personified Heaven, Dyaus (the word is related to the Greek Zeus) impregnates the Earth goddess, Pṛthivī, with rain, so that crops grow on her and are harvested. Quite another myth is recorded in the last (tenth) book of the Ṛgveda: in the "Hymn of the Primeval Person" ("Puruṣa-sūkta," 10.90) it is said that the universe was created out of parts of the body of a single primeval person (*puruṣa*), when his body was immolated and dismembered at the primordial sacrifice.

Creation and eschatology

In the same book of the Ṛgveda, mythology begins to be transformed into philosophy; *e.g.*, "in the beginning was the non-existent, from which the existent arose" (Ṛgveda 10.72.2). Even the reality of the nonexistent is questioned: "then there was neither the nonexistent nor the existent" (Ṛgveda 10.129). Such cosmogenic speculations continue, particularly in the older *Upaniṣads*. Originally there was nothing at all, or Hunger, which then, to sate itself, creates the world as its food. Alternatively, the creator creates himself in the universe by an act of self-recognition, or self-formulation, or self-formation. Or the one creator grows "as big as a man and a woman embracing" (*Bṛhadāraṇyaka Upaniṣad* I.4.3.), splits into man and woman, and in various transformations the couple create other creatures. In one of the last stages of this line of thought (*Chāndogya Upaniṣad* 6.2), there is an ac-

count that was to become fundamental to the ontology of the philosophical schools of Vedānta: in the beginning was the Existent, or Brahman, which through heaven, earth, and atmosphere, the triadic space, and the three seasons of summer, rains, and harvest, the triadic time, produced the entire universe.

Later cosmogony embroiders the ancient notion that the original creation lasted a year and is closely bound up with conceptions of time (see below *Myths of time and eternity*). In the beginning the god Nārāyāṇa (identified with Viṣṇu) floated on the snake Ananta (endless) on the primeval waters. A lotus grows from his navel, in which the god Brahmā is born, who simultaneously recites the four Vedas with his four mouths and creates the "Egg of Brahmā," which contains all the worlds. There are numerous other accounts that refer to demiurges, or creators, like Manu (the primordial ancestor of mankind).

Though the Vedas do not seem to conceive of an end to the world, classical cosmogony accounts for the destruction of the world at the close of an eon, when the Fire of Time puts an end to the universe. Elsewhere the destruction is specifically attributed to the god Śiva, who dances the *tāṇḍava* dance and destroys the world. Yet this end is not an absolute end but a temporary suspension (*pralaya*), after which creation begins again in the same fashion.

Cosmology. The Vedic texts do not show great concern with cosmology, nor are the views expressed consistent. Generally the universe is regarded as three layers of "worlds" (*loka*): heaven, atmosphere, and earth. Heaven is that part of the universe where the sun shines, and is correlated with sun, fire, and ether; the atmosphere is that part of the sky between heaven and earth where the clouds insert themselves in the rainy season, and is correlated with water and wind; earth, a flat disk, like a wheel, is here below, "holder of treasure" (*vasuṃdharā*) and giver of food. Besides this tripartite pattern, there is on the one hand an ancient dual notion of heaven as masculine and father, and earth as feminine and mother; on the other hand, in later stages there is a conception of five elements (ether-space [*ākāśa*], wind [*vāyu*], fire [*agni*], water [*āpas*], and earth [*bhūmi*]), by combinations and permutations of which the universe is formed.

The three worlds of heaven, atmosphere, and earth

In classical Hindu mythology the *Purāṇa* texts present a mythical cosmography of great elaboration. The old tripartite universe persists, but is modified; there are three levels, heaven, earth, and the nether world; the first and last are further subdivided. Earth consists of seven circular continents, the central one surrounded by the salty ocean and each of the other concentric continents by oceans of other liquids. In the centre of the central mainland stands the cosmic mountain Meru; the southernmost portion of this mainland is Bhāratavarṣa, the old name for India. Vertically, above earth there are seven layers in heaven, at the summit of which is the world of Brahmā (Brahmā-loka), and seven layers below earth, the location of hells inhabited by demons of various kinds.

Myths of time and eternity. The oldest texts speak little of time and eternity. It is taken for granted that the gods, though born, are immortal; they are called "sons of Immortality." In the Atharvaveda, Time appears personified as creator and ruler of everything. In the *Brāhmaṇas* and later Vedic texts there are repeated esoteric speculations concerning the year, which is the unit of creation, and thus identified with the creative and regenerative sacrifice and with Prajāpati (lord of creatures), the god of the sacrifice. Time is an endless repetition of the year, and thus of creation, the completion of which took a year. This is the starting point of later notions of repeated creations.

The four *yuga*s of the world

Classical myths develop around the notion of *yuga* (world age), of which there are four. These four *yuga*s, Kṛta, Tretā, Dvāpara, and Kali—they are called after the four throws, from best to worst, in a dice game—comprise a *mahāyuga* (large *yuga*), and, like the comparable ages of the world depicted by the Greek poet Hesiod, are periods of increasing deterioration. Time itself deteriorates, for the ages are successively shorter. Each *yuga* is preceded by an intermediate "dawn" and "dusk." The Kṛtayuga lasts 4,000 years, with a dawn and dusk of 400 years each, or a total of 4,800 years; Tretā a total of 3,600 years; Dvāpara 2,400 years; and Kali (the current one), 1,200 years. A *mahāyuga* thus lasts 12,000 years, which observes the usual coefficient of 12, derived from the 12-month year, the unit of creation. These years are "years of the gods," each lasting 360 human years, 360 being the days in a year. Two thousand *mahāyuga*s form one *kalpa* (aeon), which is itself but one day in the life of Brahmā, whose full life lasts 100 years; the present is the midpoint of his life. Each aeon is followed by an equally long period of abeyance (*pralaya*), in which the universe is asleep. Seemingly the universe will come to its definitive end at the end of Brahmā's life.

Another myth lays particular stress on the destructive aspect of time. Everything dies in time: "Time ripens the creatures, Time rots them" (*Mahābhārata* 1.1.188). So "Time" (*kāla*) is another name for the god of death, Yama. In classical mythology the name is associated especially with Śiva in his destructive aspect as Mahākāla and is extended to his consort, who may be known as the goddess Kālī or Mahākālī. On a mythological level the speculations on time reflect the doctrine of the eternal return in the philosophy of transmigration. The universe returns just as, after death, a soul returns to be born again. In the oldest description of the process (*Chāndogya Upaniṣad* 5.3.1.-5.3.10), the account is still mythic, but with tendencies to naturalism. The soul on departing may go either of two ways: the Way of the Gods, which brings it through days, bright fortnights, the half year of the northern course of the sun, to the full year, and eventually to Brahmā; or the Way of the Manes (spirits), through nights, dark fortnights, the half year of the southern course of the sun, and, failing to reach the full year, eventually back to earth clinging to raindrops. If the soul happens to light on a plant that is subsequently eaten by a man, the man may impregnate his woman and thus the soul is reborn. Once more the significance of the year as a symbol of complete time is clear.

Myths of the gods. According to the epic *Mahābhārata* (1. 1.39), there are 33,333 Hindu deities. In other, later sources, that number is multiplied a thousandfold.

Vedic myths. Generally speaking, Vedic gods lack the clear delineation of the gods in the Greek pantheon. Some major gods were clearly personifications of natural phenomena, and where natural phenomena were still visible behind the deity, no clearly delineated divine personality was perceived.

Principal Vedic deities

The three most frequently invoked gods are Indra, Agni, and Soma. Indra, the foremost god of the Vedic pantheon, a god of war and rain, is the most anthropomorphic. Agni (a cognate of the Latin *ignis*) is the deified fire, particularly the fire of sacrifice; Soma is the inebriating drink of the sacrifice, or the plant from which it is pressed; neither is greatly personified.

The principal focus of Vedic literature is the sacrifice, which in its simplest form can be viewed as a ritualized banquet to which a god is invited to partake of a meal shared by the sacrificer and his priest. The invocations give occasion to mention, often casually, the past exploits of the deity. The offered meal gives strength to the deity to repeat his feat and to aid the sacrificer.

The central myth of the Ṛgveda is that of Indra killing the dragon Vṛtra, who prevents the monsoon rains from breaking. As the monsoon is the greatest single factor in Indian agriculture, the event celebrated in this myth impinges on everyone's life. In the social circles represented in the Ṛgveda, however, the myth is cast in a baronial mold and the breaking of the monsoon is viewed as a cosmic battle. The entire monsoon complex is involved: Indra is the Lord of the Winds, the gales that accompany the monsoon; his weapons are lightning and thunderbolt, with which he lays Vṛtra low. To accomplish this feat he needs strengthening with soma. Simultaneously, he is the god of war, invoked to defeat the non-Āryan *dasyu*s, the indigenous peoples referred to in the Vedas. These important concerns—the promptness and abundance of the rains, success in warfare, and the Āryan conquest of the land—all find their focus in Indra.

While morality is not at issue in Indra's myth, it is in those of other principal Vedic deities. Central to ancient morality was the notion of *ṛta*, the basic meaning of which appears to have been the truthfulness with which the alliance between men, and between men and gods, was observed, and so insured the physical and moral order of the universe. Varuṇa is an older sovereign god, who with Mitra (related to the Persian god Mithra) presides over the observance of the *ṛta*. Thus Varuṇa is a judge before whom a man can stand guilty, while Indra is a king by warlike conquest. Typical requests that are made of Varuṇa are for forgiveness, deliverance from evil committed by oneself or others, and for protection; Indra is prayed to for bounty, aid against enemies, and leadership against demons and *dasyus*.

The notion of *ṛta*

Distinct from both is Agni, the fire, who is observed in all his multifarious manifestations: in the sacrificial fire, in lightning, or hidden in the logs from which fire may be drilled. As the fire of sacrifice, he is the mouth of the gods and the carrier of the oblation, the mediator between the human and the divine orders. Agni is above all the good friend of the Aryans and is prayed to to strike down and to burn their enemies and to mediate between gods and men.

Among other Vedic gods, only few stand out. One is Viṣṇu, important perhaps more in retrospect than in fact. He is famous for his "three strides," with which he traversed the universe and took possession of it. In his later mythology this pervasiveness, which invites identification with other gods, remains characteristic. His function as helper to the conqueror-god Indra is important.

Impersonality is increased by the prevalence of god pairs and groups of gods. Thus Varuṇa and Mitra are members of the group of Ādityas (sons of Aditi, an old progenitrix), who generally are celestial gods. They are also combined in the double god Mitrā-Varuṇa. Indra and Viṣṇu are combined as Indrā-Viṣṇu. There is also Rudra, an ambivalent god who is dreaded for his unpredictable attacks but is simultaneously benign insofar as he can restrain his attacks. Although there are many demons (*rākṣasas*), no one god embodies the evil spirit; rather, many gods have their devil within, inspiring fear as well as trust. Among the perpetually beneficient gods are the Aśvins (horsemen), who present themselves as helpers and healers and are frequent visitors to the lowly. Almost otiose is the personified Heaven, Dyaus, who most often appears literally as the sky, and often as day. As a person, he is coupled with Earth (in the god pair Dyāvā-Pṛthivī) as a father; Earth by herself is more predominantly known as Mother. Apart from Earth, the other goddess of importance in the text of the Ṛgveda is Dawn (Uṣas), who brings in the day and thus is said to bring forth the sun; some of the more felicitous hymns of the Veda are devoted to her.

In the later Vedic period the significance of the Ṛgvedic gods and their myths began to wane. The peculiar theism of the Ṛgveda, in which any one of several different gods might be hailed as supreme and attributes of one god transferred to another (called "kathenotheism" by scholars), stressed godhead more than individual gods. In the end this led to a pantheism of Prajāpati, the deified sacrifice or ritualized deity; with his consort Vāc (*i.e.*, the speech of ritual recitation), he is said to have begotten the world.

Vedic kathenotheism

Classical myths. The tendency toward some sort of pantheism (even theism of the moment, as in Vedic kathenotheism) increased in classical Hinduism and led to a kind of polytheistic monotheism in the exaltation of several supreme gods who are not prominently represented in the Vedic corpus, while many of the Vedic gods disappeared or were greatly diminished in stature. New patterns became apparent: the notion of *ṛta*, the basis of the conception of cosmic order, was reshaped into that of *dharma*, the sum total of the religious-social tasks and obligations of social man, which upholds order in the universe; there was a broader vision of the universe and the place of divinity.

In classical mythology three principal moments are envisioned in the life of the cosmos: creation, maintenance, and destruction. Important myths about the gods are tied to these moments. Traditionally, Brahmā is the creator, emanating the universe and simultaneously promulgating the four Vedas from his four mouths. The conception of time as almost endlessly repeating itself in aeons detracts, however, from the uniqueness of the first creation, and Brahmā becomes little more than a demiurge. Far more attention is given to the maintenance and to the destruction of the universe.

Maintenance and destruction are symptomatic of order and disorder, and order and disorder in turn are closely associated with society and the realm outside society. The god Viṣṇu, who became fixed as the god of maintenance, is thus also the social god *par excellence;* while Śiva, partly fixed as the agent of destruction, is in many respects an asocial god. Viṣṇu is the saviour from lawlessness, destroyer of those who threaten the good order, and king of the harmonious realm. Śiva represents untamed wildness, he is the lone hunter and dancer, the *yogin* (the accomplished practitioner of Yoga) withdrawn from society, and the ash-covered ascetic. The distinction between the gods is not between good and evil, but rather between two ways in which the divine manifests itself in this world—as both benevolent and fearful, both harmonious and disharmonious.

What little mythology is attached to Viṣṇu consists largely of the mythology of his incarnations (*avatāra*). Though the notion of "incarnation" is found elsewhere in Hinduism, it is basic to Vaiṣṇavism. The concept is particularly geared to the social role of Viṣṇu; whenever *dharma* (universal law and order) is in danger, Viṣṇu departs from his heaven, Vaikuṇṭha, and incarnates himself in an earthly form in order to restore the good order. In each of these incarnations there is a particular mythology.

Viṣṇu in the centre of his ten *avatāras* (incarnations): the fish, tortoise, boar, man-lion, dwarf, Paraśurāma, Rāma, Kṛṣṇa, Buddha, and Kalkin. Painting from Jaipur, India, 18th century; in the Victoria and Albert Museum, London.

The classical number of these incarnations is ten, ascending from theriomorphic (animal form) to fully anthropomorphic (human form) manifestations. These are: Fish (Matsya), Tortoise (Kūrma), Boar (Varāha), Man-Lion (Narasiṃha), Dwarf (Vāmana), Rāma-with-the-Ax (Paraśurāma), King Rāma, Kṛṣṇa (Krishna), Buddha, and the future incarnation, Kalkin. Among these, Rāma and Kṛṣṇa are singled out here to convey the kinds of myths that are typical of the god-type of Viṣṇu.

The ten *avatāras* of Viṣṇu

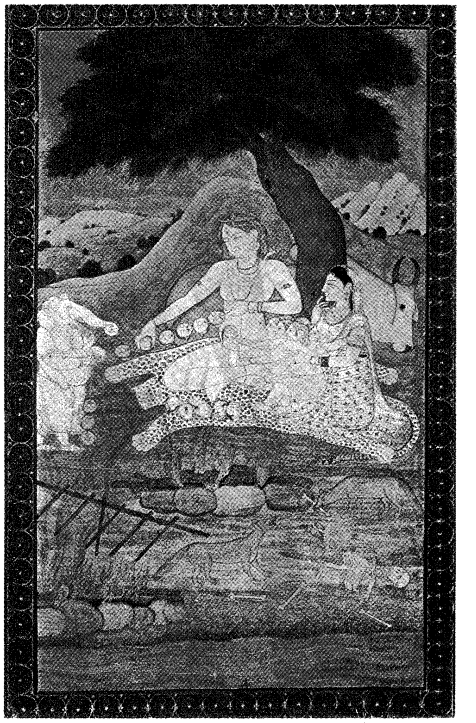
The classical narrative of Rāma is recounted in the Sanskrit epic *Rāmāyaṇa* by the sage Vālmīki, the traditional author of the epic. Rāma is deprived of the kingdom to which he is heir and exiled to the forest with his wife Sītā and his brother Lakṣmaṇa. While there, Sītā is abducted by Rāvaṇa, the demon king of Laṅkā. In their search for Sītā, the brothers ally themselves with a monkey king whose general, Hanumān (later to become a monkey deity), finds Sītā in Laṅkā. In a cosmic battle, Rāvaṇa is defeated and Sītā rescued. When Rāma is restored to his kingdom, the populace casts doubt on Sītā's chastity while a captive. To reassure them, Rāma banishes Sītā to a hermitage where she bears him two sons and eventually dies by re-entering the earth from which she had been born. Rāma's reign becomes the prototype of the harmonious and just kingdom, to which all kings should aspire. Rāma and Sītā set the ideal of conjugal love; Rāma in his relationship to his father, that of filial love; Rāma and Lakṣmaṇa that of fraternal love. Everything in the myth is designed for harmony, which after being disrupted is at last regained.

Kṛṣṇa (Krishna), the most important of the incarnations of Viṣṇu, went through a complex development as a god-hero. In the *Mahābhārata* he is primarily a hero, a chieftain of a tribe, and an ally of the Pāṇḍavas, the heroes of the *Mahābhārata*. He accomplishes heroic feats with the Pāṇḍava prince Arjuna. Typically he helps the Pāṇḍava brothers to settle in their kingdom, and, when the kingdom is taken from them, to regain it. In the process he emerges as a great teacher who reveals the *Bhagavadgītā* (part of book six of the *Mahābhārata*), the most important religious text of Hinduism, which, again, argues for *dharma*. In the further development of the Kṛṣṇa myth, this dharmic aspect recedes and makes way for an idyllic myth about Kṛṣṇa's boyhood, when he plays with and loves young cowherd women in the pasture while hiding from an uncle who threatens to kill him. The influence of this idyll on art has been profound.

A god thus active for the good of society and the individual inspires love. Viṣṇu has indeed been the object of devotional religion (*bhakti*) to a marked degree, but again mainly in his incarnations, and among them especially as Kṛṣṇa and Rāma. The god returns devotion with his grace, through which the votary may be lifted from transmigration to release. Like most other gods, Viṣṇu has his especial entourage: his wife is Lakṣmī or Śrī, the lotus goddess, granter of beauty, wealth, and good luck. She came forth, not unlike Venus, from the ocean when gods and demons churned it in order to recover from its depths the ambrosia, *amṛta*. At the beginning of the commercial year special worship is paid to her for success in one's affairs. Viṣṇu's mount is the bird Garuḍa, arch enemy of snakes, and his emblems are the lotus, club, discus (as a weapon), and a conch shell, which he carries in his four hands.

Śiva and his consorts

In contrast to this helpful, social god-type, Śiva represents the unpredictability of divinity. In him the Vedic Rudra is partly continued, but his mythology has become exceedingly complex: he is the hunter who slays and skins his prey and dances a wild dance while covered with the bloody hide. Far from society and the ordered world, he sits on the inaccessible Himalayan plateau of Mt. Kailāsa, an austere ascetic, averse to love, who burns Kāma, the god of love, to ashes with a glance from his third eye—the eye of insight beyond duality—in the middle of his forehead. Yet another epiphany is that of the *liṅga*, an upright rounded post, usually of stone, a formalized phallic symbol, in which form he is worshipped all over India. And at the end of the aeon, he dances the universe to destruction. He is, nevertheless, invoked as Śiva, Śambhu, Śaṅkara (all meaning: "the Auspicious One"), for the god that can strike can also spare. Snakes seek his company and twine themselves around his body. He wears a necklace of shells. He sits in meditation, with his hair braided like a hermit's, his body smeared white with ashes. These ashes recall the burning pyres, on which the *saṃnyāsin*s ("renouncers") take leave of the social order of the world and set out on a lonely course toward release, carrying with them a human skull.



Śiva and his family at the burning ground. Pārvatī, Śiva's wife, holds Skanda while watching Gaṇeśa (left) and Śiva string together the skulls of the dead. The bull, Nandi, rests behind the tree. Kangra painting, 18th century; in the Victoria and Albert Museum, London.

Like so many ascetics—often irascible and dangerous—Śiva demands to be seduced. His consort is Pārvatī (Daughter of the Mountain), a goddess most unlike the consorts of Viṣṇu in his various incarnations. She is also personified as the Goddess (Devī "goddess"), Mother (Ambā), black and destructive (Kālī), fierce (Caṇḍikā), and well-nigh inaccessible (Durgā). As Śiva's female counterpart, she inherits some of Śiva's more fearful aspects. She comes to be regarded as the power (Śakti) of Śiva, without which Śiva is literally powerless. Śakti is in turn personified in the form of many different goddesses, often said to be aspects of her.

The spheres of the Viṣṇu complex and the Śiva complex are thus very different ones. In important respects they represent the two different ethics of Hinduism: the *dharma* ethic, which aims at upholding the *dharma* and the cosmic and social order based on it, and the *mokṣa* (liberation) ethic, which searches for release from an order which perpetuates transmigration.

Folk and tribal myths. There is a tremendous diversity in folk and tribal mythology throughout the whole Indo-Pakistan subcontinent, but these myths have neither been fully collected nor systematically studied. Among locally important deities, Manasā, a snake goddess, worshipped in Assam and Bengal to ward off snake bites and secure prosperity, has an enormous mythology of her own. In South India one finds popular cobra cults with a variety of myths and lore. In Mahārāshtra, a form of Viṣṇu, known as Viṭṭhal or Viṭhobā, who has an important temple at Pandharpur, has also spawned a rich mythology.

Cultural heroes and god-types

Myths of cultural heroes. A cultural hero can easily be assimilated to a god-type by identifying him with an incarnation of a god. Thus great religious teachers are considered manifestations of the god of their devotional preaching, and their lives become part of mythology. There is another mythology concerning great ascetics that is very rich. These ascetics are practically gods on earth, who have amassed tremendous powers that they are not loathe to use. The sage, Kapila, meditating in the nether world, burned to ashes 16,000 princes who had dug their

way to him. Another sage, Bhagīratha, brought the River Ganges down from heaven to sanctify their ashes, in the process creating the ocean. Agastya, revered as the Brahmin who brought Sanskrit civilization to South India, drank up and digested the ocean. When the Vindhya mountain range would not stop growing, Agastya scaled it and commanded it to cease growing until his return; he still has not returned. Viśvāmitra, a king who became a Brahmin, created a new universe with its own galaxies to spite the gods. It is in such myths that the mythopoeic imagination exults in its sensitivity to the awesome, mysterious, and marvelous.

In myths concerning kings and princes, a prevailing theme is the trial of the son by the father. For example, the ancient king Yayāti had five sons, to whom he wanted to transfer his own senescence for a stipulated period. All refused except the youngest, Pūru, who agreed and as a reward became his father's successor; from him were descended the Pauravas, the line of succession or dynasty in which the heroes of the *Mahābhārata* were later born. The latter heroes too underwent a trial when they were exiled from their newly won kingdom; similarly, Rāma underwent his ordeal in exile. Heroines undergo their own trials, which usually threaten their chastity, as in the case of Sītā in the *Rāmāyaṇa* and Draupadī, the one wife of all five Pāṇḍava brothers, whose sari became endless when a lustful villain attempted to pull it off.

Moving from myth to legend, there are also stories told of the great teachers, and every founder of a sect is soon deified as an "incarnation" of a god: the philosopher Śaṅkara (*c.* 788–820) as an incarnation of Śiva, the religious leader Rāmānuja (d. AD 1137) as that of Nārāyaṇa-Viṣṇu, the Bengal teacher Caitanya (1486–1533) as that of Kṛṣṇa and his beloved Radhā at one and the same time.

Myths of holy rivers and places. Of particular sanctity in India are the perennial rivers, among which the Ganges stands first. This river, personified as a goddess, originally flowed only in heaven until she was brought down by the king, Bhagīratha, in order to purify the ashes of his ancestors. She came down reluctantly, cascading first on the head of Śiva, in order to break her fall, which would have shattered the earth. The Ganges' confluence with the Yamunā at Allāhābād is the most sacred spot in India. Another river of importance is the Sarasvatī, which loses itself in desert; it was personified as a goddess of eloquence and learning.

Every major and many a minor temple and sanctuary has its own myth; how it was founded and what miracles were wrought there. The same is true of famous places of pilgrimage, usually at sacred spots near and in rivers; important among these are Vrindāvan (Brindāban) on the Yamunā, which is held to be the scene of the youthful adventures of Kṛṣṇa and the cowherd wives. Another such centre with its own myths is Gayā, especially sacred for the funerary rites that are held there. And there is no spot in Vārānasi (Banaras) along the Ganges that is without its own mythical history.

HINDU MYTHOLOGY IN CONTEMPORARY INDIA

Myth and modernity

Much of the classical mythology persists today, and the Hindu is exposed to it in his yearly round. Meanwhile, the mass media have made their contributions: the type of motion picture called "mythological" is extremely popular, perpetuating the ancient stories down to the village level, and so are "devotionals" in which an example of *bhakti* (devotion to a god) is illustrated. The radio regularly carries *bhajan*s (devotional songs) and classical South Indian songs, the themes of which are often mythic. Every orthodox Hindu's home has at least a corner set aside as a domestic sanctuary where representations of a chosen deity are placed and *pūjā* (worship) is done with prayers, hymns, flowers, and incense. In richer establishments there will be shrine rooms. Mythic illustrations are favourites in Indian calendar art.

Mythology has adjusted itself effortlessly to modernity. The *āśram* (*āśrama*, retreat) of the mystic and religious leader Aurobindo Ghose (1872–1950) in Pondicherry, dedicated to the Mother Goddess (personified by this group as a single principle), is an extremely modern establishment complete with tennis courts. There arise new temples, like a recent one in Vārānasi, in which the entire *Rāmacāritmānas* ("Holy Lake of the Acts of Rama") of the poet Tulsīdās is written out and important scenes etched on mirrors. This same favourite poem is the basis of the annual celebration of the Rām Līlā (the play of Rāma) in northern India, in which the entire community participates. The same Rāma story was evoked by Mahatma Gandhi when he set the *Rām Rāj* (Kingdom of Rāma) as India's governmental ideal. On occasion, social protest arms itself with myth to make its point. For example, the personality of Karṇa, an antagonist in the *Mahābhārata* who is berated for his low birth, is extolled in intellectual circles as a truer champion than the aristocratic heroes. A Kannada-language play of the 1960s based on the life of King Yayāti enjoyed great popular and critical success. Antinorthern groups in Tamil Nadu State used the story of Rāma, whose expedition against Rāvaṇa is believed by some to be the Aryan invasion of South India, reversing it by abusing Rāma and glorifying Rāvaṇa.

On a popular level, people at temples and fairs are continually reacquainted with their mythological heritage by *pauraṇika*s, tellers of the ancient stories, heirs of the *sūta*s of 3,000 years ago, and no festival ground is complete without tents where the religious and pious are reminded of their myths by saintly speakers, modestly rewarded by fees, but richly by the honour in which they are held.

BIBLIOGRAPHY. Although some of his interpretations are no longer held, A.A. MACDONELL, *Vedic Mythology*, 2nd ed. (1963), is the most convenient collection of all relevant material for the mythology of Vedic times. In his *Religions of Ancient India* (1953), the master of Vedic studies LOUIS RENOU gives a fine account of the Vedic religion, while L.D. BARNETT in *Hindu Gods and Heroes* (1922), treats the Vedic and Hindu gods in a more narrative and selected form than does Macdonell. J. GONDA, *Aspects of Early Viṣṇuism* (1954), spans Vedic and epic mythology in an investigation into the development of Viṣṇu. E.W. HOPKINS, *Epic Mythology* (1915), is a basic inventory of the mythology of the Mahābhārata and *Rāmāyana*. There is no single comprehensive study of Purāṇic mythology, but a representative selection, particularly with regard to the cosmology, may be found in *The Vishńu Puráńa: A System of Hindu Mythology and Tradition*, trans. from the original Sanskrit by H.H. WILSON (1864–77).

(J.A.B.v.B.)

Hindu Sacred Literature

Hindu sacred literature consists of numerous sacred oral traditions and written texts, which in the course of their gradual development and composition have become the sources of Hindu religion and the foundations of Indian society. The scope of what may be sacred is wider to a Hindu than it is to members of most other religions. The sacred for the Hindu is not only that which bears upon the divine but also that which bears upon man's place in the family and in society and upon his relations with others; consequently Hindu sacred literature includes much that might be considered secular in other religious traditions.

The article is divided into the following sections:

I. The concept of a sacred book in Hinduism

Orthodox Hindu authors commonly divide their sacred literature into two classes, *Śruti* and *Smṛti; Śruti* (literally

Śruti and *Smṛti*

"learning by hearing") is the primary revelation, which stands revealed at the beginning of creation. This revelation was "seen" by the primeval seers (*ṛṣi*) who set in motion an oral transmission that has continued from generation to generation until today. The seers were the founders of the lineages of Brahmins (Hindu priestly elite) through which the texts have been, and continue to be, transmitted. From this heritage the Brahmins derive their function as sacred specialists and teachers. *Smṛti* (literally "recollection") is the collective term for all other sacred literature, principally in Sanskrit, which is considered to be secondary to *Śruti*, bringing out the hidden meanings of the revelation, restating it for a wider audience, providing more precise instructions concerning moral conduct, and complementing *Śruti* in matters of religion. While the distinction between *Śruti* and *Smṛti* is a useful one, in practice the Hindu acquires his knowledge of religion almost exclusively through *Smṛti*.

C.M. Natu

Brahmin priest reading the unbound folio manuscript of a sacred text, a *śrauta-sūtra*, at a Vedic *yajña* (sacrifice). The deerskin is the sacrificer's seat, the wooden cups are for drinking the *soma*.

For the present purposes *Śruti* may simply be identified with the entire Vedic literature, especially the Veda proper, or Saṃhitās (collections of the earliest hymns and ritual formulas), and the appended works: the *Brāhmaṇas* (discussions of the rite), the *Āraṇyakas* ("Books of the Forest"), and the *Upaniṣads* (doctrines concerning cosmic equations). Since the transmission of the Veda was oral, there was no notion that a written copy of it was by itself a sacred object, as for example the Torah scroll in Judaism or the Qur'ān in Islām; instead, it was the sound of Veda that was sacred, and very great weight was placed on the correct pronunciation and recitation of the texts. Also, since transmission took place in Brahmin families, it was largely out of the reach of other classes, who, if they were qualified to hear the Veda at all, would hear it only at the performance of rituals.

Orthodox Hindu thought has addressed itself to the question of where the authoritativeness of the Veda is vested. It does not accept the position that the Veda is God's word, since that would involve possible divine fallibility. It concludes that the Veda is self-authenticating, and only in matters that are completely suprasensual. It is accepted that this authoritativeness applies in two areas: (1) injunctions to perform certain rituals that lead to results not ascertainable by other means of knowledge and (2) statements on the nature of the self.

Accordingly, the Veda is divided into two parts: the "part of ritual" (*karma-kāṇḍa*) and the "part of knowledge" (*jñāna-kāṇḍa*), the former comprising all the liturgical statements of the Veda, the latter encompassing principally the *Upaniṣads*.

While the Veda is sacred of itself, so that mere recitation of it is meritorious, in the *Smṛti* texts it is necessary to distinguish between books that are similarly sacred, and books about sacred matters. There is also a distinction between texts that are sacred as a whole or only in some of their parts. For example, in regard to cultural epics, the *Rāmāyaṇa* ("Romance of Rāma") can be recited for great personal merit in its entirety as a religious observance; this is not true of the *Mahābhārata* ("Great Epic of the Bhārata Dynasty"). On the other hand, the *Mahābhārata* contains the *Bhagavadgītā* ("The Lord's Song"), which is the single most important *Smṛti* text.

Criteria of sacredness

Generally speaking, a book is sacred in Hinduism if it is widely believed or believed by particular religious groups that recitation and listening bestow a special merit. Thus many texts mention the "reward of listening" (*śravanaphala*), a specific merit proper to them. This qualification applies not only to the Sanskrit tradition but also to works in India's regional languages. In addition, a book composed by or hallowed by the use of the founder of a particular sect will be sacred to that sect; for example, the Granth Sāhib (the sacred scripture, Ādi Granth, personified) of the Sikhs (a religious and social group often regarded as being outside Hinduism), which is little known outside the sect, is not typical in that it is physically the object of cult veneration, not unlike the Qur'ān.

Another criterion for the relative sacredness of a text is the ritual use to which it is put. For example, Tulsīdās' entire *Rāmacaritmānas* ("Holy Lake of Rāma's Feats," a Hindī version of the *Rāmāyaṇa* romance) is recited and simultaneously acted out as part of the annual Rām Līlā festival. Similarly, popular litanies might become sacred by their constant use in devotional singing. Likewise certain sacred places of pilgrimage may be celebrated in "glorifications" (*māhātmyas*), which in turn can be adopted into semi-epical and encyclopaedic works called *Purāṇas* ("ancient stories"). Also of considerable importance in the daily life of the Hindu is astrology (see ASTROLOGY).

II. Nature and varieties of Hindu sacred literature in Sanskrit and Indian regional languages

ORAL TRADITIONS

The most sacred of the texts of Hinduism, the Veda, was transmitted orally. Many other Hindu sacred texts were also transmitted orally before, and after, they were written down. For example, the varieties of both oral and written versions of the Rāma story in Indian regional languages and Javanese side by side with the written Sanskrit *Rāmāyaṇa* of Vālmīki show that the oral tradition was not closed with the written Sanskrit composition.

For many religious sects, the manner of the Vedic transmission was the prototype of their own transmission. Followers of sects will speak of the "handing down" (*sampradāya*) or of a "succession of gurus or teachers" (*guruparamparā*), and it is well known that written texts contain only part of the doctrines actually handed down in a sect. This situation is not merely to be ascribed to secretiveness or even to sectarian exclusiveness but also to the nature of Hindu culture. Thus only one who is an initiate in a particular sect can have full knowledge of the beliefs and practices that pertain to it. A novice apprentices himself to a guru (religious teacher) and only after many years of association does he become fully versed in the sacred doctrines of his particular tradition.

Mantra

Secrecy will often attach to what are considered the fundamentals of a sect; for example, the esoteric significance of a particular *mantra* (spell or sound-symbol), or mystical interpretations of events in the biography of a certain god, the precise qualities of his virtues, are rarely made public. Likewise, in temple ceremonies, where every temple has its own style and tradition, the procedures and their significance are almost exclusively preserved orally. Oral tradition was probably strongest on the more popular levels of Hinduism, partly because some of the membership might have been illiterate, and partly to conceal what might be considered aberrant by other groups. Consequently, some of the texts of Tan-

trism (a syncretistic religious movement from *c.* 6th century AD on) are practically unintelligible without the aid of informants who are conversant with its unwritten tradition.

WRITTEN TEXTS

Vedic texts. The Veda (see Table) for a long period of its existence was an "oral tradition," but its transmission was so well organized and its preservation so perfect that these oral "texts" surpass the written texts in accuracy. Since its content was precisely fixed at an early date and henceforth maintained, it can legitimately be treated as a written text.

While scholars traditionally speak of the four Vedas when they mean the four oldest compilations (Saṃhitās), it is better to follow the Indian tradition and describe as Veda the entire corpus of texts that are built on these Saṃhitās. The following principles of classification are operative in the Vedic corpus: schools, branches of the schools, *Saṃhitās, Brāhmaṇas, Āraṇyakas, sūtras, Vedāṇgas.*

Schools. The Veda as a whole is divided into four complementary parts that are each transmitted by a separate school. There are four Vedic schools: Ṛgveda, Yajurveda, Sāmaveda, and Atharvaveda; often the first three are mentioned together as the "triple Veda." These four Schools derive their distinctions from their respective places in the liturgy. In those rituals in which professional priests were employed, a division of labour took place early: one did the main recitation, another the main manipulations, another chanted hymns, a fourth supervised and did acts of expiation; from these separate functions grew the four schools. Those expert in the Ṛgveda-Saṃhitā recited the hymns (*ṛc*, hence Ṛgveda) contained in that collection; the experts in the actual ritual operations accompanied by sacrificial formulas (*yajus*) formed the Yajurveda-Saṃhitā; the priests who chanted compiled their own Sāmaveda-Saṃhitā (*sāman*, melody); while the priests of the fourth category had their own Atharvaveda-Saṃhitā (*atharvan* is the name of a special priest).

Relation of priestly division of labour to formation of Vedic schools

Branches of the schools. Although the ritual practices of the Vedic priests remained remarkably similar even though scattered in widespread settlements, inevitably local variations occurred. Note was taken of these variations and the varying tradition was recognized as a "branch" (*śākhā*) of its Veda school. In every school of the Veda there are such branches, which are most numerous in the Yajurveda. These branches usually have a somewhat different version of their Saṃhitā, and always somewhat different rules concerning the rites themselves. No superiority is claimed by any one branch in a school over another. In the Yajurveda tradition, for example, one set of branches is described as black, the other as white (the colours serve merely to classify).

Saṃhitā. As pointed out, the Saṃhitā (collection) contains the basic texts of a school. It is on the material incorporated in the Saṃhitā that the four groups of priests, each belonging to a different Veda school, draw in the performance of the ritual. They provide only the hymns, formulas, and chants and give no instruction in the procedures of the ritual.

Brāhmaṇa. To each Saṃhitā are attached a number of prose texts called *Brāhmaṇa* (discussion concerning *Brahman*, or the power of word and rite), usually voluminous texts which enlarge on the ritual, setting forth its procedures and at times explaining its provenance in mythical terms. These are distributed according to the various branches; thus there are two *Brāhmaṇas* belonging to the Ṛgveda.

Āraṇyakas. More recent, but continuing the *Brāhmaṇa* tradition, are the *Āraṇyakas*, "Books of the Forest," in which the speculative element grows more important. They take their name from discussions and practices that were too important, or dangerous, to be held in the village. They may contain the *mantras* (spells) and descriptions of rituals not treated in the *Brāhmaṇas.* For example, the *Taittirīya Āranyaka* (Taittirīya is the name of a branch of the Yajurveda) gives the material for the mystical *Pravargya* rite, which in another branch is treated in the *Brāhmaṇa.*

Upaniṣads. In the *Upaniṣads*, which form an advanced stage of the *Āraṇyakas*, the speculative element predominates and the rite is simply the starting point of the speculation, if it is mentioned at all. They are of comparatively limited size, the few larger ones not exceeding 2,000 lines, and some consisting of only a few pages. Again they divide over the branches, but there is far more flexibility here: the same speculations may occur in texts belonging not only to different branches but to different schools.

Vedāṅgas (literally "studies accessory to the Veda"). The intense preoccupation with the liturgy gave rise to scholarly disciplines that were part of the Vedic erudition. There were six such "fields": (1) *śikṣā* (instruction), viz., in the proper articulation and pronunciation of the Vedic texts. Different branches may have different ways of pronouncing the texts, which are written up in *prātiśākhyas* (literally, "instructions for the *śākhās*"—branches), four of which are extant; (2) *chandas* (metre), of which there remains only a late representative; (3) *vyākaraṇa* (analysis and derivation), in which the language is grammatically described—Pāṇini's famous grammar (*c.* 600 BC) and the *prātiśākhyas* are the oldest examples of this discipline; (4) *nirukta* (lexicon), which discusses and gives meanings for difficult words, represented by the *Nirukta* of Yāska (*c.* 600 BC); (5) *jyotiṣa* (luminaries), an inchoate astronomy and astrology for fixing the right times of a ritual; and (6) *kalpa* (mode of performance), which studies the correct ways of performing the ritual.

Early scholarly disciplines

Sūtras. It is under the rubric of *kalpa* or procedures that a large number of texts called *sūtras* ("brief manuals") belong. They are manuals, written with great economy of language, explaining in detail how the office of the priests of the various schools and branches should be conducted. There are three types of *sūtras:* (1) *śrauta* (scriptural), which describe the kind of rites called *śrauta,* for which a sacrificer engages priests belonging to the different schools; (2) *gṛhya* (domestic), which describe principally the life-cycle rites; and (3) *dharma* (life rule seen as law), which lays down the life rules and conduct for any given branch.

The accompanying table of Vedic texts illustrates the relations of the various schools, branches, and texts to each other.

Post-Vedic Sanskrit texts. The post-Vedic sacred literature in Sanskrit is extremely voluminous. It does not have the authority of the Veda, or *Śruti;* it presents itself as secondary to the Vedic literature of which it is an amplification. In fact, most of the texts are original. The nontechnical texts can best be summarized under the following headings: (1) epic, (2) *Purāṇa,* (3) *Tantra,* (4) other.

The epics. As the name indicates, the epics are not primarily sacred texts; nevertheless they are important sources of knowledge of Hinduism. Apart from the extremely important sacred text the *Bhagavadgītā* (see below), which it contains, the *Mahābhārata* ("Great Epic of the Bhārata Dynasty") is a rich source of materials for Hinduism. Amid the epic events are inserted many chapters dealing with religion, especially in the 3rd, 12th, and 13th books. The *Rāmāyaṇa* ("Romance of Rāma") is both the principal text for Rāma worship and a receptacle for many legends.

Purāṇa. Purāṇa (literally "ancient story") is a general name of a long series (traditionally 18) of often voluminous texts that treat in encyclopaedic manner myths and legends, as well as genealogies, of gods, heroes, and saints. They can loosely be divided into three groups: those exalting the god Brahmā, the *Brāhma-, Brāhmāṇḍa-, Brahmavaivarta-, Mārkaṇḍeya-, Bhaviṣya-,* and *Vāmana-Purāṇas;* those devoted to the god Viṣṇu (Vishnu), the *Viṣṇu-, Bhāgavata-, Nāradīya-, Gāruḍa-, Pādma-,* and *Vārāha-Purāṇas;* and those devoted to *Śiva* (Shiva), the *Śiva-, Liṅga-, Skanda-, Agni-* (or *Vāyu-*), *Mātsya-,* and *Kūrma-Purāṇas.* The division, however, is an artificia one. Many deal with the same or similar materials.

The Vedic Texts

	Śākhā (branch)	Saṃhitā (compilation)	Brāhmaṇa	Āraṇyaka	Upaniṣads	Śrautasūtra
Ṛgveda	Śakala Bāskala	Śakala Bāskala	Aitareya Kauṣītakī	Aitareya Kauṣītakī	Aitareya Kauṣītakī	Āśvalāyana Śānkhāyana
Yajurveda						
Black	Kāṭhaka Maitrāyaṇa	Kāṭhaka Maitrāyaṇa	Kaṭha	Kaṭha	Kaṭha Maitrāyaṇa	Kāṭhaka Mānava Vārāha
	Taittirīya	Taittirīya	Taittirīya	Taittirīya	Taittirīya Śvetāśvatara	Baudhāyana Vādhūla Bhāradvāja Āpastamba Hiraṇyakeśin Vaikhānasa
White	Mādhyaṃdina Kāṇva	Vājasaneyi Kāṇva	Bṛhad	Śatapatha	Bṛhadāraṇyaka Īsā	Kātyāyana
Sāmaveda	Kauthuma-Rāṇāyanīya	Kauthuma-Rāṇāyanīya	Pañcaviṃśa	Āraṇyakasaṃhitā	Chāndogya	Lātyāyana Drāhyāyana Ārṣeyakalpa
	Jaiminīya	Jaiminīya	Jaiminīya Śāṭyāyana	Jaiminīya-Upaniṣad-Brāhmaṇa	Kena	Jaiminīya
Atharvaveda	Śaunaka	Śaunaka	Gopatha		Muṇḍaka Māṇḍūkya Praśna	Vaitāna
	Paippilāda	Paippilāda	Gopatha		Muṇḍaka Māṇḍūkya Praśna	Vaitāna

The most important *Purāṇas* are the *Viṣṇu-*, *Liṅga-*, *Bhāgavata-*, and *Skanda-Purāṇas*. This purāṇic literature continues with *Upapurāṇas* ("sub-Purāṇas") and *Māhātmyas* (glorifications) of temples and sacred places.

Tantra. *Tantras* (literally "looms") are texts exemplifying religion on a more popular level, dealing largely with spells (*mantras*), ritual (particularly temple ritual), and drawn symbols, (*maṇḍalas*). There are Vaiṣṇava, Śaiva, and Śākta *Tantras*, devoted respectively to the worship of Viṣṇu, Śiva, and the goddess Śakti (Shakti). Their metaphysical contents are meagre, but they contain a wealth of practical information. In some, particularly the Śākta *Tantras*, evidence of so-called left-handed practices (esoteric, magical, and sometimes sexual) is found, but the incidence of this material is often exaggerated.

Other. As Sanskrit literature is permeated with religion, many texts, even in the belles lettres, are at times sources for knowledge of the religion. Among them the most important one is Jayadeva's poem the *Gītagovinda* ("Poem Which Sings of the Herd God").

Dravidian texts. *Tamil.* Of the Dravidian languages, Tamil especially offers a variety of important texts. The classical Tamil poetry of the Saṅgam ("academies"; from *c.* AD 200) do not speak of religion. With the exception of the *Tirumurukārruppaṭai* (a "Guide to the Worship of the God Muruganˉ") the earliest Tamil literature is unconcerned with religion. From the 7th century AD on, a rich literature of devotion, both to Śiva and Viṣṇu, emerges.

Nayanārs and Āḻvārs

The hymns of the Śaiva saints, the Nāyaṇārs, are collected in the *Tevāram* ("A Garland of Honey [for Śiva]"), which since AD 1000 has formed the basis of south Indian Śaivism. The collection comprises the songs of Appar, Sambandar, and Sundarar. The *Tevāram* itself heads a series of 11 sacred books, among which the eighth, the *Tiruvācakam* ("Message of the Loved One"; *i.e.*, Śiva) of Māṇikkavācakar, is the most famous. In the 12th century the canon and hagiography is established with the *Periyapurāṇam* (lives of 63 Śaiva saints) of Cēkkiḻār, in which the biographies of the saints are worked out. Of importance is the *Kandapurāṇam* of Kacciyappar, which is parallel to the *Skanda-Purāṇa* in Sanskrit.

Like Śaivism, Vaiṣṇavism also developed a devotional (*bhakti*) movement with its own saints, the Āḻvārs, whose hymns were collected by Nāthamuni in the *Nālāyiram* (4,000 poetical compositions). Among the Vaiṣṇavas the most famous saint is Nammāḻvār (*c.* 800). The later period produces important translations of the epics, especially the *Rāmāyaṇa* version by Kambaṉ. Also Tamil is used as a vehicle for philosophy and theology, notably that of the Śaivasiddhānta. From the 13th to 18th centuries there is a line of Cittars (from Sanskrit *siddha*, "saint"), whose verses continue to be extremely popular among the Tamil-speaking people.

Kannada. Much of the Kannada sacred literature is associated with the Liṅgāyats, a Śaivite sect, founded by Bāsava (*c.* 1150) whose lyric *vācanams* (talks) are important.

Telugu. Much of the religious literature in Telugu centres on translations of the *Mahābhārata* and *Rāmāyaṇa.*

Texts in modern Indo-Aryan languages. *Bengali.* The oldest texts in Bengali are the hymns of the *Caryācaryāviniścaya*, ("decision concerning good and ill conduct") the *Dohākośa* ("Collection of Stanzas") of Saraha, the *Dohākośa* of Kaṇha, and the Tantric *Dākārṇava* (700–1000). The doctrines, those of the Sahajiyā sect (a school in Orissa and Bengal since the 10th century which seeks an equilibrium of self and universe through Yogic practices), are in certain ways a Buddhist hybrid. Later, Kṛṣṇaism (worship of the god Kṛṣṇa, or Krishna) predominates, notably in Caṇḍīdās' *Śri-Kṛṣṇa-kīrtan* ("Glorifications of Lord Kṛṣṇa") and *Padāvali* ("verses") (*c.* 1375) and his contemporary Vidyāpati's poetry (*c.* 1400). In that same period, Kṛttibās Ojhā made the most celebrated Bengali version of the *Rāmāyaṇa.* Nothing of the religious reformer Caitanya (1485–1533) is extant, but his doctrines and life brought about a whole literature. Noteworthy sources for Viṣṇuism are the Brajbuli poets, who glorify the child and cowherd Kṛṣṇa. Religious inspirations have also been ascribed to the works of Rabindranath Tagore, the 19th- and 20th-century Bengali poet, whose poems and songs some have elevated to the level of hymns.

Hindi. Hindi religious literature begins with an early ascetic Gorakhnāth, the authenticity of some of whose works remains doubtful, as does his date. The first great name is that of Rāmānanda (*c.* 1450) whose influence has been profound. He adored Viṣṇu in his incarnation as Rāma. Among his pupils were Kabīr (1440–1518), a social reformer who sought to reconcile Islām and Hinduism. Mīrābāī, a princess and a poetess (1503–73), composed the praises of Kṛṣṇa that are particularly famous. Similarly a devotee of Kṛṣṇa was Sūrdās (1483–1563), whose *Sūrsāgar* ("Ocean of the poems of Sūr") celebrates the young Kṛṣṇa. The predominant figure in Hindi devotional poetry is Tulsīdās (died 1623), whose *Rāmacaritmānas*, a *Rāmāyaṇa* version, is still popular today and annually enacted at the Rām Līlā celebrations of the Daśahrā. Dayananda Sarasvati, the founder of the Arya Samaj, used Hindi in sermons and organizational work.

Marathi. The first important author is Jñānadeva, also known as Jñāneśvar (*c.* 1280), who wrote a famous versified commentary on the *Bhagavadgītā.* Nāmdev (*c.* 1450?) wrote devotional poetry to Viṣṇu as the god Viṭhobā of Pandharpur. The tradition is continued by Tukārām (1607–49) whose 1,300 hymns are the culmination of *bhakti* (devotional) sentiment. In the modern period Marathi literature is distinguished by the *Gītarahasya* of B.G. Tilak (1856–1920) in which the action-philosophy of the *Bhagavadgītā* was stressed in the Indian struggle for independence.

III. Major religious texts: their contents and significance

VEDIC TEXTS

Ṛgveda-Saṃhitā. The Ṛgveda is essentially an anthology of poems addressed to gods, spirits, or deified ritual objects, such as the plant extract *soma.* It contains 1,028 hymns with a total of 10,562 lines, which are distributed over ten books, of which the first and the last are the most recent. A hymn usually goes through three phases: it begins with an exhortation that is followed in the main part by praise of the deity, prayers, and imploration, with frequent references to the deity's mythology, and finishes with a specific request. The most frequently addressed gods are Indra and Agni (the sacrificial fire), to whom are devoted 250 and 200 hymns respectively. While many hymns were eventually used in the liturgy, they were not primarily composed for this purpose but were rather inspired by the ritual. Thus a great number of hymns glorify the *soma* (both as plant and the extracted inebriating juice), the fire, and other ritual objects. Though no doubt the personality of Indra dominates, there is a general tendency of the poets to extol whatever god is being addressed above all other deities. Epithets or even individual feats of a particular god can also be applied to others.

The tenth book contains more varied materials, with some hymns referring to domestic rites, such as a marriage hymn and a set of funeral hymns. This book also contains a number of cosmogonic and cosmological hymns of great interest. In 10:90 the creation of the world is described as the sacrifice and dismemberment of a primeval "man" (*puruṣa*); out of parts of his body the components of the universe are formed. This hymn represents the social model of the four classes (*varṇa*), with the Brahmin emanating from his mouth, the Kṣatriya (kingly and warrior class) from his arms, the Vaiśya (merchants) from his thighs, the Śūdra (low castes) from his feet. This text remains the basic authority for the four classes.

Mythical origin of castes

Elsewhere, creation is described as the emergence of the Existent (*sat*) from the Nonexistent (*asat*), a notion refined in 10:129 in which the world is said to emerge from a chaos beyond either Existence or Nonexistence. Many of these notions are also found in the *Upaniṣads.*

Eventually the significance of the Ṛgveda is found wholly in ritual. The lines of the Ṛgveda are important only in so far as they are recited as part of the liturgy. Their transmission was confined to priestly circles, less interested in their content than in their ritual use. One hears little of the study of them for their own sake, although there are later commentaries, the best known of which is that by Sāyaṇa (*c.* 1400).

Yajurveda-Saṃhitā and Sāmaveda-Saṃhitā. The Yajurveda-Saṃhitā and Sāmaveda-Saṃhitā are completely subservient to the liturgy. The Yajurveda-Saṃhitā contains the lines, usually in prose and brief, with which the executive priest (*adhvaryu*) accompanies his ritual manipulations, addressing the implements he handles and the offering he pours, and admonishing other priests to do their invocations.

The Sāmaveda is a collection of lines from the Ṛgveda (and a very few new ones) that were chanted with certain fixed melodies. Both, unlike the Ṛgveda, were designed for the ritual.

Atharvaveda-Saṃhitā. The Atharvaveda stands apart. It contains 731 hymns—there are also some prose passages—of about 6,000 stanzas divided over 20 books. Books 1–7 contain magical prayers for precise purposes: spells for a long life, cures, imprecations, love charms, prayers for prosperity, charms for kingship and Brahminhood, and expiations for evil committed. They reflect the magical-religious concerns of immediate life interests, on a different level than the Ṛgveda, which glorifies the great gods and their liturgy. Books 8–12 contain similar texts, but also cosmological hymns that continue those of the Ṛgveda and provide a transition to the more advanced speculations of the *Upaniṣads.* Books 13–20 celebrate the cosmic principle (book 13) and present marriage prayers (book 14), funeral formulas (book 18), and other magical and ritual formulas. For knowledge of practical religion and magic, the text is of extreme importance, particularly where it complements the one-sided picture of the Ṛgveda. Many of the formulas had their immediate use when administered by the right priest. Many such rites are laid down in the *Kauśika-sūtra* (manual of the Kauśika family of priests) of the Atharvaveda.

Passage rite ritual formulas

Brāhmaṇas and Araṇyakas. *The Brāhmaṇas* detail and describe the liturgy, invoking, and sometimes inventing, myths to explain the ritual facts. The Brāhmaṇas are of inestimable value because they give account of the actual conduct of the ritual in a detail not to be found elsewhere. Since they are earlier than the *śrauta-sūtras* (ritual manuals), they are the oldest sources for the history of Indian ritual. Little interest is given to the Vedic gods, who are largely treated as ritual accessories. The principal religious concern is with the sacrifice, among which the *soma* sacrifice and its variations hold the first place. The sacrifice is looked upon as the generator of the power that keeps the universe in motion. Elaborate homologies (structural parallels) are devised between the sacrifice, its elements and phases, and the universe and its parts. The universalization of the dynamics of the ritual into the dynamics of the cosmos brings out a universal God-sacrifice, a deity very different from the older gods, who is called the Lord of Creatures (Prajāpati). He is not so much worshipped by means of the sacrifice as generated and regenerated by it.

These cosmic-sacrificial speculations continued in the *Āraṇyakas* (forest books), which contain materials of two kinds: *Brāhmaṇa*-like discussions of rites not believed to be suitable for the village and hence discussed in the "forest," and continuing visions of the relationship between sacrifice, universe, and man. The word Brahman —the creative power of the ritual utterances, which is used to denote the creativeness of the sacrifice as such and which underlies ritual and therefore cosmic order— is prominent in these texts.

Upaniṣads. The *Upaniṣads* continued lines of thought, similar to the *Āraṇyakas*, elaborating on the structure of the human personality and that of the macrocosm, while interest in the ritual receded. Of the *Upaniṣads* the oldest are the *Bṛhadāraṇyaka* and *Chāndogya.* They were loosely composed and not systematic in intention, presenting various accounts of doctrines; a number of them are presented in the form of debates between different sages.

Among early accounts of creation are those that look upon creation as the self-fulfillment of the creator, but the prevailing tone is one of dissatisfaction with a transitory world and the effort is to find irreducible and eternal principles. Macrocosmically, these were found in Brahman or in the Existent (*sat*), microcosmically in breath (*prāṇa*), consciousness, but particularly in the self (*ātman*). In order to shed all transiency man should seek to return to the irreducible first principle from which he derives his being. Macrocosm and microcosm were conceived to be so parallel in structure that in certain places the underlying principles were held to be the same, while elsewhere a measure of distinctness was maintained; but there was no developed systematization of ideas, and the sages were at any time willing to reconsider.

Concept of self and Brahman

Transmigration does not figure prominently in the older texts, but there is an interesting account in *Chāndogya Upaniṣad* 5. After death the migrating self may go two routes, the Road of the Gods, which brings him to Brah-

man; and the Road of the Ancestors, which returns him to earth; his station in a new life is dictated by his previous deeds. Thus the search for the first cause and irreducible principle of being becomes also a quest for release from transmigration. The method was not expressly discussed but was thought of as a reversal of creation. A famous text in *Chāndogya Upaniṣad* 6 holds that the original Existent emanated three elements that by their various combinations produce the world; the return to the Existent is following the process of creation back to its original cause.

There is little theism in the older *Upaniṣads*, although the highest principle may be described as an effulgent God; the main concern was cosmological and protosoteriological rather than popularly religious.

MAHABHARATA AND RAMAYANA

The two epics are quite distinct from the earlier literature. Interest in ritual niceties is minimal, and concerns are eminently practical. Nevertheless, the *Mahābhārata* and, less so, the *Rāmāyaṇa* are important sources; in fact, they are almost the sole documents of Hindu religion from *c.* 400 BC to AD 200, a period that, with the rise of Buddhism, brought incisive changes.

Mahābhārata ("Great Epic of the Bhārata Dynasty"). Distinction should be made between the epic itself and the pseudo-epic or the large blocks of more recent and extraneous texts that have been assimilated into the main story. In the epic the main concern of the heroes is with the *dharma*, the complex of supernaturally sanctioned moral, social, and ritual laws, which are incumbent on an individual according to his station and period of life. While the heroes are still in the process of discovering the *dharma*, in the pseudo-epic there are large portions in which *dharma* is systematically treated, and which become precursors of the later *Dharma-śāstras* (see below *Dharma-śāstras*). Religious practice takes the form of Vedic ritual on official occasions, but principally of pilgrimage, and, to some extent, adoration of gods. Apart from the Bhagavadgītā (see below *Bhagavadgītā*) much of the religious material is found in the Book of the Forest (book 3), in which sages teach the exiled heroes; and in the Book of Peace (book 12), in which the wise Bhīṣma holds forth on religious and moral matters.

Religious contents of the *Mahābhārata*

The Vedic gods have lost importance and survive as figures of folklore. The Brahman of the *Upaniṣads* is popularly personified as the god Brahmā, who presides over the gods and dispenses boons. Of far greater importance is Kṛṣṇa. In the epic he is cast in the mold of a hero, a leader of his people, and an active helper of his friends. His biography as it is known later is not worked out; still the text is the source of early Kṛṣṇaism. Not everywhere, and certainly not by everyone, is Kṛṣṇa considered a god, and even as god his stature is superhuman rather than divine. He is occasionally identified with Viṣṇu, but not significantly. Far more remote than the instantly accessible Kṛṣṇa is Śiva, who is also hailed as the supreme god in several myths recounted of him, notably the Story of the Five Indras, Arjuna's battle with him, and others. The epic is rich in information on sacred places: it is clear that the making of pilgrimages and bathing in sacred rivers constituted an important part of religious life. On occasion, these sacred places are associated with sanctuaries of gods. More frequent are accounts of mythical events concerning the particular place and enriching its sanctity. Numerous descriptions of pilgrimages (*tīrthayātrā*) give the writers opportunities to detail local myths and legends. Besides them, there are countless edifying stories that shed light on the religious and moral concerns of the age. Almost divine are the towering ascetics capable of fantastic feats, whose benevolence is sought and whose curses are feared.

Apart from its influence as a written text, the *Mahābhārata* has made its impact on the ages both in South and Southeast Asia through the continual retelling of its stories in vernacular translations and oral literature. Today the story and its tales are part of the early education of the Hindu, and their influence on Indian and Southeast Asian art has been profound.

Rāmāyaṇa. Vālmīki's *Rāmāyaṇa* ("Romance of Rāma"), the simple story of how Prince Rāma was exiled, the abduction of his wife Sītā by the demon Rāvaṇa, the latter's defeat at the hands of Rāma and his monkey allies led by Hanumān, and Rāma's restoration has had a tremendous impact on the Hindu mind. Rāma is the perfect king, Sītā the perfect wife, Lakṣmaṇa the perfect brother; and Rāma's reign is the epitome of social harmony and prosperity. While not in its oldest form, the *Rāmāyaṇa* identifies Rāma with Viṣṇu as another incarnation (*avatāra*) and remains the principal source for Rāmaism (worship of Rāma). Though not as voluminous as the *Mahābhārata*, the text contains a great deal of comparable religious materials in the form of myths, stories of great sages, and examples of human behaviour.

Its continuing influence as a religious and moral romance is dramatically illustrated by its further history. It was translated into Tamil by Kambaṇ in a poem that is one of the glories of Tamil literature; into Bengālī by Kṛttibās Ojha; and into Hindi in the *Rāmacaritmānas* by Tulsīdās. Even today a continuous reading of the *Rāmāyaṇa* is an act of great merit. A popular enactment of one version is an annual event all over northern India.

THE BHAGAVADGITA

The *Bhagavadgītā* ("The Lord's Song") is the most influential Indian religious text, although it is not strictly *Śruti* or revelation. It is a brief text, 7,000 verses divided into 18 chapters, in quasi-dialogue form. When the opposing parties in the *Mahābhārata* war stand ready to begin battle, Arjuna, the hero of the favoured party, despairs at the thought of having to kill his kinsmen and lays down his arms. Kṛṣṇa, his charioteer, friend, and adviser, thereupon argues against Arjuna's failure to do his duty as a noble. The argument soon becomes elevated into a general discourse on religious and philosophical matters. The text is typical of Hinduism in that it is able to reconcile different viewpoints, however incompatible they seem to be, and yet emerge with an undeniable character of its own. Three different ways of releasing the self from transmigration are set forth. There is the discipline of the task (*karma-yoga*): against the views held by Buddhists and Jains, as well as the Sāṃkhya philosophy, which hold that all acts bind, and that therefore abstention from action is a precondition of release, Kṛṣṇa argues that it is not the acts that bind but the selfish intentions with which they are performed. He argues for a self-discipline in which one does one's duties according to the dictates of one's prescribed tasks (*dharma*), but without any self-interest in the personal consequences of the acts. On the other hand, he does not deny the relevance for a limited group of the discipline of insight (*jñānā-yoga*), in which one seeks release in a yogic (ascetic) course of withdrawal and concentration. Then the tone changes and becomes intensely religious: Kṛṣṇa reveals himself as the Supreme God and grants Arjuna a vision of himself. Still a third, and perhaps superior, way of release is through a discipline of devotion to God (*bhakti-yoga*) in which the self humbly worships the loving God and hopes in release not so much for personal liberation from transmigration but for an eternal vision of God. In response to his votary's devotion God will extend his grace to him, through which he will overcome the bonds of this world.

Theologies of the *Bhagavadgītā*

The *Bhagavadgītā* is not a systematic theological treatise and many different elements, drawn from Sāṃkhya and Vedānta philosophy, are mixed together. Religiously, its important contribution was the new emphasis placed on devotion, which has since remained the governing force in Hinduism. Also the popular theism evidenced elsewhere in the *Mahābhārata* and the transcendentalism of the *Upaniṣads* converge; and a God of personal characteristics is identified with the Brahman of the Vedic tradition. In its three disciplines the *Bhagavadgītā* gives a typology of the three dominant trends of Indian religion: *dharma*-based brahminism, enlightenment-based asceticism, and devotion-based theism.

The influence of the *Bhagavadgītā* has been profound. It was a popular text open to all who would listen and

fundamental for all later Hinduism. Vedānta philosophy recognizes it, with the *Upaniṣads* and the *Brahmasūtras* (brief doctrinal rules concerning Brahman), as the third authoritative text, so that all school founders had to comment on it. Until today, as is evident from the lives of such diverse personalities as the Indian freedom fighters B.G. Tilak (1856–1920) and Mahatma Gandhi (1869–1948) it has continued to shape the attitudes of the Hindu.

PURANAS

It is a characteristic development of Sanskrit religious literature that certain basic texts of religious or moral importance attracted to themselves other texts with similar or related themes. The *Mahābhārata* epic attracted a great number of other texts that grew into a colossal pseudo-epic. A similar development took place with the genre of *Purāṇa* (literally "ancient story"). While it is possible that there was a single original *Purāṇa*, from which the 18 major ones somehow derive, it is more likely that there was a floating Purāṇic repertory of bards and professional reciters. Traditionally this repertory had five themes: creation (*sarga*), periodic recreation (*pratisarga*), genealogy of gods and sages (*vaṃśa*), description of eras (*manvantara*), and the *gestae* ("feats") of the dynasties (*vaṃśānucarita*). Around this core, malleable as it was, adhered a huge number of texts, known as the 18 *Purāṇas*. The *Purāṇas* deal with religious and moral matters in the widest sense of the word for the broadest possible audience. While there are a number of *Purāṇas* without any particular sectarian affiliation, many are devoted specifically to one of the *avatāras* (incarnations) of Viṣṇu, to Śiva, or to Śakti. They document religious concerns in Hinduism from about the close of the *Mahābhārata* (*c.* AD 400) to *c.* 1000. In unsystematic encyclopaedic fashion they describe sacrifices, festivals, rites of expiation, vows, donations, funerary ritual, portents, divination, the construction and erection of icons and temples, places of pilgrimage, etc., all under the general concern for *dharma*.

Bhāgavata-Purāṇa

While all *Purāṇas* have exerted influence on Hinduism —and are in turn reflections of trends in Hinduism—no one can compare in popularity with the *Bhāgavata-Purāṇa* ("The *Purāṇa* of the Devotees of the Blessed Lord Kṛṣṇa"), the *Purāṇa* of the god Kṛṣṇa par excellence. This *Purāṇa* of the Bhāgavatas (those who worship Viṣṇu as the Blessed Lord) is fairly late (*c.* 10th century) and distinguishes itself from the other *Purāṇas* in that it is planned as a unit and that far greater care is taken with both metre and style. It runs to about 18,000 stanzas, divided over 12 books. The most popular part of the *Purāṇa* is the description of the life of Kṛṣṇa, for which it has since remained the principal authority. In this work far greater emphasis than in other texts is placed on the youth of Kṛṣṇa: the threats against his life by the tyrant Kaṃsa, his flight and life among the cowherds at Gokula, and especially his adventures and pranks with the cowherd girls. This treatment has remained classic. The popularity of the text has led to the survival of many manuscripts, some beautifully illustrated. Much of medieval Indian painting and an enormous amount of vernacular literature draw upon the *Bhāgavata-Purāṇa* for their themes.

DHARMA-SASTRA

Among the texts of Vedic inspiration are found the *Dharma-sūtras*, or manuals on *dharma*, which give rules of conduct, rites, and expiations as they were practiced in a number of branches of the Vedic schools (*śākhās*). Their principal contents relate to the duties of men in the life stages of studenthood, householdership, retirement, and asceticism; dietary regulations; offenses and expiations; and the rights and duties of kings. They also address themselves to religious matters, such as purification rites, funerary ceremonies, forms of hospitality, and daily oblations. Finally, they touch on juridical matters. Among these texts the more important ones are the *sūtras* of Gautama, Baudhāyana, and Āpastamba. Although the direct relationship is not clear, this particular concern was continued in the more systematic *Dharma-śāstras*, which in turn have become the basis of Hindu law. They include some of the most important texts of classical India.

Hindu law

First among them stands the *Dharma-śāstra* of Manu (*c.* AD ?200), in 2,694 stanzas distributed over 12 chapters. It deals with various matters such as cosmogony, definition of *dharma*, the sacraments, initiation and Vedic study, the eight forms of marriage, hospitality and funerary rites, dietary laws, pollution and purification, rules for women and wives, royal law, which then leads into more strictly juridical matters, categorized under 18 headings, and then returns to more religious matters, such as donations, rites of reparation, the doctrine of *karman*, the soul, and punishment in hell. Law in the juridical sense is thus completely imbedded in religious law and practice. The framework is provided by the model of the four-class society. The influence of *Dharma-śāstra* has been enormous, as it provided Hindu society with its practical morality. For large parts of the Indian subcontinent Manu's text through its commentaries, notably that of Medhātithi (9th century), has been the lawgiver.

Second only to Manu is the *Dharma-śāstra* of Yājñavalkya, in 1,000 (1,013) stanzas, distributed under the three headings of good conduct, law, and expiation. It has been very influential through its commentary *Mitākṣarā* of Vijñāneśvara (11th century) (see CASTE SYSTEMS).

TANTRAS

Tantra (literally "loom") is the general title of a long series of texts, divisible by sectarian lines, which reflect the beliefs, cults, and practices of medieval India. In many respects they are similar to the *Purāṇas*, but the practical aspect predominates over the philosophical one. Theoretically a *Tantra* deals with (1) "knowledge," or philosophy; (2) *yoga*, or concentration techniques; (3) ritual, which includes the formation of icons and the building of temples; and (4) conduct in religious worship and social practice. In general the last two subjects preponderate, while *yoga* tends to centre on the mystique of certain sound-symbols (*mantras*) that sum up esoteric doctrines. The least developed is the "philosophy," which tends to be a syncretistic mixture of Sāṃkhya and Vedānta philosophic thought, with special and at times exclusive emphasis on the god's power or *Śakti*. The *Tantra* texts divide into three classes: (1) Śaiva *Āgamas* (traditions of the followers of Śiva), (2) Vaiṣṇava *Saṃhitās* ("collections of the Vaiṣṇavas": name borrowed from the Vedic Saṃhitās), (3) Śākta *Tantras* ("the looms of the followers of the goddess Śakti").

Śaiva Agamas. Like much other Hindu sacred literature, this literature is hardly catalogued, let alone thoroughly studied. It is only possible here to summarize classes of texts within the various traditions.

There are four sects of Āgamic Śaivas (Śiva worshippers who follow their own Āgama—"traditional"—texts): the Sanskritic Śaivasiddhāntins; *i.e.*, those who accept the philosophic premises and conclusions of Śaivism, the Tamil Śaivas (in South India), the Kashmir Śaivas (in the extreme north), and the Vīraśaivas or Liṅgāyats (from *vīra*, literally "hero"—signifies their puritanism; *liṅga* is the Śiva emblem they worship in lieu of images). The Śaivasiddhānta traditionally has 28 *Āgamas*, and another 150 sub-*Āgamas*. The principal texts are hard to date; most probably they do not antedate the 8th century. Their doctrine is that Śiva is the conscious principle of the universe, while matter is unconscious. Śiva's power, or Śakti, personified as a goddess, causes bondage and release. She is also the magic Word, and thus her nature can be sought out and meditated upon in *mantras* (sound symbols).

The basic texts of the Tamil Śaivas are the hymns of the Nāyaṇārs, which are addressed to local manifestations of Śīva and are intensely personal and devout. They date from *c.* 800. Kashmir Śaivism begins with the *Śivasūtra* or "lines of doctrine concerning Śiva" (*c.* 850) as a new revelation of Śiva. The system embraces the *Śivadṛṣṭi* ("A Vision of Śiva") of Somānanda (950) in which emphasis is placed on the continuous recognition of

Śiva; the world is a manifestation of Śiva brought about by his Śakti. The system is called *Trika* (triad), because it recognizes the three principles of Śiva, Śakti, and the individual soul. Vīraśaiva texts begin at about 1150 with the *Vācanams* ("sayings") of Bāsava. The sect is puritanical, worships Śiva exclusively, rejects the caste system in favour of its own social organization, and is highly structured with monasteries and gurus.

Vaiṣṇava Saṃhitās. There are two groups: *Vaikhānasa Saṃhitās* and *Pāñcarātra Saṃhitās*. The latter is the prevailing one; over 200 titles are known, though the official number is 108. *Vaikhānasa Saṃhitās* (collections of the Vaiṣṇava school of *Vaikhānasas*—originally, ascetics) seem to have embodied the original temple manuals for the Bhāgavatas (devotees) but by the 11th or 12th century became supplanted by the *Pāñcarātra Saṃhitās* (collections of the Vaiṣṇava school of *Pāñcarātra*—"the system of the five nights," exact meaning in dispute). The philosophy of the latter is largely a matter of cosmogony, greatly inspired by both the Sāṃkhya and Yoga philosophies.

Notion of *Śakti* in Vaiṣṇavism

Apart from their theology, in which for the first time the notion of *Śakti* is introduced into Vaiṣṇavism, they are important in so far as they give an exposition of Vaiṣṇava temple and cult practices. On the philosophical side it is maintained that the supreme god Kṛṣṇa Vāsudeva manifests himself in four co-equal "divisions" (*vyūhas*), representing levels in creation. These gods emanate as supramundane patrons before the primary creation is started by their Śakti (power). In the primary creation Śakti manifests herself as a female creative force inspired by the Indian Sāṃkhya philosophy's cosmogony. Practically, stress is laid on a new type of "incarnation"—"iconic incarnation"—in which the god is actually present with a portion of himself in a stone or statue, which thus becomes an icon; therefore the icon can be worshipped as God himself.

Śākta Tantras. Śāktism in one form or the other is evidenced since Bāṇa (*c.* 650) wrote his *Hundred Couplets to Caṇḍi* and Bhavabhūti his play *Mālatī-Mādhava* (725), in which Tantric practices are referred to. There is no traditional list of texts that is authoritative; many texts are extant.

Śāktism is an amalgam of Śaivism and folk mother-goddess cults. The Śaivite notion that not Śiva himself but his Śakti (sexual, creative power) is active is taken to its last consequence, that, without Śakti, Śiva is a corpse, and simultaneously Śakti is the creator as well as creation. In the *yoga* part great importance is ascribed to *mantras* (sound symbols), which conjure up the realities with which they are identified. Another important notion (partly derived from Yoga philosophy) is that through the body run subtle canals that carry esoteric powers connected with the spinal cord, at the bottom of which the goddess is coiled around the *liṅga* as Kuṇḍalinī; she is to be made to rise through the body to the top, whereupon release takes place. Important among the Śākta *Tantras* are the *Kulārṇava Tantra* (ocean of Tantrism), which gives details on the "left-handed" cult forms of ritual copulation; the *Kulacūḍāmaṇi* (crown jewel of Tantrism), which embroiders on ritual; and the *Saradātilaka* ("Beauty Mark of the Goddess Śaradā") of Lakṣmaṇadeśika (11th century), which treats of magic.

OTHER TEXTS

Stotras

Since so much of Sanskrit and vernacular literature is suffused by religion, it is often difficult to differentiate between "profane" and sacred literature. Extremely popular was the genre of *stotras*, "hymns of praise," to one god or the other. From 650 date the *Hundred Couplets to Caṇḍī* of Bāṇa and the *Hundred Couplets to the Sun* by Mayūra. Numerous *stotras* are apocryphally attributed to the philosopher Śaṅkara. The most popular collection of all is the *Kṛṣṇakarṇāmṛta* ("Balm to the Ears Concerning Kṛṣṇa") by Līlāśuka Bilvamaṅgala, which contributed, though it originated in the south, a great deal to the development of *bhakti* devotionalism in Bengal.

Most celebrated of all literary-religious works is the *Gītagovinda* of Jayadeva (12th century) on the subject of the loves of Kṛṣṇa and Rādhā. Its structure is an artful combination of the Mahākāvya style of the epyllion (literary short epic) in 12 chapters, interrupted by 24 series of eight-line songs. The style and language is extremely musical, with a great preference for rhyme, alliterations, and assonance.

SACRED LITERATURE IN REGIONAL LANGUAGES

The Sanskrit sources, copious as they are, are further augmented by the vernacular literatures, which in part continue, in part complement them. The vernacular sources, however, are generally less accessible than the Sanskrit ones, because editions are lacking or are defective and harder to survey. Present knowledge of them, therefore, is very imperfect. Generally, except where there was an independent literary tradition, as in Tamil, the texts are either epigonic in character, translating and restating the Sanskrit tradition, or original creations, the latter particularly to be found in the theistic literature of *bhakti*. The original creations tend to adopt a new vernacular medium to put themselves in contrast to the Sanskritic ideals. Thus frequent criticism is made of the caste system, brahmin superiority, the emptiness of *dharma* formalism; and the love of God is exalted as the sole effective means for salvation beyond learning, Veda, and ritual. Also the use of vernaculars encourages a localism not usually found in the Sanskrit sources: the god is seen as the god of a particular locality, temple, or icon. Finally it leads to a greater sense of self-identity; one is not as in the Sanskrit sources recreating what was supposedly always given from the beginning but creating anew. That these original creations themselves become canonic texts for a particular sect, with their own burden of scholastic commentaries that seek to make a system out of them, does not detract from their great value as newer contributions to the sacred literature.

Epigonic texts. "Epigonic" is used for want of a better word, because from the point of view of the earlier literature these texts are indeed epigonic in the sense that they are derived from or inspired by the epics, *Purāṇas*, etc. But as works of literature they may, and often are, not epigonic at all, but new works that frequently stand at the beginning of a new literary and stylistic tradition, though often continuing to borrow some internal features from the earlier literature. From the latter point of view many are more appropriately dealt with under the study of Indian literature. The works of which vernacular versions were most commonly made were the *Rāmāyaṇa*, the *Mahābhārata*, and the *Bhāgavata-Purāṇa;* and the *Mahābhārata*—not in its entirety but its parts. These versions are not literal translations, but free versions in which the authors place their own emphases, different from the original, and from one another. The oldest of the vernacular versions of the *Rāmāyaṇa* is the Tamil one of Kamban (*c.* 12th century), a work suffused with devotion (*bhakti*) and simultaneously a poem of high literary distinction. In Bengali several translations were made, with some interesting and probably authentic variations from the "official" Rāma story by Vālmīki, the best known one by Kṛttibās Ojhā (1450). Equally, if not more, famous is the Hindi version by Tulsīdās (*c.* 1550), entitled *Rāmacaritmānas* ("The Holy Lake of Rāma's Feats"), while a famous translation in Tamil exists from the 18th century from the hand of Villiputturar.

Regional language versions of the *Rāmāyana* and *Mahābhārata*

A Telugu rendering was made by Ranganātha *c.* 1300. The *Mahābhārata* was translated into Bengali (*c.* 1600), into Telugu by Nanayya and Tikkana (13th century). The *Bhāgavata-Purāṇa* was extremely popular both as a text, which was translated frequently (*e.g.*, into Bengali by Maladhar Vasu, 1480), and because it gave the canonical account of Kṛṣṇa's life and especially his boyhood, which is the perennial inspiration of the *bhakti* poets.

