Geraniales

The Geraniales, or geranium order, is an order of flowering plants comprising 20 families that include approximately 143 genera and about 4,000 species. Half of the families contain 50 species or less, but the two largest families (Malpighiaceae and Oxalidaceae) each have about 900 species. These two large families have predominantly tropical distributions, although the Oxalidaceae has some temperate-region representatives. The families Geraniaceae and Balsaminaceae each have over 500 species with worldwide distributions. The remaining families are mostly tropical, and two (Dirachmaceae and Lepidobotryaceae) are monotypic (*i.e.*, they contain only one genus and one species); the former is confined to the island of Socotra, where it appears to be very rare, and the latter to tropical Africa.

GENERAL FEATURES

Size range and diversity of habitat. With representatives in both the tropics and in temperate regions, the order shows considerable variation in life form, from small annual herbs—nonwoody plants with short life cycles—to trees (*e.g.*, *Lepidobotrys*) of the tropical rain forest that have leathery leaves furnished with the drip tip (a sharp point at the end of the leaf) characteristic of this habitat. The families Zygophyllaceae, Nitrariaceae, and Peganaceae are adapted to dry or saline habitats and contain numerous desert or subdesert species. Certain genera of the family Zygophyllaceae, such as *Zygophyllum* and *Tetradiclis*, show adaptations to the environment in their succulent—thick, fleshy, water-storing—vegetative parts; these are sometimes coupled with an annual habit and abundant seed production. Several *Zygophyllum* species are characteristic of the desert regions of the Near and Middle East and Central Asia, as well as Africa and Australia. *Tetradiclis*, which also grows in the Asian deserts, resembles some of the fleshy species of the family Chenopodiaceae (order Caryophyllales, *q.v.*) encountered in the same regions and can easily be mistaken for them. The genus *Sarcocaulon* (South Africa) is the only species of the family Geraniaceae adapted to desert life, although many species of *Erodium* and *Monsonia* occur in desert regions. The species of *Nitraria*, conversely, are highly salt-tolerant, deep-rooted perennials. Spines or thorns frequently develop in desert plants, presumably as a protection against grazing; two genera of the Zygophyllaceae (*Fagonia* and *Plectrocarpa*) exhibit these features markedly.

Desert adaptations

A succulent form is sometimes found in plants growing in damp ground or, particularly, in shallow water; these species commonly have translucent stems, often much branched and either sprawling or supported by the stronger waterside vegetation among which they grow. The families Limnanthaceae and Balsaminaceae provide good examples of such plants.

Certain plants in disturbed ground exhibit a feature useful in aiding distribution by vegetative means—the production of bulbils (small buds, or bulbs) on the roots, in clusters at the stem base, or in the leaf axils (angles between the leafstalks and the plant stem). Each, if broken off, is capable of growing into a new plant. This feature occurs in several species of *Oxalis*, certain of which (*e.g.*, *O. corymbosa* and *O. latifolia*), although tropical in origin, have now spread widely by this means to become troublesome weeds of cultivated areas even in temperate regions.

Perhaps one of the most striking and obvious anatomical features in the order is that of the very characteristic single-celled plant hairs (trichomes) of the family Malpighiaceae—so widespread in the family that botanists frequently refer to these two-armed hairs as malpighian hairs when describing their presence in other families. They are very diverse in form, sometimes almost without a stalk below the branching point, sometimes in a more or less elongated stalk, with the branch arms spreading or ascending, and from nearly equal to very unequal in length. Sunken, cushion-shaped, or sometimes stalked glands also occur in this family.

Economic importance. The economic importance of the order is not great, with the exception of flax (*Linum usitatissimum*), the source of a valuable fibre that has been used by man since prehistoric times. It is grown in most temperate regions, especially in central and western Europe, not only for its fibre, from which linen is made, but also for its seed, the source of linseed oil.

Timber sources

A few timber trees occur in the order, the most famous being guaiacum wood (or lignum vitae), yielded by *Guaiacum officinale* (family Zygophyllaceae). The wood —very hard, durable, and heavy in weight—is used in shipbuilding and for mallets. The heartwood of *G. sanctum* produces a resin used for making small objects that require weight, hardness, and strength. *Bulnesia arborea* is Maracaibo lignum vitae, and the timber is used as for the *Guaiacum* product. Some species of the family Malpighiaceae are locally employed as timber sources, particularly *Ctenolophon parvifolium*, the durable wood of which is employed for house construction in Malaysia. The timber of *Klainedoxa gabonensis* is tough and hard wearing. *Houmiria balsamifera* is the source of a good timber, easily polished and used for furniture, house framing, and general carpentry. *Sacoglottis gabonensis*, from western Africa, produces an easy-to-work white wood.

Three species of *Balanites* are used locally. *B. aegyptiaca* seeds yield Betu oil, employed in soap manufacture. The wood is hard and used in Africa for clubs, plows, sticks, turnery, and general carpentry. *B. maughamii* yields a clear oil similar to olive oil, and *B. orbicularis* is the source of hanjigoad, a gum resin. *Irvingia gabonensis* (family Ixonanthaceae) is the wild mango (not to be confused with the true mango, *Mangifera indica*), the fruit of which is edible; the fat from the seeds yields dika bread and dika butter, staple foods in West Africa. The tough, hard wood has been used for street paving and in houses. The seeds of *I. oliveri* are the source of cay cay fat, used in candle manufacture.

Bulnesia sarmienti (family Zygophyllaceae), the source of guaiac wood oil, which has a roselike scent, is used in soaps and perfumery. Geranium oil for perfumery is obtained from *Pelargonium radula*, *P. odoratissimum*, *P. capitatum*, and other species of this genus.

A few plants of the order have been used medicinally. The root of *Hugonia mystax*, for example, has been used locally in India as a snakebite remedy and to reduce fever. *Linum catharticum* has laxative properties similar to those of senna (*Cassia*). *Geranium maculatum* is an American species known as alumroot from the styptic and astringent properties—ability to control bleeding and draw together soft tissues—of a liquid extract from the roots. The only species of widespread true medical significance, however, is the coca, *Erythroxylum coca*. From this species the local anesthetic cocaine is prepared. The leaves of *E. coca*, the coca tree, act as a nerve stimulant, and tribal peoples of South America

Use of coca leaves

chew them so that they can perform feats of endurance without fatigue. The components of the leaves act on the gastric nerves, eliminating the sense of hunger and allowing the user to go for a long period without food. As with most stimulants, however, the use of coca is followed by depression. *Banisteriopsis caapi* (family Malpighiaceae) contains the hallucinogenic alkaloid harmine.

The fruits of some *Malpighia* species (*e.g.*, *M. punicifolia*, the Barbados, or West Indian, cherry) are edible either fresh, as preserves, or as flavouring for jellies. The gooseberry-like fruits of *Averrhoa carambola* (family Oxalidaceae) are also edible, and those of *Nitraria* species are sometimes eaten. *Klainedoxa gabonensis* and *Desbordesia glaucescens* have edible seeds; those of the former are eaten fresh or roasted, and those of the latter are used in sauces. The outer layers of the fruit are edible in several *Houmiria*, *Sacoglottis*, and *Vantanea* species; both fruit and seeds contain a fatty oil.

The families Geraniaceae and Tropaeolaceae produce many well-known decorative plants. The Geraniaceae contains not only handsome species of *Geranium* itself but also the cultivated varieties and hybrids (crosses between different species) of the genus *Pelargonium*, to which the well-known pot and bedding geraniums of gardeners belong. The garden nasturtium is *Tropaeolum majus*, and some others of this genus also appear in gardens—notably *T. peregrinum*, the canary creeper. Species of the family Tropaeolaceae contain a hot mustard oil similar to that found in certain members of the mustard family (Cruciferae), a fact that no doubt explains the name "nasturtium" as applied to the garden *Tropaeolum majus*—botanically, the genus *Nasturtium* is the watercress. Some herbaceous *Oxalis* species have been grown as ornamentals, as have one or two trees of the genus *Averrhoa*, also of the Oxalidaceae. The nuisance value of several weedy species of *Oxalis* that spread by means of readily detached bulbils is far greater than the aesthetic value of their relatives, however.

The dye Turkey red is prepared from the seeds of *Peganum harmala* (family Peganaceae), a common plant of arid regions in southwestern and Central Asia.

NATURAL HISTORY

Seed dispersal. Within the Geraniales, the family Geraniaceae is perhaps the most interesting from the point of view of seed dispersal; the genus *Erodium* (storksbill), particularly well represented in desert and subdesert areas, shows adaptation to this environment. The fruit is furnished with a long beak formed from the fused tissues of the styles, the narrow upper parts of the ovary segments, or carpels. The beak segments of all the carpels of each flower remain fused until the fruit is ripe. When the fruit ripens and dries, these segments spring apart and become spirally shaped; each seed-bearing carpel falls to the ground. With rain or increase in humidity, the beak segments absorb water and straighten, driving the carpels into the ground. In some species the inner surface of the beak segments have feathery hairs that aid in wind dispersal. In *Geranium* and some other genera, such as *Pelargonium*, the beak segments separate from the base and curl but remain attached at their tips. This abrupt dehiscence—splitting open—may either catapult the seeds away or leave them hanging by slender threads, from which they are easily dislodged.