In Marathi the teacher Jñānadeva (also known as Jñāneśvar; *c.* 1300) composed a commentary on the *Bhagavadgītā*, which remains a classic in that literature. His work was continued by Eknāth (*c.* 1600), who also composed *bhakti* poetry.

The bhakti lyricists. Although all have their individual genius, the *bhakti* (devotional) lyricists share a number of

common features whatever their language. The premium of a Sanskrit education exacted for authors of Sanskrit texts, which limited them largely to the Brahmin class and thus put a definite stamp on them, was not demanded. Consequently a *bhakti* poet could arise from any class. He brought to his poetry a familiarity with folk religion unknown to or ignored in the Sanskrit texts. The use of the spoken language, even though formalized, made possible immediate expression of an unmediated vision that needed no further context; thus the lyrics are short, intensely personal, and precise. These works illustrate the localistic and reformist tendency evidenced all over India in the vernacular literatures.

Oldest among the *bhakti* lyricists are those of Tamil: they evoke and invoke in particular Śiva and Viṣṇu in numerous local identifications. The Śaiva lyricists (Nāyaṉārs) are Appar, Sambandar, and Cuntarar whose hymns are collected in the *Tevāram* (*c.* 11 century). More or less contemporary were their Vaiṣṇava counterparts, the Āḻvārs, Poykai, Pūtaṉ, Pēyār and Tirumalicaialar Āḻvār, and in the 8th century the poetess Āṇḍaḷ, Periyāḻvār, Kulacēkarar, Tiruppāṇāḻvār, and notably Nammalvar, who is held to be the greatest. The devotion of which they sing exemplifies the new *bhakti* movement that seeks a more direct contact between man and God, carried by a passionate love for the deity who reciprocates by extending his grace to man. These saints also became the inspiration of theistic systematic religion: the Śaivas for the Śaivāsiddhānta, the Vaiṣṇavas for Viśiṣṭādvaita. In Kannada the same movement was exemplified by Basava, whose *vācanams* ("sayings, talks") achieved a very great popularity. His religion, that of Vīraśaivism, was perhaps the most "protestant" of the *bhakti* religions.

Bengali and Hindi devotional texts

A particularly rich tradition developed in Bengal. The inspiration there was largely Kṛṣṇaite, centring on the love of Rādhā, who symbolizes the human soul, for Kṛṣṇa, the supreme God. In this tradition are Caṇḍīdās and the Maithili poet Vidyāpati (*c.* 1400). The greatest single influence was Caitanya (born 1485), who renewed Kṛṣṇaism. He has left no writings but inspired a number of hagiographies, among the more important of which is the *Caitanya-caritāmṛta* ("Nectar of Caitanya's Life") by Kṛṣṇa Dās (born 1517). The religious lyric continues in the so-called *padas* (verses); one of the greatest poets in this *bhakti* genre in which divine love is symbolized by human love is Govinda Dās (1537–1612). The songs of Rāmprasād Sen (1718–75) similarly honour the Śakti as mother of the universe and are still in wide devotional use.

Hindi literature produced its own great religious lyricists beginning with the disciples of Rāmānanda (*c.* 1450), who was a follower of the philosopher Rāmānuja. Among them the most famous is Kabīr (died 1518), whose *bhakti* was nonsectarian. The princess Mīrā Bāī (1503–73) composed elegiacs and praises in honour of Kṛṣṇa, whereas Tulsīdās, apart from his *Rāmacaritmānas*, composed Rāmaite lyrics. Sūrdās (1483–1563), a follower of the Vallabha school of Vedānta, is famous for his Sūrsāgar ("Ocean of the Poems of Sūr"), a collection of poems based on the childhood of Kṛṣṇa, following the account of the *Bhāgavata-Purāṇa*. In the Marāthi tradition Nāmdev (*c.* 1300) celebrated Viṣṇu, particularly in his manifestation as Viṭhobā at the Pandharpur temple; and Tukārām (1607–49), the greatest poet of this literature, sang of the god of love in numerous hymns.

Other regional texts. No exhaustive inventory can be given of all of the major religious texts in the modern vernaculars. An exception may be made for the Bengali *maṅgal-kāvya* literature, which centres on folk deities. *Maṅgals* are distinguished from other forms of religious literature by their contents: a eulogy to the deity to which they are dedicated; often, an account of the conversion or other experiences of the writer; a lengthy, semi-epical account of the *deus ex machina* through which worship of the deity on earth has come about; and an account of other significant activities of the deity on behalf of his devotees. Numerous *maṅgals* have been composed in honour of many local deities, including Manasā (goddess of snakes), Śītalā (goddess of smallpox), Dharma Ṭhakur (or Dharma Ray), Ṣaṣṭhī (goddess of childbearing and infant welfare), and several forms of the Goddess, such as Kālī and Caṇḍī. Most widely known within Bengal is the folk goddess Manasā, a snake deity of surely hoary antiquity, who in the course of time was assimilated to the Śakti of Śāktism. The *Manasā-maṅgal* gives a Purāṇic account of the greatness and powers of the goddess (see HINDUISM, HISTORY OF; SOUTH ASIAN PEOPLES, ARTS OF).

IV. Religious uses of the sacred texts

The various uses to which the texts have been and are put have been indicated, for the most part, under their descriptions. The range of these uses is enormous. The Vedic texts found their use in the huge edifice of ritual that was erected from *c.* 1000 to 600 BC. Their later parts, especially the *Upaniṣads*, became the foundation of the principal Hindu philosophical school, the Vedānta. The epics, on the other hand, were used directly for the instruction and edification of a much larger audience than was intended for the Vedas; and their later role in Sanskrit and vernacular literatures shows sufficiently their effectiveness. Similar instruction was provided by the *Purāṇas*, but here a greater degree of localization sets in. Although they remain Pan-Indian in intention, they may contain glorifications of specific spots; the *Bhāgavata-Purāṇa* is generally believed to be a southern creation evoking Kṛṣṇa traditions from there.

Of immediate impact on family life are those parts of the Veda that deal with the domestic rites, the life-cycle sacraments, the offerings to the dead, the code of behaviour for the four classes of society, and the four stages of life. But also important are the numerous stories of epic and *Purāṇa* in which signal instances of generosity, of paternal and filial love, and of fraternal relations are celebrated. In personal religious life, texts of many kinds find their uses. The caste Hindu is brought up on the ancient stories that become part of the framework in which he experiences life. Special emergencies may necessitate vows in which the recitation of a text is an important part. He may make a particular *mantra* his own as an aid to his meditations.

On public occasions other texts may come into use. The great festivals at the temples call for the use both of the texts on fundamental procedures proper to that temple, and the special recitations for which the festival calls. On such festive occasions there will be professional reciters who may retell in Sanskrit or vernacular languages the old stories of gods, saints, and heroes. At the great pilgrimage places to which millions may flock, sages have their own booths in which they patiently set forth, day after day, the teachings of the *Bhagavadgītā*.

Rām Līlā festival

Perhaps the most dramatic use of a sacred text is that of Tulsīdās's Rāma epic, at the Rām Līlā festival, which is particularly popular in northern India. While the text is continuously recited, actors take the role of the different characters of the *Rāmāyaṇa*, culminating in a pyrotechnic killing and exploding of the giant demon Rāvaṇa, to both the delight and the edification of the public. An entire city can participate in this event. Similar uses of the texts can be found all over the South Asian subcontinent.

Hindu sacred literature thus embraces an enormous repertory of texts of startling antiquity and variety, and touching upon practically every aspect of individual, family, and social life. The texts have provided religion with its substance, philosophy with its principal assumptions, art with its themes, literature with its topics, music and dance with their soul.

BIBLIOGRAPHY. The fullest general description, with an extensive bibliography has been given by J.N. FARQUHAR, *An Outline of the Religious Literature of India* (1922, reprinted 1967); a briefer but more up-to-date treatment may be found in LOUIS RENOU and JEAN FILLIOZAT, *L'Inde classique*, vol. 1 (1947). For the Vedic ritual literature, see A. HILLEBRANDT, *Altindische Ritual-Literatur* (1897).

(J.A.B.v.B.)

Hipparchus

Hipparchus, who flourished between the years 146 and 127 BC, was the greatest astronomical observer of antiq-

uity and an able mathematician. He was born at Nicaea in Bithynia (part of modern Turkey), on the eastern shore of the Propontis (the modern Sea of Mármara). The dates of his birth and death and the place of his death are not known. He carried out his observations in Bithynia, at Rhodes, where he spent much time, and also, it seems, at Alexandria. The year 127 BC is usually cited as the last date known for his actual work, and a French astronomer, Jean-Baptiste-Joseph Delambre (1749–1822), clearly demonstrated that some observations of Hipparchus on the star Eta Canis Majoris could well have been carried out in that year.

Most of contemporary knowledge of Hipparchus is contained in the writings of Strabo of Amaseia (flourished *c.* AD 21) and in the great astronomical compendium, *Almagest* by Ptolemy (flourished AD 127–151). Ptolemy often quotes Hipparchus, and it is obvious that he thought highly of him; indeed, as a result of the slow progress of early science, he speaks of him with the respect due a distinguished contemporary, although almost three centuries separated the work of the two men. It is difficult always to determine to which of them credit is due.

Influence of Hipparchus on Ptolemy

It is certain, however, that in all his work Hipparchus showed a clear mind and a dislike for unnecessarily complex hypotheses. He rejected not only all astrological teaching but also the heliocentric views of the universe that seem to have been proposed, according to Archimedes (*c.* 287–212 BC), by Aristarchus of Samos (flourished *c.* 270 BC) and that were resuscitated by Seleucus the Babylonian, a contemporary of Hipparchus. In this connection, it is necessary to recall that strong arguments had been advanced against the idea of the motion of the Earth, and the general climate of opinion had never been favourable to following up the lead given by Aristarchus. Moreover, the system of movable eccentrics, and that of epicycles and deferents, accounted well for most of the irregularities observed in the motions of the Sun, the Moon, and the planets. These two systems were based on the erroneous belief that all celestial movement is regular and circular, or at least that it is best described in terms of a system of regular motion in circles. In the system of movable eccentrics, the centres of the supposed orbits of bodies around the Earth were themselves revolving around the Earth. In the other, epicycles were small circles theoretically imposed on the great circular orbital paths, which were called deferents. The epicycle–deferent mechanism was found with that of the movable eccentric in Ptolemy's late form of the geocentric system of cosmology. It was, of course, this Ptolemaic geocentric system that was handed down to western European science, but it must be remembered that the views of Hipparchus had a profound influence on Ptolemy, as he himself acknowledged. It was not until the 15th century that regular observations over very long periods showed the geocentric hypothesis to be too complex to be acceptable and Copernicus proposed that the Sun is the centre of the universe.

Few details are known of the instruments that Hipparchus used. It seems likely that he observed with the usual devices current in his day, although Ptolemy credits him with the invention of an improved type of theodolite with which to measure angles.

Precession of the equinoxes. Hipparchus is best known for his discovery of the precessional movement of the equinoxes; *i.e.*, the alterations of the measured positions of the stars resulting from the movement of the points of intersection of the ecliptic (the plane of the Earth's orbit) and of the celestial equator (the great circle formed in the sky by the projection outward of the Earth's equator). It appears that he wrote a work bearing "precession of the equinoxes" in the title. The term is still in current use, although the phenomenon is more usually referred to merely as "precession." This notable discovery was the result of painstaking observations worked upon by an acute mind. Hipparchus observed the positions of the stars and then compared his results with those of Timocharis of Alexandra about 150 years earlier, and with even earlier observations made in Babylonia.

He discovered that the celestial longitudes were different, and that this difference was of a magnitude exceeding that attributable to errors of observation. He therefore proposed precession to account for the size of the difference and he gave a value of 45″ or 46″ (seconds of arc) for the annual changes.

Measured differences in star positions

This is very close to the figure of 50.26″ accepted today and is a value much superior to the 36″ that Ptolemy obtained.

Tropical and sidereal years. The discovery of precession enabled Hipparchus to obtain more nearly correct values for the tropical year (the period of the Sun's apparent revolution from an equinox to the same equinox again), and also for the sidereal year (the period of the Sun's apparent revolution from a fixed star to the same fixed star). Again he was extremely accurate, so that his value for the tropical year was too great by only 6½ minutes.

Star catalog. Observations of star positions measured in terms of celestial latitude and longitude, as was customary in antiquity, were carried out by Hipparchus and entered in a catalog—the first star catalog ever to be completed. Hipparchus measured the stellar positions with greater accuracy than any observer before him, and his observations were of use to Ptolemy and even later to Edmond Halley. To catalog the stars was thought by some of Hipparchus' contemporaries to be an impiety, but he persevered. Hipparchus had been stimulated in 134 BC by observing a "new star." Concluding that such a phenomenon indicated a lack of permanency in the number of "fixed" stars, he determined to catalog them, and no criticism was able to deflect him from his original purpose.

Hipparchus' catalog, completed in 129 BC, listed about 850 stars (not 1,080 as is often stated), the apparent brightnesses of which were specified by a system of six magnitudes similar to that used today. For its time, the catalog was a monumental achievement.

Lunar and solar work. In his work on the Sun and Moon Hipparchus used the observations of others as well as his own. He showed that the system based on movable eccentrics, and that based on epicycles and deferents, were equivalent in the motions they gave for the Sun and Moon and, indeed, for the planets. Both methods gave the position of the Sun correct to within 1′, and Hipparchus rejected the peculiar notion, prevalent in his day, that the Sun moved in an orbit inclined to the ecliptic. Hipparchus also redetermined the inclination of the ecliptic and obtained a value correct to within 5′ of the modern figure.

The motion of the Moon is more complex than that of the Sun, owing to the perturbations that the Moon suffers from both Earth and Sun; in consequence, there are more irregularities to be taken into consideration. Hipparchus satisfactorily accounted for that inequality of the Moon's motion that is now known to be due to the elliptical form of its orbit; he utilized the system of circular epicycles and deferent but proposed that the deferent was inclined at an angle of 5° to the ecliptic. His theory gave reasonably satisfactory results for the motion at Full and New Moon. Hipparchus was dissatisfied however, for, as he appreciated, the errors at quadrature (when the Moon stands at first and last quarters) were too great. He concluded that there was some further inequality in the Moon's motion, but he was unable to discover any means of solving this problem, and he said candidly that he was leaving the solution of this question to those who were to follow him.

Hipparchus also attacked the problem of the relative size of the Sun and Moon and their distance from the Earth. It had long been appreciated, of course, that the apparent diameter of each was the same, and various astronomers had attempted to measure the ratio of size and distance of the two bodies. Eudoxus obtained a value of 9:1, Phidias (father of Archimedes) 12:1, Archimedes himself 30:1, while Aristarchus believed 20:1 to be correct. The present-day value is, approximately, 393:1. Hipparchus followed the method used by Aris-

Lunar and solar parallax

tarchus, a procedure that depends upon measuring the breadth of the Earth's shadow at the distance of the Moon (the measurement being made by timing the transit of the shadow across the Moon's disk during a lunar eclipse). This method really gives the parallax (the apparent change in the position of a celestial body when observed from two different directions), and thus the distance, of the Moon, the parallax for the Sun being too small to give a significant result; moreover the accuracy obtainable for the distance even of the Moon is poor. Dissatisfied with his results, Hipparchus attempted to find the limits within which the solar parallax must lie for observations and calculations of a solar eclipse to agree; he hoped that differences between solar and lunar parallax might thus also be revealed. He obtained no satisfactory result from his efforts, however, and concluded that the solar parallax was probably negligible. At least he appreciated that the distance of the Sun was very great indeed.

Planetary studies. Hipparchus was unsuccessful in forming a satisfactory planetary theory and was a scientist enough to avoid building hypotheses on insufficient evidence. Theon claims that Hipparchus preferred the mathematical device of the epicycle to that of the movable eccentric, but it seems clear that he looked upon such devices purely as mathematical conveniences and was not concerned with the reality or otherwise of these combinations of circular motion. Ptolemy went further in his description of the planetary work of Hipparchus and wrote

> It was, I believe, for these reasons and especially because he had not received from his predecessors as many accurate observations as he has left to us, that Hipparchus, who loved truth above everything, only investigated the hypotheses of the sun and moon, proving that it was possible to account perfectly for their revolutions by combinations of circular and uniform motion, while for the five planets, at least in the writings which he has left, he has not even commenced the theory, and has contented himself with collecting systematically the observations and showing that they did not agree with the hypotheses of the mathematicians of his time. He explained in fact not only that each planet has two kinds of inequalities but also that the retrogradations of each are variable in extent, while other mathematicians had only demonstrated geometrically a single inequality and a single arc of retrograde motion; and he believed that these phenomena could not be represented by eccentric circles nor by epicycles carried on concentric circles, but that, by Jove, it would be necessary to combine the two hypotheses. (J.L.E. Dreyer, *History of the Planetary Systems From Thales to Kepler*, Cambridge University Press, 1906.)

Those who studied this problem before the time of Hipparchus had but one main aim, to explain the irregularities that occurred when a planet was in opposition; *i.e.*, in a direction opposite to that of the Sun. No notice was taken of those irregularities that occurred when a planet was in other parts of its orbit, doubtless because of the habit of observing only around times of opposition. Hipparchus advocated more frequent observations made over longer periods, and he carried out such work himself with an accuracy unsurpassed in his time. Ptolemy used the older observations that Hipparchus had sifted, those that Hipparchus himself had made, and his own before he formulated the planetary views enshrined in his *Almagest*. In his own planetary work Hipparchus adopted the generally accepted order for the Sun, Moon, and planets. With the Earth as the centre, they were, in order from the Earth, the Moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn.

Mathematics. It is to be expected that the astronomical work of Hipparchus should have led him to develop certain departments of mathematics. He made an early formulation of trigonometry and tabulated a table of chords—*i.e.*, the length of the line joining two points on a unit circle corresponding to the given angle at the centre; *e.g.*, chord of $\alpha = 2 \sin(\alpha/2)$: he is known to have had a method of solving spherical triangles. It is also generally agreed that the theorem in plane geometry known as "Ptolemy's theorem" was originally due to Hipparchus and was later copied by Ptolemy. The French statesman and mathematician Lazare Carnot (1753–1823) showed that the whole of plane trigonometry can be deduced from these formulas.

Geographical work. Hipparchus criticized severely the geographical work of Eratosthenes (*c.* 276–*c.* 194 BC) and himself did some work in this field. His main contribution was to apply rigorous mathematical principles to the determination of places on the Earth's surface, and he was the first to do so by specifying their longitude and latitude—the method used today. Hipparchus was, no doubt, led to this method by his work on the trigonometry of the sphere. He tried to measure latitude by utilizing the ratio of the longest to the shortest day at a particular place instead of following the customary method of the Babylonians of measuring the difference in length of day as one travels northward. Hipparchus also divided the then known inhabited world into climatic zones, and suggested that the longitude of places could be determined by observing, from these places, the moments when a solar eclipse began and ended; but this bold scheme, while theoretically satisfactory for a small area of the Earth's surface, was not a practical proposition in his day.

BIBLIOGRAPHY. J.L.E. DREYER, *History of the Planetary Systems from Thales to Kepler* (1906; reprinted as *A History of Astronomy from Thales to Kepler*, 1953), a readable but scholarly book in which the work of Hipparchus is clearly set out; GEORGE SARTON, *A History of Science*, vol. 2, *Hellenistic Science and Culture in the Last Three Centuries B.C.* (1959), a volume containing an excellent well-written résumé of Hipparchus and his achievements; PTOLEMY, *The Almagest*, reprinted in an English translation in "Great Books of the Western World," vol. 16 (1952), the main original source of references to the astronomical work of Hipparchus, and the clarity of Ptolemy's text makes clear his contribution.

(C.A.R.)

Hippocrates

Hippocrates of Cos was a Greek physician of the 5th and 4th centuries BC. Referred to from antiquity as "Hippocrates the Great" to distinguish him from others of that name, he was regarded from classical times as the father of medicine. His name is traditionally associated with the so-called Hippocratic Oath—certainly not written by him —which in modified form is still often required to be taken by medical students on graduating.

The Hippocratic tradition

Life. Trustworthy information about Hippocrates' life is scanty. His younger contemporary Plato referred to him twice. In the *Protagoras* Plato called Hippocrates "the Asclepiad of Cos" who taught students for fees and implied that Hippocrates was as well-known as a physician as Polyclitus and Phidias were as sculptors. It is now widely accepted that an "Asclepiad" was not a temple priest or a member of a physicians' guild but instead was a physician belonging to a family that had produced well-known physicians for generations. Plato's second reference occurs in the *Phaedrus*. Hippocrates is referred to as a famous Asclepiad who had a philosophical approach to medicine. Further, Hippocrates regarded the body as "a whole"—that is, as an organism. His medical practice resulted from his collection of information regarding parts of the body into an embracing concept and, thereafter, the division of the whole into its parts.

Meno, a pupil of Aristotle, specifically stated in his history of medicine the views of Hippocrates on the causation of diseases, namely, that undigested residues were produced by unsuitable diet and that these residues excreted vapours, which passed into the body generally and produced diseases. Aristotle said that Hippocrates was called "the Great Physician" but that he was small in stature (*Politics*).

These are the only extant contemporary, or near-contemporary, references to Hippocrates. Five hundred years later, the Greek physician Soranus wrote a life of Hippocrates, but the contents of this and later lives were largely traditional or imaginative. It seems possible, however, that Hippocrates was the son of a physician and was born about 460 BC on the island of Cos. Throughout

his life he travelled widely in Greece and Asia Minor practicing his art and teaching his pupils, and he frequently taught at the medical school at Cos. There is a strong tradition that he died about 377 BC at Larissa. His birth and death dates are traditional but may well be approximately accurate. Undoubtedly Hippocrates was a historical figure, a great physician who exercised a permanent influence on the development of medicine and on the ideals and ethics of the physician.

Multiple authorship of the Hippocratic Collection

The Hippocratic Collection. From shortly after the Hippocratic period, references were made to named works by "Hippocrates," and this tradition continued. The number of works "by Hippocrates" known in ancient times was about 70, but the number now extant is about 60. They became known as the Hippocratic Collection (*Corpus Hippocraticum*), of which the earliest surviving manuscript dates from the 10th century AD.

Even in antiquity it was realized that not all the works attributed to Hippocrates had actually been written by him—hence the later attempts to designate the "genuine works." This endeavour started at least as early as the 2nd century AD and continues to the present day. The works differ enormously in length and style, in the opinions expressed, and in the types of their intended users. Some are written for professional physicians, some for their assistants and students, some for laymen, and some are philosophical works. From internal and other evidence the approximate dates of some of the treatises are known, and it seems fairly certain that at least a century —and possibly much longer—separates the date of the earliest work from that of the latest. One feature is common: all the works were written in the Ionic dialect, which thus became the language of Greek science.

There has long been general agreement that the collection constituted the library of a medical school, probably that at Cos, and that, during the 3rd or 2nd century BC, it passed to the great library at Alexandria, where the works were edited and made available. The collection deals with the following subjects: anatomy; clinical subjects; diseases of women and children; prognosis; treatment by diet and drugs; surgery; and medical ethics.

Prominent among the works in the Hippocratic Collection were a treatise on *Epidemics*, in seven books and written by at least two authors; *On the Sacred Disease*, a treatise on epilepsy; *Prognostics; Airs, Waters and Places;* and *Aphorisms*, a collection of 412 short counsels regarding diagnosis, prognosis, and treatment (see MEDICINE, HISTORY OF: *Early Greek and Roman Medicine*).

BIBLIOGRAPHY. The only modern edition of the whole of the Greek text of the Hippocratic Collection is EMILE LITTRE, *Oeuvres complètes d'Hippocrate*, 10 vol. (1839–61, reprinted 1961). This work also gives a French translation of the complete collection, and is the only complete translation into any modern language. A selection of 28 of the treatises are given in Greek text and English translation by W.H.S. JONES and E.T. WITHINGTON in *Hippocrates*, 4 vol. ("Loeb Classical Library," 1923–31, reprinted 1957–59). The English translation of selected works by FRANCIS ADAMS, *The Genuine Works of Hippocrates*, 2 vol. (1849), is still of great value. An excellent modern translation of 13 treatises may be found in JOHN CHADWICK and W.N. MANN, *The Medical Works of Hippocrates* (1950).

An excellent discussion of Hippocrates and his influence is in CHARLES SINGER, *Greek Biology and Greek Medicine* (1922). A shorter discussion, from a slightly different aspect, is in CHARLES SINGER and E.A. UNDERWOOD, *A Short History of Medicine*, 2nd ed. (1962). The whole Hippocratic question is very fully discussed, from the medical and philological aspects, in H.E. SIGERIST, *A History of Medicine*, vol. 2 (1961). For the Hippocratic oath, see W.H.S. JONES, *The Doctor's Oath* (1924); and LUDWIG EDELSTEIN, "The Hippocratic Oath," *Bull. Hist. Med.*, suppl. no. 1 (1943), reprinted in Edelstein's *Ancient Medicine* (1967). For a modern discussion of the therapeutic armamenterium of Hippocrates, see J. STANNARD, *Bull. Hist. Med.*, 35:497–518 (1961).

Hiroshige

A noted Japanese print artist, Andō Hiroshige was the last major figure in the development of what has become known as the *Ukiyo-e* ("Pictures of the Floating World") school. In particular, he consolidated the landscape print as an independent genre and depicted the total range of his nation's scenic beauties in a manner that could be, for the first time, readily appreciated by the common man. When the Japanese woodcut was rediscovered in the Europe of the later 19th century, it was Hiroshige who gave such Western artists as Whistler, Cézanne, Toulouse-Lautrec, Gauguin, and van Gogh a new vision of nature.

Hiroshige was born in 1797, the son of Andō Genemon, warden of the Edo (Tokyo) fire brigade, which was entrusted with the protection of Edo Castle. Hiroshige had three sisters, two of them considerably older than himself. Various episodes indicate that the young Hiroshige was fond of sketching and probably had the tutelage of a fireman, Okajima Rinsai, who had studied under a master of the traditional Kanō school of painting.

In the spring of 1809, when Hiroshige was 12, his mother died. Shortly after, his father resigned his post, passing it on to his son. Early the following year, his father died as well.

Despite his age, the young fire warden conducted himself with distinction in times of actual conflagration, but, although holding a position of some prestige, Hiroshige's actual daily duties were minimal, and his wages were small. Undoubtedly, these factors, plus his own natural bent for art, eventually led him to enter, in about 1811, the school of the *Ukiyo-e* master Utagawa Toyohiro.

Schooling under Toyohiro

Hiroshige is said to have first applied to the school of the more popular artist Toyokuni but was turned down due to the latter master's large number of applicants. Toyokuni's less renowned confrere Toyohiro, too, is said to have first refused Hiroshige, acquiescing only after the latter's persistent requests. Had Hiroshige been accepted as pupil by Toyokuni, he might well have ended his days as a second-rate imitator of that artist's specialty of gaudy prints of girls and actors. It was doubtless the more modest and refined taste of Toyohiro that helped form Hiroshige's own style—and led his genius eventually to find full expression in the new genre of the landscape print.

Although receiving a *nom d'artiste* and a school license at the early age of 15, Hiroshige was no child prodigy, and it was not until six years later, in 1818, that his first

"Kambara" by Hiroshige, woodblock colour print from the series, "Fifty-three Stages on the Tōkaidō," 1834. 25 cm × 37 cm.
By courtesy of Peter Morse

published work appeared. In the field of book illustration, it bore the signature Ichiyūsai Hiroshige. No earlier signed works are extant, but it is likely that, during this student period, Hiroshige did odd jobs (*e.g.*, inexpensive fan paintings) for the Toyohiro studio and also studied, on his own, the Chinese-influenced Kanō style and the impressionistic Shijō style—both of which were to strongly influence his later work.

As soon as he was able, Hiroshige transferred to his own son the post of fire warden and devoted himself to his art. As is customary with artists of the plebeian *Ukiyo-e* school, early biographical material regarding Hiroshige is scarce: he and his confreres were considered to be only artisans by the Japanese society of the time, and, although their works were widely enjoyed and sometimes even treasured, there was little interest in the personal details of their careers. Thus, Hiroshige's adult years must be traced largely through his works.

Stages in Hiroshige's artistic life

Hiroshige's artistic life may be characterized in several stages. The first was his student period, from about 1811 to 1830, when he largely followed the work of his elders in the field of figure prints—girls, actors, and samurai, or warriors. The second was his first landscape period, from 1830 to about 1844, when he created his own romantic ideal of landscape design and bird-and-flower prints and brought them to full fruition with his famed "Fifty-three Stages of the Tōkaidō" (a product of his sketching journey in 1832 on the famed Tōkaidō highway between Edo and Kyōto) and with such later series as "Famous Places in Japan," "Views of Kyōto," "Eight Views of Lake Biwa," "Sixty-nine Stations of the Kiso Highway," and various series of views featuring Edo and environs. His last stage was his later period of landscape and figure-with-landscape designs, from 1844 to 1858, during which overpopularity and overproduction tended to diminish the quality of his work.

Hokusai (*q.v.*), Hiroshige's early contemporary, was the innovator of the pure landscape print. Hiroshige, who followed him, was a less striking artistic personality but frequently achieved equivalent masterpieces in his own calm manner. Hokusai's approach is more powerful and realistic. Hiroshige lacked Hokusai's broad and yet intensive training in many styles but created his own genial, poetic view out of the tradition of Japanese popular painting. There was in his work a human touch that no artist of the school had heretofore achieved; these pictures revealed a beauty that seemed somehow tangible and intimate, even to men who had hitherto thought little of nature's wonders.

Unlike Hokusai, Hiroshige's life was relatively uneventful: his life was his work, with neither peaks nor valleys. Hiroshige leaves the impression of a largely self-taught artist who limited himself to the devices and capacity of his own nature.

Hiroshige was fond of travel, loved wine and good food, and in his other tastes was a true citizen of Edo. Dying in the midst of a cholera epidemic in the autumn of 1858, he enjoined his family to refrain from an excessive funeral ceremony by quoting in his final will and testament an old verse that well expresses the hedonism of old Edo:

When I die
don't cremate me don't bury me:
just throw me in the fields
and let me fill the belly of
some starving dog.

Hiroshige's own farewell verse went:

Leaving my brush behind
in Edo
I set forth on a new journey:
let me sightsee all the famous views
in Paradise!

(1934–40), an impressionistic monograph, well illustrated; RICHARD LANE, *Masters of the Japanese Print* (1962), includes a critical survey of Hiroshige's work, based on original sources; MINORU UCHIDA, *Hiroshige*, text in Japanese, with English index (1930), a comprehensive source work; JUZO SUZUKI, *Hiroshige*, text in Japanese, with English catalog of plates (1970), scholarly study of the basic Hiroshige materials, well illustrated.

(Ri.L.)

Histamine and Antihistamines

Histamine is a compound found in nearly all tissues of the mammalian body and in some plants and foodstuffs. It belongs to a group of substances called autocoids that are released from tissues during conditions of stress, inflammation and allergy. Other autocoids are serotonin, polypeptides, adenyl compounds, and prostaglandins. The term H-substance was once used to describe a material (found in extracts of mammalian skin) that was released under conditions of oxygen deficiency and injury and was thought to be responsible for local expansion of blood vessels (vasodilatation). It has now been established that H-substance is histamine.

Antihistamines are synthetically prepared compounds

that selectively counteract the pharmacological effects of histamine, following its release from certain large cells (mast cells). Antihistamines replace histamine at its active sites, thereby preventing histamine-triggered reactions.

General properties of histamine. *Chemistry.* Formed by the action of the enzyme histidine decarboxylase on the amino acid histidine, histamine is stored chiefly in tissue mast cells and blood mast cells (*i.e.*, basophils). It can also be prepared synthetically. Histamine readily combines with heparin (the anticoagulant); this complex is stable in water but not in the presence of negative ions. In most tissues, histamine is bound with heparin, in large granules of mast cells.

Physiology. The lung and gastrointestinal tract of most mammals contain relatively large amounts of histamine. There is, however, no simple relationship between the histamine content of a tissue and the ability of that tissue to form histamine, to destroy it, or to respond to it. The physiological importance of histamine remains unsolved. It is a potent activator of acid gastric secretion, and this may be its major role in mammals. It has also been identified as forming part of (1) a mechanism that affords protection, by localizing damage and assisting repair of tissues; (2) a process related to growth, increasing the availability of food and oxygen to developing tissues; and (3) a process involving pregnancy, contributing to the control of uterine movement and producing dilatation of fetal and maternal blood vessels. The presence of histamine in the hairs of stinging nettles of plants may also be protective since it is partly responsible for the swelling and itching produced by contact with *Urtica* leaves. It is also present in many insect venoms.

Possible roles in mammals

The release of histamines from lung mast cells causes local contraction of the smooth muscle cells and can result in asphyxiation. The smooth muscles of the uterus and intestine of most vertebrate species (the rat and mouse are exceptions) are very sensitive to histamine, which causes spasms of these muscles. Histamine, however, produces relaxation of vascular smooth muscle and a profound fall in blood pressure as permeability of the blood vessels increases and fluid passes from them into the tissues. The combination of vasodilatation and loss of circulating volume result in shock and collapse. These effects are often observed after injuries. Intradermal injections of histamine produce the "triple response"; *i.e.*, dilatation of skin vessels, increased permeability leading to edema, and dilatation of the surrounding arterioles. Histamine stimulates acid gastric secretion, probably by acting directly on the glandular secretory cells of the gastric mucosa; this is the only action of histamine that is not antagonized by antihistamines.

Histamine liberators

Certain chemicals are capable of releasing histamine from tissue stores, either by displacing it from the binding site or by damaging the mast cell membrane. Compounds that release histamine include snake and wasp venoms, certain enzymes, detergents, and a large group of chemicals (*e.g.*, amines, amidines, and guanidines). Histamine release may also follow the ingestion of foodstuffs (*e.g.*, fresh egg white, strawberries, and shellfish).

Following the injection of a foreign protein (termed an antigen) into an animal, compounds called antibodies are formed from blood globulins (see IMMUNITY). These circulate in the bloodstream and are absorbed by the tissues. If the same antigen is injected intravenously into such a sensitized animal three or more weeks later, the antigen combines with the antibodies, tissue mast cells are disrupted and their constituents (including histamine) are released. These events can lead to a condition termed anaphylactic shock. The effects of the second antigen injection are similar in many respects to those produced by an injection of histamine. An anaphylactic shock response may occur in a sensitized man after repeated ingestion of certain foods or treatment with drugs such as penicillin. Sensitization for certain antigens as manifested by allergy and asthma is related to the phenomenon of anaphylactic shock (see ALLERGY AND ANAPHYLACTIC SHOCK).

In the body histamine is changed to 1,4-methylhistamine, which is either excreted directly or deaminated (nitrogen is removed) by action of the enzyme histaminase before excretion. The product imidazolylacetic acid is excreted in the urine, usually combined with the sugar ribose.

General properties of antihistamines. Antihistamines oppose selectively all the pharmacological effects of histamine except those on gastric secretion. Development of antihistamines dates from about 1937, when French workers discovered compounds that protected animals against both the lethal effects of histamine and those of anaphylactic shock. The first antihistamines were derivatives of ethylamine; aniline-type compounds, tested later and found to be more potent, were too toxic for clinical use. However, in 1942, the forerunner of most modern antihistamines (an aniline derivative called Antergan) was discovered; then more potent, more specific, and less toxic compounds were prepared. More than 100 antihistaminic compounds soon became available for treating patients.

Since histamine is involved in the production of some symptoms of allergy and anaphylaxis, antihistamines can control certain allergic conditions, among them being hay fever and vasomotor rhinitis; the nasal irritation and watery discharge are most readily relieved. Persons with urticaria, edema, itching, and certain sensitivity reactions respond well. Antihistamines are not usually beneficial in treating the common cold and asthma. Antihistamines with powerful antiemetic properties are used in the treatment of motion sickness and vomiting. Used in sufficiently large doses, nearly all antihistamines produce undesirable side effects; the incidence and severity of the side effects depend both on the patient and on the properties of the specific drug. The most common side effect in adults is drowsiness; cerebral stimulation may occur in infants. Other side effects include gastrointestinal irritation, headache, blurred vision, and dryness of the mouth. If a patient does not improve after three days of treatment with antihistamines, it is unlikely that he will benefit from them. Antihistamines are readily absorbed from the alimentary tract, and most are inactivated by monoamine oxidase enzymes in the liver.

Historiography and Historical Methodology

Modern historians aim mainly at reconstructing an accurate record of human activities and at achieving a more profound understanding of them. This conception of their task is quite recent, dating only from the development in the late 18th and early 19th centuries of scientific history, cultivated largely by professional historians. It springs from an outlook that is very new in human experience: the assumption that the study of history is a natural, inevitable kind of human activity. Before the late 18th century, historiography (the writing of history) did not stand at the centre of any civilization. History was almost never an important part of regular education, and it never claimed to provide an interpretation of human life as a whole. This was more appropriately the function of religion, of philosophy, even perhaps of poetry and other forms of imaginative literature.

This article is divided into the following sections:

I. Historiography in the West

ANCIENT HISTORIOGRAPHY

Classical historiography. The older, pre-18th-century outlook has been particularly well studied in the historiography of the ancient Greeks and Romans. But, although two of the most important ancient historians, Herodotus and Thucydides, wrote as early as the 5th century BC, when recorded Greek historiography was only just beginning, they had few successors of comparable quality. It is a symptom of the relative lack of importance attached in antiquity to this type of activity.

Ancient history was a branch of literature. The most appreciated historians were the writers who, like Thucydides, were able to touch on universal human problems or who, like the Roman author Tacitus (died *c.* AD 120), wrote in a dramatic way about important events or who, at least, attracted readers by their excellent style and skill in composition. Many of the works that lacked some of these literary qualities failed to survive.

About 1,000 ancient Greeks wrote in antiquity on historical subjects, but most of these writers are mere names. Many of the losses appear to have occurred in antiquity itself. Even historians of first rank have fared badly. Only in a few cases have complete texts of all their writings survived. Of the voluminous history of Polybius (covering originally the period 220–144 BC) only about one-third survives. Nearly half of Livy's Roman history (originally covering the period 753–9 BC) is lost. The text that remains is reasonably good only through the efforts of a group of Roman aristocrats who, in about AD 500, were trying to salvage the chief glories of Roman literature. A considerable part of Tacitus is missing, and the surviving portions of his *Annals* and *Histories* (originally AD 14–96) derive from two unique manuscripts.

Herodotus, whom the Roman statesman Cicero called "the father of history," came from the western coast of Asia Minor. The writers who preceded him were mainly Ionians from the Greek settlements in the same area. The origin of Greek historiography lies in the Ionian thought of the 6th century. The Ionian philosophers were doing something unprecedented: they were assuming that the universe is an intelligible whole and that through rational inquiries men might discover the general principles that govern it. Hecateus of Miletus, the most important Ionian predecessor of Herodotus, was applying the same critical spirit to the largely mythical Greek traditions when he wrote, early in the 5th century, "the stories of the Greeks are numerous and in my opinion ridiculous." Herodotus was more of a traditionalist, but he introduced his work as an "inquiry" (*historia*).

Egyptian and Babylonian historiography

A glance at the older historiography of the Egyptians, the Babylonians, and the other peoples of the ancient Near East will heighten one's appreciation of the novelty of the task undertaken by Herodotus. The kings of Egypt, of Babylonia and Assyria, and of the Hittites and the Persians all sought to preserve their glorious deeds for posterity in monumental inscriptions. The more important rulers also accumulated large archives, including both ordinary administrative documents and records specially commemorating their achievements. Some 20,000 clay tablets remain from the collections written for Ashurbanipal of Assyria (668–627 BC). Both in Egypt and in Babylonia lists of kings were kept in the temples, and these were sometimes supplemented by brief annals recording the principal events, though the hatred felt by certain rulers for their predecessors led to periodic destructions of older material. The exceptional meagreness of the narrative sources for Babylonian history before 747 BC seems due to the obliteration of the older annals by Nabonassar of Babylonia (ruled 747–734). Apart from changes in literary style, there was surprisingly little development over a period of more than 1,000 years in all these types of commemorative records. The inscriptions and temple records were normally intended to perpetuate the glory of the gods in whose service these rulers had accomplished great deeds. The names and dates of dynasties and of particular rulers can be reconstructed fairly adequately with the aid of these sources, but it would be absurd to expect much accurate or even true information about particular events. Nor, with very rare exceptions, were the men who had access to this material interested in using it to write continuous histories.

Herodotus and his immediate Ionian predecessors shared a very novel outlook. Its distinctive features were a lively curiosity and a capacity to treat sources in a critical spirit. Boundless curiosity about people and their diverse customs is one of the most endearing traits of Herodotus. Like other Greeks from western Asia Minor, he was particularly stimulated by contacts with the great Persian Empire, which offered opportunities for reasonably secure travel. The resultant immense widening of historical perspective is illustrated by a story told by Herodotus about Hecateus. When the latter assured the Egyptian priests at Thebes that he could trace his descent through 16 generations, the Egyptians showed him evidence of the descent of their high priests through 345 generations. Herodotus was the first to link his geographic inquiries with true history. His descriptions of the barbarian world that confronted the Greeks provided an introduction to the epic of the successful Greek resistance to the Persians.

The types of history written by the ancient Greeks and Romans influenced profoundly all subsequent historiography down to the 18th century. In order to interpret sympathetically this classical historiography, it is necessary to bear in mind the literary conventions that governed this branch of literature. The ancient Greeks distinguished between history and biography. The origin of both forms can be traced back to at least the 5th century BC, and the differences between them were observed throughout antiquity. The writer of history was supposed to aim at giving a true story, but the purpose of biography was to praise and to edify. The biographer was entitled to treat historical personages in a manner that resembled legend rather than sober history. There existed, of course, some exceptions. The lives of the early Roman emperors written by Suetonius in the 2nd century AD, while conforming to the traditional, topical arrangement of biographies, constitute an unusually valuable historical source, especially for Augustus, whose correspondence is repeatedly quoted. Yet another distinction was drawn between history and the study of "antiquities," to use a term employed by Varro (116–27 BC), perhaps the greatest of all the ancient Roman scholars. This distinction was already implicit in Aristotle's contemptuous dismissal of history (in his *Poetics*) as a branch of literature dealing with the particular rather than with things of general significance. The histories he condemned provided chronological narratives of wars and political events. Aristotle and his disciples were engaged in several enterprises that they regarded as something quite different from history. For example, they embarked on the study of the constitutions of all the Greek states. Such work was to be based on systematic inquiries. The student of the "antiquities" tried to use a wider range of evidence than the sources normally consulted by the ancient historians, and he arranged his results systematically by topics.

Ancient biography

In antiquity a writer of history was usually preoccupied at least as much with style as with content. A generation before Aristotle, the rules of rhetoric, as they might be applied to history, were fully elaborated by Isocrates, a teacher of rhetoric at Athens. Cicero tried (especially in his *De oratore*, 55 BC) to familiarize the Romans with

these Isocratean precepts. History was to be written in a clear but solemn style, akin to fine oratory. The historian was to introduce all manner of literary embellishments but was also to stress the moral lessons of his story. At its worst this type of historiography could lead to serious misrepresentations of the past. Among the Roman historians, Livy (died AD 17) was an important practitioner of this kind of writing, which was particularly well suited to the patriotic myths that he was trying to immortalize, of a Rome that owed its magnificent destiny to the unique virtues of its citizens and the perfection of its antique institutions. Some outstanding historians, such as Polybius (2nd century BC) and Caesar (died 44 BC), eschewed these rhetorical precepts, but in all the ancient writers an important element of literary artifice was always present. This is one of the reasons why they offend modern standards, which demand absolute accuracy in the presentation of evidence. One of the most striking contrasts is the reluctance of the ancient historians to quote documents. Tacitus might rely heavily on the archives of the Roman Senate, but he never mentions his documentary sources. An inscription discovered at Lyons, France, preserves a speech delivered by the emperor Claudius to the Senate in AD 48, and it is clear that Tacitus utilized another version of the same text. His skill in using it is matched by the freedom with which he adapts it to suit his purpose.

The greatest and the most original achievement of the best Greek historians lay in their clear grasp of the need to distinguish truth from fiction and their conscious preoccupation with the methods of achieving this. This is admirably conveyed in a famous passage of Thucydides.

Methods of Thucydides

> And with reference to the narrative of events, far from permitting myself to derive it from the first source that came to hand, I did not even trust my own impressions, but it rests partly on what I saw myself, partly on what others saw for me, the accuracy of the report being always tried by the most severe and detailed tests possible. My conclusions have cost me some labour from the want of coincidence between accounts of the same occurrences by different eye-witnesses, arising sometimes from deficient memory, sometimes from deficient impartiality.

His practice did not fully live up to this ideal, however. The greatest of his Greek successors, Polybius, is reasonably impartial, except in his treatment of some of the events in Greece. Among the Romans, the writing of history was chiefly the preserve of members of the senatorial class, who almost invariably had some personal axes to grind. But the correctness of the rules formulated by Thucydides was accepted, in principle, by most ancient historians.

Thucydides had deliberately restricted himself to the history of his own time, and many of the subsequent ancient historians did likewise. They could depend on their own experience or could question well-informed contemporaries. The surviving fragments of Livy relating to his own lifetime (64/59 BC–AD 17) are much more vivid and convincing than the earlier books of his history (surviving today only down to 167 BC). The tendency to prefer contemporary history was strengthened by the practical bent of many of these writers. Several ancient historians were men of action familiar with warfare and politics. Interested in history as a source of instruction for statesmen, they could write with authority only about wars and political transactions of their own time. Polybius, the exiled Achaean general and a great traveller, derides unpractical, sedentary historians such as Timaeus, who had been writing about the peoples of the western Mediterranean without stirring for 50 years from Athens.

The historians of antiquity were much less skillful in dealing with noncontemporary history, for which they relied on older historians. Where none was to be found, they felt lost, as Livy complains in the early portions of his Roman history. The modern recourse to non-narrative sources was alien to the habits of most ancient historians. They were usually incapable of doing this successfully, just as they were ill equipped to discuss critically the sources used by the older writers.

Herodotus chose for his theme the successful resistance of the Greeks against the Persians at the beginning of the 5th century BC. Thucydides wrote about the Peloponnesian War, in which virtually all the Greek states became involved in the last decades of that century. These were limited subjects of obvious importance for which it was possible to find ample evidence. The strength of the ancient historians lay precisely in imposing an interesting pattern on the events of a selected period, usually contemporary or fairly recent, for which they had manageable sources. The best of them could thereby achieve a sense of dramatic unity and produce literary masterpieces. The speeches that Thucydides invented for some of the main protagonists in his story are artistically the most satisfying parts of his work, and at times they even seem to recapture the spirit of what might have been said on these occasions. In a superb writer like Tacitus, whose political career had included long periods of frustration and insecurity, one does not look for impartiality or for scrupulous truthfulness but, rather, for fascinating insights into what the development of Roman imperial power from Augustus to Domitian (the period AD 14–96) meant to the proud, sophisticated Roman aristocracy for whom he was writing.

Classical study of "antiquities"

The study of "antiquities," as opposed to narrative history, did not normally produce works of literary merit, and this is probably the main reason why most of them disappeared. One important group of such writings originated with Aristotle and his collaborators, writing in the third quarter of the 4th century BC. They were interested in both literary "antiquities" and in the systematic study of the constitutions of Greek states. They had described 158 different constitutions, though only their account of Athens now survives. A comparison of its two main parts illustrates the contrast between the deficiencies of ancient historiography and the impressive achievements of the antiquarian researchers. In the introductory, historical section, Aristotle was baffled by the problem of dealing with the fairly remote past. For each particular period he tried to follow some contemporary sources. The resultant juxtaposition of several writers differing widely in their political outlook produced an account full of contradictions. The second part, however, containing a systematic description of the Athenian constitution, is a masterpiece of shrewd analysis, as are the empirical portions of Aristotle's *Politics* (Books IV–VI), which are based on a wealth of concrete examples derived from the different Greek states.

Aristotle inspired in the 3rd and 2nd centuries BC a great mass of philological and antiquarian research. The most important scholars were to be found in the new Hellenistic states, especially at Alexandria in Egypt and at Pergamum in Asia Minor. Among the surviving Hellenistic fragments, there are commentaries on Herodotus and Thucydides. The Hellenistic scholars were interested in many subjects connected with history and did pioneering work in chronology, geography, and topography. They were accustomed to using every kind of source and to quoting documents extensively. Their greatest Roman disciple was Varro, who tried to recover all the vestiges of the old Roman society and to make a systematic survey of Roman life based on the evidence provided by language, literature, religion, and ancient customs. Most of his writings have been lost, but he supplied the conjectural (though incorrect) date of 753 BC for the foundation of Rome and knowledge of the probable boundaries between some of the groups whose union produced the city of Rome. Unfortunately, antiquarian researches of such penetrating nature were almost never applied in antiquity to the writing of narrative histories.

Early Christian historiography. The triumph of Christianity in the Roman Empire during the 4th century assured the predominance of a type of historiography radically different from the works of the pagan Greek and Roman historians. Its origins were Jewish. The Jews were the only people of antiquity who had the supreme religious duty of remembering the past because their traditional histories commemorated the working out of God's plan for his chosen people. By contrast, no Greek ever heard his gods ordering him to remember. It was the

Purpose of Jewish histories

duty of every Jew to be familiar with the Jewish sacred writings, which were ultimately gathered into what became the Old Testament. The writers of these biblical books only gave an authoritative version of what everybody was supposed to know, and they were only concerned with the selection of such facts as seemed relevant in interpreting God's purpose. In addition, the Jews also cherished unwritten traditions. To quote Josephus, a Jewish historian of the 1st century AD, "what had not been written down, was yet entrusted to the collective memory of the people of Israel and especially of its priests."

The Christians took over the Old Testament and added to it an additional body of sacred history. The writers of the four Gospels included in the New Testament were bearing witness to assured truths that the faithful ought to know, and no convincing reconstruction of historical facts is possible from these books of the New Testament. The only avowedly historical book in it is the Acts of the Apostles. The New Testament as a whole represents merely a selection from the early Christian writings. It includes only what conformed to the doctrine of the church when, later on, that doctrine became fixed in one form. Between the Acts of the Apostles, dating probably from the late 1st century, and the writings of Eusebius of Caesarea (died *c.* 340) and his contemporaries in the first quarter of the 4th century, there is an almost complete gap in Christian historiography.

For the Christian writers the story of Jesus, as recorded in the Gospels, represented the fulfillment of the prophecies that could be found in various parts of the Old Testament. The Jewish part of the Bible also assured for Christianity the authority of a long antiquity. The history contained in the two parts of the Bible, now indissolubly linked together, became the only authentic record of God's revelation for mankind, dwarfing into insignificance all the records of other peoples and religious groups. The concept of a universal history had not been wholly unknown to the pagan world, but the Christians were the first to apply it effectively. Christian history had to be a universal history, though of a very peculiar sort, where only one sequence of privileged events, Jewish and Christian, deserved detailed record. The Christian claims must have seemed more extravagant to the pagans than even the Jewish ones. Thus Eusebius stated that the Christians were, in fact, born with the world, anticipating St. Augustine's vision of the city of God existing since the beginning of time.

In defending their religion against hostile critics, the early Christians were forced to fit some pagan history into their universal scheme. This was achieved by means of universal chronologies from the creation of the world to each writer's own time. The events of Jewish and Christian history were thus synchronized with the main dates of the pagan myth and history. Sextus Julius Africanus, who wrote in the early 3rd century, is the first Christian writer known to have attempted this feat. He allotted 6,000 years to the whole span of human history and placed the birth of Christ in the year 5500 from the creation of the world. This work provided the model for the more elaborate *Chronographia* (*Chronicle*) of Eusebius. It became the foundation for a long succession of Greek chronographies produced by Byzantine writers. A Latin adaptation by St. Jerome (died 419/420) was immensely influential in western Europe for more than 1,000 years. A modern scholar is filled with mingled admiration and despair at the ingenuity of Eusebius and of his more eminent successors and at the absurdity of many of their conclusions. But they did originate and impose on the world a unified scheme of universal chronology. The dating from the birth of Christ was introduced by Dionysius Exiguus, who wrote at Rome in the early 6th century, and it was successfully popularized in the 8th century by the English historian Bede.

Universal chronologies

The writing of history of their own time was not an essential task for the Christians of the 4th and 5th centuries. When they did so, they wrote primarily in defense of their religion against the pagan world or against rival Christian groups branded as heretical. All these histories belong to religious apologetics. They suffer from inevitable distortions in the choice of what should be mentioned and what must be suppressed, and they are often excessively unfair to outsiders and opponents. These faults were not uncommon among the classical historians, though the Christians were somewhat unusual in their extreme conviction that they alone must be right. A comparison between the Christian historians and an outstanding pagan writer, such as Ammianus Marcellinus (second half of the 4th century), who was very ready to admire those Christians who merited it, brings out the intolerance and narrowness of outlook of his Christian contemporaries.

Eusebius was the earliest and the most important of the Christian historians of the 4th century. He is quite frank about the practical and apologetic aims of his *Historia ecclesiastica* (written 312–324; *Ecclesiastical History*) designed to show how, through a long series of acts of Divine Providence, a Christian empire was finally brought into existence by Constantine. He admits that "we shall introduce into this history in general only those events which may be useful first to ourselves and afterward, to posterity." This work, like his other historical writings, is a mixture of devout fiction and invaluable detail. But there is plenty of the latter in *Ecclesiastical History*. Contrary to the usual practice of the ancient historians, Eusebius tries to specify his sources, and he quotes from them extensively in order to document as fully as possible the developments that resulted in the triumph of Christianity. He provided in this respect a valuable model for his medieval successors. The most astonishing thing about Eusebius was his capacity to handle his sources critically, in matters where it seemed permissible to do so. In one passage of his *Chronicle* he sets aside the authority of St. Paul in favour of a piece of evidence contained in the Book of Judges. In later patristic literature nothing similar is found.

Biography, as it was habitually written in antiquity, could be readily adapted to Christian purposes. St. Jerome modelled himself on Suetonius in compiling the lives of 135 Christian writers (written in 392) as a way of demonstrating the high level of culture attained by his co-religionists. The ancient biographers had freely mingled fact with fiction for the edification of their readers and could be readily imitated by the writers of the lives of Christian saints. The life of St. Anthony of Egypt by St. Athanasius (mid-4th century) set the pattern for this most popular type of medieval literature.

St. Augustine

St. Augustine, the greatest of the Latin Church Fathers of the 4th and 5th centuries, was certainly not concerned with writing of history in any ordinary sense of the term. In his *De civitate Dei* (*City of God*) he might invoke historical evidence to demonstrate the utter degradation of all the non-Christian societies, and he encouraged his pupil Orosius to develop this theme more fully in the latter's *Historiarum libri VII adversus paganos* (*Seven Books of History Against the Pagans,* to 417). Nearly 200 manuscripts of Orosius have survived, testifying to the immense popularity of his work in the Middle Ages. Augustine's greatest influence on historiography lay in his main message. His vision of the divine and the earthly cities confronting each other dominated the outlook of all the medieval Christian thinkers and profoundly affected their treatment of history. Within that divine plan for the world, purely secular history seemed an insignificant thing.

HISTORIOGRAPHY IN THE MIDDLE AGES

The 5th to the 11th century. The period stretching from the 5th to the 11th century was a time of very profound cultural decline in regions that had once constituted the western half of the Roman Empire. Almost all the inhabitants of these provinces again became illiterate. There are long periods for which there are virtually no narrative sources, and the bulk of surviving historical writings consists merely of meagre factual annals. Virtually all the writers were ecclesiastics, in marked contrast to the Byzantine lands, where a strong tradition of lay historiography persisted throughout the Middle Ages.

The annalists and chroniclers of the West were predominantly monks, and their lack of experience of the secular world outside their cloisters made them into blinkered and unpractical historians. This was true even of Bede, an Anglo-Saxon monk, who was by far the greatest historian of the early Middle Ages.

All the historians of this period were seriously affected by the cultural decline around them. They were having to write in part for a more uncultured audience. Sulpicius Severus, probably the best Western historian of the early 5th century, still intended his *Chronica* (to 403) for educated Roman Christians, but his life of St. Martin of Tours is a piece of medieval hagiography. This model could inspire lives full of folklore and miracle, from which the real human personalities of the saints were almost wholly absent. The same duality of purpose is a notable feature of Bede's voluminous writings. He explicitly recognized that he must adapt himself to his audience when he explained that he was writing in a simple Latin style so that he might be more easily understood by his Anglo-Saxon readers. There is a marked contrast of tone between his theological and his historical writings. As a theologian, Bede follows Eusebius and the earlier Church Fathers in not exaggerating the frequency of miracles and in believing that they were most common in the earliest days of Christianity. But Bede's lives of the English saints and his *Historia ecclesiastica gentis Anglorum* (*Ecclesiastical History of the English People*), covering chiefly the years 597–731, are full of miracles and visions. There is one or other on almost every page. It is possible that some of these incidents were included by Bede because he thought that his readers expected mentions of these familiar, traditional stories.

Bede's *Ecclesiastical History*

In preparing his historical works, Bede not only took great care to assemble the widest possible collection of sources but also tells the reader what he is using. In dedicating his *Ecclesiastical History* to King Ceolwulf of Northumbria, he requests that

> in order to remove all occasions of doubt about those things I have written, either in your mind or in the minds of any others who listen to or read this history, I will make it my business to state briefly from what sources I have gained my information.

An impressive list follows, including mentions of documents copied for him by friends at Rome, Canterbury, and other places. Like Eusebius, on whom Bede modelled himself, he quotes some of the documents integrally. Bede's methods of securing and recording information are so similar to the practices of modern historians and the judicious tone of his writing is so impressive that the reader is almost taken in into treating him as if he were a modern scholar. But Bede's *Ecclesiastical History* was written as a work of edification in order to strengthen the faith of his readers in Divine Providence, through which, as he saw it, his Anglo-Saxon countrymen had been converted to Christianity. All matters not connected with his main theme are ignored. Bede's handling of evidence on subjects that he regarded as embarrassing inspires mistrust. But these are small matters in comparison with the enormous mass of information that he alone has preserved and the encouragement that Bede continued to give for many centuries to the writing of history.

The influence of Bede and other Anglo-Saxon scholars was greatly felt during the later 8th and the 9th centuries in the Frankish kingdom, where under Charlemagne and his successor, Louis the Pious, there was a modest revival of historical writing. Besides the annals kept at various monasteries, which tended to convey information in a manner that suited the Frankish rulers, there were a few more ambitious ventures. The important *Historia Langobardorum* (*History of the Lombards*), written *c.* 774–785 by Paulus Diaconus, or Paul the Deacon, was the work of one of the best educated men of the time. Nithard, a grandson of Charlemagne, left an invaluable narrative of the disintegration of the Carolingian state during his lifetime. The work that exerted the greatest influence on the medieval writers of biographies was Einhard's *Vita Karoli imperatoris* (written 817–830; *Life of Charlemagne*). The author was a leading official and a close companion of Charles, and his work was naturally intended as a eulogy of the great king. Einhard says that Charlemagne retreated safely from Spain, returning with his army safe and sound, except that on a ridge of the Pyrenees, on the way home, he happened to experience some small effects of Gascon perfidy. Nobody would gather from this that the Franks had narrowly escaped a major disaster. Einhard was merely echoing the story told in the semi-official contemporary annals. Another source of distortion was Einhard's use of a classical model, the *Lives of the Caesars* by Suetonius. The subject headings under which he described Charles and even the very words used were partly borrowed from the lives of Roman emperors, but his Charlemagne is probably in essentials an authentic and credible portrait.

If bulk alone is to be taken as a criterion, annals were the main product of medieval historiography. The annalist merely sets down the most important events of the current year. In the case of the earliest medieval annals, the events were often noted down in Easter tables, in the blank spaces between the dates calculated for the forthcoming Easters. Such paschal annals would be extremely brief. When, as often happened, annals came to be written down in separate manuscripts, distinct from the Easter tables, there was room for the expansion of individual entries. In either case, the resultant annals cannot be regarded as history since the events are necessarily recorded in isolation. But they preserve in a right order the essential facts, which could be rearranged into a continuous narrative. Such a narrative, if it still followed the chronological arrangement of its various annalistic sources, should properly be termed a chronicle.

Medieval historians show little awareness of the process of historical change. They were unable to imagine that any earlier age was substantially different from their own. The unawareness of the meaning of anachronism helps to explain the strange wanderings of medieval annals and chronicles. If a religious community wanted to acquire a historical narrative, it copied some work that happened to be most readily accessible. A continuation might then be added at the manuscript's new abode, and, later on, this composite version might be copied and further altered by a succession of other writers. Hence there are at least six main versions of the annals known as the *Anglo-Saxon Chronicle*. They all derive from the annals kept down to 892 at Winchester, the West Saxon capital. Thereafter, copies were acquired by religious centres in the most diverse parts of England, and one manuscript was being kept up to date at the abbey of Peterborough as late as 1154. An extreme case of wanderings is represented by the annals of the cathedral church of Cracow, the medieval Polish capital. The first section is based on Orosius, the next comprises annals beginning with the death of Bede and containing notices of Frankish and German events, while the Polish section starts with the conversion of Poland to Christianity (965–966) and ends in the 13th century.

The *Anglo-Saxon Chronicle*

The 12th, 13th, and 14th centuries. Historians are accustomed to regarding the late 11th and 12th centuries as an age of intensified progress in culture and learning; this development, however, did not greatly affect historiography. There was a modest revival of interest in some of the ancient Latin writers, but would-be historians were unsure which ancient models they ought to imitate. A whole series of attempts was made to apply to other races the theme in Virgil's *Aeneid* of a noble group of people guided by the gods toward a splendid destiny. The first essential step was to establish the descent of one's nation from the ancient Trojans and then to trace subsequent history through a series of heroic conquests. The most ambitious of these writings was the *Historia regum Britanniae* (*History of the Kings of Britain*), by Geoffrey of Monmouth (died 1155), which attempted to establish for the Celts a historical destiny greater than any other. Although some, even contemporary, readers were not deceived by the work, and William of Newburgh, one of the best English historians of the 12th century, denounced it as a tissue of absurdities, many seriously accepted it as history.

With a few exceptions, the ablest minds of the 12th century were attracted into enterprises that ignored history; they were more concerned with systematization of thought and with philosophical speculations. One of the exceptions was Otto, bishop of Freising, in Bavaria. He was a grandson of the Holy Roman emperor Henry IV. He received the best education that his age could give, but he was also briefly a Cistercian monk during the most austere period of that order's history. Otto was torn between conflicting impulses to seek the city of God as the only reality and yet to hope for the progress of the German empire. Out of this conflict came his first work, *Chronica* (*The Two Cities*), a chronicle of world history to 1146, perhaps the most profound medieval attempt at a Christian philosophy of history. As Otto himself confessed, it was composed "in bitterness of spirit . . . in the manner of tragedy." The election in 1152 of his nephew and friend Frederick Barbarossa, as emperor, filled Otto with a new elation. The excellence of his second work, *Gesta Friderici I imperatoris* (*The Deeds of Frederick Barbarossa*), derives in a considerable measure from a quality rare in medieval historians, a sense of optimistic belief in the value of writing history because it might become a record of human progress. *The Deeds of Frederick Barbarossa* contains a penetrating analysis of the problems encountered by the German rulers in trying to rule the precociously urbanized Italian society.

The works of Otto of Freising

As in antiquity, the best medieval works were accounts of contemporary history by men who had participated in the events that they were describing. It is, however, very significant that some of the writers that are prized most highly today survive in only very few manuscripts and were presumably not appreciated by most of their contemporaries. One such work was the *Historia pontificalis* ("Pontifical History") covering the period 1148–52, of John of Salisbury, one of the most accomplished scholars of his age, who was writing about the period when he was in the papal service. Another instance of undeserved neglect is furnished by the *Liber de regno Siciliae* ("Book of the Kingdom of Sicily") covering the period 1154–69, written by an anonymous member of the Sicilian court.

Unlike the ancient historians, the medieval writers of contemporary history had no inhibitions about extensively quoting official documents. In England, a succession of writers preserved a large quantity of such texts. Roger of Hoveden was, in the last quarter of the 12th century, treated by the English kings as a kind of court historian. He preserved valuable legal and administrative records with which he was familiar through his activities as a royal official and justice. Matthew Paris, the most important English monastic historian of the 13th century, was highly regarded by King Henry III and had excellent sources of information. He left behind a collection of transcripts of royal and ecclesiastical documents that today fills a large printed volume. Some writers made their chronicles into an anthology of official records, thinly connected by the author's brief comments. Such is the chronicle of Robert of Avesbury, consisting mainly of the military dispatches of King Edward III and other interesting documents to 1356. Another variant of the same method was for a wholly mediocre chronicle to incorporate exciting pieces of eyewitness narratives by other writers. A dull English monastic product of the late 14th century, the *Anonimalle Chronicle*, includes a narrative of the Peasants' Revolt of 1381, which is one of the most dramatic and interesting eyewitness accounts to be found in medieval historiography.

The most popular histories of the 13th and 14th centuries were encyclopaedic compilations giving all the important facts neatly arranged under the dates of popes, emperors, and other rulers. There were even more ambitious ventures aiming at summarizing all the important facts from all the different branches of human activity. The Dominican Order, created at the beginning of the 13th century, was especially concerned with producing such aids for the dissemination of useful knowledge. The best known of these Dominican works is the immense *Speculum historiale* ("Mirror of History"), by Vincent of Beauvais, written under the patronage of King Louis IX of France. It is a compilation made up of excerpts from many authors.

The 13th and 14th centuries were not a period of any fundamental innovations in the techniques and nature of historiography, but there was a growing diversity of types of historical writing. Very detailed, chatty narratives multiplied, often badly organized and inaccurate, but conveying the authentic atmosphere of the times and vividly portraying leading personalities. Such were the St. Albans chronicles of Matthew Paris (to 1259), the reminiscences of Joinville about St. Louis during the Seventh Crusade (1248–54), the Lombard chronicle of Fra Salimbene (to 1287), or the vast history of the first part of the Hundred Years' War written in the second half of the 14th century by Froissart. Memoirs and histories written in vernacular languages, such as those of Joinville and Froissart, came to be quite common. Laymen began to write histories. Some were great men, like Geoffroi de Villehardouin, one of the leaders of the Fourth Crusade (which captured Constantinople 1202–04), of which he wrote an account. Important urban chronicles began to appear, such as the Florentine chronicle of Giovanni Villani, with its invaluable statistics of Florentine population and activities around 1338. The extraordinary personality of St. Francis, who died in 1226, inspired lives of him more convincingly human than any previous medieval biographies of saints.

Vernacular histories

The Humanist historians of the 15th century tried to make a deliberate break with the tradition of medieval historiography. By their insistence on a more coherent arrangement of subject matter, by their superior critical outlook, and, above all, by their much more accurate awareness of the process of historical change, they had introduced innovations of fundamental importance. In part they owed their grasp of these new possibilities to the influence of Byzantine scholars. In historiography, as in other matters, the new humanistic scholarship was a joint product of Western and Byzantine traditions.

BYZANTINE HISTORIOGRAPHY

During the millennium that elapsed between the collapse of the Roman Empire in the West in the 5th century AD and the Italian Renaissance of the 15th century, in no part of Europe did the writers of history consistently maintain as high a standard of achievement as in the Byzantine Empire. Parts of the 7th and the 8th centuries form lengthy gaps in the record of Byzantine historiography, but this seems mainly to be the result of subsequent losses of manuscripts. When, in the middle of the 9th century, Photius, future patriarch of Constantinople, compiled a record of some 280 books that he had read, he mentioned works of 33 Greek historians, dating mostly from the late Roman Empire and the Byzantine period, 20 of which are now lost. But, among the Byzantines of the 7th and 8th centuries, there was certainly no parallel to the Dark Ages in western Europe.

The Byzantine historians were heirs to the combined traditions of classical Greek writing, of the subsequent Hellenistic historiography, and of the Christian historical writing of the 4th century. Few ancient Latin historians were ever translated into Greek, and their influence on the Byzantines was, therefore, very slight. The older classical Greek historians provided the Byzantines with their cherished models of language and style. Like all educated Byzantines, the historians continued for a millennium to write in a literary language that soon became unintelligible to the vast majority of their compatriots. Hence, from the 6th century onward, there appeared, side by side with the learned historiography, a succession of popular chronicles written in the ordinary language. Most of these popular writings form—in their prejudice, ignorance, and crudity—a startling contrast to the works of the more eminent classicizing historians, but they do provide valuable glimpses of the sort of hagiographical history, more religious myth than sober fact, that ordinary Byzantines apparently wanted to read.

Sources of Byzantine historiography

Herodotus and Thucydides were frequently invoked by

Byzantine historians as models of fine prose. The influence of these two writers on the substance of what was written usually remained slight and superficial, however. The only Byzantine writers who seriously modelled themselves on these two oldest Greek historians wrote during the 15th century. The earlier Byzantine historians owed most to Polybius and to the Greek biographer Plutarch (died *c.* AD 119), the two Hellenistic writers who had the greatest influence on Byzantine notions of how history and historical biography should be written.

Like Polybius, the majority of Byzantine historians, including most of the best ones, preferred to write about their own times; and within these limits they produced some real masterpieces. Unlike the majority of the ancient historians, Polybius had included much autobiographical detail, and his influence reinforced the readiness of the Byzantine historians to talk about themselves, thus providing abundant information about several of these authors. Their histories are likely to be one-sided and full of details about what interested them, while remaining silent about a great mass of other contemporary happenings. They are frequently gossipy and patently prejudiced, inspiring much less confidence than the austere, impartial writings of authors such as Thucydides. This is one of the main reasons why the Byzantine historians have often been excessively underestimated by modern readers. The bulk of the Byzantine contemporary histories were written by statesmen, high officials, and prelates—men with access to important information. They have to be used critically and cautiously but can be immensely valuable.

Priscus of Panium (*c.* 450), a member of a Byzantine embassy to Attila's camp, is the best source of information about that terrible king of the Huns and his followers. A century later, the reconquest of Vandal Africa and of Ostrogothic Italy by the emperor Justinian was the main theme of the *History of the Wars* of Procopius, a leading civilian adviser of Belisarius, the Byzantine commander. Subsequently, Procopius also wrote a *Historia arcana* (*Secret History*), containing a horrible indictment of the activities of Justinian and Belisarius. Many of his details about the corruption at court and the oppressive nature of the government may be substantially correct. In the 11th century Michael Psellus, who wrote a history of his own times, was a leading Byzantine scholar and official, for a time even the chief adviser of emperors. His *Chronographia* is concerned almost entirely with the happenings at the Byzantine court and is one of the most gossipy and amusing narratives ever written on such a subject. His psychological insight and his lively and subtle style delighted the educated Byzantines. Anna Comnena, the daughter and biographer of the emperor Alexius I, greatly admired Psellus. Her own *Alexiad* is a much less fascinating work, but the recovery of the Byzantine power under her father provided her with an important theme.

Procopius' histories

The last, increasingly disastrous, centuries of Byzantine history are recorded by a series of scholarly and interesting historians. Nicetas Acominatus, a high imperial official, provides a surprisingly balanced eyewitness account of the siege and capture of Constantinople by the forces of the Fourth Crusade (1202–04). George Acropolites, a leading adviser of the Greek emperors of Nicaea, carries the story from 1203 to the recapture of Constantinople by the Byzantines in 1261. The later 13th and 14th centuries are covered by a succession of writers deeply immersed in contemporary theological disputations. Perhaps the most readable of all Byzantine histories is the largely autobiographical work of the leading politician and emperor John VI (reigned 1347 to 1354), written after his deposition during his years of enforced retirement in a monastery. George Sphrantzes, a close friend of the last emperor, Constantine XI, included in his history an eyewitness account of the siege and capture of Constantinople by Mehmed II in 1453. Two of Sphrantzes' contemporaries chose to write primarily about the Turks. Their methods place them among Renaissance historians. Laonicos Chalcocondyles wrote (in about 1464) an account of the rise of the Turkish state. He did so in the manner of Herodotus, with long digressions on various neighbouring nations. A little later, Critobulos of Imbros, in his account of the Turkish conquest of Constantinople, made Mehmed II his chief hero and modelled his history on Thucydides.

The study of what might be called "historical antiquities" was not much cultivated by Byzantine scholars. The most notable exception was the emperor Constantine VII, but only some fragments of his voluminous collections have survived (dating from about 940 to 959). They include a very interesting account of the various peoples with whom the Byzantines had to deal. Such ancient Greek literature as still survives, including that of all the historians, was preserved by the Byzantine scholars. When, around the year 1400, the teaching of Greek was introduced into Italian universities by Byzantine scholars, they brought also their superior techniques of literary scholarship, transforming thereby the study of Latin authors as well as introducing into western Europe the treasures of Greek literature. One result was the emergence of the new Renaissance historiography.

HISTORIOGRAPHY IN THE RENAISSANCE

If there is one thing that united the men of the Renaissance, it was the notion of belonging to a new time. Lorenzo Valla, one of the ablest of the early Humanists, in a preliminary draft of his history of King Ferdinand I of Aragon (written in 1445–46), proudly enumerates the modern technical inventions made in recent centuries, and especially near his own day. The sense of the novelty and excellence of their achievements was particularly felt by the men of the Renaissance in connection with their attempts to imitate the works of the ancient Greek and Roman writers and artists. They were not yet claiming that an era of unlimited progress was dawning for mankind—such concepts belong to the 18th century—but the belief in the progressiveness of their own age soon spurred the best Renaissance scholars and artists into achievements that, in some important respects, surpassed their ancient models. This happened in historiography, and especially in the sciences connected with it. The pace of change must not be exaggerated, however. Despite promising beginnings, historiography as a systematic discipline did not emerge during the Renaissance and, in fact, this development did not occur until the 19th century. The reasons for this delay form one of the main problems in any study of historiography between the years 1400 and 1800.

In the early Renaissance one by-product of the newly won sense of modernity was the tendency to regard the millennium between the collapse of the Roman Empire in the West and the 15th century as an era of prolonged decline. The concept of the Middle Ages was thus introduced for this intervening period. Two very important histories written in the first half of the 15th century deliberately concentrate on the medieval centuries. Their authors were leading Italian Humanists. The first to appear was the *Historiae Florentini populi* ("History of Florence") of Leonardo Bruni, the city's chancellor from 1427 to 1444. The second, the *Historiarum ab inclinatione Romanorum imperii decades* ("Decades"; mainly devoted to Italy) was written by Flavio Biondo, an important papal official. It covered the period from the sack of Rome by Alaric in AD 410 to the writer's own time. The "invention" of the Middle Ages as a separate historical period remains one of the most enduring legacies of Renaissance historiography.

Denigration of the Middle Ages

Unlike the medieval historians, the Renaissance Humanists became much more acutely aware of the process of historical change. This was a gradual development. They were trying to understand the ancient writers, whom they were seeking to emulate, and they became increasingly aware of the need to replace these writers in their correct historical setting. When Petrarch (1304–74), the pioneer Italian Humanist, unearthed in 1345 a collection of Cicero's letters, he was shocked to discover that Cicero was not a cloistered scholar of the medieval tradition but a busy politician who wrote his dialogues in moments of banishment from active life. In 1361, in a

letter to the Holy Roman emperor Charles IV, Petrarch was able to use his increased familiarity with classical documents to expose a medieval forgery of the Austrian archduke masquerading as a charter of Julius Caesar.

Between about 1440 and his death in 1457, Valla was one of the most influential Humanists. His *Elegantiae linguae latinae* (1444; "Elegancies of the Latin Language") was a treasury of information about correct Latin usages. For Valla the meaning of words was not natural but conventional and historical, because it was derived from changing custom. Thus a sense of ceaseless historical evolution was planted at the very centre of Humanist preoccupations with the recovery, the correction, and the interpretation of ancient texts.

In 1440 Valla's patron, King Alfonso of Naples, at war with the papacy, asked Valla to write some treatise against Pope Eugenius IV. Valla obliged by decisively disproving, on both linguistic and historical grounds, the genuineness of the "Donation of Constantine." From the middle of the 8th century, when this document was probably concocted, it had been used by the popes as one of the weightiest justifications for their claims to secular authority in Italy. Its authenticity had been sometimes questioned in the past by some of the acutest minds, such as Bishop Otto of Freising in the 12th century and Marsilius of Padua in the first half of the 14th century, but it required Valla's expert techniques to dispose of the "Donation" forever. The validity of Valla's methods of historical criticism was at once recognized by at least one other leading Humanist. Biondo wrote the relevant portions of his "Decades" of papal and Italian history between 1440 and 1443, while remaining in the service of the very same Eugenius IV who had been the chief object of Valla's attack. Yet Biondo tacitly accepted Valla's conclusions, and he never mentions the "Donation of Constantine." Biondo's critical outlook found still another expression in his summary dismissal of the fabulous history of Geoffrey of Monmouth. In his copy of Geoffrey he entered only a single note: "I have never come across anything so stuffed with lies and frivolities."

Historical philology

Valla's work on the texts of the New Testament proved in the long run to be one of the most influential applications of the new science of historical philology. His aim was to recover, so far as possible, the original Greek version through the use of the oldest extant manuscripts. He defended these researches by pointing out that he was not correcting the Holy Scriptures but merely the Latin Vulgate translation of St. Jerome that had been adopted by the Catholic Church. The revolutionary nature of Valla's historical approach comes out most strikingly in his comment that "none of the words of Christ have come to us, for Christ spoke in Hebrew and never wrote down anything." The corrections assembled by Valla became generally known when, in 1505, Erasmus published them as *Annotationes* on the New Testament. They provided a model for Erasmus' edition of a Greek New Testament in 1516, from which stem all the new Protestant versions of the 16th century.

The new historical philology was also soon applied to the study of philosophical and legal texts. In this, the most striking progress was made in the second half of the 15th century by Politian, who lectured at Florence, and by his friend Ermolao Barbaro, who taught at Padua. They were inaugurating the history of ideas and of intellectual movements. In his studies of Aristotelian texts, Barbaro insisted on using only the commentators of antiquity. In his lectures and writings (1489–94), Politian tried to re-establish from internal evidence the correct sequence of Aristotelian treatises, and he traced the gradual liberation of Aristotle's thought from the influence of Plato. The meaning of the terms used by Aristotle was rigorously investigated in the light of the linguistic usage of his Greek contemporaries. Politian's ventures into the field of legal texts proved particularly influential. He had at his disposal a very good 6th-century version of the Digest—that is, the section of Justinian's Corpus (body of civil law) based on the rulings of the Roman jurists. Politian's collation of it with the first printed edition of the Digest (in 1490) formed part of an inquiry into the transmission of the texts of the Roman law during the Middle Ages. Politian's researches stimulated a remarkable school of Humanist jurists, mostly Frenchmen, headed by Guillaume Budé, who published the first historical commentary on the Digest in 1508. In the course of the 16th century, these scholars laid the foundations of a new branch of scholarship, the history of laws and institutions.