Self-planting fruits

Within the family Zygophyllaceae is the genus *Tribulus*, which derives its name from the Latin name of an instrument of warfare—the caltrop, a four-pronged device that served as a horse-crippling spike. The fruit of *Tribulus* is similarly formed; the carpels become hard and are heavily covered with sharp spines and bumps. They are

Hutchinson, *The Families of Flowering Plants;* The Clarendon Press, Oxford

picked up by grazing animals that disperse them to other parts of the arid regions. A further specialized form of distribution occurs in the genus *Impatiens* (family Balsaminaceae); the fleshy, five-valved capsule opens explosively. The valves remain attached at the base and apex when ripe but split along the joints, their elastic nature drawing base and apex together so that the seeds are shot, often for a considerable distance, through the spaces thus created between the valves. When the fruit is ripe, this explosive rupturing may be set off by a very light brush with the fingers—hence the name of a well-known European species, *Impatiens noli-tangere*, or touch-me-not. A Himalayan species, *I. glandulifera*, has spread widely along waterways in Europe and in North America by this means in a comparatively short space of time. Explosive dehiscence—opening of seed-bearing fruits—also occurs occasionally in the family Oxalidaceae, in this case activated by the elastic separation of the aril, an appendage on the seed, from the seed coat. Wind-distributed samaras, winged one-seeded fruits, as in the maples, occur in the family Malpighiaceae. Otherwise, dehiscent dry capsules, schizocarps, berries, and drupes are prevalent, with distribution by birds in the last two cases. Some (*e.g.*, *Vantanea* in the family Houmiriaceae) are distributed by flowing water.

Pollination. Pollination is almost universally by insects—generally by bees, wasps, and flies, but also by beetles and butterflies. Some North American species of *Impatiens*, however, are pollinated by hummingbirds. In the family Linaceae, floral dimorphism, the existence of two forms of flowers, has long been known. At least 29 species of *Linum* have been shown to exhibit long- and short-styled flowers. (The style is the narrow, upper part of the ovary, bearing the pollen-receiving surface, or stigma.) Fertility is greatest when the long-styled form is fertilized with pollen from the short-styled form and vice versa. The long-styled form is almost self-sterile, but the short-styled form is not; when both kinds of pollen are put on one kind of stigma, only that from the opposite kind of flower is capable of fertilization. Several species of *Linum* are self-fertilizing in the absence of insect visitors; the filaments bend inward, and the style branches spread with age.

Pollination mechanism in the flax family

In *Geranium* both self-sterility and self-fertility are known; it is well established that the more inconspicuous the flower, the more advanced the ability for selfing by movement of the styles and filaments, as in *Linum*. In the allied genus *Erodium*, the flowers may be radially symmetrical (regular or actinomorphic) or strongly bilaterally symmetrical (zygomorphic) in forms of the same species. Apparently, forms with regular flowers tend to be self-fertilizing, and those with zygomorphic flowers to be insect fertilized, the enlarged lower petals serving as a landing platform for visiting insects.

Flowers of the remaining large genus of the Geraniaceae, *Pelargonium*, are odorous at night and are visited by nocturnal insects. Such genera as *Tropaeolum* and *Impatiens* have bee-pollinated flowers with nectar secreted at the end of a spur formed by the sepals. The anthers shed their pollen shortly after the flowers open, the stigma of the same flower remaining immature. Insect visitors, dusted with pollen, transfer it to the mature stigmas of older flowers in which the anthers have fallen, thus ensuring cross-pollination. Insect-pollinated genera often have nectar guides in the form of dark blotches or streaks at the base of the petals. One member of the family Malpighiaceae, *Bunchosia gaudichaudii*, has bee-attracting glands on the outside of the calyx (sepals).

EVOLUTION

Fossil record. Fossils of the order are not of great quantity, and older records, such as those for *Balanites* and *Zygophyllum* from the Tertiary Period (about 65,000,000 to 2,500,000 years ago) of Europe, are considered suspect. The remains have been mostly as fruit or pollen. About 12 or 13 fossil plant groups have been placed in the family Houmiriaceae, and fruits of three different species of *Houmiria* have been found in Tertiary deposits in South America. A fruit of a *Sacoglottis* has been found in Tertiary deposits in Germany. *Wetherellia* fossils occur abundantly as fruits in the London Clay (Eocene Epoch—38,000,000 to 54,000,000 years ago) at the Isle of Sheppey, Kent, as do those of *Decaplatyspermum*. Fossil remains of *Erodium* and *Geranium* have been recorded from Baltic amber, as well as fruiting pedicels (stalks) of *Oxalidites* and a *Linum* fruit. *Linum* seed has been found in the Russian Pliocene Epoch (about 7,000,000 to 2,500,000 years ago), and pollen of *Geranium* in the Miocene Epoch (26,000,000 to 7,000,000 years ago).

Phylogeny. The order Geraniales is considered to have its closest affinity with the order Rutales; indeed, the general relationship is so close that it is difficult to distinguish the two orders. It is also very difficult to plot phylogenetic (evolutionary) relationships between the families included within the order Geraniales. Both the

Geraniales and the Rutales are among the many orders believed to have arisen from the order Saxifragales.

Uncertain relationships of order and families

Within the Geraniales, the families Tropaeolaceae and Balsaminaceae, with their specialized floral structure, are probably the most advanced families. The Balsaminaceae presents certain problems, however. It differs from the Geraniaceae in anatomy and pollen structure, and the disposition of the ovules is similar to that found in the Sapindaceae (order Sapindales, *q.v.*); on this basis, some authorities have included it in that family. It has also been placed near the family Vochysiaceae in the order Polygalales—an opinion given some weight by the similarity in development of the embryo in *Impatiens* and *Polygala*. Overall resemblances with the remaining families in the order Geraniales, however, outweigh these contradictory features.

The tropical family Hugoniaceae is considered to be the most primitive in the order; from it the family Linaceae probably arose. The families Ixonanthaceae, Houmiriaceae, and Erythroxylaceae may also be derivatives. The family Malpighiaceae, however, is close to the Erythroxylaceae and Nitrariaceae, and through the latter, a transitional family, to the Zygophyllaceae.

Two families are of particular interest for the form of their pollen grains. Those of the Limnanthaceae are unique and serve to emphasize its isolated position. They appear to be asymmetrically bicolpate (*i.e.*, they have two unequal germination pores or furrows). In the family Balsaminaceae the grains are very strongly flattened, with three or four germination furrows and a reticulate (netted, ridged) surface pattern. This strong compression clearly differentiates them from the Geraniaceae, with which they are most commonly allied, and all other families of the order. The closest resemblance is with *Jollydora* in the Connaraceae (order Connarales).

The order Geraniales is as diverse in anatomy as in pollen structure, particularly the family Linaceae and the small families that have been separated from it. Diversities within this group are so complex in pattern as to render difficult any phylogenetic interpretation based on anatomy. Similarly, anatomy provides no clues on the separation of the family Oxalidaceae or the Biebersteiniaceae from the Geraniaceae, all of which have the same basic vascular structure—the system of internal water- and food-conducting tubes, the vessels—and the same characteristic ring of thick-walled cells (sclerenchyma cells) in the pericycle, a layer of cells surrounding the central vascular cylinder in roots. This ring, however, is absent in other families that have been closely linked with the Geraniaceae, notably the Tropaeolaceae, Balsaminaceae, and Limnanthaceae. The family Balsaminaceae also differs from the Geraniaceae in the presence of raphide (needle-like crystals) sacs in the leaf and stem, which are sometimes visible as transparent dots. In addition, the vascular bundles in the leafstalks (petioles) are arranged in an arc, not a full ring.

The woods of the Zygophyllaceae are very specialized, showing this family to be a natural group. The family Balanitaceae differs from it in having high, wide wood rays; nevertheless, the general anatomy suggests affinity with the Zygophyllaceae rather than the family Simaroubaceae. The anatomy of the family Erythroxylaceae differs considerably from that of the Linaceae, with which it was formerly believed to be united. The wood structure in Malpighiaceae, more highly specialized than in the Linaceae, Houmiriaceae, and Erythroxylaceae, differs also from that of the Zygophyllaceae.

Thus, relationships within the order follow a confusing pattern because so many anomalous members are included, and no clear phylogenetic conclusions are possible.

CLASSIFICATION

Annotated classification. The geranium order is very heterogeneous, consisting of a number of families united by apparent general relationship rather than by a readily defined common group of characters. It is thus difficult to define by features that do not break down at some point or other.

ORDER GERANIALES

Leaves commonly alternate. Flowers hypogynous (*i.e.*, sepals, petals, and stamens arise at the base of the ovary), usually bisexual and radially symmetrical (actinomorphic). Sepals overlapped (imbricate) or rarely merely touching at the edges (valvate), free or more or less fused. Petals generally free, contorted (twisted), or imbricate, rarely valvate or convolute (rolled up, lengthwise). Anthers (pollen sacs) open by longitudinal slits. Nectar-producing disk or disk glands frequently present. Ovary of fused carpels with ovule attachment along central axis near base or apex of ovary chambers, ovules mostly solitary to few in each locule (chamber). Seeds mostly without endosperm (starch nutrient tissue for developing embryo).

Family Hugoniaceae

Trees, shrubs, or woody lianas with hooked prickles on the branchlets or flower stalks. Leaves alternate, simple, with entire or toothed margins, with deciduous (falling) stipules. Flowers actinomorphic, bisexual, in terminal or axillary (the upper angle between a leafstalk and stem) cymes (flower clusters that mature from the top downward) or panicles (many-branched flower clusters); more rarely in axillary clusters of spikes, or solitary, often yellow. Sepals and petals 5, free. Sepals generally imbricate, petals contorted. Stamens fused into a short tube at the base, almost invariably 10, except in the genus *Indorouchera* (5–7 stamens). Stamen filaments frequently with nectar-producing glands at the base. Ovary 3- to 5-locular, each locule with 2 ovules. Styles free or slightly fused at the base, with capitate—headed, with enlarged ends—stigmas. Fruit a slightly fleshy or berrylike drupe, the stones woody or bony, seed usually with scanty endosperm. Six genera and about 60 species distributed in the tropics of both hemispheres.