The methods of textual criticism used by Politian and his friends were designed to produce definitive editions of classical texts. Politian was aware of the need to establish the correct descent of manuscripts and to disentangle the best textual tradition. In all this he was far ahead of almost all his contemporaries, and he was anticipating the procedures that were systematically adopted for the first time by Karl Lachmann and other German scholars in the 19th century. The historical philology of Politian was a program for the future rather than a dawn of a new era in the editing of classical texts. In contrast to his methods, most of the other Humanist editions of the Latin and Greek classics are very unsatisfactory. This is particularly true of the editions produced between about 1400 and 1550. The reckless emendations of Humanist editors, coupled with the subsequent disappearance of some of the manuscripts used by them, created grave problems for later scholars. Ever since the 17th century the task of the more modern editors has consisted largely in reconstructing, so far as possible, the manuscript versions available before 1400.

Modern historiography was created in the 19th century through a successful combination of the use of narrative sources with every other type of evidence. Some 15th-century Italian Humanists were already aware of these possibilities. The idea of recovering an entire civilization through a systematic collection of all the relics of the past was not alien to them. Biondo used mainly conventional narrative sources for his "Decades" of Italian history, but his description of the city of Rome in antiquity (*Roma instaurata*, 1444–46) was based on a novel combination of the narratives of other historians with a wide range of miscellaneous sources. These included topographical guides, public and private documents, studies of surviving buildings, inscriptions, and coins. But in practice most histories and biographies continued to be written in a conventional way, while the revived study of "antiquities" was cultivated in separation from narrative historiography.

Biondo's description of ancient Rome

Imitation of ancient models is the feature most often stressed in the modern descriptions of Humanist histories. This meant that style mattered at least as much as content and that historical truth might be obscured by literary conventions. On the more positive side, there was the renewed insistence on the choice of definite, clearly delimited subjects and on a more coherent arrangement of material. The abler Humanist historians, however, were also making innovations that bring their practice a little nearer to present notions of writing history.

Several Humanist historians were particularly attracted to the study of the origins of the states about which they were writing. In the 15th century Bruni did this for Florence, and Biondo and Bernardo Giustiniani for Venice, to mention some notable examples. In the 16th and early 17th centuries, French and English scholars inaugurated a critical study of the origins of their national institutions. Humanist historians prided themselves on their critical ability to overthrow the legends in which various countries had concealed their ignorance of their own origins. The incentives to revise the earliest history were often political. Bruni deemed it essential to prove that Florence had not been founded under the tyranny of the Roman emperors but in the time of the free republic. He happened to be right. The Humanist historians were more confident than their ancient predecessors that they could write competent histories of a remote past. In practice they were much less successful in this than they imagined. In dealing with periods before their own time, they usually followed only a restricted number of earlier narratives, though the best of them, such as Bruni and Biondo, displayed in their histories of medieval Italy

a novel ingenuity in combining well-chosen sources. Biondo, for example, made effective use of Dante's correspondence.

There was also some modest progress through the better use of documentary sources. This is often far from obvious, because Humanist historians, like their ancient predecessors, do not usually refer to their sources, even when they quote texts verbatim. Hence came Leopold von Ranke's utter misjudgment of the historical value of the *Storia d'Italia* ("History of Italy") of Francesco Guicciardini. Before Ranke's time it was universally accepted as the most authoritative contemporary history of Italy in the years 1494 to 1534. Ranke, who became one of the pioneers of "scientific" history in Germany, first established his reputation in 1824 by his attack on the reliability of Guicciardini. Ranke argued that the statements of that great Florentine statesman were contradicted by documentary evidence and that his history must have been based on unreliable secondary authorities. The discovery in the 20th century of Guicciardini's private archive proved that his history was scrupulously based on original documents of the highest value.

Guicciardini's history of Italy

Guicciardini, in a work that forms the nearest Renaissance parallel to the history of Thucydides, tries to comprehend the succession of tragedies that befell Italy from the start of the French invasions in 1494. This desire to recapture the rational causes of events is one of the most mature features of the best Renaissance historiography.

EARLY MODERN HISTORIOGRAPHY

Italian Humanist historians provided models that could be imitated easily in other countries. Almost everywhere in western and central Europe, local writers were encouraged to produce descriptions and histories of their own lands, intent with patriotic pride. In such countries as Spain and Poland, which had only recently achieved their unity, this was a way of commemorating their newly won cohesion. In the 15th century it was the object of a pioneer work on the earliest antiquities of Spain, the *Paralipomena Hispaniae*, by the Catalan Humanist bishop Joan Margarit i Pau, and of the invaluable *Annales seu cronicae incliti regni Poloniae* ("History of Poland"), by Jan Długosz, which included an exceptionally precise geographic description of his country. In Germany a sense of national identity could be vindicated by Humanist historians striving to minimize the importance of the continued political division of their land. The *Germania* of Tacitus was printed in Germany as early as 1473 and started the fashion of using this collective name for that country. Tacitus called the Germans "the indigenous inhabitants." This was used by a leading patriotic Humanist, Conradus Celtis, as a proof that Germany should be free from all foreign domination. Celtis and his other Humanist contemporaries deliberately hunted for manuscripts of medieval German writers to prove that their country, despite its disunity, could have a national history. Some important masterpieces were recovered, including the histories of Otto of Freising. Celtis' pet project of a description of Germany modelled on Biondo's *Italia illustrata* was carried out in 1530 by Sebastian Münster, and Münster's fuller *Cosmographia* (1544; "Cosmography"), though purporting to describe the known world, devoted one-half of its 818 pages to "the German nation." There was also a spate of histories of Germany, mostly very laborious and unreflective but incorporating the newly rediscovered medieval narratives and even some documentary sources. Greater originality came only in the wake of the Reformation. The same thing happened in France and in England. In both countries patriotic preoccupations were a leading feature of works written by Humanist historians, and the appearance of Protestantism reinforced in a peculiar way the existing nationalist tendencies.

The influence of the Reformation on historiography must first be discussed at a more universal level. As the philosopher Francis Bacon shrewdly observed, Martin Luther had been obliged "to awake all antiquity and to call former times to his succours . . . so that the ancient authors . . . which had a long time slept in libraries, began generally to be read." This was not because Luther would have regarded himself as a historian. But as early as 1519, in his disputation with Johann Eck, he encountered the assertion that the primacy of the pope was of divine origin. In order to disprove this and to demonstrate that they alone represented the true church, the Protestants had to retell in a new way the entire history of Christianity. In a preface to the *Vitae Romanorum pontificum* ("Lives of the Pontiffs"), published by Robert Barnes in 1535, Luther himself confessed that, although he himself had not originally attacked the papacy with historical arguments,

> now it is a wonderful delight to me to find that others are doing the same thing . . . from history—and it gives me the greatest joy . . . to see . . . that history and Scripture entirely coincide in this respect.

The starting point for the Protestant rewriting of Christian history could best be found in St. Augustine's teachings. The true church, the city of God, had always existed, even though at times it seemed to be overshadowed by the enemies of the divine order. Those enemies were not only the pagans and the heretics, as St. Augustine had believed. In more recent times they had included also the upholders of the papal authority and the persecutors of such medieval true Christians as John Wycliffe (died 1384) and John Hus (died 1415). The writings of Eusebius provided the model for chronicling the sufferings of the faithful until the dawn of freedom for the true church in the 16th century. These views about the correct history of Christianity were presented with exceptional cogency in John Calvin's *Christianiae religionis institutio* (fullest edition 1559; *Institutes of the Christian Religion*) and were shared by most Protestant scholars. The only obvious disagreements arose when Protestants tried to pinpoint the moment at which the church took the fatal turn away from God's true purpose. While the radical sectarians considered that the papacy had always been corrupt, less extremist Protestants were prepared to accept the earlier popes and to argue that the rot set in at some date between the time of Eusebius (died *c.* 340) and the 7th century. The choice of precise date might depend on the national traditions of each country. Thus, Bishop Richard Davies, in his preface to the New Testament in Welsh (1567), treats Pope Gregory the Great (died 604) as a special enemy because Gregory's effort to convert the Anglo-Saxons led ultimately to the subjugation of the autonomous British church.

Protestant history

Historians writing in this spirit were incapable of impartiality. But the historical controversies between the Catholics and the Protestants produced from both sides huge compilations. Their authors were determined to prove their respective cases by a stupendous marshalling of authorities and documentary sources. The habit of giving copious references and long, exact quotations, missing from the Humanist historiography, was reintroduced by the religious controversialists. On the Protestant side, the largest work is the *Ecclesiastica historia*, or the so-called *Centuriae Magdeburgenses* (13 volumes, 1559–74; "Magdeburg Centuries"), retelling the history of the church down to 1200. The Catholic reply, equally huge and graceless, was produced in 12 volumes by Cardinal Baronius. The chief Protestant critic of this work, the great Greek scholar Isaac Casaubon, was astonished by the Cardinal's ignorance of Greek and Hebrew, his gross mistakes, and his boundless credulity.

The narratives of contemporary events written in the 16th and early 17th centuries by the participants in the religious struggles, though equally partisan, include some works of great historical value and high literary merit. The earliest and best German Protestant narrative, that by Johannes Sleidanus, received a grudging tribute from his great opponent, the Holy Roman emperor Charles V, who remarked that "the rogue has certainly known much . . . ; he has either been in our privy council or our Councilors have been traitors." John Foxe's *Book of Martyrs* (1563) contains a great mass of exact information about the persecution of reformed religion in England and Wales during the reign of Mary Tudor, and it has influenced many generations of British Protestants.

Foxe's *Book of Martyrs*

The achievements of Queen Elizabeth I and the Anglican Church's settlement of her reign found an outstanding defender in William Camden, who was encouraged to write by Elizabeth's leading ministers. In his *Annales Rerum Anglicarum, et Hibernicarum Regnante Elizabetha* ("Annals of Elizabeth's Reign") Camden made excellent use of a mass of official records at his disposal, though his treatment of confidential matters had to be discreet.

Out of a conflict between Venice and the papacy in the first years of the 17th century was born the *Istoria del consilio tridentino* (1619; *History of the Council of Trent*) of Fra Paolo Sarpi. A Catholic friar, but a passionate defender of Venetian autonomy, Sarpi drew a dark picture of worldly papal policies and the unscrupulous machinations of the Jesuits. It is a bitter, prejudiced, but splendidly written and well-informed work, which profoundly influenced the anticlerical historians of the 18th century. All these contemporary narratives, however, have one serious limitation. They deal almost exclusively with political events and with changes in ecclesiastical organization. The Protestant schism is treated as merely a revolt against the abuses of the old church, and the deeper reasons for the alienation of the Protestants from the Catholic faith are never explained. Furthermore, these historians, by attributing the origins of the schism almost exclusively to Luther's sudden conflict with the papacy, obscured the existence in the early 16th century of numerous Catholic reformers, whose sole aim was to transform the Catholic Church from within. This one-sided approach to the history of the Reformation was destined to persist for a long time. Two influential histories published in the years 1683–88, one by a great Catholic prelate, Bishop Jacques-Bénigne Bossuet, and the other by Pierre Jurieu, a leading Protestant, still agreed on the same superficial account of the causes of the Reformation.

The rewriting by the Protestants of universal church history naturally involved a drastic revision of the history of the national churches. In Germany, particularly, the history of the church had become inextricably intermixed with the destinies of the German empire. Their hatred of the papacy made the Lutherans visualize the course of German history with unusual clarity. Nobody before them had attempted to impose on that history a single intelligible pattern of any sort. Theirs was bound to be a prejudiced pattern, a story of gradual national disintegration as the result of the successive defeats of the German emperors by the papacy. Johannes Stumpf's tragic chronicle of the Holy Roman emperor Henry IV (published in 1556) treated his struggles with Pope Gregory VII as the beginning of the empire's tribulations. The whole course of German history was retraced in this fashion under the influence of Luther's chief Humanist collaborator, Philipp Melanchthon, in the so-called *Chronicle* of Carion, written in its final versions (1572–73) by Melanchthon's son-in-law, Caspar Peucer.

One of the most novel features of the English Protestant historiography was the reawakening of scholarly interest in the period before the Norman Conquest of England in the 11th century. Matthew Parker, Queen Elizabeth's first archbishop of Canterbury, thought he could discern in the pre-Conquest church elements of true Christianity that were destroyed thereafter and had only been reintroduced by the Protestants. The Anglican Church could be represented as a return to the traditional practices and beliefs of the early English Christians. Thus the replacement of Latin by English in the Protestant church services could be justified by citing the presence in Anglo-Saxon England of Bibles, liturgies, and devotional literature in the Old English language. Parker and his friend Lord Burghley, Elizabeth's most trusted minister, gathered around them a circle of enthusiastic scholars, whose work preserved most of the important Anglo-Saxon texts as well as of some leading post-Conquest chronicles. Parker's own method of editing texts horrifies modern scholars, but some of the antiquarian works published by members of this group were of high quality. Camden's *Britannia* (first edition 1586, later much enlarged) was a pioneer work on the topography of Roman and early medieval Britain. The edition by Sir Henry Spelman of the records of the pre-Conquest church councils was the first serious attempt to apply to an important type of early sources the methods of best continental scholarship.

Camden's *Britannia*

The growth of a historical outlook can be traced in the 16th century in many diverse fields of learning. For the first time men were realizing that there was a historical side to every branch of knowledge concerned with human affairs. "I have become aware that law books are the products of history," wrote the French legal historian François Baudouin in 1561. In each branch of study there developed a special historical technique particularly appropriate to it. The most sophisticated scholarship was to be found in the field of classical studies. A group of scholars active in the second half of the 16th century were achieving results much superior to the work of the earlier Renaissance classicists. They combined philological expertise with a determination to reach a really adequate understanding of the ancient Greek and Roman civilizations. A few were Italians, such as Carlo Sigonio, but most of the important works were written in France and in the Protestant centres of Switzerland and Holland. As textual critics these scholars were reacting sharply to the earlier, more haphazard, methods of emending and editing classical authors. They were trying to bring the text of one writer after another to a state of near perfection. Some leading ancient historians, such as Tacitus, benefitted greatly from this treatment (edition of Lipsius in 1575). Though their methods do not quite reach the standards of modern scholarship, they anticipate intelligently many of the procedures more systematically adopted in the 19th century. Isaac Casaubon was the first to point out in his edition of Suetonius (1595) that Einhard's 9th-century life of Charlemagne was modelled on the work of that Roman historian. Casaubon's friend Joseph Scaliger renewed the science of classical chronology (1583) and was the first to reconstruct the original Greek *Chronicle* of Eusebius lying behind St. Jerome's Latin translation. Sigonio's pioneer work on the rights and duties of Roman citizens (1560) was later much used by Theodor Mommsen, one of the founders in the 19th century of the modern study of Roman history.

In the course of the 16th century, non-narrative historical work of the highest originality and complexity was being carried on in the legal faculties of French universities. One important stimulus was provided by the existence in France of different legal systems—the uncodified provincial customs in the north and the written law in the south. The latter ultimately derived from the Roman law, and, in the southern French universities, there arose an eager demand for the introduction of the new Italian methods of interpreting the Roman legal texts. Andrea Alciato, a pioneer in the historical treatment of the Roman law, taught at Bourges from 1529 to 1533, and his pupils founded the "Romanist" school of French legal historians.

Legal histories

Important advances were made in the study of both the Roman law and of the origins of the French legal customs, laying virtually the foundations of a new branch of scholarship, the history of law and institutions. François Baudouin published in 1545 the first historical survey of the development of the Roman legal science. The treatise on the custom of Paris by Charles Dumoulin (published 1539–58) resulted from his advocacy of the codification of the northern French legal customs. It was the first scholarly exposition of a body of customary French law derived from feudal practices, and it amounted to a first comprehensive history of European feudalism. It prompted a series of controversial works by a succession of scholars. The Roman, the Germanic, and the Celtic roots of feudalism all found advocates, and the respective claims of Lombard and Frankish texts to provide the best clues were vigorously canvassed. The complexity of the problems presented by the unravelling of the origins of feudalism dawned on scholars for the first time. The most valuable of these attempts to rediscover the "ancient French constitution" were the re-

searches on "the antiquities of France" of Étienne Pasquier (published 1560–1607), which form a basis for all later study of medieval French institutions.

One of the novel features of European civilization in the later 16th and 17th centuries was a secularization of mental interests. Secular learning could now produce ideas more fascinating to intelligent men than theology. History was one of the most popular types of literature sought by a growing reading public. Several treatises on the proper way of writing history appeared in the third quarter of the 16th century. An anthology consisting of 12 such works, including the famous *Methodus* of the French political philosopher Jean Bodin, was published at Basel in 1576. Nearly 100 years later a "Catalogue of the Most Vendible Books in England" (1657) showed that history books constituted a large proportion of the total works published. It has been estimated that between 1460 and 1700 at least 2,500,000 copies of 17 leading ancient historians were published in Europe.

The late 16th century and the 17th witnessed the publication of several great collections of historical materials. The men who undertook these gigantic tasks often were antiquarians accumulating miscellaneous records rather than historians, but they were supplying materials for generations of future historians. Some of the most important publications of sources appeared in France and the Netherlands. Pierre Pithou was a pioneer in editing materials for the history of the Frankish period. The collections of André Duchesne are a vast storehouse of chronicles and other sources for the study of medieval French history. Le Nain de Tillemont edited 20 volumes of records devoted to Roman and church history during the first six centuries of the Christian Era, which a century later furnished one of the principal sources for Edward Gibbon's work *The History of the Decline and Fall of the Roman Empire*. In 1629 a Belgian Jesuit, Jean Bolland, embarked systematically on the editing of records connected with all the saints whose feasts had at any time been celebrated by the church, and this series of publications has been continued to the present day. In the second half of the 17th century, the French Benedictine congregation of Saint-Maur started an immense series of publications commemorating the history of the Benedictines and of other monastic orders. The greatest Maurist scholar, Jean Mabillon, was accepted throughout Europe as the most erudite historian of his time.

In spite of its popularity among an expanding reading public and of the large number of learned editions of materials that it inspired, history was not, for most of the 17th century, one of the sciences that made men proud of living in a modern age. Immense progress was taking place in mathematics, astronomy, and physics. History not only did not seem capable of much further development, but scientifically minded men were beginning to dismiss it as a branch of knowledge that would never be worthy of serious respect. Mabillon's *De Re Diplomatica* (1681) helped to challenge this pessimistic view, but a further century elapsed before history began to be accepted as an authoritative discipline.

Hostility of rulers toward historiography

One major obstacle to the progress of historiography was the hostility of rulers to publications that did not favour their governments. The growth of an influential reading public made rulers increasingly suspicious of historical writings; for example, the censorship exercised by Cosimo I de' Medici, ruler of Florence from 1537 to 1574, precipitated the decline of Florentine historiography. Comparisons with the past also could be invidious. In 1599 Elizabeth I of England censured an author for describing the deposition of one of her predecessors, Richard II, 200 years earlier. Fear of possible trouble made highly intelligent scholars into one-sided historians. The great jurist Hugo Grotius avoided in his history of the wars of the Dutch against Spain discussions of the religious aspects. Samuel Pufendorf, the historian of the Swedish conquests, carefully left out the internal developments in 17th-century Sweden.

The scholars who in that century were responsible for the great advances in the mathematical sciences were convinced that their achievements would ultimately give mankind a novel mastery over its natural environment. This is particularly true of Francis Bacon and of René Descartes. Their optimism was laying the foundations for a belief in a possibility of continuous progress without which the purposeful and assured historiography of the 19th century would be inconceivable. But the attitude toward history of most of the leading thinkers and scientists of the 17th century was not helpful to its immediate development. Bacon, who wrote a readable and rationally argued biography of King Henry VII of England, attached no importance to accuracy; for example, he antedated Henry's death by a whole year and could not be bothered to undertake any detailed research. Gottfried Wilhelm Leibniz was a great mathematician, but his attempts to apply science to historiography led to mechanistic constructions from which real human beings were largely missing. Numerous influential thinkers were decidedly hostile to history. Descartes, the most eminent of the anti-historical scientists, was not simply disgusted by the unsystematic and imprecise methods of the historians of his time but also doubted whether, strictly speaking, history could be regarded as a branch of knowledge at all. But it is important to remember that much of the 17th-century criticism of history was an attitude of men who simply had other priorities and were concerned to attack doctrines that, for one reason or another, historians seemed to support. In the late 17th century the most successful defenders of history were the members of certain particularly scholarly Catholic orders. Catholicism rested its authority on tradition to a much greater extent than did its Protestant opponents. For Catholic scholars such as Mabillon, the defense of history became really a defense of their religion. They were trying to show that historians were capable of discovering scientifically demonstrable truths. The decisive publication was Mabillon's *De Re Diplomatica* of 1681. A member of a rival order, the Jesuit Daniel Papebroch, had challenged (in 1675) the authenticity of the oldest charters of two French Benedictine monasteries, Saint-Denis and Corbie. Mabillon applied his powerful critical intelligence not only to vindicating these documents but also to formulating the general rules that must be used to prove the authenticity of medieval records. He illustrated his rules by admirable examples and stated his conclusions with a candor and a common sense that convinced most readers. Mabillon's survey of the tests that must be applied by scholars covered the writing materials, the scripts (thus founding the science of medieval Latin paleography), the seals and other devices of authentication, the official formulas, and the vocabulary used at different periods. Above all, he stressed that the authenticity of a document usually rested not just on isolated details but on consistent correctness of all its features.

The rules of diplomatics

Mabillon was not just a "historical scientist." He had a passionate interest in the past and a vivid historical imagination. He displayed these qualities abundantly in his last and most important work, the *Annales Ordinis s. Benedicti* ("Annals of the Benedictine Order," to 1066). In the *Traité des études monastiques* (1691; "Manual of Monastic Studies"), he defended the importance of scholarly work as the principal activity of an elite of Benedictine monks. But it would be an anachronism to regard Mabillon and his chief associates as fully comparable to modern historians. They were constrained by the limitations of their time and of their special position as monks. For example, Bernard de Montfaucon, Mabillon's most important successor, is the creator of the science of medieval Greek paleography. But he shares with most of his contemporaries a complete inability to treat the Old Testament as a historical source.

Historical and antiquarian studies developed in 17th-century England in several very distinctive ways. The political struggles and religious controversies of that period made some issues of older English history into matters of immediate practical importance. The other distinctive feature was the delay in the absorption of European continental learning, so that the great progress made in the study of feudal origins in the 16th century began to affect the thinking of English scholars only by

about 1625. But there persisted also elements of continuity growing out of earlier Tudor scholarship. The interest in the Anglo-Saxon church and civilization continued to stimulate important editions of records throughout the 17th and early 18th centuries, including, especially, Sir Henry Spelman's edition of the records of church councils and Sir William Dugdale's *Monasticon Anglicanum* (1655–73), which is still valuable today. Another element of continuity with the Tudor period was the perennial interest of the English notables in heraldry, genealogy, and the antiquities of their native regions. Dugdale's *Antiquities of Warwickshire* (1656) set a pattern and a standard for county histories.

Students of English law and institutions, lacking the stimulus provided for French lawyers by the diversity of legal systems and by the notable progress in the study of Roman law in that country, continued to ascribe immemorial origins to the common law of England and to approach the development of English institutions in a completely unhistorical spirit. Among the parliamentary opposition to the Stuarts, these attitudes were part of a belief in the "ancient constitution," which these sovereigns were supposed to be defying. Spelman, a devout Anglican and a royalist, though a moderate one, was perhaps the first major scholar to break away from this myth. Under the influence of continental publications and correspondents, he accepted that feudal tenure had been introduced into England after the Norman Conquest and that all the English institutions after 1066 must be redefined in feudal terms. But his discoveries were hidden in a dictionary of antiquarian words (*Archaeologus*, vol. 1, 1626; 2 vol. 1664) and made very little impact until some 50 years had elapsed. Spelman had an acute sense of historical development, and he sadly castigated his countrymen for their lack of it in their attitude to parliamentary origins:

Achievement of Sir Henry Spelman

> when States are departed from their original Constitution and that original by tract of time worn out of memory; the succeeding Ages viewing what is past by the present, conceive the former to have been like to that they live in. (*Of Parliaments*, written in about 1640, published 1698.)

His greatest contribution to English history was to grasp that parliaments had developed out of feudal assemblies convoked by the Norman kings and that the Commons were introduced into parliaments subsequently, as a result of the growing prosperity of the lesser landholders. These views first became generally accessible in the 1664 edition of Spelman's dictionary. They were adopted by Robert Brady (in 1681) and by other partisans of the Stuarts and expanded into a Royalist statement of the English past. Violently polemical though this view was, it did at least lay to rest the myth of the immemorial "ancient constitution." The Whig triumph at the Glorious Revolution of 1688, which established a doctrine that the king ruled by parliamentary consent, led to the neglect of these discoveries for much of the 18th century. This was the common fate of much of the research of 17th-century antiquarians, who were very much ahead of their time and were writing for a limited audience. John Aubrey's pioneer description in the 1670s of the prehistoric sites of Avebury and Stonehenge had to wait two centuries for full publication. Even the best of these antiquarians, such as Spelman and Dugdale, were less critical in their handling of the original sources than Mabillon was. Higher standards were reached by a few of their successors in the early 18th century, especially by Thomas Madox, whose *Formulare Anglicanum* (1702) imitated Mabillon by attempting a systematic introduction to English medieval documents. But this did not save Madox from prolonged oblivion. After about 1730 this English tradition of antiquarian scholarship largely ended and remained unfashionable for most of the 18th century.

HISTORIOGRAPHY IN THE AGE OF THE ENLIGHTENMENT

The impulse given to historiography by the Italian Humanists and the religious controversialists had largely spent itself by about 1715. Men knew again how to write rationally satisfying contemporary histories, though often it needed courage to do so. Much less progress had been achieved in reconstructing the more distant past. Impressive collections of historical materials were being accumulated, but most scholars still lacked the capacity to rethink the thoughts of past generations and thus really to understand them. Mabillon could write with insight about early Benedictine history, as he possessed both sympathy with the subject and adequate technical expertise, but he was exceptional. Spelman had grasped that a particular society would be molded in a peculiar way by its institutions. He could not reconstruct and explain the gradual changes from one set of institutions to a later one, but he was aware of the problem.

Judged by the quality of its historical output, the 18th century was not, on the whole, an age of successful historians, but some of the defects of earlier historiography were beginning to be overcome. There were also losses, however, for some of the achievements of the preceding period were in danger of being forgotten. In the leading countries of western Europe, religious controversies were becoming less important, and a massive secularization of interests took place, which affected even ecclesiastical scholars. The French Maurists continued until 1790 to publish imposing historical collections, but their choice of subjects was determined much less than in the time of Mabillon by religious priorities. The greatest Italian ecclesiastical disciple of Mabillon was Ludovico Antonio Muratori, a social reformer. In a divided country like Italy, the best way of expressing his patriotism lay in reminding Italians of the former greatness of their country. Muratori spent much of his long life on his editions of Italian medieval sources.

The nationalist motivation shown by Muratori was peculiar to Italy and also to parts of Germany, another divided country. Elsewhere in Europe there was a danger that, as men lost interest in constitutional or religious disputes that might be settled by appeals to the past, they might turn away altogether from history or at least neglect long stretches of it. This did happen to some extent in the 18th century. Some of the radical French reformers, such as Jean Le Rond d'Alembert, one of the main inspirers in the 1750s of the French *Encyclopédie*, wanted to jettison completely much of the past. The Marquis de Condorcet (*q.v.*), an early prophet of the doctrine of endless progress of mankind and a pioneer historian of European civilization, was a prominent member of a French parliamentary commission that in 1792–93 deliberately destroyed some of the royal records as comprising relics of past servitude.

During much of the 18th century it was safer and easier to publish controversial works of history than it had been in the past. The point is important, as without this greater freedom, the peculiarly radical "philosophical" historiography, so typical of that century, would have been inconceivable. In Italy such writing was still dangerous. Pietro Giannone, the author of an anticlerical history of Naples (1723), was tracked down by the Inquisition and spent 12 years in prison, where he died in 1748. Even the great Muratori, who tried to help Giannone, came into danger of having some of his works banned and had to be rescued by the personal intervention of Pope Benedict XIV. In France, Louis XIV in 1714 imprisoned Nicolas Fréret in the Bastille for alleging (correctly) that the Franks were originally a confederacy of German tribes and not descendants of more illustrious ancestors. Under the successors of Louis, nothing quite so absurd happened again, but critics of the government or the church were often in trouble. Great Britain, Holland, Switzerland, and parts of Germany, on the other hand, provided safe oases where most things could be published. It was no accident that the most independent and historically minded group of German professors should have congregated at the University of Göttingen, founded in 1734, in the Hanoverian territory of the kings of Great Britain.

"Philosophical" historiography

A real renewal of historiography in the 18th century could only come if fresh reasons were discovered for making it again worthwhile. Nationalism could supply one such motive; but this only became decisively influential in the 19th century. An alternative was a histo-

riography inspired by the progress in the natural sciences and based on formulating the general rules governing the development of human societies. The chief features of this "new" historiography were a sense of the unity of all human history, including an interest in the continents outside Europe; a capacity for bold generalizations about the salient features of particular periods or societies; and a preference for topics connected with the progress of human civilization. Condorcet's historical sketch of the progress of the human mind, written in 1794, subdivided all known history into nine periods, each starting with some great invention or with geographical discoveries.

The shortcomings of this "rationalistic" historiography have been rehearsed often enough. For many of its writers it was primarily a weapon of propaganda against their enemies in church and state. Their redeeming virtue was the fearlessly critical attitude to all existing authorities, however august or sacred. The vast scale of their generalizations often precluded any detailed research. This was particularly true of the attempts to write histories of civilization, as the existing collections of printed materials did not cater for such interests, while systematic research in archives was seldom possible in the 18th century. In preparing his pioneer essay on the history of civilization, covering the millennium from the Carolingians to Louis XIV (*Essai sur les moeurs et l'esprit des nations*, 1745–53), the French author Voltaire had to collect bits and pieces from most diverse sources.

One of the most valuable achievements of the thinkers of the 18th century was their capacity to study particular societies as coherent units and to formulate the theory that the various aspects of each society's life were closely interrelated. This was not an entirely novel idea, but it first became commonly accepted during this period. Nor were all its adherents anticlericals. Giambattista Vico (*q.v.*), a Neapolitan Catholic, was ahead of his contemporaries in his particularly subtle sense of the complex influences by which one phase of society gives place to another. In his reconstruction of these transitions during the early stages of Roman history, he makes no clear lines between periods. His countryman Giannone explains in his autobiography that he had studied Roman law not for its own sake but in order to understand the changes in the society of the Roman Empire. The French philosopher Montesquieu, who owed much to Giannone, was not really a historian, but he displays an acute sense of historical realities. His *De l'esprit des lois* (1748; *The Spirit of the Laws*), more than any other book, accustomed his contemporaries to ponder the complex factors that shaped each society. It inspired Gibbon's definition of the kind of history he wanted to write. It was to be a "history related to and explained by the social institutions in which it is contained."

Gibbon's *Decline and Fall*

This ideal was realized in Gibbon's *History of the Decline and Fall of the Roman Empire* (1776–88), one of the masterpieces of "philosophical" historiography. Gibbon was preoccupied above all with the problem of human progress. The belief that continuous progress was possible for mankind had been publicly formulated in the mid-18th century by Anne-Robert-Jacques Turgot in France and by Adam Smith in Scotland, independently, it seems, of each other. Gibbon had read works and known scholars influenced by both these thinkers. A belief in continuous progress would confer a new purposefulness on the study of the entire course of human history and could justify a lengthy account of what otherwise might have seemed very obscure stretches of the past. Such a justification was to inspire most of the historiography of the 19th century. But the problem of progress had a special urgency for Gibbon's generation, which worried at the thought that their own enlightened civilization might also subsequently collapse. By unravelling the causes of the decline of the Roman Empire, Gibbon was determined to show that the Europe of his own day had attained a much superior degree of development and was immune from the fate of the ancient world.

In the 18th century, historiography was still only very rarely connected with the universities; and thus, except in such isolated places as Göttingen in Germany, no continuous schools of history could develop. Some of the most important achievements of the 18th-century historians meant much less to their contemporaries than to their successors in the 19th century. Gibbon was a pioneer in utilizing in a "rationalist" history the vast materials accumulated by generations of erudite antiquarians, but he had no immediate followers. The German archaeologist Johann Joachim Winckelmann tried to revive the true understanding of Greek sculpture and to make the history of art into something more than just the biographies of artists, but his work bore little fruit until the next century. The saddest fate was that of Vico's work. He was hardly ever read before the 19th century, when he at last influenced Barthold Georg Niebuhr and the rest of the German historical school, while Jules Michelet's rediscovery of Vico in 1824 started a new era in French writing on the Middle Ages.

HISTORIOGRAPHY IN THE 19TH AND 20TH CENTURIES

From the early 19th century, historiography began to develop in a radically different way. The decisive changes occurred among the German historians, largely through a reaction to the French Revolution and to a temporary subjugation of their country by Napoleon. Organized teaching of history in schools and universities became a matter of national importance, first in Prussia and then in other parts of Germany. As universal education spread to most European countries in the course of the 19th century, history was accepted everywhere as a necessary subject in schools. For the first time the bulk of historical writing came to be done by professional historians, for whom it became a condition of securing academic appointments or of consolidating their standings as university teachers. Historiography eventually became a continuously cooperative venture, where the achievements of past historians could be used systematically by their successors. But the growth of specialization and the bewildering number of types of works that came to be published constituted a new danger. In the past, important discoveries were frequently lost through lack of interest. But, by the second half of the 20th century, discoveries were in danger of being simply overlooked amid the flood of publications.

Growth of specialization

Another great change lay in the growth of intellectual freedom. Free expression of independent or unorthodox ideas had become dangerous during the French Revolution and under Napoleon, both in the territories controlled by the French and, by way of frightened reaction, in the lands of their unconquered opponents. After 1815 conditions for freer historiography improved gradually in much of Europe. Charles Darwin's *Origin of Species* (1859), which put forth a theory of evolution at first unacceptable to church authorities, probably could not have been published with the same impunity any earlier.

One feature of the growing tolerance of governments toward historiography was the gradual creation of public archives, such as the British Public Record Office in London, created in 1838, and the freer opening of the collections already in existence. Even the papacy accepted these changes, and Pope Leo XIII opened up the papal archive in 1883 as part of a deliberate new policy of encouraging historical study of Catholicism. For the first time historiography came to be based largely on unpublished records, and scholars were tempted into excessive reliance on original documents while unduly neglecting the older types of narrative sources.

In the 20th century some grievous threats to the persistence of free scholarship recurred, and historiography suffered with other branches of humane studies. The establishment of a Communist regime in Russia led, at first, to the rejection of most pre-1917 history as a fit subject for schools and universities. This decision was reversed in the 1930s, and from 1945 Communist countries were encouraging a form of historiography especially concerned with economic history and the class struggles of the past. There was also an enthusiastic interest in the material remains of past ages, leading to an impressive development of archaeology, particularly in Poland. The rise of dictatorships in Italy and Germany

had disastrous effects on historiography in those countries, and recovery after World War II was only gradual.

Judged merely by the number of "practicing" historians and of their publications, historiography seemed in a very flourishing state in the 1970s. Its European traditions had spread to all the other continents and were largely accepted in all non-Communist countries.

The *Introduction aux études historiques* (*Introduction to the Study of History*) of Charles V. Langlois and Charles Seignobos (1898), supplemented by critical comments of another outstanding French historian, Ferdinand Lot (in *Le Moyen Age*, 1898), provides an excellent starting point for the discussion of modern historical methods. History is an autonomous branch of learning, and some of its methods may be unique. Historians should not try to formulate general laws; their branch of learning merely "aims at explaining reality." Langlois and Seignobos particularly stress that history is not a science of observation but a science of reasoning how to extract from imperfect documentary or narrative records some glimpses of what actually happened.

The historian's task

A historian has to subject his sources to a whole series of preliminary investigations. First comes "external criticism," aimed at determining whether the sources are appropriate and adequate for the particular task in hand. The provenance, date, and authenticity of each source must be established by using the techniques of diplomatic, the detailed study and assessment of documents, and of paleography, the study of ancient handwriting, and of other auxiliary sciences that were elaborated after the 17th century. In France a special institution for teaching some of these techniques, the École des Chartes, was created in 1821. The first specialized seminar for instruction in these subjects was established in 1854 at Vienna by Theodor von Sickel, one of the greatest medievalists of the 19th century, and it was gradually imitated by leading German universities. One of the most important critical refinements introduced in the course of the 19th century was the improved handling of narrative sources brought about by seeking to discover the literary sources that lay behind them. Leopold von Ranke, one of the foremost German historians, who began his career as a teacher of classics, was gradually attracted to history through a desire to understand better the sources of the Greek and Latin authors whom he was expounding. In the later decades of the 19th century, such a quest became a normal feature of historical scholarship.

Once a historian has decided, through the application of "external criticism," on the sources that are relevant to his purpose, he must next, by "internal criticism," make sure that he fully understands what he has selected. German classical philologists were the first to bring these latter investigations to a high degree of perfection. Karl Lachmann, an editor of the Latin poets is justly regarded as the creator of modern textual criticism in its most rigorous forms, and historians gradually adopted similar methods. The language of the sources must be understood, corruptions in the text must be eliminated, and the historian must, as accurately as possible, penetrate the minds of the authors with whom he is dealing.

All these critical operations on the sources are merely preliminaries, and the work of the historian proper only starts when he attempts a synthesis of his materials. F. Lot stresses that in this qualities other than the erudite skills come into play. There must be sympathy with the subjects under study, for without it there can be no imaginative insight into the past. Ideally, a historian must display capacities akin to those of a poet or an artist.

Such a quality was, by and large, lacking in the work of the historians of the Enlightenment, who had been unable to achieve imaginative insight into civilizations very different from their own. The greatest shortcoming of Gibbon was his temperamental inability to appreciate religion. The new historiography of the 19th century was created chiefly by Germans, who, through a reaction to the ungodly and cosmopolitan Enlightenment, were endowed to excess with a passion for extolling the unique nature of their fatherland and for tracing the roots of this uniqueness through the whole course of German history. These developments in German historiography can be traced back to some strands of German thought in the 18th century, especially to some features of the writings of Johann Gottfried von Herder. He denied that the purpose of history was to provide a bird's-eye view of the progress of the human mind. It was, rather, to reconstruct history as it had been, which means that all countries and periods are equally deserving of study. This view anticipated Ranke's oft-quoted aim to describe what has actually happened and his conviction that the description of all human history displays the workings of God's providence. The disasters inflicted upon Germany by Napoleon brought forth a patriotic school of historians whose urgent task it became to propagate these views as a means of restoring German independence. The centre of this movement was in Prussia, at the newly founded University of Berlin (1809). Wilhelm von Humboldt, its effective founder, believed that the task of the historian lay in discovering the ideas behind the facts. The concepts that had special validity for him were ideas of religion and of a national state. The German historical school prided itself on the scientific precision of its methods, on its determination to get all the details right, and on the scrupulous quotation of sources. This display of exact scholarship represented a great gain for historical sciences, but its chief purpose was to convince the reader. Yet these German historians were fundamentally inspired by a prejudiced, arbitrary set of assumptions. It is particularly difficult to detect Ranke's hidden bias, as he made a parade of refusing to pass judgments on the past. His preference for the study of foreign relations between states and his treatment of states as natural entities with a right to fulfill their individual destinies justified the successes of Prussia. The defeat in 1848 of the German aspirations to national unity inspired his pupil Wilhelm von Giesebrecht to write the history of the medieval German empire to remind his countrymen of their past glories. When German unification was achieved in 1871, Giesebrecht doubted whether there was any need to bring out any further volumes of his great work. But many German historians, having contributed mightily to the unification of Germany, continued to describe complacently the triumphs of the Bismarckian state. This was one of the purposes of the school of historical economists led by Gustav von Schmoller. There were some dissenting voices. Theodor Mommsen (*q.v.*), the greatest historian of antiquity produced by the 19th century, deplored the tendency of his countrymen to worship state power. Friedrich Meinecke, a leading German historian of political ideas, who until 1914 accepted the ordinary nationalistic assumptions of his countrymen, gradually entirely changed his views and, after the defeat of Germany in two world wars, pleaded in his *Deutsche Katastrophe* (1946; *The German Catastrophe*) for a historiography concerned with the higher values of general civilization. Among the German historians, particularly striking progress was achieved in medieval studies. Meanwhile, attempts at imaginative reconstructions of the past were being made in other countries of western Europe. Jules Michelet wrote in 1833–43 the first history of medieval France based on the French national archives, of which he was at that time keeper. Macaulay's *History of England* (1848–61), covering chiefly the years 1685–1702, represented again a remarkable though prejudiced attempt to relive the past.

German patriotic historians

German scholarly techniques and the methods of German historical teaching spread to other countries in the course of the later 19th century, though it is important to note that until 1914 a significant proportion of leading historians from states outside Germany spent some time in that country. This is particularly true of some of the greatest Russian scholars, such as M.I. Rostovtzeff, one of the most important modern historians of antiquity. In England, William Stubbs, though self-taught, applied the results of German scholarship to the reconstruction of English medieval history. Gabriel Monod, who had studied in Germany, was prominent in introducing more scientific techniques into medieval French historiography, and he founded in 1876 the *Revue Historique*

as the main organ of French historical scholarship. A succession of American students went to Germany, and some, on their return home, reorganized historical studies. Measured by the sheer bulk of publications, the amount of American history written since the 18th century is probably greater than that of any other modern nation. But apart from editions of sources, very few works on American history published before around 1900 are of much practical use today. The most influential pioneer in organizing scientific historiography was Herbert Baxter Adams, who between 1876 and his death in 1901 made the Johns Hopkins University at Baltimore into the foremost American centre of historical studies. He was also one of the founders of the American Historical Association in 1884 and played a large part in successfully launching the *American Historical Review* in 1895 as the main organ of historical scholarship. Some of Adams' pupils became great scholars in various fields of general history. Charles Homer Haskins' works on Norman institutions and on science and culture in the 12th and 13th centuries made him one of the foremost medievalists of the 20th century. But a movement for creating a purely American history was launched in 1893 by another of Adams' pupils, Frederick Jackson Turner, who inaugurated a "progressive" school of historians through his conviction that the fundamental fact of American history down to 1890 was the settlement of a continent. In Turner's eyes the main theme of American history in the 19th century was the conflict between the patrician and capitalist groups of the Eastern Seaboard and the needs of the new settlers in the Middle West. Charles A. Beard inaugurated by his *Economic Interpretation of the American Constitution* (1913) an attempt to rewrite the entire history of the U.S. in terms of conflicts between different groups of economic interests. The weakness of this type of historiography was that it encouraged an excessive parochialism. After 1945 the "progressive" historians came under fire both from more conservative scholars who preferred to stress elements of common tradition and purpose in American development and from the historians of the "new left." In the 1960s and 1970s the close connection between writings on American history and the active political life was infusing great variety and vitality into its historiography, though making it perhaps too susceptible to rapidly changing exernal pressures.

The work of Henry Baxter Adams

Non-Western historiographical traditions

MUSLIM HISTORIOGRAPHY

A study of Muslim historiography in Asia and North Africa and of the historical writings of the peoples of South and East Asia confirms one main feature of the parallel European story. Except when the needs of religion necessitated it, as happened to some extent during the early centuries of Muslim expansion, the writing of history has seldom formed a vital component of any civilization until very recent times. Muslim historiography appears to have originally developed independently of European influences. Until the 19th century Muslim writers only very seldom consulted Christian sources and almost never noted events in Christian countries. Fortunately, they displayed at times more curiosity about the non-Muslim peoples of Asia. The first and best history of the Mongol conquests in the first half of the 13th century was the work of a Persian, Joveynī. On a visit to Mongolia in 1252–53, he was able to consult the recently compiled, earliest Mongol narrative (*Secret History of the Mongols*). The older Chinese historiography developed for over two millennia in isolation, and this led to a series of striking contrasts with Muslim and European tradition of historical writing.

Origins of Arabic historiography

The origins of Arabic historiography still remain obscure because of the gap between the legendary traditions of pre-Islāmic Arabia before the start of the Muslim era (AD 622) and the sophisticated and fairly exact chronicles that began to appear in the later 8th and 9th centuries. But while the detailed stages of this development still await reconstruction, the main influences shaping the early Muslim historiography are clear enough. As in the case of the ancient Jews, it was created and perpetuated by religion. Muḥammad (died 632) regarded himself as a successor to a long series of Jewish and Christian prophets, and he made Islām a religion with a strong sense of history. The Qur'ān, Islām's holy book, is full of warnings derived from the lessons of history.

Teachings of Muḥammad not included in the Qur'ān came to be regarded after his death as authoritative tradition left behind by him. All his sayings and actions were therefore carefully treasured and ultimately came to form, in combination with the Qur'ān, the foundation for the body of Muslim law (Sharī'ah), common to all Islāmic communities. These traditions (Ḥadīth) were transmitted orally for several generations, until they were written down in the 8th and 9th centuries. The resultant collections were only partly historical, as myths and inventions crept into them. The scholars who were engaged in preserving and verifying these traditions were chiefly preoccupied with organizing them into legal and theological systems, and they were frequently hostile to the historians. The earliest authoritative life of Muḥammad, written by Ibn Isḥāq (died 768), was attacked by a leading exponent of the legal "traditionist" learning. This confirms the independence of the historical scholars from the theological and legal interests. But both groups shared some common materials, and the strict rules evolved by the legal "traditionists" for recording their sources and tracing a continuous chain of authoritative transmitters of the traditions encouraged similar exact habits in the Muslim historians. The resultant histories were often pedantic, full of unrelated facts, and deficient in reflective comment, though there are some astonishing exceptions, such as the writings of Ibn Khaldūn (1332–1406). But the better Muslim historians scrupulously quoted their authorities and tried to be truthful. This was particularly true of the "classical" school of historians, who were writing at the centre of the 'Abbāsid caliphate in Iraq in the 9th and 10th centuries. Aṭ-Ṭabarī (died 923), the most authoritative of them all, wrote his "History of Prophets and Kings" as a supplement to his earlier commentary on the Qur'ān, and subsequent Muslim historians were content to follow his reconstruction of the early Islāmic history. The Syrian and Iraqi historiography of the 12th and early 13th centuries is at least as valuable as the Western historical writing of this period, and sometimes it is clearly better.

To orthodox Muslims, the development of the Islāmic community represents a continuous manifestation of God's purpose. Consequently, the recording of the religious progress of the Islāmic society continued to be sacred duty. One of the original features of Muslim historiography is the large amount of attention devoted to the lives of devout men and of scholars. To many Muslim historians, these spiritual and intellectual activities were of much greater importance than the doings of princes and warriors. One of the peculiarities of Muslim historiography was the liking for encyclopaedic dictionaries of famous men. The earliest of these were devoted to the Companions of Muḥammad and to the early transmitters of the Muslim traditions. For a thousand years extremely diverse types of biographical collections have continued to appear in the Muslim world. Those devoted to religious scholars attained a particularly wide diffusion. Saladin (Ṣalāḥ ad-Dīn), who took Jerusalem from the crusaders in 1187 and later opposed the Third Crusade, offered to the Muslim writers the particularly congenial subject of a ruler dominated by a sense of religious duty. A particularly fine example of medieval Muslim historiography is the biography of Saladin by Bahā' ad-Dīn (died 1234), which gives an exceptional insight into Saladin's motives for many of his critical decisions.

The works of Ibn Khaldūn

But the greatest Arab historian and one of the most penetrating thinkers about historiography in any time or place was undoubtedly Ibn Khaldūn. The introduction (*al-Muqaddimah*) to his *Kitāb al-'ibar*, a universal history (begun in 1375), is, in A.J. Toynbee's judgment (1934), "the greatest work of its kind that has ever yet been created by any mind." Ibn Khaldūn had absorbed all the learning accessible to a Muslim of his time. He

was a master of religious learning, an outstanding judge, a writer on logic. He turned a subtle and most disciplined mind to historiography in order to explain his personal tragedy. He had served a succession of rulers in Islāmic Spain and the Maghrib (Northwest Africa) as a general, a politician, and even once as a chief minister, and his activities had always ended in disaster. In order to explain what had gone wrong, he sought to achieve a correct understanding of the forces that governed the societies known to him. He concluded that political stability had become impossible in his native Maghrib, because over centuries economic prosperity had declined excessively and the forces of lawlessness had become too strong.

As a detailed chronicler of events Ibn Khaldūn is not always exact, but, like contemporary historians, he knew how to reconstruct correctly the main trends over several centuries. His ability to formulate general laws that govern the fate of societies and to establish rules for the criticism of sources provided him with an intelligent framework for the correct reconstruction of past history.

Ibn Khaldūn's *Muqaddimah* has survived in at least a score of manuscripts, but he has had no effective influence on Muslim historiography until recently; after his time, as before, the writing of history continued to be a normal feature of Muslim civilization in the more advanced Islāmic societies. In several countries, notably in parts of India, the first works that deserve the name of history appeared only after the Muslim conquest or the conversion to Islām. After the 12th century Arabic ceased to be the main language of Muslim historiography. Distinguished histories were written in Persian in the 13th century, and subsequently Turkish and other vernaculars came to be used by historians in different parts of the Islāmic world. But, in its isolation from non-Muslim influences and its traditional interests, Islāmic historiography underwent no intrinsic change until the 19th century, when it began to be affected by the impact of modern Western civilization.

EAST ASIAN HISTORIOGRAPHY

The preservation of some records of historical events can be traced in China to at least the early part of the 1st millennium BC. Confucius (551–479 BC) was credited, rightly or wrongly, in the later Chinese tradition with editing the annals of his native state of Lu. But the appearance of the first works fully deserving the name of histories resulted from the unification of China under a single ruler in 221 BC. The first such work to survive, the *Shih chi* ("Historical Records"), dates from *c.* 85 BC. Its author, Ssu-ma Ch'ien, is quite justifiably called the father of Chinese historiography. His history exhibits many of the main features of the later Chinese official histories as they continued to be written down to the deposition of the last Chinese imperial dynasty in 1911. Within this fairly unified tradition, China produced a mass of historical writings unequalled by any other country before modern times. Until the late 19th century, Japanese historiography formed an offshoot of this tradition.

The "Historical Records" of ancient China

Chinese scholars showed an interest in the history of China from the earliest times. According to the Chinese conception, history makes sense only if it can furnish practical directives for action or supply correct information upon which action can wisely be based. All the schools of Chinese thought quoted the lessons of history. Confucius, with his stress on the moral content of these lessons, formed part of this universal belief in the value of history. One of the duties inculcated by him was the scrupulous transmission of authentic records. When, some centuries after his death, the unified Imperial state began to recruit its bureaucracy among the Confucian scholars, the recording of all the necessary information and the careful preservation of records became one of the main functions of the Chinese government, both centrally and locally. A long series of official histories and of records connected with them has survived from the time of the T'ang dynasty (618–907) onward. From then on, the great bulk of Chinese history was written by bureaucrats for bureaucrats. From a practical point of view this immense body of historical writings fulfilled a very useful purpose. Such histories were bound to be highly stereotyped and restricted in content to what interested the higher officialdom. It is easy to condemn it by modern Western standards for its excessive preoccupation with concrete details and inability to produce works of wider synthesis. But this Chinese tradition did gradually evolve in the direction of greater rationality and subtlety. Its scope widened as the sphere of government expanded. Furthermore, within this tradition there appeared from time to time writers of genius, men of bold critical spirit, genuine historical insight, and overriding integrity. One of the greatest was Liu Chih-chi (661–721), the writer of the *Shih t'ung*, the first thorough treatise in Chinese, or any other language, on historical method, which also constituted in effect a history of Chinese historiography. He had a successor in Ssu-ma Kuang (1019–86), the author of the first fairly comprehensive general history of China (covering the years 403 BC–AD 959). In the 17th century a remarkable group of historical scholars virtually founded a school of critical Chinese philology. None of these writers succeeded in radically transforming Chinese historiography, but they created an increasingly sophisticated and critical tradition. Their successors in the 20th century assimilated some valuable features of modern Western historiography.

WINKS (eds.), *Pastmasters: Some Essays on American Historians* (1969).

The emergence of modern historiography (late-18th and 19th centuries): LORD ACTON, *Historical Essays and Studies* (1907), see especially "German Schools of History"; J.B. BURY, *The Idea of Progress: An Inquiry into Its Origin and Growth* (1920, reprinted 1960); EDMUND WILSON, *To the Finland Station* (1940), especially for French historiography; PIETER GEYL, *Napoleon, voor en tegen in de Franse geschiedschrijving* (1946; Eng. trans., *Napoleon, For and Against*, 1949); *Some Modern Historians of Britain: Essays in Honour of R.L. Schuyler* (1951); G.P. GOOCH, *History and Historians in the Nineteenth Century*, 2nd rev. ed. (1952); FERDINAND SCHEVILL, *Six Historians* (1956), particularly interesting on Ranke; GEORG G. IGGERS, "The Image of Ranke in American and German Historical Thought," in *History and Theory*, 2: 17–123 (1962); and *The German Conception of History* (1968); HENRY E. BELL, *Maitland: A Critical Examination and Assessment* (1965); FREDERICK M. BARNARD, *Herder's Social and Political Thought: From Enlightenment to Nationalism* (1965).

Twentieth century: EUGENE N. ANDERSON, "Meinecke's *Ideengeschichte* and the Crisis in Historical Thinking," in *Medieval and Historiographical Essays in Honor of James Westfall Thompson* (1938); MARC BLOCH, *Apologie pour l'histoire; ou, Métier d'historien* (1949; Eng. trans., *The Historian's Craft*, 1953); *Architects and Craftsmen in History: Festschrift für Abbott Payson Usher* (1956), biographies of leading historians; JACK H. HEXTER, *Reappraisals in History* (1961); RICHARD PARES, *The Historian's Business, and Other Essays* (1961), particularly valuable for the works of ARNOLD TOYNBEE; FRIEDRICH MEINECKE, *Die Idee der Staatsräson in der neueren Geschichte* (1957; Eng. trans., *Machiavellism: The Doctrine of Raison d'État and Its Place in Modern History*, 1957); DONALD C. WATT (ed.), *Contemporary History in Europe* (1968).

Russian historiography: There is no satisfactory general survey in English. The following can be useful for particular periods or historians: ANATOLE G. MAZOUR, *Modern Russian Historiography*, 2nd ed. (1958); ALEXANDER S. VUCINICH, *Science in Russian Culture: A History to 1860* (1963); and RICHARD PIPES (trans.), *Karamzin's Memoir on Ancient and Modern Russia* (1966); JOHN S. CURTISS (ed.), *Essays in Russian and Soviet History, in Honor of Gerold Tanquary Robinson* (1962), especially on Semevsky; ALAN D. FERGUSON and ALFRED LEVIN (eds.), *Essays in Russian History: A Collection Dedicated to George Vernadsky* (1964); JOHN KEEP and LILIANA BRISBY (eds.), *Contemporary History in the Soviet Mirror* (1964).

Muslim historiography: FRANZ ROSENTHAL, *A History of Muslim Historiography*, 2nd rev. ed. (1968).

East Asian historiography: WILLIAM G. BEASLEY and E.G. PULLEYBLANK, *Historians of China and Japan* (1961); CHARLES S. GARDNER, *Chinese Traditional Historiography* (1938, reprinted 1961).

(E.B.Fr.)

History, Philosophy of

The term history may be employed in two quite different senses: it may mean (1) the events and actions that together make up the human past, or (2) the accounts given of that past and the modes of investigation whereby they are arrived at or constructed. When used in the first sense, the word refers to what as a matter of fact happened, while when used in the second sense it refers to the study and description of those happenings. The notion of philosophical reflection upon history and its nature is consequently open to more than one interpretation, and contemporary writers have found it convenient to regard it as covering two main types of undertaking. On the one hand, they have distinguished philosophy of history in the traditional or classical sense; this is conceived to be a first-order enquiry, its subject matter being the historical process as a whole and its aim being, broadly speaking, one of providing an overall elucidation or explanation of the course and direction taken by that process. On the other hand, they have distinguished philosophy of history considered as a second-order enquiry; here attention is not focussed upon the actual sequence of events themselves but, instead, upon the procedures and categories used by practicing historians in approaching and comprehending their material. The former, often alluded to as speculative philosophy of history, has had a long and varied career; the latter, which is generally known as critical or analytical philosophy of history, has only risen to prominence during the 20th century.

SPECULATIVE THEORIES

The idea of an order or design in history. The belief that it is possible to discern in the course of human history some general scheme or design, some all-encompassing purpose or pattern, is very old and has found expression in various forms at different times and places. The reasons for its persistence and vitality are numerous, but two very general considerations may be identified as having exercised a fairly continuous influence. First, it has often been supposed that, if the belief in an overall pattern is abandoned, one is obliged to acquiesce in the view that the historical process consists of no more than an arbitrary succession of occurrences, a mere agglomeration or patchwork of random incidents and episodes. But such a view (it has been contended) cannot be seriously entertained, if only because it conflicts with the basic demand for system and order that underlies and governs all rational enquiry, all meaningful thought about the world. Second, it has frequently been felt that to refuse to allow that history is finally intelligible in the required manner implies a skepticism concerning the value of human life and existence that constitutes an affront to the dignity of human nature. The 18th-century German philosopher Immanuel Kant, for example, spoke of the "repugnance" that is inevitably experienced if the past is viewed

The necessity for a meaningful view of history

> as if the whole web of human history were woven out of folly and childish vanity and the frenzy of destruction, so that one hardly knows in the end what idea to form of our race, for all that it is so proud of its prerogatives.

In more recent times, a comparable attitude is discernible beneath Arnold Toynbee's uncompromising repudiation of the idea that history is "a chaotic, disorderly, fortuitous flux, in which there is no pattern or rhythm of any kind to be discerned." Thus, it has been the object of a long line of theorists, representative of widely divergent outlooks, to demonstrate that such pessimism is unjustified and that the historical process can, when appropriately viewed, be seen to be both rationally and morally acceptable.

Theological origins. Western speculation concerning the meaning of history derived in the first instance chiefly from theological sources. The belief that history conforms to a linear development in which the influence of providential wisdom can be discerned, rather than to a recurrent cyclical movement of the kind implicit in much Greco-Roman thought, was already becoming prevalent early in the Christian Era. Traces of this approach are to be found in the conception of the past set forth by St. Augustine in his *City of God* and elsewhere; it is, for example, compared on one occasion to "the great melody of some ineffable composer," its parts being "the dispensations suitable to each different period." Yet the cautious subtlety of Augustine's suggestions and the crucial distinction he drew between sacred and secular history make it important not to confuse his carefully qualified doctrines with the cruder positions advanced by some of his self-proclaimed successors. This applies, *par excellence*, to the work of the most renowned and thorough of these, Jacques-Bénigne Bossuet. Written 1,000 years after Augustine's death, Bossuet's *Discours sur l'histoire universelle* (1681; "Discourse on Universal History") is imbued throughout with a naïve confidence that the entire course of history owes its pervasive character to the contrivance of a "higher wisdom." In the eyes of Bossuet, to grasp and understand the great procession of empires and religions was "to comprehend in one's mind all that is great in human affairs and have the key to the history of the universe." For the rise and fall of states and creeds depended in the end upon the secret orders of Providence, the latter being the source of that manifest historical justice and retribution to which, on nearly every page, the annals of the past bore clear and unmistakable witness. Bossuet's vast survey was, in fact, the last major contribution to its genre. Though it made a considerable impression when it was first published, it appeared just before the discoveries of Sir Isaac Newton effected a massive transformation of the European outlook, and the book's impact was short-lived. Thus, the development of historical speculation in the 18th century was generally marked by a tendency to reject theological and providential interpretations in favour of an approach more closely aligned, in method and aim, to that adopted by natural scientists in their investigations of the physical world.

Augustine and Bossuet

Secular approaches: the Enlightenment and beyond. For many Enlightenment and post-Enlightenment thinkers, the project of establishing a science of history and society, comprising hypotheses and laws of an explanatory power analogous to that attained by theories in the physical sciences, acquired an almost obsessive importance. The age of religious and metaphysical conjectures concerning the destiny of human affairs had, in their opinion, come to a close. The task that now presented itself was one of constructing, upon the basis of hard observable facts, interpretations that would not only rescue the human studies from ignorance, uncertainty, and primitive superstition but also put into men's hands an instrument for predicting and controlling their fate. Thus, the idea of creating a universally valid social science, capable of accounting for the phenomena of history in terms of causal principles comparable to those employed in the natural sphere, came to be linked with the promotion of reformist and revolutionary ideals. Men such as Condillac and Condorcet in the 18th century and Henri de Saint-Simon, Auguste Comte, John Stuart Mill, and Henry Thomas Buckle in the 19th century all believed that it was feasible to apply scientific procedures to the study of human development. But equally—though in widely different ways—they were men deeply concerned with practical objects and committed to changing existing institutions and ways of life. To these men, theory was complementary to practice; knowledge was power.

Yet even in the 19th century, when speculation of this type was at its height, there were informed skeptics—Joseph de Maistre and Arthur Schopenhauer, for example, and later the great Swiss historian Jacob Burckhardt—who challenged the optimistic and rationalistic presuppositions on which it was founded. It was pointed out that notions such as that of the perfectibility of man or of the existence of some foreseeable goal toward which the course of events was inexorably leading were not empirically established truths but mere articles of faith; in subscribing to them, historical theorists often appeared to be tacitly importing into their allegedly scientific interpretations teleological conceptions of a kind that it had been their declared intention to banish forever from social enquiry. These objections have been repeated and amplified by 20th-century critics such as Karl Popper, who have also maintained that the theorists in question were, in any case, working with an unacceptably crude notion of scientific reasoning and that their high-sounding generalities conspicuously failed to measure up to the requisite standards of conceptual precision and observational testability.

Nineteenth-century skepticism

Although such strictures have considerable force, they should not obscure the significant contribution that had been made toward extending human knowledge and understanding. The tendency, for example, to insist upon the relevance of scientific modes of procedure to the areas of historical and social investigation at least achieved the salutary effect of throwing into relief the inadequacy of previous work in these domains; moreover, it indirectly brought to the fore the entire question of the status of history as a legitimate form of thought. For, if history should prove resistant to attempts to assimilate it to other accredited branches of enquiry, it would be necessary to show why this was so and to exhibit those features of historical thinking that lent it its distinctive and irreducible character.

The new science: Vico and Herder. Among the 18th-century theorists, two writers can indeed be picked out who—while remaining firmly within the speculative tradition—at the same time possessed sufficient genius and prescience to realize that the solution to the problem of establishing history as a reputable discipline might be found by pursuing a course different from one modelled upon the methodology of the natural sciences. Partly because of the obscure and scholastic manner in which it was written, Giambattista Vico's *Scienza nuova* (3rd ed. 1744; "New Science") was a work whose importance remained for a long time wholly unrecognized, and it is only fairly recently that its significance and originality have been fully appreciated.

Central to the book is the contention that the kind of knowledge that men can achieve of their own actions, creations, and institutions is of a radically different type from the knowledge that is acquired by the observation and investigation of the nonhuman or natural world; knowledge of the former variety is, moreover, held to be in principle superior to that of the latter. For, in Vico's opinion, in order truly to know something it is necessary in some sense to have made it: it followed that, whereas the reality studied by the physical scientist is the creation of God and therefore only properly known by God, the "world of nations" that forms the subject matter of history is the creation of men and is therefore something that men can "hope to know." Thus, Vico was led to stress the differences rather than the analogies between historical and other forms of enquiry; in particular, he emphasized the need for the historian to enter imaginatively into the spirit of past ages, re-creating the outlooks and attitudes that informed them as opposed to seeking to impose upon them inappropriate or falsifying interpretations—"pseudomyths"—that derived from the cultural ethos of his own time. Vico propounded a cyclical theory of human history, according to which "nations" or societies pass through determinate stages, and he combined this with the idea that a providential principle is in some man-

Vico's notion of unique historical knowledge

ner immanent within the various forms of life that men construct. He employed such conceptions, however, in a fashion that underlined man's nature as a historical being, whose powers and capacities do not conform to a fixed or static pattern but are necessarily subject to change and development in the course of time.

In a similar vein, the German writer Johann Gottfried von Herder, in his influential *Ideen zur Philosophie der Geschichte der Menschheit* (4 vol., 1784–91; Eng. trans., *Outlines of a Philosophy of the History of Man*, 1800), implied that it was vital to view human actions and achievements from a standpoint that took proper account of "time, place and national character"—in other words, cultural milieu and the inevitable limits imposed by historical situation and circumstance. In its general direction, Herder's historical thought reflected the Enlightenment preconceptions of man as a progressive being. Herder's chief importance lies, however, in his insistence upon the misconceptions involved in treating the products of past thought and action as if they were the manifestations of an unchanging human consciousness and as if they could be explained by reference to abstract laws eternally valid for men everywhere. According to Herder, such an approach failed to recognize the complex influences that act upon human beings as members of particular historical societies; each of these societies possessed its unique life-style, subtly but inescapably determining the mentalities of those born within its confines in a manner that rendered futile all attempts to reduce human propensities and needs to the terms of some simple set of abstract formulas.

Herder's rejection of static laws

Many of Vico's and Herder's ideas appear familiar today, but it is easy to forget that the emergence of what has come to be known as the "historical sense" is a comparatively recent phenomenon, one that represents a genuine revolution in European thought. It is largely because of this revolution that social and political theories of the kind elaborated by men such as Thomas Hobbes and Benedict de Spinoza in the 17th century seem oddly artificial to 20th-century eyes, so remote are the categories in which they sought to explain human life and behaviour from those that have subsequently found acceptance.

History as a process of dialectical change: Hegel and Marx. The suggestion that there is something essentially mistaken in the endeavour to comprehend the course of history "naturalistically" and within an explanatory framework deriving from scientific paradigms was powerfully reinforced by conceptions stemming from the development of German Idealism in the 19th century. Hegel's "philosophy of the spirit" made its appearance upon the intellectual scene contemporaneously with Saint-Simonian and Comtean Positivism, rivalling the latter in scope and influence and bringing with it its own highly distinctive theory of historical evolution and change. Hegel's stress upon the "organic" nature of social wholes and the incommensurability of different historical epochs owed evident debts to Herderian ideas, but he set these within an overall view that pictured the movement of history in dynamic terms. Regularities and recurrences of the sort that typically manifest themselves in the realm of nature are foreign, Hegel maintained, to the sphere of mind or spirit, which was characterized instead as involving a continual drive toward self-transcendence and the removal of limitations upon thought and action. Man was not to be conceived according to the mechanistic models of 18th-century Materialism; essentially he was free, but the freedom that constituted his nature could only achieve fulfillment through a process of struggle and of overcoming obstacles that were themselves the expression of his own activity; it was in this sense that Hegel claimed that spirit was "at war with itself"—"it has to overcome itself as its most formidable obstacle" (*Lectures on the Philosophy of History*). In concrete terms, this meant that historical advance did not proceed through a series of smooth transitions. Once the potentialities of a particular society had been realized in the creation of a certain mode of life; its historical role was over; its members became aware of its inadequacies, and the laws and institutions they had previously accepted unquestioningly were now experienced as fetters, inhibiting further development and no longer reflecting their deepest aspirations. Thus, each phase of the historical process could be said to contain the seeds of its own destruction and to "negate" itself; the consequence was the emergence of a fresh society, representing another stage in a progression whose final outcome was the formation of a rationally ordered community with which each citizen could consciously identify himself and in which there would therefore no longer exist any sense of alienation or constraint. Somewhat curiously, the type of community Hegel envisaged as exemplifying this satisfactory state of affairs bore a striking resemblance to the Prussian monarchy of his own time.

History as a dynamic process

The notion that history conforms to a "dialectical" pattern, according to which contradictions generated at one level are overcome or transcended at the next, was incorporated—though in a radically new form—in the theory of social change propounded by Karl Marx. Like Hegel, Marx adopted a "directional" view of history; but, whereas Hegel had tended to exhibit it as representing the unfolding in time of an inner spiritual principle, Marx looked elsewhere for the ultimate determinants of its course and character. Man, according to Marx, was a creative being, situated in a material world that stood before him as an objective reality and provided the field for his activities; this primitive truth, which had been obscured by Hegel's mystifying abstractions, afforded the key to a proper understanding of history as a process finally governed by the changing methods whereby men sought to derive from the natural environment the means of their subsistence and the satisfaction of their evolving wants and needs. The productive relations in which men stood to one another, resulting in such phenomena as the division of labour and the appearance of economically determined classes, were the factors fundamental to historical movement. What he termed the superstructure of society—which covered such things as political institutions and systems of law, ethics, and religion—was in the last analysis dependent upon the shape taken by the "material production" and the "material intercourse" of human beings in their struggle to master nature: "it is not the consciousness of men that determines their being, but, on the contrary, their social being that determines their consciousness." Hence, the inner dynamic of history was held to lie in conflicts arising from changes in the means of production and occurring when modes of social organization and control, adapted to the development of the productive forces at one stage, became impediments to it at another; they were to be resolved, furthermore, not by abstract thought but by concrete action. Thus, the Hegelian conception of spirit as involved in a relentless struggle with itself and with what it had created underwent a revolutionary transformation, explosive in its implications.

Economic determinism

Marx's interpretation of the historical process, with its stress upon necessity and the operation of ineluctable laws, has often been portrayed by its proponents as being scientific in character. It has, however, more than one aspect, and it would be an error to identify its underlying methodology with that associated with Comtean Positivism. Generally speaking, the basic categories within which it was framed derived from a theory of human nature that had more in common with the postulates of German romantic thought than with those of British and French Empiricism: to this extent, the logical structure Marx sought to impose upon the data of history belonged to a tradition that stressed the differences rather than the resemblances between the human and the natural world.

Twentieth-century systems. The tendency to detect in history the presence of large-scale patterns and comprehensive uniformities continued into the 20th century in the work of a number of writers, most notably Oswald Spengler and Arnold Toynbee. Spengler's *Decline of the West* (originally published in German, 1918–22), wherein the history of mankind was presented in terms of biologically conceived cultures whose careers conformed to a predetermined course of growth and decay, was

widely acclaimed during the years of disillusionment that followed World War I; and a somewhat similar reception was given to Toynbee's massive *Study of History* (1934–59) immediately after World War II. Toynbee, like Spengler, undertook a comparative study of civilizations, thereby repudiating attempts to treat the past as if it exhibited a single linear progression: at the same time, he diverged from Spengler in suggesting that current Western society might not after all be necessarily doomed to extinction and in tempering a predominantly deterministic mode of thought with reservations that allowed a place for human free will and the possibility of divine intervention. Yet, as some of his critics were quick to point out, such qualifications were not easy to reconcile with his original insistence upon the need to adopt "a scientific approach to human affairs"; nor was it clear that his own use of inductive methods to establish the laws governing the development of civilizations was above logical suspicion or reproach. Toynbee's experiment might have been impressive as an individual achievement; nevertheless, with the multiplication of objections and in a theoretical climate that had become skeptical of speculative system-building of any kind, the very feasibility of engaging upon a project of the type he had undertaken came to be seriously questioned. It was felt increasingly that philosophy of history in the traditional sense—resting largely upon uncriticized assumptions concerning the nature of historical enquiry and its relations with other disciplines—had reached something of an impasse; if history was still to be treated as a proper subject for philosophical examination, it must be along lines quite different from those previously pursued.

Toynbee's system

ANALYTICAL PROBLEMS

The concept of history. The task of trying to delineate the specific character of historical knowledge and understanding, rather than of seeking to construct vast speculative schemes in the earlier manner, first began to attract the attention of philosophers toward the end of the 19th century. To such thinkers as Wilhelm Dilthey and Benedetto Croce, the claim that, in the absence of some all-embracing system of a teleological or quasi-scientific kind, the course of history could be regarded as constituting nothing better than a meaningless chaos appeared to be totally unacceptable. History is intelligible, they believed, in the sense that historians make it so; moreover, this was the only type of intelligibility it was either necessary or legitimate to demand. What could reasonably be looked for was a clearer and deeper insight into the conditions that render historical knowledge possible, an elucidation of the presuppositions upon which historical enquiry is founded and of the principles according to which it proceeds. It was with such an investigation in mind that R.G. Collingwood, a British philosopher who owed much to Crocean ideas, wrote in his *Autobiography* that "the chief business of twentieth-century philosophy is to reckon with twentieth-century history." By contending that the philosopher should eschew the grandiose ambition of providing a synoptic vision of the entire historical process and concern himself, instead, with the articulation and justification of existing historical procedures, Collingwood and his continental precursors made, in effect, a crucial contribution toward setting philosophy of history on a new path. Their proposals were, moreover, given additional impetus by the widespread acceptance of analytical approaches in other branches of philosophy. In consequence, contemporary thinkers have tended to focus attention upon the explication of concepts and terms that perform a key role in historical thought and description as these are actually carried on: among other things, they have been led into discussing the ways in which historians typically divide up and classify the past, the manner in which they argue for and substantiate their interpretations, and the logical structure of the explanations they are accustomed to offer.

The work of R.G. Collingwood

Explanation and understanding. Both Croce and Collingwood, in their criticisms of earlier theorists, were especially anxious to expose what they believed to be recurrent and fundamental misconceptions regarding the method and subject matter of history: central to these was the assumption that historical occurrences could be subsumed under, and explained in terms of, universal laws of the sort that played an essential part in scientific interpretations of inanimate nature. This assumption was, in their opinion, a gross error. As Collingwood put it, the moment had arrived for history to be released from "its state of pupilage to natural science." With this in mind, he went on to develop an account of historical understanding according to which the historian explains events by exhibiting them as the expressions of past thinking on the part of self-conscious purposive agents—thinking that the historian must imaginatively reconstruct or re-enact in his own mind—rather than by showing the events to be instances of general uniformities or regularities that are established by induction. In propounding this view—which Croce, though he formulated it less clearly and precisely, basically shared—Collingwood set in motion a controversy concerning knowledge and explanation in history that has been central to much subsequent discussion. As Collingwood himself was fully aware, a position similar to his own had been originally advanced (though in a very different context) by Vico; and it is indeed noteworthy that the general division, evident at the speculative level, between those who wished to comprehend historical phenomena in ways suggested by the physical sciences and those who, by contrast, argued for an altogether distinct pattern of interpretation has tended, in recent times, to re-emerge at the level of methodological and conceptual analysis.

Thus, on one side of the dispute, there have been ranged philosophers who have taken their stand upon what has been called "the unity of science" and who have insisted that the categories and procedures appropriate to the human studies do not enjoy a unique or privileged status that somehow sets them apart from those characteristic of systematic empirical enquiry in other domains. In a classical 18th-century discussion, David Hume had argued that, if two events were said to be causally related, this could only be in the sense that they instantiated certain regularities of succession that had been repeatedly observed to hold between such events in the past: to presume otherwise was to fall back upon an unacceptable belief in "intuitable" connections that had no warrant either in reason or experience. This doctrine may be said to have been given more rigorous expression among Positivist philosophers of the present century in the shape of what is variously known as the "deductive-nomological" or "covering law" theory of explanation; as originally applied to history by Carl Hempel, it amounted to the claim that explaining a given historical occurrence in terms of some other event or set of events necessarily involves an appeal, which need not be more than tacit, to laws or general propositions correlating events of the type to be explained with those of the kind cited as its causes or conditions. Although the proposed analysis has received a variety of different formulations, each designed to meet specific objections that have been raised against it, its adherents have not wavered from the conviction that some such account must be in principle correct if explanations in history are to be open to rational assessment of the sort properly demanded within any legitimate branch of empirical investigation. It is for this reason, together with others, that they have been strongly opposed to *Verstehen*, or "empathy," theories of historical knowledge, regarding the contention that historical understanding presupposes an allegedly direct identification with the mental processes of past human agents as representing at best a heuristic recommendation of doubtful utility, at worst an obscurantist doctrine that transparently fails to provide an objective criterion whereby divergent historical interpretations can be evaluated.

The unity of science approach

Resistance to the Positivist approach has come from more than one direction. To a number of practicing historians, for instance, the account offered has appeared implausible inasmuch as it overlooks the "irreducible particularity" of historical occurrences and because it postulates an unjustifiably high degree of reliance upon the presence of discernible uniformities in the sphere of

human affairs. So far as philosophers are concerned, dissatisfaction has been voiced both by those to whom the Croce–Collingwood notion of historical thinking as the "re-enactment of past experience" has seemed to contain an important element of truth and also by those followers of Ludwig Wittgenstein who have been impressed by the skepticism concerning the adequacy of scientific models apparent in his later discussions of mental concepts. A leading representative of the former group, W.H. Dray, not only constructed a series of arguments to demonstrate the deficiencies of the covering-law theory but further proposed an alternative conception of "rational explanation," which—it was suggested—fitted many of the familiar ways whereby historians seek to render the past intelligible. Thus, Dray has maintained that the function of much historical explanation consists of showing the actions of historical persons to have been "appropriate" when viewed within the perspective of their specific beliefs, aims, and principles: it was this consideration, he claims, that was uppermost in the minds of theorists who were concerned to stress the part played by imaginative or empathetic understanding in historical reconstruction, their point being primarily a "logical" one and not necessarily carrying any of the dubious epistemological implications attacked by Positivist critics. From a different standpoint, Anglo-U.S. writers influenced by Wittgenstein have challenged the entire assumption that explanations involving the notions of human intention and purpose are susceptible to a Humean pattern of causal analysis; they have also (for example, in the work of Peter Winch) stressed the extent to which historical descriptions of past behaviour require to be framed in terms the agents themselves would have recognized as giving meaning to their activities, terms embodying references to ideas and conventions that defined the social reality in which they participated.

The criterion of appropriateness

Objectivity and evaluation. Fundamental issues concerning the status of historical enquiry of the kind just mentioned have arisen in another crucial area of discussion, centring upon the question of whether—and, if so, in what sense—history can be said to be an objective discipline. Some modern philosophers have inclined to the view that the entirely general problem of whether history is objective cannot sensibly be raised; legitimate questions regarding objectivity are only in place where some particular piece of historical work is under consideration, and in that case there are accepted standards available, involving such matters as documentation and accuracy, by which they can be settled. To others, however, things have not seemed so clear, and they have drawn attention to the doubts that may be felt when history is compared with different branches of investigation, such as chemistry or biology: by contrast with such enquiries, the historian's procedure, including the manner in which he conceptualizes his data and the principles of argument he employs, may appear to be governed by subjective or culturally determined predilections that are essentially contestable and, therefore, out of place in a supposedly reputable form of knowledge. One topic that has been recurrently examined in this connection has been the role of evaluation (specifically, of moral evaluation) in historical writing—a subject, incidentally, about which historians themselves are apt to exhibit a certain uneasiness. Nevertheless, recommendations to the effect that value judgment can and should be totally excluded from history and, indeed, from the social studies as a whole have met with a mixed philosophical reception. Among Positivists and Logical Empiricists, traditionally skeptical of the rationality of value judgments and anxious in any case to reduce the differences between the human and the natural sciences, they have found some measure of support. But that has been by no means a general response. Thus, objectors have pointed out that the language the historian customarily uses, adapted as it is to the assessment and appraisal of human motives and characteristics, makes some degree of evaluation unavoidable; they argue that, even if the possibility of a drastically revised historical vocabulary allows the ideal of a *wertfrei*, or objective history, to be theoretically conceivable, such an ideal can scarcely be seriously entertained as a realizable practical goal. These considerations have been reinforced by the further point that every historian, insofar as he has to select from the mass of material confronting him, is necessarily committed to forming judgments ascribing relative importance and significance; such attributions cannot, however, be simply read off from the facts and must, rather, be said to depend upon the prior acceptance of certain critical standards. To this extent, then, one is required to acknowledge the presence in historical writing of an ineliminable evaluative component, which is liable to obtrude itself into even so "objective" a field as that of causal analysis: it is notorious that disputes between historians as to the "true" causes of occurrences such as wars or revolutions often appear to resist resolution at a purely empirical level, and it has been persuasively maintained by some philosophers that the basic grounds for such disputes may often be traced back to the historian's adherence to a moral or political standpoint not shared by his opponent.

The question of value judgments

Conclusions. Although the topics discussed above have occupied a central position in 20th-century critical discussion, they represent only a sample of the issues with which analytical philosophers of history have been concerned: other problems that have attracted attention have included the role of freedom and responsibility of historical agents, the nature and description of historical events, and the role of narrative in history. Here, as elsewhere, the approach adopted has often produced results of considerable interest, throwing a revealing light on features of historical enquiry that are easily missed or ignored by theorists in the grip of some powerful dogma or ideology. Even so, it has perhaps been accompanied by a too ready acquiescence in the view that history is "in order as it is," the philosopher's function being confined to offering a purely descriptive elucidation of typical modes of historical thought and argument. In accepting this conception of their role, analytical philosophers of history have no doubt been partly, and understandably, influenced by a desire to avoid emulating the heady ambitions of their speculative predecessors. Yet, normative questions regarding the validity or adequacy of established procedures within any domain can always be legitimately raised; in the case of history, there seems to be no compelling reason to assume that such problems necessarily lie beyond the scope of philosophical criticism and appraisal.

(P.L.G.)

Hitler, Adolf

The dictator of Nazi Germany, Adolf Hitler, was born on April 20, 1889, at Braunau am Inn, Austria-Hungary. His father, Alois (born 1837), was illegitimate and for a time bore his mother's name, Schicklgruber, but by 1876 he had established his claim to the surname Hitler. Adolf never used any other name, and the name Schicklgruber was only revived by his political opponents in Germany and Austria in the 1930s.

Early life. Adolf Hitler spent most of his childhood in the neighbourhood of Linz, the capital of Upper Austria, after his father's retirement from the Habsburg customs

service. Alois Hitler died in 1903 but left an adequate pension and savings to support his wife and children. Adolf received a secondary education and, although he had a poor record at school and failed to secure the usual certificate, did not leave until he was 16 (1905). There followed two idle years in Linz, when he indulged in grandiose dreams of becoming an artist without taking any steps to prepare for earning his living. His mother was overindulgent to her willful son, and even after her death in 1908 he continued to draw a small allowance with which at first he maintained himself in Vienna. His ambition was to become an art student, but he twice failed to secure entry to the Academy of Fine Arts. For some years he lived a lonely and isolated life, earning a precarious livelihood by painting postcards and advertisements and drifting from one municipal lodginghouse to another.

Hitler already showed traits that characterized his later life: inability to establish ordinary human relationships; intolerance and hatred both of the established bourgeois world and of non-German peoples, especially the Jews; a tendency toward passionate, denunciatory outbursts; readiness to live in a world of fantasy and so to escape his poverty and failure.

Military service in World War I

In 1913 Hitler moved to Munich. Temporarily recalled to Austria to be examined for military service (February 1914), he was rejected as unfit; but when World War I broke out he volunteered for the German army and joined the 16th Bavarian Reserve Infantry Regiment. He served throughout the war, was wounded in October 1916, and was gassed two years later. He was still hospitalized when the war ended. Except when hospitalized, he was continuously in the front line as a headquarters runner; his bravery in action was rewarded with the Iron Cross, Second Class, in December 1914, and the Iron Cross, First Class (a rare decoration for a corporal), in August 1918. He greeted the war with enthusiasm, as a great relief from the frustration and aimlessness of his civilian life. He found comradeship, discipline, and participation in conflict intensely satisfying and was confirmed in his belief in authoritarianism, inequality, and the heroic virtues of war.

Rise to power. Discharged from the hospital in the atmosphere of confusion that followed the German defeat, Hitler determined to take up political work in order to destroy a peace settlement that he denounced as intolerable. He remained on the roster of his regiment until April 1920 and as an army political agent joined the tiny Germany Workers' Party in Munich (September 1919).

In 1920 he was put in charge of the party's propaganda and left the army to devote his time to building up the party, which in that year was renamed the Nationalsozialistische Deutsche Arbeiterpartei (of which Nazi was an abbreviation). Conditions were ripe for the development of such a party. Resentment at the loss of the war and the peace terms added to economic chaos brought widespread discontent. This was sharpened in Bavaria, where Hitler lived throughout the 1920s, by traditional separatism and dislike of the republican government in Berlin. In March 1920 a coup d'etat by the army established a strong right-wing government. Munich became the gathering place for dissatisfied former servicemen and members of the Freikorps, which had been organized in 1918–19 from units of the German army unwilling to return to civilian life, and for political plotters against the republic. Many of these joined the Nazi Party. Foremost among them was Ernst Röhm, a member of the staff of the district army command, who had actually joined the German Workers' Party before Hitler and who was of great help in furthering his schemes for developing it into an instrument of power. It was he who recruited the "strong arm" squads used by Hitler to protect party meetings, to attack Socialists and Communists, and to exploit violence for the impression of strength it gave. In 1921 these were formally organized under Röhm into a private party army, the SA (Sturmabteilung). Röhm was also able to ensure the protection of the Bavarian government, which depended on the local army command for the maintenance of order and which tacitly accepted his breaches of law and his policy of intimidation.

Although conditions were thus favourable to the growth of the party, only Hitler was sufficiently astute to take full advantage of them. When he joined the party he found it small, ineffective, committed to a program of nationalist and socialist principles but uncertain of its aims and divided in its leadership. He accepted its program but regarded it only as a means to an end—political power. His propaganda methods and his personal arrogance caused friction with the other members of the committee, which was resolved when Hitler countered their attempts to curb his freedom by offering his resignation. Aware that the future of the party depended on his power to organize publicity and to acquire funds, they were forced to give in, and in July 1921 he became president with unlimited powers. From the first he set out to create a mass movement, whose mystique and force would be sufficient to bind its members in loyalty to him. He engaged in unrelenting propaganda through the party newspaper, the *Völkischer Beobachter* ("Racist Observer," acquired in 1920), and through a succession of meetings, rapidly growing from audiences of a handful to thousands, where he developed his unique talent for magnetism and mass leadership. At the same time, he gathered around him several of the Nazi leaders who later became infamous—Alfred Rosenberg, Rudolf Hess, Hermann Göring, and Julius Streicher.

The Munich *Putsch*

The climax in this rapid growth of the Nazi party in Bavaria came in an attempt to seize power in the Munich (Beer Hall) *Putsch* of November 1923, when Hitler and Gen. Erich Ludendorff took advantage of the prevailing lawlessness and opposition to the Weimar Republic to force the leaders of the *Land* government and the local Reichswehr commander to proclaim a national revolution. When released, however, they rescinded the proclamation. When placed on trial, Hitler, although his part in the *Putsch* had been far from glorious, characteristically took advantage of the immense publicity afforded to him. He also drew a vital lesson from the *Putsch*—that the movement must achieve power by legal means. He was sentenced to prison for five years, but served only

nine months, and that in comfort at Landsberg. He used the time to prepare the first volume of *Mein Kampf*.

Mein Kampf

Hitler's ideas included little that cannot be traced to earlier writers or to the commonly accepted shibboleths of Viennese right-wing radicalism in his youth. He regarded inequality between races and individuals as part of an unchangeable natural order and exalted the "Aryan race" as the sole creative element of mankind. The natural unit of mankind was the *Volk*, of which the German was the greatest; and the state only existed to serve the *Volk*—a mission that the Weimar Republic betrayed. All morality and truth was judged by this criterion: whether it was in accordance with the interest and preservation of the *Volk*. For this reason democratic government stood doubly condemned. It assumed an equality within the *Volk* that did not in fact exist, and it supposed that what was in the interests of the *Volk* could be decided by discussion and voting. In fact the unity of the *Volk* found its incarnation in the *Führer*, endowed with absolute authority. Below the *Führer* the party (which Hitler often called the "movement" to distinguish it from democratic parties) was drawn from the best elements of the *Volk* and was in turn its safeguard.

The greatest enemy of Nazism was not, in Hitler's view, liberal democracy, which was already on the verge of collapse. It was rather the rival *Weltanschauung*, Marxism (which for him embraced Social Democracy as well as Communism), with its insistence on internationalism and class conflict. Behind Marxism he saw the greatest enemy of all, the Jew, who was for Hitler the very incarnation of evil, a mythical figure into which he projected all that he feared and hated.

During Hitler's absence in prison the Nazi Party disintegrated through internal dissension. In the task of reconstruction after his release, he faced difficulties that had not existed before 1923. Economic stability had been achieved by currency reform and the Dawes Plan; the republic had become more respectable. Hitler was forbidden to make speeches, first in Bavaria, then in many other German states (these prohibitions remained in force until 1927–28). Nevertheless, the party grew slowly in numbers, and in 1926 Hitler successfully established his position against Gregor Strasser, who had built up a rival Nazi movement in north Germany.

Alliance with Alfred Hugenberg

The slump of 1929 opened a new period of economic and political instability. Hitler made an alliance with the Nationalist Alfred Hugenberg in a campaign against the Young Plan. Through it Hitler was able for the first time to reach a nationwide audience with the help of Hugenberg's Nationalist Party organization and the newspapers it controlled. It also enabled him to commend himself as a gifted agitator to the magnates of business and industry who controlled political funds and were anxious to use them to establish a strong right-wing, anti-working-class government. The subsidies he received from the industrialists placed his party on a secure financial footing and enabled him to make effective his emotional appeal to the lower middle class and the unemployed, based on the proclamation of his faith that Germany would awaken from its sufferings to reassert its natural greatness. Like his later intrigues with the conservatives, Hitler's dealings with Hugenberg and the industrialists exemplify his skill in using those who sought to use him.

Mass agitation and unremitting propaganda, set against the failure of the government to achieve any success in internal or external affairs, produced a steadily mounting electoral strength for the Nazis, who became the second largest party in the country, with more than 6,000,000 votes at the 1930 election. Hitler opposed Hindenburg in the presidential election of 1932, capturing 36.8 percent of the votes on the second ballot.

Placed in a very strong position by his unprecedented massfollowing, he took part in a series of intrigues for the favour of the aging president in which the other principal participants were Franz von Papen, Gen. Kurt von Schleicher, Otto Meissner, and Hindenburg's son, Oskar. In spite of a decline in the party's votes in November 1932, he held to the chancellorship as the only office he would accept, and this by constitutional, not revolutionary, methods. Throughout, he showed a unique ability to exploit conditions favourable to success. He created the Hitler myth; he propagated it by every device of mass agitation and with an actor's ability to be absorbed in the role that he created for himself. Yet all the time he remained a shrewd and calculating politician, aware of the weaknesses of his own position, perceiving more quickly than anyone else how a situation could best be turned to his own advantage. In January 1933 he reaped his reward when Hindenburg invited him to be chancellor of Germany, and he took office with the support of Papen and Hugenberg and with Field Marshal Werner von Blomberg as minister of defense.

Hitler's personal life had grown more relaxed and stable with the added comfort that accompanied the success of the party. After his release from prison, he went to live on the Obersalzberg, near Berchtesgaden. His income at this time was derived in a haphazard manner from party funds and from writing in nationalist newspapers. When he became chancellor he accepted the material comforts that followed but remained independent of them. He was indifferent to clothes and food, never smoking or drinking tea, coffee, or alcohol. He continued, even as *Führer*, to rebel against routine or regular work—a characteristic that he ascribed to his artistic temperament.

When he went to live at Berchtesgaden, his half sister Angela Raubal and her two daughters accompanied him. Hitler became devoted to one of them, Geli, but his possessive jealousy drove her to suicide in September 1931. For weeks Hitler was inconsolable. Later Eva Braun, a shop assistant from Munich, became his mistress. Hitler rarely allowed her to come to Berlin or appear in public with him and would not consider marriage on the grounds that it would hamper his career. Eva was a warmhearted girl with no intellectual ability. Her great virtue in Hitler's eyes was her unquestioning loyalty, and in recognition of this he made her his legal wife at the end of his life.

Eva Braun

Dictator: 1933–39. Once in power, Hitler proceeded to establish an absolute dictatorship. He secured the President's assent for new elections on the grounds that a majority in the Reichstag could not, after all, be obtained. The Reichstag fire, on the night of February 27, 1933 (apparently the work of a Dutch Communist, Marinus van der Lubbe), provided an excuse for a decree overriding all guarantees of freedom and for an intensified campaign of violence. In these conditions, when the elections were held (March 5), the Nazis polled 43.9 percent of the votes. The Reichstag assembled in the Potsdam Garrison Church, a theatrical gathering designed by Hitler to show the unity of his own movement with the old conservative Germany, represented by Hindenburg. Two days later an enabling bill, giving full powers to Hitler, was passed in the Reichstag by the combined votes of Nazi, Nationalist, and Centre party deputies (March 23, 1933).

Thus far successful, Hitler had no desire to carry too far a radical revolution. Conciliation was still necessary if he was to succeed to the presidency and retain the support of the army; nor had he ever intended to disappropriate the leaders of industry, provided they served the interests of the Nazi state. Ernst Röhm was the chief protagonist of the "continuing revolution"; he was also, as head of the SA, greatly distrusted by the army. Hitler tried first to secure Röhm's support for his policies by persuasion and by giving him government office but failed to win him over. Göring and Heinrich Himmler were eager to remove Röhm, but Hitler hesitated until the last moment. Finally, on June 29, 1934, he reached his decision. Röhm and his lieutenant Edmund Heines were executed without trial, together with Gregor Strasser, Schleicher, and others. The army leaders, satisfied at seeing the SA broken up, approved Hitler's actions. When Hindenburg died, on August 2, they, together with Papen, assented to the merging of the chancellorship and the presidency—with which went the supreme command of the armed forces of the *Reich*—and officers and men

took an oath of allegiance to Hitler personally. Economic recovery and a reduction in unemployment (coincident with world recovery, but for which Hitler took credit) made the regime more acceptable, and a combination of success and terrorism brought the support of 90 percent of the voters in a plebiscite.

In power, Hitler devoted little attention to the organization and running of the domestic affairs of the Nazi state. Responsible for the broad lines of policy, as well as for the system of terror that upheld the state, he left detailed administration to his subordinates. Each of these exercised arbitrary power in his own sphere, but, by deliberately creating offices and organizations with overlapping authority, Hitler effectively prevented any one of these private empires from ever becoming sufficiently strong to challenge his own absolute authority.

Foreign policy claimed his greater interest. His objectives were laid down in *Mein Kampf*, and Hitler worked toward them with consummate skill. He had early admired the pan-Germanism of the Austrian Georg Ritter von Schönerer, and the reunion of the German peoples was his first ambition. Beyond that, the natural field of expansion lay eastward, in Poland, the Ukraine, and the U.S.S.R.—expansion that would necessarily involve renewal of Germany's historic conflict with the Slav peoples, who would be subordinate in the new order to the Teutonic master race. He regarded Fascist Italy as a natural ally in this crusade against Bolshevism, provided its rivalry with Germany in central Europe could be overcome, and was ready to abandon the Germans of the Tirol to this end. Britain was a possible ally, provided it abandoned its traditional policy of maintaining the balance of power in Europe and limited itself to its interests overseas. France alone in the west was the natural enemy of Germany and must, therefore, be subdued to make expansion eastward possible.

Planning eastward expansion

Before such expansion was possible, it was necessary to remove the restrictions placed on Germany by the Treaty of Versailles. Hitler used all the arts of propaganda to allay the suspicions of the other powers. He posed as the champion of Europe against the scourge of Bolshevism and insisted that he was a man of peace who wished only to remove the inequalities of the Versailles Treaty. Germany withdrew from the Disarmament Conference and from the League of Nations (October 1933), but Hitler hastened to sign a nonaggression treaty with Poland (January 1934). Every repudiation of the treaty was followed by an offer to negotiate a fresh agreement and insistence on the limited nature of Germany's ambitions. Only once did he overreach himself: when the Austrian Nazis, with the connivance of the German embassy, murdered Chancellor Engelbert Dollfuss of Austria and attempted a coup d'etat (July 1934). The attempt failed, and as Mussolini moved troops to the frontier, Hitler disclaimed all responsibility and sacrificed those who had acted with his sanction. In January 1935 a plebiscite in the Saarland returned that territory to Germany, and Hitler took the opportunity to renounce any further claims on France. In March of the same year, he announced the introduction of conscription, and, although this provoked the united opposition of Britain, France, and Italy at the Stresa Conference, his peace propaganda was sufficiently successful to persuade the British to negotiate a naval treaty (June 1935) recognizing Germany's right to rearm. His greatest stroke came in March 1936, when he used the excuse of a pact between France and the Soviet Union to remilitarize the Rhineland—a decision that he took against the advice of his own general staff. Meanwhile, the alliance with Italy, foreseen in *Mein Kampf*, rapidly became a reality as a result of the sanctions imposed by Britain and France against Italy in the Ethiopian war. In October 1936 the Rome–Berlin axis was established; shortly afterward came the Anti-Comintern Pact with Japan; and these two were linked a year later.

By 1937–38 a new stage had been reached. In November 1937 Hitler outlined his plans of future conquest (beginning with Austria and Czechoslovakia) to a secret meeting of his military leaders. He now dispensed with the services of those who were not wholehearted in their acceptance of Nazi dynamism—Hjalmar Schacht, who declared Germany's further rearmament a danger to its economy; Werner von Blomberg and Werner von Fritsch, representatives of the caution of professional soldiers; and Konstantin von Neurath, Hindenburg's appointment at the foreign office.

Austria and Czechoslovakia

In February 1938 Hitler invited the Austrian chancellor, Kurt von Schuschnigg, to Berchtesgaden and forced him to sign an agreement giving the Austrian Nazis virtually a free hand. When Schuschnigg attempted to repudiate the agreement and announced a plebiscite on the question of an *Anschluss* with Germany, Hitler immediately ordered the occupation of Austria by German troops. The enthusiastic reception that Hitler himself received decided him to settle the future of Austria by outright annexation. He returned in triumph to Vienna, the scene of his youthful humiliations and hardships. No resistance was encountered from Britain and France. Hitler had taken special care to secure the support of Italy, and when this was forthcoming proclaimed his undying gratitude to Mussolini.

Having given assurances that the *Anschluss* would not affect Germany's relations with Czechoslovakia, Hitler proceeded at once with his plans against that country. Konrad Henlein, leader of the German minority in Czechoslovakia, was instructed to agitate for impossible demands on the part of the Sudetenland Germans, thereby enabling Hitler to justify the annexation of Czechoslovakia. But the willingness of Britain and France to compel the Czech government to cede the Sudetenland areas to Germany presented Hitler with the choice between substantial gains by peaceful agreement and even greater acquisitions by a spectacular war against Czechoslovakia. Mussolini's intervention appears to have decided him, and he accepted the Munich Agreement on September 30—only to feel resentment immediately afterward at being cheated out of an impressive military conquest.

It was to be expected, therefore, that Hitler would waste no time in provoking an occasion for occupying the whole of Czechoslovakia. This he did by fostering Slovak discontent. On March 16, 1939, from the Hradčany Castle in Prague, he proclaimed the dissolution of the state whose existence he, as an Austrian, had always regarded as unnatural. Immediately afterward the Lithuanian government was forced to cede Memel (Klaipéda), on the northern frontier of East Prussia, to Germany.

Hitler was now ready to advance toward the ultimate objective of *Lebensraum* in the East. Confronted by an uncompromising Poland, guaranteed by Britain and France, he strengthened the alliance with Italy (the "Pact of Steel," May 1939) and negotiated a nonagression pact with the Soviet Union, signed on August 24—just within the deadline set for an attack on Poland before the winter. He still disclaimed any quarrel with Britain, but to no avail, and the invasion of Poland (September 1) was followed two days later by a British and French declaration of war.

Invasion of Poland

In his foreign policy Hitler combined complete opportunism in means and timing with unwavering pursuit of the objectives laid down in *Mein Kampf*. He showed astonishing skill in judging the mood of the democracies and exploiting their weaknesses—in spite of the fact that he had scarcely set foot outside Austria and Germany and spoke no foreign language. Up to this point every move had been successful—even his anxiety over British and French entry into the war was dispelled by the rapid success of the war in Poland. The result was to convince him more and more of his own infallibility and to induce him to push ahead still faster with his plans for conquest.

World War II. Hitler from the first had assumed direction of the major strategy of the war. When the success of the campaign in Poland failed to lead to the peace negotiations with Britain for which he had hoped, he ordered the army to prepare for an immediate offensive in the west. Bad weather, however, provided the reluctant generals with the opportunity to postpone the western

offensive, and this in turn led to two major changes in planning. The first, on the suggestion of Adm. Erich Raeder, commander in chief of the navy, was Hitler's order to occupy Denmark and Norway in April 1940. Hitler took a close personal interest in the operation, and from this time his intervention in the detail of military operations was to grow steadily greater.

The second was the adoption of Gen. Erich von Manstein's plan for an attack through the Ardennes (opened May 10), instead of through the Low Countries. Against his generals' advice, Hitler held back Gen. Heinz Guderian's tanks south of Dunkirk, thus enabling the British to organize the evacuation of their army. But the campaign as a whole was a brilliant success, and Hitler could claim the major credit for its overall planning. On June 10 Mussolini entered the war on the side of Germany, and at the end of June Hitler avenged the Treaty of Versailles by signing an armistice with France on the site of the Armistice of 1918.

The next step was the subjugation of Britain by aerial bombardment, followed by invasion. But in the summer of 1940, long-term preparations were begun for the invasion of the Soviet Union, and, as the expected surrender of Britain still failed to materialize, the eastern campaign quickly came to dominate Hitler's conception of the grand strategy of the war to the exclusion of everything else. The Soviet Union had occupied eastern Poland and Bessarabia, and Hitler sought to counter any further moves by forcing the governments of Hungary and Romania to accept an agreement that he dictated and by urging the abandonment of Mussolini's plans for the invasion of Greece. Mussolini, however, piqued at being kept in ignorance of Hitler's intentions, invaded Greece; and the lack of success of the Italian armies made it necessary for German forces to come to their aid in the Balkans and North Africa. Hitler's plans were further disrupted by a coup d'etat in Yugoslavia in March 1941, overthrowing the government that had made an agreement with Germany. Regarding this as an insult to Germany and himself, Hitler immediately ordered his armies to subdue Yugoslavia. The campaigns in the Mediterranean theatre, although successful, remained subordinate to the eastern offensive, with which Hitler was so preoccupied that he lost the opportunism and flexibility that he had shown in political affairs. Even when Raeder and Erwin Rommel urged Hitler to destroy the whole British Middle East position by a final blow at Suez, he would spare no more forces from Operation "Barbarossa"—the planned invasion of the Soviet Union.

The attack against the U.S.S.R. was launched on June 22, 1941, with Hitler so confident of success that he refused to provide winter clothing and equipment for his troops. The German Army advanced swiftly into the Soviet Union, but failed to destroy its Russian opponent. Hitler became completely overbearing toward his generals. He disagreed with them about the object of the main attack and he wasted time and strength by failing to concentrate on a single objective and by frequently reversing his own decisions. In December 1941 an unexpected Russian counterattack made it clear that Hitler's hopes of a single campaign would not be realized.

War with the United States

The next day came the Japanese attack on Pearl Harbor. Hitler precipitately declared war on the United States—although the pact with Japan was purely defensive and he had not been informed of the Japanese intentions. Misled by an essentially central European view of world politics, he apparently took no account of the force that a mobilized United States could bring to bear in Europe.

Hitler's conduct throughout 1942 was marked by further errors of judgment—he paid insufficient attention to the Mediterranean and the Atlantic at a time when a relatively small additional effort in those theatres might have been decisive. In the Soviet Union his continued unreadiness to concentrate on a single objective probably forfeited the opportunity to capture Stalingrad while it was still lightly defended.

Meanwhile, he directed Himmler to prepare the ground for the "new order" in Europe. The concentration camps were expanded, and there were added to them extermination camps such as Auschwitz and Mauthausen, as well as mobile extermination squads. The Jews of Germany, Poland, and the Soviet Union were most numerous among the victims; in German-occupied Europe between 4,500,000 and 5,500,000 had been killed by the end of the war as the only solution in Hitler's view of the Jewish "problem." The sufferings of other races were only less when measured in numbers killed. Such barbarism was indiscriminate, even where, as in the Ukraine, Hitler might have encouraged nationalist feelings to his own advantage.

At the end of 1942, defeat at el-Alamein and at Stalingrad brought the turning point in the war, and Hitler's character and way of life began to change. Hitherto, the success that he had imagined had been largely realized, but to preserve the world of fantasy from defeat and failure he isolated himself more and more from reality. Directing operations from his headquarters in the east, he refused to visit bombed cities or to read reports of setbacks; those close to him, especially Martin Bormann, his secretary, took care that only pleasing information reached him; and he became increasingly dependent on his physician, Theodor Morell, and the injections that he supplied. Even so, he had not yet lost the power to react vigorously in the face of misfortune. After the arrest of Mussolini in July 1943 and the Italian armistice, he not only directed the occupation of all important positions held by the Italian army but ordered the kidnapping of Mussolini, with the intention that he should head a new Fascist government. On the eastern front, however, the refusal to withdraw led only to greater losses without any possibility of holding up the Soviet advance. Inevitably, relations with his army commanders grew increasingly strained, the more so with the growing importance given to the SS divisions, directly responsible to Hitler. Meanwhile, the failure of the U-boat campaign and the bombing of Germany made more evident how reduced were the chances of victory.

Assassination attempt

All these factors made more desperate the few soldiers and civilians who were ready to remove Hitler and negotiate a peace. Several attempts were planned in 1943–44; the most nearly successful was made on July 20, 1944, when Col. Claus von Stauffenberg exploded a bomb at a conference at Hitler's headquarters in East Prussia. But Hitler escaped with superficial injuries, and, with few exceptions, those implicated in the plot were executed. The reduction of the army's independence was now made complete, and National Socialist political officers appointed to all military headquarters.

Thereafter, Hitler was increasingly ill and fatigued; but he did not relax or lose control over the Nazi Party or the army, and he continued to exercise an almost hypnotic power over his close subordinates, none of whom was able to wield any independent authority. In December 1944 he moved his headquarters to the west to direct an offensive in the Ardennes for which the last reserves of manpower were mobilized. When it failed, his hopes for victory became ever more visionary, based on the use of new weapons or on the breakup of the grand alliance, especially after the death of Roosevelt. Far from trying to save what could be rescued from defeat, he ordered mass material destruction and condemned his armies to death by refusing to allow surrender.

From January 1945 Hitler never left the chancellery in Berlin or its bunker, abandoning a plan to lead a final resistance in the south as the Soviet forces closed in on Berlin. In a state of extreme nervous exhaustion, prematurely senile if not insane, he at last accepted the inevitability of defeat and thereupon prepared to take his own life, leaving to its fate the country over which he had taken absolute command. Before this, two further acts remained. In the small hours of April 29, he married Eva Braun. Immediately afterward he dictated his political testament, justifying his career and appointing Karl Dönitz as head of the state and Josef Goebbels as chancellor.

Hitler's death

On April 30 he said farewell to Goebbels, Martin Bormann, and the few others remaining, then retired to his suite and either shot or poisoned himself. His wife took poison. In accordance with his instructions, their bodies were burned.

Hitler's success must be attributed to the susceptibility of postwar Germany to his own unique talents as a political leader. His rise to power was not inevitable, and any change in a complex conjunction of circumstances might have relegated him to the obscurity and failure of his youth; yet there was no one who equalled his ability to exploit and shape events to his own ends. The power that he wielded was unprecedented, both in its scope and in the technical resources at its command; but he made no permanent contribution, moral or material, to mankind. His originality and distinctiveness lay in his methods rather than his ideas and purpose, which were shared in whole or in part by millions of people, in Germany and elsewhere. By the time he was defeated, he had broken down the whole structure of the world in which he lived and left behind a Germany and a Europe that have remained divided ever since.

Hobbes, Thomas

Thomas Hobbes, whose long life actively covered most of the 17th century, was one of the greatest of British political philosophers. Paradoxically, he was a political absolutist while qualifying also as one of the founders of Liberalism. His importance lies in his having insisted that the first requirement of political and moral institutions is that they should provide the citizens with security. Thus, Hobbes's starting point was the individual, his rights and need for security—from which he passed to the social contract by which a sovereign is invested with absolute authority. In ethics he was an egoist verging on psychological hedonism (pleasure is the good) and in metaphysics a Materialist, to whom all is body in motion.

Hobbes was born at Westport (now part of Malmesbury), Wiltshire, on April 5, 1588, the son of Thomas Hobbes, vicar of Westport and Charlton. Reports of the Spanish Armada were filling England with alarm at the time of his birth, and Hobbes afterward attributed his own love of peace to the fact that fear and he were twins. His father was "a choleric man," however; and he disappeared after engaging in a brawl at his own church door and abandoned his three children to the care of his brother, a well-to-do glover in Malmesbury.

Early life. At the age of four Hobbes was sent to the church school at Westport, then to a private school, and finally, at 15, to Magdalen Hall, Oxford, where he devoted most of his time to books of travel and the study of maps and charts. On graduating (February 5, 1608), Hobbes became a private tutor to William Cavendish, afterward 2nd earl of Devonshire, and so began a lifelong connection with the Cavendish family. He grew very fond of his pupil, who was only a little younger than himself. In 1610 Hobbes visited France and Italy with his pupil. There he probably found that the Aristotelian philosophy that he had been taught at Oxford was beginning to crumble before the discoveries of Galileo and of Johann Kepler, who formulated the laws of planetary motion. But Hobbes was not yet a philosopher. On returning home he decided to make himself a classical scholar.

Studies and travels

At some time between 1621 and 1625, he came into contact with Francis Bacon, known for his philosophy of the inductive method. John Aubrey, a contemporary antiquary, related that Hobbes occasionally acted as Bacon's amanuensis and helped him to render a few of his *Essays* into Latin. But the chief fruit of Hobbes's classical studies was his translation of Thucydides, the Greek historian. Its publication in 1629 was inspired by the troubles of the time, for Hobbes saw in the fate of ancient Athens a salutary warning against democracy. It was also in 1629, the year after the death of the 2nd earl of Devonshire, that Hobbes went abroad again as travelling companion to the son of Sir Gervase Clifton.

The turning point in his intellectual history occurred about the time of this trip, when, in Euclid's *Elements*, he traced the proofs back through proposition after proposition and was thus demonstratively convinced of their truth. As Aubrey wrote, "This made him in love with geometry." The method of proceeding by clear steps from equally indubitable premises seemed thereafter to be the only possible one for science and philosophy.

In 1630 Hobbes was recalled from Paris to teach the young earl of Devonshire, William Cavendish, son of his late patron. In his prose autobiography, Hobbes himself related how he was in a gathering of learned men when the question was asked, "What is sense?" No one appeared to know the answer, but it occurred to Hobbes that, if material things and all of their parts were always at rest or in uniform motion, there could be no distinction of anything and consequently no perception; thus, the cause of all things must lie in diversity of motion. He was therefore driven to geometry to gain insight into the principles of motion. Hobbes laid out these ideas in his first known philosophical work, *A Short Tract on First Principles*, which dates from this period. During a third trip abroad, this time with the younger Cavendish, Hobbes's interest in science and philosophy was stimulated by his contact with the leaders of the new thought in Europe. He became obsessed with the idea of motion. He decided that the basic reality is matter in motion, and he aimed to deduce from this fact, by strict demonstrative arguments (as in geometry), the nature of everything else. He was able to discuss his ideas in Paris with the circle of Marin Mersenne, a learned mathematician and theologian, and, in 1636, with Galileo. He then planned a philosophical trilogy: *De Corpore* (1655; "Concerning Body") was to show that physical phenomena are explicable in terms of motion; *De Homine* (1658; "Concerning Man") was to show what specific bodily mo-

tions are involved in human cognition and appetition; and *De Cive* (1642; "Concerning Citizenship") was to deduce from what had already been established the proper organization of men in society.

Political interests

In 1637 Hobbes returned to England to find the country in the political ferment that preceded the Civil War, and he decided because of this threat to publish the last part of his planned philosophy first. He set out to prove that the royal powers and rights called in question were inseparably annexed to sovereignty, which at that time was admitted to reside in the king. *The Elements of Law, Natural and Politic*, part I on man and part II on citizenship, was circulated in manuscript in 1640. It already embodied Hobbes's characteristic doctrine that men can only live together in peace if they agree to subject themselves to an absolute and undivided sovereign, and it contained most of the political and psychological doctrines for which Hobbes is famous and which reappeared in *De Cive* and *Leviathan* (see below). It differed from his *Leviathan*, however, by stressing that primary democracy is the first form of commonwealth by institution, monarchy and aristocracy arising when the democratic sovereign created by the social contract between individuals annihilates itself by transferring its power absolutely to one man or to a few. Unfortunately, Hobbes antagonized both parties in the current constitutional struggle: the believers in the divine right of kings were irritated by his social contract theory, the Parliamentarians by his advocacy of absolute monarchy.

Exile in Paris. When strife became acute in 1640, Hobbes feared, perhaps unjustifiably, for his safety and retired to Paris, "the first of all that fled." He was soon in contact with later fugitives from England. He rejoined the Mersenne circle, wrote "objections" to the *Meditationes* and the *Dioptrique* of Descartes, and in 1642 published *De Cive*, which expanded the argument of the second part of *The Elements of Law* and concluded with a section on religion that dealt more fully with the relation between church and state. A Christian church and a Christian state, he held, were one and the same body; of that body, the sovereign was the head; he therefore had the right to interpret Scripture, decide religious disputes, and determine the form of public worship. Hobbes spent the next four years working on optics and on *De Corpore*. In 1646 the young prince of Wales, later to become Charles II, sought refuge in Paris, and Hobbes accepted an invitation to instruct him in mathematics. Contact with exiles from England made it increasingly difficult to concentrate on natural philosophy, and he turned once more to political theory. In 1647 he published a second, augmented edition of *De Cive* and, in 1651, an English version. In 1650 the manuscript of *The Elements of Law* was published in two parts, as *Human Nature* and *De Corpore Politico* ("Of the Body Politic").

Contents of the *Leviathan*

Hobbes's masterpiece, however, was the *Leviathan, or the Matter, Form, and Power of a Commonwealth, Ecclesiastical and Civil* (1651). In the first two parts, "Of Man" and "Of Commonwealth," he reworked the ground already covered in the earlier treatises; in the last two, "Of a Christian Commonwealth" and "Of the Kingdom of Darkness," he embarked upon a discussion of Scripture and made a vigorous attack on the attempts of papists and Presbyterians to challenge the right of the sovereign.

Hobbes's reputation as a thinker rests mainly on his contributions to the philosophy of man, in which he propounded an influential egoistic psychology. In moral theory he is generally regarded as a pioneer of the Utilitarian school. He justified obedience to moral rules on a purely secular basis, as the means to "peaceable, social, and comfortable living." Yet he also said that the laws of nature were God's commands.

In his political theory Hobbes first analyzed the conditions necessary for peace and security and then, in his version of the social contract, provided a recipe for constructing an ideal state in which these conditions could be satisfied. His fundamental concept was natural right rather than natural law. It is essentially a right to self-preservation. No man is obliged to act in accordance with the law of nature if he thinks such conduct inimical to his own security. Yet peace cannot be achieved unless the law of nature is generally observed. Hobbes's solution was to give everyone a guarantee of the good behaviour of his fellows by creating a power sufficient to keep them in awe. This power will be created if each individual promises every other individual that he will carry out whatever commands some selected person (or an assembly) shall consider necessary for the peace and defense of all. A sovereign so established may survive even if all the subjects desire to depose it. The sovereign's right will be as absolute as its power; it is responsible only to God. It cannot be unjust to its subjects, since these have authorized its actions. Nor is it bound by any covenant with the people.

By 1651 Charles I was dead and the Royalist cause seemed hopelessly lost; accordingly, at the end of *Leviathan*, Hobbes attempted to define the circumstances under which submission to a new sovereign became legitimate. He had always maintained that a subject had the right to abandon a ruler who could no longer protect him and to transfer his allegiance to one who could; but the statement of this view in *Leviathan* gave serious offense to Prince Charles's advisers, who concluded that Hobbes was trying to curry favour with the new regime in England in order to facilitate his own return. Barred from the exiled court and under suspicion by the French authorities for his attack on the papacy, Hobbes thus found his position in Paris becoming daily more intolerable. At the end of 1651, he returned to England and made his peace with the new regime.

Controversies. Though Hobbes was now 63 years of age, he was to retain his vigour for another quarter of a century. For a time he worked quietly on *De Corpore*, but in 1654 he became involved in one of the controversies that were to play so large a part in his later life. In 1646 he had discussed the problem of free will with John Bramhall, bishop of Londonderry; a written interchange ensued. One of the philosopher's admirers then published an unauthorized copy of Hobbes's answer under the title *Of Liberty and Necessity*. Bramhall, incensed, proceeded to issue the whole correspondence in a work entitled *A Defence of True Liberty from Antecedent and Extrinsical Necessity* (1655), and Hobbes retorted with *The Questions Concerning Liberty, Necessity, and Chance* (1656), in which he reprinted the correspondence with animadversions on the Bishop's replies. In 1658 Bramhall issued *Castigations of Mr. Hobbes, His Last Animadversions*, which contained a charge of atheism, to which Hobbes replied ten years later (published 1682).

Disputes on free will and mechanism

Hobbes had made enemies at Oxford by the publication of *Leviathan*, which attacked the university system as having supported the pope and as still working social mischief by adherence to the old learning. Oxford was therefore quick to avail itself of the opportunities for criticism offered by *De Corpore*, which was published at last in 1655.

Hobbes had been so impressed by Galileo's achievements in mechanics that he sought to explain all phenomena and, indeed, sense itself in terms of the motion of bodies. Thus his a priori mathematical approach to natural philosophy separated him decisively from Francis Bacon, who had advocated an experimental–inductive method. Hobbes's main antagonists, opposed to such a mechanistic metaphysics, were Seth Ward, professor of astronomy, and John Wallis, author of the great treatise *Arithmetica Infinitorum*, both of them much abler mathematicians than Hobbes. He replied to their attacks in *Six Lessons to the Professors of Mathematics in the University of Oxford* (1656). After more rough thrusts on both sides, Hobbes retired to complete his *De Homine* (1658), which consisted for the most part of an elaborate theory of vision, with a brief account of human psychology.

In the spring of 1660 Hobbes published an onslaught on the newfangled methods of mathematical analysis in six dialogues. In *Dialogus Physicus, sive de Natura Aeris* (1661; "Dialogue on Physics, or on the Nature of Air") he fulminated against Robert Boyle and other friends of

Wallis, who were then forming what became (in 1660) the Royal Society, dedicated to experimental research, in opposition to the deductive method of *De Corpore*. Wallis retorted in a scathing and devastating satire, accusing Hobbes, quite unjustly, of having written *Leviathan* in support of the Puritan leader Oliver Cromwell's title and of having deserted his royal master in distress. Hobbes answered these charges in a letter to Wallis, published under the title *Mr. Hobbes Considered in His Loyalty, Religion, Reputation, and Manners* (1662). In this piece, which is of great biographical value, he told his own and Wallis' "little stories during the . . . rebellion" so effectively that Wallis attempted no reply.

After a time Hobbes began a third period of controversial activity, which did not end on his side until his 90th year. His *De Principiis et Ratiocinatione Geometrarum* (1666) was designed to humble the professors of geometry by showing that their works contained much uncertainty and error. *Quadratura Circuli, Cubatio Sphaerae, Duplicatio Cubi* (1669; "The Squaring of the Circle, The Cubing of the Sphere, The Doubling of the Cube") gave Hobbes's solutions to these famous problems—solutions promptly refuted by Wallis. In 1678 appeared his last piece of all, *Decameron Physiologicum* ("Ten Questions of Physiology"), a new set of dialogues on physiological questions.

Favour at court amid charges of atheism

Meanwhile, from the time of the Restoration in 1660, Hobbes enjoyed a new prominence. Charles II, whom he had tutored in mathematics, received Hobbes again into favour. Though Hobbes's presence at court scandalized the bishops and the prim virtue of the Chancellor, the King relished his wit. He even granted Hobbes a pension of £100 a year and had his portrait hung in the royal closet. But "Hobbism" was frequently identified with freethinking and even with atheism because of his attack on the church. His enemies were many and powerful. Though he was pressed by the hostile church party as early as 1662, it was not until 1666, when the House of Commons prepared a bill against atheism and profaneness, that he felt seriously endangered; for the committee to which the bill was referred was instructed to investigate *Leviathan*. Hobbes, then verging upon 80, burned such of his papers as he thought might compromise him and set himself to inquire into the state of the law of heresy.

The results of his investigations appeared in three short dialogues and in a tract entitled *An Historical Narration Concerning Heresy and the Punishment Thereof* (published posthumously in 1680), in which he maintained that since the abolition of the high court of commission there was no court of heresy to which he was amenable and that, in any case, nothing was to be declared heresy but what was at variance with the Nicene Creed—as the doctrine of *Leviathan* was not.

Although Parliament dropped the bill on atheism, Hobbes could never afterward get permission to print anything on subjects relating to human conduct, the King apparently having made it the price of his protection that no fresh provocation should be offered to popular sentiment. The most important of the works thus withheld from publication was the spirited dialogue *Behemoth, The History of the Causes of the Civil Wars of England* (composed about 1668). To the same period probably belongs the unfinished *Dialogue Between a Philosopher and a Student of the Common Laws of England* (1681), a trenchant criticism of the constitutional theory of English government as upheld by Edward Coke. His *Historia Ecclesiastica* (1688), consisting of Latin elegiacs exposing the methods through which ecclesiastics encroached upon the civil power, may also date from this period.

Last years and historical influence. Though he was impugned by enemies at home, no Englishman of the day stood in such high repute abroad as Hobbes, and distinguished foreigners who visited England were always eager to pay their respects to the old man, whose vigour and freshness of intellect remained unquenched.

In his last years Hobbes amused himself by returning to the classical studies of his youth. The autobiography in Latin verse with its playful humour, occasional pathos, and sublime self-complacency was brought forth at the age of 84. In 1675, he produced a translation of the *Odyssey* in rugged English rhymes, with a lively preface, "Concerning the Virtues of an Heroic Poem." A translation of the *Iliad* appeared in the following year. As late as August 1679 he was promising his publisher "somewhat to print in English." He died at Hardwick Hall in Derbyshire on December 4 of that year and was buried in the neighbouring church of Hault Hucknall.

Personal appearance and character

Hobbes was tall and erect in figure. Believing that "a beard did not make a philosopher," he had himself shaved close except for a little tuft under his lip. He lived a temperate life. His favourite sport was tennis, which he continued to play occasionally, even at the age of 75. Socially he was genial and courteous, though in argument he sometimes lost his temper. Cautious in practical matters but intellectually bold in the extreme, he claimed to have read little and boasted that he would have known as little as other men if he had read as much. He is said to have had an illegitimate daughter, for whom he made generous provision.

Hobbes was not only the architect of a grand metaphysical design, but he was also a critical philosopher with a lively interest in language and a keen eye for its snares. Indeed, his account of the sources of absurdity, which provided him with a potent weapon against the Scholastics, gives him some title to be regarded as a forerunner of modern logical analysis.

Hobbes's reputation was soon overshadowed by that of Locke; and when the theory of the social contract went out of fashion, he suffered a period of neglect in Great Britain. But in the 19th century interest in him was revived by the Utilitarians—*i.e.*, by the followers of Jeremy Bentham, a moralist, and in particular by John Austin, a jurist, who made a modified version of Hobbes's doctrine of sovereignty and law the basis of his jurisprudence —and since Austin's day, Hobbes has gradually been accorded recognition as one of the greatest English political thinkers.

MAJOR WORKS

IN LATIN: *Elementorum Philosophiae Sectio Tertia: De Cive* (1642); *Elementorum Philosophiae Sectio Prima: De Corpore* (1655); *Elementorum Philosophiae Sectio Secunda: De Homine* (1658).

IN ENGLISH: *Human Nature; or, The Fundamental Elements of Policie* (1650); *De Corpore Politico; or, The Elements of Law, Moral and Politick* (1650); *Leviathan; or the Matter, Forme, and Power of a Commonwealth, Ecclesiasticall and Civil* (1651); *The Questions Concerning Liberty, Necessity, and Chance* (1656).

BIBLIOGRAPHY. The standard edition of Hobbes's complete works is that by SIR WILLIAM MOLESWORTH (1839–45, reprinted 1962), comprising *English Works*, 11 vol., and *Latin Works*, 5 vol. Notable modern editions of separate works are: *Leviathan*, ed. by MICHAEL OAKESHOTT (1946); *The Elements of Law, Natural and Politic* (including *A Short Tract on First Principles*) and *Behemoth*, ed. from early manuscripts by FERDINAND TONNIES (1889; 2nd ed., 1969); and the English version of *De cive*, ed. by STERLING LAMPRECHT (1949). For details of original editions, see HUGH MACDONALD and MARY HARGREAVES, *Thomas Hobbes: A Bibliography* (1952).

Further studies: GEORGE C. ROBERTSON, *Hobbes* (1886); FERDINAND TONNIES, *Thomas Hobbes, der Mann und der Denker* (1912); FRITHIOF BRANDT, *Den mekaniske naturopfattelse hos Thomas Hobbes* (1921; Eng. trans., *Thomas Hobbes' Mechanical Conception of Nature*, 1928); LEO STRAUSS, *The Political Philosophy of Hobbes* (1936, reprinted 1952); RICHARD S. PETERS, *Hobbes*, 2nd ed. (1967); HOWARD WARRENDER, *The Political Philosophy of Hobbes* (1957); FRANCIS C. HOOD, *The Divine Politics of Thomas Hobbes* (1964); J.W.N. WATKINS, *Hobbes's System of Ideas* (1965); KEITH C. BROWN (ed.), *Hobbes Studies* (1965); M.M. GOLDSMITH, *Hobbes's Science of Politics* (1966); F.S. MCNEILLY, *The Anatomy of Leviathan* (1968); DAVID P. GAUTHIER, *The Logic of Leviathan* (1969). There are also substantial treatments of Hobbes in CRAWFORD B. MACPHERSON, *The Political Theory of Progressive Individualism* (1962); and JOHN PLAMENATZ, *Man and Society*, vol. 1 (1963). A delightful biographical account of Hobbes is included in *Aubrey's Brief Lives*, ed. by OLIVER L. DICK, 3rd ed. (1960).

(Ed.)

Hobbies

Hobbies, broadly defined, are constructive leisure-time activities that may have a variety of goals: pleasure, relaxation, therapy, self-improvement, travel with a purpose, community service, achieving recognition and popularity, or making new friends and social contacts. Other goals may include developing an avocation or making money. Hobbies may also be defined by focussing on the individual's attitude toward any particular leisure-time activity: if he thinks of it as a hobby, if it fills his nonworking hours in a relaxing and rewarding fashion that gives him pleasure or satisfaction, to him it is a hobby. The term hobbies thus covers thousands of leisure-time activities.

Distinction between hobbies and sports and games

For the purposes of this article, sports and games are not included as hobbies, although they may have similar characteristics and goals, and, indeed, there is unresolved disagreement as to whether sports are hobbies. Athletes and sportsmen are not to be considered precluded from having hobbies, however. Outdoor enthusiasts of small-game hunting and fishing, for example, are noted for enjoying such hobbies as taxidermy, fly tying, writing, photography, and collecting books, movies, art, and accessories that reflect their special interests.

This article covers the history of hobbies and the evolution and continued growth of the many kinds of hobbies available to and pursued by modern man, including hobbies relating to art, hobbies relating to nature, hobbies relating to the past, and hobbies relating to handicrafts and skills. For specific information regarding hobbies, the reader should consult the sources listed in the *Bibliography*.

Evolution and growth of hobbies

The present-day interest in and encouragement of hobbies throughout the world has no counterpart in any other period of civilization. Once the prerogative of the leisured classes, of royalty and wealth, in the second half of the 20th century hobbies have achieved the status of a necessity for practically everyone. No age group is exempted. Hobbies are no longer considered something for the very young, the idle rich, the retired, or the infirm. They are accepted as a natural corollary of free time directly tied in with shorter working hours, timesaving and laboursaving computerized technology, more and longer holidays, and early retirement from regular work, as well as man's longer life-span. Some economists foresee a 30-hour or even a 25-hour workweek before the end of the 20th century. More and more, the need to learn how to use nonworking hours in a way that will afford pleasure, repose, and satisfaction becomes increasingly urgent.

EARLY DEVELOPMENTS

Origins. Some of today's favourite hobbies were not always associated with free time and pleasure. The activity of collecting, for example, is rooted in the origins of human society. It preceded the arts of metallurgy and agriculture, for the earliest economy was based on food-gathering and the instinct for making oneself as comfortable as humanly possible. Early man lived by picking and choosing, identifying, sampling, and exploring, spurred on by his curiosity and aided by the developing powers of his memory and his ingenuity. The importance in the modern world of this oldest manifestation of human culture is revealed not only by the existence of museums and institutions filled with the results of man's urge to collect but also by the widespread and persistent popularity of collecting—of stamps, coins, books, seashells, autographs, figurines, antique furniture, automobiles, glassware, weapons, and inumerable other items and artifacts.

Many hobbies date back through centuries, some to prehistoric times, hence it is not possible to pinpoint the origins of hobbies per se as being the exclusive discovery of any one people or the product of any one period in history. A sampling of familiar hobbies that date back to the beginnings of early civilization in one form or another would include: music, dance, poetry and prose, drawing and painting, sculpture, carving and whittling, weaving, embroidery, basketry, pottery making, beadwork, kite, toy, and doll making, leathercraft, raising pets, making hunting decoys and fishing lures, making jewelry and miniatures, and folklore, magic, and astrology. They were not referred to as hobbies, of course; the word did not even exist.

Hobbies of early civilizations

There is a popular notion that cavemen were the first known creative hobbyists. Prehistoric cave paintings and drawings authenticated as 10,000 to 15,000 years old, some even older, were discovered in 1879 near the village of Santillana, about 20 miles west of Santander, Spain, and at Lascaux in central France in 1940. The paintings and drawings, considered excellent by any critical standards, were often found in the farthest recesses and most forbidding corners of the caves. Some of the caves were entirely uninhabitable. There is mixed anthropological opinion as to whether these drawings were done for magical, religious, or decorative purposes. They could have been drawn to identify the animal to be slain and in what manner. It is to be hoped that the caveman enjoyed his task, but there are questions that becloud any certainty that it was a free-time pursuit for pleasure.

While many rulers in ancient times collected art treasures and rare manuscripts and other documents by conquest or threats of force, Aristotle is probably the most famous of the earliest hobbyists. Strabo, the Greek historian and geographer, declares that Aristotle was the first person who collected a library in Greece, and that it was he who communicated the taste to the Egyptian sovereigns. Cicero and Pliny are known to have been collectors of the writings of their famous predecessors and contemporaries. Any collector who has searched for some choice elusive items will sympathize with Pliny's complaint that letters of Julius Caesar were very scarce and hard to come by even in his own time.

Contributions of the Middle Ages. Doing something for pleasure in one's spare time was certainly not encouraged during the Middle Ages, although it was a period of great productivity of fabulous *objets d'art*, paintings, sculpture, book illumination, and great tapestries, mostly with religious connotations. The themes of the tapestries were broader in scope than any other contemporary works of art and included ancient legends, mythology, sport, chivalry, and history—such as the famous "Bayeux Tapestry" depicting the Battle of Hastings in 1066, which was, in fact, embroidered. Many of the finest examples of these works now repose in the museums of the world.

In those periods of history that divided men into nobles, commoners, and slaves, few were permitted to have a hobby. That was the prerogative only of the noble, the rich, and the venturesome. Free time was not a commodity available to everyone, and, although museums and private collections house notable examples of ancient decorative arts and handcrafts, little of it can be attributed solely to peoples' hobbies. Perhaps the one exception would be children's toys.

In the 16th century, conceivably earlier, a hobby referred exclusively to one thing—a hobbyhorse—eventually shortened to hobby. The hobbyhorse was a favourite and universal toy for children of all ages. In appearance the hobbyhorse, or hobby, ranged from a simple stick to a gaily caparisoned framework or the like, surmounted by an imitation of a horse's head. Either way, it served adequately for the meaningful and relevant games of the times that involved war, knighthood, chivalry, the good men and the bad. In time, the popularity of the hobbyhorse as a toy declined, but the fervour in pursuit of the pastime that had historically marked children's enjoyment of the hobbyhorse remained in the language to signify unusual interest in any subject outside routine daily activities.

Origin of the term hobby

GROWTH IN MODERN TIMES

"Renaissance man." Before the age known as the Renaissance, however, there had appeared many examples of "Renaissance man"—"complete men," many-sided individuals who pursued their wide and varied interests in

many fields—history, art, literature, the natural sciences, and philosophy. Later, before the fields of physics, chemistry, biology, geology, and meteorology were divided into separate sciences, many men who were physicians, barristers, tax collectors, farmers, or engaged in other professions and trades made surveys and field trips; travelled to other countries; collected minerals, fossils, plants, and artifacts; formulated and carried out experiments; studied, wrote, and read papers; and were known as natural philosophers.

This article does not attempt to identify the broadly ranging interests and activities of such men as prototypes of modern hobbies. It does intend to suggest that the sense of pleasure and satisfaction such men obtained in the pursuit of interests and activities outside of their main line of work is similar to the sense of pleasure and satisfaction sought and obtained by modern hobbyists. Before the term hobby came into general use, many men engaged in constructive and satisfying activities outside the routine of their principal occupations.

The arts-and-crafts movement. Specific inclusion of the creative arts and crafts as hobbies both on a participating as well as a collecting basis would appear to have gained concrete impetus in the second half of the 19th century with the publication of the English magazine *The Hobby Horse*, which publicized the arts-and-craft movement that centred around the artist and craftsman William Morris and his contemporaries.

Appearance of the magazine *The Hobby Horse*

Following public exhibitions of handicrafts held in England between 1888 and 1896, similar exhibitions were held in Boston and Chicago in 1897.

Victorian ladies whiled away their winter evenings making household elegancies that were certainly of the hobby class: the 1870 shadow box with dried flowers, leaves, and grasses; the hand painting of cheap, undecorated pottery called Albert ware; the wax fruits; Berlin woolwork (brilliant worsteds on canvas) for needlecraft novelties; transparencies mounted on glass—all are treasured as charming examples of the Victorian lady's hobbies.

Unlike the ladies, Victorian gentlemen, although many made collections of minerals, coins, or other items, did not engage in handicraft hobbies to any great extent, at least not until fretsaws, or scroll saws, began to appear during the 1850s. Thereafter, for about 20 years, thousands of men produced whatnots, fancy picture frames, bracket shelves, even scroll-work cutouts of inscriptions and quotations, although the supplier of printed patterns warned that only experienced fretsawyers should attempt the prodigious task of sawing out the Lord's Prayer.

Kinds of hobbies

Choosing a hobby may be an extension of many things: a person's habits, character traits, and personality, daily work, tastes, and ambition. It may be in direct contrast to the hobbyist's daily job as an escape from routine, fragmented work, and boredom. It may fill what would otherwise be idle time with an interesting activity, in the case of an older person with time on his hands. Chance and opportunity may be factors. Available time for a hobby, the probable cost, equipment if any, and the facilities that may be necessary are all considerations.

Popularity of work-around-the-house hobbies

Large numbers of people have been asked in surveys what they would like to do if they had more time. The largest proportion said that they would do more work around the house, and the second largest that they would spend more time with their families. Work around the house incorporates such hobbies as gardening and landscaping, gourmet cooking and canning, woodworking, making and restoring furniture, decorating, remodelling and repairing small appliances, toys, china, and bric-a-brac. For those who would spend more time with their families there are hiking tours and nature walks, enjoyment of the arts as spectators or participants, astronomy, model building, and raising pets, to indicate but a few of the possibilities.

Information about any hobby may be obtained through books, magazines, and newspaper articles devoted to the subject; stores, shops, galleries, and other places offering related items; instruction and discussion in schools, colleges, adult-education programs, and community centres; clubs and organizations actively interested in specific hobbies; private and public exhibitions, special sales, and auctions of items in a particular field. Many hobbies are promoted in large-scale exhibitions and sales with participating dealers and exhibitors. Those presented with the greatest frequency are antiques, coins, stamps, photography and sound equipment, vintage automobiles and other nostalgic interests, rare and old books, horticulture and flower arrangements, bottles, model-building kits, home improvement, and works of art in all categories.

HOBBIES RELATING TO THE ARTS

The arts are usually accepted as the most significant and important of all hobbies but not necessarily the most popular. It is possible to be active in both the visual and performing arts on many levels of participation: the role of artist or craftsman itself, sponsor, entrepreneur, student and scholar, critic, collector, viewer, and auditor.

Painting and sculpture. The arts have been enjoyed without benefit of money, formal education, prior knowledge, or experience, instruction, or guidance. A modicum of each is useful, however, and not prejudicial to enjoyment. The amateur status of the hobbyist in art provides a latitude for doing something badly without too much skill and still enjoying it enormously. Amateur painters have included such distinguished hobbyists as U.S. president Dwight D. Eisenhower and British prime minister Sir Winston Churchill. Churchill was the first concededly amateur artist ever to have a retrospective show of his own at New York City's Metropolitan Museum of Art. As an amateur's show, it was accorded a most favourable and enthusiastic reception; by professional standards it would not have been as graciously received.

Those who would eschew formal training in the arts will find encouragement in Lloyd Goodrich's comment on early American primitive painting: "For the fullest pictorial record of America in the eighteenth and early nineteenth centuries, one looks more to naive than professional art." A notable example is the American primitive Grandma Moses, who, in her 70s, too frail to work any longer about the farm, started painting and achieved both a critical and financial success.

For the tyro there are packaged beginner's kits with an assemblage of materials and instruction for painting by the numbers, collage, decoupage, papier-mâché, the making of mobiles, sculpture, linoleum- and wood-block printing, and other art forms.

Decoupage and collage

Decoupage and collage have been described as the age-old kindergarten pastimes of cutouts and paste-ups on a modern adult scale. In simplest terms, decoupage, which originated in France in the late 17th century, is the cutting out of designs and patterned materials and applying them permanently to any surface with adhesives to create an attractive decoration. Decoupage and collage are frequently exhibited framed. Decoupage as a decoration for furniture, screens, wall panels, and trays is at least several centuries old. In Italy it was once called the poor man's art; those who could not afford an artist's services did their own decorating with decoupage. Still one of the great appeals of this activity, which costs practically nothing to enjoy, is that many plain but useful everyday items, such as containers, frames, and metalware of all kinds, can be made to look appealingly distinctive and can be easily sold in boutiques and other specialty shops. An offshoot of decoupage, collage, a 20th-century art form, employs the technique of decoupage usually within the limitations of a frame, like a picture, to create an artist's statement with the same authority as a painting done with oils, watercolour, or other mediums of expression. The mediums may be mixed: the Spanish painter Pablo Picasso was one of the first modern painters to use the technique, combining materials with paint on canvas.

Sculpture and painting are usually presented together, but the actual molding of clay under one's hands with the thumbs as tools has an appeal for some not matched by the application of paint with a brush. Modelling with clay can be begun with a packaged kit of all the materials

and instructions. Many famous sculptor-teachers have thought that preliminary training is unnecessary; according to them, the only way to learn is to take the tools in hand and begin. The beginner is advised to start with clay as a medium before advancing to the more difficult carving of stone or wood. Not all sculpture is done with traditional materials. Hobbyists have undertaken sculpture with such items as soap, bread dough, vegetables, wax, nuts and bolts, pieces of scrap metal, various plastics, automobile-radiator cores, and heaps of discarded junk. Sculpture can stir the imagination; its limitations are only the sculptor's own.

Music. Music has become for many people a passionate interest combining hobby and avocation. Business and professional men and women, housewives, and others seeking to sooth emotions tensed by the increasingly hectic pace of modern living have learned to play guitars, recorders, and many, many other instruments. Those who enjoy vocal music participate in choirs or choruses or form duets, trios, quartets, octets, or other groups to study and sing folk music, popular songs, the music of particular or many cultures, nations (*e.g.*, Slavic; Israeli), or periods (*e.g.*, the Renaissance), or other categories of music. Many persons, of course, enjoy learning and singing solo, for their own satisfaction or to entertain others. Many also take up an instrument, the guitar, for example, to accompany themselves or others in song.

Group instruction for musical amateurs

For amateur music makers, group instruction has many advantages. Class or group rates are much lower per student, and there is also an element of stimulation in a class of music makers that speeds up the learning processes and increases enjoyment.

Some instrumental music-oriented hobbies that have a large following are: playing in amateur chamber-music groups, participating in community concert events, collecting ancient or unusual musical instruments, and collecting duplicate recordings of symphonies, concertos, and other performances by different artists.

Theatre. The theatre has always been a stimulating intellectual hobby and retains its popularity, despite the competition in many countries of television and in all countries of radio and other activities that compete for people's free time and interest.

Anyone who is even marginally associated with a civic theatre or a similar group becomes aware of the great range of opportunities, not to say needs, for hobbyists in many fields, from the inception and execution of stage and set design and lighting and costuming to directing and acting in the final production. Information as to current activities of performing-arts groups usually is available in libraries, bookshops, and local newspapers.

Not all performing-arts groups develop the same activities; the very differences from one group to another offer a choice for prospective participants. What an amateur group produces usually reflects the tastes and interests of the group's membership. It may range from folk theatre, Greek drama, Shakespeare, Ibsen, or Gogol to original works written by a member or members of the group and various forms of spontaneous theatre. A current trend is toward meaningful plays that relate to solutions of contemporary problems. Some groups stage seasonal or annual pageants or mystery or morality plays, including passion plays or revivals, especially in Great Britain and on the Continent, particularly in France, Germany, The Netherlands, and Austria. Taking part in various aspects of these productions is a hobby for at least some of the participants.

A delightful hobby related to the theatre is going to the theatre itself; for some, even a bad play is better than no play at all, and a great play is an experience long remembered. Collecting playbills, scenes from the plays, and reviews and studying the history and origins of particular types and forms of theatre are offshoot hobbies that engage many people who enjoy the theatre.

Photography. Photography is certainly the best served of all hobbies. Books, magazines, newspaper columns, and special shops are devoted to it, and many stores that never sell cameras have films for sale and a film-developing service for colour and black-and-white pictures. Taking pictures has seemingly been reduced to remarkable simplicity, with cameras so automatic as to relieve the picture taker of any thoughts other than to make certain that what he wants to take a picture of shows in the viewfinder and that there is enough film on hand.

Photography as a hobby commands the respect and interest of those who look upon photography as an art form and those who use it as a second hobby to document another hobby or interest. Photography as an art form derives from an understanding of what every phase of picture production can contribute to the finished work from the concept of an idea to the framing. As in all art forms, each artist must find his own answers. A camera club or an experienced photographer companion can accelerate the processes of learning.

Photography as art and to document another hobby

Some hobbyists will work only in black-and-white, some only in colour. Some are interested only in slides or transparencies, some only in prints, some in the arts of developing, cropping, printing, and enlarging their own photos, and some in the many aspects of making motion pictures.

As for subject matter, one enthusiast will photograph anything and everything that appeals to him; another will specialize in portraits, wild flowers, scenes of the city, birds, temples, cathedrals, or any other subject of special interest. Some of the subjects that have later developed into books include celebrities, architectural oddities, wild animals, insects, ghost towns, unusual craft skills, covered bridges, gardens, flower arrangements, and advertising incongruities. Other persons connect photography with travel: the camera has become the badge of the tourist around the world.

Writing. Whether writing is an art or a craft has never been definitely resolved. A newspaperman who can write a story while the composing room is waiting to set it up would be embarrassed by any reference to himself other than as a craftsman. A poet who polishes each bit of imagery until it takes wings and soars considers himself an artist and not a craftsman.

Many people take up writing—poetry or prose, fiction or nonfiction—as a hobby because they think they will enjoy doing it or that it will fill a void in their lives. Writing as a hobby has enriched the field of hobbies itself. Many hobbyists have added to their hobby's enjoyment by keeping a written record, as in the form of a journal, notebook, or diary, of their progress in collecting coins or antiques or in creating a garden. Such a record, indeed, is considered by many to be an essential part of the hobby of bird watching. Also, many of the books, pamphlets, and articles available on practically every hobby that exists were prepared by other hobbyists who over the years specialized to a degree that they could write with authority. This represents a valuable supplement to the professional writing in these areas.

Types of literary hobbies

Another field of interest that has attracted many hobbyists is local history. Local historical data is collected and written about by residents of that region whose routine jobs are unrelated to writing. Local historical societies encourage the writing of regional history and reminiscences. An example of a small city newspaper in the United States that publishes local history by amateur writers is the Kingston (N.Y.) *Daily Freeman*. It has run outstanding articles on forgotten industries of the past—the Hudson River steamboats, the Delaware and Hudson Canal, and the vanishing Catskill Mountains resorts—all contributed by readers with no professional writing experience.

Finally, the family trees of many countries would be missing many of their branches but for the amateur genealogists who made a permanent record of their research and findings.

Workshops in the arts. Where practicable, workshops in both the arts and crafts are to be preferred to working alone with the aid of a textbook. The usual workshop provides equipment, supplies, and reference materials, demonstration, criticism, a new environmental experience, the possibility of making new friends, and working with others, all of which can be stimuli in crystallizing the participant's objectives.

Collecting objets d'art. The doors to collecting *objets d'art* as a hobby were never open more widely to everyone than they are today. The traditional *objets d'art* that have attracted amateur collectors have been porcelains, tapestries, silver, china, antiquities, jewelry, sculpture, and bronzes. Miniatures, playing cards, clocks, buttons, paperweights, toys, and thousands of other classes of objects also have been the subjects of collections.

Influence of Pop culture

In the 1960s Pop culture, which had a profound influence on all the arts, made its impact on what are *objets d'art* and what are collectables. Examples of Pop art were not rare, not precious, not beautiful, nor skillfully crafted—even "incredible" to some critics—and yet they were accepted and sought after by the start of the 1970s. The artistic maelstroms of the 1950s and 1960s brought about change and sometimes reversals of many entrenched attitudes about art as well as other aspects of culture.

A dateline for the new standards and inclusions of articles of artistic worth would be the early 1960s. The new identity was Pop art, exemplified in the United States by the transfer of a can of Campbell's soup from the shelves of a supermarket to the walls of New York City's Museum of Modern Art. For the collector of *objets d'art*, the trickle of items that were sometimes indeed strained to qualify as having any artistic worth other than the exorbitant price tag became a flood of new possibilities. In addition, the new regime opened a haven to the collecting of "found" art objects. An assemblage of shells, pebbles, bits of glass, metals, pieces of driftwood, stones in abstract shapes, round and flowing like the nonfigurative sculpture of Henry Moore, the work of time and nature to be wondered at and valued only in aesthetic terms, may now grace any collection without apology.

This has in no way diminished the demand or weakened the market for the collectors' pieces of the pre-Pop-culture era. The supply of traditional *objets d'art* is not inexhaustible, and it diminishes as demand grows. When a rarity comes on the market, say, one of an existing known number of pieces, the bidding usually goes to a new high.

Many people enjoy collecting paintings, sculpture, or other works of art as a hobby. For an overall view of this field of endeavour, see the article ART COLLECTING.

HOBBIES RELATING TO THE PAST

Two popular fields of interest relating to the past have been mentioned above under writing—local history and genealogy. Many categories of *objets d'art* also relate to the past, as do all historical aspects of painting and sculpture, music, and the theatre. People's interests in the past are seemingly inexhaustible and form the basis of many rewarding hobbies centred on periods of history, historic and prehistoric peoples and cultures, historic personages and events, and social movements, to name a few. Hobbyists of history usually read everything available relating to their particular area of interest. They may also visit museums, historic sites, or restorations. They may re-enact battles, for example, with armies of toy soldiers or armadas of model ships. Or they may retrace in person the routes of campaigns or explorations or migrations. But whatever else the pursuit of hobbies relating to the past may entail (or offer), they nearly always include the collection of items either from the past or directly relating to it.

Three of the oldest and most persistently popular hobbies relating to the past are collecting antiques, collecting coins, and collecting stamps. These three are briefly dealt with below, as are three examples of the collecting of memorabilia—of transportation, of sports, and of military history.

Antiques. To the collector, antique means old, but it also carries connotations of aesthetic, historic, and financial value. Thus the decorative arts of all past eras have come to be considered antiques.

Many countries permit objects that qualify as genuine antiques to be imported duty free. In 1952 the so-called Florence agreement, sponsored by UNESCO, agreed to "facilitate the free flow of educational, scientific and cultural materials," and antiques were affected by subsequent legislation adopted in the participating countries. By the 1970s, 50 countries were applying the agreement, including the United States, which in 1966 passed a new tariff act permitting the duty-free importation of "antiques made prior to 100 years before their date of entry" (previously, under the U.S. Tariff Act of 1930, an object had to predate 1830 to qualify).

The antiquity of collecting antiques

The collecting of antiques goes back almost as far as history, beginning with preservation of temple treasures. In England, concern for antiques led to collections as early as the 16th century. Such collecting subsequently increased, stimulated by Romanticism, growing interests in antiquities in general, and the start of archaeology. In the second half of the 19th century, museums and collections of decorative arts, intended to stimulate designers as well as collectors, were established in London, Vienna, Paris, and New York. Antique collecting in the United States was given its first strong impetus by the Philadelphia Centennial Exhibition, 1876, which awakened interest in the national past.

When antiques are collected as a hobby, investment, although antiques have been recommended by financial publications as an investment, should be only part of the consideration for buying. Every collector has experienced at some time or other pleasure in these aspects of the activity: the search and discovery of a much-wanted addition for a collection; the possibility of a bargain; the reluctant straining of the purse strings when an item is too good to pass up and the avowal to economize on something else; the moment of adding a new treasure to a collection; the moment of showing it to others, especially other collectors; the study of books that may establish an acquisition as rare.

The search for antiques is a favourite travel hobby, and many vacation itineraries are planned for antique hunting. The numerous published price lists for popular antiques rarely leave a dealer in doubt as to what his wares are worth, but then the established price of today's particularly choice piece may be tomorrow's bargain.

Coins. Coin collecting, or numismatics, the scientific term for coin collecting, is related to many fields of study including history, archeology, languages, religion, geography, and economics. Coin collecting has always been recognized as a favourite hobby. Together with stamp collecting, it has been widely recommended for its educational value, the good habits it promotes, the friendships that develop with fellow collectors, and the benefits of quiet relaxation that are inherent in this activity. The thought of financial return at some time in the future when the collection will be ultimately sold is always a pleasant consideration but rarely is of primary consideration with the beginning collector.

Coin collecting stimulated by the Renaissance

The collection of ancient coins was stimulated by the Italian Renaissance, and many collections of Greco-Roman coins were made during the 15th and 16th centuries. In the 17th century, numismatic scholars undertook analysis of existing great collections, of which Italy had more than 350, France and the Low Countries about 200 each, and Germany not many less. Many collections had been uncritically accumulated and most included spurious pieces. From the 18th century onward greater discrimination was exercised.

The number of lesser collectors grew in the 19th century, aided by the publication of reliable handbooks and authoritative catalogs, such as the British Museum series from 1873. Numismatic societies were founded in many European countries, beginning with the Numismatic Society of London, now the Royal Numismatic Society, in 1836. London emerged and remains as the world's largest numismatic market, serving public and private collectors in many lands. International cooperation is promoted through the International Numismatic Commission (founded 1936) associated with the International Committee for Historical Sciences.

A coin collector may gather coins from all over the world; may limit himself to the coins or paper money of one country; or concentrate on current coins or on

one period, one denomination, or one particular coin. In general, private collectors of the 20th century, greatly increased in numbers, have had to specialize in order to build a satisfactory collection.

Stamps. Stamp collecting, or philately, attracts the greatest number of collecting hobbyists. Most daily newspapers carry some stamp news: at a minimum, post-office news releases that tell of new commemorative issues, dates of issue, where these are to be first placed on sale, and something of the historical background of the stamps themselves. Many newspapers have weekly stamp columns, occasionally expanded into full departments with dealer advertising. There are the weekly, semiweekly, and fortnightly publications for both collectors and dealers.

Entertaining, fascinating, engrossing, challenging, an armchair adventure in prospecting for rarities and bargains—these are all valid descriptions of stamp collecting. Obviously it may be pursued at almost any age and anywhere by anyone.

The first postage stamps for the prepayment of letter postage were issued in England in 1840; stamp collecting began almost immediately thereafter. In 1841 an advertisement in *The Times* of London asked "if any good-natured person" would assist a young lady in collecting cancelled postage stamps to cover her dressing room, and in 1842 *Punch* labelled stamp collecting "a new mania." From the practically simultaneous appearance of catalogs in the 1860s, it seems clear that collecting was spontaneous, with Great Britain, France, Germany, Belgium, and the United States apparently having active collectors before 1862.

Beginnings of stamp collecting

The Philatelic Society (from 1906 the Royal Philatelic Society) was founded in 1869 in London, the American Philatelic Society in 1886, and the Society of Philatelic Americans in 1894. In addition to the many national societies there are clubs or societies of collectors in most cities of the world.

With standard catalogs listing more than 200,000 items, the tendency toward specialization is even greater among stamp collectors than among coin collectors. Speciality clubs dealing with the philately of, for example, France, Germany, Italy, Luxembourg, Japan, Switzerland, Israel, and the United Nations as well as special subjects, such as airmails, exist to serve almost any interest.

Thematic or topical philately attracts many people as an extension of some other activity. Some familiar topical interests are transportation, music, literature, statesmen, arts and crafts, naturalists, inventors, liberators, and other heroic figures. Whatever a collector's other interests, there are stamps pictorially reflecting some historical or promotional phase of the subject.

Memorabilia. Progress and the changing face of society bring thousands of new hobbyists into the collecting field each year. Nostalgia, sentiment, a desire for continuity with the past, and a reminder of a way of life that has passed are reflected in the things that interest and appeal to collectors. Many collectors treasure memorabilia relating to antique automobiles, ferries, the circus, apothecaries, steam engines, steamboats, and other symbols of a past that is disappearing.

Collecting activities frequently start with the accumulated contents of an attic or cellar of any house, or a garage, barn, or shed used for storage. The greater the accumulation of discarded items and the longer they have been untouched the greater the possibility of converting trash into treasure. Before doing anything with an accumulation of forgotten potential treasures, it is worthwhile to attend a few antiques shows and flea markets to see what is collected and sold. Interest in nostalgic items is not just in genuine antiques more than 100 years old. Nostalgia may encompass any period—a collector's youth or childhood, his parents' or grandparents' time. It may be as recent as the 1920s, 1930s, or 1940s, which already have their collecting vogues. Collectibles of these periods are hopefully referred to as tomorrow's antiques. Typical atticana includes collections of postcards, boxes of assorted buttons, stereoptican slides, books, newspapers, periodicals, advertising cards, paper fans, political buttons, tokens, road maps, license plates, automobile-operating manuals, home-remedy bottles, valentines, phonographs and records, fruit jars, mail-order catalogs, kerosene and carbide lamps, travel souvenirs, sheet music, tin boxes, scrapbooks, inkwells, dolls and paper cut-outs, toys, sewing machines, pictures and frames, coin banks, tokens and badges, war mementos, circus, theatre, vaudeville, and sports programs, paperweights, miniatures, odd pieces of china and silver, player-piano rolls, brass beds, comic books, figurines, hatpins, buttonhooks, watch fobs, pocketknives, banners and posters, family photo albums, local directories, and old almanacs and atlases.

Collecting tomorrow's antiques

All of these items may be worth money and are constantly sought and sold through collector and hobby publications.

Transportation. All means of transportation, defunct or still in existence, such as railroads, sailboats, steamboats, ferries, trolley cars, stagecoaches, and public liveries, are of interest to collectors. Their memorabilia include contemporary photographs, prints, paintings, advertising posters, and travel circulars, stock certificates, signs, bells and whistles, lamps and other fixtures, imprinted hardware, furniture, silverware, passes, copies of construction plans and specifications, waybills, handmade models or toys, and route maps and other paper ephemera. Books and articles on these subjects frequently represent a lifetime of interest and might otherwise never be written.

Nautical memorabilia frequently has more than just sentiment to recommend it. Sailors of the mid-19th century—1820–70—produced some notable examples of scrimshaw and carvings in wood. Scrimshaw is engraving on the bones and teeth of the sperm whale and on walrus tusks. The etched portion was usually inked or rubbed with pigment to bring out the design detail. Sailors' carvings of eagles and figureheads sometimes equalled the skills of professional carvers of the period. Much of this work was whittled out with only a jackknife.