Family Linaceae (flax family)

Entirely shrubs, subshrubs, and herbs—no trees. Leaves alternate (rarely opposite), simple (entire or toothed). Stipules commonly absent or represented by stipular glands; if present, then falling early or, rarely, persisting and becoming conspicuous (in *Anisadenia*). Flowers actinomorphic, bisexual, disposed in cymes, racemes (spikelike flower clusters that mature from the bottom upward), or corymbs (flat-topped flower clusters), or very rarely solitary and lateral. Sepals and petals sometimes 4, usually 5; sepals sometimes fused at their bases, imbricate; petals free and contorted. Stamens equal in number to the petals, but between each pair of stamens a minute to conspicuous and bristle-like staminode (sterile stamen) frequently occurs. Stamen filaments more or less expanded at the base and fused into a short tube that usually bears small nectar-producing glands. Ovary occasionally 2- but usually 3- to 5-locular, each locule with 2 ovules. Styles free or shortly fused at the base, with capitate or more rarely linear stigmas. Fruit a capsule, rarely breaking up into 1-seeded segments twice as numerous as the styles (*Reinwardtia*) or not opening (indehiscent; *Anisadenia*). Endosperm usually scanty. About 6 genera and 240 species with nearly worldwide distribution.

Family Ixonanthaceae

Trees or shrubs with simple, alternate leaves that can be entire, toothed, or crenate. Stipules usually present, sometimes small and early deciduous; sometimes conspicuous, very long and convolute, leaving a conspicuous ring-shaped scar on the twig when they fall. Inflorescence an axillary or terminal raceme, cyme, or panicle. Flowers small, bisexual or rarely with male and female flowers on separate plants (dioecious), actinomorphic. Sepals and petals 5 or sometimes 4; sepals free or fused at the base, imbricate; petals free, imbricate, sometimes persistent and becoming firm in texture. Stamens 5 to 20, the filaments slender, free, inserted on or below the conspicuous annular or cup-shaped nectar-producing disk; anthers short and small. Ovary normally 4- or 5-locular, more rarely with only 2 locules, with a single simple or shortly divided style; ovules 1 or 2 in each locule. Fruit variable in form from large, fleshy (and edible) drupes, to winged samara, and 2- to 5-locular septicidal capsule. Arils (fleshy appendages on the seeds) present and variable, from vestigial to large organs completely enveloping the seed. Eight genera and about 45 species, exclusively tropical in distribution.

Family Houmiriaceae

Trees or shrubs with simple, entire- or lobe-margined, opposite leaves. Stipules either absent or small and early deciduous. Inflorescences axillary or rarely terminal, cymose or paniculate. Flowers hermaphroditic and actinomorphic. Sepals 5, imbricate, fleshy at the base and persistent, shortly fused at the base or united almost throughout their length into 5-toothed cup. Petals 5, contorted or imbricate, deciduous and membranous or persistent and of thick texture. Stamens variable in number, mostly 10 to 30 in 1 or 2 series, sometimes very numerous (50–180) and then in several rows. Stamen filaments slender or thick, more or less fused below;

staminodes sometimes also present. Nectar-producing disk present, annular and often toothed, or divided into separate scales. Ovary typically 5-locular but sometimes 4-, 6-, or 7-locular, with a single simple style. Ovules 1 to 3 in each locule, pendulous. Fruit a drupe, the outer layers slightly to distinctly fleshy, the inner layer hard and woody and often with resin-bearing cavities, usually with only 1 or 2 seeds developing; endosperm of seeds fleshy and oily. Eight genera and about 50 species distributed in tropical regions of the New World and 1 species in tropical West Africa.

Family Erythroxylaceae

Trees and shrubs with simple, entire, alternate leaves often showing 2 persistent longitudinal folds (leaves opposite in the genus *Aneulophus*, however). Flowers bisexual, actinomorphic, small, disposed in axillary fascicles, or solitary. Sepals 5, fused into bell-shaped calyx with valvate or imbricate teeth. Petals 5, free, deciduous, convolute or imbricate, frequently with a tonguelike appendage within. Stamens 10 in 2 whorls, more or less fused into a tube below, persistent. Ovary 2- or 3-locular, usually only 1 locule fertile. Ovules 1 or 2 pendulous. Styles free or fused, with oblique stigmas. Fruit drupaceous. Seeds usually with fleshy endosperm. Four genera and more than 200 species distributed in the tropics of both hemispheres, mostly in Africa, however; only the genus *Erythroxylum* is found in America.

Family Lepidobotryaceae

Small tree with alternate, single-bladed leaves with stipules, the single leaflet subtended by stipels—appendages similar to stipules—which, like the stipules, are deciduous. Petioles (leafstalks) and petiolules (the petiole, or stalk, of a leaflet in a compound leaf) jointed. Flowers actinomorphic, small, dioecious, the male flowers in short, sessile, catkin-like axillary inflorescences; female flowers in fasciculoid racemes. Sepals 5, imbricate, shortly fused at the base. Petals 5, free. Male flowers with 10 stamens on the margin of a flesh disk and a rudimentary ovary. Female flowers similar but with sterile stamens and a 3-chambered ovary with 2 collateral ovules in each locule. Styles 3, fused at the base. Fruit a single-seeded capsule. Seeds partly covered by a fleshy aril. One genus and species (*Lepidobotrys staudtii*), native to tropical Africa.

Family Malpighiaceae

Small trees, shrubs, or very frequently woody lianas. Malpighian hairs—characteristic 1-celled, 2-branched plant hairs—present. Leaves normally opposite and entire-margined (though occasionally alternate or in whorls of 3 or with wavy, toothed, or lobed margins), and frequently dotted with glands. Stipules usually present and deciduous, rarely absent, sometimes large, conspicuous, fused together, and persistent. Inflorescence in terminal or axillary raceme. Flowers usually large, bisexual or rarely polygamous (with male, female, and bisexual flowers on the same plant), commonly yellow or red (sometimes white or blue), obliquely zygomorphic, some cleistogamous (closed, self-pollinated) flowers often occurring. Sepals 5, imbricate, free or slightly fused at the base, some or all frequently with a large sessile (stalkless) or stalked gland on the lower outer surface. Petals also 5, free, imbricate, usually distinctly clawed and often toothed or fimbriate (ragged or fringed) along the margin. Stamens 10, in 2 whorls, usually fused into a ring at the base, all fertile or frequently with some reduced to staminodes; disk inconspicuous. Ovary asymmetrically disposed, carpels usually 3 (rarely 2 or 4), free or more or less fused, each with 1 ovule. Styles equal in number to the carpels, free or rarely fused, or very rarely only 1 carpel with a style. Fruit typically a schizocarp breaking up into 3 frequently winged mericarps, but sometimes nutlike or drupaceous. Seeds without endosperm. Sixty genera and 800 to 900 species distributed exclusively in tropical regions of the world, especially in South America.

Family Nitrariaceae

Stiff shrubs, often armed with spines or rigid leafstalks. Leaves alternate or clustered, thick and fleshy, simple, entire or with a few teeth at the apex, and furnished with small stipules. Flowers small, yellowish or white, actinomorphic, bisexual, in short lax cymes in the axils of the bracts. Sepals considerably fused below, imbricate, persistent. Petals 5, free and valvate, concave. Stamens 10 to 15 with 5 opposite the sepals and the remainder opposite the petals singly or in pairs. Stamen filaments subulate (awl-shaped), without appendages; disk absent. Ovary of 3 carpels, rarely of 6, gradually narrowing above into 3 decurrent stigmas; each carpel with a single pendulous ovule. Fruit berrylike, with a fleshy exocarp and a thin, bony, grooved endocarp. Seeds without endosperm. One genus (*Nitraria*) with about 10 species occurring in saline deserts, mostly from the Sahara to Central Asia and Siberia, with 1 species in Australia.

Family Zygophyllaceae

Mostly woody perennials; if annual they are sometimes very succulent (some *Zygophyllum* species); rarely trees (*Guaiacum*). Branches often jointed at the nodes in the more fleshy species. Leaves usually (but not invariably) opposite, mostly pinnately compound (with small leaflets on both sides of a central axis), sometimes simple or with 2 leaflets (these also jointed to the leafstalks in fleshy *Zygophyllum* species. Stipules present, often persistent, sometimes in the form of spines. Flowers in cymes or solitary and terminal, actinomorphic or rarely zygomorphic, bisexual. Sepals 5 (rarely 3 or 4), free or sometimes fused at the base, imbricate or rarely valvate. Petals equal in number to the sepals (or rarely none), free, usually imbricate or contorted. Stamens in 1 or 2 whorls, each whorl containing the same number as the sepals and petals. Stamen filaments frequently furnished with straplike appendages at the base. Nectar-producing disk usually present between the stamens and the ovary. Ovary usually with 4 or 5 carpels, sometimes as few as 2 or up to 12, each carpel with 1 or many pendulous ovules. Ovary narrowed above into a single unparted or shortly divided style. Fruit a capsule, frequently angled or even broadly winged, or rarely dividing into single-seeded mericarps. Seeds with or without endosperm. About 23 genera and 225 species distributed almost entirely in arid or semi-arid areas of the tropics and subtropics of the world.