Scrimshaw

Sports. Sports enthusiasts create much of their own memorabilia in the form of autographs and photographs of sports figures, scrapbooks devoted to a particular sport or to individual players or contestants. Some hobbyists collect souvenirs, items of clothing, or other articles bearing their team's name, emblem, or colours, or miniature replicas of players, equipment, or trophies. Some sports created a legacy of antiquities for collectors, gutta-percha- and feather-stuffed golf balls, for example, and antique golf clubs, guns, and fishing rods and reels. For many sports, especially those that maintain established collections of their own, such as the baseball and football halls of fame in the United States, it is difficult to obtain any genuine items except under circumstances that authenticate the source. The triumphs of hunting and fishing, however, can be reflected in mounted trophies of the collector's own.

Military history. In the United States, the years 1861–65 attract more leisure-time interest than any other four-year period in American history. The war between the states has broad areas of specific interest: historical reading and writing; stamps and money; photography; music; weapons; discovery and invention; military souvenirs; and Lincolniana. Stamps and money of the Confederacy have increased in demand and value. It is still possible to collect a complete set of Confederate stamps at modest cost. Some Confederate coinage is scarce, though the paper money is plentiful. The state notes, which were limited in quantity and for use only within the issuing state, are in some instances more valuable but still to be had. The field of collecting toy soldiers of many lands is well represented by examples of Civil War soldiers in addition to the ordnance of both sides. In all countries, World War I posters and captured enemy matériel of World War II are the more prominent collectibles of those periods, although books about various battles and campaigns and the various generals on all sides of the conflicts have been best sellers.

The American Civil War as a hobby

Military figures are widely collected by historical china hobbyists. The Napoleon crest on china, porcelain, glass-

ware, and other materials is a collector's item, just as in the same manner elephants, owls, eagles, monkeys, occupational memorabilia and miniatures in all materials are collected by other specialists.

HOBBIES RELATING TO NATURE

Nature is man's oldest hobby. It is now his greatest concern. Environmental deterioration has affected many aspects of such simple pleasures as watching and studying birds and other wildlife, hiking and nature walks along trails and streams, even the breathing of "country air." Conservation and improvement of the environment have become corollaries of interest to every nature lover who has witnessed the corroding deterioration of the natural resources. Conservation is in itself an activity of growing involvement for everyone. The study of conservation and participation in improved environmental projects can involve important public service and encourage others to enlist in environmental improvement programs over the long term.

Conservation as a hobby

The nature story is as involved and varied as the human story. It is more than trout fishing in the spring, camping outdoors in the summer, and deer hunting in the fall. The nature story invites the study of wild flowers, trees, and shrubs, birds and bird sanctuaries, small game, brooks, and rocks and fossils, all of which should be seen in their environment.

The city or suburban family can enjoy 52 weekends a year in the country without venturing more than 50 to 100 miles from its doorstep. Not everyone has the time or facilities for travel. Most cities and suburban areas have developed the local resources of parks, nature trails, wildlife sanctuaries, zoos, and museums within their own area, however, so that much can be seen and learned about nature within walking distance or a local bus ride. Enjoying the outdoors may be a family or group activity, while the experienced nature hobbyist will not object to travelling alone; in fact he may prefer to. But the novice or beginner usually will find companionship more pleasurable, safer, and more instructive.

Gardening. Gardening is a popular hobby activity that has undergone a change of emphasis and attracted new adherents in the process. The 20th-century exodus from city to the suburbs and the hinterlands of intensively industrialized and urbanized areas has both new and traditional gardeners thinking in practical terms of better home and garden planning to ensure maximum green areas and the best land use, something beyond the expanse and expense of a well-kept lawn.

The thought now is to have the trees, shrubs, and other plants work together, the purpose being to improve the environment with its resulting benefits. Emphasis, for example, is on soil improvement through green manures and other organic materials that were once burned up and polluted the air or were hauled away as garbage. Fresh vegetables organically grown on a home plot have a status of involvement, the unmatched taste of freshness, and the saving of time and money in shopping. The home canning or freezing of fresh fruits and vegetables produced in one's own garden is an expanding activity in the same tradition.

Flowering and fruit-bearing trees do more than contribute to the variety of each season. They provide shade, play a cleansing role in air and water pollution, and contribute to an appealing environment for birds, squirrels, and other small animals.

City gardening

No space or land should be considered too small if there is adequate light and water. Soil and containers can be brought to the site if necessary. City gardeners, for example, find the challenge of the pocket-size garden on terraces, rooftops, backyards, and miniature parks in open lots a rewarding experience when the urban handicaps are overcome and the rewarding green oasis is used and enjoyed.

The best gardens are usually planned gardens, demanding no more time, labour, and expense than the hobbyist is prepared to put into the gardening project. It may be a family affair or a personal activity.

The creation of gardens for pleasure is a most ancient art. Egyptian wall and tomb paintings, Minoan frescoes, descriptions in the *Odyssey*, the records of classical Rome, the writings of ancient China, and the culture of Japan all testify to the enduring history of gardens as havens of quiet and peace in a troubled world.

Modern gardening hobbyists usually become interested in one or more of several broad categories encompassing flower, woodland, rock, water (or pool), scented, herb, and vegetable gardens. Other interests include arboretums, roof gardens, greenhouse or conservatory gardens, and indoor plants and window boxes. (See also the article GARDENING.)

Bird watching. Public awareness of the environment has contributed to a vast increase in the number of bird watchers, and indeed changes in the environment have contributed to changes in bird ranges. One of the many by-products of concern over the environment has been man's curiosity to find out what its components are. One of these components, of course, is the bird life of a country. Birds are sensitive indicators of change.

In order to be able to observe these changes, the bird watcher must first be able to identify the birds and the different components that make up their habitat. As the bird watcher must go where the birds are to observe them, he becomes familiar with these habitat components and subsequent changes, whatever the cause.

Equipment for bird watching

The bird watcher's equipment is modest—a pair of binoculars or a spotting scope, a field guide, notebook, and pencil; many also carry cameras. Early in the morning, soon after sunrise, is the best time for bird watching. The next best time is late afternoon, when the flocks are feeding and almost ready to roost. An attractive feature of bird watching is that it takes practically no effort at all to get started. Activities in bird watching are well established and organized almost everywhere. Local museums, libraries, and nature study clubs are excellent points of beginning for inquiries.

Nature walks. Hiking on a planned trip with a specific destination or walking leisurely and observantly through a wooded area or across fields can be more enjoyable when one recognizes the geological causes of the terrain features or perhaps the more familiar wild flowers or even a single plant that is scarce or not indigenous to the area. In the course of travel, one may discover footprints or other evidence of the presence of animals in the vicinity. For the beginner, guided instructional tours heighten the enjoyment of the first experiences and accelerate the learning processes.

Nature collecting hobbies. Along the trails, butterflies and moths are frequently seen and captured and added to private collections. Sometimes the specimens are preserved just for viewing and identification or used in arrangements with dried wild flowers reminiscent of Victorian displays. An extension of interest in collecting butterflies and moths would include the gathering of wild flowers, leaves, branches, bark, and driftwood where available. Wooded and marshy areas are ideal sources of this material.

Collecting rocks and minerals. Collecting rocks and minerals is probably one of the least expensive hobbies to start and maintain. Rocks and minerals are probably the most plentiful and unevenly distributed substances known. In some localities anywhere from 75 to 100 different minerals may be found within the space of a few miles, whereas in other areas possibly as few as five or ten. Mountains, stone quarries, gravel pits, and road cuts through hilly areas are among the favourite locations for collecting rocks, and old mines and dumps are common sources of minerals. Most collectors agree, however, that the hobbyist's immediate vicinity will generally yield a sufficient variety with which to start a collection. Collectors of stones may look for particular colours or varieties of colours, shapes, or textures or may concentrate on places of origin. The amateur collector may become a member of a local mineral or gem society, attend regular meetings, and go on conducted tours and trips to obtain specimens in other locations.

Sources of rocks and minerals

Shell collecting. A hobbyist who collects and studies seashells is a conchologist or a malacologist. Experts say

that there are 75,000 known species of seashells. One basic appeal of seashells is that they are plentiful and frequently may be obtained without cost. Seashells can be found at almost any hour of the day, but, to obtain the best specimens available, experienced collectors search for shells at low tide when they have the entire area between tides to explore. Shells of animals that live in shallow water but beyond the tide line are washed up on the beach only after storms and must be hunted then. Shells of animals that live in deeper water have attracted many of the growing numbers of skin divers to the hobby of shell collecting.

The rarity of certain specimens is of greater interest and importance to the collector than to the craftsman. Some shell dealers specialize in shells for collectors, others sell shells in bulk for shell craft. Needless to say, bulk shells are less rare and cost less. The opportunity to earn money with shell craft attracts many people, especially in those areas where shells are to be had for the gathering. There are numerous salable items that are made with shells: jewelry, trays, picture frames, bookends, greeting cards, sometimes with shells as the sole material and sometimes in combination with other materials.

Collecting artifacts and fossils. Other hobbies related to nature include searching for artifacts of historic and prehistoric man and for fossils of animals that inhabited the earth millions of years ago. These outdoor hobbies reflect widespread interests in archaeology and paleontology and are similar in many respects to the hobbies of collecting rocks and minerals and shells.

Raising animals. Raising horses, dogs, cats, monkeys, canaries, parakeets, or other cage birds, tropical fish, snakes, or any of the numerous common four-legged animals such as rabbits, guinea pigs, and hamsters has long been a popular hobby. Some people raise herds of purebred cattle or raise sheep, goats, or other animals as a hobby. Some hobbyists raise animals to sell as a leisure-time source of income. Some plan to sell only their surpluses. The owner of a pet dog, cat, or other animal for companionship is not usually considered a hobbyist in this sense.

To raise animals, including pets, as a hobby requires knowledge and observance of all the improved methods of animal care. Location—in city, suburb, or country—influences the type of pets that may be raised, as local ordinances may limit the raising of pets in quantity except under supervised conditions and may forbid such activity entirely.

HOBBIES RELATING TO HANDICRAFTS

Goals of handicraft hobbies

In handicraft hobbies, the ultimate goal is to fuse the intangible qualities of creativity, aesthetic sensibility, and skill into a work of art in its own right. It is most desirable for the hobbyist to examine the techniques and finishing that distinguish one example of handicraft from another of similar character and to note the differences that make one piece worth many times more than its counterpart. Art in craftsmanship is often unobtrusive while it brings the beauty of a work to the fore. Details of style and craftsmanship can be financially rewarding in those fields often regarded as women's domain: dressmaking, ladies' accessories, knitting, embroidery, quilting, and other forms of needlework and rug making.

Some handicrafts require more equipment than others. Experts advise starting with a minimum of simple tools and then acquiring others as skill and need grow. Tools used for one craft are often suitable for others as well.

Some "work alone" crafts have a special appeal for people who prefer to work unhurriedly in the quiet of their own company. Anyone who develops a reasonable proficiency can, if he so desires, attract a clientele from far beyond the limits of his own city or town in such fields as taxidermy, clock repair, ship-model building, cleaning and repair of prints and paintings, doll repairs and restoration, bookbinding, antique auto restoration, caning, and the repair of antiques, glass, china, and bric-a-brac. The degree of skill a craftsman has acquired and his knowledge of the craft should determine the area of repairs, restoration, or new work he should consider undertaking. Age is not a handicap in these crafts in any sense. Most people who adopt these activities have many of the characteristics displayed by professionals in these fields, the only difference being in the degree of experience. Often retired from regular work, they are usually unhurried, knowledgeable, patient, like to handle a job through from start to finish, and are satisfied with nothing less than the best job possible. The best instruction is through apprenticeship.

Packaged kits. The manufacture of hundreds of millions of dollars worth of hobby materials each year is the largest single segment of supply and inspiration for hobby activities. Model making and the occupational arts and crafts are the major aspects of the hobby material industry. Advances in technology, science, and educational methods as well as changes in public taste are quickly reflected in the manufacture of hobby materials.

Model and hobby kits

In the model-building group of hobbies, airplanes, rockets, racing cars, boats, and ships provide the action of speed, remote control, and competition with specific rules and regulations as to class of model and cost. The upsurge in popularity of track auto racing of all classes is reflected in model-car racing, where performance and the competitive elements are stressed. Model-railroad building and operation retains its popularity with both young people and adults. These action hobbies all have a strong father-and-son appeal.

At the start of the 1970s, plastic models for cars, planes, ships, boats, military vehicles, human anatomy, birds, and animals comprised the most popular type of hobby kits sold in terms of dollar volume.

Second in demand were package and bulk materials for painting by the numbers, mosaic kits, and crafts utilizing plastics, wood, leather, textiles, metal, cork, clay, beads, and sequins, shells and stone, raffia, ribbon, wool for rug making, yard goods, and laces. This list is representative but by no means inclusive of the materials available in hobby kits.

The sciences are represented by hobby kits in chemistry, biology, physics, astronomy, including telescopes, and the earth sciences, including weather stations.

Some hobbyists resist the idea of using prepared kits; some welcome the challenge of using discarded waste materials, such as tin cans and old newspapers. Practically every operation practiced with silver, copper, brass, or pewter may start with tin. Pieces may be finished off with decoration reflecting the fashions in tinware sold by the early 19th-century peddlers. Newspapers, paste, and powdered glue are the start of modelling in papier-mâché, a craft of old traditions and many beautiful *objets d'art*. The technique is easy to learn, the possible uses extensive: masks, puppets, theatrical props, float displays, model-railroad tunnels, figurines, and parlor accessories reminiscent of the Victorian era, when papier-mâché was widely used.

Of the many hobbies relating to handicrafts, three involving ancient crafts—needlework, ceramics, and woodworking—are covered in slightly greater detail below.

Needlework. Many people enjoy needlework in their spare time. The most attractive features are the many forms of needlework possible—embroidery, sewing, quilting, to mention only a few—and the fact that all forms of needlework may be taken up and put down at will. Needlework may be done alone or with others at sewing circles, craft guilds, church groups, farm and home bureaus, and rehabilitation centres.

Varieties of needlework

There is certainly no craft that requires less equipment than embroidery: needle, thimble, and thread. The methods follow the most ancient of traditions. Examples of precious fragments of embroidered pieces that date back many centuries show that buttonhole, matting, square, darning, double-running, chain, cross, and split stitches, all in use today, were used then. Although the tools and techniques are centuries old, this is not a restrictive art form. In embroidery the design need not come in repeats, even when based on counted threads. With needle and thread, ideas are given design and provide texture and form on the ground weave.

Sewing—especially the making of clothes—is as popular as ever. It is a highly functional craft. Sewing centres, adult-educational classes, simplified patterns, the trend to do-it-yourself activities, all contribute to the continued popularity of sewing.

Quilts of all types—patchwork, crazy, hit-and-miss, appliqué, and all the variations with different names—are among the best selling items at antique shows. They need not be the finished quilts, just tops. A well-designed quilt, well executed, is destined to become a treasured heirloom. Quilts are made and used because they represent warmth, comfort, and time-binding to a degree unmatched by any other single household article. Many quilts are signed and dated by their makers; all quilts should be, because few things more truly catch the personality of the maker forever.

The boundaries of needlework are being pushed forward with unusual uses of thread. Jack Lenor Larsen, a noted contemporary designer, says "Weaving is almost as obsolete a term as tapestry is for what is happening today." Fibre forms" or "art fabrics" are current terms for the ultramodern creations. The modern artisan is said to find inspiration in many places—in eastern European peasant tapestries, in modern painting and sculpture, in the pre-Columbian weavings of Peru. In contemporary exhibitions it is not unusual to see works sometimes as tall as 20 feet (six metres) and combining as many as 20 massive elements into environments, usually without figural pattern.

The birth of this innovative art-craft was proclaimed in the United States in exhibitions at the Museum of Contemporary Crafts in New York City at its 1963 show, with further developments seen at the Museum of Modern Art five years later. Since then artists have increasingly combined weaving with other nonwoven techniques, or they have given up the loom entirely to concentrate on knotting, twisting, looping, braiding, or needlework. It is possible to be startlingly innovative with the classic forms of needlework and the related craft-arts and find a ready audience for the work.

Ceramics. The making of pottery and other ceramic ware is a craft of unique extremes. The hobbyist can become active in it on so many levels of participation that it is understandably one of the most popular of all crafts, not necessarily in numbers participating in it but certainly in intensity of enthusiasm and fervour.

As a major art field, ceramics involves creative design; the techniques of building pottery forms by hand, wheel, and casting methods; the chemistry and application of glazes; and the techniques of kiln operation. At its best, pottery is one of the most controversial of all crafts. Contemporary art institutes and museums join the designer-craftsman in insisting that despite the utilitarian uses to which pottery may be put, it must be evaluated as art. In exhibitions, pottery is frequently coupled with modern art.

Pottery making and ceramics for beginners

Fortunately there is a less controversial and more conventional but satisfying range of pottery making and ceramics for those who are beginners and intermediate craftsmen. As an example of the basic level of this craft field, there are nonfired pottery methods of using clays that will dry at room temperature and others that may be baked in a kitchen oven at about 300° F (about 150° C) and later decorated with liquid glaze. These materials and these methods are used in many situations: schools, camps, and hospitals, and in homes where it is not possible to have a kiln available for firing pottery, (although groups of ceramacists frequently have a jointly owned kiln). The kitchen is often used with satisfying success for the making of one-of-a-kind pottery and ceramic pieces. Self-instruction books have been found most useful in this field and are constantly used as a reference by even the most skilled artisans. Catalogs of ceramic supply houses, which advertise in hobby and craft publications, should not be overlooked as a source of simple instruction on methods of using their materials and ideas for items to make. The two largest items of equipment generally used in a ceramic and pottery workshop are a potter's wheel and a kiln. It is possible to make a potter's wheel and to build a kiln outdoors that will be serviceable and cost little more than the time and effort.

Interest in ceramics and pottery may centre around the making of one type of item in which a person acquires a dexterity, skill, and individual design style. This may be in the form of jewelry, tiles, animal sculpture, personalized pottery, and other items ranging from highly utilitarian to merely decorative.

A natural extension of an interest in making pottery and ceramics is the collecting of unusual and outstanding pieces made by others, organizing classes and group instruction, reading and writing on the subject, becoming a member of craft museums, and enlarging one's knowledge of the art.

Woodworking. This has been traditionally a man's craft, but women are increasingly doing outstanding woodworking themselves. In the United States this is especially true in New England, where women cabinetmakers have distinguished themselves.

Many things are still made of wood not of necessity but because no other material or craft is so satisfying. The first tools that practically every man acquires, no matter what his favourite craft may ultimately be, are those for woodworking. Hammer, saw, try square, ruler, chisel, vise, knife—these are essential in every shop. Those who use power tools start with a drill, table saw, and sander.

What to make depends upon the degree of skill that can be applied, the purpose for which wood items are intended, the availability of needed wood (especially of the kiln-dried variety), and the possible use of other skills and interests. The one obvious advantage of woodworking is that everything a person can make is in demand, either for his own home, as a gift, or for sale. Among the many possible divisions of woodworking are carving and whittling, cabinetry, repairs, and restoration. The experienced woodworker's prime interest in his craft is to make things that are better styled and better executed than anything that is available in the ready-to-buy market. A few examples in addition to tables, chairs, and other items of furniture would be bird and game decoys, antique reproductions, plaques and panels, toys, miniatures such as doll houses and furniture for doll houses, ship models, and cabinets for the display of minerals and other collectibles.

REWARDS OF HOBBIES

Some rewards of hobbies can be measured by material achievements: money, medals and ribbons, citations, testimonials, a scrapbook of clippings.

Intangible rewards

Beyond the tangibles are the intangibles. These intangibles include added self-esteem, release from monotony and boredom, the revitalization of interests and of capacity to work, the aesthetic and intellectual stimulation missing from so many essential routine tasks. Any exact expression of the intangible rewards of hobbies must be personal and must be experienced. In effect, time spent in pursuing a hobby is an escape to an alternate way of life. A person may work hard at a hobby, harder perhaps than at a job, but such work is free of the tensions, accountability, and possibly the responsibilities that attend much economic work. Unlike daily, committed routines, the hobbyist's knowledge that he may stop at any time and turn to something else is part of the freedom of the alternate way of life. Conversely, much that is routine is made more endurable because of the prospect of getting back to a hobby.

From the very moment of decision to take up a hobby there is stimulation in embarking on a search for an activity that will provide the pleasure and change sought. It is stimulating to find new items and add to any collection; it is aesthetically stimulating to become so expert at an adopted craft that it wins recognition as an art; it is intellectually stimulating to know that it is still possible to assemble an important collection in many categories of books, art, or antiques.

The money that may be made from a hobby can be important money; it is unlike any other money earned. This is money from pleasure that can generate new pleasures.

The actual amount may be small; the use to which it is put, very large. It can be the difference between a tight budget and small luxuries.

Financial rewards can vary greatly from one hobby to another, but to select an activity on the basis of its possible monetary rewards invalidates both the spirit and intent of pursuing a hobby. It then becomes a form of working on a second job. There is no specific formula that can be applied with absolute assurance to determine just how much money can be earned from any given activity. One thing is certain: expertise and authority in any area, based on ability, whether it is in the collecting field, in the arts or crafts, will eventually bring requests for advice and services. Talks, lectures, demonstrations, and workshops bring in supplemental fees to many hobbyists. A substantial percentage of dealers in most hobby and collecting fields were once hobbyists and collectors. This is especially true in antiques, where the system of trading up from a poor example of an item to a superlative one leads to the accumulation and the filling in and enlarging of a collection until the collector must become a dealer to sell off unwanted surplus items. Most hobbyists who turn their hobby into an avocation for a secondary income or a new business entirely find that specialization in at least one art, one craft, or one collecting field will attract potential customers from far beyond the boundaries of their own community.

General Works: WILBERT D. NEWGOLD, *Newgold's Guide to Modern Hobbies, Arts and Crafts* (1960), a standard reference work that still introduces some popular hobbies and crafts not found elsewhere in a single volume; LUCILE ROOD, *How to Find Leisure Time and Use It Creatively* (1968), a practical, common-sense approach to an increasingly urgent subject requiring solution; ARTHUR LIEBERS, *Fifty Favorite Hobbies* (1968), an experienced hobbyist and researcher provides an introduction and sampling of some all-time favorites.

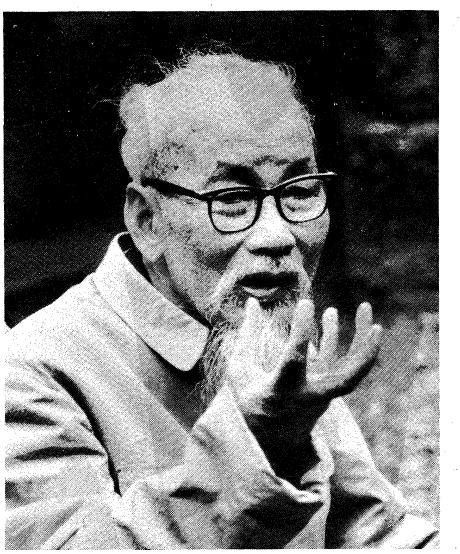
Selected references to specific hobbies: ALINE B. SAARINEN, *The Proud Possessors* (1958), an authoritative, well-researched, and well-written account of the beginnings and making of some of America's famous art collections; WESLEY TOWNER, *The Elegant Auctioneers* (1970), an informative and entertaining insight into the world of auctioneers and collectors; JOHN MEBANE, *The Poor Man's Guide to Antique Collecting* (1969), for those who believe the real point of collecting is the thrill of finding a bargain; DOROTHY JENKINS, *A Fortune in the Junk Pile: A Guide to Valuable Antiques* (1963), on finding treasure in trash; WILLIAM HILLCOURT, *The New Field Book of Nature Activities and Hobbies* (1970), a handy reference manual that has been updated since its original publication in 1961 as the *Field Book of Nature Activities and Conservation*; F.F. ROCKWELL and ESTHER C. GRAYSON, *The Rockwells' Complete Guide to Successful Gardening* (1965), an excellent reference work for gardeners; L.J. HUSSEY and C. PESSINO, *Collecting Small Fossils* (1970), makes the subject inviting and enjoyable; DONA Z. MEILACH and LEE ERLIN SNOW, *Creative Stitchery* (1970), a highly usable, easy-to-follow introduction to an increasingly popular hobby; DANIEL RHODES, *Clay and Glazes for the Potter* (1957), a practical book for the potter, student, teacher, designer, collector, or industrial ceramist; JOHN G. SHEA, *Woodworking for Everybody*, 4th ed. (1970), a good starting point on this subject.

(W.D.N.)

Ho Chi Minh

Ho Chi Minh (real name Nguyen That Thanh), leader of the Vietnamese national movement for nearly three decades and president of the Democratic Republic of Vietnam (North Vietnam) from 1945 to 1969, was one of the prime movers of the post-World War II anticolonial movement in Asia and one of the most influential Communist leaders of the 20th century.

Early life. The son of a poor country scholar, Nguyen Sinh Huy, Ho Chi Minh was born on May 19, 1890, in the hamlet of Hoang Tru, in the Nghe An province of present North Vietnam, then French Indochina. He was brought up in the village of Kim Lien. He had a wretched childhood, but between the ages of 14 and 18 he was able to study at a grammar school in Hue. He is next known to have been a schoolmaster in Phan Thiet and then was apprenticed at a technical institute in Saigon. In 1911,



Ho Chi Minh, 1968.
Marc Riboud—Magnum

under the name of Ba, he found work as a cook on a French steamer. He was a seaman for more than three years, visiting various African ports and the American cities of Boston and New York. After living in London from 1915 to 1917, he moved to France in the middle of World War I. There he worked, in turn, as a gardener, sweeper, waiter, photo retoucher, and oven stoker.

Years in France

During the six years that he spent in France (1917–23), he became an active Socialist, under the name Nguyen Ai Quoc (Nguyen the Patriot). He organized a group of Vietnamese living there and in 1919 addressed an eight-point petition to the representatives of the Great Powers at the Versailles Peace Conference that concluded World War I. In the petition, Ho demanded that the French colonial power grant its subjects in Indochina equal rights with the rulers. This act brought no response from the peacemakers, but it made him a hero to many politically conscious Vietnamese. The following year, inspired by the success of the Communist revolution in Russia and Lenin's anti-imperialist doctrine, Ho joined the French Communists when they withdrew from the Socialist Party in December 1920, and he denounced the evils of French and British colonialism in his journal *Le Paria* ("The Outcast"; Paris).

After his years of militant activity in France, where he became acquainted with most of the French working class leaders, Ho went to Moscow at the end of 1923. In January 1924, following the death of Lenin, he published a moving farewell to the founder of the Soviet Union in *Pravda*. Six months later, from June 17 to July 8, he took an active part in the fifth Congress of the Communist International, during which he criticized the French Communist Party for not opposing colonialism more vigorously. The text of his statement to the congress is noteworthy because it contains the first formulation of his belief in the importance of the revolutionary role of oppressed peasants (as opposed to industrial workers). From then on he was an important figure in world Communism.

In December 1924, under the assumed name of Ly Thuy, Ho went to Canton, China, a Communist stronghold, where he recruited the first cadres of the Vietnamese nationalist movement, organizing them into the Vietnam Thanh Nien Cach Mang Dong Chi Hoi (Association of Young Vietnamese Revolutionaries), which became famous under the name Thanh Nien. Almost all of its members had been exiled from Indochina because of their political beliefs and had gathered together in order to participate in the struggle against French rule over their country. Thus, Canton became the first home of Indochinese nationalism.

When Chiang Kai-shek, then commander of the Chinese Army, expelled the Chinese Communists from Can-

ton in April 1927, Ho again sought refuge in the Soviet Union. In 1928 he went to Brussels and Paris and then to Siam (now Thailand), where he spent two years as a representative of the Communist International, the world organization of Communist parties, in Southeast Asia. His followers, however, remained in South China. Meeting in Hong Kong at the beginning of May 1929, members of the Thanh Nien decided to form an Indochinese Communist Party. Others, in the Vietnamese cities of Hanoi, Hue, and Saigon, began the actual work of organization, but some of Ho's lieutenants were reluctant to act in the absence of their leader, who had the confidence of Moscow. Ho was brought back from Siam, therefore, and on February 3, 1930, he presided over the founding of the party. At first it was called the Vietnamese Communist Party, but after October 1930, Ho, acting on Soviet advice, adopted the name Indochinese Communist Party (PCI). Thus, the movement received greater international recognition and avoided the suggestion of "petit-bourgeois nationalism" implied by the earlier title. In this early phase of his career, Ho acted more as an arbiter of conflicts among the various factions, allowing the organization of revolutionary action, rather than as an initiator. His prudence, his awareness of what it was possible to accomplish, his care not to alienate Moscow, and the influence that he already had achieved among the Vietnamese Communists can be seen in these actions.

The founding of the PCI

The creation of the PCI coincided with a violent insurrectionary movement in Vietnam. Repression by the French was brutal; Ho himself was condemned to death in absentia as a revolutionary. He sought refuge in Hong Kong, where the French police obtained permission from the British for his extradition, but friends helped him escape, and he reached Moscow via Shanghai.

In 1935 the seventh Congress of the International, meeting in Moscow, which he attended as chief delegate for the PCI, officially sanctioned the idea of the Popular Front (an alliance with the non-Communist left against Fascism)—a policy Ho had advocated for some time. In keeping with this policy the Communists in Indochina moderated their anticolonialist stance in 1936, allowing for cooperation with "antifascist colonialists." The formation of Premier Léon Blum's Popular Front government in France in the same year allowed leftist forces in Indochina to operate more freely, although Ho, because of his condemnation in 1930, was still not permitted to return from exile. Repression returned to Indochina with the fall of the Blum government in 1937, and by 1938 the Popular Front was a dead letter.

World War II and the founding of the Vietnamese state. In 1938 Ho returned to China and stayed for a few months with Mao Tse-tung at Yen-an. When France was defeated by Germany in 1940, he and his lieutenants, Vo Nguyen Giap and Pham van Dong, plotted to use this turn of events to advance their own cause. About this time he began to use the name Ho Chi Minh (He Who Enlightens). Crossing over the border into Vietnam in January 1941, the trio and five comrades organized in May the Viet Nam Doc Lap Dong Minh Hoi (League for the Independence of Vietnam), or Viet Minh; this gave renewed emphasis to a peculiarly Vietnamese nationalism.

The new organization was forced to seek help in China from the government of Chiang Kai-shek. But Chiang distrusted Ho as a Communist and had him arrested. Ho was then imprisoned in China for 18 months, during which time he wrote his famed *Notebook from Prison* (a collection of short poems written in classic Chinese, a mixture of melancholy, stoicism, and a call for revolution). His friends obtained his release by an arrangement with Chiang Fa-k'uei, a warlord in South China, agreeing in return to support Chiang's interests in Indochina against the French.

In 1945 two events occurred that paved the way to power for the Vietnamese revolutionaries. First, the Japanese completely overran Indochina and imprisoned or executed all French officials. Six months later the United States dropped the atomic bomb on Hiroshima, and the Japanese were totally defeated. Thus, the two strongest adversaries of the Viet Minh and Ho Chi Minh were destroyed.

Ho Chi Minh seized his opportunity. Within a few months he contacted U.S. forces and began to collaborate with the OSS (Office of Strategic Services, a U.S. undercover operation) against the Japanese. Further, his Viet Minh guerrillas fought against the enemy in the mountains of South China.

At the same time, commandos formed by Vo Nguyen Giap, under Ho's direction, began to move toward Hanoi, the Vietnamese capital, in the spring of 1945. After Japan's surrender to the Allies, they entered Hanoi on August 19. Finally, on September 2, before an enormous crowd gathered in Ba Dinh Square, Ho Chi Minh declared Vietnam independent, using words ironically reminiscent of the U.S. Declaration of Independence: "All men are born equal: the Creator has given us inviolable rights, life, liberty, and happiness . . . !"

All obstacles were not removed from the path of the Viet Minh, however. According to the terms of an Allied agreement, Chiang Kai-shek's troops were supposed to replace the Japanese north of the 16th parallel. More significantly, France, now liberated and under the leadership of Charles de Gaulle, did not intend to simply accept the *fait accompli* of an independent Vietnam and attempted to reassert its control. On October 6 Gen. Leclerc landed in Saigon, followed a few days later by a strong armoured division. Within three months, he had control of South Vietnam. Ho had to choose between continuing the fight or negotiating. He chose negotiations, but not without preparing for an eventual transition to war.

Ho Chi Minh's strategy was to get the French to make the Chinese in the north withdraw and then to work for a treaty with France in which recognition of independence, evacuation of Leclerc's forces, and reunification of the country would be assured. Negotiations began in late October 1945, but the French refused to speak of independence, and Ho was caught in a stalemate. In March the deadlock was broken: on his side, Ho Chi Minh allowed parties other than the Viet Minh to be included in the new government, in an attempt to gain a wider base of support for the demands made on the French; at the same time, the French sent a diplomatic mission to China to obtain the evacuation of the Chinese soldiers. This was done, and some of Leclerc's troops were also removed from Haiphong, in the north. Having secured the withdrawal of the Chinese, Ho signed an agreement with the French on March 6. According to its terms, Vietnam was recognized as a "free state with its own government, army, and finances," but it was integrated into a French Union in which Paris continued to play the key role. Twelve days later, Leclerc entered Hanoi with a few battalions, which were to be confined to a restricted area.

The agreement was unsatisfactory to extremists on both sides, and Ho Chi Minh went to France for a series of conferences (June to September 1946) and concluded a second agreement with the French government. But the peace was broken by an incident at Haiphong (November 20–23, 1946) when a French cruiser opened fire on the town after a clash between French and Vietnamese soldiers. Almost 6,000 Vietnamese were killed, and hope for an amicable settlement ended. Sick and disillusioned, Ho Chi Minh was not able to oppose demands for retaliation by his more militant followers, and the first Indochina war began on December 19.

The first Indochina war

After a few months, Ho, who had sought refuge in a remote area of North Vietnam, attempted to re-establish contact with Paris, but the terms he was offered were unacceptable. In 1948 the French offered to return the former Annamese (Vietnamese) emperor Bao Dai, who had abdicated in favour of the revolution in August 1945. These terms were more favourable than those offered to Ho Chi Minh two years earlier, because the French were now attempting to weaken the Viet Minh by supporting the traditional ruling class in Vietnam. But his policy was not successful. The Viet Minh army, commanded by Giap, was able to contain the French and

Bao Dai's forces with guerrilla tactics and terrorism, and, by the end of 1953 most of the countryside was under Viet Minh control, with the larger cities under a virtual state of siege. The French were decisively defeated at Dien Bien Phu on May 7, 1954, and had no choice but to negotiate.

The Geneva Accords and the second Indochina war. From May to July 21, 1954, representatives of eight nations—with Vietnam represented by two delegations, one composed of supporters of Ho Chi Minh, the other of supporters of Bao Dai—met in Geneva in an attempt to find a peaceful solution. They concluded with an agreement according to which Vietnam was to be divided at the 17th parallel until elections, scheduled for 1956, after which the Vietnamese would establish a unified government.

It is difficult to assess Ho's role in the Geneva negotiations. He was represented by Pham van Dong, his most faithful associate. The moderation exhibited by the Viet Minh in accepting a partition of the country despite their triumph at Dien Bien Phu and in accepting control of less territory than they had conquered during the war follows the pattern established by the man who had signed the 1946 agreements with France. But this flexibility, which was also a response to pressures exerted by the Russians and Chinese, did not achieve everything for the Viet Minh. Hanoi lost out because the elections that were to guarantee the country's reunification were postponed indefinitely by the United States and by South Vietnam, which was created on a de facto basis at this time.

North Vietnam, where Ho and his associates were established, was a poor country, cut off from the vast agricultural areas of the south. Its leaders were forced to ask for assistance from their larger Communist allies, China and the Soviet Union. In these adverse conditions Ho Chi Minh's regime became repressive and rigidly totalitarian. Attempted agricultural reforms in 1955–56 were conducted with ignorant brutality and repression. "Uncle" Ho, as he had become known to the North Vietnamese, was able to preserve his immense popularity, but he abandoned a kind of humane quality that had distinguished some of his previous revolutionary activities despite ruthless "purges" of Trotskyists and bourgeois nationalists in 1945–46.

The old statesman had better luck in the field of diplomacy. He travelled to Moscow and Peking (1955) and to New Delhi and Jakarta (1958), skillfully maintaining a balance between his powerful Communist allies and even, at the time of his journey to Moscow in 1960, acting as a mediator between them. Linked by old habit, and perhaps by preference, to the Soviet Union, but aware of the seminal role China had played in the revolution in Asia, preoccupied with using his relations with Moscow to lessen China's influence in Asia, and, above all, careful to assert Vietnamese rights, Ho Chi Minh skillfully maintained a balance between the two Communist giants. When the war was resumed, he obtained an equal amount of aid from both.

Aid to the Viet Cong

Beginning about 1959, North Vietnam again became involved in war. Guerrillas, popularly known as the Vietcong, were conducting an armed revolt against the U.S.-sponsored regime of Ngo Dinh Diem in South Vietnam. Their leaders, veterans of the Viet Minh, appealed to North Vietnam for aid. In July 1959, at a meeting of the central committee of Ho Chi Minh's Lao Dong (Worker's Party), it was decided that the establishment of socialism in the North was linked with the unification with the South. This policy was confirmed by the third congress of the Lao Dong, held shortly thereafter in Hanoi. During the congress, Ho Chi Minh ceded his position as the party's secretary general to Le Duan. He remained chief of state, but from this point on, his activity was largely behind-the-scenes. Ho certainly continued to have enormous influence in the government, which was dominated by his old followers Pham van Dong, Truong Chinh, Vo Nguyen Giap, and Le Duan, but he was less actively involved, becoming more and more a symbol to the people. His public personality, which had never been the object of a cult comparable to that of Stalin, Mao, or even Tito, is best symbolized by his popular name, Uncle Ho. He stood for the essential unity of the divided Vietnamese family.

This role, which he played with skill, did not prevent him from taking a position in the conflict ravaging his country, especially after American air strikes against the North began in 1965. On July 17, 1966, he sent a message to the people ("nothing is as dear to the heart of the Vietnamese as independence and liberation") that became the motto of the North Vietnamese cause. On February 15, 1967, in response to a personal message from U.S. President Lyndon Johnson, he announced: "We will never agree to negotiate under the threat of bombing." Ho lived to see only the beginning of a long round of negotiations before he died on September 3, 1969.

The removal of this powerful leader undoubtedly damaged chances for an early settlement. His funeral was held in Hanoi's Ba Dinh Square, where, 14 years earlier, he had proclaimed the resurgence of the state of Vietnam. Le Duan, Ho's successor as party head, read his remarkable last will and testament. In it, Ho spoke of the Vietnamese people as his "nephews," reflecting a peculiarly Vietnamese relationship suggested by the words *bac* (a paternal uncle even more highly respected than a father) and *nghia* (a term implying self-sacrifice and the necessity of helping one's kin). Equally characteristic are his references to the "plains and mountains" of Vietnam and his insistence that Vietnam must again be united under one "roof." These phrases are suggestive of the realities of peasant life and its relationship to the land and hearth, which alone give meaning to Vietnamese national feeling. But he links this national feeling to the hope for a "worldwide revolution," which is again characteristic of the man who devoted 50 years of his life to Marxism–Leninism.

Ho Chi Minh left no family. He is not known to have had a wife, and his brothers and sisters died before him. His death caused no great changes either in the conduct of the Indochina war or in the power structure of his country. The collective leadership he fostered during his lifetime seems to have filled the gap left by his death.

Ho Chi Minh's importance

Among 20th-century revolutionaries, Ho waged the longest and most costly battle against the colonial system of the great powers. One of its effects was to cause a grave crisis in the national life of the mightiest of capitalist countries, the United States. As a Marxist, he stands with the Yugoslav leader Tito as one of the progenitors of the "national Communism" that developed in the 1960s, and (at least partially) with Communist China's Mao Tse-tung in emphasizing the role of the peasantry in the revolutionary struggle.

Most of Ho Chi Minh's writings are collected in the two-volume *Selected Works*, published in Hanoi in 1960, in the series of Foreign Language Editions. (J.La.)

BIBLIOGRAPHY. The best known biography of Ho Chi Minh is that of the French journalist JEAN LACOUTURE, *Hô Chi Minh* (1967; Eng. trans., 1968). A short, well-written account is that by the Pulitzer Prize-winning American journalist, DAVID HALBERSTAM, *Ho* (1971). Two somewhat more scholarly works are CHRISTIANE PASQUEL RAGEAU, *Ho Chi Minh* (1970); and N. KHAC HUYEN, *Vision Accomplished? The Enigma of Ho Chi Minh* (1971). JEAN SAINTENY, *Face à Ho Chi Minh* (1970), tells of Ho's life from the standpoint of a noted French diplomat who was a close personal friend of Ho and had many long conversations with him, which he reports in the book. The Committee for the Study of the History of the Vietnamese Worker's Party has compiled an English-language book, *Our President Ho Chi Minh* (1970), which has an introduction by North Vietnamese Prime Minister PHAM VAN DONG. HO CHI MINH, *Selected Works*, 4 vol. (1960–62), has also been published in English by the Vietnamese government, as has his *Prison Diary*, 2nd ed. (1965). Finally, CHARLES FOURNIAU, *Ho Chi Minh, notre camarade* (1970), has assembled recollections of Ho Chi Minh from members of the French Communist Party.

Hockey (Field)

Field hockey is an outdoor game played with a hard ball by two opposing teams of 11 players each, using hooked

or bent sticks with which each side attempts to drive the ball into the other's goal. Often called simply hockey, the term field hockey is used to distinguish it from ice hockey (*q.v.*). It is played much more widely throughout the world than the latter game.

This article is intended for the general reader who may have no knowledge of the sport. Therefore, in addition to tracing its history and outlining its present status, the article is designed to help a spectator understand a game he may be watching. For information on the specific rules or how to play the reader should consult the works listed in the bibliography.

History. Hockey is believed to be the oldest game in the world played with a stick and ball and, according to historians, had its roots in Persia around 2000 BC. The game was acquired by the Greeks, who in turn passed it on to the Romans. A discovery made at Athens in 1922 gives reason to believe that a form of stick game came from the East. This was a bas-relief found in a wall built by Themistocles (*c.* 514–449 BC), which depicts six youths taking part in a game resembling hockey and shows what is termed a face-off, or bully, in the modern game, but with the hooked sticks pointed downward instead of upward. Traces of a sort of stick game played by the Aztec Indians have also been found, and evidence indicates that probably most of the American Indian tribes played a rough stick game for centuries. The sport can also be identified with early games called shinty, hurling, and bandy. During the Middle Ages the game was played in France under the name *hoquet* (the French word for shepherd's crook). When the British took it up it is said this word was anglicized to hockey. In England and other countries, at one time, it was forbidden along with certain other sports because it interfered with archery, a part of the national defense.

Modern hockey

About 1875 a game resembling modern hockey began to be played in England. No goal could be scored if hit from a distance of more than 15 yards from the goal, but players did not for a time realize the need of a definite, marked-out striking circle. A landmark in the progress of hockey was the formation of the famous Wimbledon Club in 1883. A few more clubs soon came into being in the London area and the game spread throughout England. The real birthday of modern hockey was, however, Jan. 18, 1886, the date of the formation in London of the Hockey Association and of the adoption of the striking circle and other rules. In 1895 the first "international" match was played, in which England defeated Ireland 5–0. About 1900 the need for a body to frame the rules for the entire British Isles was realized and the International Hockey Board consisting of England, Ireland, Wales, and Scotland, was formed.

The modern game spread rapidly, particularly on the Continent and in India, due there largely to the influence of the British Army. Although not played to the same extent as association football (soccer), the game is popular in many countries. The national associations of these countries, including those making up the rest of the British Commonwealth and also the United States, became members of the Fédération Internationale de Hockey (FIH, founded 1924). Hockey was included in the Olympic Games in 1908 and 1920, and in each Olympics from 1928. Great Britain, after an absence of several decades, again competed in hockey in the Olympic Games held in London in 1948, and a close working arrangement was instituted at that time between the International Hockey Board and the FIH whereby observance of the same playing rules by all countries was assured. The first Western Hemisphere country to compete in Olympic hockey was the United States, in 1932.

The modern game emanates from England and the rules are to a large extent determined there. Until recent years India has dominated Olympic and other international competition, but more recently Pakistan and a number of non-Asian nations have improved greatly. The leading countries in this sport in the second half of the 20th century have been India, The Netherlands, Great Britain, Germany, and Pakistan. Australia, New Zealand, Spain, Japan, and a number of African countries, however, have developed great proficiency and, with interest in hockey increasing everywhere, the standard of play has risen and international matches tend to be more closely contested. In some countries (*e.g.*, India and Pakistan) hockey is the national sport. Sports writers covering the Olympic Games of 1932 at Los Angeles voted the performance of the Indian team the outstanding exhibition of skill in any sport.

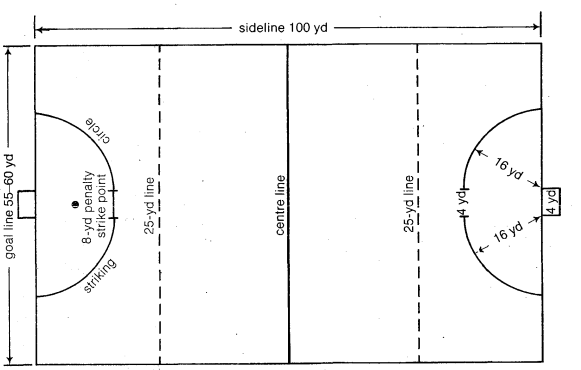
Styles of play and rules. The Indian style of play features short, controlled passes as opposed to the European type, in which the tendency is to hit the ball about the field more. The short-toed stick, developed in India and Pakistan, is now used by most players. By using this stick and employing a left-handed grip well to the rear of the stick they are able to reverse the stick (*i.e.*, play the ball with the toe of the stick pointing downward) without changing the grip and thus attain remarkable control of the ball.

The game has been progressing rapidly in the Western Hemisphere, where formerly only the United States was a member of the FIH. In 1967 it was played for the first time in the Pan-American Games, with eight countries competing. The order of finish was Argentina, Trinidad-Tobago, the United States, and Canada. The Olympic rules now provide that the winner of the Pan-American Games shall be one of the countries included in the Olympic competition, which is limited to 16 teams.

A version of the game to be played indoors has been devised, utilizing special rules and a limited number of players.

Playing the game

The game is played by two teams of 11 players on a rectangular ground (see the accompanying diagram). The goals are four yards wide and seven feet high. For a goal (which counts one point) to be scored the ball must go into the goal and while within the striking circle must have been touched by the stick of an attacker. The ball originally was a cricket ball (cork centre, string-wound, and covered with leather), but plastic balls are also approved. The stick is usually 36 to 38 inches long and weighs 18 to 28 ounces. The striking surface is flat on the left side only and only the flat surface may be used.



Field hockey playing field for men.

The usual composition of a team is five forwards, three halfbacks, two fullbacks, and a goalkeeper. A game consists of two halves of 35 minutes each, with a 5-minute intermission. Under international rules, no substitution is allowed, but in the United States, Bermuda, and some other countries it is permitted by agreement between the teams. A time-out is called only in case of injury. The goalkeeper wears heavy pads and while in the striking circle is allowed to kick the ball or stop it with the foot or body. All other players, however, may stop the ball with the hand or stick only. They wear no particular protective gear.

Play is started (and restarted after a goal is scored and after half-time) by a face-off, or bully, in the centre of the field. Two players, one from each team, face each other with the ball on the ground between them. After alternately tapping the ground and then his opponent's stick three times, each player tries to strike the ball, thus putting it into play. Until the ball is in play all other players must be onside (*i.e.*, between the ball and their own goal

line). There are various provisions for putting the ball in play in case it goes off the field. Most fouls are penalized by giving the opposition a free hit from the point of infraction, but more severe penalties (penalty corners and penalty strokes) can be awarded for fouls by the defense in the vicinity of the goal. An umpire—there is one for each half of the ground—may decline to enforce any penalty if, in his opinion, enforcing it would give an advantage to the offending team. Minor infractions, where in the opinion of the umpire no advantage results to the offender, are not penalized.

The following is a brief explanation of some of the fouls that might seem puzzling to the uninitiated spectator. The off-side rule, which is similar to that of soccer, is designed to prevent a player from getting an advantage by staying up the field ahead of the ball and ahead of less than three members of the opposing team. Raising the heavy stick above the shoulder while playing the ball is obviously dangerous. Advancing the ball with the hand instead of stopping it dead is contrary to the purpose of the game, as is stopping it with the body or foot. Finally, the obstruction rule: in most sports one of the most effective ways of preventing an opponent from getting at the ball (or other playing object) is to interpose the body between the ball and the opponent. Since the hockey stick is heavy and is often used with considerable force, to expect a player to defend the ball in that manner would surely invite injuries. Accordingly, if an opposing player is within striking distance of the ball, it is a foul to obstruct him, intentionally or otherwise.

Women's field hockey

Field hockey is also played extensively in many countries by women. Although women do not compete in this sport in the Olympic Games, they do engage in international competition. The international governing body, the International Federation of Women's Hockey Associations, was formed in 1927. Teams representing England have, for the most part, dominated international competition. The game was introduced in the United States in 1901 by Constance M.K. Applebee, a member of the British College of Physical Education, and thereafter became the most popular outdoor team sport among women in the United States. It is played in schools, colleges, and clubs, and sectional and national tournaments are held.

The rules used by women are similar to those used by men, the more important exceptions including: the striking circle measurement is 15 yards; the dotted lines are 5 yards from the sidelines; and playing time does not exceed two 30-minute halves.

Hogarth, William

An invigorating satirist and critic of art and society, William Hogarth made significant contributions in the fields of portraiture, genre, and historical painting. His fame rested, however, on his comic narrative engravings, which, until relatively recently, obscured his great originality as a painter and theorist. His career marked a new departure in English art. Fiercely independent and chauvinistic, he became the focal point of artistic opposition to the conservative, academic tradition at home and the first native-born artist to inspire notable admiration abroad. Pugnacious and opinionated, he incited controversy; and while his prolific talents never went unrecognized, a series of disappointments embittered his later life and inhibited the full expression of his mature powers as a painter. Hogarth attached enormous importance to his public career, while his private life has remained in a shadow. Apart from what his works reveal of their author, an assessment of his character and experience must rely chiefly on two sources: autobiographical notes written shortly before his death in 1764 in a spirit of self-vindication and the equally selective comments of an engraver, George Vertue, which betray the grudging admiration that characterized contemporary criticism of Hogarth.

By courtesy of the trustees of the Tate Gallery, London

Hogarth, self-portrait, "The Painter and His Pug," oil on canvas, 1745. In the Tate Gallery, London. 91.17 cm × 69.85 cm.

Youth and early career. Hogarth, the only son of Richard Hogarth, a minor classical scholar who made a living as a schoolmaster and publishers' hack, was born on November 10, 1697, in London and grew up with two younger sisters, Mary and Ann, in the heart of the noisy, teeming city. Richard's evident abilities as a classicist brought him scant reward but provided an educated and industrious, if not prosperous, home. Looking back on this period in his autobiographical notes, Hogarth dwelt almost exclusively on his father's shabby treatment at the hands of printers, booksellers, and wealthy patrons. The notes were compiled in a jaundiced mood, but it is evident that he was oversensitive to neglect of parental worth. Apart from confirming his distrust of learning, his resentment at his father's disappointing experiences fostered the boy's self-assertiveness and independence of character.

As a boy with little inclination to scholarship but gifted with a lively perception of the busy world around him, he enjoyed mimicking and drawing striking characters he observed, interests that were encouraged by visits to a local painter's workshop. While not discouraging his artistic inclinations, his father, Hogarth later complained, could do little more "than put me in a way of shifting for myself." He consequently sought the security of a solid craftsman's training and became apprenticed, at about the age of 15, to Ellis Gamble, a silversmith. Hogarth presumably moved to his master's house, where he learned to engrave gold and silver work with armorial designs—in his own phrase, the "monsters of heraldry." Valuable years lost on, what Vertue aptly termed, "low-shrubb instructions" had crucial bearing on Hogarth's

Apprenticed to a silversmith

subsequent development. Apart from the insecurity they bred, Hogarth's frustration with his training led him to exploit unorthodox methods of self-instruction in order to make up for lost time. His great originality and flexibility as an artist owed much to this pragmatic and unconventional approach to his career.

Hogarth's years of apprenticeship were by no means devoted exclusively to hard work, however. Sociable and fond of fun, a keen and humorous observer of human behaviour, with a special love of the theatre and shows of all kinds, he was evidently a gay companion. Never prudish, he knew the exuberant life of the London streets, bawdy houses, fairs, and theatres at first hand and derived from them a fertile appreciation of the vitality of popular tradition. At the same time, he felt drawn to the coffeehouses and taverns frequented by writers, musicians, actors, and liberal professionals, forming lasting friendships in such lively intellectual circles. His sympathies rested with the middle classes and, specifically, with the critical, enlightened element—rational, tolerant, and humanitarian—that played such a prominent role in the cultural life of Hanoverian England.

George I had been king for six years when Hogarth set up shop on his own at the age of 23, resolving to escape the rigid limitations of his trade. He began by attending a private drawing school in St. Martin's Lane, where he joined other students drawing from casts and live models. He had a natural distaste for copying, however, likening it to emptying water from one vessel into another, and this instinctive rejection of formal training, combined with a natural waywardness, convinced him that the best method of learning to draw lay in direct attention to actual life. An intuitive realist, primarily concerned with expressive rather than formal values, he developed a kind of visual mnemonics: "the retaining in my minds eye without drawing on the spot whatever I wanted to imitate." From close observation of the everyday scene ("Nature" for this confirmed city dweller), Hogarth trained his unusual visual memory until, unlike the majority of artists, he could dispense with preliminary studies, committing his ideas directly to paper or canvas. This inspired improvisation, adopted partially as a means of reconciling work and pleasure, was supplemented by a formidable knowledge of the European tradition in art, acquired through familiarity with a vast range of reproductive engravings. Meanwhile, he earned his living as a copper engraver, executing trade cards, tickets, and book illustrations that assumed an increasingly authoritative stamp as fresh influences transformed the decorative mannerisms of his apprenticeship. His growing success as an illustrator brought Hogarth little satisfaction, for it entailed unwelcome dependence on the booksellers who had exploited his father; he later insisted that engraving "did little more than maintain myself in the usual gaities of life but (was) in all a punctual paymaster." He had long been an admirer of Sir James Thornhill's fluent, if provincial, adaptation of the late Baroque style, and in 1724 he joined a free drawing school, newly opened in Thornhill's house. It was the start of a critical association. Holding the official post of serjeant painter to the King and being the first knighted English-born artist, Thornhill in his career affirmed the vitality of native art and the social respectability of the artist. Hogarth cared passionately about both, primarily for personal reasons but also because he believed in art as a vital creative force in society. He despised the connoisseurs' exclusive admiration for the old masters and their snobbish prejudice in favour of foreign artists. In his first major work, published independently of the booksellers in 1724, "Masquerades and Operas," Hogarth attacked the degeneracy of contemporary taste and expressed attitudes that were vigorously sustained throughout his life. Boldly questioning the standards of an influential clique that was supported by the Earl of Burlington, an influential art lover and patron, Hogarth's first blow in a private war with the connoisseurs was shrewdly designed to appeal to his hero, Thornhill, who was himself, at this time, suffering the hostile effects of Burlington's Neoclassical revival. Thus, Hogarth made powerful enemies at the start of his career, and when they retaliated around 1730 by nullifying royal interest in his early work, he was cruelly disappointed. Indeed, despite his own intransigent frankness, Hogarth was always discouraged and offended when his opponents hit back.

Development of visual mnemonics

Association with Sir James Thornhill

A lawsuit he brought in 1728 against Joshua Morris, a tapestry weaver, throws eloquent light on his susceptibilities. The details of the case reveal that, by the age of 30, Hogarth felt sufficiently confident of his abilities to embark on a painting career. Morris failed to share this confidence and rejected a painting he had ordered on grounds that it was not finished. Hogarth indignantly sought and obtained public vindication with the help of professional witnesses, including Thornhill. Their testimony was amply justified by his first dated painting, "The Beggar's Opera" (1728), a scene from John Gay's popular farce on lowlife, which emphasized Hogarth's prevailing interests: his involvement with the theatre and with down-to-earth, comic subjects. Closely attentive to realistic detail, he recorded the scene exactly as it appeared to the audience and included portraits of the principal actors and spectators. He thus anticipated both his later narrative paintings and the small, informal group portraits, or "conversation pieces," that occupied him in the years immediately after this auspicious debut.

"The Beggar's Opera"

Encouraged by his success and, possibly, also by his close friendship with Thornhill's son John, Hogarth eloped in March 1729 with Thornhill's daughter Jane. The marriage proved stable and contented, though childless, but Thornhill initially showed little enthusiasm for the match; and the couple took lodgings in South Lambeth. There Hogarth met Jonathan Tyers, who was planning to re-open pleasure gardens at Vauxhall. The project naturally appealed to Hogarth, and he encouraged Tyers to invite artists to decorate the pavilions with genre scenes. Although his direct involvement was minimal, Hogarth's cheerful sympathies influenced the whole scheme, especially the subject matter.

Reputation and success. A few months after Hogarth's marriage, Vertue remarked on his public success with "conversations," and in the next few years, these small paintings, which acknowledged a great debt to the early 18th-century painter Antoine Watteau and the elegance of French Rococo art, brought Hogarth an appreciative and wealthy clientele. For a particularly important patron, the Duke of Richmond, he painted "Conquest of Mexico" (1731), a brilliant and charming portrayal of the amateur performance of Dryden's *Indian Emperor* before the royal children. His deft and fastidious handling of the paint and graceful disposition of the child players in relation to their audience are quite unmatched in English art of the period and demonstrate Hogarth's masterly control of the painting medium at the very outset of his career.

Though he displayed remarkable energy at the time, Hogarth quickly tired of these little paintings, which involved numerous portraits for relatively poor remuneration. For his own enjoyment he began, while still executing "conversations," to record humorous scenes from everyday life. The crowded canvas of "Southwark Fair" (1733) captures the noisy and exuberant vigour of a popular festival and shows Hogarth feeling his way toward a completely new kind of narrative art based on vivid appreciation of contemporary life. Friends he made in the theatrical world, the actor-manager David Garrick and writer Henry Fielding, shared his enthusiasm for honest naturalism in art. The theatre continued to play a central role in Hogarth's life, not only supplying rich enjoyment and visual material for his paintings but, in a deeper sense, shaping his ideas on the scope and purpose of art. Literary and theatrical associations governed his approach to his "modern moral subjects" initiated by "A Harlot's Progress" (1731–32), painted and engraved in six parts. As he explained, in consciously Shakespearean terms:

"A Harlot's Progress"

> Subjects I consider'd as writers do. My Picture was my Stage and men and women my actors who were by Mean of certain Actions and express[ions] to Exhibit a dumb shew.

Like his great predecessor, the 16th-century Flemish

painter Pieter Bruegel the Elder, Hogarth wanted to extract entertaining and instructive incidents from life. In telling the story of a young country girl's corruption in London and her consequent miseries, he not only ridiculed the viciousness and follies of society but painted an obvious moral. The engravings were aimed at a wide public, and their tremendous success immediately established Hogarth's financial and artistic independence. He was henceforth free, unlike most of his colleagues, to follow his own creative inclinations. Private subscriptions to the prints brought Hogarth over £1,200, far more than he could hope to earn annually from painting, but, even so, numerous pirated editions absorbed further profits. To safeguard his livelihood from unscrupulous printers, he fought to obtain legislation protecting artist's copyright and held back the eight-part "Rake's Progress" until a law of that nature, known as the Hogarth Act, was passed in 1735.

In an informal moment in May 1732, at the close of a merry evening's drinking, Hogarth embarked down the Thames with four equally inebriated companions on a madcap tour of Kent. They spent five lighthearted days roistering about the countryside and produced an amusing record of this "peregrination" for their friends, in the form of a burlesque on the continental excursions of the gentry.

In the following year Hogarth moved into the house in Leicester Fields that he was to occupy until his death and, with a teasing glance at the art pundits, installed a gilded head of the 17th-century painter Sir Anthony Van Dyck over his door. Too little a flatterer to become a fashionable portrait painter, with provoking gestures of this kind as well as assiduous newspaper publicity, Hogarth strenuously cultivated his public image, never missing an opportunity of self-advertisement. His critics called him conceited and remarked with distaste on his astute business tactics.

Historical and portrait painting. After Thornhill's death, in 1734, Hogarth re-established his drawing school on a cooperative basis, and it became an important arena for artistic discussion and experiment. He also was evidently tempted to assume Thornhill's mantle as a painter in the grand manner. "Before I had done anything of much consequence in this walk," he recalled, disingenuously dismissing the two "Progresses," "I entertained some hopes of succeeding in what the puffers in books call 'the great style of history painting.'" In 1735, in line with the humanitarian concern that occupied enlightened opinion of the day, he was elected a governor of St. Bartholomew's Hospital; and he seized this opportunity to decorate the main staircase with two large religious works, "Pool of Bethesda" and "The Good Samaritan." In abandoning comic narrative and genre for history painting, he was generally held to have overreached himself, though Vertue conceded that the results were "by everyone judged to be more than could be expected of him." Modern critics have tended to endorse this opinion. Hogarth himself deeply resented this attitude and attached great importance to his historical works. He wanted desperately to be taken seriously as a painter and realized that the popularity of his topical engravings interfered with his ambitions. His comic narrative pictures had broken radical new ground in English art but stereotyped him as a caricaturist. Conscious of his originality and encouraged by Fielding's distinction between comic realism and the grotesque, Hogarth claimed the respect traditionally paid to the old masters. Without this recognition, his successes appeared meaningless to him, and he fought ceaselessly to confound his critics and establish himself as the leader of a vigorous, new school of English painting.

Paintings for St. Bartholomew's

Around 1740 he turned once again to painting portraits, chiefly of middle class sitters, and retrospectively remarked, comparing himself to Rembrandt with less modesty than justice, that these were said "by some Nature itself by others exicrable." He derived special enjoyment from painting the full-length, seated portrait of his friend, the philanthropist Captain Thomas Coram—a compelling and deeply sympathetic image that injected the dead aristocratic tradition with forthright realism and carried far-reaching implications for European portraiture. Hogarth, well aware of its importance, judiciously placed it on semipublic display at the Foundling Hospital, a benevolent institution for orphan children established by Coram in 1739. From the start Hogarth played a very active role in the affairs of this charitable venture, and when the buildings were completed in 1745, he persuaded a group of fellow artists to join him in contributing paintings as edifying decoration. Their cooperative effort produced the first public exhibition of contemporary art in England and was a vital step toward the foundation of the Royal Academy in 1768.

Self-portrait

The famous self-portrait of 1745, a year that marked, in many ways, the high point of Hogarth's career, was also an artistic manifesto. He mischievously juxtaposed his own blunt and intelligent features with those of his sturdy pug-dog, Trump, and placed volumes of the great English writers William Shakespeare, John Milton, and Jonathan Swift beside a palette inscribed with the sinuous "line of beauty," his shorthand symbol for the variety, intricacy, and expressiveness of Nature. In the same year he published the long-announced prints of "Marriage à la Mode," censuring the marriage customs of the upper classes. He had completed the paintings in May 1743, when he made a brief visit to Paris to secure French engravers for the plates, as he wished them to be particularly elegant. Vertue implied that the extra cost entailed in this venture dissuaded Hogarth from repeating the practice, though he probably chose to execute his own plates from an understandable impatience with "translators." On his return in June, he arranged an auction of his earlier serial and narrative paintings. The ticket of admission, "The Battle of the Pictures," depicted a contest between the "ancients" (admirers of old pictures regardless of their merits or state of preservation) and the "moderns" (himself), underlining the defiant spirit in which he viewed the affair. As a further thrust at the "lovers of dark pictures," he excluded dealers and artists and conducted the bidding by the clock, two eccentric circumstances that probably contributed to the extremely low prices fetched. Hogarth interpreted the sale as a stinging defeat, which, combined with unenthusiastic notice of his Foundling picture, caused him to withdraw from painting temporarily.

Return to prints. Apart from a gratifying commission for a large history piece, which he won from the lawyers of Lincoln's Inn (one of the four legal societies and schools in London), and a further visit to Paris in 1748, Hogarth concentrated for the next few years on simple, didactic prints aimed at an unrefined public, executed from drawings not paintings. "Beer Street," "Gin Lane," and "Four Stages of Cruelty" (1751) he cut deliberately crudely on wood blocks to make them cheaper and facilitate a wide distribution. "Industry and Idleness" (1747) contains, in addition to its obvious moral message, a good deal of self-dramatization, depicting the virtuous apprentice made good in a hostile world. In these years Hogarth's uncertainty and frustration expressed themselves in a number of unfinished paintings. In several spontaneous sketches, he succeeded where he had failed in his heroic pictures and synthesized dynamic elements of the 17th-century Baroque style with an uncompromising realism and fully expressive handling of the paint. Unregarded in his lifetime, it is only in the wake of the 19th-century Impressionist movement that such sketches have received serious attention.

In 1751 Hogarth again organized a sale even more bizarre than the first. When the six paintings for "Marriage à la Mode" went to the only bidder for £120, Vertue complacently observed that Hogarth, in anger and mortification, took down the Van Dyck sign. He retreated into aggrieved isolation, pursuing his philanthropic interests but adopting, in public, a defiant and defensive pose that involved him in increasingly rancourous debate on artistic matters. He expounded his own theories in *The Analysis of Beauty* (1753), combining practical advice on painting with criticism of the art establishment. He expressed his belief in the "beauty of a composed intricacy

The Analysis of Beauty

of form," which "leads the eye a kind of chace" and advocated variety, irregularity, movement, and exaggeration in the interests of greater expressiveness. Though his ideas were respectfully received, especially on the Continent, the book inspired much adverse comment from his opponents. He even quarrelled with his colleagues in his academy over a proposal to adopt the French academic system, which Hogarth opposed as he did rules and rigidity of any kind. Yet he must have been painfully aware that the future now lay with Joshua Reynolds and other artists unsympathetic to his ideals.

His large "Election" series (1754–58), painted with elaborate care, was a last attempt to prove the dignity of "comic history painting," and thereafter he painted little of importance. His appointment as serjeant painter to George III, contrived in 1757, revived some interest in portraiture, but his last years, when he probably suffered considerable ill health, were dominated by the acrimony attendant on his painting "Sigismunda" (1759) and his print "The Times, I" (1762). The first represented a characteristic bid by Hogarth to outdo an old master painting recently sold for £400. His pride suffered a harsh blow when his patron, expecting a light genre subject, rejected the finished picture.

Appointment as serjeant painter

An ill-advised departure into political satire, "The Times, I" attacked William Pitt the Elder and the extremely popular war party that supported the war with France. Hogarth claimed it was executed "to stop a gap in my income," but general irritability and a desire to pose as a persecuted heretic and lone defender of truth lay behind this reckless challenge to public opinion. The storm of abuse it excited wounded him deeply and soured his last years. Obsessive to the last, a few months before his death on October 26, 1764, he executed an engraving sardonically titled "Tail-Piece" or "The Bathos," in which he sombrely depicted the demise of his own artistic world. In a sense it was prophetic, for as the 19th-century English painter Constable rightly remarked, "Hogarth has no school, nor has he ever been imitated with tolerable success." His immediate influence had been more strongly felt in literature than painting, and after his death it was significantly the Romantics, many of whose ideas Hogarth had anticipated, who first recognized his greatness. Though never neglected, Hogarth was chiefly remembered for his satiric engravings, and like that other lonely pioneer, the 19th-century painter J.M.W. Turner, the implications of his work were better understood on the Continent than in England.

MAJOR WORKS

PAINTINGS: "The Beggar's Opera" (1728; Tate Gallery, London); "Captain Woodes Rogers and His Family" (1729; National Maritime Museum, Greenwich, London); "The Wedding of Stephen Beckingham and Mary Cox" (1729–30; Metropolitan Museum of Art, New York); "A Musical Party" (*c.* 1730; Fitzwilliam Museum, Cambridge); "The Fountaine Family" (*c.* 1730; Philadelphia Museum of Art, Philadelphia); "A Fishing Party" (*c.* 1730; Dulwich College Picture Gallery, London); "The Conquest of Mexico (The Indian Emperor)" (1731; Earl of Ilchester's Collection, London); "The Cholmondeley Family" (1732; Marquis of Cholmondeley's Collection); "A Rake's Progress" (eight scenes, begun 1732; Sir John Soane's Museum, London); "Southwark Fair" (1733; Lady Oakes' Collection); "The Distressed Poet" (*c.* 1735; City Museum and Art Gallery, Birmingham, England); "The Good Samaritan" (1735; St. Bartholemew's Hospital, London); "The Four Times of the Day" (*c.* 1736; Viscount Bearsted and the Earl of Ancaster Collection); "Captain Thomas Coram" (1740; Foundling Hospital, London); "Miss Mary Edwards" (*c.* 1740; Frick Collection, New York); "The Graham Children" (1742; National Gallery, London); "Marriage à la Mode" (six scenes, 1743; Tate Gallery, London); "Garrick in the Character of Richard III" (1745; Earl of Feversham Collection); "Mrs. Elizabeth Salter" (1744; National Gallery, London); "Self-Portrait" (1745; National Gallery, London); "Lord George Graham in His Cabin" (1745; National Maritime Museum, Greenwich, London); "Moses Brought Before Pharoah's Daughter" (1746; Foundling Hospital, London); "An Election" (four scenes, 1754–58; Sir John Soane's Museum, London); "The Ascension" (1756; St. Mary Redcliffe, Bristol); "Hogarth's Servants" (*c.* 1758; National Gallery, London); "Picquet, or Virtue in Danger" (1758–59; Albright-Knox Art Gallery, Buffalo); "The Shrimp Girl" (*c.* 1759; National Gallery, London).

ENGRAVINGS: "Masquerades and Operas" (1724; Burlington Gate); "A Harlot's Progress" (1731–32); "A Rake's Progress" (1735); "The Strolling Actresses Dressing in a Barn" (1738); "Marriage à la Mode" (1745); "Industry and Idleness" (1747); "Beer Street" and "Gin Lane" (1751); "The Four Stages of Cruelty" (1751); "The Invasion" (two plates, 1756); "The Bench" (1758); "The Times, I" (1762).

(S.E.B.)

Hōjō Family

The Hōjō family, as hereditary regents to the military government of Japan, were the actual rulers of Japan from 1199 to 1333. During that period, nine successive members of the Hōjō family held the regency. The Hōjōs took their name from their small estate in the Kanogawa Valley in Izu Province.

Hōjō Tokimasa (1138–1215), the first known member of the family, was charged by the Japanese ruler Taira Kiyomori with the co-wardenship of the exiled Minamoto Yoritomo in 1160. In 1180, however, when Yoritomo rallied the armed men of the Kantō, a region in Central Japan, against Taira rule, Tokimasa fought with him. Yoritomo acquired all power in Japan by 1189 and ruled as shogun (military commander); Tokimasa became the warden of Kyōto, while his daughter Masako married Yoritomo, with whom she had long had a liaison. At Yoritomo's death in 1199 Tokimasa became the guardian of the heir Yoriie and in effect regent, although Masako governed in the name of her son. The Hōjō family kept in good order and improved the simple but effective machinery of rule that Yoritomo had established. Yoritomo had received permission from the Emperor to place his own men as constables (*shugo*) and tax collectors (*jitō*) in each province. These appointees were responsible to the Samurai *dokoro*, or private military staff of the shogun, at Kamakura. The staff was headed by the *shikken*, or regent to the shogun. Thus, this office controlled the law, the peace, and the revenues of Japan, and the Hōjō family came to monopolize the office of *shikken* and to make it hereditary among them.

Rise to power

By 1247, when members of the house and clan held, through appointment, dominion over half the provinces of Japan, Hōjō rule tended to become authoritarian, and the regency was run not from its titular office but from Hōjō headquarters as a family council. This assumption of power, beginning with Tokimasa, was not difficult because the armed class did not wish to relinquish the peace, profits, and stability the *bakufu* (military government) had brought it. They were reluctant to permit the heir Yoriie, a youth of uncertain temper and strong ap-

petites, to become shogun. Yoriie attempted the murder of Tokimasa but was himself exiled and killed. When the remaining heir, Sanetomo, was murdered (1219) the last impediment to Hōjō domination was gone. The final accretion of Hōjō power came in 1221, when the emperor Toba II raised the Taira of western Japan against the Hōjō. The revolt (Shōkyū no Ran) not only failed but in its failing the Hōjō were able to confiscate thousands of estates and place them in the hands of landless adherents and friends. Many landless warriors, created by the litigious system of family inheritance in Japan, had little love for the Hōjō but less for hunger and dispossession. Their number, as it rose and fell, was an indication of the stability of the *bakufu*, and until the late 13th century the Hōjō kept their numbers small. The first three Hōjō regencies—Yoshitoki, who succeeded Tokimasa in 1205, was murdered in 1224 and replaced by his brother Yasutoki (1183–1242)—were the apex of capable feudal rule in Japan. Dependable cadastral records were created in 1222–23. In 1232 a brief and workable code (Jōei shikimoku) for the conduct and regulation of the armed class in a feudal society was promulgated. Slowly, between 1221 and 1232, the simple military system of Yoritomo was transformed by the Hōjō family into a capable private government.

Relationship with the court and the aristocracy

Essentially, this meant maintaining a cordial but careful relationship with the court and its complex system of reigning, retired, and cloistered emperors and with the great aristocracy of Kyōto, who wished an end to the *bakufu* system. A Hōjō commander and garrison were stationed in Kyōto; but the property, revenues, and ceremonials of the Imperial family and nobility were protected. The powerful Buddhist clergy were kept in hand by strict auditing of their accounts. The vassals of Hōjō were kept solvent, peaceful, and apart from the court. The peasant was protected in his freedom and tenure. The regency drew its income from the Hōjō estates, which comprised nearly the whole of the Kantō. The family adhered firmly to Yoritomo's dictum that the simple warrior life would best preserve this class from the pervasive decadence of the Kyōto aristocracy. Yasutoki died in 1242 and was succeeded by the Hōjō regents Tsunetoki (1224–46) in 1242, Tokiyori (1227–63) in 1246, and Tokimune (1215–84) in 1256. Tokimune's regency was the last stable and powerful epoch of the Hōjō. Tokimune refused the Mongol Kublai Khan's demand (1271) that Japan pay tribute to him. The result was an unsuccessful Mongol–Chinese–Korean assault on Hakata Harbour in Kyushu. In 1281 a massive second joint assault on Kyushu was again beaten back; but the cost of preparing the defense, of the two months' battle around Hakata, and of maintaining a war footing until Kublai died in 1294 was deadly. For 20 years Hōjō resources had been under great strain in the defense of Japan; the resources of their vassals had been consumed in the war.

Decline of Hōjō power

When Sadatoki (1270–1311) became regent in 1284, he found himself so embroiled in a succession dispute between two powerful factions of the Imperial family—a struggle beginning to split all Japan—that he secluded himself in a temple, from where he continued to administer Japan during the last ten years of his life. His successor, the ninth and last Hōjō regent, Takatori (1303–33), passed his minority dissolutely and extravagantly. On attaining his majority (1316) he left the affairs of the regency in the hands of inept men at a time when only a severe and powerful man could have managed the difficult economic and political situation. In 1331, because of the continuing quarrel over the Imperial succession, Takatori exiled the emperor Daigo II. Escaping from exile, the Emperor found it easy to raise war against the Hōjō. Takatori was betrayed by his own general, Ashikaga Takauji, who seized Kyōto from its Hōjō garrison. The *bakufu*'s own domain of the Kantō rose in revolt under Nitta Yoshisada (the opposition to the Hōjō was, in part, a revolt of the family's own constables and stewards, who had become locally powerful). Nitta sacked Kamakura, and on May 22, 1333, the last Hōjō regent committed suicide. But the foundation the Hōjō had laid was enduring. Daigo's attempt to restore a civil Imperial government lasted only three years. Ashikaga Takauji declared himself shogun in 1336, and from then until 1868 a form of *bakufu*—as created by Yoritomo and refined by the Hōjō—ruled Japan.

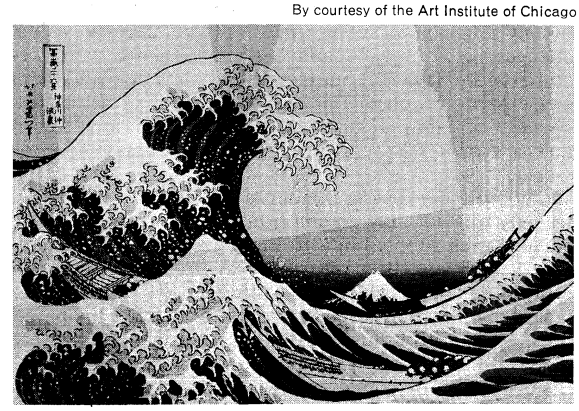
Hokusai

A famed Japanese artist, Hokusai embodied in his long lifetime the essence of the *Ukiyo-e* (Pictures of the Floating World) school of art during its final century of development. His stubborn genius also represents, in its 70 years of continuous artistic creation, the prototype of the single-minded artist, striving only to complete a given task. Moreover, Hokusai constitutes a figure who has, since the later 19th century, impressed Western artists, critics, and art lovers alike, more, possibly, than any other single Asian artist.

By courtesy of the Art Institute of Chicago



"The Breaking Wave off Kanagawa," woodblock print by Hokusai, from the series "Thirty-six Views of Mt. Fuji," 1826–33. 36.4 cm × 25.4 cm.

Birth and youth

Born in 1760, in the Honjo quarter just east of Edo (Tokyo), Hokusai became interested in drawing at the age of five. He was adopted in childhood by a prestigious artisan family named Nakajima but was never accepted as an heir—possibly supporting the theory that, though the true son of Nakajima, he had been born of a concubine.

Hokusai is said to have served as a youth as clerk in a lending bookshop; and from 15 to 18 was apprenticed to a wood-block engraver. This early training in the book and printing trades obviously contributed to Hokusai's artistic development as a printmaker.

The earliest contemporary record of Hokusai dates from the year 1778, when, at the age of 18, he became a pupil of the leading *Ukiyo-e* master, Katsukawa Shunshō. The young Hokusai's first published works appeared the following year—actor prints of the Kabuki theatre, the genre that Shunshō and the Katsukawa school practically dominated.