Family Balanitaceae

Similar to the Zygophyllaceae in most respects, but leaves totally without stipules; spines in leaf axils, not modified stipules. Disk thick. Fruit drupaceous with a very thick, bony, 5 angled endocarp but only a thin fleshy mesocarp. One genus (*Balanites*) with 25 species in tropical Africa and Asia.

Family Peganaceae

Perennial herbs or subshrubs. Leaves alternate, deeply divided into narrow segments, with stipules. Flowers solitary, leaf opposed, actinomorphic, and bisexual. Sepals 4 or 5 valvate, sometimes pinnately divided. Petals 4 or 5, free, imbricate. Stamens 12–15, in alternating rows, the filaments thicker below but without appendages, inserted on an annular or angular nectar-producing disk. Ovary 2-, 3-, or occasionally 4-locular, each locule with numerous ovules disposed along the central axis. Style simple, 2- or 3-keeled above with the stigmatal surfaces on the keels. Fruit a many-seeded capsule (*Peganum*) or a 2-loculed berry (*Malacocarpus*). Seeds with a fleshy endosperm. Two genera with about 6 species distributed in dry places from the Mediterranean area to Mongolia and in the southern U.S. and Mexico.

Family Oxalidaceae

Mostly herbs (sometimes fleshy), sometimes shrubs, rarely trees. Fleshy axillary or underground tubers or bulbils frequently produced. Leaves alternate, palmately or pinnately divided (often trifoliolate—3 leaflets—in *Oxalis*), rarely simple by suppression of all but 1 leaflet; stipules absent. Flowers actinomorphic, bisexual, solitary or in umbels, more rarely in cymes or racemes, minute, nonpetalled, cleistogamous flowers sometimes present. Sepals usually fused below and imbricate. Petals 5, free or only shortly fused below and contorted. Stamens 10, in 2 alternating rows, basally fused, 5 of them sometimes reduced to antherless staminodes. Ovary 5-locular, each locule with 1 or more axile ovules. Styles 5, distinct; stigmas capitate or shortly divided. Fruit a capsule. Five genera with more than 900 species distributed predominantly in the tropics, particularly in southern Africa, South America, and Mexico.

Family Geraniaceae (geranium family)

Plants chiefly herbaceous but sometimes suffrutescent (woody at the base only) or shrubby, the leaves alternate or opposite, mostly lobed or palmately or pinnately divided, and generally with stipules. Flowers large and showy to small, radially or bilaterally symmetrical, bisexual, solitary to umbellate. Sepals 4 or 5, free or fused to the midpoint, imbricate with valvate tips, a series of bracts resembling sepals (epicalyx) sometimes present. Petals five, rarely 4 or none, free, imbricate or contorted, usually with alternating nectar-producing glands. Stamens mostly 10, usually fused at the base, in 2 rows (but the row opposite the petals sometimes reduced to staminodes), or more rarely 15 and fused in bundles of 3. Ovary of 3 to 5 carpels with 1 or 2 ovules in each locule (many in *Balbisia*). Style simple or very short, with 5 stigmas. Fruit of 3 to 5 separating mericarps, each commonly bearing a water-absorbing awn of hardened tissue ("beak"), rarely a capsule. Seeds without or with scanty endosperm. Eight genera and about 800 species with worldwide distribution, especially in temperate regions.

Family Vivianiaceae

Woody herbs or subshrubs. Leaves opposite, simple, entire to toothed, lacking stipules. Flowers radially symmetrical, bisexual, in loose clusters or laxly cymose in the upper leaf axils. Calyx (sepals) tubular or bell-like with 4 or 5 "teeth." Petals 4 or 5, free, contorted, alternating with nectar-producing glands. Stamens sometimes 8, usually 10, free. Ovary 2- or

3-locular with 2 ovules in each locule. Styles 2 or 3, fused or almost free. Fruit a 3-lobed, 3-valved capsule. Seeds with a fleshy embryo. One genus (*Viviania*) with 30 species, confined to Brazil and Chile.

Family Biebersteiniaceae

Perennial herbs with multicellular glandular hairs. Leaves pinnate or pinnatipartite, alternate, with stipules. Flowers radially symmetrical, bisexual; disposed in terminal racemes or panicles. Sepals 5, free, imbricate. Petals 5, free, frequently with "teeth" at the tip, and alternating with nectar-producing glands. Stamens 10, filaments shortly fused into a ring at the base. Ovary of 5 carpels, deeply lobed, set on a short stalk. Styles 5, arising from the base of the lobes and fused into a capitate stigma. Ovules solitary in each locule, pendulous. Fruit of 5 indehiscent, 1-seeded mericarps. Seeds with scanty endosperm. One genus (*Biebersteinia*) with 5 species occurring in arid places from southeastern Europe to Central Asia.

Family Dirachmaceae

Shrubs with long and short shoots bearing alternate, simple, serrate leaves and persistent stipules. Flowers solitary in the leaf axils of the long shoots, bisexual, and subtended by an epicalyx of 4 small bracts. Sepals 8, free, valvate. Petals 8, contorted. Stamens 8, opposite the petals, with large anthers. Ovary of 8 carpels, deeply lobed, each locule containing 1 ascending ovule. Style solitary with 8 linear stigmas. Fruit a capsule, with 8 ventrally opening sections, woolly within. Seeds with scanty endosperm. One genus and species (*Dirachma socotrana*) occurring on the island of Socotra.

Family Tropaeolaceae

Succulent herbs climbing by prehensile leafstalks. Leaves alternate, entire (often shield-shaped) or variously lobed or palmate, with stipules (stipules, however, sometimes rudimentary). Flowers bilaterally symmetrical, bisexual, often showy in shades of red or yellow, solitary in the leaf axils. Sepals 5, fused below, the dorsal sepal modified and produced into a long spur, imbricate or valvate. Petals 5, the upper 2 often different from the lower 3 (which may be absent), clawed, inserted on the calyx, imbricate. Stamens 8 in 2 rows of 4, curved downward, with slender filaments. Ovary 3-locular, 1 pendulous ovule in each locule. Fruit of 3 finally hardening indehiscent carpels separating from a central axis. Seeds without endosperm. Two genera, *Magallana* (2 species) and *Tropaeolum* (about 90 species), confined to Central and South America from Mexico to Chile.

Family Balsaminaceae (balsam family)

Weak herbs with juicy, frequently translucent stems and alternate or opposite simple leaves. Stipules indicated by small glands. Flowers solitary or in umbel-like clusters, strongly bilaterally symmetrical, frequently showy in shades of pinks, purple, yellow, and orange. Sepals 5 (but 2 frequently reduced or aborted), the lowest prolonged into a spur, coloured. Petals 5, corolla 2-lipped, the upper petal large and ascending, the laterals fused in pairs. Stamens 5, with short, broad filaments fused at the tip; anthers fused around the ovary. Ovary 5-locular with numerous ovules in each locule. Styles short, or the 1 to 5 stigmas almost sessile (set directly on the ovary). Fruit a succulent capsule opening elastically by action of fleshy arils attached to seeds, rarely a berrylike capsule (*Hydrocera*). Seeds with scanty endosperm or none. Two genera with more than 450 species mostly in tropical Asia and Africa but some in Europe and North America.

Family Limnanthaceae

Succulent annual marsh plants. Leaves alternate, much divided, without stipules. Flowers solitary on long stalks in the leaf axils, radially symmetrical, bisexual. Sepals and petals 3 to 5, the former valvate and the latter contorted. Stamens 6 or 10 in 2 rows, the outer row alternate with the petals, frequently with basal glands. Carpels 3 or 5, almost free, with a single common enlarged gynobasic style and 1 ovule in each locule. Fruit of free indehiscent carpels. Seed without endosperm. Two genera and 11 species confined to North America.

Family Hypseocharitaceae

Stemless perennial herbs. Leaves in a rosette, pinnately divided, without stipules. Flowers bisexual, radially symmetrical, either sessile (no stalks) or with short stalks in few-flowered cymes. Sepals and petals 5, the former imbricate, the latter contorted. Stamens 15 in a single series, with persistent slender filaments. Ovary 5-locular, lobed, with a single style and numerous axile ovules in each locule. Fruit an irregularly loculicidal capsule, opening late. Seeds numerous, lacking endosperm. One genus (*Hypseocharis*) with 8 species occurring in the Andes.

Critical appraisal. Above the generic level, it seems unlikely that orthodox taxonomic methods based on external morphology will shed much more light on classification within the order or between the Geraniales and allied orders—particularly the Rutales, Sapindales, and Polygalales. In addition, many conclusions based on other plant disciplines, such as palynology and phytochemistry, are still founded on inadequate sampling of the families concerned, and more complete information may shed the necessary light, particularly if species showing primitive characters are first selected. At the generic level and below, taxonomic revisions of such large and troublesome genera as *Oxalis* and *Impatiens* are still much needed.