To judge from the ages of his several children, Hokusai must have married in his mid-20s. Possibly under the influence of family life, from this period his designs tended to turn from prints of actors and women to historical and landscape subjects, especially *uki-e* (semi-historical landscapes using Western-influenced perspective techniques), as well as prints of children. The artist's book illustrations and texts turned as well from the earlier themes to historical and didactic subjects. At the same time, Hokusai's work in the *surimono* genre during the subsequent decade marks one of the early peaks in his career. *Surimono* were prints issued privately for special

occasions—New Year's and other greetings, musical programs and announcements, private verse selections—in limited editions and featuring immaculate printing of the highest quality.

Hokusai's early 30s were to prove years of personal change. His master Shunshō died early in 1793, and somewhat later his young wife passed away, leaving a son and two daughters. In the year 1797 he remarried and adopted the name Hokusai. This change of name marks the beginning of the golden age of his work, which was to continue for a half century.

In format, Hokusai's *oeuvre* from this period covers the gamut of *Ukiyo-e* art: single-sheet prints, *surimono*, picture books and picture novelettes, illustrations to verse anthologies and historical novels, erotic books and album prints, and hand paintings and sketches. In his subject matter, Hokusai only occasionally (in a few notable prints, in paintings, and erotica) chose to compete with Utamaro, the acknowledged master of voluptuous figure prints. Aside from this limitation, however, Hokusai's work encompassed a wide range, with particular emphasis on landscape views and historical scenes in which figures were often of secondary interest. Around the turn of the century he experimented for a time with Western-style perspective and colouring.

From the early 19th century Hokusai commenced illustrating *yomihon* (the extended historical novels that were just coming into fashion). Under their influence, his style began to suffer important and clearly visible changes between 1806 and 1807. His figure work becomes more powerful but increasingly less delicate; there is greater attention to classical or traditional themes (especially of samurai, or warriors, and Chinese subjects) and a turning away from the contemporary *Ukiyo-e* world.

In about the year 1812, Hokusai's eldest son died. This tragedy was not only an emotional but also an economic event, for as adopted heir to the affluent Nakajima family, the son had been instrumental in obtaining a generous stipend for Hokusai, so that he did not need to worry about the uncertainties of income from his paintings, designs, and illustrations, which at this period were paid for more with "gifts" than with set fees.

The *Hokusai manga*

Whether for economic reasons or not, from this time on Hokusai's attention turned gradually from novel illustration to the picture book and, particularly, to the type of wood-block-printed copybook designed for amateur artists (including the famous *Hokusai manga*). Very likely his intention was to find new pupils and hence new patronage, and in this he succeeded to some degree.

Though famed for his detailed prints and illustrations, Hokusai was also fond of displaying his artistic prowess in public—making, for example, huge paintings (some fully 200 square metres [about 2,000 square feet] in area) of mythological figures before festival crowds, in both Edo and Nagoya. He was once even summoned to show his artistic skills before the shogun (the military leader who, although theoretically subordinate to the emperor, was in fact the ruler of Japan).

In the summer of 1828, Hokusai's second wife died. The master was then 68, afflicted intermittently with paralysis and left alone, evidently with only a profligate grandson, who had proved to be an incorrigible delinquent. It is probably no coincidence, therefore, that before long Hokusai's favourite daughter (and pupil), O-ei, broke her unhappy marriage with a minor artist named Tōmei and returned to her father's side, where she was to stay for his remaining years.

An energetic artist, Hokusai rose early and continued painting until well after dark. This was the customary regimen of his long, productive life. Of Hokusai's thousands of books and prints, his "Thirty-six Views of Mt. Fuji" is particularly notable. Published from about 1826 to 1833, this famous series (including supplements, a total of 46 colour prints) marked a summit in the history of the Japanese landscape print; in grandeur of concept and skill of execution there was little approaching it before and nothing to surpass it later—even in the work of Hokusai's famed late contemporary Hiroshige (*q.v.*).

Hokusai's frequent changes in domicile (more than 90 dwellings) and of his own name are indicative of the artist's restless nature. Besides his principal *noms d'artiste* (roughly one per decade)—Shunrō, Sōri, Kakō, Hokusai (often with the prefix Katsushika), Taitō, Gakyō, Iitsu, Manji—the artist had also some two dozen other occasional pseudonyms, though these were normally used as adjuncts to his principal name of a given period.

Despite his appeals to heaven for "yet another decade—nay, even another five years," on the 18th day of the fourth month (*i.e.*, mid-May in the Western calendar) in the year 1849 "the old man mad with painting," as he called himself, breathed his last. He was 89 but still insatiably seeking for an ultimate truth in art—as he had written some 15 years earlier:

> From the age of five I have had a mania for sketching the forms of things. From about the age of 50 I produced a number of designs, yet of all I drew prior to the age of 70 there is truly nothing of any great note. At the age of 73 I finally apprehended something of the true quality of birds, animals, insects, fishes, and of the vital nature of grasses and trees. Therefore, at 80 I shall have made some progress, at 90 I shall have penetrated even further the deeper meaning of things, at 100 I shall have become truly marvelous, and at 110, each dot, each line shall surely possess a life of its own. I only beg that gentlemen of sufficiently long life take care to note the truth of my words.

MAJOR WORKS

PRINTS AND ILLUSTRATIONS: "Festivals of the Green Houses" (*c.* 1790); "Festivals for the Twelve Months " (*c.* 1790); "Foreigners Observing Japanese Customs" (1796); *Chūshingura* series (I) (*c.* 1800); "Brocade Prints of the Thirty-six Poetesses" (1801); "Fifty Fanciful Poets, Each with One Poem" (1802); "Fuji in Spring (1803); "A Picture Book of Kyōka" (1803–04); "Fifty-three Stations on the Tōkaidō" (1804); *Chūshingura* series (II) (1806); *Suikoden* (1807); "Portraits of Six Poets" (*c.* 1810); "Quick Lessons in Simplified Drawing" (1812); *Hokusai manga*, vol. 1 (1814); *Hokusai gashiki* (1819); *Hokusai sōga* (1820); "Paintings with One Stroke of the Brush" (1823); "Thirty-six Views of Mt. Fuji" (*c.* 1826–33); "Views of Famous Bridges" (*c.* 1827–30); "Snow, Moon, and Flowers" (*c.* 1827–30); "Flowers and Birds" (*c.* 1827–30); "The Poems of China and Japan Mirrored to Life" (*c.* 1828–33); "Tōshi-sen" (1833–36); "Hundred Views of Mt. Fuji" (1834–35); "Hundred Poems Explained by the Nurse" (*c.* 1845).

BIBLIOGRAPHY. J.R. HILLIER, *Hokusai: Paintings, Drawings, and Woodcuts* (1955), the best general appreciation of Hokusai in English, though the biographical material is based on outdated sources—includes a detailed listing of his illustrated books; JAMES A. MICHENER (ed.), *The Hokusai Sketchbooks: Selections from the Manga*, with translations by RICHARD LANE (1958), a comprehensive sampling of the *Hokusai manga*, with commentary, and translation of all prefaces; THEODORE R. BOWIE, *The Drawings of Hokusai* (1964), a pioneer study, but flawed by being based largely on forgeries and school copies; RICHARD LANE, *Masters of the Japanese Print* (1962), includes a critical survey of Hokusai's work and times, based on original sources.

(Ri.L.)

Holbein, Hans, the Younger

Hans Holbein, the Younger, 16th-century German painter, was one of the greatest portraitists and most exquisite draftsmen of all time. He was both prolific and versatile, painting religious panels, portraits, and miniatures, designing woodcuts and stained-glass windows, and executing large interior and exterior murals. It is the artist's record of the court of King Henry VIII of England, as well as the taste that he virtually imposed upon that court, that was his most remarkable achievement.

Holbein was born in Augsburg. The exact date is not known, but because he was 46 when he died, it is commonly assumed that he was born late in 1497 or early in 1498. He was a member of a family of important artists. His father, Hans Holbein the Elder, and his uncle Sigmund were renowned for their somewhat conservative examples of late Gothic painting in Germany. One of Holbein's brothers, Ambrosius, became a painter as well, but he apparently died about 1519 before reaching maturity as an artist. The Holbein brothers no doubt first studied with their father in Augsburg; they both also be-

gan independent work in about 1515 in Basel, Switzerland. It should be noted that this chronology places Holbein firmly in the second generation of 16th-century German artists. Albrecht Dürer, Matthias Grünewald, and Lucas Cranach all were born around 1470 and were producing their mature masterpieces by the time Holbein was just beginning his career. Holbein is, in fact, the only truly outstanding German artist of his generation.

Early years in Basel

Holbein's work in Basel during the decade of 1515–25 was extremely varied, if also sometimes derivative. Trips to northern Italy (*c.* 1517) and France (1524) certainly affected the development of his religious subjects and portraiture, respectively.

Holbein was associated early with the Basel publishers and their Humanist circle of acquaintances. There he found not only portrait commissions (*e.g.*, "Portrait of Bonifacius Amerbach") but was especially active in designing woodcuts for title pages and book illustrations. The artist's most famous work in this area, a series of 41 scenes illustrating the medieval allegorical concept of the "Dance of Death," was designed by him and cut by another artist as early as *c.* 1523–26 but was not published until 1538. Holbein entered the painters' corporation in 1519, married a tanner's widow, and became a burgher of Basel in 1520; by 1521 he was executing important mural decorations in the Great Council Chamber of the town hall.

Protestantism, introduced into Basel as early as 1522, grew considerably in strength and importance there during the ensuing four years. By 1526 severe iconoclastic riots and strict censorship of the press swept over the city. In the face of what, for the moment at least, amounted to a freezing of the arts, Holbein left Basel late in 1526, with a letter of introduction from the Dutch Humanist scholar Erasmus, to travel by way of the Netherlands to England. Still only about 28 years old, he achieved remarkable success in England. His most impressive work of this time was executed for the statesman and author Sir Thomas More and included a magnificent single portrait of the Humanist as well as a group portrait of the scholar's family (now lost; preserved in copies and preparatory drawing, Basel, Kunstmuseum). The latter was the first example in northern Europe of a large group portrait in which the figures are not shown kneeling—the effect of which is to suggest the individuality of the sitters rather than impiety.

First trip to England

Before Holbein journeyed to England in 1526, he had apparently designed works both pro- and anti-Lutheran in character. On returning to Basel in 1528, he was admitted, after some hesitation, to the new—now official—faith. It would be difficult to interpret this as a very decisive change, for Holbein's most impressive religious works, like his portraits, are brilliant observations of physical reality but seemingly were never inspired by Christian mysticism or spirituality. In any case, Holbein apparently quite voluntarily gave up almost all religious painting after *c.* 1530.

In Basel, from 1528 to 1532, Holbein continued his important work for the Town Council. He painted as well what is perhaps his only psychologically penetrating portrait, that of his wife and two sons (Kunstmuseum, Basel). This picture no doubt conveys some of the unhappiness of the abandoned family. In spite of generous offers from the city of Basel, Holbein left his family there for a second time, in 1532, to spend the last 11 years of his life primarily in England.

By 1533 Holbein was already painting court personalities, and four years later he officially entered the service of Henry VIII. Commissions from the King were varied and demanding but must have been above all enormously satisfying to the artist's professional and personal ambitions. It is estimated that during the last ten years of his life Holbein executed about 150 portraits, life-size and miniature, of royalty and nobility alike. Holbein acted not only as a portraitist but also as a fashion designer for the court. The artist made designs for all the state robes of the King; he left, in addition, more than 250 delicate drawings for everything from buttons and buckles to pageant weapons, horse outfittings, and bookbindings for the royal household. This choice of work indicates Holbein's Mannerist concentration on surface texture and details of design, a concern that probably precluded the incorporation of serious psychological depth. Holbein died in a London plague epidemic in 1543.

The fact that Holbein's portraits do not reveal the character or spiritual inclinations of his sitters is perfectly paralleled by knowledge of the artist's life. His biography is basically a recounting of disparate facts; about his personality practically nothing is known. Not one note or letter from his own hand survives. Other men's opinions of him are often equally inscrutable. Erasmus, one of Holbein's most renowned sitters, praised and recommended him on one occasion but scorned the artist as opportunistic at another time. Indeed, Henry VIII, who sent him to the Continent to help select a bride by providing a dependable portrait for his scrutiny, was perhaps the only person who had absolute confidence in Holbein.

The biographical problem

The artist's detachment and his refusal to submit to an authority that might inhibit his own creative (but very worldly) powers enabled him to produce works whose beauty and brilliance have never been questioned. Had he been a more devout Christian or more subject to the turmoil of his times, his artistic achievement might have been quite different. In recent times, the lack of spiritual involvement in his work has been consistently noted, especially inasmuch as the 16th century was a time when few artists managed to remain above the religious conflict sweeping Europe. Thus, the effect of Holbein's life and work has often been felt to be more artistic and external than expressionistic or emotional. Only in that sense, however, is his achievement finally limited.

MAJOR WORKS

PAINTINGS: "Portrait of Bonifacius Amerbach" (1519; Kunstmuseum, Basel, Switzerland); "The Last Supper" (1519–20; Kunstmuseum); "The Flagellation" (1519–20; Kunstmuseum); "Dead Christ" (1521; Kunstmuseum); "Portrait of Erasmus" (1523–24; Louvre, Paris); "Virgin with the Family of the Burgomaster Jakob Meyer" ("Darmstadt Madonna"; 1526; Schlossmuseum, Darmstadt); "Magdalena Offenburg as Venus" (1526; Kunstmuseum); "Sir Thomas More" (1526; Frick Collection, New York); "Portrait of William Warham, Archbishop of Canterbury" (1527; Louvre, Paris); "Sir Henry Guildford" (1527; Windsor Castle, Berkshire); "Portrait of Lady Guildford" (1527; St. Louis Art Museum, St. Louis); "Portrait of Nicolas Kratzer" (1528; Louvre); "Double Portrait of Sir Thomas Godsalve and His Son Sir John" (1528; Gemäldegalerie, Dresden); "Portrait of the Artist's Wife with Katharina and Philipp" (1528; Kunstmuseum); "Erasmus in the Roundel" (1532; Kunstmuseum); "Portrait of a Member of the Wedigh Family" (1532; Metropolitan Museum of Art, New York); "Hans of Antwerp" (1532; Windsor Castle); "Portrait of the Merchant Georg Gisze" (1532; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Derick Born" (1533; Windsor Castle); "Dirk Tybis of Duisburg" (1533; Kunsthistorisches Museum, Vienna); "Jean de Dinteville and Georges de Selve" ("The Ambassadors"; 1533; National Gallery, London); "Portrait of Charles de Solier, Sieur de Morette" (1535; Gemäldegalerie, Dresden); "Sir Richard Southwell" (1536; Uffizi, Florence); "Henry VIII" (1536; Thyssen-Bornemisza Collection, Castagnola, Switzerland); "Jane Seymour" (1536; Kunsthistorisches Museum, Vienna);

"Christina of Denmark, Duchess of Milan" (1538; National Gallery, London).

WOODCUTS: *Dance of Death* (1538; designed *c.* 1523–26); *Icones historiarum Veteris Testamenti* (94) (1538; designed before 1531); "Erasmus im Gehüs" (1535); title page, Coverdale's Bible (1535; British Museum).

MINIATURES: "Portrait of Mrs. Pemberton" (*c.* 1540; Victoria and Albert Museum, London); "Anne of Cleves" (*c.* 1540; Victoria and Albert Museum); "Charles Brandon" (*c.* 1540; Windsor Castle).

PARKER, *The Drawings of Hans Holbein in the Collection of His Majesty the King at Windsor Castle* (1945), the most recent scholarly account of what is probably the single most important collection of Holbein's mature drawings; H.A. SCHMID, *Hans Holbein der Jüngere; sein Aufstieg zur Meisterschaft und sein englischer Stil*, 2 vol. (1945–48), a lengthy and valuable monograph on the artist in German; PAUL GANZ (ed.), *Hans Holbein: Die Gemalde* (1949; Eng. trans., *The Paintings of Hans Holbein*, 1950), the most detailed monograph on Holbein's painted work in English; BASEL, UNIVERSITAT, KUNSTSAMMLUNG, *Die Malerfamilie Holbein in Basel* (1960), a comprehensive catalog of the most important exhibition ever organized concerning Holbein and his family; R.C. STRONG, *Holbein and Henry VIII* (1967), the most recent treatment in English of this important aspect of Holbein's career.

(C.S.Ha.)

Hölderlin, Friedrich

One of the outstanding lyric poets in the German language, Johann Christian Friedrich Hölderlin gained little recognition during his lifetime and was almost totally forgotten for nearly 100 years. It was not until the early years of the 20th century that he was rediscovered in Germany and that his reputation was established in Europe. Today he is ranked among the greatest of German poets, especially admired for his uniquely expressive style: like no one before or since, he succeeded in naturalizing the forms of classical Greek verse in the German language. With passionate intensity he strove to reconcile the Christian faith with the religious spirit and beliefs of ancient Greece; he was a prophet of spiritual renewal, of "the return of the gods"—utterly dedicated to his art, hypersensitive, and therefore exceptionally vulnerable. In the end his mind gave way under the strains and frustrations of his existence.

Hölderlin was born in the little Swabian town of Lauffen, on the River Neckar, on March 20, 1770. His father died in 1772, and two years afterward his mother married the burgomaster of the town of Nürtingen, where Friedrich attended school. But his mother was again widowed, in 1779, and left alone to bring up her family —which included Friedrich, his sister Heinrike, and his half-brother Karl. His mother, a parson's daughter, and a woman of simple and rather narrow piety, wanted Friedrich to enter the service of the church. Candidates for the ministry received free education—a chance not to be missed by a gifted but impecunious boy—and accordingly he was sent first to the "monastery schools" (so called since pre-Reformation times) at Denkendorf and Maulbronn and subsequently (1788–93) to the theological seminary in the University of Tübingen, where he obtained his master's degree and qualified for ordination.

Hölderlin, pastel by Franz Karl Hiemer, 1792. In the Schiller-Nationalmuseum, Marbach, West Germany.

Training for the ministry

Hölderlin could not, however, bring himself to enter the ministry for which he had studied. Contemporary Protestant theology, an uneasy compromise between faith and reason, offered him no safe spiritual anchorage, while acceptance of Christian dogma was not wholly compatible with his devotion to Greek mythology, which made him see the gods of Greece as real living forces whose presence manifests itself to men in sun and earth, sea and sky. The strain of divided allegiance remained a permanent condition of his existence. Although he did not feel called to be a Lutheran pastor, Hölderlin did have a strong sense of religious vocation; for him, being a poet meant exercising the priestly function of mediator between gods and men.

Meeting with Schiller

In 1793 Hölderlin was introduced to Friedrich Schiller, and it was through Schiller's recommendation that he obtained the first of several posts as a tutor (in most of which he failed to give satisfaction). Schiller befriended the younger man in other ways too; in his periodical *Neue Thalia*, he published some of the poetry that Hölderlin had begun to write, as well as a fragment of his novel *Hyperion*. This elegiac story of a disillusioned fighter for the liberation of Greece remained unfinished. Hölderlin held Schiller in great reverence; he saw him again when in 1794 he left his tutor's post in order to move to Jena. His early poems clearly reveal Schiller's influence, and several of them acclaim the new world the French Revolution had seemed to promise in its early stages: they include hymns to freedom, to humanity, to harmony, to friendship, and to nature.

In December 1795 poverty forced Hölderlin to take a post in the house of J.F. Gontard, a wealthy Frankfurt banker. Before long, the susceptible young tutor was deeply in love with his employer's wife, Susette, a woman of great beauty and sensibility, and his affection was returned. In a letter to his friend C.L. Neuffer (February 1797), he described their relationship as "an everlasting happy sacred friendship with a being who has really strayed into this miserable century." Susette appears in his poems and in his novel *Hyperion*, the second volume of which appeared in 1799, under the Greek name of "Diotima"—a reincarnation of the spirit of ancient Greece. Their happiness was short-lived; after a painful scene with Susette's husband, Hölderlin had to leave Frankfurt (September 1798).

Onset of mental illness

Though physically and mentally shaken, he finished the second volume of *Hyperion* and began a tragedy, *Der Tod des Empedokles* (*The Death of Empedocles*), the first version of which he nearly completed; fragments of a second and a third version have also survived. Symptoms of great nervous irritability alarmed his family and friends. Nevertheless the years 1798–1801 were a period of intense creativity; in addition to a number of noble odes, they produced the great elegies "Menons Klagen um Diotima" ("Menon's Lament for Diotima") and "Brot und Wein" ("Bread and Wine"). In January 1801, he went to Switzerland as tutor to a family in Hauptwyl. His employer, however, found himself obliged to make other arrangements and Hölderlin returned home in April of the same year.

After vainly attempting to obtain a lectureship in Greek literature at Jena through the influence of Schiller, he once more accepted a post as tutor, this time at Bordeaux,

in France. Susette Gontard died in June 1802; in the same summer, Hölderlin suddenly left Bordeaux and travelled homeward on foot through France, arriving at Nürtingen completely destitute and mentally deranged, in an advanced stage of schizophrenia. He seemed to recover somewhat as a result of the kind and gentle treatment he received at home. The poems of the period 1802–06, including "Friedensfeier" ("Celebration of Peace"), "Der Einzige" ("The Only One"), and "Patmos," products of a mind on the verge of madness, are apocalyptic visions of unique grandeur. He also completed verse translations of Sophocles' *Antigone* and *Oedipus Tyrannus*, published in 1804. In this year a devoted friend, Isaak von Sinclair, obtained for him the sinecure post of librarian to the landgrave Frederick V of Hesse-Homburg. Sinclair himself provided a modest salary, and Hölderlin improved noticeably under his care and companionship. In 1805, Sinclair (who refused to believe that Hölderlin was insane) was falsely accused of subversive activities and held in custody for five months. By the time he was released, Hölderlin had succumbed irretrievably and, after a spell in a clinic in Tübingen, was moved to a carpenter's house in that town, where he died on June 7, 1843, having passed the last thirty-six years of his life under the shadow of insanity.

Two years before he became mentally unbalanced, Hölderlin had summed up his destiny in the concluding lines of his ode "Die Heimat" ("Home"):

> For they who lend us the heavenly fire, the Gods, give us sacred sorrow too. Let it be so. A son of earth I seem; born to love and to suffer.

MAJOR WORKS

Hyperion, oder der Eremit in Griechenland, vol. 1 (1797), vol. 2 (1799), epistolary novel; verse translations of Sophocles' *Antigone* and *Oedipus Tyrannus* (1804). *Hyperion* and the translations were the only works published in book form before the onset of Hölderlin's madness. Several editions of selected poems were published in the 19th century, the first in 1826 (edited by L. Uhland and G. Schwab), but it was not until the 1920s that a reliable and comprehensive edition was available. Among his best known poems are: (written before 1802) "Der Mensch," "Hyperions Schicksaalslied," "An die Parzen," "An die Hoffnung," "Brod und Wein"; (written between 1802 and 1806) "Hälfte des Lebens," "Der blinde Sänger," "Germanien," "Der Rhein," "Der Einzige," and "Patmos."

BIBLIOGRAPHY. For detailed bibliographical information, see F. SEEBASS, *Hölderlin-Bibliographie* (1922); A. KELLETAT and M. KOHLER, *Hölderlin-Bibliographie 1938–1950* (1953); and the periodical surveys in the *Hölderlin-Jahrbuch*.

The major modern edition of Hölderlin's works is *Sämtliche Werke*, ed. by FRIEDRICH BEISSNER (vol. 1–5, 1946–52) and ADOLF BECK (vol. 6–7; the Letters, 1954–). Beissner has also edited a plain text of the complete works in one volume (1964). There is a one-volume collection of Hölderlin's letters, edited by ERNST BERTRAM (1935). The poems of Hölderlin's maturity, together with the second and third fragmentary versions of his drama *Der Tod des Empedokles*, have been translated by MICHAEL HAMBURGER: *Friedrich Hölderlin: Poems and Fragments*, bilingual edition (1966). A translation of *Selected Poems* was published in 1944 (2nd ed., 1954) by J.B. LEISHMAN. *Hyperion* has been translated by W.R. TRASK (1965).

There are several biographical and critical studies in English: RONALD PEACOCK, *Hölderlin* (1938); AGNES STANFIELD, *Hölderlin* (1944); and L.S. SALZBERGER, *Hölderlin* (1952). Important aspects of Hölderlin's art are discussed by E.L. STAHL in *Hölderlin's Symbolism* (1945); and in "Hölderlin's Idea of Poetry," in *The Era of Goethe* (1959). WHILHELM DILTHEY'S essay on Hölderlin in *Das Erlebnis und die Dichtung* (1906) remains a classic. A number of illuminating recent studies by various hands are gathered together in *Über Hölderlin*, ed. by J. SCHMIDT (1970). ALESSANDRO PELLEGRINI has written a detailed history of Hölderlin criticism: *Friedrich Hölderlin: Sein Bild in der Forschung* (1965).

(W.Wi.)

Holiness Churches

At least 20 religious groups in the United States with a combined membership in excess of 1,000,000 comprise the Holiness movement. Most of these churches place great stress on a doctrine of sanctification (from the Latin *sanctus*, "holy"), a postconversion experience that enables a believer to live a sinless, perfect, holy, Christian life. Some of these perfectionist bodies have incorporated the term holiness in their official church names: Holiness Methodist Church (which was absorbed by the Evangelical Church of North America in 1969), Church of Christ Holiness U.S.A., Fire Baptized Holiness Church; others, like the Wesleyan Church, Free Methodist Church of North America, Primitive Methodist Church, Church of God (Anderson, Indiana), Church of the Nazarene, Christian and Missionary Alliance, and the Salvation Army, do not.

NATURE AND SIGNIFICANCE

The beliefs that are characteristic of most Holiness churches include (1) the basic tenets of Fundamentalism —*i.e.*, biblical inerrancy, the virgin birth of Christ, his substitutionary atonement (*i.e.*, the reconciliation of man with God through Christ), physical resurrection, and imminent return of Christ to earth; (2) the principles of Arminian theology, namely the doctrines of free will and free grace; (3) the truths proclaimed by John Wesley, founder of the Methodist Church, and popularized during the Methodist revivals of the 18th and 19th centuries (*i.e.*, that by "praying through" at a mourners' bench every sinner can experience a positive inner assurance of personal salvation followed by a "second blessing"—sanctification); and (4) a doctrine of separatism that advocates the avoidance of "worldly" practices such as attending the movies, dancing, using tobacco or alcohol, or belonging to "secret societies."

Methodist and Pentecostal influences

In many ways, a number of Holiness churches are quasi-Methodist sects. They are Wesleyan in faith and practice, their founders frequently were Methodist ministers, and their original members were former Methodists. One of the largest Holiness bodies, the Church of the Nazarene, clearly illustrates this: its polity is Methodistic; its *Manual* is admittedly an adaptation of the Methodist *Discipline*; and five of its first seven general superintendents had once been Methodist preachers. On the other hand, the doctrinal stance of still other Holiness groups—their Fundamentalism, millenarianism (doctrines concerning the earthly aspects of the consummation of history), revivalism (activities encouraging religious conversions), and asceticism (denial of bodily pleasures or needs)—has allowed them to gravitate toward theologically conservative bodies, such as the National Association of Evangelicals. Currently, the Free Methodist Church and the Wesleyan Church are actively affiliated with that organization. Finally, the emphasis that many Holiness churches place on a second-blessing experience, the result of the direct operation of the Holy Spirit in the heart of a believer, closely resembles the primacy accorded the work of the Spirit by Pentecostal groups, which stress the marvels of the Spirit's first coming to the church (Acts 2). Although it is a fact, however, that the taproots of a number of the older Pentecostal denominations reach back into the Holiness revivals of the 19th century and despite the fact that both groups teach that there is a blessing to be sought and to be experienced subsequent to and distinct from conversion, most Holiness churches are reluctant to be identified with the Pentecostal movement. As a matter of fact, early in its development (the General Assembly in 1919) the Church of the Nazarene deleted the word Pentecostal from its official church name. Many of the larger Holiness denominations have presently abandoned an earlier view that unbridled expressions of emotion—boisterous praying, vigorous bodily movement, or vociferous shouting—are normative outward evidences of the inward sanctifying work of the Holy Spirit. Most Pentecostals, on the other hand, still believe that their second-blessing experience is certified by an outward sign, the ecstatic manifestation of speaking in tongues.

HISTORY OF THE HOLINESS MOVEMENT

The quest for perfection, or personal holiness, is to those who seek it as old as Christianity itself. The pursuers of perfection find sufficient warrant for it in the Gospels

as well as in the apostolic writings, in passages such as "You, therefore must be perfect, as your heavenly Father is perfect" (Matt. 5:48), or "For God has not called us for uncleanness, but in holiness" (I Thess. 4:7). Yet opponents of perfectionism hasten to point out that throughout the history of Christianity those who have espoused such views have, for the most part, been pneumatics (spiritualists), heretics, or fanatics, forming groups such as the Gnostics, Pelagians, Montanists, Fraticelli, Anabaptists, or Shakers. Moreover, they argue that the principal orthodox theologians from St. Augustine to John Calvin have staunchly declared that one can never be entirely free from sin and its temptations and, therefore, can never achieve perfection in this life.

Opponents of perfectionism

Methodist roots. On the whole, this view prevailed until the 18th century when John Wesley, the founder of Methodism, issued his call to Christian perfection. For Wesley, the doctrine of perfection was a principle based upon a scriptural foundation. Perfection was to be the goal of all those who desired to be *altogether* Christian; it implied that the God who is good enough to forgive sin (justify) is obviously great enough to transform the sinner into a saint (sanctify), thus enabling him to be free from outward sin as well as from "evil thoughts and tempers," in short, to attain to a measure of holiness. And indeed, concepts such as Christian perfection, entire sanctification, and personal holiness were central both in Wesley's preaching as well as in the evangelical revival that swept across 18th-century England and eventually reached the American colonies.

From the outset, the motto of American Methodism was "to spread Christian holiness over these lands." The 1787 edition of the *Discipline* admonished those who planned to be itinerant preachers "to save as many souls as you can; to bring as many sinners as you possibly can to Repentance, and with all your power to build them up in that holiness without which they cannot see the Lord." All this notwithstanding, the doctrine of holiness was largely ignored by American Methodists during the early decades of the 19th century. The slackening of interest in perfectionism has been attributed to the rising national prosperity, which did little to encourage deepening piety, and to excesses that were associated with it in the popular mind because of the conduct of certain contemporaneous antinomian (antilegalistic) perfectionist societies, such as the Oneida Community. The neglect of the doctrine of holiness was only temporary, however. In the 1830s perfectionism received new impetus with the publication of a monthly periodical entitled *Guide to Christian Perfection* and the inauguration of the "Tuesday Meeting for the Promotion of Holiness" in the Manhattan home of Phoebe Palmer, a laywoman active in the Allen Street Methodist Church. Moreover, many prominent leaders in Methodist circles, including Bishops Edmund S. Janes and Leonidas L. Hamline, heartily endorsed the revival of interest in holiness and "the higher Christian life."

Growing polarization

By the time of the Civil War, tensions were developing. In some quarters of Methodism, at least, the principles of Christian perfection and holiness had become merely part of official doctrinal statements. In practice these ideals were largely ignored, and some church papers reflected a growing hostility to the subject of entire sanctification and an increasing skepticism in regard to the role of the camp meetings; *i.e.*, revivalist retreats, often attended for several days, centring around services at a large tent. On the other hand, however, there were many Methodists who were convinced that personal sanctification, or holiness, was, at the very least, one of the cardinal ideas of their founder, and they were determined to remain loyal to their Wesleyan heritage. They looked askance at the proposed abandonment of camp meeting revivalism; they bemoaned the expanding autocracy of the bishops and the increasing indulgence of worldly amusements, "broidered hair," gold, pearls, and costly array. When differences between these factions became irreconcilable, withdrawals and schisms resulted.

Schisms and associations. In 1843 about two dozen ministers and 6,000 members withdrew from the Methodist Episcopal Church to found the Wesleyan Methodist Church of America. Then, in 1860, after a decade of controversy over the issues of perfectionism and the power of the episcopacy, another body of Methodists left the Genessee (N.Y.) Conference to establish the Free Methodist Church of North America. Despite these defections, however, it is a fact that most Protestants who favoured holiness or perfectionist views were reluctant to abandon their churches. They preferred to retain their memberships therein and then to seek fellowship with other like-minded Christians in independent organizations such as the National Campmeeting Association for the Promotion of Holiness, which was established in 1867. As a matter of fact, in the years that followed, this organization became an effective means of disseminating Holiness ideas. At diverse encampments, on both coasts—hundreds of conferees testified to receiving the second blessing, the consciousness of sanctifying grace.

This arrangement to retain one's denominational affiliation while simultaneously finding an outlet for one's perfectionistic proclivities in some local, regional, or national society for the promotion of holiness worked temporarily. As time passed, however, it became increasingly difficult for people who were thus inclined to keep up the practice. For one thing, sizable numbers of Protestants from the rural areas of the Midwest and South were joining the Holiness movement. These people had a penchant for Puritan-like codes of dress and behaviour. Most of them had little sympathy for the "superficial, false, and fashionable" Christians whose preoccupation with wealth, social prestige, and religious formalism was repelling. Therefore, they began to advocate a policy of separatism. Besides, a growing cleavage began to develop between some of the denominational leaders and the pro-Holiness sector of their constituency.

Policy of separatism

It was especially difficult for some Methodist bishops, who were used to functioning in a denomination accustomed to tight discipline, to countenance the seeming plethora of "voluntary alliances, leagues, unions, and associations." They were also concerned with the increasing number of Holiness evangelists who were conducting campus revivals, camp meetings, and city-wide crusades without any sort of "official" sanction, as well as with the rapidly expanding Holiness press with its ever growing capacity for promoting second-blessing views. They urged that all such activities be placed under "some official supervision or limitation," but their advice went unheeded. Therefore, in the Bishops' Address for 1894, they denounced all those who proclaimed "holiness as a watchword" and who maintained "holiness meetings, holiness preachers, holiness evangelists, and holiness property." Doubtless such pronouncements only served to hasten the schismatic process that had begun in 1843, when 6,000 dissidents withdrew to found the Wesleyan Methodist Church.

Emergence of Holiness groups. Accordingly, between 1880 and World War I a number of new Holiness groups emerged. Some, such as the Church of God (Anderson, Ind.), were established to protest against bureaucratic denominationalism. Others, such as the Christian and Missionary Alliance and the Church of the Nazarene, were organized to serve the spiritual and social needs of the urban poor, who quite frequently were ignored by the stylish downtown congregations of churches, representing the so-called mainstream of Protestantism. Substantially all of these Holiness bodies arose in order to facilitate the proclamation of a second-blessing experience of sanctification with its concomitants—a life of separation and practical holiness, views that apparently could no longer be endorsed by or tolerated within the larger, more established denominations. On the whole, these newly emergent Holiness groups were destined to have limited spheres of influence.

Holiness associations

The Metropolitan Church Association, an outgrowth of the Metropolitan Methodist Church of Chicago, was organized in 1894 for the purpose of serving the helpless and the outcast in the densely populated environs of that city. A recent report reflects its modest rate of growth:

15 churches with an inclusive membership of 443. In 1896 the Church of God (Apostolic) was established at Danville, Ky. Presently 22 churches, principally located in West Virginia and South Carolina, with a total constituency of 600 make up this branch of the Holiness movement. The Missionary Church Association—known as the Missionary Church since its merger with the United Missionary Church in 1969—was organized in 1898 to promote the cause of Holiness in Pennsylvania, Michigan, Indiana, and Ohio, states wherein most of its 278 churches and 17,700 members are still located. Two years later the Lumber Mission Conference of the Holiness Methodist Church was established "to bring new emphasis to home missions and scriptural holiness" to the rural areas of North Carolina. At last count, it was supervising three churches with a membership of 240.

During the pre-World War I years, still other Holiness churches appeared on the American religious scene: one, the Pillar of Fire, in 1901, was largely the handiwork of a dynamic woman, Alma White, who, despite the opposition of the Methodist Church in which her husband was ministering, organized the Pentecostal Union, which later changed its name to that mentioned above, in order to spread "Scriptural holiness similar to the societies which John Wesley organized." Mrs. White's work survives chiefly in New Jersey, Pennsylvania, and Colorado, where there are 61 churches and 5,100 members. Another group, the Churches of Christ in Christian Union, traces its beginning to 1909, when a controversy over holiness wracked the Council of the Christian Union Church. The pro-Holiness contingent withdrew to form this new denomination, which, over the years, has concentrated its efforts in Ohio, where in 1968 its 7,930 members attended 242 churches. The last group of this type, the Church of God (Holiness), dates back to 1914, when Rev. K.H. Burruss began preaching the gospel of entire sanctification to a congregation of eight people in Atlanta, Ga. Recent statistics show that this small Holiness denomination now comprises 42 churches and 25,600 members, primarily in Georgia and South Carolina.

Although most of the aforesaid churches are relatively small and only locally or regionally important, a number of others that make up the Holiness movement have demonstrated a remarkable capacity for sustained growth. Among these, one might include the "older" denominations—the Wesleyan Church (82,400 members) and the Free Methodist Church of North America (63,000)—as well as the newer ones: the Church of God (Anderson, Ind.; 146,800), the Christian and Missionary Alliance (119,800), the Salvation Army (329,500), and the Church of the Nazarene (364,800). The Church of the Nazarene, whose members constitute nearly a third of the total membership of the Holiness movement, is generally recognized as being its most influential representative.

Church of the Nazarene

The Church of the Nazarene was founded in Los Angeles in 1895 by Phineas Bresee, who had been a pastor and a presiding elder in the Methodist Church. Although he did testify that he experienced "a transformed condition of life and blessing and unction and glory, which I had never known before," the chief cause for leaving the Methodists was apparently criticism of his methods for evangelizing the poor in a Los Angeles mission called Peniel Hall. When his superiors removed him from the supervision of this project, he and 82 people, most of whom were recent converts from the slums, joined together to organize the Church of the Nazarene. From the outset, Bresee announced that this new venture would be "a simple, primitive church, a church of the people and for the people." In the years that followed, Bresee's efforts prospered. By 1903 he was pastoring a congregation of 1,500 and supervising the work of a host of other Nazarene churches in the environs of Los Angeles. Shortly thereafter, in 1907, this group of churches that was headed by Bresee united with the Association of Pentecostal Churches of America, which had been founded in New York in 1895. A year later, 1908, the recently formed Pentecostal Church of the Nazarene voted to join the Holiness Church of Christ, an organization of Southern Holiness churches. This merger added a substantial number of churches to the expanding denomination; more important, perhaps, it climaxed the process of geographical consolidation, which for the first time gave the church a truly national character. When the term Pentecostal began to be used to identify that segment of the Holiness movement that stressed charismatic manifestations such as glossolalia (speaking in tongues), healings, and prophesyings as normative outward evidences of the work of the Holy Spirit in the heart of the believer, the General Assembly of 1919 voted to delete the word Pentecostal from the official church name. Henceforth the denomination would be known simply as the Church of the Nazarene.

BELIEFS AND PRACTICES

Much difficulty is encountered in describing those elements of faith and practice that are held in common by all Holiness groups, principally because so many different individuals representing such a wide variety of religious traditions and revivalistic and pietistic movements had a part in shaping the Holiness movement. For example, there were men such as Charles G. Finney, the Presbyterian-Congregational revivalist and president of Oberlin College, who, during his 19th-century revival campaigns, popularized the notion that "a mighty Baptism of the Holy Spirit" could transform the lethargic spiritual life of a believer. Likewise, Asa Mahan, a Congregationalist and also onetime president of Oberlin College, who, contrary to the generally accepted Wesleyan view that sanctification provided absolute perfection instantaneously, interpreted sanctification simply as an experience that allowed the believer "to grow in grace" toward perfection. Others were William E. Boardman, an American Presbyterian whose volume *The Higher Christian Life* (1859) kindled a widespread interest in perfection among non-Methodists; A.B. Earle, who was described as the most prominent Baptist evangelist of the antebellum period; Society of Friends evangelist David B. Updegraff; and Dougan Clark, professor of Bible at Earlham College. All of the aforesaid people, together with a host of others, either were influenced by the Holiness revival or, in turn, exerted a profound influence upon its development. Doubtless they were chiefly responsible for the differing doctrinal emphases and interpretations as well as the diversities in polity and practice that are manifested by the churches that make up the Holiness movement.

Individuals influencing Holiness beliefs and practices

Theological positions. These diversities notwithstanding, it is possible to provide a general estimate of the theological stance of most contemporary Holiness bodies.

Most of the churches claim loyalty to the historic Wesleyan tradition. Time and again, statements such as these appear in their official declarations: "In doctrine the Church of the Nazarene is essentially in accord with historic Methodism." "The great cardinal doctrines of Christianity as interpreted in the general standards of Methodism are received by this church" (the Wesleyan Church). Accordingly, most Holiness churches, patterning their beliefs on the tenets of Methodism, ignore the stricter doctrines of Calvinism, predestination and reprobation, and accept the milder emphases of Arminianism as regards repentance, faith, and holiness. In addition, most Holiness churches still stand resolutely by John Wesley's views regarding Christian perfection, despite the fact that such principles have become less vitally important to the majority of 20th-century Methodists. Having been affected by 19th-century pietism and revivalism, contemporary Holiness churches tend to stand closer, doctrinally speaking, to Fundamentalism than to their Methodist antecedents. In examining their tenets, one encounters such evidences of conservative evangelical belief as "plenary inspiration (verbal inspiration of the whole Bible)," "Christ's atonement for the entire human race," and "the personal second coming of Christ." In the doctrinal statements of a few churches—Church of the Nazarene and Christian and Missionary Alliance—brief allusions to divine healing and a Pentecostal experience do appear. However, these must not be construed as

Wesleyan theological tenets

constituting sufficient grounds for their being identified with the Pentecostal movement, the so-called left wing of perfectionism, against which, in fact, many right-wing Holiness groups have inveighed.

Social, economic, and political positions. Needless to say, the task of defining the position of Holiness churches on nondoctrinal matters such as interchurch relations, ecumenism, missionary and evangelistic activity, styles of worship, and socioeconomic problems is an equally enigmatic one. As noted above, some Holiness bodies have remained numerically small and have spheres of influence that are merely local or regional. As might be expected, these groups have retained their sectarian character: they shun all forms of worldliness—dancing, theatre attendance, card playing, lotteries, membership in oathbound secret orders, "superfluous ornaments and costly apparel." They deprecate both internal organization as well as extramural fellowship with other national and international bodies of Christians, and they make little attempt to grapple with the intricate socioeconomic problems that have emerged in our highly industrialized, urbanized, secularized society. On the other hand, a number of other Holiness churches have grown in size, wealth, and administrative complexity. These have renounced or have modified many of the so-called sectarian practices and attitudes that, initially, had set them apart from other religious groups. Thus, many of the critical appraisals of Holiness churches that were made concerning the early years of their development, and, moreover, that are still rather widely circulated, are no longer creditable. No longer do critics describe Holiness churches as refuges of the urban poor, the crassly emotional, or the anti-intellectual rural "come-outers" with their narrow-minded antipathy toward worldliness.

Sectarian versus accommodating churches

According to recent studies there may be no existing denomination more loyal to the principle of Christian perfection and yet more free from emotional extremes than the Wesleyan Methodist Church. Furthermore, forceful, personal evangelism and boisterous revival meetings are apparently giving way to make room for greater emphases on Christian education and a trained clergy and laity. This is attested to by the fact that most of the larger Holiness groups presently operate a dozen reputable, regionally accredited colleges and seminaries. Besides this, the process of accommodation is causing conflicts among constituents of the same denomination to be eliminated and tensions between members of different religious groups to be reduced. Thus, whereas early leaders of the Church of God (Anderson, Indiana) believed that all religious organizations were Satanic conceptions and refused to form one of their own or to cooperate with any other, recent administrators have encouraged churches to join local councils of churches and pastors to become members of ministerial associations. Moreover, while the denomination is not a member of the National Council of Churches, each of its general agencies is integrated into the appropriate divisions of that council. Although the primary objective of Holiness churches has been the spiritual regeneration of mankind, one should not gloss over the correlative activity of groups like the Salvation Army in the area of social service. In striving to meet the needs of the errant, the wayward, the orphaned, or the unemployed "down-and-outer" by establishing settlement houses, industrial centres, orphanages, rescue missions, and hospitals, the Salvation Army has challenged the often repeated contention that Holiness churches lack a vital social concern.

Salvation Army

Holiness churches have been experiencing phenomenal growth. (In the 30-year period 1933–63, the Nazarenes multiplied their membership by 80 percent.) And, unquestionably, Holiness churches have experienced dramatic change. In the eyes of most observers, however, they have remained constant in their devotion to a distinctive doctrine—the postconversion experience of sanctification. Moreover, they have not deviated appreciably from their position regarding a life of personal holiness with its concomitant renunciation of "worldly" preoccupations such as tobacco, liquor, movies, and high fashion. Camp meetings, revivals, and the mourners' bench, where sinful men can be restored to holiness of heart and life, still remain as hallmarks of the contemporary Holiness movement. Amid the pervasive intellectualism, formalism, and moral ineffectuality that seemed to characterize the American religious scene during the post-Civil War period, as well as during the early decades of the 20th century, these "Spirit centred" churches have survived. More than that, they have so flourished that they have been lauded as constituting a "third force" (in conjunction with traditional Protestantism and Roman Catholicism) in American Christianity.

(J.T.N.)

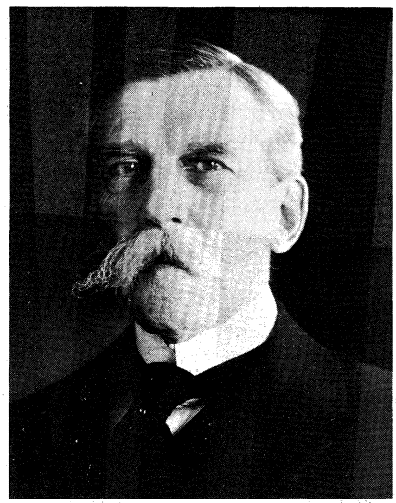
Holmes, Oliver Wendell

A distinguished historian and philosopher of the law and for 30 years a justice of the United States Supreme Court, Oliver Wendell Holmes, Jr., earned renown as a persuasive advocate of judicial restraint. He was born in Boston, Massachusetts, on March 8, 1841, the first child of the celebrated writer and physician Oliver Wendell Holmes. The family background on both sides represented the New England "aristocracy" of character and accomplishment. The Doctor was descended from the Puritan poetess Anne Bradstreet; he married Amelia Lee Jackson, whose father, Charles, was a justice of the Supreme Judicial Court of the State of Massachusetts, a bench on which Oliver Wendell Holmes, Jr., was to sit for 20 years. He was proud of this heritage and spoke of it often. It helped shape his mind and character.

Young Holmes went to a private school and then to Harvard College. He was graduated in the class of 1861 and like his father before him was class poet. At the outbreak of the Civil War he enlisted as a private in the 4th Battalion of Infantry and began training at Boston's Fort Independence, not expecting to finish the academic year or take his degree. The battalion was not called up, and after graduation the young man applied for and received, in July, a commission as first lieutenant in the 20th Massachusetts Regiment of Volunteers. He was 20 years old at that time.

Service in Civil War

His letters and diary give vivid pictures of his war experiences. He was seriously wounded three times, at the battles of Ball's Bluff, Antietam, and Chancellorsville. He left the army after three years, having been commissioned lieutenant colonel although mustered out with the rank of captain. Holmes described war as "an organized bore." He said, "I trust I did my duty as a soldier respectably, but I was not born for it and did nothing remarkable in that way." In a Memorial Day address to fellow veterans, in 1884, he attributed a certain value to



Holmes.

the war experience: "Through our great good fortune, in our youth our hearts were touched with fire. It was given to us to learn at the outset that life is a profound and passionate thing." This is an aspect of his conviction that ". . . it is required of a man that he should share the passion and action of his time at peril of being judged never to have lived."

Legal studies

In the autumn of 1864 he entered Harvard Law School, ironically without any clear sense of vocation. He had even contemplated medicine, to which his father objected. On different occasions, he said that his "Governor" "put on the screws to have me go to the Law School" or "kicked" him into it. There is a story that when young Holmes announced to his father the decision to enter the law school, the Doctor said, "What's the use of that, Wendell? A lawyer can't be a great man." There was not a deep affinity between father and son. The little Doctor's puns and quips, his easy display of emotion, and a somewhat patronizing attitude chafed the tall, less talkative, inherently shy law student. The philosopher William James, perhaps the closest friend of Wendell in the immediate postwar years, once remarked that "no love is lost" between father and son.

Holmes experienced a certain restlessness in law school, finding the tradition of the law as presented in an uninspired curriculum to be stagnant and narrowly precedent centred. The science, philosophy, or history of law were slighted, and these, rather than what he later called "the small change of legal thought," were what captured Holmes's mind and drew him into the depths of a profession toward which at first he had not felt a powerful incentive.

After finishing law school in 1866 he made the conventional "pilgrimage" abroad, visiting England, France, and Switzerland and meeting a variety of distinguished men. He was admitted to the bar in 1867 and for 15 years practiced law as a member of several firms. From 1870 to 1873 he was an editor of the *American Law Review*. He edited the 12th edition of the classic survey of early American law, Chancellor James Kent's (1763–1847) *Commentaries on American Law* (1873). He also lectured at Harvard on law.

During this busy time he was engaged in courtship. Always something of a ladies' man, he had maintained a long friendship with Fanny Bowditch Dixwell, daughter of his onetime schoolmaster. She had waited patiently through wartime, his law studies, travel, and apprenticeship. Holmes and Fanny were married at last on June 17, 1872. The marriage, happy and long lasting, was childless.

The Common Law

In 1880–81 Holmes was invited to lecture on the common law at the Lowell Institute in Boston, and from these addresses developed his book *The Common Law* (1881). Here the genius of Holmes was first clearly revealed and the consistent direction of his thought made evident. A fresh voice was speaking in his words:

> The life of the law has not been logic: it has been experience. The felt necessities of the time, the prevalent moral and political theories, intuitions of public policy, avowed or unconscious, even the prejudices which judges share with their fellow-men, have had a good deal more to do than the syllogism in determining the rules by which men should be governed. The law embodies the story of a nation's development through many centuries, and it cannot be dealt with as if it contained only the axioms and corollaries of a book of mathematics. In order to know what it is, we must know what it has been, and what it tends to become. We must alternately consult history and existing theories of legislation. But the most difficult labor will be to understand the combination of the two into new products at every stage. The substance of the law at any given time pretty nearly corresponds, so far as it goes, with what is then understood to be convenient; but its form and machinery, and the degree to which it is able to work out desired results, depend very much upon its past.

In January 1882 Holmes was made Weld Professor of Law, a chair established for him at Harvard Law School. In December of the same year he accepted appointment to the Supreme Judicial Court of the State of Massachusetts, knowing the judgeship was his destiny and the function through which he could most influence the development of law. He was to sit on that bench for 20 years, becoming its chief justice in 1899. In 1902 President Theodore Roosevelt appointed him associate justice of the United States Supreme Court. He sat on that court to a more advanced age than did any other man, retiring on January 12, 1932, soon before his 91st birthday.

Fanny Holmes, devoted, witty, wise, tactful, perceptive, died on April 30, 1929. Holmes wrote to his intimate friend, the English jurist Sir Frederick Pollock, "For sixty years she made life poetry for me and at 88 one must be ready for the end. I shall keep at work and interested while it lasts—though not caring very much for how long." He died two days before his 94th birthday on March 6, 1935.

Justice of the Supreme Court

In that long span of years on the Supreme Court he became acknowledged as one of the most notable jurists of the age—in the opinion of many the foremost. Often he has been called "The Great Dissenter" because of the brilliance of his dissenting opinions, but the phrase gives a falsely negative emphasis, and his penetration and originality are seen as fully in the opinions in which he expressed or concurred in the majority view of the court as in those in which he was in dissent.

Holmes believed that the making of laws is the business of legislative bodies, not of courts, and that within constitutional bounds the people have a right to whatever laws they choose to make, good or bad, through their elected representatives. He stated the concept of "clear and present danger" as the only basis for curtailing the right of freedom of speech, illustrating it with the homely example: "The most stringent protection of free speech would not protect a man in falsely shouting fire in a theatre and causing a panic."

He wrote that "the best test of truth is the power of the thought to get itself accepted in the competition of the market. . . . That at any rate is the theory of our Constitution." Again: "If there is any principle of the Constitution that more imperatively calls for attachment than any other it is the principle of free thought—not free thought for those who agree with us but freedom for the thought that we hate."

A man austerely dedicated to his work, he also enjoyed the earthy and the droll. He loved Rabelais. Sometimes in Washington he attended burlesque shows and was said to have remarked, "I thank God I am a man of low tastes." The newly inaugurated President Franklin D. Roosevelt called upon the retired justice and found him reading Plato. "Why do you read Plato, Mr. Justice?" "To improve my mind, Mr. President," replied the 92-year-old man.

Holmes won the love and admiration of generations of lawyers and judges in his long career. When he resigned

from the Supreme Court, his "brethren," as he always addressed his fellow justices, wrote him a letter signed by all, saying in part:

> Your profound learning and philosophic outlook have found expression in opinions which have become classic, enriching the literature of the law as well as its substance. . . . While we are losing the privilege of daily companionship, the most precious memories of your unfailing kindliness and generous nature abide with us, and these memories will ever be one of the choicest traditions of the Court.

Lief (1931); *Justice Oliver Wendell Holmes: His Book Notices and Uncollected Letters and Papers,* ed. by Harry C. Shriver (1936); *Holmes-Pollock Letters* (1941), *Touched with Fire: Civil War Letters and Diary of Oliver Wendell Holmes, Jr., 1861–1864* (1946), *Holmes-Laski Letters* (1953), and *The Occasional Speeches of Justice Oliver Wendell Holmes* (1962), all ed. by Mark de Wolfe Howe.

BIBLIOGRAPHY. The principal biography, not yet concluded, is MARK DEWOLFE HOWE, *Justice Oliver Wendell Holmes,* vol. 1, *The Shaping Years, 1841–1870* (1957), vol. 2, *The Proving Years, 1870–1882* (1963). Others are: CATHERINE DRINKER BOWEN, *Yankee from Olympus: Justice Holmes and His Family* (1944); FRANCIS BIDDLE, *Mr. Justice Holmes* (1942); and SILAS BENT, *Justice Oliver Wendell Holmes* (1932). A good selection from Holmes's writings is *The Mind and Faith of Justice Holmes,* edited with Introduction and Commentary by MAX LERNER (1943). Both appraisal and biographical material may be found in FELIX FRANKFURTER (ed.), *Mr. Justice Holmes: A Collection of Essays* (1931), and *Mr. Justice Holmes and the Supreme Court* (1938).

(E.Fu.)

Holocene Epoch

The Holocene Epoch, sometimes referred to as the Recent, is the latest interval of geological time, covering approximately the last 10,000 years of the earth's history. The sediments of the Holocene, both continental and marine, cover the largest area of the globe of any epoch in the geological record, but the Holocene is unique because it is coincident with the late and post-Stone Age history of man. The influence of man is of world extent and is so profound that it is appropriate to have a special geologic name for this time. In 1833 Sir Charles Lyell proposed the name Recent for the period that has elapsed since "the earth has been tenanted by man." It is now known that man has been in existence a great deal longer. The term Holocene was proposed in 1867 and was formally submitted to the International Geological Congress at Bologna in 1885. It was officially endorsed by the U.S. Commission on Stratigraphic Nomenclature in 1969.

The Holocene is also the latest division of the Quaternary Period, about the last 2,000,000 years of geologic time and often referred to as the Great Ice Age. A characteristic of ice ages is the permanent ice cover of some areas, like Antarctica today, while other regions in more temperate latitudes are invaded by continental glaciers repeatedly in an oscillatory manner. Such oscillatory cycles, called glacial and interglacial stages, are further modulated by minor oscillations, called stadials and interstadials (or stades and interstades). The Holocene Epoch is the latest interglacial interval of the Quaternary Period. The preceding and much longer sequence of alternating glacial and interglacial ages is referred to as the Pleistocene Epoch. Because there is nothing to suggest that the Pleistocene, or Great Ice Age, is now ended, some authorities prefer to extend the Pleistocene up to the present time; this tends to ignore man and his geologic role, however.

The Holocene forms the chronological framework for human history. Archaeologists use it as the time standard against which they trace the evolution of man, his economy, and his art and architecture. At the beginning of the Holocene, there were faunas such as the woolly mammoth, the giant elk, the cave bear, and many other species of large mammals, all of which are now extinct. Some scientists think that these animals were exterminated by the sudden change in conditions due to a shift of climatic belts, but others consider that man was responsible. The role of man in the disappearance of these animals is not proven, though sometimes his artifacts occur in close association with their skeletal remains.

This article treats Holocene stratigraphy, chronology, and climate, and the diverse manifestations of the climatic change from Pleistocene to Holocene time in continental and marine areas. For additional information on the place of the Holocene Epoch in early history, see EARTH, GEOLOGICAL HISTORY OF; CENOZOIC ERA; and STRATIGRAPHIC BOUNDARIES; for details of the glaciation that occurred prior to Holocene time and discussion of the climatic factors involved, see PLEISTOCENE EPOCH; and CLIMATIC CHANGE. See also articles on specific landforms or natural features that reflect Pleistocene and Holocene environmental conditions (*e.g.,* RIVER DELTAS; SOILS; CONTINENTAL SHELF AND SLOPE; LAKES AND LAKE SYSTEMS; DESERTS).

HOLOCENE STRATIGRAPHY

Chronology and correlation. The Holocene is unique among geological epochs because varied means of correlating deposits and establishing chronologies are available. One of the most important means is radiocarbon dating. A radiocarbon date is usually expressed in years BP (before the present), the reference year being AD 1950, and the date depends upon the radioactive decay of carbon originally present in organic matter (see DATING, RELATIVE AND ABSOLUTE). Since 1950, all vegetation, bones, shells, and other organic matter containing carbon have been contaminated to some extent by radiocarbon created by nuclear explosions. Studies of wood from ancient tree rings show, however, that there were only small variations in the radiocarbon values (amounting to several percent) during the past. Because the date or age that is provided by the geochemical procedure may be appreciably different from the true age, it is customary to refer to those dates in "radiocarbon years." These dates, obtained from a variety of deposits, form an important framework for Holocene stratigraphy and chronology.

Radiocarbon dating

The limitations of geochemical accuracy are expressed as ± a few tens or hundreds of years, but in addition to this calculated error, there also is question of error due to contamination of the material measured. For instance, an ancient peat may contain some younger roots and thus given a falsely "young" age unless it is carefully collected and treated to remove contaminants. Marine shells consist of calcium carbonate ($CaCO_3$), and in certain coastal regions there is upwelling of deep oceanic water that can be 500 to over 1,000 years old. An "age" from living shells in such an area can suggest that they are already hundreds of years old.

Table 1 shows the comparative dates of radiocarbon years and those obtained by other means. Two sets of radiocarbon years are given because the half-life (time required for one-half of a unit amount of an element to decay due to radioactivity) of carbon-14 was reassigned a value of 5,730 years by agreement of scientists. Many dates available in the literature, however, are based on the originally established half-life of 5,570 years.

In certain areas a varve chronology can be established. This involves counting and measuring thicknesses in annual paired layers of lake sediments (*varv* in Swedish) deposited in lakes that suffer an annual freeze-up (see VARVED DEPOSITS). Because each year's sediment accumulation varies in thickness according to the climatic conditions of the melt season, any long sequence of varve measurements provides a distinctive "signature" and can be correlated for moderate distances from lake basin to lake basin. The pioneer in this work was the Swedish investigator Baron Gerard de Geer (1858–1943), who developed a long chronology on which that shown in Table 1 is partly based.

Table1: Comparative Dating Systems for the Holocene Epoch* (and latest Pleistocene)

11,000	11,330	(11,550)	9600	11,200
12,000	12,350	(12,550)	10,600	12,200

*Wood from the tomb of the pharaoh Djoser at Saqqārah, Egypt, is dated historically at 4650 ± 75 BP in sidereal years, but according to multiple analyses by many laboratories it is about 4100 BP in radiocarbon years, or 550 years too young. The anomaly is most probably explained in terms of solar radiation, residence time of CO_2, and paleomagnetics. Tree-ring dating combined with ^{14}C measurements has confirmed this trend and provides a general curve for correcting Holocene ^{14}C dates. Almost all radiocarbon dates given are uncorrected. U.S. tree-ring chronology most closely resembles the sidereal dates; the Scandinavian varve chronology also is close to the astronomical chronology, subject to a 350 ± 200 year correction. †T_2 signifies half-life. ‡Dates older than 7450 BP are based on varve years, corrected by 350 ± 200 years. §Dates for varve years less than 6550 BP are extrapolated.

In some relatively recent continental deposits, obsidian, a black, glassy rock of volcanic origin, can be used for dating. Obsidian weathers slowly at a uniform rate, and the thickness of the weathered layer is measured microscopically and gauged against known standards to give a date in years. This has been particularly useful where arrowheads of obsidian are included in deposits.

Paleomagnetism is another phenomenon used in chronology. The earth's magnetic field undergoes a secular shift that is fairly well known for the last 2,000 years. The magnetized material to be studied can be natural, such as a lava flow; or it may be man-made, for example an ancient brick kiln or smeltery that has cooled and thus fixed its magnetic orientation of the bricks to correspond to the geomagnetic field of that time. See ROCK MAGNETISM for the methods involved in this type of dating.

Another form of dating is tephrochronology, so called because it employs the tephra (ash layers) generated by volcanic eruptions. The wind may blow the ash 1,500–3,000 kilometres (1,000–2,000 miles), and, because the minerals or volcanic glass from any one eruptive cycle tend to be distinctive from those of any other cycle, even from the same volcano, these can be dated from the associated lavas by stratigraphic methods (with or without absolute dating). The ash layer then can be traced as a "time horizon" wherever it has been preserved. When the Mt. Mazama volcano in Oregon exploded at about 6600 BP (radiocarbon dated by burned wood), 70 cubic kilometres (16 cubic miles) of debris were thrown into the air, forming the basin now occupied by Crater Lake. The tephra were distributed over ten states, thereby providing a chronologic marker horizon. A comparable eruption of Thera on Santorin in the Aegean Sea about 3,400 years ago left tephra in the deep-sea sediments and on adjacent land areas. Periodic eruptions of Mt. Hekla in Iceland have been of use in Scandinavia, which lies downwind.

Biological dating

The most important biological means of establishing Holocene chronology involves palynology, the study of pollen, spores, and other microscopic organic particles. Pollen from trees, shrubs, or grasses is generated annually in large quantities and often is well preserved in fine-grained lake, swamp, or marine sediments. Statistical correlations of modern and fossil assemblages provide a basis for estimating the approximate makeup of the local or regional vegetation through time. Even a crude subdivision into tree pollen (AP) and nonarboreal pollen (NAP) reflects the former types of climate (see POLLEN STRATIGRAPHY). The tundra vegetation of the last glacial epoch, for example, provides predominantly NAP, and the transition to forest vegetation shows the climatic amelioration that heralded the beginning of the Holocene.

The first standard palynological stratigraphy was developed in Scandinavia by Axel Blytt (1843–98), Johan Rutger Sernander (1866–1944), and E.J. Lennart von Post (1884–1951), in combination with a theory of Holocene climate changes. The so-called Blytt–Sernander system was soon tied to the archaeology and to the varve chronology of Gerard de Geer. It has been closely checked by radiocarbon dating, establishing a very useful standard. Every region has its own standard pollen stratigraphy, but these are now correlated approximately with the Blytt–Sernander framework. To some extent this is even true for remote areas such as Patagonia and East Africa. Indeed, it was by palynology that the climatic events of Scandinavia were demonstrated to match changes in equatorial mountain regions and in the Southern Hemisphere.

The Blytt–Sernander classification, together with standard pollen zone codes, is indicated in Table 2, together with an estimation of mean annual temperature departures for midlatitude countries. Particularly important is the fact that the middle Holocene was appreciably warmer than today. In Europe this phase has been called the Climatic Optimum (zones Boreal-1 to Atlantic-2), and in North America (zones B-2 to C-2) it has been called the hypsithermal (also altithermal and xerothermic).

Finally, the measurement and analysis of tree rings, or dendrochronology, must be mentioned. The age of a tree that has grown in any region with a seasonal contrast in climate can be established by counting its growth rings. Work in this field by the University of Arizona's Laboratory of Tree-Ring Research, by selection of both living trees and deadwood, has carried the year-by-year chronology back over 7,500 years. As with palynology, certain pitfalls have been discovered in tree-ring analysis. Sometimes, as in a very severe season, a growth ring may not form. In certain latitudes the tree's ring growth correlates with moisture, but in others it may be correlated with temperature. From the climatic viewpoint these two parameters are often inversely related in different regions. Nevertheless, in experienced hands, just as with varve counting from adjacent lakes, ring measurements from trees with overlapping ages can extend chronologies back for many thousands of years. The bristle-cone pine of the White Mountains in California has proved to be singularly long-lived and suitable for this chronology; some individuals still living are over 4,000 years old, certainly the oldest living organisms. Wood from old buildings and even old paving blocks in western Europe and in the U.S.S.R. have contributed to the chronology. This technique not only offers an additional means of dating but also contains a built-in documentation of climatic characteristics. In certain favourable situations, particularly in the drier, low latitudes, tree-ring records sometimes document 11- and 22-year sunspot cycles.

The Pleistocene–Holocene boundary. Arguments can be presented for the selection of the lower boundary of the Holocene at several different times in the past. Some Soviet specialists have proposed a boundary at the beginning of the Allerød, a warm interstadial age that began about 12,000 BP. Others, in Alaska, proposed a Holocene section beginning at 6,000 BP. Marine geologists have recognized a worldwide change in the character of deep-sea sedimentation about 10,000–11,000 BP. In warm tropical waters, the clays show a sharp change at this time from chlorite-rich particles often associated with fresh feldspar grains (cold, dry climate indicators) to kaolinite and gibbsite (warm, wet climate indicators).

Some of the best preserved traces of the boundary are found in southern Scandinavia, where the transition from the latest glacial stage of the Pleistocene to the Holocene was accompanied by a marine transgression. These beds, south of Göteborg, have been uplifted and are exposed at

Pleistocene–Holocene boundary dates

the surface. The boundary is dated around 10,300 ± 200 years BP (in radiocarbon years). This boundary marks the very beginning of warmer climates that occurred after the latest minor glacial advance in Scandinavia. This built the last Salpausselkä moraine, which corresponds in part to the Valders Substage in North America. The subsequent warming trend was marked by the Finiglacial retreat in northern Scandinavia, the Ostendian (early Flandrian) marine transgression in northwestern Europe.

NATURE OF THE HOLOCENE RECORD

The very youthfulness of the Holocene stratigraphic sequence makes subdivision difficult. The relative slowness of the earth's crustal movements (usually rates of less than one millimetre per year) means that most areas that contain a complete marine stratigraphic sequence are still submerged. Fortunately, in areas that were depressed by the load of glacial ice there has been progressive postglacial uplift (crustal rebound) that has led to the exposure of the nearshore deposits.

In southern Scandinavia postglacial lakes and bogs lay immediately landward of the shoreline of each stage, so that the pollen classification can be applied to the corresponding marine facies. Some of these old beachlines are richly fossiliferous, and numbers of them have been named after the most distinctive fossil of the assemblage (*e.g.*, *Litorina*, *Limnaea*, *Mya*) and thus are technically "biozones." In contrast to the central and northern glaciated areas, the outer peripheries have been subsiding in recent millennia. In the southern Baltic, for example, the nearshore Holocene beds are found only by boring in vertical successions, and similar facies are traceable in southern Denmark, northwest Germany, The Netherlands, and Belgium. The situation is somewhat similar in the southern New England area of the U.S. and in eastern Canada.

Deep oceanic deposits. The marine realm, apart from covering about 70 percent of the earth's surface, offers far better opportunities than coastal environments for undisturbed preservation of sediments. In deep-sea cores, the boundary usually can be seen at a depth of about 10–30 centimetres, where the Holocene sediments pass downward into material belonging to the late glacial stage of the Pleistocene. The boundary often is marked by a slight change in colour. For example, globigerina ooze, common in the ocean at intermediate depths, is frequently slightly pinkish when it is of Holocene age because of a trace of iron oxides that are characteristic of tropical soils. At greater depth in the section, the globigerina ooze may be grayish because of greater quantities of clay, chlorite, and feldspar that have been introduced from the erosion of semi-arid hinterlands during glacial time.

Character and fossil content of globigerina ooze

During each of the glacial epochs the cooling of the ocean waters led to reduced evaporation and thus fewer clouds, then to lower rainfall, then to reduction of vegetation, and so eventually to the production of relatively more clastic sediments (due to reduced chemical weathering). Furthermore, the worldwide eustatic (glacially related) lowering of sea level caused an acceleration of erosion along the lower courses of all rivers and on exposed continental shelves, so that clastic sedimentation rates in the oceans were higher during glacial stages than during the Holocene. Turbidity currents, generated on a large scale during the low sea-level periods, became much less frequent following the rise of sea level in the Holocene.

Studies of the fossils in the globigerina oozes show that at a depth in the cores that has been radiocarbon dated

at about 10,000–11,000 BP the relative number of warm-water planktonic foraminifera increases markedly. In addition, certain foraminiferal species tend to change their coiling direction from a left-handed spiral to a right-handed spiral at this time. This is attributed to the change from cool water to warm water, an extraordinary (and still not understood) physiological reaction to environmental stress. Many of the foraminifera, however, responded to the warming water of the Holocene by migration poleward, by distances of 1,000–3,000 kilometres, in order to remain within their optimal temperature habitats.

It appears also that there was some evolution of new subspecies during the Holocene. Within the Holocene itself, the foraminifera also show a fluctuation in the ratio of warm and cool species, which suggests a sensitivity to relatively minor temperature changes.

Nannoplankton and oceanic circulation

In addition to foraminiferans in the globigerina oozes there are nannoplankton, minute fauna and flora which are mainly coccolithophorids. Research on the present coccolith distribution shows that there is maximum productivity in zones of oceanic upwelling, notably at the subpolar convergence and the equatorial divergence. During the latest glacial stage the subpolar zone was displaced toward the Equator, but with the subsequent warming of waters it shifted back to the borders of the polar regions.

The distribution of the carbonate plankton bears on the problem of rates of oceanic circulation. Is the Holocene rate higher or lower than during the last glacial stage? It has been argued that because of the higher mean temperature gradient in the lower atmosphere from Equator to poles during the last glacial period, there would have been higher wind velocities and, because of the atmosphere–ocean coupling, higher oceanic current velocities. There were, however, two retarding factors for glacial age currents. First, the eustatic withdrawal of oceanic waters from the continental shelves reduced the effective area of the oceans by 8 percent. Second, the greater extent of floating sea ice would have further reduced the available air–ocean coupling surface, especially in the critical zone of the westerly circulation. According to climatic studies by Hubert H. Lamb, British meteorologist, the presence of large continental ice sheets in North America and Eurasia would have introduced a strong blocking action to the normal zonal circulation of the atmosphere, which then would be replaced by more meridional circulation. This in turn would have been appreciably less effective in driving major oceanic current gyres.

Continental shelf and coastal regions. It was recognized as early as 1842 that a logical consequence of a glacial age would be a large-scale withdrawal of ocean water. Consequently, deglaciation would produce a post-glacial "glacioeustatic" transgression of the seas across the continental shelf. The trace of this Holocene rise of sea level was first discerned along the New England coast and along the coast of Belgium, where it was named the Flandrian Transgression by Georges Dubois in 1924. Some writers prefer to call the entire Holocene the "Flandrian Epoch." The transgression itself, however, began at least 5,000 years before the Holocene proper.

Whereas the deep-sea Holocene sediments usually follow without interruption upon those of the Upper Pleistocene, on the continental shelf there is almost invariably a break in the sequence upon the continental formations there. As sea level rose it paused or fluctuated at various stages, leaving erosional terraces, beach deposits, and other indicators of the stillstand. Brief regressions (withdrawal of the seas) in particular permitted the growth of peat deposits that are of significance in the Holocene record because they can be dated by radiocarbon analysis. Dredging in certain places on the shelf, such as off eastern North America, also is useful because terrestrial fossils from the latest glacial period or early Holocene have been found; these range from mammoth and mastodon bones and tusks to human artifacts. On about 70 percent of the world's continental shelves today the amount of sedimentary accumulation since the beginning of the Holocene is minimal, so that dredging or coring operations often disclose hard rock, with older formations at or very close to the surface. In other places, especially near the former continental ice fronts, the shelf is covered by periglacial fluvial sands (meltwater deposits), which, because of their unconsolidated nature, became extensively reworked into beaches and bars during the Holocene Transgression.

Sedimentary deposits and coral reefs

In places of strong shelf currents today many of these deposits still are being dynamically shifted around, disclosing giant sand ripples with amplitudes as great as ten metres.

In warm coral seas the major pauses in the Holocene eustatic rise were long enough for fringing reefs to become established; and when the eustatic rise resumed, the reefs grew upward, either in ribbonlike barriers or from former headlands as patch reefs or shelf atolls. Since coral generally does not colonize a sediment-covered shelf floor at depths of more than about ten metres, those reefs now rising from greater depths must have been emplaced during the early Holocene or must have grown on foundations of ancient reefs (see also CORAL ISLANDS, CORAL REEFS, AND ATOLLS).

Strandlines and the Holocene marine limits

The great ice-covered areas of the Quaternary Period included Antarctica, North America, Greenland, and Eurasia. Of these, Antarctica and Greenland have relatively high latitude situations and do not easily become deglaciated. Some melting occurs, but there is a very great melt-retardation factor in high latitude ice sheets (high albedo or reflectivity, short melt season, etc.). In the case of midlatitude ice sheets, however, once melting starts, the ice disappears at a tremendous rate. The melt rate reached a maximum around 8,000 BP, liberating 18,000,000,000,000 (18×10^{12}) metric tons of meltwater annually. This corresponds to a five-centimetre-per-year rise of sea level. Hand in hand with melting, the sea level responded so that, as the ice began to retreat from its former terminal moraines, the sea began to invade the former coastlands (now the outer continental shelf). Radiocarbon-dated shell beds, for example, from the continental shelf off the eastern United States clearly show the stages of the transgression according to American marine geologist Kenneth Orris Emery and his colleagues at the Woods Hole (Mass.) Oceanographic Institution.

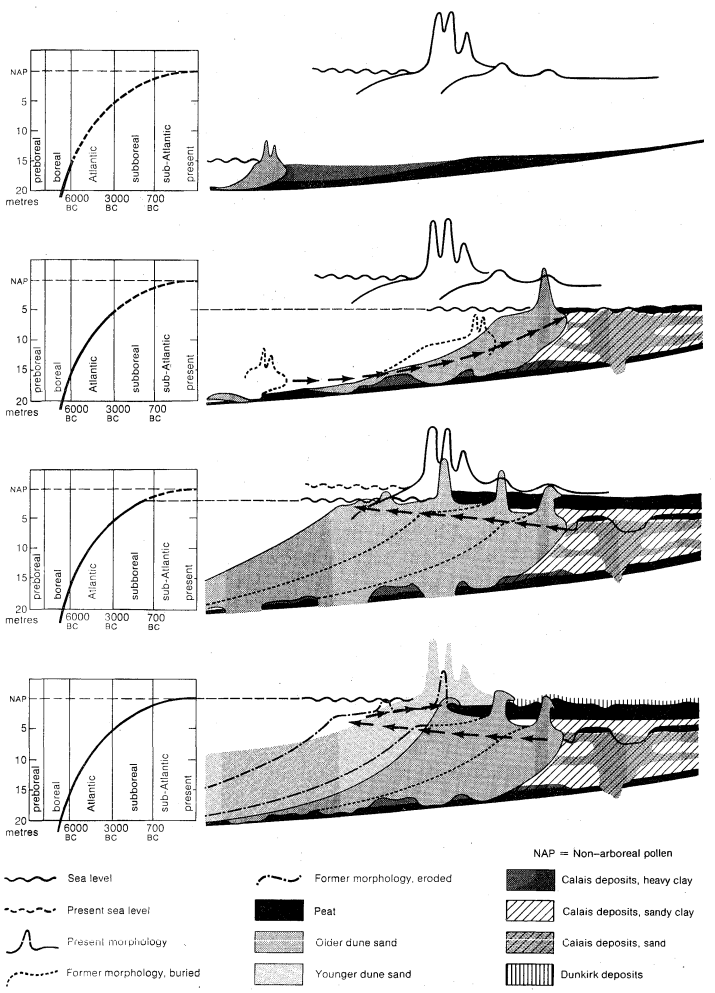

Figure 2: Deltaic accumulation in the western part of The Netherlands during the Holocene.
From B. Hageman, *Geologie en Menjnbouw*, vol. 48 (1969)

As the sea level rose, the earth's crust responded buoyantly to the removal of the load of ice, and at critical times the rate of rise of the water level was outstripped by the rate of rise of the land. In these places the highest ancient shoreline that is now preserved is known as the marine limit. The nearer the former centre of the ice sheet, the higher is the marine limit. In northern Scandinavia, Ontario and northwestern Quebec, around Hudson Bay, and in Baffin Island it reaches more than a 300-metre elevation. In central Maine and Spitsbergen it may exceed 100 metres, whereas in coastal Scotland and Northern Ireland it is rarely above 10–15 metres. A most typical development of the marine limit has been carefully mapped across central Sweden. The age of the beach there is about 7000 BP and is known as Litorina I. This maximum marine limit does not equal the highest eustatic transgression of the Holocene but merely represents the position of the shoreline when the rate of crustal uplift exceeded the eustatic rise. The marine limit varies in height and age in different places.

In addition to the marine-limit strandlines there are row upon row of lower beach levels stretched out across Scandinavia, around Hudson Bay, and on other Arctic coasts. These strandlines are dated and distinctive and do not grade into each other. Each represents a specific period of time when the rising crust and rising sea level remained in place long enough to permit the formation of beaches, spits and bars, and sometimes the erosion of headlands ("fossil cliffs"). The end of beach building at any one strandline occurred when the rise of sea level was reversed. The shoreline rapidly withdrew across the rising landmass and then became re-established at a lower site for another few decades or perhaps centuries.

According to Scandinavian workers, the negative eustatic fluctuations amounted to up to three–five metres. The crust seems to have been rising steadily, and it is principally the eustatic level that fluctuated, because the raised strandlines are roughly parallel and only locally disclose variations due to irregularities in crustal response. In the area of the Kattegat of southwestern Sweden there was a long interplay between the ice front and the transgressing sea in late glacial and early Holocene time. This was closely studied by the Swedish scientist N.A. Mörner, who concluded in 1969 that there was "a striking agreement between the changes in ice recession, climate as recorded by pollen and mollusks, shore-level displacement, isostasy and eustasy."

The old strandlines are associated with well-dated shell beds and swamp deposits. Each high strandline corresponds to a warm phase in the climatic (palynological) history, and every negative fluctuation, namely the retreat stage, during which no beach was preserved, to a cool phase. It is believed that each oscillation was controlled by advance of glaciers situated mainly in the intermediate latitudes (*e.g.*, in the Alps, Alaska, or Iceland) where glacial response to climate variations is rapid and without retardation, that is, on a year to year basis. Rapid response of the great ice sheets to short-lived climatic oscillations seems to be ruled out because of melt-retardation.

A complicating factor near the periphery of former ice sheets is the so-called marginal bulge. Reginald Aldworth Daly, American geologist, postulated that if the ice load pressed down the middle of the glaciated area, then the earth's crust in the marginal area tended to rise up slightly, producing a so-called marginal bulge. With deglaciation the marginal bulge should slowly collapse. A fulcrum should develop between postglacial uplift and peripheral subsidence. In North America that fulcrum seems to run across Illinois to central New Jersey and

Adapted from J. Donner, in *The Quaternary* (1965); Interscience Publishers, John Wiley & Sons

swing northeastward, paralleling the coast and turning seaward north of Boston. In the Scandinavian region the fulcrum crosses central Denmark to swing around the Baltic Sea and then trends northeastward across the Gulf of Finland, north of Leningrad, so that the southeastern Baltic and northwestern Germany are subsiding. The Netherlands area is subsiding also, but here the pattern is complicated by the long-term negative tectonic trend of the North Sea Basin and the Rhine Delta.

It seems likely that this fulcrum shifted inward toward the former glacial centre during the early part of the Holocene. Passing inland, the lines of equal uplift (isobases) are positive, whereas seaward they are negative. The coastal area of southern New England is still slowly subsiding at the present time (1–3 millimetres per year). The eastern United States and Gulf Coast areas are complicated somewhat because they both are long-lived geosynclinal features (areas of major subsidence). Tide gage data show that these coasts were submerging faster than the world sea level rise of the first half of the 20th century would justify in terms of a eustatic explanation.

The great deltas of the world, those of the Mississippi, Rhine, Rhône, Danube, Nile, Amazon, Niger, Tigris-Euphrates, Ganges, and Indus, all coincide with regions of tectonic subsidence. Because water-saturated sediment has a tendency to compact under further sediment loading, there is an additional built-in mechanism that adds to the subsidence in such areas (see also RIVER DELTAS).

The deltaic environment and sedimentary facies

In this deltaic setting Holocene sequences are found that are quite different from those in the postglacial uplifted regions. Whereas the Holocene beaches in the uplift areas extend horizontally across the country in concentric belts, the Holocene sequence in the deltaic regions is, for the most part, vertical in nature and can be studied only from well data.

In both the Mississippi and Rhine deltas sediments that represent the earliest marine Holocene are missing. The sediments must lie seaward on the shelf margin, and the oldest marine layers are found to rest directly upon the late Pleistocene river silts and gravels. In a delta settling at around 0.5 to 3 millimetres per year, the rising sea of the Flandrian Transgression extended quickly across the river deposits to the inner margin (where there is a fulcrum comparable to that of the glaciated regions), marking the boundary between areas of downwarp and those of relative stability or gentle upwarp. The marine beds alternate with continental deposits that represent river or swamp environments. Six major fluctuations are recognizable in both the Mississippi and Rhine deltas. By radiocarbon dating the transgressive and regressive phases (Table 3) have been shown to be correlative in time.

On a subsiding coast there tends to be an alternation in importance between two types of associated sedimentary facies. During a regression of the sea the river distributaries are rejuvenated and there is an increase in the supply of sand and silt; beaches are widened and beach ridge dunes or cheniers may be formed. During a transgressive stage the saltwater wedge at river mouths causes a backup, and the estuary becomes much more sluggish (thalassostatic).

In the case of the Rhine Delta, the coast is bounded by extensive dunes, in contrast to the cheniers of Louisiana, and peat is much thicker than in the Mississippi Delta.

Beaches, dunes, and peat deposits

In The Netherlands the basal Holocene is buried in the fluvial deposits of the Lower Rhine. The postglacial eustatic rise had to traverse the North Sea Plain and advance up the English Channel several hundred kilometres before it reached the Netherlands area. At about 9000–8500 BP (Ancylus Stage in the Baltic) the coastal beaches still lay seaward from the present shore. Subsequently they became stabilized by a brief eustatic regression, while the high water table permitted the growth of the Lower Peat. This is contemporaneous with the late Boreal Peat that is widespread in northern Europe, as well as Peat #5 of the Mississippi Delta (Table 3).

A further eustatic rise (of about 10–12 metres) ensued around 7750 BP, corresponding to a warming of the climate marked by the growth of oak forests in western Europe (the BAT, or "Boreal–Atlantic Transition"). In The Netherlands the barrier beaches reformed close to the present coastline, and widespread tidal flats developed to the interior. These are known as the Calais Beds (or Calaisian) from the definition in Flanders by Dubois.

In the protected inner margins, the peat continued to accumulate during and after the "Atlantic" time. Because the peat has compacted much more than the muds and silts, it has contributed to the continued maintenance of low elevations in The Netherlands today with its lakes and swamps or man-made polders behind artificial dikes.

From evidence outside the areas of subsidence, it seems likely that the worldwide eustatic sea level rise reached its maximum sometime between 5500 and 2500 BP (many workers consider the date to be about 2000 BP). In The Netherlands, in spite of subsidence, the western coastline became more or less stabilized around 4000 BP with the beginning of the formation of the Older Dunes alternating with interdune soils. At the same time in the tide flat

Table 3: Peat Building, Sea-Level Fluctuation, and the Holocene Record of the Mississippi Delta

Mississippi stage	years BP	international correlation (regression)	probable eustatic range
Balize Delta	300	Late Medieval	0 to −0.5 m
Plaquemines Delta	700	Paria	+0.5 to −1.5 m
Lafourche Delta	1500	pre-Dunkerquian III	0 to −1 m
Peat #1 (St. Bernard or La Loutre Delta)	1700–2100	Florida (Roman)	+1.5 to −2 m
Teche Delta	2800–3300	Pelham Bay	+2 to −2 m
Peat #2 (Cocodrie Delta)	4000–4300	Bahama	? +3 to −3 m
Peat #3 (Marinquin, Sale, or Cypremort Delta)	4700–5000	early Subboreal	? +3 to −3 m
Peat #4	6000–6500	Rhine Delta	−4 to −9 m
Peat #5	7000–7500	late Boreal	−12 to −22 m

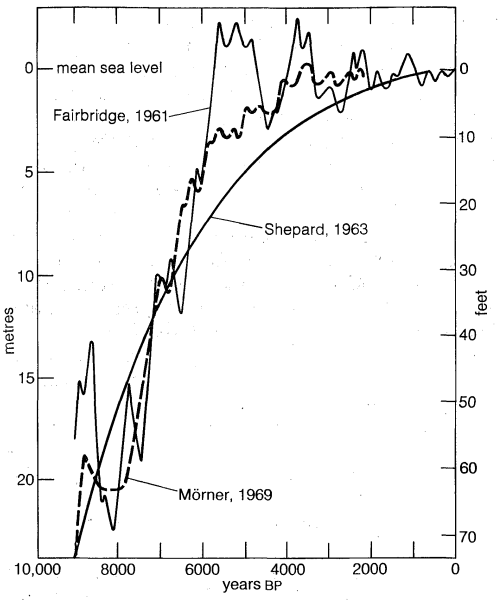

Figure 5: *Holocene sea level curves.*
The smooth curve of Shepard represents an average of many radiocarbon-dated shoreline indicators from both stable and subsiding areas; the oscillating curve of Mörner is based upon the isostatically emerged coast of western Sweden, corrected for uplift; and the oscillating curve of Fairbridge is based upon the geomorphology and radiocarbon dates of coastal features of the world, adjusted for crustal movements.
Adapted from N. Morner, *Sveriges Geologiska Undersokning*, Series C, no. 640 (1969)

areas the Calaisian was followed by the Dunkirk Stage or Dunkerquian. There are three important stages of accelerated tide flat sedimentation (transgressions) corresponding to three stages of Older Dune soils, around 3700 BP, 2500 BP, and 1700 BP (see Figure 2).

The Younger Dune sequence of The Netherlands began with a dry climatic phase in the 12th century AD. With several fluctuations of cold continental climates, dune building continued until the 16th century. Only brief positive oscillations of sea level occurred until the 17th century, when the "modern" warming and eustatic rise started, accompanied also by dune stabilization.

Broadly comparable patterns occur in other areas, from France and Britain to Texas, Oregon, and Brazil. There is normally a threefold or fourfold subdivision in all the Holocene coastal dune belts, each extensively vegetated and consolidated before the successively younger dune belt was added. In a number of cases there is evidence from buried beach deposits that the foundations of the inner dunes are older strandlines that were instituted when the sea was somewhat higher than today. An important regressive phase seems to have initiated each new dune belt.

Other coastal regions. Besides regions of glacioisostatic crustal adjustment, both positive and negative, and the deltaic or geosynclinally subsiding areas, there are many tens of thousands of kilometres of coastlines that are relatively stable and a smaller fraction that are tectonically active.

Holocene terraces and the eustatic curve

Most striking scenically are the coasts with Holocene terraces undergoing tectonic uplift. Terraces of this sort, backed in successive steps by Pleistocene terraces, are well developed in South America, the East Indies, New Guinea, and Japan. By careful surveys every few years the Japanese geodesists have been able to establish mean rates of crustal uplift (or subsidence) for many parts of the country and have been able to construct a residual eustatic curve that is comparable with those obtained elsewhere.

Besides uplifted coasts outside of glaciated areas there are also certain highly indented coasts that show clear evidence of Holocene "drowning." These coasts typically are characterized by the rias, or drowned estuaries, sculptured by fluvial action, but many of the valleys were cut 10,000,000 to 20,000,000 years ago, and the Holocene history has been purely one of eustatic rise.

On the basis of the known climatic history of the Holocene, from the strandline record of Scandinavia and from the sedimentologic evolution of the Mississippi and Rhine deltas, an approximate chronology of Holocene eustasy can be worked out. The amplitudes of the fluctuations and the finite curve are less easily established. A first approximation of the oscillations was published in 1959 and in a more detailed way in 1961 (the so-called Fairbridge curve). Smoothed versions have been offered by several other workers.

Early Holocene Preboreal and Boreal stages (10,000–7750 BP)

Continental regions. In the formerly glaciated regions the Holocene has been a time for the reinstitution of ordinary processes of subaerial erosion and progressive reoccupation by a flora and fauna. The latter expanded rapidly into what was an ecologic vacuum, although with a very restricted range of organisms, because the climates were initially cold and the soil was still immature.

Wind erosion in the deglaciated alluvial valleys and on piedmont fans often was quite severe in the early Holocene because of the limited vegetation. In the driest and coldest areas, loess (a periglacial dust, characteristic of the very cold and arid phases of glaciation) was deposited, but mostly the eolian deposits were limited to sand dunes, downwind of the meltwater river valleys. In the high Arctic, such as in parts of Alaska, loess accumulation has continued until the present.

In the midlatitudes and tropics the end of the last glacial period was marked by a tremendous increase in rainfall, which some believe corresponds to a peak in solar radiation that occurred about 10,000 BP at 65° N (which is critical because of the high land to water area ratio in this belt). The increased radiation would have led to increased westerly and trade wind velocities, greater zonal circulation, increased evaporation from the sea surface, and thus increased rainfall.

The increased precipitation toward the end of the Pleistocene was marked by a vast proliferation of pluvial lakes (those extant and expanded during Pleistocene time) in the Rocky Mountain region, notably Lake Bonneville and Lake Lahontan (giant ancestors of the present Great Salt Lake and Pyramid Lake). Two peaks of lake levels were reached at about 12,000 ± 500 BP (the beginning of the Allerød Warm Stage) and about 9000 ± 500 BP (the early Boreal Warm Stage). At Lake Balaton (in Hungary) high terrace levels also mark the Allerød and early Boreal Warm stages. Lake Victoria (in East Africa) shows the identical twin oscillation in its terrace levels (see further CLIMATIC CHANGE).

In equatorial regions the same evidence of high solar radiation and high rainfall at the end of the Pleistocene and during the early Holocene is apparent in the record of the Nile sediments. The Nile, like the other great rivers of Africa (notably, the Congo, Niger, and Senegal), became very reduced, if not totally blocked, by silt and desert sand during the low-precipitation, arid phases of the Pleistocene. An erroneous correlation between glacial phases and pluvial phases in the tropics has been widely accepted in the past, although cold ocean water means less precipitation, not more. The pluvial phases correspond to the high solar radiation states, the last maximum being about 10,000 BP. Thus tremendous increases of Nile discharge are determined, by radiocarbon dating, to have occurred around 12,000 and 9000 BP, separated and followed by alluviation, indicating reduced runoff in the headwaters. These impressive fluctuations coincide with overflows into the White Nile from Lake Victoria, corresponding to the high lake levels noted above. The lake's outlet was closed during the dry stages prior to 12,000 BP and again, briefly, around 10,000 BP. Erosion of the bar at Ripon Falls has kept the Nile running since then, but drying trends in the headwaters have greatly decreased its discharge.

The expansion of monsoonal rains during early Holocene in the tropical latitudes permitted an extensive spread of moist savanna-type vegetation over the Sahara in North Africa and the Kalahari in South Africa and in

broad areas of Brazil, India, and Australia. Most of these areas had been dry savanna or arid during the last glacial period. Signs of late Paleolithic and Late Stone Age men can be seen throughout the Sahara today, and art is representative of the life and hunting scenes of the time. Lake deposits have been dated as young as 5000–6000 BP. Lake Chad covered a vast area in the very late Pleistocene and up to 5000 BP. The Dead Sea throughout the early Holocene shows a record of sedimentation from humid headwaters; there was a Neolithic settlement at Jericho around 9000–10,000 BP.

Atlantic Stage (7750–5100 BP)

In the high to midlatitudes after the early Holocene, with its remnants of ice-age conditions (tundra passing to birch forests), there was a transition to the mid-Holocene, marked by a progressive change to pine forest and then oak, beech, or mixed forest. The mean annual temperature reached 2.5° C above that of today. Neolithic man pressed forward across Europe and Asia. In North America the paleo-Indians reached into the region of the Great Lakes and the St. Lawrence Valley. In the Canadian Arctic and in Manitoba the mean temperature passed 4° C above present averages. It was a "milk-and-honey" period for primitive men over much of the world, and in Europe it paved the way for the cultured races of the Bronze Age. Navigators started using the seaways to trade between the eastern Mediterranean, the British Isles, and the Baltic.

In the Atlantic Stage in the midlatitudes there was widespread development of chocolate-brown soils and *terra rossa*. The vegetational cover became almost worldwide, except in the high mountains. As a result, the fluvial regimes passed from braided streams to meandering streams adjusted to a high degree of equilibrium.

Subboreal Stage (5100–2200 BP)

In the midlatitude continental interiors there was still evidence of hot summers, but the winters were becoming colder and partly drier. There was an expansion of steppe or prairie conditions and their associated fauna and flora. Many lake levels showed a fall. The Dead Sea first showed a rise, followed by desiccation and deposition of evaporites (*q.v.*) at about 4300 BP. In the later part of the stage the first signs of the late Holocene climatic deterioration can be detected.

In Europe there was also the beginning of widespread deforestation as Bronze Age man started to use charcoal for smelting and extended agriculture to tilling and planting. In consequence, soil erosion began almost immediately, hillsides developed lynchets (terracettes), and "anthropogenic sediments" began to accumulate on the lower floodplains. In western Europe, at about 3500 BP, there was a crescendo of megalithic cultures, with giant statues, menhirs, burial mounds, and the mathematical ingenuity of Stonehenge.

At this time, in the eastern Mediterranean, the Minoan culture (of Crete) rose, and then catastrophically declined, some believe because of climate change, others because of the ash showers and tidal waves from the Santorin eruption (*c.* 3450 BP). It was replaced by the Mycenaean civilization (3400–3200 BP). It has been suggested that drought was the basic reason for the Cretan decline in the period 3200–2700 BP. Northern Europe at that time was cool and dry; the Alps were also in a dry phase and world sea level was low. High rainfall did not return to the Mediterranean until the mild period that was marked by the historical date 776 BC (2736 BP), which marked the First Olympiad in Greece.

At the corresponding latitudes in the Southern Hemisphere (approximately 30°–35° S), pollen analysis indicates increasing desiccation during the Subboreal Stage, with a maximum dryness about 3200 BP.

In the subtropical regions of Mesopotamia and the Nile Valley, people had learned to harness water. The stationary settlements, advanced agriculture, and mild climates favoured a great flowering of human culture. It is surmised that when the normal floods began to fail, man's ingenuity rose to the occasion, and he devised irrigation canals and machinery. In the reign of the pharaoh Ramses II (about 1230 BC, or 3180 BP) a freshwater canal was dug from Cairo to Suez, initially for irrigation, but for

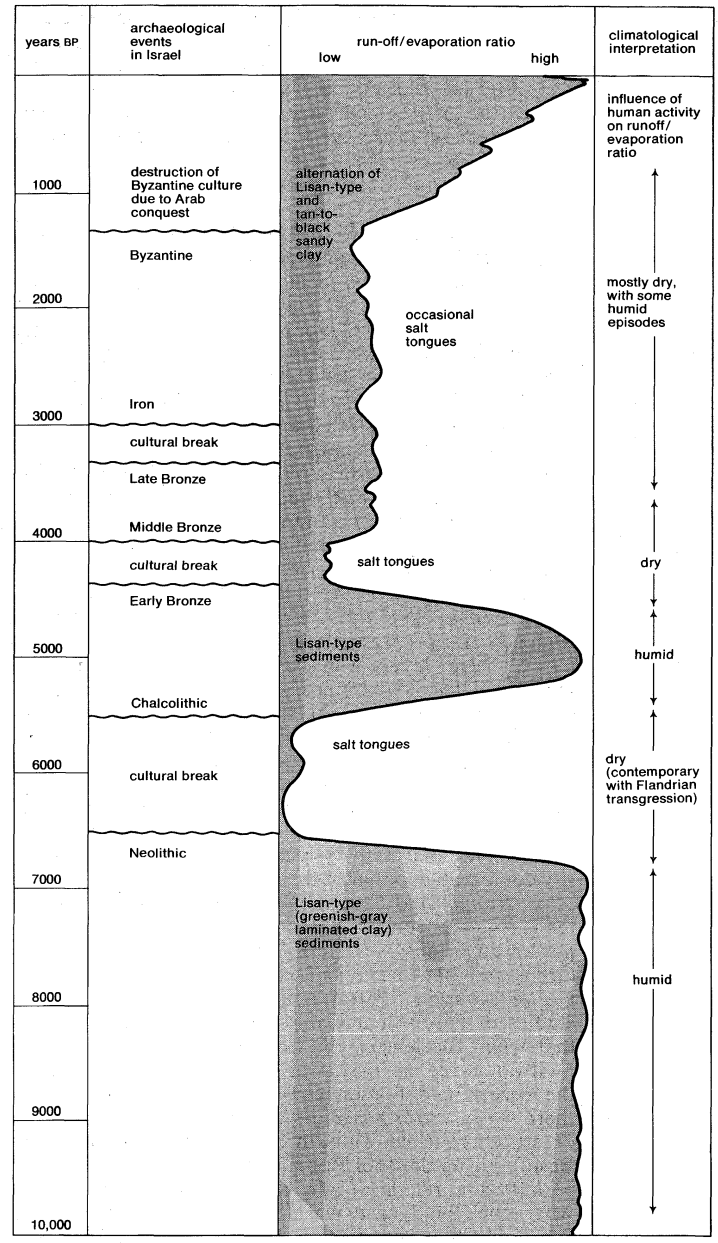

Figure 6: Holocene history of Dead Sea and Jordan Valley.

the first time small ships were able to go from the eastern Mediterranean (and thus from Britain and the Baltic) to the Red Sea, East Africa, India, and China.

Sub-Atlantic Stage (2200–0 BP)

This is the last major physical division of the geological record. Historically its beginning coincides with the rise of the Roman Empire in Europe, the flowering of the classical dynasties of China, the Ptolemies in Egypt, the Olmecs of central Mexico and Guatemala, and the pre-Incan Chavin cultures of Peru.

It is important to recognize that as the present day is approached, the minor cycles and modulations become relatively more and more prominent; indeed, it is all too easy to confuse minor fluctuations with the long-term trends. Numerous additional sources of information have become available for the study of these last two millennia. Most fundamental probably is the record of solar activity, as disclosed by documentation of aurora in ancient Chinese court records and later by sunspot numbers. Both phenomena reflect solar activity in general, but correlation with weather records in the higher latitudes is complicated. Other indicators of climate, such as tree-ring analysis and palynology, were previously mentioned, but many documentary indications are also useful: the time of the cherry blossom festival in Kyoto,

Japan, the freezing of lakes, the incidence of floods, blizzards, or droughts, the economics of harvests, salt evaporation production, some disease statistics, and so on. The water levels of closed basins such as the Caspian Sea and particularly the evaporite basin of the Kara Bogaz Gulf reflect runoff to the Volga. The Dead Sea reflects eastern Mediterranean precipitation.

The main trends of the Sub-Atlantic are identifiable as follows:

Classical Roman Period. This time interval is marked by the Florida or Roman emergence in the eustatic record about the BC–AD boundary and succeeded by a transgression.

The solar record is not complete, but indications are for low activity. Records of rainfall kept by the astronomer Ptolemy (AD 127–151) in Alexandria noted thunderstorm activity in every summer month in comparison with the totally dry summer today, which suggests a slightly wetter overall pattern in this latitude.

In northern Europe and in other high latitudes, in contrast, the cool stage at the beginning of the 1st century AD may have been drier and more continental, as shown by dune building. It was immediately followed in the 2nd century by much stronger westerly activity, as indicated by a 6-metre rise in the Kara Bogaz Gulf.

Late Roman Period. After the 1st century AD there is evidence of a progressive rise in sea level. Roman buildings and peat layers were covered by the marine transgression in The Netherlands, southern England, and parts of the Mediterranean. At the same time, drying and warming trends were associated with alluviation of streams and general desiccation in southern Europe and North Africa. Similar alluviation occurred in the American Southwest. This warming and desiccation trend is evident also in the subtropics of the Southern Hemisphere. The solar activity record indicates a mean intensity comparable to that of the mid-20th century.

Post-Roman and Carolingian Period. This period extends roughly from AD 400 to 1000 (Dunkirk II). The important invasions of western Europe by the Huns and the Goths may have been generated by deteriorating climatic conditions in Central Asia. Radiocarbon dating and studies of the ancient Chinese literature have disclosed that when the glaciers of Central Asia were large, the meltwaters fed springs, rivers, and lakes on the edge of the desert, and human communities flourished. When there was a warm phase the water supply failed and the deserts encroached. Thus, in Central Asia (and the Tarim Basin) during the cool Roman Period, the Old Silk Road permitted a regular trade between Rome and China, where the Han dynasty was flourishing. During the Ch'in, Wei, and Chou dynasties this trade declined. In the T'ang dynasty (AD 618–907) there was a reopening of the trade routes, and likewise during the Yüan dynasty (AD 1279–1368). Marco Polo passed this way in AD 1271. Radiocarbon dates of the 8.6-metre-high lake level at Sogo Nuur showed overflow conditions from AD 1300–1450, after which gradual, fluctuating, but progressive desiccation followed, and today the area is almost total desert.

In North America the Post-Roman–Carolingian Period was marked by warm temperatures in the northern parts, with mean paleotemperatures in central Canada about 1° C above the present. In the semi-arid Southwest of the United States, the arroyos, washes, and ephemeral river valleys were filling slowly with alluvium (younger "Tsegi alluvium"), an indication that stream energy was generated by the summer flash floods. The Sierra Nevada experienced a warm phase, and there were marginal retreats in almost all the mountain glacier regions of the world from the Alps to Patagonia.

The radiation fluctuations of the 7th to 9th centuries is reflected by flood levels on the Nile. On a ruined temple built by Ramses II north of Wādī Halfā (now drowned by Lake Nasser) the early Christians had built a superstructure that was destroyed by floods around AD 750–800; a second church suffered the same fate around AD 940–980 when there was another high solar activity peak.

In the tropical region of Central America there was the unexplained decline of the coastal Mayan people (Mexico and Guatemala) about the 10th century AD. The mountain Mayas continued to flourish, however, and it is possible that the high precipitation of this warming period introduced critical ecological limits to continued occupation of the (now) swampy coastal jungles.

Decline of the Mayas in 10th century

The Viking–Norman Period. Approximately AD 1000–1250 the worldwide warm-up that culminated in the 10th century and has been called the early Medieval Warm Period or the "Little Climatic Optimum," continued for two more centuries, although there was a brief drop in mean solar activity in the period around 1030–70. In the 8th to 10th centuries the Vikings had extended as far afield as the Crimea and had established coastal salt pans, the existence of which speak for seasonally high evaporation conditions and eustatic stability.

The levels of the Caspian Sea and Kara Bogaz Gulf were lowered at this time, reflecting high temperatures and low rainfall there and in the Volga Basin. Corresponding to the increased solar activity there were heavier monsoonal rains in the equatorial regions, and lake levels were high in East Africa.

In the Arctic regions during the 10th, 11th, and 12th centuries there was widespread navigation by the Vikings. Partly in response to reduced sea-ice conditions and milder climates they were able to establish settlements in Iceland, southern Greenland (Eric the Red, *c.* 985), and in eastern North America (Vinland; Leif Eriksson, *c.* 1000). In Alaska, from tree-ring evidence, the mean temperature was 2–3° C warmer in the 11th century than today. Eskimos had settled in Ellesmere Island about AD 900. Records of sea-ice off Iceland show negligible severity from 865–1200. Often the westerly storm tracks must have passed north of Europe altogether.

After a brief interval of cold winters in Japan, the cherry blossoms returned to early blooming in the 12th century. In the semi-arid Southwest of the United States there appears to have been increased precipitation, leading to a spread of vegetation and agriculture. Pueblo campsites dated AD 1100–1200 are found on top of the youngest Tsegi Alluvium. The snowline in the Rocky Mountains was about 300 metres (1,000 feet) higher than today.

Similar trends are recorded in the Southern Hemisphere, notably in Australia and Chile. The first immigration of Maori peoples into New Zealand probably occurred at this mild time.

Early Medieval Cool Period (AD 1250–1500). This interval corresponds to the Paria Emergence in the eustatic record and has been called one of the "little ice ages" by certain authors. Solar activity records show a decline from 1250 to 1350, a brief rise from 1350 to 1380, and then a phenomenal low that lasted until 1500. Pollen records in northern Europe reveal rather consistently cool conditions, and smoothed mean temperature curves show a cumulative drop during this period. Stalactite studies in a karst cave in France showed a travertine growth peak (indicating cool, moist conditions) in 1450. In North America cool, moist conditions were widespread at first, becoming dry later. The arroyos and washes became filled with the Naha Alluvium, and the human population decreased markedly. There is pollen evidence of a temperature drop of about 1° C. This is the period of the "Great Drought." In the upper Mississippi Valley the Indian cultures began a general decline, accompanied by a transfer from agriculture to hunting. It was similar in the western prairies, and it was this hunting culture that the first Spanish explorers encountered.

In the Canadian north the mean temperatures had dropped about two degrees below the previous high. In the Sierra Nevada, the Rockies, and in Alaska there were glacial readvances, with evidence of a 2° C temperature drop. In the Arctic regions, the Eskimo economy underwent a marked change to adjust to these more extreme conditions, which amounted to about 5 or 6° C below the mean of the climatic optimum.

The Norse settlements in Greenland were abandoned altogether as the permafrost advanced. Pollen studies at

Godthåb indicate a shift from a maritime climate to a cold, dry continental regime. The sea ice off Iceland reveals an extraordinary growth in severity, from zero coverage before the year 1200 to eight-week average cover in the 13th century, rising to 40 weeks in the 19th century, and dropping again to eight weeks in the 20th century. In Japan there were glacial readvances and a mean winter temperature drop of 3.5° C. Summers were marked by excessive rains and bad harvests.

The equatorial regions now began a marked desiccation, with a drop in level of all of the great African lakes. The Nile suffered a decreased flow and alluviation, although brief fluctuations also are recorded. (A detailed documentation is available because taxes in Egypt were based on the effectiveness of the Nile flood, and careful readings were taken.) Many early Christian settlements along the middle Nile were abandoned at this time.

South of the Equator in the temperate belts there was a general return to cooler and wetter conditions that have continued (with oscillations) until the present time in southern Chile, Patagonia, southernmost Africa, southwest Australia, and New Zealand.

Medieval Little Ice Age (AD 1500–1850). Throughout most of this period the mean solar activity was quite low, but positive fluctuations occurred around 1540–90 and 1770–1800. The main westerly storm belts shifted about 500 kilometres to the south, and for much of the time the northern latitudes came under cool continental conditions. Observed temperature series in Europe from Paris to Leningrad show large fluctuations until 1850.

Glacier advances are recorded in the Alps, in the Sierra Nevada, and in Alaska. Corresponding low sea levels are recorded by early tide gauge records in The Netherlands and Germany. Even in equatorial latitudes there are traces of mountain glacier advances (as in the Andes of Colombia).

The Industrial Age (AD 1850–1950). The year 1850 started a brief warming trend that persisted for 100 years. It also approximates a critical turning point in climatic, sea level, glacial, and sedimentologic records. In many regions of central and southern Europe "anthropogenic" sediments (or cultural layers) started to appear in Neolithic times (early to mid-Holocene). But elsewhere in the world (*e.g.*, in North America, Australia, South Africa) this type of sedimentation began around the middle of the 19th century, depending upon soil erosion stimulated by mechanized (disk) plowing, large-scale deforestation, and engineering activity. Thus, independently of natural climatic change, the century 1850–1950 is marked outstandingly by anthropogenic aridification, the time of man-made deserts.

The earth now is on a long-term cooling trend of the glacial-interglacial cycles and is likely to continue so for several thousand years, but there are numerous modulating influences, meteorological, geological, and man-made. These may accelerate or reverse the general trend, and from the point of view of human history they can well play a critical role.

BIBLIOGRAPHY. There is a vast array of specialized research papers that treat the many aspects of the Holocene Epoch. This results from the fact that evidence of Holocene environments is based on data so diverse as Paleolithic stone axes and sunspot magnitude and frequency. The bibliography presented here is restricted to readily available books or parts of books that cover the Holocene record in general and will serve as a guide to the more specialized literature.

Holography

Holography is, in principle, a means of creating a unique photographic image without the use of a lens. The photographic recording of the image is called a hologram, which appears to be an unrecognizable pattern of stripes and whorls but which—when illuminated by coherent light, as by a laser beam—organizes the light into a three-dimensional representation of the original object.

An ordinary photographic image records the variations in intensity of light reflected from an object, producing dark areas where less light is reflected and light areas where more light is reflected. Holography, however, records not only the intensity of the light but also its phase, or the degree to which the wave fronts making up the reflected light are in step with each other, or coherent. Ordinary light is incoherent; that is, the phase relationships between the multitude of waves in a beam are completely random; wave fronts of ordinary light waves are not in step.

Dennis Gabor, Hungarian-born scientist, invented holography in 1948, and received the Nobel Prize for Physics in 1971. Gabor considered the possibility of improving the resolving power of the electron microscope, first by utilizing the electron beam to make a hologram of the object and then by examining this hologram with a beam of coherent light. A degree of coherence can be obtained by focussing light through a very small pinhole, but this technique reduces the light intensity too much for it to serve in holography; therefore, Gabor's proposal was for several years of only theoretical interest. The development of lasers in the early 1960s (see LASER AND MASER) suddenly changed the situation. A laser beam not only has a high degree of coherence but high intensity as well.

Of the many kinds of laser beam, two have especial interest in holography, the continuous-wave (CW) laser and the pulsed laser. The CW laser emits a bright continuous beam of a single, nearly pure colour. The pulsed laser emits an extremely intense, short flash of light that lasts only about $\frac{1}{100,000,000}$ of a second. Two scientists in the United States, Emmett N. Leith and Juris Upatnieks of the University of Michigan, applied the CW laser to holography and achieved great success, opening the way to many research applications.

PRINCIPLES AND BASIC TYPES OF HOLOGRAPHY

Gabor coined the name holography from the Greek *holos*, or "whole," and *gram*, "message," because the image-forming mechanism he conceived recorded all the optical information in a wave front of light. Basically the problem Gabor conceived in his attempt to improve the electron microscope was the same as the one photographers have confronted in their search for three-dimensional realism in photography. To achieve it, the light streaming from the source must itself be photographed. If the waves of this light, with their multitude of rapidly moving crests and troughs, can be frozen for an instant and photographed, the wave pattern can then be reconstructed and will exhibit the same three-dimensional character as the object from which the light is reflected. Holography accomplishes such a reconstruction by recording the phase content as well as the amplitude content of the reflected light waves of a laser beam. How this works is shown in Figure 1 at the top.

Gabor's search for three-dimensional realism

Continuous-wave laser holography. *Producing a hologram.* In a darkened room, a beam of coherent laser light is directed onto object O from source B. The beam is reflected, scattered, and diffracted by the physical features

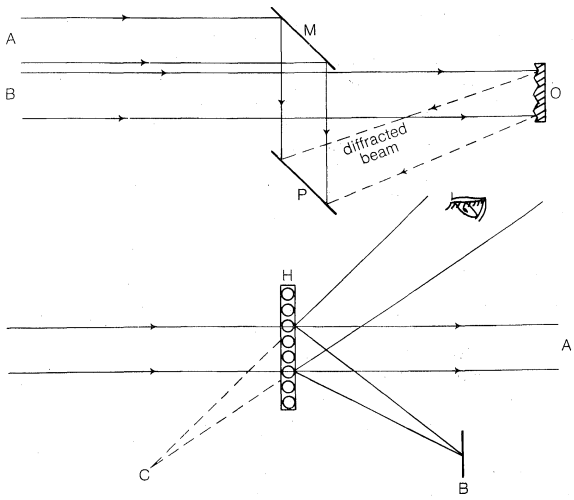

Figure 1: Arrangements for (top) creating a hologram and (bottom) reconstructing an image from a hologram (see text).

of the object, and arrives on a photographic plate at P. Simultaneously, part of the laser beam is split off as an incident, or reference, beam A and is reflected by mirror M also onto plate P. The two beams interfere with each other; that is, their respective amplitudes of waves combine, creating on the photographic plate a complex pattern of stripes and whorls called interference fringes. These fringes consist of alternate light and dark areas. The light areas result when the two beams striking the plate are in step—when crest meets crest and trough meets trough in the waves from the two beams; the beams are then in phase, and so reinforce each other. When the two waves are of equal amplitude but opposite phase—trough meeting crest and crest meeting trough—they cancel each other and a dark area results (see also LIGHT).

The plate, when developed, is called a hologram. The image on the plate bears no resemblance to the object photographed but contains a record of all the phase and amplitude information present in the beam reflected from the object. The two parts of the laser beam—the direct and the reflected beams—meet on the plate at a wide angle and are recorded as very fine and close-packed interference fringes on the hologram. This pattern of fringes contains all the optical information of the object being photographed.

Reconstructing the image. By reversing the procedure, as shown at the bottom in Figure 1, an image of the original object can be reconstructed. The coherent light of a laser beam illuminates the hologram negative H. Most of the light from the laser passes through the film as a central beam A and is not used. The close-packed, fine-detailed fringes on the hologram negative act as a diffraction grating, bending or diffracting the remaining light to exactly reverse the original condition of the coherent light waves that created the hologram. The diffracted light is transmitted at a wide angle from that of the laser's reference beam.

Diffraction grating in hologram negatives

On the light source side of the hologram, at C, a virtual image visible to the eye is formed. On the other side, at B, a real image that can be photographed is formed. Both these reconstituted images have a three-dimensional character because in addition to amplitude information, which is all that an ordinary photographic process stores, phase information also has been stored. This phase information is what provides the three-dimensional characteristics of the image, as it contains within it exact information on the depths and heights of the various contours of the object. It is possible to photograph the reconstituted image, at B, by ordinary photographic means, at a selected depth, in exact focus.

The difference in appearance between a hologram and the reconstituted image is remarkable, as illustrated in Figure 2. The object in this instance was a model of a royal crown, decorated with fur trim. The hologram, an enlarged part of which is shown at the left, is a complex pattern of fringes. On the right is the astonishingly crisp, reconstructed image obtained from this hologram.

The real image from a hologram—that is, the one that can be photographed—appears pseudoscopic, or with a reversed curvature. This reversal can be eliminated by making a double hologram, first by preparing the single hologram and then by using it as an object in the creation of a second hologram. With a double reversal the image becomes normal again, as when a mirror image of writing is made legible by viewing it in a second mirror. The real image of a hologram has valuable properties. A viewing camera or microscope can be positioned and focussed on various selected positions in depth. The original object also can be brought into the position in space.

The hologram not only offers images at different depths (different cross-sections of the object) but also images seen along different directions if the viewer moves off the axis on which the principal image is viewed. Direct images can be seen under these conditions. In holography it is also possible to record on the same plate a succession of numerous multiple images that can be reconstructed as one image, leading to the possibility of holography in colour. Three holograms could be superimposed on the same plate, using three lasers of different colours. Reconstruction with the three different lasers would produce an image in its natural colour, even though the hologram plate itself is black-and-white.

Colour holography from three black-and-white holograms

Pulsed-laser holography. A moving object can be made to appear to be at rest when a hologram is produced with the extremely rapid and high-intensity flash of a pulsed ruby laser. The duration of such a pulse can be less than $\frac{1}{10,000,000}$ part of a second; and, as long as the object does not move more than $\frac{1}{10}$ of a wavelength of light during this short time interval, a usable

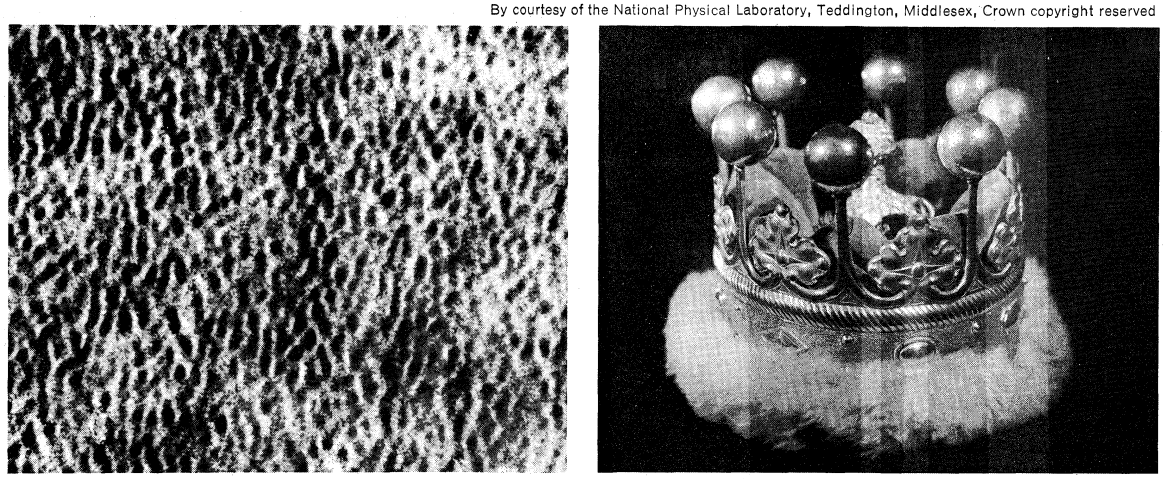

Figure 2: (Left) The complex pattern of fringes in a hologram. (Right) The reconstructed image from the hologram.

hologram can be obtained. A continuous-wave laser produces a much less intense beam, requiring long exposures; thus it is not suitable when even the slightest motion is present.

With the rapidly flashing light source provided by the pulsed laser, exceedingly fast-moving objects can be examined. Chemical reactions often change optical properties of solutions; by means of holography, such reactions can be studied. Holograms created with pulsed lasers have the same three-dimensional characteristics as those made with CW sources.

Pulsed-laser holography has been used in wind-tunnel experiments. Usually high-speed air flow around aerodynamic objects is studied with an optical interferometer (a device for detecting small changes in interference fringes, in this instance caused by variations in air density). Such an instrument is difficult to adjust and hard to keep stable. Furthermore, all of its optical components (mirrors, plates, and the like) in the optical path must be of high quality and sturdy enough to minimize distortion under high gas flow velocities. The holographic system, however, avoids the stringent requirements of optical interferometry. It records interferometrically refractive-index changes in the air flow created by pressure changes as the gas deflects around the aerodynamic object.

The arrangement is illustrated in Figure 3. Coherent

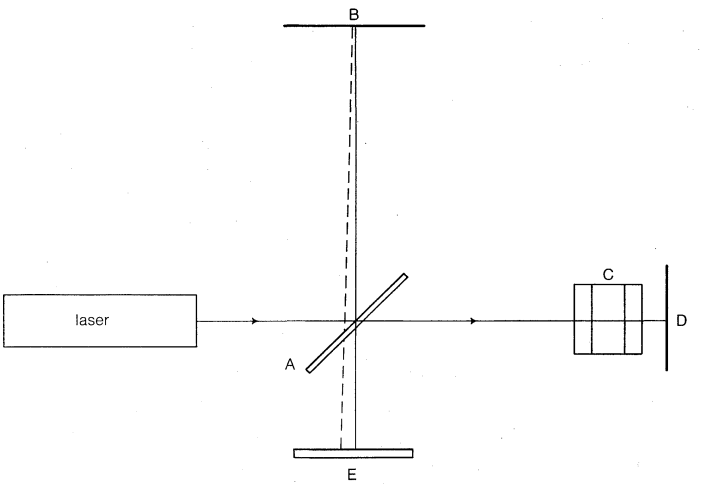

Figure 3: Arrangement for detecting changes in the refractive index of gas (see text).

light from a laser is divided by beam splitter A. One-half reflects to reference mirror B. The other half passes through gas chamber C, in which the refractive-index change takes place, and is then reflected from D to photographic plate E, on which the first holograph image is formed. A hologram is made with the gas in chamber C undisturbed. The refractive-index change is then induced in chamber C. Here, the change is induced in a flow chamber, but it also could be in the heat flow in a flame, the chemical change in a solution, or the alteration of a liquid with the passage of high-energy particles. From the induced refractive change a second hologram is doubly exposed, superimposed on the first. A later reconstruction shows a fringe pattern the same as that given by an optical interferometer.

At first, holography applied to standard interferometry may seem to be elaborately complex, but it is not. The instrument just described is in reality a type of Michelson interferometer. The process is easier to handle and less expensive than previous arrangements; it is referred to as the Michelson holograph system. The standard Michelson interferometer is not used in the classical optical method in wind-tunnel studies because of the awkward localization of fringes that appear on plane B and not on the object. It is not possible to photograph the object and fringes simultaneously in focus. The defect does not exist in the Michelson holograph system, because the fringes in holography can be seen in coincidence with the object producing the fringes.

Of equal or greater importance is the fact that in holography there is no need to be restricted to highly precise optical mirrors, windows, and lenses. With imperfect optical components, all of the optical imperfections appearing in one holographic image are faithfully repeated in the second image and therefore do not contribute to interference fringes when the two images are superimposed. The fringes seen are created only by the deliberately imposed refractive-index changes. Furthermore, in this system, since the second hologram is being matched against that from a reasonably plane surface, the fringe pattern is of the type familiar in optical interferometry and thus quite easy to evaluate.

Imperfections permitted in optical components

Nonphotographic holography. Holograph images are recorded also on materials other than photographic plates. These nonphotographic materials can be classed as either fixed or erasable.

Fixed holograms. Although some fixed holograms are similar to photographic plates, their primary purpose is to raise the resolving power, which is limited in photographic plates by emulsion grain. Holograms can be recorded by the use of a glass plate coated with gelatin containing dichromate. When illuminated, the gelatin hardens in those areas receiving light and after immersion in water produces differential swelling. An etched "photographic" record is created when the water is later removed from the gelatin. This type of hologram records extremely fine detail, of the order of several thousand lines per millimetre, far exceeding the performance of a good photographic emulsion. As yet, however, such holograms are difficult to prepare, as they are subject to defacement and distortion because of water absorption from the atmosphere.

In another approach, a photopolymer, a polymerized material sensitive to light and more stable than gelatin, is employed. A typical photopolymer is a metallic-acrylate monomer that contains a dye catalyst. The monomer can be polymerized; that is, transformed from a soft gel to a hard solid by using ultraviolet light. The process is not reversible and so produces a permanent record. With laser-scattered illumination, small, solid particles faithfully following the hologram patterning are formed on the hologram plate. These particles are fixed by the ultraviolet light as soon as the hologram is formed. Concurrently, the ultraviolet light bleaches out the catalyst dye. Since there is a different refractivity between gel and solid, a hologram in transparent material can be created.

Erasable holograms. Erasable holograms offer intriguing technical possibilities, and several types have been proposed. An erasable hologram could store information in computer systems. Furthermore, it could be used as a temporary hologram for reasons of economics. In photochromic (colour-sensitive) materials, the absorption of light varies with the wavelength of light that illuminates them. One wavelength can increase light absorption, while another can return the material to normal transmission (*i.e.*, it can remove the absorption formerly created). Thus a hologram can be created and viewed with one wavelength and wiped off with another because of the photoelectric effect in the molecule of the dye, which is called a photochrome. Phase-erasable holograms have been developed using thin films of special crystals, such as lithium niobate. When holographic light falls on the crystal, electrons are excited in the area stimulated by the light because of the crystal's photoelectric properties. The excited electrons cause a local change in refractivity, causing a phase shift in the incident light. The phase hologram can be used later to reconstitute an image. Ultraviolet-light illumination or heat can be applied to erase the image.

Phase-erasable holograms on thin crystal films

Another promising material consists of thermoplastic, photoconductor, and transparent conductor layers. The incident light pattern creates an electric charge pattern on the material. If the material is then heat softened, the thermoplastic deforms in areas that contain residual electric charges, producing a wrinkled surface and a hologram. When the charge disappears, a reheat results in an erasure.

High resolution is possible with thin, magnetizable

films. When illuminated, local changes in magnetization are created in the material because it exhibits a large magneto-optical effect; that is, its magnetic characteristics are altered by exposure to light. The changes in magnetization cause physical changes in the pattern of magnetic domains (regions in which all element dipoles are aligned in the same direction), creating the hologram. The hologram is erased by subjecting it to a suitable magnetic field.

EXPERIMENTAL DIFFICULTIES IN HOLOGRAPHY

Most of the nonphotographic devices are in an experimental stage, and the photographic production of holograms remains the only widely used process. Yet it continues to encounter practical problems. As a rule, theoretically predictable perfection in the appearance of the reconstituted image is not attainable for a variety of reasons. There is always some loss in the recorded information and subsequently in the final image. As the field of view is necessarily restricted to the dimensions of the photographic plate that records the hologram, the ability of the system to resolve fine detail is also limited. To reconstitute the image, an adequately large diffracting angle must be provided so that the images will appear far off the axis of the laser beam illuminating the hologram. To produce a wide angle, the hologram's fringe lines must be close together to provide a very fine line grating. Making the hologram behave in this manner depends both on the structural detail of the object and on the angle formed by the directions of the diffracted wave front from the object and the auxiliary interfering wave front deflected to mix with it. The need for such very fine fringe detail thus imposes a condition of high resolution on the photographic plate that records the hologram. No matter how good the plate, invariably some detail is lost.

Speckle patterns

Another frequent source of trouble is the speckle pattern. When coherent light strikes a nonspecular (nonmirror-like) body, its high coherence creates interference effects because its waves are diffused by the uneven surface of the body. As a consequence, a rough object appears covered with a peculiar random pattern of small, bright speckles, or light dots. Such speckling can seriously affect the resolution of detail in the reconstituted image.

Since a hologram is essentially a record of optical interference fringes, slight alterations in the optical distances can cause bad blur and reduce definition. Thus distance between the object and the holographic plate must be maintained uniform to within close limits during exposure. The holograph pattern will be distorted by any changes in the optical properties of the space between the object and the recording plate. There must be good temperature control and careful exclusion of drafts. Movements and optical length changes greater than $\frac{1}{10}$ of a light wave lead to blurring and a reduction in definition of the final reconstituted image. As will be shown later, this extreme sensitivity can be exploited holographically to detect small movements and small changes in the optical properties of materials.

Some small random imperfections in laser light occur; occasionally these imperfections can introduce defects into the holograph image. Furthermore, laser coherence may vary during exposure time; fine-grain, high-resolution plates are low in light sensitivity and thus require ten or more minutes of exposure. A wavelength drift can also occur. The greater the depths within the object (depths can exceed 50 centimetres), the more stringent are coherence conditions. For high-performance holography, high laser stability is required, increasing considerably the cost of the equipment.

APPLICATIONS OF HOLOGRAPHY

It is possible to obtain high-resolution holographic reconstructions that compare favourably with ordinary, good-quality microscope images, but such an application is hardly justified. Resolution tests with holograms indicate that lines 0.01 millimetre (0.0004 inch) apart can be resolved, but this does not remotely approach what can be accomplished with high-resolution optical microscopy. Speckle effects often reduce resolution. Some success has been achieved in averaging out and reducing speckle by moving the hologram plate during exposure, but this is an awkward procedure.

Use of cameras and microscopes in hologram studies

Many applications are made possible because the real image from the hologram can be viewed by a camera or microscope, making it possible to examine difficult and even inaccessible regions of the original object. A deep, narrow depression on a plane, for example, cannot often be reached by a microscope objective because of working distance limitations. If the detail can be reached by coherent light, however, a hologram can be taken and its image reconstructed. Since this image is aerial, the microscope can be positioned in such a way that it can focus on the required region. In the same way, a camera also can be focussed at the required depth and can photograph objects inside a deep transparent chamber.

Many holographic applications exploit the fact that composite repeat holograms of a surface tilted slightly after each exposure can be treated as composite, repeat wave patterns. If two such patterns are matched, a condition arises that is effectively the same as that which exists in ordinary classical two-beam interferometry, in which a single light source is split into two beams and the beams recombined to form interference patterns. Such an arrangement can be set up in several ways; in one, a holographic exposure is made of a surface, then before the hologram is removed or developed, the surface is slightly tilted and a repeat hologram is made, superimposed on the first hologram. When this double hologram is reconstructed, the object as well as the surface covered by the interference fringes caused by surface irregularities can be seen. These fringes reveal microtopographic information about the object.

It is much easier to interpret surface microtopography from fringe patterns that arise when the surface being studied is matched against a perfectly flat surface, rather than from the fringes that arise when the surface is matched against a slight displacement of itself—a condition known in classical interference optics as differential interferometry. One important advantage of holographic interferometry is that it makes possible the examination of rough, nonspecular surfaces as well as smooth, polished, or naturally specular surfaces.

Use in the study of elastic deformation effects

Holographic interferometry can be applied successfully to any situation in which the wave front is modified slightly, no matter how complex the surface may be. Elastic deformation effects can be studied by superimposing the two wave fronts on the hologram, reflected before and after the elastic distortion effect has been introduced. When reconstructed, the hologram provides a clear picture of the object, crossed by interference fringes. Even highly complex shapes respond to this approach in a manner that would be impossible in classical interferometry. There is also great flexibility in the choice of methods used to apply distortions, and even these conditions alone often completely exclude optical interferometry. Not only static distortion but also slow dynamic variations can be studied in this manner. And with pulsed ruby lasers, very fast, short-time variations can be studied.

Time variations in the shape of an object are not usually studied with a single, double-exposure hologram but by an alternative method. First, a hologram is made of the object in its free, unstressed condition. Then the object is stressed and a new hologram made. The stressed hologram is viewed through the original unstressed hologram, and the superposition provides the interference fringe pattern that would have been produced by a double exposure. By such means, time variations can be studied. Valuable studies have been made of mechanically vibrating systems, such as diaphragms, musical instruments (*e.g.*, the belly of a violin), vibrating steam-turbine blades, and the like. The examination of large engineering components, measuring as much as one metre in length, imposes special problems. The distance between the hologram plate and the object must be great enough to ensure that all of the object can be seen at once. In turn, laser power must be increased, high demands on the

coherence of light are imposed, and mechanical stability of the whole setup must be exceptionally good.

When hologram interferometry is applied to the examination of vibrations set up in a rapidly rotating turbine blade, stroboscopic techniques aid the analysis. The laser light is stroboscopically interrupted at the same frequency as the rotation of the turbine blade, and, with the blade thus apparently at rest, a hologram is produced. Consequently, a holographic interferometric pattern is created for the blade whose motion is stopped by stroboscopic action. By slightly altering the frequency of the stroboscope arrangement, a slow scan can be made over the complete vibrational stress pattern to which the blade is subjected. Much information about stresses in turbine blades and other rotating or vibrating objects can be obtained from such holograms.

Although holography can solve many problems, it still is a relatively expensive procedure. It has been used—or misused—in applications more amenable to simpler and cheaper methods. The laser system by itself is a fairly complex and costly piece of equipment, and costs are aggravated further by the additional equipment and the long exposure times required to produce holograms and reconstruct images. Holography is therefore applied only when other methods have failed or are not precise enough.

(S.To.)

Holostei

The Holostei are one of the three major groups of ray-finned fish (Actinopterygii). Most paleontologists divide the Holostei into the Holosteans proper, which include living and extinct forms, and the Halecostomi, an extinct group.

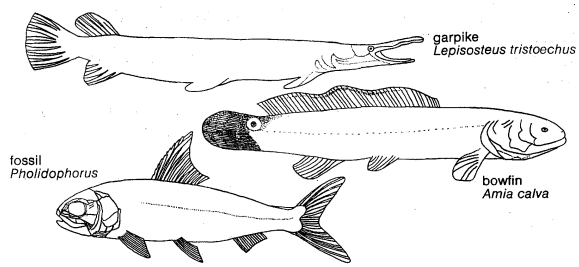
The origin of the Holosteans and the Halecostomi is not fully understood, but it is believed that they arose from some advanced chondrostean fishes (a group that includes the sturgeon). The Holostei were particularly abundant and diversified during the Mesozoic Era (65,000,000–225,000,000 years ago). Today they are represented by only two living genera, *Amia* (bowfin) and *Lepisosteus* (gar). One species of bowfin has been recognized, and about eight species of gar have been described so far.

Size range, distribution, and abundance

The gar occurs only in North America and Central America from southeastern Canada to Panama; it is not found west of the Rocky Mountains. The longnose gar (*L. osseus*) is the most widely distributed species. The gar is primarily a freshwater fish but sometimes ventures into saltwater or brackish water. The so-called alligator gar (*L. spatula*), one of the largest of freshwater fishes, is particularly abundant in the Everglades region of southern Florida, where it is caught locally as a food fish; it sometimes grows to a length of nearly three metres (ten feet) and may attain a weight of 136 kilograms (300 pounds). The names gar, garfish, and garpike are sometimes applied, especially in Europe, to the needlefishes (Belonidae), which are coastal fishes of warm seas and have very long and slender jaws. These fishes, however, are not closely related to the Holostei.

The bowfin, also known as grindle, mudfish, and dogfish, is found in sluggish waters from the Great Lakes to the Gulf of Mexico. It was once common throughout Europe but is now extinct there. Females grow to about 75 centimetres (30 inches) and weigh up to 3.5 kilograms (eight pounds); males are smaller. Bowfins eat all kinds of fish and invertebrates and are sometimes destructive to game-fish populations. Bowfins are seldom caught as food fish.

Drawing by J. Helmer, from (top, centre) N.B. Marshall, *The Life of Fishes* (1965), Weidenfeld & Nicolson, London, (bottom) A.S. Romer, *Vertebrate Paleontology* (1966), University of Chicago Press



Living and fossil forms of Holostei fishes.

Natural history. *Reproduction.* The bowfin spawns in weedy areas along the edges of streams and lakes. The male constructs the nest and guards the eggs as well as the newly hatched young. The young bowfin has an adhesive organ at the tip of its snout that enables it to cling to weeds. The fish grows rapidly and at the end of its first year may be as long as 23 centimetres (nine inches).

The female gar lays its large, yolk-filled eggs in shallow water in the spring. The gar hatchlings grow rapidly, feeding on minnows. The long rows of needle-sharp teeth are effective in capturing fast-swimming prey.

Ecology. Gars and bowfins are voracious predators, feeding on invertebrates and other fishes. All the amiiform fishes (the bowfin order) of former times were probably predaceous. For the most part they were a marine group; the modern bowfin, however, is confined to freshwater. Because of its highly developed air bladder, which can also function as a lung, the bowfin is able to live out of water for as long as 24 hours.

Gars occasionally venture into saltwater, but apparently they do not feed there. They often float quietly at the surface of sluggish waters, breathing atmospheric air.

Form and function. *General features.* The Holostei are characterized by having the dermal bone of the upper jaw (maxilla) freed from the cheek elements and attached to the skull only in the ethmoid region or near the nasal chambers. The palate is separated from the cheek elements, and the adductor mandibulae muscle, which closes the jaws, is larger and more subdivided than it is in the chondrosteans. Primitively, the centrum (*i.e.*, the lower, heavy part of a vertebra) surrounding the notochord (a flexible rod that passes through the vertebral column) was absent, but this structure apparently developed independently in most of the holostean orders. The scales, too, were primitively rhomboidal, or diamond shaped, with a reduced or absent layer of dentine (*i.e.*,

the substance of which teeth are largely made). The scales, however, became thin and cycloidal (*i.e.*, rounded and overlapping) in several groups. The fin rays of the unpaired fins are always equal in number to their basal supports, and the fins themselves may or may not be bordered at the anterior end by fulcra (*i.e.*, modified scales or spines). The caudal, or tail, fin is typically hemiheterocercal (*i.e.*, the upper lobe larger than the lower) and externally symmetrical. The braincase is always composed of separate ossifications (centres of bone formation) that resemble, in number and placement, those found in the teleosts.

The division Holosteans includes the orders Semionotiformes, Pycnodontiformes, Amiiformes, and perhaps Pachycormiformes. In these orders the preoperculum (an L-shaped bone anterior to the operculum, or gill cover) is tied to the palatal elements and provides part of the originating area for the adductor mandibulae muscle.

Extant groups. The order Semionotiformes includes two families. The oldest known holostean, *Acentrophorus* (Upper Permian—about 225,000,000,000–250,000,000 years ago), belongs to the Semionotidae. Members of this family have small mouths and strong teeth; heavily ossified (*i.e.*, composed of true bone rather than cartilage) dermal bones; and hemiheterocercal tails. The body may be fusiform (*i.e.*, tapered at both ends), as in *Semionotus*, or flat and disk-shaped, as in *Dapedium*.

Body structure of living gars

The other semionotiform family, the Lepisosteidae, includes the living gar. The snout of the gar is greatly lengthened by multiplication of the small tooth-bearing bones anterior to the eye. The premaxilla bone is situated at the anterior end of the series; the maxilla bone seems to be reduced to a small, bony sliver at the angle of the mouth.

The body of the gar is encased in an armour of thick, diamond-shaped, enamelled (ganoid) scales. The jaw ends in a beak that, in the alligator gar, is broad and relatively short; in the longnose gar the beak is long and forceps-like. The dorsal and anal fins, both located far back on the body, are without spines and have fewer than 12 rays each.

The Amiiformes, represented today by one species of bowfin, include about six families that show considerable diversity in the length of the jaw, the development of the teeth and fins, and details of the dermal skull pattern. In general, the earlier amiiforms had well-developed rhombic scales and a persistent notochord. In later forms the scales usually became thinner and cycloidal. Ossified centra developed around the notochord, either restricting it or eliminating it. The caudal fin was either forked or lobed. The amiiform body was generally fusiform, similar to that of the living bowfin.

The bowfin has a long, spineless dorsal fin with about 58 rays. This extends over most of the back to near the tail. The males have an orange- or yellow-encircled dark spot near the tail. In females either the outer circle or the entire marking is absent. Bony plates cover the head; the rest of the body has cycloid (*i.e.*, fan-shaped) scales.

Extinct groups. In some ways the Pachycormiformes superficially resemble certain living teleosts, such as mackerels and swordfishes. Their bodies are generally fusiform, with a widely forked caudal fin, a fairly wide gape, and moderately well-developed teeth. The pectoral fins may be elongated and the dorsal and anal fins somewhat enlarged.

The Pycnodontiformes, which may be related to the Semionotiformes, are unique among the holosteans in having their upper and lower dentitions modified to form an open pavement of crushing teeth. In many cases, however, the anterior teeth of the premaxilla and the dentary are incisiform and thus must have been used for grasping (as such teeth are in the living porgies and sparids). In addition to skull modifications related to feeding, the pycnodonts are characterized by deep, almost disk-shaped bodies, elongated anal and dorsal fins, and an externally symmetrical caudal fin. In a number of genera scales are absent on the posterior part of the body, a condition that apparently increased flexibility. Scales were usually present but modified on the anterior half. The body and fin form of pycnodonts suggest that they were fairly fast and powerful swimmers. The affinities of this order remain problematical, as the ossification pattern of the braincase and the caudal-fin skeleton do not closely resemble those of other Holosteans or Halecostomes.

The second major division of the subclass Holostei is the Halecostomes; all are relatively small, fusiform fishes. The group presently includes only one order, the Pholidophoriformes. Some authorities include a second order, Leptolepiformes.

Historical origin of gars and bowfins

Evolution. The gars probably arose in the Cretaceous Period (136,000,000 to 65,000,000 years ago) from some semionotid stock. They are known from freshwater Tertiary deposits in India, Africa, North America, and Europe. The bowfins also made their first appearance in Cretaceous times. Pycnodont fossils range from the Upper Triassic to the Eocene (from about 190,000,000 to 50,000,000 years ago). Pachycormiforms are known only from marine rocks of Jurassic and Cretaceous age. The pholidophorids are known from the Triassic to the Cretaceous; the other pholidophoriform families all ranged from the Jurassic to the Cretaceous.

Among the seven families presently assigned to the Pholidophoriformes, the pholidophorids probably show the closest resemblance to the early teleosts. Trends toward thinning of the scales and the loss of ganoin (an enamel-like material) on the fin rays, along with the dermal-bone pattern and the development of intermuscular bones, point toward the teleosts. The major difference between the pholidophorids and the teleosts is in the structure of the caudal-fin skeleton. In pholidophorids of the early Jurassic, the caudal fin was still structurally heterocercal, with a fairly stiff axial lobe. Modification toward the teleost condition involved changes that brought about equal flexibility of the upper and lower lobes. The other six families currently assigned to the order Pholidophoriformes are specialized in various ways, but none can be regarded as involved in the ancestry of the teleosts.

Classification. Groups marked with a dagger (†) are extinct and known only from fossils.

Distinguishing taxonomic features. The principal features on which classification of the Holostei is based include general body shape, scale structure, and the number and placement of head bones.

Annotated classification.

SUBCLASS HOLOSTEI

Tail hemiheterocercal; maxilla free of preopercle; rays of median fins approximately equal in number to basal elements; trend toward thinning of scales and loss of ganoid (enamel) layer.

Division Holosteans

Preopercle intimately bound to and supporting the posterior border of the palate.

Order Amiiformes (bowfin and fossil relatives)

Lower Triassic (about 210,000,000–225,000,000 years ago) to Recent; body generally fusiform; early forms with well-developed rhombic (diamond-shaped) scales and persistent notochord; scales thinner and cycloidal (fan-shaped) in later forms; 6 families; 1 living species.

†*Order Pachycormiformes*

Lower Jurassic (about 160,000,000–190,000,000 years ago) to Upper Cretaceous (about 65,000,000–100,000,000 years ago); body fusiform, caudal fin widely forked, long snout; 2 families; Europe and North America.

Order Semionotiformes

Upper Permian (about 225,000,000–250,000,000 years ago) to Recent; 2 families of widely divergent fishes; fossil Lepidotidae with normal holostean fusiform bodies, which became relatively deep and slab sided in some members; marine and freshwater, widely distributed; gars (Lepisosteidae) are elongated, long snouted, primarily freshwater predators, extant in North America.

†*Order Pycnodontiformes*

Upper Triassic (about 190,000,000–210,000,000 years ago) to Eocene (about 38,000,000–54,000,000 years ago); upper and lower teeth modified to form crushing pavement; body nearly disk-shaped; anal and dorsal fins elongated; caudal fin externally symmetrical.

Division Halecostomi (or Halecostomes)

Relatively small; body fusiform; preopercle not buttressing the bones of the palate.

†*Order Pholidophoriformes*

Middle Triassic (about 200,000,000 years ago) to Lower Cretaceous (100,000,000–136,000,000 years ago); holosteans with some trends toward teleosts, notably: loss of ganoin from fin rays, scales, and dermal bones; loss of peg and socket joints between scales; about 7 families; marine and freshwater, of wide distribution.

Critical appraisal. According to some authorities, the Leptolepiformes, a teleost group, should be included among the Halecostomes. This opinion indicates that the boundary between the Halecostomes and the Teleostei is difficult to define. The family Pholidophoridae, in particular, has a skull pattern almost identical with that of the leptolepids; the feeding mechanisms are also quite similar.

Holstein, Friedrich von

For the greater part of his career a subordinate official in the German Foreign Office, Friedrich von Holstein nevertheless played a dominant role in German politics and diplomacy. As the "Grey Eminence of the Wilhelmstrasse" (the street in which the foreign office was located), he has long been regarded as a man of mystery who exercised an uncanny influence on German foreign policy.

Born on April 24, 1837, in Schwedt on the Oder, Holstein was raised on his family's estate in Pomerania and their town house in Berlin. Throughout his youth, his family spent a great deal of time travelling abroad, and Holstein became fluent in several foreign languages. A sickly boy, he was educated mostly by private tutors, and, after studying at the University of Berlin, he joined the legal section of the Prussian government.

Bismarck's protégé

Always a proud and self-witted man, Holstein rarely deferred to his superiors and took a cavalier attitude toward his official duties. He could afford to do so, for his family was wealthy, and he himself enjoyed the patronage of a neighbour of his father, Otto von Bismarck, who was already in the 1850s a power in Prussian politics.

With the support of Bismarck, Holstein entered the Prussian diplomatic service in 1860, serving his apprenticeship under Bismarck at the Prussian legation in St. Petersburg. After being posted to Rio de Janeiro, he returned to Germany at the time of Prussia's war with Denmark in 1864, acting as one of Bismarck's diplomatic representatives at army headquarters and taking part in the international conference in London in 1864–65 to settle the Danish question.

From 1865 to 1867 he was stationed in the United States and there had the opportunity to observe the operation of a democratic government at first hand and to travel in what was then still the "wild" West. In America he became interested in a project for the development of a mechanical device for towing barges and invested in this venture the greater part of his fortune, most of which he appears to have lost. Holstein was recalled by Bismarck but not, as has been alleged, as a result of a love affair with the wife of Senator Charles Sumner.

Just before the outbreak of war with France in the summer of 1870, Bismarck, alarmed by the possibility that the Italian monarchy might side with France, instructed Holstein to enter into secret negotiations with Italian republicans. After the war broke out, Holstein grew bored in Berlin and appeared at Bismarck's headquarters in France. He was attached to Bismarck's staff, though officially he did little more than serve as a translator during the armistice negotiations with France. But Bismarck, who liked to be as fully informed as possible, allowed him a more independent role in maintaining unofficial contact with leaders of the Paris Commune, the city's left-wing government that refused the Prussian peace terms and opposed France's regular government.

After the conclusion of peace with France, Holstein served under the German ambassador to Paris, Count Harry von Arnim. An opponent of Bismarck's support of republican France, Arnim was also believed by the Chancellor to be planning to supplant him. When papers were found to be missing from the embassy, Arnim was disgraced. The story spread by Bismarck's enemies that Holstein had served as Bismarck's spy in bringing about Arnim's eventual ruin was proved false in the course of Arnim's trial for the removal of official documents.

Domination of German foreign policy

In April 1876 Holstein was recalled to the German Foreign Office, where his thorough study of every problem and his network of connections soon enabled him to exert a predominant influence not only on foreign policy but also on domestic policy. To remain at the centre of affairs in Berlin, he declined several offers of advancement to diplomatic posts. In 1900 he even refused Chancellor Bernhard, Fürst von Bülow's offer to make him head (state secretary) of the Foreign Office, reportedly because he did not wish to operate in the limelight, a refusal he himself later acknowledged to have been the greatest mistake of his career.

One of the greatest puzzles in Holstein's life was his metamorphosis from an ardent partisan of Bismarck, whom he served during the 1870s as close collaborator and political confidant, into a bitter critic and opponent of the older statesman. This change in attitude, which took place gradually over many years, was in fact largely prompted by Bismarck's alignment with Russia. Holstein advocated instead a firm alliance with Austria and Britain, and after Bismarck's dismissal in 1890, he joined with other counsellors of the new chancellor, Leo von Caprivi, in advising against the renewal of the Russian treaty.

Under Caprivi, Holstein assumed a more important role in the formulation of German foreign policy, for the new chancellor had no experience in this field. Although Holstein had played an important part in formulating the new anti-Russian and pro-British direction of German policy, he also warmly supported Caprivi's reciprocal trade treaties, including the one with Russia, which reduced tariffs on agricultural imports, thus lowering German food costs and stimulating Germany's export trade.

Holstein's influence increased further under Caprivi's successor, Chlodwig Karl Viktor, Fürst zu Hohenlohe-Schillingsfürst, who became chancellor in 1894, and he retained his influential role as the confidential adviser of Hohenlohe's successor, Bernhard von Bülow, who became head of the German Foreign Office in 1897 and chancellor in 1900. Yet Holstein found himself stymied in the most extended and crucial fight of his career. He was powerless to oppose the policies of his unpredictable sovereign, Emperor William II, nor could he persuade his superiors to do so.

Checkmated by the Kaiser

For the most important German policies in the years after Bismarck's dismissal—the feverish quest for colonies, the construction of a German battle fleet and the ensuing Anglo-German naval rivalry, the tortuous negotiations for an Anglo-German alliance that not only failed but actually heightened the tension between the two countries—were in large part inspired by the Kaiser, often without consulting the members of his government.

Holstein saw the folly of many of these policies. Had he restricted himself to warning against them, he might have gone down in history as the Cassandra of the Wilhelmin-

ian era. But the policies he himself formulated and tried to carry out were hardly more beneficial to his country than those of his emperor. After helping to sever the German alliance with Russia, he failed to secure the alliance he desired with Britain; and when he once again sought an understanding with Russia, that country had formed an alliance with France. Meanwhile, Germany was left with only one reliable ally, the moribund Habsburg Empire, which presented ever greater demands in return for its friendship. Holstein's most notable diplomatic campaign, his attempt to break up the newly formed Anglo-French entente of 1904 by fomenting a crisis over Morocco, only served to expose Germany's global isolation. At the height of the crisis, in April 1906, the Emperor dismissed him. Holstein died in Berlin on May 8, 1909.

Assessment

Holstein was a conservative Prussian aristocrat, an individualist, proud, anxious to make his mark in the world, but with very independent ideas as to how to attain his goal. He was not a German nationalist but rather a proponent of the status quo for Germany, for although he had loved and sought adventure in his youth, he feared and disliked adventures in foreign policy. He himself believed he would go down in history, if he were remembered at all, as an intriguer, although in his opinion he had only tried to be of service to his country. Holstein's greatest weakness was his excessive confidence in his own judgment and his immense grasp of political facts, for the wisdom of his decisions was often debatable. He also overemphasized the personal element in any political situation. He liked to think himself the equal of any man, no matter how exalted, and would concede others superiority only in having greater means at their disposal. He did not know the meaning of political fear, and the greater the power of a potential opponent, the more heedlessly he plunged into the fray, whether it was against Bismarck's son-in-law, while Bismarck was still at the height of his power, or against a favourite of the Kaiser. He was equally unconcerned about his economic status. Although he enjoyed spending money while he still had it, in his old age he lived in almost penurious modesty in his bachelor quarters. The last half of his life was completely taken up with politics, which to the day of his death remained his overriding obsession.

Homeostasis

Homeostasis is the self-regulating process by which biological systems tend to maintain stability while adjusting to conditions that are optimal for survival. If homeostasis is successful, life continues; if unsuccessful, disaster or death ensues. The stability attained is actually a dynamic equilibrium, in which continuous change occurs yet relatively uniform conditions prevail—very much as occurs in a pool below a waterfall. Such systems are called open, as contrasted with the closed systems of, for example, solutions in test tubes. Biological systems are all of the open-system type, and the dynamic equilibrium, or steady state, achieved through homeostatic control implies a controlled environment.

THE NATURE OF HOMEOSTATIC SYSTEMS

The conception of homeostasis. Homeostatic mechanisms are essential to survival in a ceaselessly changing world. Any system in dynamic equilibrium—whether a clock, a cat, a community, or a computer—tends to reach a steady state, a balance that resists outside forces of change. When such a system is disturbed (a clock is wound, a cat becomes hungry, a forest is burned, or a computer is activated), built-in regulatory devices respond to the departures (or feedback) to establish a new balance (the clock unwinds, the cat eats, plants restore the forest, the computer "reads out" a solution). All processes of integration and coordination of function, whether mediated by mechanical circuits or by nervous and hormonal systems, are examples of homeostatic regulation.

Claude Bernard, a 19th-century French physiologist, first expressed the steady-state concept in terms of the constancy of the internal environment of an organism. The idea of self-regulating mechanical devices was already firmly established (James Watt's "governor" and Andrew Ure's "thermostat" were well-known by the late 1800s) when W.B. Cannon, an American physiologist, formalized the biological concept and coined the term homeostasis in his book *The Wisdom of the Body* (1939). Cannon, himself, limited the concept to physiology but suggested it was applicable in many other areas of biology as well. His observation was well founded: today homeostasis is considered one of the most important concepts in biology. Homeostatic responses can be observed in operation at all levels of life—atom, molecule, cell, organ, organism, population, and community—and in a wide range of time intervals—from a fraction of a second for enzyme-catalyzed reactions to hundreds of years for community changes. The concept also can be applied to analogous nonliving systems, such as W. Ross Ashby's automaton "homeostat," guidance controls of aircraft, and digital computers. The application of self-regulation to complex machine operations resulted in devices called servomechanisms. Crystallization of the mathematics of servomechanisms spawned a new science, cybernetics, the strictly biological aspects of which are the province of bionics.

Ludwig von Bertalanffy, a Canadian biologist, expressed the constant change but apparent persistence of living systems as follows: "Living forms are not *in being*, they are *happening;* they are the expression of a perpetual stream of matter and energy which passes the organism [or cell or population] and at the same time constitutes it." This stream of energy and matter appears to be governed by the same laws of thermodynamics that hold for reactions in test tubes and combustion engines. The fact is often obscured by the extraordinary complexity of living systems and the extremely elusive and tenuous energy relationships between life, nonlife, and the ultimate source of energy, the sun.

Technological versus biological systems

Comparison of homeostatic systems. The stability in the self-regulating devices commonly used in engineering and industry is achieved primarily through the use of such regulators as gyroscopes, mechanical governors, and inducers. Biological systems, of greater complexity, have regulators only very roughly comparable to such mechanical devices. The two types of systems are alike, however, in their goals—to sustain activity within prescribed ranges, whether to control the thickness of rolled steel or the pressure within the circulatory system. The basic difference between the two systems is, theoretically at least, that mechanical regulating devices are characterized by rigidity of operation, whereas biological ones are more flexible and adaptable. This becomes a moot distinction, however, in the light of technological advances that have created sophisticated computer-controlled servomechanisms that seem almost to have "minds" of their own.

Through homeostasis, biological systems perform efficiently enough to survive. A tremendous variety of responses is possible to any set of stimuli; however, some sort of filtering or guiding mechanism is necessary if effort is not to be wasted. Homeostasis permits the storing of blueprints, so to speak—instead of spare parts—which are used only if needed. The pattern of response is economical because it is called into play only when predetermined organismic limits are exceeded and then only until the normal range of action has been obtained.

Types of homeostatic regulation. There are two basic types of homeostatic regulators: off–on switches, in which an action does or does not occur, and feedback controls, in which the system is under continuous adjustment. Off–on switches normally react within well-defined limits and range, whereas feedback controls react proportionally to the governing effect of some product of the system. Neither type of adjustment produces a con-

stant response but fluctuates, or oscillates, about some mean value that is preset for off–on controls and self-determining for feedback controls.

Off–on control. A familiar example of off–on regulation is the action of a room-temperature regulator, or thermostat. The heart of the thermostat is a bimetallic strip that responds to temperature changes by completing or disrupting an electrical circuit. When the room cools, the circuit is completed. The furnace operates, and the temperature rises. At a preset level the circuit breaks, the furnace stops, and the temperature drops.

Typical closed-loop system

Feedback control. In a typical feedback or closed-loop system, input (information) is connected to output (effector) by way of a control modulator. Feedback from the output is routed into the system, where it has some effect on the level of activity of the control modulator, negative when it reduces activity, and positive when it accelerates activity. In technological systems the control modulator is a computer, flywheel, or some other driving mechanism. In biological systems, this modulator—and frequently the input as well—is inaccessible within the system and consists of such things as concentrations of substances in the blood. Response of the system to the input information may be either linear, directly proportional to the input, or nonlinear, variable to the input. Biological systems almost always show a nonlinear response.

The homeostatic pattern. *The homeostatic plateau.* The pattern that identifies a homeostatic system represents equally well the level of white blood cells in the bloodstream, the number of mice in a wheat field, or the concentration of phosphorus in bone. The range between high and low levels constitutes the homeostatic plateau—the "normal" range that sustains life. As either of the two extremes is approached, corrective action (through negative feedback) returns the system to the normal range. Oscillations inherent in the system represent the compensatory adjustments to any deviations from the normal. The adjustments are not perfect, and a lag in response is always present. If the lag becomes too great, the compensating reaction may occur out of phase, resulting in overshoots of increasing magnitude. If such overshoots continue, a condition termed "runaway" may occur, resulting in collapse of the system. Under certain circumstances, the homeostatic plateau may be adjusted upward or downward; oscillations then must be maintained within newly established limits if the system is to survive.