WARBURG, "Taxonomy and Relationship in the Geraniales in the Light of Their Cytology," *New Phytol.*, 37:130–159, 189–210 (1938), an interesting and useful paper dealing with the families Linaceae, Zygophyllaceae, Geraniaceae, Limnanthaceae, Oxalidaceae, Tropaeolaceae, and Balsaminaceae; O. WARBURG and K. REICHE, "Balsaminaceae," in A. ENGLER and K. PRANTL (eds.), *Die natürlichen Pflanzenfamilien*, 3: 383–392 (1897), a brief conspectus—more recent literature is extensive but scattered; O.E. SCHULZ, "Erythroxylaceae," in A. ENGLER (ed.), *Das Pflanzenreich IV*, 134:1–176 (1907), a very competent monograph, still the only general account of the family; R. KNUTH, "Geraniaceae," and "Oxalidaceae," *ibid.*, vol. 129–130 (1912, 1930) not of outstanding taxonomic merit, but the only general treatments of these families available; J. CUATRECASAS, "A Taxonomic Revision of the Humiriaceae," *Contr. U.S. Natn. Herb.*, 35:25–214 (1961), a very fine revision including an account of the relationships and evolution of the family, with an invaluable bibliography; H. WINKLER, "Linaceae," in *Die natürlichen Pflanzenfamilien*, 2nd ed., 19a:82–130 (1931), a now rather dated but still useful account, including in subordinate rank the Houmiriaceae, Ixonanthaceae, and Hugoniaceae; J. LEONARD, "*Lepidobotrys* Engl., type d'une famille nouvelle de Spermatophytes: les Lepidobotryaceae," *Bull. Jard. Bot. État. Brux.*, 20:31–40 (1950), the case for the separation of this genus into a new family; C.T. MASON, "A Systematic Study of the Genus *Limnanthes* R. Br.," *Univ. Calif. Publs. Bot.*, 25:455–506 (1952), a sound taxonomic revision of the genus, containing most of the Limnanthaceae, with information on cytology and experimental genetics; F. NIEDENZU, "Malpighiaceae," in *Pflanzenreich IV*, 141:1–870 (1928), of average taxonomic merit, marred by the fact that little or no use was made of the great British or American herbaria in its preparation but still quite invaluable; F. BUCHENAU, "Tropaeolaceae," *ibid.*, 131:1–36 (1902), competent, but of limited value since the number of species recognized has now almost doubled; A. ENGLER, "Zygophyllaceae," *ibid.*, 2nd ed., 19a:144–184 (1931), a brief conspectus of the family.

(C.C.T.)

German Democratic Republic

The most developed and prosperous of the Communist countries of eastern Europe and one of the major industrial nations of the world, the German Democratic Republic (often referred to as the GDR and called East Germany in the West) lies in a vital strategic region. The nation was established on October 7, 1949, as one of the two Germanys that emerged from the ruins of the Nazi period, a circumstance that molded much of the character of the young state during the years of the Cold War, as it attempted to construct a new and emphatically Communist society. By the 1970s the republic had attained a strong position economically and politically; its location in the continental heartland gives it a significant place—symbolized by the annual trade fair at Leipzig—in trade between eastern and western and between northern and southern Europe.

The country also derives trade advantages from the Baltic Sea coastline, its northern boundary. On the east the Oder and Neisse rivers form a long and important frontier with Poland; this boundary, part of the post-World War II Potsdam agreement, was confirmed in the Treaty of Zgorzelec of 1950. On the south the boundary with Czechoslovakia corresponds to an earlier boundary of 1918, renewed by treaty in 1945. On the west another long and major boundary separates the republic from the Federal Republic of Germany; it is based on the lines of demarcation, agreed upon at the Yalta Conference of 1945, separating the then Soviet occupation zone of Germany from the zones occupied by the Western allies, on whose territory the German Federal Republic subse-

Boundaries

quently emerged. Situated within the republic's territory, the 185 square miles of West Berlin form a unique political unit based on the three sectors of the city originally held by the Western powers; long a major potential source of conflict during the Cold War era, the western part of the city faded somewhat in international significance following a settlement by the major powers, announced in the summer of 1971. The republic's frontiers have thus had more than usual significance in determining the course of internal events.

The German Democratic Republic has an area of 41,768 square miles (108,178 square kilometres) and by the mid-1970s was the home of nearly 17,000,000 people. East Berlin ("Democratic Berlin") is the capital.

The following article covers various aspects of the land, people, and society of the contemporary republic. For related historical information, see GERMANS, ANCIENT; and GERMANY, HISTORY OF. See also BERLIN; LEIPZIG; ELBE RIVER; and ODER RIVER.

THE LAND

Topography. The German Democratic Republic lies across two major European topographic zones: a northern lowland belt, which narrows from east to west, and the smaller but rugged strip of the Mittelgebirge, or Mid-German Highlands, which borders it to the south. This basic division has had great influence on many aspects of the contemporary nation.

The northern lowlands. The northern lowlands of the republic consist mainly of wide, flat, and rolling plains, with the Elbe and the Oder river systems cutting only slightly into the terrain. Only the east–west ridges of the Nördlicher and Südlicher Landrücken rise to some 330 feet (100 metres) above the level plains.

The rocks underlying the plains are young Pleistocene sediments (less than 2,500,000 years old), thickening northward. Underlying older rocks include lignite (brown-coal) deposits in the south, but they lie too deep for easy exploitation. Exceptions include the important limestone quarries northeast of Berlin and the ancient rock-salt and potash deposits, which can be mined because of upthrusts associated with later mountain-building movements.

Effects of the Ice Age

The surface of the plains was shaped largely by Ice Age forces; a line from Wilhelm-Pieck-Stadt Guben, on the Polish frontier, to Brandenburg, west of Berlin, separates a region molded by southward-moving Scandinavian glaciers, which were formed during the Weichsel (or Vistula) Glacial Stage (the last Ice Age advance), from the more southerly belt, affected only by the earlier Saale and Elsterian Glacial stages. The northern portion of the lowlands exhibits the classic features of glacial molding—a lumpy, lake-strewn relief with terminal moraine ridges marking the limit of glacier-carried debris—while the older southern surfaces have been levelled, and their lakes have become dry land.

The plains, which were covered by clay and studded with ice-scoured boulders, thus generating loamy soils, are important agriculturally, but the terminal moraines tend to be heaped with boulders and sand, are much less fertile, and are often forest clad. Trees also cover the dry, sandy valley regions, but prehistoric meltwater valleys are marked by a natural grassland cover.

The southern edge of the lowlands is marked by a loess belt of windblown deposits laid down during the Weichsel Glacial Stage. Given favourable conditions, a rich, black soil developed on this rolling countryside, with less fertile podzol soils developing in the areas of higher rainfall. The whole belt, which stretches from the Harz Mountain foothills as far as Magdeburg (the Magdeburger Börde) in the west and the area of Lusatia, or Lausitz (Lausitzer Gefilde) in the east, has supported agriculture based on wheat, barley, and sugar beets.

The uplands of the south and southwest. South of the loess belt rises the contrasting topography of the Mittelgebirge region. In addition to the Harz mountains and the Erzgebirge (Ore Mountains) and the mountains of the Oberlausitz (Upper Lusatia) and the Thüringer Wald (Thuringian Forest), the region contains the rolling hills of the Thuringian and Erzgebirge basins and, near Dresden, the lowlands of the Elbe Valley. The core of the whole region is hard, crystalline rock associated with the ancient Hercynian mountain-building period (some 300,000,000 years ago), when molten granitic intrusions formed ore deposits. Toward the end of the Paleozoic Era (about 250,000,000 years ago), this eroded mountain range was filling its associated structural depressions with debris, and it was here that the region's valuable hard-coal beds—such as those of the Erzgebirge basin—were formed. Sediments of limestone, clays, and sands were packed into gigantic hardened rock masses during the ensuing Mesozoic Era, and the vast upthrusts associated with the Alpine mountain-building process consolidated them into the ranges seen today, although much of the Mesozoic cover has been worn away.

The highlands are thus a mosaic of many-layered structural blocks, some lifted and some sunk deeper during the Tertiary upheavals. Climatic and soil conditions have stimulated the growth of extensive forests—now largely spruce, as a result of 19th-century planting—above the 2,300-foot mark, whereas the rain-favoured higher meadows are increasingly utilized for cattle raising. The high rainfall is retained by an extensive dam system and is then piped to the industrial cities of the foothills and basins. Bismuth, cobalt, uranium, silver, zinc, lead, and tin ores are still mined in the mountains to which they have given their name, and, although industrialization has left its harsh mark on the regional landscape, the more rural areas retain a considerable scenic charm, which has fostered tourism.

Climate. The climate of the German Democratic Republic reflects the transitional climate of central Europe, which is determined by constantly interchanging air masses of maritime and continental origin. The exposed Baltic coastline enhances the maritime component.

The lowlands. In the lowland belt, precipitation diminishes eastward as the plains open toward the Eurasian interior, and the average temperatures for the warmest and coldest months become more extreme. Schwerin, in the northwest, for example, has an annual rainfall of 24.7 inches (627 millimetres), a mean annual maximum of 63.5° F (17.5° C), and a mean January minimum of 31.8° F (−0.1° C), while for Frankfurt an der Oder the corresponding figures are 21.3 inches (540 millimetres), 65.7° F (18.7° C), and 30.2° F (−1.0° C).

The uplands. To the south the mountains have a wetter and cooler climate, with westward-facing slopes receiving the highest rainfall from maritime air masses. At a station on the Brocken, a mountain in the Harz near the western frontier, annual precipitation reaches 58.4 inches (1,483 millimetres) at an altitude of 3,747 feet (1,142 metres). The sheltered lee slopes and the basins, by contrast, being in a rain shadow, are actually arid. The basins and low-lying tracts also tend to be warmer and hence are especially favourable to agriculture; fruit and grapes for wine, for example, are grown in the Elbe Valley region.

The human imprint. *Traditional regions and modern planning.* The human imprint on the republic's landscape also reflects a basic division, this time between a highly industrialized south and a predominantly rural north. Until 1945 metropolitan Berlin was the only industrial cluster north of a line from Wilhelm-Pieck-Stadt Guben to Magdeburg.

The rural north and the industrialized south

The precious metals of the southern mountains supported a dense population from late medieval times until silver mining declined with the discovery of New World deposits. The people turned to the development of other crafts, trades, and, notably, the textile and metalworking industries. The elaborate transportation network and the lignite- and salt-mining industry, developed in the later 19th century, diversified and enlarged the regional economy to encompass chemicals, heavy machinery, and power plants. In the north, meanwhile, the lack of mineral wealth, poor transport and marketing conditions, a sparse population, and, notably in Mecklenburg and Brandenburg provinces, the presence of a powerful class of landowning Junkers all impeded industrial development.

MAP INDEX

Political subdivisions

The names of the political subdivisions do not appear on the map because they are the same as the names of their capital cities.

A major goal of overall Socialist planning has been the development of the national territory as a whole. The southern industrial clusters, centred on, among others, the cities of Dresden, Karl-Marx-Stadt, Halle, and Leipzig, were restructured to diminish the disproportions created by the dismemberment of the Third Reich. With similar goals in mind, the formerly backward northern regions developed such new industries as, for example, shipbuilding, supplied by an industrial hinterland, in the port cities of Rostock, Wismar, and Stralsund. Special efforts were made to modernize agriculture and to develop a coordinated, industrialized food-producing and food-processing system of communes—model, state-owned farms and cooperatives and food-processing plants associated with them—in coordination with an extensive restructuring of the transportation system.

Urban settlement. The GDR considers communities of more than 2,000 persons urban; by this definition, almost three-quarters of the population is urban. Yet the distribution of city dwellers is very uneven; the largest concentration is in a zone beginning in the west, between the Harz and Magdeburg, reaching southeast through Dessau, Halle, and Leipzig, and then penetrating into the Erzgebirge valleys through Karl-Marx-Stadt and Zwickau, continuing eastward to Freiberg and Dresden. To the west the city series Gera–Jena–Weimar–Erfurt–Gotha–Eisenach forms a link to the fringe of the Thüringer Wald. In the north a cluster of urban centres has formed around Berlin, but, apart from that, generally in this region only local and provincial administrative centres are significant, which is directly opposite to the pattern in the industrialized south. Roughly one-third of the country's population still inhabits the great metropolitan complexes of Berlin, Halle, Leipzig, Karl-Marx-Stadt, Zwickau, and Dresden, but this pattern is changing with the accelerating need for new housing outside the old city centres.

Rural settlement. National plans call for the restructuring of villages. Many village communities were established in the 13th century in connection with a feudal eastward expansion policy. They tend to dissolve into smaller settlements with fewer than 100 inhabitants, notably in the Rostock, Schwerin, Neubrandenburg, Frankfurt, and Cottbus districts. The creation of large communal societies and cooperative units has been a catalyst in transforming rural settlement: such villages have multistoried housing blocks and a careful zonation into work areas, schools, and rural shopping, cultural, and service centres. Barns, sheds, haylofts, storerooms, and industrial meat-processing centres are set apart. The process has done away with privately owned farm property and even individual houses.

Changes in village communities

THE PEOPLE

Ethnic, linguistic, and religious divisions. The population of the German Democratic Republic, declining since World War II, dropped below the 17,000,000 mark in 1973 and by the end of 1975 was estimated to have fallen to 16,820,000. The overwhelming majority is made up of Germans who speak the German language. Regional dialects, notably the Plattdeutsch, or Low German, of the northern Mecklenburg region and the Saxon of Saxony in the south, continue to have significance in everyday life. In addition, many thousands (according to Western estimates, 35,000 to 70,000) of Sorbs (or Wends), descendants of early Slavic settlers, live in Lusatia, in Cottbus and Dresden districts. Other Slavs who had settled early in the Elbe and Saale basins and even farther westward retreated or were pushed out or Germanized during the medieval German colonization eastward. The Sorbs have preserved their individuality, and the region is officially bilingual, there are Sorbian schools and theatres, and the Domowina (the official Sorb homeland organization) protects the Sorbian heritage.

In religious affiliation, Protestants outnumber Catholics eight to one; adherence to religious groups is declining, however, especially among the young, although religious affiliations are ostensibly protected by the constitution.

Demographic structure. The German Democratic Republic is virtually unique among the major countries of Europe in that its population in 1976 was less than it was in 1947, when a peak was reached in the chaotic conditions following the collapse of the Third Reich. It declined steeply until 1961 and since then has declined at a slower rate. Distribution, as noted above, is very uneven, with a concentration in the southern industrial belt and in the north around Berlin. Urbanization is greatest in the Karl-Marx-Stadt and Leipzig districts and least in rural, northern Neubrandenburg.

German Democratic Republic, Area and Population

	area		population†

The legacy of World War II. As a result of World War II and its aftermath, and also because of emigration, the demographic structure of the republic has been markedly distorted. Such factors as the scarcity of young people, the large surplus of women in middle and older age groups, and, indeed, the general concentration in the older age groups continue to exert an influence. Birth rates and death rates emphasize the significance of these factors. Live births in the mid-1970s were only a low 11 per 1,000 population, and this in spite of the extremely low degree of infant mortality. Similarly, in a population with a predominance of elderly persons the death rate is high (about 14 per 1,000) in spite of a steadily declining mortality rate among younger people and an average life expectancy of 69 years for men and 74 years for women. The highest live-birth figures are found in the rural areas of the north, with a decline southward as urbanization increases.

No other European country has such a high proportion of pensioners—almost 20 percent in 1974, compared with 11 percent for the same areas in 1939. The proportion of the population in the labour force declined from 68 to 50 percent over the same period. Questions concerning automation, the rationalization and mechanization of the national economy, and the problems and potential of the social-welfare resources of the country become much clearer when seen against such a demographic background.

Another peculiarity is the surplus of women. In 1946 there were 135 women for every 100 men as a result of World War II and its aftermath. This disproportionality subsequently improved with the return of prisoners of war and with the death of women who strongly predominate in the older age groups; by 1974 the ratio had fallen to 116 to 100. This female surplus tends to increase with the size of communities; the trend toward equalization of the sex ratio is strongest in places with such male-oriented industries as mining and power plants, as in Halle-Neustadt and the Cottbus district.

The surplus of women

Contemporary trends in the labour force. By the mid-1970s more than 8,309,000 persons were gainfully employed. The increase of more than 500,000 since the early 1950s resulted largely from the entry of women into the labour force; the number of male workers showed a decrease. The fact that almost half the labour force is fe-

male has important consequences, notably in the provision of children's nurseries, kindergartens, play centres, all-day (rather than the usual 8 AM to noon) schools, and so on. A growing number of women are moving into leading professional positions, particularly in Berlin and in the industrial south, where both supply of and demand for trained personnel are highest. The working force is also augmented (to about 7 percent of the total) by persons who have qualified for retirement pensions but prefer to continue working.

Declining agricultural employment

More than a third of the working force is now employed in industry, and the proportion is steadily rising. A similar increase is taking place in commerce and service industries, while agriculture takes a declining eighth of the total, still a high figure compared with other countries. The steadily increasing need for workers, especially in industry, has caused planners to consider further automation and rationalization plans. In the geographic distribution of the labour force, the basic north–south contrast again emerges: agricultural workers in 1974 accounted for 29 percent and industrial workers for 17 percent of the total in the Neubrandenburg district, but in the district of Karl-Marx-Stadt the percentages were 6 and 51, respectively.

Internal migrations also take place in the republic, though to a declining extent; former movements trended from smaller rural settlements to larger towns, especially where these were the focus of new, planned industrial expansion. Men and young persons (18–30 years old) are prominent in this internal migration, causing social and economic changes in both the departure and reception areas. Centres of attraction are Berlin and the Cottbus and Frankfurt regions (both focal points for planned new growth). Karl-Marx-Stadt and Halle, because of a declining mining industry, and rural Neubrandenburg and Magdeburg are the main losers. Before the sealing of the national boundaries (especially around West Berlin) in 1961, a substantial migration, including much trained manpower, to West Germany caused severe problems to the national economy.

The outlook. It is of some significance that the low point of available working people seems likely to occur by the mid-1970s. The disproportionality is expected to diminish through the end of the decade and beyond, with the proportion of older people who are pensioners, to take a key gauge, falling from some 20 percent in 1970 to an estimated 14 percent by 2000. The final working out of the asymmetry introduced by World War II should strengthen immensely the economic and social development of the country. (H.-J.K./R.E.H.M.)

THE NATIONAL ECONOMY

The German Democratic Republic is eastern Europe's most developed and prosperous country. Its national income per person has been estimated by the World Bank to be considerably higher than that in any other European Communist country, with the exception of Czechoslovakia. While its agriculture accounts for a fairly small part of total east European farm production, in industry it occupies a very prominent position. It is an important producer of machinery, especially of advanced equipment, much of which is sold to other eastern European countries. Compared with other countries of the region, however, its overall economic progress has been relatively slow; during 1970–74, for example, its net material product grew by only about 26 percent, a rate that was exceeded in every east European country except Czechoslovakia.

International standing of the country's industry

The extent and distribution of resources. *Mineral resources.* The republic is relatively poor in mineral resources: only lignite, potash, and rock salt are found and produced in significant quantities, although other minerals, such as hard coal, iron ore, copper, bismuth, cobalt, and uranium are mined on a small scale. A small quantity of natural gas is produced, but there are no oil resources to speak of. By 1975, annual output of lignite (brown coal) amounted to about 270,000,000 tons, making the country the world's largest producer. Output grew rapidly up to 1964, but in subsequent years it showed little change. Much of the country's lignite comes from two main fields: Niederlausitz (northeast of Dresden) and the Halle–Leipzig region. There are a number of smaller producing areas, of which that lying near Magdeburg and Stassfurt is the most important. The lignite is easy to extract but has a high water content and a low calorific value; its main use is in the form of briquettes for thermal power stations and as domestic fuel, though large quantities are also used by the chemical industry.