"Runaway" resulting in calamity or death

The limits of homeostatic regulation. The homeostatic control of body temperature in humans will clarify some of the subtle aspects of homeostasis as well as some of the limits to its action. Temperature regulation appears to be an off–on type of control, working, superficially at least, like a thermostat that regulates heat in the home. In humans, the normal body temperature fluctuates around the value of 98.6° F. A large number of factors, however, affect this normal value—*e.g.*, hormones, exposure, metabolic rate, and disease. While a high temperature level is advantageous to man, since it permits enzymes to function at an optimal rate, it also creates a continuous demand for a large supply of energy and, at times, confounds the problem of getting rid of excess heat produced by metabolic activities.

Temperature regulation is thought to be controlled by a region in the brain known as the hypothalamus. Feedback information, carried through the bloodstream, results in compensatory adjustments in the breathing rate, the level of blood sugar, and the metabolic rate. Heat loss in mammals is aided by reduction of activity, by sweating and panting, and by heat-exchange mechanisms that permit large amounts of blood to circulate near the surface (*e.g.*, beaver tails or rabbit ears). Heat loss is reduced by insulation (fur or fat), decreased circulation to the skin, and behavioral and cultural modifications such as the use of clothing, shelter, and fire.

Temperature extremes can be survived through hibernation—with the accompanying reduction in metabolic activity—or by temporarily shifting the homeostatic plateau, as happens during a fever.

A SURVEY OF HOMEOSTATIC PROCESSES

Physiological homeostasis. Human physiology, the first great proving ground for homeostasis, continues to be the realm of greatest interest. Communication within cells and between cells helps maintain the proper functioning of the vital enzymatic activities. Internal communication above the cellular level occurs primarily through and between the nervous and endocrine systems. The nervous system is a complex information network the activities of which function through an extensive feedback circuitry. Many of the responses in the nervous system are of the off–on type. Nerve endings, or receptors, provide input information that is routed to the spinal cord and the brain. The output occurs largely through the action of muscles.

Responses of the nervous system

Most of the endocrine glands are under the influence of the hypothalamus and the anterior lobe of the hypophysis (pituitary gland); for example, the hypophysis produces thyroid-stimulating hormone (TSH), which prompts the thyroid gland to produce thyroxine. Thyroxine, in turn, acts in negative feedback manner on the hypophysis to diminish production of TSH—resulting in a balance, or steady state, between the two hormones. Any illness that restricts the production of TSH will automatically promote the uncontrolled production of thyroxine.

In a similar manner, hormones from the hypophysis affect the activities of the ovary. This relationship is complex and involves concurrent interactions of several feedback systems. Follicle-stimulating hormone (FSH), produced by the hypophysis, stimulates the ovary to produce estrogen, which in turn stimulates the hypophysis to produce luteinizing hormone (LH). Luteinizing hormone stimulates the ovary to produce progesterone, which in turn stimulates the hypophysis to produce FSH, and so on. Feedback from each of the hormones helps control this cyclic steady state. The balance is further complicated by the presence of other hormones. Contraceptive "pills" are able to function because of negative feedback; they consist primarily of progesterone, which inhibits LH production and, hence, prevents ovulation and possible conception.

A class of plant hormones called auxin works in homeostatic fashion to regulate plant growth. Acting primarily through regulation of water intake, auxin stimulates or inhibits cell size and growth. The outer coat of some seeds also contains substances that inhibit germination; rain removes the inhibiting influence, permitting the seeds to grow. Dormancy in trees also appears to be controlled by a balance of inhibiting and stimulating substances.

In man, the blood-forming elements are produced in the bone marrow, from embryonic cells called cytoblasts. Cytoblasts may develop into such diverse cell types as bone cells, white blood cells, red blood cells, or platelets—depending upon the feedback demands of the body. If this dynamic equilibrium is disrupted—as in the case of leukemia—an increased number of white blood cells may be produced, to the corresponding detriment of the red blood cells.

Genetical homeostasis. Each of the body cells of an organism contains identical genetic information. But only those genes that control traits or functions that each part of the body is noted for are activated. The capabilities of the organism are limited only by the variety of input information that can be expressed through its complement of genes.

Enzymatic homeostasis

Genes control metabolism through the production of enzymes. Metabolic pathways frequently involve a series of steps, each of which is under the control of a different enzyme. Inhibition of an enzyme may lead to blocked pathways and accumulations of intermediate products. The accumulation of these products—or of the end product for that matter—may in turn stimulate or inhibit other activities.

Genes appear to be of three types: regulator, operator, and structural. Regulator genes produce a substance that represses operator genes. If operator genes are repressed, structural genes cannot function. The presence of certain metabolites, however, can inhibit the regulator genes

and thus free the operator genes to "switch on" the activity of the structural genes.

Several genetic deficiencies (and resulting enzyme deficiencies) block metabolic pathways in similar fashion; for example, if an enzyme that participates in cortisone synthesis is lacking, cortisone inhibition on the control of adrenal activity is lost, and a metabolic disease called the adrenogenital syndrome results.

Genetic homeostasis also occurs at the population level. New gene combinations provide better opportunities for adaptation to changing environmental situations. In population or community dynamics, the death of individuals is a necessity since only with new individuals may new genetic combinations occur. Populations composed of individuals most of whom are pure breeding for a given trait show less adaptability to changing conditions than do populations consisting of hybrid individuals. The greater the variation within the population, the greater its survival value.

It may be that the gradual breakdown of homeostatic stability is inherent in the genetic makeup of organisms —ensuring that death will eventually occur and clear the way for new gene combinations.

Developmental homeostasis. The control of growth and development is a biological question the answer to which—when found—may permit the slowing down or even reversal of the aging process. Aging is a testimonial to the fallibility of homeostasis. Humans grow older in an increasingly uncomfortable and degenerative manner. Eventually death occurs due to unstable homeostatic oscillations beyond the body's compensatory ability. Proposals involving homeostatic control have been advanced to explain the aging process; see AGING.

Long-term versus specific control

Developmental processes are under two kinds of regulation: long-term control, which regulates maturation from fertilized egg to senility, and specific control, which regulates the ultimate size or mass obtained by organs and tissues and stabilizes and maintains their integrity when once formed.

Maturation patterns are highly stable, although alternative pathways of development exist within the genetic makeup of individuals that permit development to continue under a variety of stressful conditions.

Long-term control is somehow exercised over mitosis—the process of cell division—a fundamental aspect of growth the controlling forces of which are not well understood. It is especially perplexing to realize that during the series of mitotic divisions an organism gradually passes through a series of states the appearance, function, and structure of which may be radically different from those of previous generations of cells.

Specific control of the size reached by an organ such as the liver may be based upon an antimitotic substance produced as a consequence of cell division, the gradual accumulation of which ultimately inhibits further cell division through negative feedback. The liver's normal size would be maintained unless injury or disease—with the accompanying reduction in level of antimitotic substance—once again stimulated growth.

The controls that regulate the growth of different tissues are usually independent of one another. Broken bones, for instance, knit without influencing the growth of the kidney. The removal of one kidney, however—and reduction of antimitotic inhibitor—results in the increase in size of the remaining kidney.

Phototropism—the turning of plants toward the light—occurs because auxin is inactivated by light. Auxin on the shaded side of plants functions normally and results in uneven growth that eventually turns plants toward the light. Similar homeostatic controls, through stimulation and inhibition by auxin concentrations, cause roots to grow downward (positive geotropism) and plant shoots to grow upright (negative geotropism).

Ecological homeostasis. Most of the homeostatic regulators in biotic communities are based on feedback controls. Predator–prey relationships are an example. The population level of the predator regulates the population density of the prey. The predator population builds up until competition for the food supply becomes intense and increased numbers of prey are consumed. With the reduced food supply, the predator population level falls—through negative feedback. Starvation and migration of the predators release the inhibiting effect, and the prey become abundant once more. Predator–prey relationships are less well defined in temperate and tropical regions because alternate food sources may be available.

A similar relationship is found in host–parasite arrangements such as fish–lamprey, dog–tapeworm, or corn plant–smut fungus. In each case the abundance of the parasite population is always directly dependent upon the abundance of the host species.

Oscillations occur routinely in populations of land animals such as rodents, rabbits, and insects. Violent oscillations normally occur only in relatively simple ecosystems (as in the Arctic) that contain a limited number of species. Periodic population crashes and die-offs frequently occur as a result of disease or crowding.

Population control

Crowding also limits the growth of many populations. Competition for a limited food supply may be a partial answer to this condition, but there also seems to be some environmental product that reduces the growth rate of many organisms in negative feedback fashion. Suppression of growth through crowding has been noted in populations of protozoans, diatoms, bacteria, water fleas, flatworms, tadpoles, fishes, and muskrats. The inhibiting substances, which in some cases are excretory products, appear to be species specific; *i.e.*, they do not affect the growth rates of other species that may be present. Spacing in terrestrial plants is under homeostatic control in much the same manner. The wide spacing of desert shrubs and trees results in part from inhibiting substances released from the roots and branches of the plants.

Behavioral patterns contribute to homeostasis. The weaving of a snake's head as it searches for a prey may be plotted as an oscillation. Burrowing, staying in the shade, or having periods of quiescence provide negative feedback to help stabilize temperature environments for animals such as insects, lizards, and snakes. Much of learning, in fact, is accomplished through feedback and adjustment, as when a bird learns its song, a horse its gaits, or a child its language.

Medical homeostasis. Hippocrates viewed health as a harmony between man, the forces within his body, and his external environment. This dynamic viewpoint of health still holds a great deal of merit today. Some investigators have suggested that many minor ailments—headaches, upset stomach, diarrhea—may be normal by-products of homeostatic adjustment taking place within the body as the organism seeks to regain its balance or harmony.

The body's response to disease is definitely a homeostatic response. Disease-causing organisms produce severe stresses, which result in oscillations. White blood cells, antibodies, lysosomes, and other defense mechanisms provide negative feedback to steer conditions back to the homeostatic plateau. Physicians may prescribe medicines or other treatment to help preserve the dynamic equilibrium of the body when a person is ill.

Homeostatic mechanisms occasionally overreact, however. Positive feedback and overshoots, resulting in overproduction of a normal body chemical, may create such conditions as rheumatoid arthritis, allergies, epilepsy, multiple sclerosis, cirrhosis of the liver, and nephritis. Cancer is a classical case of homeostasis gone astray. Normally, cell division stabilizes through negative feedback when a certain concentration of cells is reached. In cancer the inhibitors of cell division do not function adequately, and cells continue to divide.

Hunger and thirst, among many bodily needs, are under feedback control. A satiety centre in the hypothalamus influences the amount of food consumed and helps regulate the level of the sugar in the blood. If eating stops when hunger is satisfied, body weight is stabilized. The satiety centre is not in complete control, however, but is modified by other factors, since some people continue to eat long after the hunger signals have ceased.

Mental health is also under homeostatic regulation. The contributing factors include the external world, the

physiological processes of the body, and the workings of the mind and intellect. Psychology and psychiatry make use of homeostatic concepts in explaining malfunctions, overreactions, and exaggerated forms of behaviour. Feedback pressures are in operation here in the same way as in all other homeostatic situations.

HOMEOSTATIC CONTROL HIERARCHIES

The importance of circulation

In organisms. Homeostasis is attained in the organism as a whole through several ordered levels of control and subsystems. In man, circulation maintains the internal environment. The circulation system works in tandem with the renal system (kidneys) for the regulation of such things as water levels in the body. In addition, the kidneys regularly filter all of the contents from the bloodstream except the red blood cells. Most of the materials are subsequently reabsorbed into the blood, but waste materials remain in the urine and are eliminated. Hormones and other chemical substances are transported in the circulatory system and provide the feedback essential to homeostatic control.

Many muscular activities are complexly controlled. Eye movement, in particular, shows a complicated feedback mechanism of subsystems at work. Focussing involves the coordination of six major muscles for each eye, through input from the brain and semicircular canals in the inner ear.

In natural communities. Social insects such as ants and bees show a division of labour that is similar in pattern to the division of labour found in a group of multicellular organisms. In fact, a population or society of individuals may, for illustrative purposes, be considered to be a "super organism." Such an entity functions with specialized subsystems for maintenance, defense, movement, and nutrition integrated homeostatically into a whole. Similarly, several populations of animals and plants, combined into a more highly integrated system, constitute a community. Both negative and positive feedback, in the form of individual and species behavioral patterns, are involved in maintaining the overall dynamic equilibrium of the community. This large steady state is often referred to as a "web of life."

Many activities are keyed to the external environment through biological rhythms. Familiar rhythms include the heartbeat, the daily tides, seasonal changes in vegetation, and the annual migrations of birds. Less noticeable but equally important rhythms are involved in almost every facet of life.

Plant succession—the replacement of one population of plants by another—functions under homeostatic control. Succession is influenced by factors such as soil texture, moisture, temperature, and nutrients. Populations vary in their degrees of adaptation to these factors and therefore show varying degrees of success in surviving. Conditions under which a plant population may flourish change in time through the activities of the population itself until the environmental conditions become more optimal for a population other than the original one; for example, in one type of succession, shrubs replace grass and trees replace shrubs—as a result of negative feedback from self-condemning activities.

Cybernetics uses an approach similar to community analysis for the planning and management of social, governmental, and political problems. Plotting, directing, and maintaining flight in space, for example, is accomplished through these same system analysis techniques (see OPTIMIZATION, THEORY OF).

ORIGIN AND EVOLUTION OF HOMEOSTASIS

Life seems to defy the laws of physics by creating order (organisms) out of chaos (inert matter)—active, self-regulating systems out of passive, acted-upon units. The appearance of such systems can be explained by known scientific laws; it is not necessary to evoke predetermined or preordained designs.

Self-regulation is of primary evolutionary significance, since it operates for the species and the organism as well as for lesser subsystems such as enzyme concentrations. Life is thought to have first developed through chemical evolution in the oceans. The uniform physical environment provided by the seas made the regulatory systems of less importance initially. As life moved to terrestrial environments, however, the need for stable and self-regulating internal environments became fundamental for the continuation of organisms.

Even under homeostatic control, evolution shows a great deal of latitude. It is incidental whether homeostasis functions well, since efficiency of operation is not a criterion—survival is all that nature demands. Some controls are obviously more finely developed than others. The subtle interplay involved in the hormone balance of the estrus cycle is a far cry from the harsh oscillations exhibited in a predator–prey relationship. Yet the results are the same—survival of the system.

What are the limitations of homeostatic regulation, especially for man? The ultimate success or failure of the human race depends upon the adaptive abilities of homeostatic mechanisms the limits of which may already be under challenge by environmental and emotional stresses: contaminants, pollutants, food additives, and crowding. The fact that man can survive in the face of these assaults does not guarantee that the long-term effects of such stresses are harmless. And, although man himself may in time become extinct, life, in some new self-regulatory capacity, will continue.

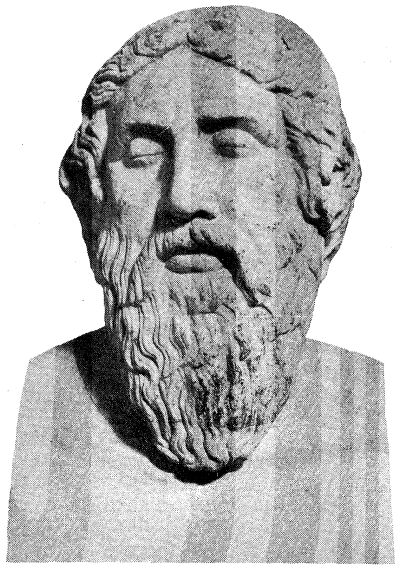
Homer

By Homer is meant the poet or poets primarily responsible for the *Iliad* and *Odyssey*, the two great epic poems of ancient Greece. Very little is known of him beyond the fact that his was the name attached by the Greeks themselves to the two great poems. The dearth of objective information about him has led to such eccentric theories as that of a German critic and philologist that the epics were in origin a kind of spontaneous emanation from the whole people, or Samuel Butler (1835–1902) that the *Odyssey* was composed by a woman. That there was an epic poet called Homer and that he played the primary part in shaping the *Iliad* and *Odyssey*—so much may be said to be probable. If this assumption is accepted, then Homer must assuredly be one of the very greatest of the world's literary artists.

Homer's influence

He is also one of the most influential in the widest sense, for the two epics provided the basis of Greek education and culture throughout the classical age and, indeed, formed the backbone of humane education down to the time of the Roman Empire and the spread of Christianity. Indirectly, through the medium of Virgil's *Aeneid* (which was loosely molded after the pattern of the *Iliad* and *Odyssey*), directly through their revival under Byzantine culture from the late 8th century AD onward, and subsequently through their passage into Italy with the Greek scholars who fled westward from the Ottomans, the Homeric epics had a profound impact on the Renais-



Homer, restored bust copied from a Greek original, *c.* 450 BC. In the Sala delle Muse, the Vatican.

sance culture of Italy. Since then the proliferation of translations has helped to make them the most important poems of the classical European tradition, valued even above the works of Virgil and Dante.

It was probably through their impact on classical Greek culture itself that the *Iliad* and *Odyssey* most subtly affected Western standards and ideas. The Greeks regarded the great epics as something more than works of literature; they knew much of them by heart and valued them not only as a symbol of Hellenic unity and heroism but also as an ancient source of moral and even practical instruction. The roots of the epic lay in the popular oral tradition, and Homer was, thus, a stumbling block for Plato when Plato tried to substitute a more rational model of behaviour for what he conceived to be the artificial histrionics of poetry.

Early references. Implicit references to Homer and quotations from the poems date back to the middle of the 7th century BC. Archilochus, Alcman, Tyrtaeus, and Callinus in the 7th century, Sappho and others in the early 6th, adapted Homeric phraseology and metre to their own purposes and rhythms. At the same time, scenes from the epics became popular in works of art. The pseudo-Homeric Hymn to Delian Apollo, probably of late-7th-century composition, claimed to be the work of "a blind man who dwells in rugged Chios," a reference to a tradition about Homer himself; and, like many others, the historian Thucydides accepted the claim. The idea that Homer had descendants known as "Homeridae," and that they had taken over the preservation and propagation of his poetry, goes back at least to the early 6th century BC. Indeed, it was not long before a kind of Homeric scholarship began: Theagenes of Rhegium in southern Italy toward the end of the same century wrote the first of many allegorizing interpretations. By the 5th century biographical fictions were well under way; the Pre-Socratic philosopher Heracleitus of Ephesus made use of a trivial legend of Homer's death—that it was caused by chagrin at not being able to solve some boys' riddle about catching lice—and the concept of a contest of quotations between Homer and Hesiod (after Homer, the most ancient of Greek poets) may have been initiated in the Sophistic tradition. The historian Herodotus, usually an inspired purveyor of exotic tales, found little to say about Homer but was commendably cautious over his date; after assigning the formulation of Greek theology to Homer and Hesiod he claimed that they could have lived no more than 400 years before his own time, the 5th century BC. This should be contrasted with the superficial idea, popular in many circles throughout antiquity, that Homer must have lived not much later than the Trojan War about which he sang.

Personal history

It is plain from these and other references that factual information about the poet (who gives little away in the epics themselves) is sadly lacking. Even his home is uncertain. The general belief that it was in Ionia (the central part of the western seaboard of Asia Minor) was a reasonable conjecture, supported by the predominantly Ionic dialect of the poems themselves. Cities like Smyrna and Chios early began competing for the honour (the poet Pindar, early in the 5th century BC, associated Homer with both), and others joined in; it is extraordinary but true that nowhere did any authenticated local memory survive of someone who, oral poet or not, must have been remarkable in his time. The absence of hard facts puzzled but did not deter the Greeks; the fictions that had begun even before the 5th century BC were developed in the Alexandrian era in the 3rd and 2nd centuries BC (when false scholarship as well as true abounded) into fantastic pseudobiographies, and these were further refined by derivative scholars under the Roman Empire. The longest to have survived purports to be by Herodotus himself; it does not scruple to assign to Homer several generations of ancestors and a detailed catalog of travels; in spite of a faintly rational tone and the elimination of Orpheus and the Nymphs from the poet's genealogy, however, this work is quite devoid of objective truth.

If the ancient tradition about Homer as a person is so feeble, what can be deduced by modern scholarship, with its wider knowledge of the history and archaeology of the Bronze Age and Early Iron Age and its ability to study the text and texture of the poems in minute detail?

Modern inferences. Modern scholars agree with the ancient sources only about Homer's general place of activity. The most promising information of the ancients was that Homer's descendants, the Homeridae, lived on the Ionic island of Chios. It is theoretically conceivable, of course, that the predominantly Ionic dialect of the poems was simply a convention of the epic tradition and was adopted by Homer for that reason. Yet an east Aegean environment is suggested for the main author of the *Iliad* by certain local references in the poem; *e.g.*, to the peak of Samothrace just appearing over the intervening mass of Imbros when seen from the plain of Troy, to the birds at the mouth of the Cayster near Ephesus, to storms off Icaria and northwest winds from Thrace. East Aegean colouring is fainter in the *Odyssey*, which is set primarily in western Greece; but the poem's vagueness over the position of Ithaca, for example, is not incompatible with the idea of a poet in Ionia elaborating materials derived from the farther side of the Greek world.

Admittedly, there is some doubt over whether the *Iliad* and *Odyssey* were even composed by the same main author. Such doubts began in antiquity itself and depended heavily on the difference of genre (the *Iliad* being martial and heroic, the *Odyssey* picaresque and often fantastic); but they may be reinforced by subtle differences of vocabulary, even apart from those imposed by different subjects. Aristotle's conception of the *Odyssey* as a work of Homer's old age is not impossible; but if the *Iliad* is the earlier of the two (as seems likely from its simpler structure and the greater frequency of relatively late linguistic forms in the *Odyssey*), then the *Odyssey* could have been created after its image, and as a conscious supplement, once the example of monumental composition had been given. In this case the similarities of the two poems could be partly due to the coherence of the heroic poetical tradition that lay behind both. The possibilities are manifold; but at least one can nowadays avoid some of the greater implausibilities of the "Higher Criticism" and the old "Homeric Question" and can reasonably conclude that there *was* a major poet called Homer, that he was an Ionian, that he was substantially the composer of the *Iliad*, and that, whether or not it was directly his work, he was at the very least the inspirer of the *Odyssey*. One other important point about him will be expanded later: that he was an "oral poet," one who lived toward the end of a long line of singers who sang their poems to the ac-

companiment of the kithara, or lyre, and developed a mass of heroic poetry, much of it touching upon the Trojan War, without the use of writing.

Date of the epics

The internal evidence of the poems is of some use in determining when Homer lived. Certain elements of the poetic language, which was an artificial amalgam never exactly reproduced in speech, indicate that the epics were not only post-Mycenaean in composition (that is, later than the end of the Bronze Age around 1100 BC) but also substantially later than the foundation of the first Ionian settlements around 1000 BC. The running together of adjacent short vowels and the disappearance of the semivowel digamma (a letter formerly existing in the Greek alphabet) are the most significant indications of this. At the other end of the time scale the development in the poems of a true definite article, for instance, represents an earlier phase than is exemplified in the poetry of the middle and late 7th century. Both stylistically and metrically, the Homeric poems appear to be earlier than the Hesiodic poems, which many scholars place not long after 700 BC. A different and perhaps more precise criterion is provided by datable objects and practices mentioned in the poems. Nothing, except for one or two probably Athenian additions, seems from this standpoint to be later than around 700; on the other hand, the role assigned in the *Odyssey* to the Phoenicians as traders, together with one or two other phenomena, suggests a date of composition—for the relevant contexts at least—of after 900. A few passages in the *Iliad* may imply a new form of fighting in close formation, dependent on the development of special armour for the foot soldiers (hoplites) after about 750; and references to the Gorgon mask as a decorative motif point in the same direction. It is true that the poems do contain many traditional and archaic elements, and their language and material background are a compound of different constituents originating at different dates. Nonetheless, it seems plausible to conclude that the period of composition of the large-scale epics (as distinct from their much shorter predecessors) was the 9th or 8th century, with several features pointing more clearly to the 8th. The *Odyssey* may belong near the end of this century, the *Iliad* closer to its middle. It may be no coincidence that cults of Homeric heroes tended to spring up toward the end of this same 8th century, and that scenes from the epic begin to appear on pots at just about the same time.

Homer as an oral poet. But even if his name is known and his date and region can be inferred, Homer remains primarily a projection of the great poems themselves. Their qualities are significant of his taste and his view of the world, both as an individual and as heir to the heroic tradition, but they also reveal something more specific about his technique and the kind of poet he was. It has been one of the most important discoveries of Homeric scholarship, associated particularly with the name of an American scholar, Milman Parry (1902–35), that the Homeric tradition was an oral one—that this was a kind of poetry made and passed down by word of mouth, without the intervention of writing. Indeed Homer's own term for a poet is *aoidos*, "singer." The *Odyssey* describes two such poets in some detail: Phemius, the court singer in the palace of Odysseus in Ithaca, and Demodocus, who lived in the town of the semi-mythical Phaeacians and sang both for the nobles in Alcinous' palace and for the assembled public at the games held for Odysseus. On this occasion he sings of the illicit love affair of Ares and Aphrodite in a version that lasts for exactly 100 Homeric verses. This and the other songs assigned to these singers —for example, that of the Trojan Horse, summarized in the *Odyssey*—suggest that ordinary *aoidoi* in the heroic tradition worked with relatively short poems that could be given complete on a single occasion. That is what one would expect, and it is confirmed by the habits of singers and audiences at other periods and in other parts of the world (the tradition of the poet-singers of Muslim Serbia has provided the most fruitful comparison so far). Whatever the favoured occasion for heroic song—whether the aristocratic feast, the religious festival, or popular gatherings in tavern or marketplace—a natural limitation on the length of a poem is imposed by the audience's available time and interest as well as by the singer's own physique and the scope of his repertoire. Such relatively short songs must have provided the backbone of the tradition inherited by Homer, and his portraits of Demodocus and Phemius are likely to be accurate in this respect. What Homer himself seems to have done is to introduce the concept of a quite different style of poetry, in the shape of a monumental poem that required more than a single hour or evening to sing and could achieve new and more complex effects, in literary and psychological terms, than those attainable in the more anecdotal songs of his predecessors.

Poetry sung by the *aoidos*

Poetic techniques. How can one be so confident in classing Homer himself as an oral singer? If he differed from Phemius or Demodocus in terms of length, may he not also have differed radically in his poetic techniques? The very nature of his verse may provide a substantial part of the answer. The style of the poems is "formulaic"; that is, they rely heavily on the use not only of stock epithets and repeated verses or groups of verses—which can also be found to a much lesser extent in a literate imitator like Virgil—but also on a multitude of fixed phrases that are employed time and time again, with occasional minor adjustments, to express a similar idea in a similar part of the verse. The clearest and simplest instance is the so-called noun-epithet formulas. These constitute a veritable system, in which every major god or hero possesses a variety of epithets from which the choice is made solely according to how much of the verse, and which part of it, the singer desires to use up. Odysseus is called divine Odysseus, many-counselled Odysseus, or much-enduring divine Odysseus simply in accordance with the amount of material to be fitted into the remainder of the hexameter (six-foot) verse. A ship is described as black, hollow, or symmetrical not to distinguish this particular ship from others but solely in relation to the qualities of the rhythmical context. The whole noun-epithet system is both extensive and economical—it covers a great variety of subjects with almost no exact reduplication or unnecessary overlap. It would seem that so refined and complex a system could not be the invention of a single poet but must have been gradually evolved in a long-standing tradition that needed both the extension and the economy for functional reasons—that depended on these fixed phrase-units because of its oral nature, in which memory and improvising replace the deliberate, self-correcting, word-by-word progress of the pen-and-paper composer. Admittedly, the rest of Homer's vocabulary is not as markedly formulaic as its noun-epithet aspect (or, another popular example, as its expressions for beginning and ending a speech). Many expressions, many portions of sentences are individually invented for the occasion, or at least so it seems. Even so, there is a strongly formulaic and ready-made component in the artificial language that was used by Homer, including its less conspicuous aspects such as the arrangement of particles, conjunctions, and pronouns.

The monumental poem

It looks, therefore, as though Homer must have trained as an ordinary *aoidos*, who began (like most of the present-day Yugoslav *guslars*) by building up a repertoire of normal-length songs acquired from already established singers. The greatest heroic adventures of the past must already have been prominent in any repertoire, especially the Panhellenic adventures of the Seven against Thebes, the Argonauts, and the Achaean attack on Troy. Some aspects of the Trojan War might already have been expanded into songs of unusual length, though one that was still manageable on a single occasion. Yet the process was presumably carried much further in the making of the monumental *Iliad*, consisting of over 16,000 verses, which would take four long evenings, and perhaps more, to perform. This breakthrough into the monumental, which made exceptional and almost unreasonable demands of audiences, presupposes a singer of quite exceptional capacity and reputation—one who could *impose* the new and essentially nonfunctional concept upon his audiences by the sheer unfamiliar genius of his song. The 8th century BC was in other respects, too, an era of cultural in-

novation, not least in the direction of monumentality; and huge temples (like the early temple of Hera in Samos) and colossal funerary vases (like the mixing bowls and amphoras in the so-called Geometric style from the Dipylon cemetery in Athens) may have found a literary analogue in the idea of a vast poetical treatment of the Trojan War. But in an important sense, Homer was merely extending a tendency of all known oral heroic poetry toward elaboration and expansion. The singer does not acquire a song from another singer by simple memorization. He adjusts what he hears to his existing store of phrases, typical scenes, and themes, and he tends to replace what is unfamiliar to him with something he already knows, or to expand it by adding familiar material that it happens to lack. Every singer in a living oral tradition tends to develop what he acquires. There is an element of improvisation, as well as of memory, in his appropriation of fresh material; and judging by the practice of singers studied from the middle of the last century onward in Russia, Yugoslavia, Cyprus, and Crete the inclination to adjust, elaborate, and improve comes naturally to all oral poets.

Typical elements of an oral poem

Cumulative poetic structure. Homer must have decided to elaborate his materials not only in quality but also in length and complexity. All oral poetry is cumulative in essence; the verse is built up by adding phrase upon phrase, the individual description by adding verse upon verse. The whole plot of a song consists of the progressive accumulation of minor motifs and major themes, from simple ideas like "the hero sets off on a journey"—or "addresses his enemy"—through typical scenes like assemblies of men or gods to developed but standardized thematic complexes like scenes of recognition or reconciliation. Homer seems to have carried this cumulative tendency into new regions; in this as in other respects (for example, in his poetical language) he was applying his own individual vision to the fertile raw material of an extensive and well-known tradition.

The result is even more complex than with an ordinary traditional poem. Understanding the origin and essential qualities of the *Iliad* or *Odyssey* entails trying to sort out not only the separate components of the pre-Homeric tradition but also Homer's own probable contributions, whether distinguishable by their dependence on the specifically monumental structure or by their apparent novelty vis-à-vis the tradition as a whole or by other means. Dialectal and linguistic components must be identified as far as possible—for example, survivals of the Mycenaean language, words used exclusively in the Aeolian cities of the west coast of Asia Minor, or Athenian dialect forms introduced into the poems after the time of Homer; so must details of armour, clothing, houses, burial customs, political geography, and so on, that are likely to be assignable to the Late Bronze Age, the Early Iron Age, or the period of Homer's own activity —at the very least as relatively early or late within the whole range of the poetic tradition down to Homer. These are the tasks of modern Homeric scholarship. Yet such different forms and ideas in Homer are not conveniently separated into distinct sections of the text, which can therefore be assigned to early or late phases of composition. On the contrary, they may co-exist in a single (artificial) linguistic form or a single descriptive phrase. Any member of the tradition, not least Homer himself, may, moreover, have chosen to archaize on one occasion, to innovate on another. One result is that the epics are dubious and equivocal authorities for the reconstruction of historical realities like the attack on Troy or the status of workpeople, just as they are ambiguous source books for early Greek grammar or theology. Another is that they are timeless, generic, not bound to a single world view or period or mode of perception; rather, they have taken on a quality that is genuinely mythic, that unites judgments and experiences never seen together in "real" life into a whole that is literary but nevertheless almost traumatically revealing of the underlying structure of human existence.

Stabilizing the text. An important and difficult question, which affects the accuracy of modern Homeric texts, is that of the date when the epics became really "fixed"—which means reduced to authoritative written form, since oral transmission is always to some extent fluid. An alphabetic writing system reached Greece in the 9th or early 8th century BC; before that was a gap of 200 or 300 years, following the collapse of Mycenaean culture and the disappearance of Linear B (writing with each sign generally representing a syllable), during which Greece seems to have been nonliterate. During that gap, certainly, much of the epic tradition was formed. The earliest alphabetic inscriptions to have survived, a few of them containing brief scraps of hexameter verse, date from around 730 BC onward. Therefore, if Homer created the *Iliad* at some time after 750 BC, he could conceivably have used writing to help him. Some scholars think that he did. Others believe that he may have remained nonliterate (since literacy is not normally associated with oral creativity) but dictated the poem to a literate assistant. Still others believe that the poems may have been preserved orally and not too inaccurately at least until the middle years of the following, the 7th, century, when "literature" in the strict sense appeared in the poetry of Archilochus. There are objections to all three theories, but this much can be generally agreed: that the use of writing was at all events ancillary, that Homer behaved for the most part like a traditional oral poet. Some scholars are convinced that certain of the more subtle effects and cross-references of Homer's poetry would be impossible without the ability to consult a written text. That is doubtful; certainly the capacities even of ordinary oral poets in this direction are constantly surprising to habitual literates.

At least it may be accepted that partial texts of the epics were probably being used by the Homeridae and by professional reciters known as rhapsodes (who were no longer creative and had abandoned the use of the lyre) by the latter part of the 7th century BC. The first *complete* version may well have been that established as a standard for rhapsodic competitions at the great four-yearly festivals at Athens, the Panathenaea, at some time during the 6th century BC. Even that did not permanently fix the text, and from then on the history of the epics was one of periodical distortion followed by progressively more effective acts of stabilization. The most important of these (apart from the widespread dissemination following the growth of the Athenian book trade in the 5th century and the proliferation of libraries after the 4th) were due to the critical work of the Alexandrian scholar Aristarchus of Samothrace in the 2nd century BC, and much later to the propagation of accurate minuscule texts (notably the famous manuscript known as Venetus A of the *Iliad*), incorporating the best results of Greco-Roman scholarship, in the Byzantine world of the Middle Ages. Rare portions of either poem may have been added after, but not long after, the main act of composition: the night expedition that results in the capture of the Trojan spy Dolon and that fills the 10th book of the *Iliad*, some of the underworld scenes in the 11th book of the *Odyssey*, and much of the ending of the *Odyssey* after line 296 of the 23rd book (regarded by Aristarchus as its original conclusion) —these are the most probable candidates on the grounds of structure, language, and style.

Even apart from the possibilities of medium-scale elaboration, the *Iliad* and *Odyssey* exemplify certain of the minor inconsistencies of all oral poetry, and occasionally the composer's amalgamation of traditional material into a large-scale structure shows through. Yet the overriding impression is one of powerful unity.

The story of the *Iliad*

The Iliad. Not only a distillation of the whole protracted war against Troy, the *Iliad* is at the same time an exploration of the heroic ideal in all its self-contradictoriness—its insane and grasping pride, its magnificent but animal strength, its ultimate if obtuse humanity. The poem is, in truth, the story of the wrath of Achilles, the greatest warrior, that is announced in its very first words; yet for thousands of verses on end Achilles is an unseen and unmentioned presence as he broods among his Myrmidons, waiting for Zeus's promise to be fulfilled—the promise that the Trojans will fire the Achaean ships and

force King Agamemnon to beg him to return to the fight. Much of the poetry between the first book, in which the quarrel flares up, and the 16th, in which Achilles makes the crucial concession of allowing his friend Patroclus to fight on his behalf, consists of long but subtly distinct scenes of battle. Moreover it is carefully punctuated by highly individualized episodes and set pieces: the catalog of troop contingents, the duels between Paris and Menelaus and Ajax and Hector, Helen's identifying of the Achaean princes, Agamemnon inspecting his troops, the triumph of Diomedes, Hector's famous meeting back in Troy with his wife Andromache, the building of the Achaean wall, the unsuccessful embassy to Achilles, the night expedition, Hera's seduction of Zeus and Poseidon's subsequent invigoration of the Achaeans. Patroclus' death two-thirds of the way through the poem brings Achilles back into the fight, although not before the recovery of Patroclus' body, the making of new divine armour for Achilles, and his formal reconciliation with Agamemnon. In book 22 he kills the deluded Hector; next he corroborates his heroic status by means of the funeral games for Patroclus; and in the concluding book Achilles is compelled by the gods to restore civilized values and his own magnanimity by surrendering Hector's body to King Priam.

The Odyssey. The *Odyssey* tends to be blander in expression and less vigorous in the progress of the action, but it presents an even more complex and harmonious structure than the *Iliad*.

The story of the *Odyssey*

The main elements are the situation in Ithaca, where Penelope and the young Telemachus are powerless before her arrogant suitors as they despair of Odysseus' return; Telemachus' secret journey to the Peloponnese for news of his father, and his encounters there with Nestor, Menelaus, and Helen; Odysseus' dangerous passage from Calypso's island to that of the Phaeacians, and his narrative there (from book 9 to book 12) of his previous adventures after leaving Troy; his arrival back in Ithaca at the poem's halfway point, followed by his elaborate disguises, his self-revelation to the faithful swineherd Eumaeus and then to Telemachus, their complicated plan for disposing of the suitors, and its gory fulfillment. Finally comes the recognition by his faithful Penelope.

Homer's influence seems to have been at its strongest in some of the most conspicuous formal components of the poems. The participation of the gods in human events confers, at different times, lightness, severity, or universality; it must for long have been part of the heroic tradition, but the frequency and the richness of the divine assemblies in the *Iliad*, or the peculiarly personal and ambivalent relationship between Odysseus and Athena in the *Odyssey*, probably reflect the taste and capacity of the main composer. The manysidedness of battle, the equivocal realism of death in a hundred forms, must have been developed among Homer's predecessors but can never before have been deployed with such massive and complex effect. In the extended similes the strain of heroic action is relieved by the illuminating intrusion of a quite different and often peaceful contemporary world, in images developed for a moment gratuitously and almost longingly beyond the immediate point of comparison. These similes, in their placing and their profusion at least, surely depend on the main composer. And yet, beyond such general intuitions as these, the attempt to isolate his special contributions often becomes self-defeating. The *Iliad* and *Odyssey* owe their unique status precisely to the almost spiritual and therefore unanalyzable confluence of tradition and design, the generic and the particular, the divine or heroic and the intensely human, the crystalline fixity of a formulaic style and the mobile spontaneity of a brilliant personal vision. "Homer" implies, above all, this fusion.

Homer, Winslow

One of the most important of all American artists, Winslow Homer is especially admired for his brilliant watercolours and paintings of the sea. He combined exceptional technical ability with a rare sense of colour, texture, and design. His subjects, often deceptively simple on the surface, dealt in their most serious moments with the theme of man's efforts to establish his humanness in the face of an indifferent universe.

Homer was born on February 24, 1836, in Boston, to an old New England family. When he was six, the family moved across the Charles River to Cambridge, then a rural village, where he enjoyed a happy country childhood. His artistic inclinations were encouraged by his mother, an amateur painter. When he was 19, he was apprenticed to the lithographic firm of John Bufford in Boston. At first, most of his work involved copying the designs of other artists, but within a few years he was submitting his own drawings for publication in such periodicals as *Ballou's Pictorial* and *Harper's Weekly*. In 1859 Homer moved from Boston to New York to begin a career as a free-lance illustrator. The following year he exhibited his first paintings at the National Academy of Design.

Civil War drawings

With the outbreak of the Civil War, Homer made drawings at the front for *Harper's*, but unlike most artist-correspondents his scenes dealt more often with everyday camp life than fighting. As the war dragged on, he concentrated increasingly on painting. In 1865 he was elected to the National Academy of Design. Admirably capturing the dominant national mood of reconciliation, his "Prisoners from the Front" was warmly received when exhibited at the academy shortly after the war ended.

Although Homer's studio was in New York City, the city was rarely his theme. During the warm months he travelled to Pennsylvania, the Hudson River Valley, and New England, camping, hunting, fishing, and sketching. In 1866 he went to France for about a year. Although influenced by French Naturalism, Japanese prints, and contemporary fashion illustration, his work after his return to America did not change markedly, except that the pictures were generally somewhat brighter. Such early pictures as "Snap the Whip" and "Long Branch, New Jersey" depict happy scenes, the former of children frolicking in a meadow after school and the latter of fashionable ladies promenading along the seashore. In a few early pictures a disquieting note of human isolation is struck, premonitory of Homer's later, more powerful work.

In 1873 Homer began to work in watercolour, which allowed him to make rapid, fresh observations of nature. In this demanding medium he explored and resolved new artistic problems, and paintings of the next few years, such as "Breezing Up," reflect the invigorating effect of the watercolours.

Winslow Homer matured slowly as an artist, but his development was constant. With the passage of years his oil paintings became larger, his figures more solitary, his concern for naturalistic detail greater. He painted many

women, increasingly as single figures, intimate, withdrawn, feminine. From the late 1870s Homer began to devote his summers exclusively to direct painting from nature in watercolour. Greater concern for atmospheric effects and reflected light added complexity to the images but at the same time enabled him to achieve greater pictorial unity.

Although Homer received some recognition during his early years, he had not had any real success by midcareer. By 1880 he began to show signs of increasing antisociality, deliberately shunning the company of other people. In 1881 he unexpectedly went to England, where he spent about two years sketching and painting in Tynemouth, a remote fishing port on the North Sea. Here, at the age of 45, his period of greatest artistic growth began. He was intrigued by the life of the hardy fisherfolk of Tynemouth, who struggled against the sea to earn their livelihood, but he did not paint that struggle directly. He depicted instead the robust and courageous women of Tynemouth, who mended the nets, kept house, and waited for their men to return from the sea. The English coastal atmosphere posed a new and difficult artistic challenge, but Homer mastered the diffused light, limited in colour but infinitely varied in tone, in a series of subtle watercolours.

Period of greatest artistic growth

After Homer's return to America in 1883, the sea became the dominant theme in his work. He moved to Prouts Neck, a fishing village on the bleak, desolate coast of Maine. He travelled extensively but always returned to his Prouts Neck studio, with its large balcony facing the sea like the bridge of a ship, to convert his sketches into major paintings. Solitude became for Homer not simply a preference but an absolute necessity, as he turned his mind and his art to subjects dealing with man's fate in confronting the elemental forces of nature.

In the summer of 1883 Homer saw a demonstration in Atlantic City of the use of a breeches buoy for rescue from the sea. The following year he painted his large, impressive, and immediately popular painting "The Life Line," one of several he did at this time on the rescue theme, depicting the dramatic transfer of an unconscious female from a wrecked ship to shore.

Seascape paintings

During the next few years, Homer's interest shifted from the edge of the sea to the sea itself. Perhaps inspired by a putative trip to the Grand Banks of Newfoundland with a fishing fleet, he painted heroic men in the act of pitting their strength, intelligence, and experience against the mighty sea. In the most impressive of these works, "Fog Warning," night is falling, fog is rolling in, and a lone fisherman in a dory calculates the distance and the time remaining for him to get back to his home ship in safety. Although the monumental narrative paintings Homer produced in his studio in the mid-1880s lack the freshness of his earlier works, Homer simultaneously painted innumerable brilliantly coloured watercolours during his travels north to Canada and south to the Caribbean.

While Homer's fishermen and their women are heroic in their confrontations with the physical world, the artist occasionally took a more jaundiced view of his fellowman. In "Huntsman and Dogs" of 1891, set in a cheerless autumnal landscape, a sullen-faced young hunter, pausing on a hillside levelled by timbering and blackened by fire, epitomizes man as a despoiler of nature, killing for trophies rather than food.

Homer abandoned the human subject entirely in "The Fox Hunt" of 1893. A fox ventures forth to forage for berries on the snow-covered land, and a sinister line of starved black crows converges to attack him. The ensuing life-and-death struggle will be over quickly, but the pulse of nature that drives the winter ocean against the cliffs in the distance will go on forever. "Northeaster" (1895) distills this theme, and only the viewer witnesses the endless struggle between the irresistible sea and the immovable rocky shore. In "Northeaster," Homer successfully wedded the freshness of his watercolours to the power of his oils to achieve an impressive pictorial effect that, as in many of his later works, transcends the subject matter.

"The Gulf Stream" (1899) stands at the apex of Homer's career. A black man lies inert on the deck of a small sailboat. A hurricane has shredded the sails, snapped off the mast, and snatched away the rudder. Unlike the boys in "Breezing Up" or the fisherman in "Fog Warning," this man is powerless to control his vessel. He is at the mercy of the elements. Sharks circle the boat, a waterspout hovers in the distance, and a boat on the distant horizon passes by unseeing and unseen. As in Stephen Crane's comparable short story, *The Open Boat*, nature is seen as not caring whether a man lives or dies.

Homer, ever more crusty and isolated in his old age, continued to paint vigorously and adventurously through the first decade of the 20th century. Similar in subject matter to his earlier work, although with more emphasis on pure seascape, his late paintings, in their unconventional composition and brilliant colour, reflect increasing concern with the abstract and expressive possibilities of art. Homer died in his Prouts Neck studio on September 29, 1910. Although by the 1890s he had become generally recognized as one of the leading American painters, and his work brought top prices, his passing was but briefly noted, and appreciation of his artistic achievement came only in the years following his death.

MAJOR WORKS

PAINTINGS IN OIL: "Pitching Quoits" (1865; Fogg Art Museum, Cambridge, Massachusetts); "Prisoners from the Front" (1866; Metropolitan Museum of Art, New York); "Croquet Scene" (1866; Art Institute of Chicago); "The Bridle Path, White Mountains" (1868; Sterling and Francine Clark Art Institute, Williamstown, Massachusetts); "Long Branch, New Jersey" (1869; Museum of Fine Arts, Boston); "High Tide" (1870; Metropolitan Museum of Art, New York); "The Country School" (1871; City Art Museum, St. Louis, Missouri); "Snap the Whip" (1872; Butler Institute of American Art, Youngstown, Ohio); "Breezing Up," or "A Fair Wind" (1876; National Gallery of Art, Washington, D.C.); "The Gale" (1883, repainted 1893; Worcester Art Museum, Massachusetts); "The Life Line" (1884; Philadelphia Museum of Art); "Fog Warning" (1885; Museum of Fine Arts, Boston); "The Herring Net" (1885; Art Institute of Chicago); "Eight Bells" (1886; Addison Gallery of American Art, Andover, Massachusetts); "Huntsman and Dogs" (1891; Philadelphia Museum of Art); "Northeaster" (1895; Metropolitan Museum of Art, New York); "The Lookout—'All's Well'" (1896; Museum of Fine Arts, Boston); "The Gulf Stream" (1899; Metropolitan Museum of Art, New York); "Huntsman and Dogs" (1891; Philadelphia Museum of Art); "West Point Prouts Neck" (1900; Clark Art Institute, Williamstown, Massachusetts); "Searchlight Harbor Entrance, Santiago de Cuba" (1901; Metropolitan Museum of Art, New York); "Early Morning After a Storm at Sea" (1902; Cleveland Museum of Art).

PAINTINGS IN WATERCOLOUR: "Fresh Air" (1878; Brooklyn Museum, New York); "Gloucester Harbor and Dory" (1880?; Fogg Art Museum, Cambridge, Massachusetts); "The Green Dory" (1880?; Museum of Fine Arts, Boston); "Inside the Bar, Tynemouth" (1883; Metropolitan Museum of Art, New York); "Tynemouth" (1883; Fogg Art Museum, Cambridge, Massachusetts); "Conch Divers" (1885; Minneapolis Institute of Arts, Minnesota); "Shark Fishing" (1885; private collection, New York); "Street Scene, Santiago, Cuba" (1885; Philadelphia Museum of Art); "After the Hunt" (1892; Los Angeles County Museum of Art); "Adirondacks" (1892; Fogg Art Museum, Cambridge, Massachusetts); "The Adirondack Guide" (Museum of Fine Arts, Boston); "The Turtle Pound" (1898; Brooklyn Museum, New York); "After the Hurricane, Bahamas" (1899; Art Institute of Chicago).

Hominidae

Hominidae (superfamily Hominoidea, infraorder Anthropoidea, order Primates) is the taxonomic family to which man (*Homo sapiens*) belongs. *Homo sapiens* is the sole genus and species of living primates included in the family Hominidae. The Hominidae also include extinct populations or lineages of primates known only from fossil remains. At least three genera usually are recognized: *Ramapithecus*, a late Miocene–Pliocene genus; *Australopithecus*, a Pleistocene form; and *Homo*, a Pleistocene–Recent form. The living species *Homo sapiens* is, perhaps, the most successful mammalian species to have evolved. It is highly variable and exhibits much greater sexual dimorphism than do most other primates. Since the days of Charles Darwin (1809–1882) it has been clear that *Homo sapiens* is a zoological object, an animal that reached its present biological status through genetic mutation, natural selection, and adaptation to changing environments on earth. These processes characterize the evolution of all other living species. The most generally accepted and the most empirically plausible thesis is that man and the extinct Hominidae are part of a natural unit of quite closely related animals, the mammalian order Primates. In view of the evidence, the formerly sacrosanct opinion that man is a unique, separate creation sharply waned, many religious leaders endorsing the evolutionary interpretation.

In the not too distant past it was believed a tenable hypothesis that Hominidae, containing only *Homo sapiens*, was a taxonomic entity of considerably higher rank in the Linnaean hierarchy than that of a taxonomic family. According to this hypothesis, ancestors of *Homo sapiens* were a lineage that had evolved separately since the earliest differentiation of the primates, stemming directly from a tarsier-like prosimian of the Eocene Epoch. This is no longer considered tenable, particularly since the fossil record suggests that the Pongidae (anthropoid apes) and the Hominidae had a common ancestor no later than the Oligocene Epoch or early Miocene (roughly 30,000,000 years ago) and that each was clearly distinct by late Miocene times (perhaps 15,000,000 years ago).

Difficulties in classifying man and other hominids

Difficulties in interpreting the evolutionary history of the Hominidae largely stem from attitudes conditioned by the more traditional studies of human variation. *Homo sapiens* ranges from less than four feet tall among so-called Pygmies of Africa and some islands of East Asia, to almost seven feet among some residents of Central Africa, northern Europe, and North America. Fossil Hominidae were smaller than most living men; australopithecines were probably under five feet tall, although some were massively built. Variability in stature is matched to some extent in modern man by that of other features, such as pigmentation or shape of nose.

Homo sapiens is extraordinarily egocentric and finds fossil hominids almost as fascinating as his living fellows. Every little variation among members of his species is given weighty consideration by some scholar. One trait excessively emphasized in attempts to classify *Homo sapiens* is skin colour. Considerable variation is found as well in eye colour, hair colour and form, and skull form. All, and more, have been used to define or describe subspecies or races of man. At least 15 subspecies of *Homo sapiens* have been proposed formally since the days of Linnaeus, and many more informally.

No wonder, then, that differences in teeth, jaws, and skulls among primate fossils were treated as generic, familial, and even superfamilial distinctions. Many such fossils, only now being related to the ancestral lineage from which pongids and hominids diverged, were left to languish in taxa that suggested no relationship at all to the Hominidae. Several fossils now referable to the Hominidae were placed in the lineage of living anthropoid apes, being given generic status within the Dryopithecinae (family Pongidae, superfamily Hominoidea). William King Gregory seems to have been the only investigator of the first half of the 20th century to suspect something amiss, stating that the ancestors of modern man would be found within that group.

Homo sapiens occupies every environment on the planet: windy, cold, desolate Tierra del Fuego; the high Andes; the frigid Arctic; the deserts of Africa; the steppes of Central Asia; the humid, hot, tropical rain forests; the temperate climates of Europe and North America. Antarctica appears to be the only major land mass on which *Homo sapiens* did not live until recently.

Hominid age, distribution, and abundance

Ancient Hominidae also were widely distributed; fossil hominids from 1,000,000 to 5,000,000 years old are found in South Africa, East Africa, North Africa, and Asia. The Dryopithecinae, related to the common ancestor of Pongidae and Hominidae, also are found widely distributed in the Old World. Hominids of between 600,000 and 800,000 years ago lived in northern Europe where the climate was particularly rigorous as well as in the more hospitable regions of Asia and Africa. The hominid genus *Ramapithecus* has been found in Africa and India. Several authorities accept evidence that dates *Ramapithecus* as at least 14,000,000 years old, suggesting that species of the Hominidae in their earliest forms were widely distributed over the Eurasian–African land mass. They apparently did not penetrate the New World, however, until less than 100,000 years ago, well after the most modern form of *Homo sapiens* developed.

Australopithecine fossil fragments found in southern and eastern Africa as well as those from North and Central Africa and Asia constituted several hundred individuals by the 1970s. At least 200 examples of later fossil Hominidae were known, sometimes colloquially called Peking man, Java man, and Neanderthal man (all quite referable to the species *Homo sapiens*). The distribution and number of fossil fragments suggest that the Hominidae, although not excessively abundant until recently, were present over most of the major land masses of the Old World and attained respectable population size. Rather fragmentary remains of *Ramapithecus* from East Africa and India support the view that hominids were widely distributed as early as the late Miocene.

Unsettled problems in classification

Controversy on the number of genera and species within the Hominidae continued in the 1970s. The usual position—that Hominidae consist of the genera *Ramapithecus*, *Australopithecus*, and *Homo*—has been noted above. A more conservative interpretation favoured including the genus *Paranthropus*, an australopithecine. A more radical view was to eliminate the genus *Australopithecus*, placing both *Australopithecus* and *Paranthropus* in the genus *Homo*.

PHYSIOLOGICAL AND BIOLOGICAL CHARACTERISTICS

Body structure. Skeleton and musculature among hominids are adapted for erect posture, bipedal gait, and extreme functional differentiation of the limbs. The hand of the forelimb is uniquely suited for grasping and for very fine, skillful manipulation. The hindlimb's foot is a pedestal for the weight of the body, the foot and leg together providing a strong propulsive lever for such activities as walking, standing, running, and ballet dancing.

Orthograde posture. Orthograde (upright) posture is common to all Primates. While man is an erect biped, all other living primates are best characterized as orthograde quadrupeds. Similarities in the structure of the trunk found among Primates are likely the result of this upright posture, a fundamental characteristic of all members of the order. Orthograde posture is habitually assumed by even the most primitive of Primates but has been so refined in mature humans that erect posture is the only one normally taken. Far too little is yet known of the postcranial skeletons of the earliest hominids to estimate how long almost wholly erect posture has been a trait of the Hominidae. The existing evidence suggests that australopithecines were essentially erect, their immediate predecessors having been well on the way to upright posture. Alternative views have been based on differing interpretations of the fragmentary skeletal remains of a single foot from the australopithecine deposit at Olduvai Gorge, Tanzania.

Bipedal locomotion. Hominidae are distinguished by evolutionary trends that are particularly evident in progressive modifications of the skeleton for erect posture and bipedal gait. The most significant include proportionate lengthening of the lower extremity and changes in proportion and in morphological details of the pelvis, femur, and foot (Figures 1 and 2). All are related to the mechanical requirements of bipedal locomotion.

From J. Buettner-Janusch, *The Origins of Man* (1966); John Wiley & Sons, Inc.

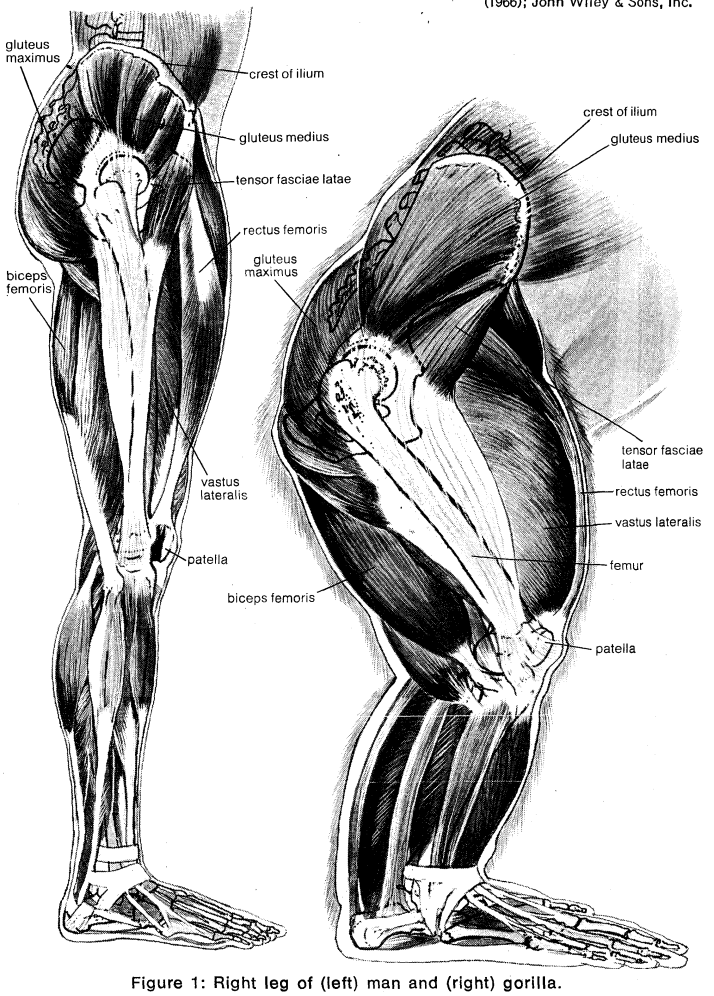

Figure 1: Right leg of (left) man and (right) gorilla.

The hominid pelvis includes at least three bones (ilium, ischium, and pubis) that mirror evolutionary change. The form of the pelvis in man is a functional compromise that permits erect and stable bipedal locomotion, providing support to keep the trunk from falling backward when one stands upright. Including a birth canal adequate for the large-brained human fetus, pelvic structure also serves to support a variety of viscera.

The earliest bipedal hominid seems to have been *Australopithecus*, on the basis of inferences from several well-preserved pelvic fragments and an almost intact fossil pelvis. Australopithecine pelvic and limb bones differ from those of *Homo* in their relationships among several anatomical landmarks, exhibiting forward prolongation in the region of the anterior superior spine of the ilium and a relatively small sacroiliac surface. The australopithecine ischial tuberosity is usually low, and there is a marked forward prolongation of the intercondylar notch of the femur (see SKELETAL SYSTEM, HUMAN).

Inferences from pelvic bones

Analyses of australopithecine and modern human pelvises allow us to postulate evolutionary changes that led to bipedalism: the ilium became shortened and bent back on the ischium; the angle between ilium and ischium grew smaller. Such bone changes seem to have been part of a process that brought the gluteus maximus muscle behind the hip joint and made it a powerful extensor of the leg.

Although many postural and locomotor demands have been met, the human pelvis is not the efficient structure an engineer might design. Many disorders in man arise from incomplete adaptation of the back and pelvic girdle to erect bipedalism. The lumbosacral region of the spine is structurally weak, and mechanical strains will produce such severe ailments as herniated intervertebral disks and spondylolisthesis (forward displacement of individual vertebrae) and less severe, but common, chronic lower back pain.

Efforts to trace the evolution of gait and posture among the Hominidae face the critical question of whether the australopithecine pelvis is that of a hominid or more like that of a pongid. At least one characteristic of australopithecine pelvic remains is clearly hominid—the ilium is bent back, shortened, and broadened so that the iliac blade has the characteristics expected of a pelvis that is part of the bipedal complex. Investigators who favour the view that the earliest known hominid pelvis is that of the australopithecines are well aware that it is not exactly like that of the contemporary hominid pelvis in other respects. It is the major functional change, however, that assumes significance in attempts to reconstruct the past.

Inferences from bones of the foot

The foot is essential in the locomotor adaptation of the Hominidae. Structural modifications of the ancestral prehensile primate foot produced man's plantigrade platform; *i.e.*, sole and heel both touch the ground. The foot of erect bipedal man must completely support the body and be strong enough to lift the load by its lever action. Specializations that permit this include the shape of the arch and the position and robustness of the big toe. Bones associated with the lever action of the foot are in such proportion that they provide support adequate to man's unique walk; man strides. In striding, the repeated sequence in which the foot bears the weight is heel, lateral edge of the foot, big toe. The big toe bears all the weight at the end of one step and at the beginning of the next. The metatarsal and phalangeal bones of man's big toe are more robust than are those of the other toes.

A foot skeleton of *Australopithecus* can be reconstructed from a dozen bones recovered at Olduvai Gorge. Many of the proportions and articulations among the bones are typically hominid. The sturdy first metatarsal of the Olduvai australopithecine resembles that of contemporary man. While the bone is not as robust relative to the other metatarsals as is that of *Homo*, the Olduvai hominid was a much smaller animal.

Forelimb structure and manipulation. Man's hand is an impressive organ that distinguishes him from all other living primates. Beyond nonlocomotor and nonprehensile function (*e.g.*, shoving, clubbing, or poking with the fingers), prehension and the precise movements of the human hand are unique, generated by what probably is the most elegantly skillful biological organ ever evolved. All Primates except man rely on their forelimbs and hands as major organs of locomotion. Man alone has freed his hands for manipulation by specializing for erect posture and bipedal locomotion.

Fossil evidence for the evolution of the hands of hominids other than man was meagre in the 1970s: a few australopithecine bones from Olduvai Gorge. The reconstructed hand appears to have more similarity to those of juvenile pongids and of adult *Homo sapiens* than to hands of adult great apes.

Man's opposable thumb

The most characteristic feature of the hand is a truly opposable thumb—that is, one that rotates at the carpometacarpal joint so that it opposes the other four fingers. A thumb that does not rotate (moving only in one plane at this joint) is called pseudo-opposable.

Facial structure. The hominid face is already distinct in the australopithecines. Subnasal prognathism (protrusion of the jaws) is reduced, and ultimately there is an early disappearance of the facial component of the premaxilla (bones of the upper jaw) through fusion. The contour of the forehead, the supraorbital tori (bony ridges above the eyes), the high position of the zygomatic arch of bone below the eyes, the orientation of the eye sockets, and the reduction of the temporal process on the

From J. Buettner-Janusch, *The Origins of Man* (1966); John Wiley & Sons, Inc.

zygomatic bone comprise a total pattern quite distinct from that found in pongids of similar size (Figures 3, 4, and 5). This pattern is consistent with that found in the skulls of later Pleistocene hominids such as the Peking, Java, and Neanderthal fossils. The face of *Ramapithecus* has been reconstructed only from maxillary fragments,

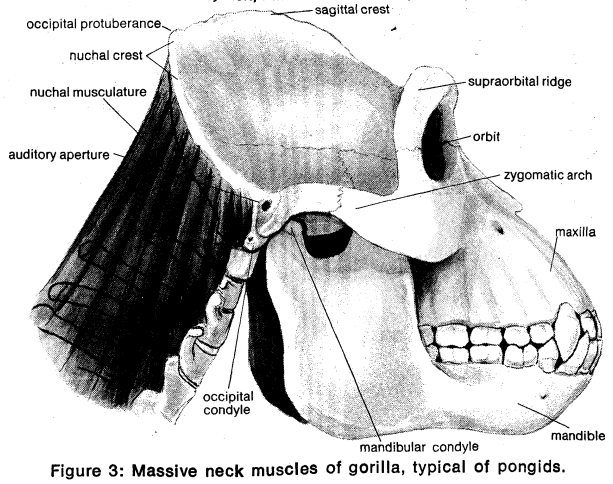

Figure 3: Massive neck muscles of gorilla, typical of pongids.

and the most that can be said with confidence is that *Ramapithecus* had a short face and an arcuate (arched) palate.

The mandible (lower jaw) has undergone major modifications since the Hominidae became distinct, being massive and large among early hominids. The association of large mandible, small braincase, and relatively high face once led many to conclude that both *Ramapithecus* and *Australopithecus* had clear pongid affinities. Among australopithecines, marked prognathism (although reduced compared to that of pongids) and the occurrence of a small sagittal crest atop some skulls reflect a large jaw powered by rather massive temporal muscles. Morphological differences between pongid sagittal crests and those found on some fossil hominid skulls are clear. The latter are the evolutionary consequence of upward displacement on the skull of bony supports for the temporal muscles. These supports developed during growth, occurring only on some skulls.

Dentition and diet. Hominid dentition is evident in both *Ramapithecus* and *Australopithecus*, especially in the reduction of the anterior teeth (canines and incisors) believed to signal a major change in diet and in behaviour (Figure 6). The massive anterior dentition of the Pongidae is most suitable for tearing and breaking up such vegetable foods as wild celery and bamboo, and their great canine teeth are socially important in displays of emotional states. As inferred from limited knowl-

edge, particularly of patterns of interstitial wear on the teeth, the principal hominid diet was not tough, succulent, green vegetation; meat may have been eaten, but it is believed that the essential shift was to consuming small, hard objects such as seeds.

Brain and nervous system. While the hominid brain is known directly only from *Homo sapiens*, deductions may be made from Pleistocene (*e.g.*, australopithecine) cranial fragments and intact skulls, and from Peking, Java, and Neanderthal remains. The brain increased in volume, and ratio of brain weight to body weight probably grew larger. The cerebral cortex expanded markedly and evolved with modern man to a large, highly complex structure for integration and control. Almost nothing is known about other parts of the nervous system among extinct hominid genera, although unreliable speculations based on reconstructions from fossil remains often are made. The same may be said for evidence of reproduction and growth based on the fossil record, almost all information being derived from man and contemporary pongids (see MAN, EVOLUTION OF).

Biomolecular characteristics. Chromosomes, hemoglobins, blood groups, many serum proteins, and red-cell enzymes (among other genetically controlled traits) have been studied extensively in contemporary *Homo sapiens*.

From J. Buettner-Janusch, *The Origins of Man* (1966); John Wiley & Sons, Inc.

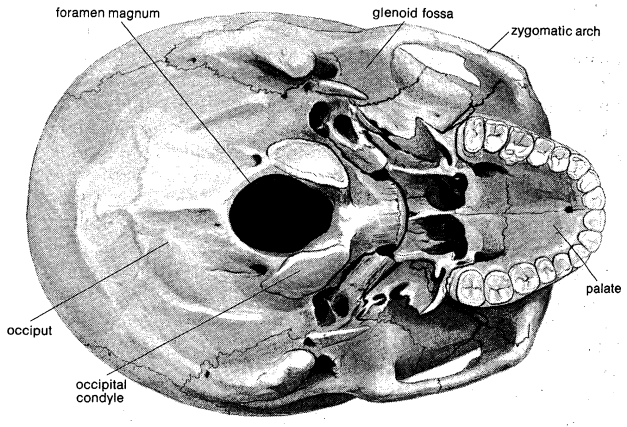

Figure 5: Base of hominid skull.

No reliable information on homologous traits of any extinct hominid exists, since chromosomes and proteins do not fossilize. Data available for man and living pongids, however, are compatible with modern notions of the affinities between hominids and pongids. Precise immunological and biochemical comparisons, representing efforts to refine views of the phylogenetic relationship of pongids and hominids, have been inconclusive at best. Use of these data to specify the time of divergence of the Hominidae and Pongidae seems premature, since results thus far are inconsistent with geochronological and chronometric estimates of the ages of hominid and pongid fossils.

BEHAVIORAL CHARACTERISTICS

Mentality is a zoological characteristic of major interest in any assessment of the Hominidae. Since fossils are not capable of such behaviour, however, most of the relevant evidence stems from *Homo sapiens*. The most salient characteristic of hominids is their extraordinarily different path of neurological evolution as contrasted with other families of primates. The distinct cognitive feature of hominids (especially man) is the ability to use symbols —to give arbitrary meaning to material objects. This feature is well illustrated by White's classic example that no chimpanzee can ever distinguish holy water from drinking water but that any man can be taught the difference. An eloquent account of the act of symbolling is found in the autobiography of Helen Keller, describing the moment when her teacher finally showed her that the word water meant the liquid she hitherto knew only by touch and taste. This is a superb, if metaphoric, indica-

Symbolic behaviour

tion of what the process of becoming a human hominid must have involved.

Toolmaking capabilities. In their difficult attempt to discover how and when the distinctive attributes of the brain of man became manifest in evolutionary history, most scholars look to the hominid fossil record and its associated archaeological sequences. Tools are obvious remnants, and signs of their planned, systematic production give evidence of symbolic communication among individuals and generations.

The use of tools—that is, employment of physical objects to perform certain tasks—is not unknown among so-called lower animals. Sea otter can be said to use rocks as tools to smash open oysters or clams against their chests as they float on their backs. Such investigators as W. Köhler (1925) and Jane van Lawick-Goodall (1964) showed that chimpanzees use objects as tools; other Primates, notably baboons, have been reported to behave similarly. Chimpanzees will lick a bit of grass or a stick to poke into termite nests, eating the insects that cling to the moistened surface. Vultures are known to crack ostrich eggs with rocks to feast on the contents. While such acts may be called tool *use*, these special and isolated manipulations are not equivalent to hominid tool*making*. Clearly, it would be most speculative to say that these animals think about making tools in a hominid manner homologous to man. Since firm evidence of traditions or styles of toolmaking has not been found among such animals, it would appear that only a rudimentary ability to explore the environment with tools is derived from the general primate heritage of the Hominidae.

It is unlikely that the first appearance of toolmaking ability will ever be precisely established. Any hominid fossil found with recognizable tools clearly comes after the cultural stage at which the first tools were made. These are most apt to have been bits of stick or other perishable material that no longer survive.

Brain evolution and culture

Specifically human behaviour evolved from an ability to manipulate symbols, a product of neuroanatomical change. There is ample evidence that the cerebral cortex increased in size during primate evolution. Major trends were the elaboration of the special senses and the expansion of cortical centres for conscious control over complex behaviour and muscles. Studies of comparative neuroanatomy suggest that cortical association areas that process complex sensory data and that mediate voluntary actions have increased in size. Although only the crudest estimate of changes in the cortex has resulted from study of fossil hominids, the neurological basis for culture, as in toolmaking, seems to be found in the evolution of the cortex.

Cranial volume does not have major significance as a measure of the degree to which fossil hominids approached the human condition. Even the ratio of brain weight to body weight is suggestive rather than definitive. It is not the amount of neural tissue in the cranium but the way it is differentiated and organized that is critical. The fossil record yields little beyond total volume, a crude estimate of the weight ratio, and (from an occasional endocranial cast) a few hints about the gross morphology of the brain surface. It seems reasonable, however, that by the time the potential for toolmaking developed, the size of the brain was not critical.

Acceptable evidence that a particular species made tools implies that symbolic communication and education were in the repertory of the hominid (whose fossil bones are found with the tools), whatever the brain size. If an australopithecine with about 600 cubic centimetres of brain volume is found with tools, this signifies a hominid brain large enough for symbolic communication and toolmaking. Tools indeed have been reported with australopithecine fossils, and it is therefore presumed that toolmaking was part of the behavioral repertory of the genus *Australopithecus*. There is little doubt that hominid fossils from the Middle and Late Pleistocene are those of toolmakers. It is a question of greatest interest whether sufficient postcranial material and tools of *Ramapithecus* ever will be found together *in situ*.

Language and related symbolic behaviour. The origins of symbolic vocal communication (oral language) in man probably will not be found in the fossil record despite the evidence of symbolic communication (making tools to a plan, occurrence of tool styles and traditions). Vocal and facial displays of other living primates do offer limited sources of information for an inquiry into the origins of spoken language. Man's imitation of what is heard, including the sounds of other animals, must be one root of origin. Vocal language must have arisen as a modification of already existing vocal systems. It can reasonably be postulated that language arises in a species in which auditory control over vocalization is sufficiently developed to permit individuals to imitate each others' sounds.

Vocalization

Control of vocalization in man largely involves controlling changes in resonance properties of the buccal (mouth) cavity. Humanoid grunts take advantage of all the resonant properties of the mouth and upper respiratory tract. Ability to contract the orbicularis oris (the circular muscle of the lips) would have developed through natural selection to produce the vocal range and variability available to modern man. Any change that makes transmission of information by vocal or facial expressions more explicit and less ambiguous also enhances social interaction, and selection would favour a coherent and well-organized society. The grunts of *Homo sapiens* may have evolved in the ancestral hominids by conveying vocal information simultaneously with facial expressions, just as the grunts of baboons seem to have evolved.

While human vocal cords are more blunt on the edges than those of baboons or apes, the principal difference in vocal apparatus is the position of the larynx, relative to the rest of the respiratory tract. Man's larynx is lower in the throat and farther from the soft palate than in other primates, directly reflecting development of erect posture and expansion of the braincase. The position of the larynx changed as the foramen magnum (the skull's aperture for the spinal cord) moved forward and as the mandible grew smaller. The foramen magnum, in turn, moved in response to the way the head is balanced on the neck and to the expansion of the posterior portion of the base of the skull. The consequent descent of the larynx created a long, tubular resonating cavity that permits the low-pitched speech of man. Auditory discrimination in man probably evolved along with the vocal apparatus, as it is most acute in discriminating pitch within the normal human range. Symbolic meaning, however crude, would not be attached to particular sounds if one animal could not imitate vocalizations of others. The development of vocal mimicry must have been important in the origin of language and may well have depended in part on the ability to manipulate the behaviour of others through vocalization. Chimpanzees give particular calls that direct the attention of others to specific objects. Although the chimpanzee larynx allows rich, variable vocal function, its structure prevents reproduction of many human phonetic elements. Although no fossil larynges have been found, the morphology of the base of the fossil cranium suggests that the human condition was developing in the earliest hominids.

Facial displays also are related to the evolution of vocal language, since changes in such facial muscles as the orbicularis oris and zygomaticus (that control lip movements) were of critical importance (Figure 7). Primate

facial displays have evolved to the point that they can occur without vocalization; among chimpanzees and *Homo sapiens* the sight of a desired object may elicit a silent smile.

Social organization. Social behaviour or social groupings, of course, do not fossilize. Speculations and rather tenuous deductions in reconstructing the social life of early hominids are based on fossil morphology, on living nonhuman primates (*e.g.*, baboon troops and anarchic chimpanzee bands), and on contemporary *Homo sapiens*.

Small, erect, bipedal hominids, with dentition no longer suitable for tough, succulent stems and leaves ripped in foraging the dense humid forest, probably developed a mode of life suitable to hunting and to gathering grains, seeds, and fruits. The socially organized activity that this shift may be said to imply required differentiation of the roles of males and females. Relatively stable integrated family units very likely arose and, with cooperative hunting and gathering, further division of roles. Though it is fairly clear that these social developments occurred in populations that eventually generated human hominids, that australopithecines were so organized is uncertain.

CONTRASTING ADAPTATIONS OF HOMINIDAE AND PONGIDAE

Hominidae are distinguished from Pongidae (anthropoid apes) by evolutionary trends that illustrate the adaptations of each for different environmental situations. Obvious morphological contrasts in skeleton and musculature between living pongids and hominids suggest the functional significance of homologous features observed in fossil representatives of the two families. The contrasts are particularly evident in progressive skeletal modifications in adapting to erect bipedalism. Most significant in hominids are a proportionate lengthening of the lower extremity and changes in the proportions and morphological details of the pelvis, femur, and pedal skeleton—all related to the mechanical requirements of erect posture and bipedal gait. Associated soft tissues also are modified, most particularly the hamstring tendons, gluteus muscles, and the complex (iliopsoas muscle) that flexes the trunk and thigh. The hominids preserve a well-developed pollex (thumb) and have lost opposability of the hallux (big toe).

Locomotion and posture

Pongid skeletal modifications sometimes are interpreted as deriving from a rather small brachiating (arm-swinging) ape (presumably one of the dryopithecine fossils of the Miocene Epoch). The proportionate segmental and overall lengthening of the upper extremity in pongids is believed to support this view. The pongid pollex is reduced, there is a strong and opposable hallux, and details of the limb bones are modified. The forelimb and hand of some pongid genera seem to be adaptations to knuckle or fist walking. Increase in size and mass of some individuals in the pongid lineage (including the large, extinct genus *Gigantopithecus*) probably made a shift from arboreal or terrestrial quadrupedal locomotion to the knuckle-walking gait a distinct advantage.

The pongid pelvis retains the main proportions characteristic of quadrupedal mammals. Although to some the anatomy of the pectoral girdle of pongids suggests a brachiating ancestor, all Miocene Hominoidea (Hominidae and Pongidae) recovered and described by the 1970s fail to show specific adaptations for brachiation. At least, the Miocene hominoids do not resemble modern gibbons (*Hylobates*), whose arboreal acrobatics led to the definition of brachiation. Analyses of both living pongids and extinct forms suggest that the basic adaptation is dominated by forelimb locomotor and feeding behaviour, knuckle walking distinguishing pongids from their Oligocene or early Miocene ancestors.

The hominid skull bears marks of a way of life that contrasts strongly with that of pongids. In fossil skulls of australopithecines the occipital condyles (protuberances on the base of the skull that articulate with the vertebral column) are more anterior than in pongids. Their position is associated with increased flexure of the basicranial axis, leading to upward displacement of the braincase relative to the face, with resultant increase in cranial height. These changes often are cited as serving to maintain the balance of the head, consequent to development of erect posture and bipedal gait. They are also a result of the expansion of the braincase.

The pongid skull is that of a quadrupedal, orthograde primate. There is marked prognathism and, in larger species, massive jaws associated with strong muscular ridges on the skull. The extensive nuchal (nape) area of the occiput, the relatively high inion (occipital protuberance), the position of the occipital condyles well behind the level of the auditory apertures, and the limited degree of flexion of the basicranial axis are all features consistent with knuckle or fist walking. These characteristics of the skull are found in Miocene and Pliocene Pongidae as well.

That hominid dentition differs significantly from that of the pongids is now viewed as an adaptation to a diet that varies markedly from that of the pongids. Significant hominid features include reduction of the incisors and canines, appearance of bicuspid premolars, and changes in the occlusal relationship of the jaws. The canines have diminished to a spatulate form and interlock slightly or not at all. There is no pronounced sexual dimorphism of canines, and the spaces between these teeth (diastemata) largely have vanished. First premolars adapted for cutting are replaced by bicuspids, with secondary reduction of the inner (lingual) cusp in later hominid forms. Occlusal alterations tend to promote wear in all teeth to a flat, even surface at an early stage of attrition. The dental arcade is even and rounded, and there is a marked tendency in later stages of the fossil record (as in modern man) toward a reduction in molar size. Deciduous teeth appear to be replaced earlier (relative to eruption of permanent molars) and there is progressive molarization of the first deciduous premolar. This is the dentition of a plains-living animal that had forelimbs not primarily used in locomotion and that hunted and gathered seeds, fruits, and grasses.

Differences in dentition