Coal, potash, and iron ore

Local supplies of hard coal are not adequate to meet domestic requirements. Production, which is based on two small fields lying, respectively, between Karl-Marx-Stadt and Zwickau and between Freital and Dresden, has been declining, and by 1975 it amounted to scarcely 600,000 tons annually. Hard-coal imports (including coke), mainly from the Soviet Union, Poland, and Czechoslovakia, amounted to about 15 times as much. Potash and salt, which are found in large quantities on the eastern edge of the Harz Mountains, near Halle, play a significant part in the country's chemical industry and are important export products. Iron ore is mined in Thuringia and near Ilsenburg in the Harz, but reserves are small, the ore is of poor quality, and production had virtually ceased by 1975. Copper is found at Mansfeld in Thuringia, and uranium is produced in the Elster Valley and in the Erzgebirge.

Other resources. More than 60 percent of the country's total land area is agricultural land. Most of it is arable, only about an eighth being classified as meadows and pastures. The quality of the soil varies considerably from area to area, but, with the exception of that in the Thuringian basin and between Leipzig, Halle, and Magdeburg, it is not very productive. More than a quarter of the country's surface is wooded; some 80 percent of the forest area consists of coniferous trees, notably Scotch pine, spruce (especially in the Harz Mountains), and fir. Deciduous forests are made up of beech, oak, and birch. Extensive reforestation has taken place since the country was established. Hydroelectric potential is limited; small amounts are generated in the Erzgebirge and the Sudeten region.

Sources of national income. *Agriculture.* In the mid-1970s GDR agriculture, which is fairly advanced when compared with that of its Communist neighbours, contributed about 11 percent of the country's net material product and occupied about 11 percent of the labour force. There is one 15-horsepower tractor for every 76 acres (31 hectares) of arable land, a figure surpassed only by Czechoslovakia in eastern Europe, and the consumption of chemical fertilizers—at more than 220 pounds per acre (260 kilograms per hectare)—is one of the highest among Socialist and a number of European capitalist countries. As a result, yields are relatively high, but the country is still dependent on imports for a large part of its food.

Farming is organized on the basis of nearly 5,800 cooperatives and a number of state farms. The latter occupy about 7 percent of the socialized land area, which itself takes up all but 5 percent of the total agricultural area. The principal crops include potatoes, followed by sugar beets, barley, wheat, rye, oats, and oilseeds. Livestock raising is also important. Western observers feel that one of the main problems in agriculture has been the relatively slow and uneven growth in output, resulting from the lack of adequate investment funds and the lack of incentive thought to be associated with collectivization. From time to time there have been large shortages of certain commodities, necessitating large-scale imports. The position was particularly difficult in 1969, when, partly as a result of unfavourable weather, the cereal crop was some 12 percent lower than in the previous year, while the output of oil-bearing crops and sugar beets was, respectively, 28 and 26 percent lower than the average of the previous five years.

Industry. The German Democratic Republic is one of the most heavily industrialized Communist countries. Industry contributed more than 67 percent of the total net material product by the mid-1970s—more than in any

other east European country except Czechoslovakia—and engaged more than 38 percent of the total labour force. Industrial development was very rapid, the index of industrial production advancing more than 170 percent during the 1950s, 70 percent during the '60s, and 28 percent in 1970–74. Much of this progress resulted from improvements in labour productivity, which, per person, rose almost 210 percent between 1955 and 1974.

Industrial policy

The main early feature of industrial policy was the disproportionate attention given to heavy industry and a preoccupation with quantitative rather than qualitative progress. By the 1960s it was realized that these and other policy shortcomings were beginning to have an adverse effect on the rate of growth. A more rational economic and industrial policy, involving a limited decentralization of decision making and responsibility and a more equitable distribution of resources among the various sectors of industry, was initiated. The share of industrial investment devoted to energy, fuel, and metallurgy fell by half, to about a quarter of the total, during the early to late 1960s, but the share of light industry and the textile and food industries was expanded from 12 percent to 18 percent. Investment in the electronics industry more than doubled, to about 10 percent; engineering saw a rapid growth, but the share of chemicals remained constant.

The policy of the early and mid-1970s was to improve quality, make greater use of advanced technology, and raise productivity. The main emphasis is placed on fuel and power, engineering, chemicals, and electronics; specialization, especially in the field of sophisticated electronic and complex engineering products, is actively encouraged.

Chemicals, machinery, and electric and electronic products have been among the fastest growing branches of industry. Output in engineering (including vehicles), for example, grew by 90 percent in the 1960s and by the mid-1970s was the largest single branch of industry, accounting for nearly a quarter of total output. Food has a 17 percent share, closely followed by chemicals, light industry, and the rapidly expanding electronics sector. Other important branches include metallurgy and the relatively slowly advancing textile industry.

The output of electricity has been growing rapidly, expanding to more than 84,500,000,000 kilowatt-hours by the mid-1970s, but has failed to keep up with the expansion of demand. Most electricity is generated from lignite and coal. Oil, which is pumped from Kuybyshev in the Soviet Union to Schwedt and Leuna by means of the Comecon (the Communist bloc economic organization) Friendship (Russian Druzhba) pipeline, covers only a very small part of the country's total energy requirements. A similarly small amount (less than 5 percent) of electricity is derived from hydroelectric power stations and from the country's small atomic power plant, which opened in 1966.

The country is eastern Europe's principal producer of plastics and synthetic fibres; other important industrial products are pig iron, crude steel, rolled steel, chemical fertilizers, sulfuric acid, paper, and various passenger and freight vehicles.

Foreign trade. In per capita terms the country is eastern Europe's second largest foreign trader after Czechoslovakia, and foreign trade was about 75 percent higher during 1971–75 than during the previous five years. As it has no significant nontrade sources of foreign revenue, it has had to balance its trade (and sometimes even earn a small surplus) by limiting the growth of its imports to match its exports. In practice, however, exports have often exceeded imports by a fair margin. In contrast to the trend seen in other eastern European countries, the importance of the Communist world in the country's foreign trade has not declined significantly; by the mid-1970s the Communist bloc's share of the total was about 64 percent, only slightly less than in 1960, and among the highest in east Europe. Trade with the capitalist countries, which has grown faster than total trade, constituted about 31 percent of the total, and the remainder (about 5 percent) was made up of trade with the developing world.

Trading partners

The country's largest trading partner, namely, the Soviet Union, accounted for about a third of both exports and imports.

The GDR's principal non-Communist customer and supplier was the Federal Republic of Germany, which accounted for about 8 percent of both exports and imports. Since the mid-1960s the balance of trade between the two Germanys has been in favour of West Germany.

The scarcity of official statistics makes it difficult for Western observers to establish detailed commodity composition of the republic's foreign trade, but it is known that in the mid-1970s one-third of all imports consisted of raw materials (notably hard coal, coke, and crude oil), while another third was made up of the products of the metalworking industries. Products of the food, light, and related industries constituted more than 20 percent of the total, with agricultural produce (including wheat and oilseeds) accounting for roughly one-tenth. On the export side, more than 50 percent was derived from sales of machinery and metalworking products; the remainder was shared, about equally, by basic raw materials and light industrial and related goods. Sales to the republic by the advanced western European countries included machinery and foodstuffs (accounting jointly for just over half the total), manufactured products, and crude materials and chemicals. Exports to those countries included manufactured products and machinery (about half the total), chemicals, and food.

Management of the economy. *The role of the government.* As in other Communist countries, the government plays an all-important role in the economy. Agriculture is in the hands of the collectives and the state farms, while industry and most trading and financial enterprises are owned and controlled by the state. Reforms begun in 1972 and completed by 1975 virtually eliminated private enterprise, although about 14 percent of retail trade was still handled outside the Socialist sector.

Economic plans and the more important production targets are laid down, after discussion at all levels, by the government, as are the detailed economic policies necessary to fulfill these plans. The result, Western observers conclude, is a highly centralized and bureaucratic system of economic management, in which market forces are not allowed to operate to any significant extent. Western observers would, nevertheless, agree with the republic's own economists that, as a result of a gradual process of economic reform embarked on in 1963, the current system of controlling the economy is more flexible and sophisticated than it was at the start of the 1960s. The aim of these reforms was to eliminate some of the worst features of rigid central planning and detailed state supervision without seriously weakening the central control of the economy. As a result, economic plans were less detailed and binding production targets were laid down in respect to fewer goods; although prices were still determined by the state, price-fixing methods had been greatly improved.

Centralized economic management

At the same time, steps have been taken to give at least a limited role to such economic forces and instruments as demand, profit, taxation, and interest. Production targets for individual enterprises are now expressed in terms of profit and sales value rather than in terms of physical volume, and enterprises have been given some independence in deciding such matters as the type of goods produced, incentive payments, and the allocation of investment resources.

Direct control over the larger enterprises is exercised by some 80 industrial associations (Vereinigungen volkseigener Betriebe) that check the performance and coordinate the plans of individual enterprises and are responsible to the appropriate ministry. Smaller firms report to regional economic organizations (*Bezirkswirt-schaftsräte*).

Trade unions. The country's trade unions are organized on the basis of industries and are affiliated with the national group known as the Freier Deutscher Gewerkschaftsbund (FDGB; Free German Trade Union Association), which claims a membership of some 8,000,000. They are not active in social and economic affairs in the

same way as their Western counterparts; as in other Socialist countries, they take part in discussions concerning, and then assist in the implementation of, national planning policies.

They may, in this respect, be considered an important part of the overall state apparatus, with responsibility for such matters as labour discipline.

TRANSPORTATION

The basic geographical division in the republic again may be seen in its transportation network, with a dense pattern of railways and highways in the southern industrialized regions contrasting with a thinner network in the agricultural north. Requirements of internal and foreign trade have strengthened this pattern, and topographic conditions have also played a part; both the rugged topography of the Mittelgebirge and the northern fens, swamps, and lakes have made route construction expensive.

Coastal conditions have strongly influenced the flow of shipping and harbour construction; fogs, low winter temperatures, snow, and the freezing of inland waterways are also important factors affecting costs, performance, and the accident rate.

The railway system. The state railway system, the Deutsche Reichsbahn (DR), still partly suffers from extensive war damage and reparations dismantling, but it is being modernized and rationalized. Uneconomical secondary lines, whose traffic is handled more efficiently by road vehicles, have been closed. Some short, local narrow-gauge lines remain. Added emphasis has been given to fast, modern intercity traffic. Railway tracks are most dense in the southern industrial agglomerations, and important lines connect Berlin to the major regional centres, which are themselves interlinked. Main freight lines in Saxony have been electrified.

A noteworthy feature is the Seddin marshalling yard south of Potsdam, a vast control centre handling international traffic at the very heart of the whole central European railway system.

Roads and highways. Highway traffic is playing an increasing role in transport. Most vehicles are state-owned, but a few private or semiprivate companies survive. Private motorcar ownership is low by western European standards. The road network is dense—thinner in the rural north but very dense and congested in the industrial south. The arterial system dates from the mostly long, straight 19th-century highways, the *Chausseen*. The *Autobahnen* (expressways) system, dating from Nazi times and influenced in design by military considerations, is only partially suited to contemporary traffic needs in the republic. Starting from the incomplete Berliner Ring, expressways radiate to the northeast, east, southeast, southwest, and west. In the south a cross-connection joins Dresden, Karl-Marx-Stadt, Gera, and Erfurt. The Leipzig–Dresden link was completed in the 1970s, the Berlin–Rostock expressway and remaining Berliner Ring are under construction, and plans exist for a Halle–Magdeburg connection.

The *Autobahnen*

Inland waterways. The lowland portions of the republic offer favourable conditions for a part natural, part artificial waterway system. About 80 percent of the total network is made up of regulated or canalized river reaches, while wholly artificial canals make good use of the east–west courses of ancient riverbeds. Main natural thoroughfares are the Elbe and its tributaries, the Saale (navigable up to Halle–Trotha), the Havel (navigable up to Zehdenick), and the Oder. The Elbe–Havel, Havel, Oder–Havel, Hohensaaten–Friedrichsthaler, and Oder–Spree canals and, farther west, a portion of the important Mittelland Kanal as far as the locks at Magdeburg–Rothensee form the main artificial links connecting the rivers; the east–west routes carry the most traffic. As the waterway system does not extend to the industrialized south, insofar as larger vessels are concerned, it carries only a small portion of freight; tourist traffic is of some significance, especially along the Elbe and on the scenic Baltic coast.

In spite of unfavourable natural conditions, the Baltic coast also has a number of commercial shipping port facilities, which are capable of handling all of the republic's overseas trade. In addition to the traditional port cities of Wismar, Rostock, and Stralsund, new deepwater harbour facilities on the Breitling at Rostock–Petersdorf serve as a gateway to the world.

Air traffic. Regular, scheduled air traffic was instituted in 1956 between more than half a dozen internal airfields and to 36 destinations in Europe, Asia, and Africa. The Berlin-Schönefeld Central Airport (Zentralflughafen Berlin-Schönefeld) dominates the system. Interflug is the small domestic airline and the Soviet airline Aeroflot the other major operator.

Pipelines. The important Schwedt refinery is the terminus of the Friendship (Druzhba) pipeline that brings crude oil from Russia. Schwedt also has links to the oil port at Rostock and to the Leuna chemical works near Leipzig, while further links for crude oil and products are planned.

ADMINISTRATION AND SOCIAL CONDITIONS

The structure of government. *The constitutional framework.* Under the terms of a constitution ratified in April 1968, the German Democratic Republic is a Socialist country. According to the prevailing interpretation of Marxist–Leninist theory, all classes of the population belong to an alliance known as the National Front of the German Democratic Republic (Nationale Front der Deutsche Demokratische Republik), an organization that embraces all political parties and mass organizations. This, it is claimed, represents an organizational expression of the principle that each citizen carries a responsibility for the direction of the entire community. Political power is exercised through the People's Delegations (Volksvertretungen), which form the basis of all political, economic, social, and cultural agencies in the republic, according to the principle embodied in the slogan "Work together, plan together, govern together" ("*Arbeite mit, plane mit, regiere mit!*"). Elections to the delegations are open to those who have attained their 18th birthday on the day of the election. Citizens over 21 can participate in elections to the national People's Legislature (Volkskammer). As in other Communist countries, much guided public discussion of basic questions of policy, as well as public examination of the candidates offered, precedes the actual election. The names of all candidates appear on a unified list approved by the ruling SED (see below).

The Volkskammer is the supreme agency of political power, resolving the main principles under which social and political life are to be carried on, both for individuals and for the various agencies and bodies concerned. It consists of 500 delegates elected for four-year terms.

The Council of State (Staatsrat) carries on the function of the legislative body between sessions. The Ministerial Council (Ministerrat), executive of the Staatsrat, carries out administrative and policy decisions that include planned development of the economy. Each council member is responsible for the management of the region assigned to him.

The regional People's Delegations function as elective agencies of the central government, and each produces its own councils and commissions to carry out national policies.

The dominant spearhead of this political movement is the Sozialistische Einheitspartei Deutschlands (SED), a product of the merger in 1946 of the Kommunistische Partei Deutschlands (KPD) and the Sozialdemokratische Partei Deutschlands (SPD). Other political parties tolerated are the Liberal-Demokratische Partei Deutschlands (LDPD, established 1945), the Christlich-Demokratische Union (CDU, established 1945), the Demokratische Bauernpartei Deutschlands (DBD, established 1948), and the Nationaldemokratische Partei Deutschlands (NDPD, also set up in 1948). Mass trade-union, youth, and women's organizations belong to the Demokratischer Block der Nationalen Front.

Political parties

International associations of the republic include adherence to the military Warsaw Pact and to Comecon, the economic organization linking east Europe; economic

ties are particularly close with the Soviet Union. More broadly, the GDR maintains economic and cultural links with many nations and is a member of more than 200 international organizations. The German Democratic Republic was accepted as a member of the United Nations in September 1973, following the signing of a mutual recognition treaty with the Federal Republic of Germany in December 1972.

The legal system. The highest judicial body is the Supreme Court (Oberstes Gericht), and its members (elected for four years), as well as those of the local and regional courts, are selected carefully for their understanding of the Socialist character of the social system. Prosecution for violations of law is handled by a body of public prosecutors, headed by an attorney general.

The armed forces. In 1956 the National People's Army (Nationale Volksarmee) replaced the garrison units of the People's Police (Volkspolizei, or VP), formed in 1952. It cooperates closely with the Soviet armed forces (which have some 300,000 troops stationed in the republic) and those of other Communist countries. There are also armed combat groups and the VP. These forces (equipped with Soviet weapons), along with Soviet troops and Czechoslovak forces periodically stationed in the republic, guard an important western sector of the border of the Communist bloc. Compulsory military service for men has existed since 1962.

Education. The school system of the German Democratic Republic is uniform and carefully structured. Its nucleus is the polytechnic public school (*Oberschule*), which consists of 10 grades and offers a general education. There is also an extensive preschool system of day nurseries and kindergartens. After the 10-year public school education, studies may be continued, first in vocational schools, then, after gaining the skilled workman's certificate known as the *Facharbeiterbrief*, in trade and technical schools and schools for engineering. Apprentices may earn their high school diplomas (*Abitur*) in a special course offered in the vocational school itself, at evening high schools, or at factory schools or then may take a mature student's high school diploma. The *Abitur* enables the student to continue studies at a *Hochschule* or university. Polytechnic high schools offering a general education also confer the *Abitur*. Other specialized institutions include factory schools, village academies, radio and television academies, and bodies specializing in agriculture and health care.

The *Abitur*

The public colleges (*Volkshochschulen*) and factory training schools (*Betriebsoberschulen*), together with other special schools, complete a complex educational system generally acknowledged as having a high level of proficiency though heavily imprinted by Marxist dogmas. Advancement is based on ability; there are no tuition fees.

The well-organized system of public libraries is also part of the educational apparatus; it is focussed on the Deutsche Staatsbibliothek (a significant centre of science collections) in Berlin and the Deutsche Bücherei, the national library based in Leipzig. The latter includes a collection of almost all the literary output in German since 1913. There is an elaborate system of regional, university, and specialist libraries, in addition to some 12,600 public library branches. There are also many valuable museums.

Social conditions and services. The republic possesses an extensive health-care system, administered by a Cabinet office. Financial support and free medical assistance, medicine, and nursing care are available in case of sickness or accident. The scheme, which is available to all citizens, is funded in part by a uniform and obligatory national insurance system, the management of which is part of the national budget responsibility. There is, in addition to the health-care system, a comprehensive preventive medical program and care, including a pension system, for the aged, who form a significant element in the population. Certain occupational groups—including miners, postal and railroad workers, and professionals—receive higher pensions. There are about 170 sanatoriums.

The republic's housing policy allows each citizen and his family the right to adequate quarters insofar as it is consistent with local conditions and the political and economic situation. The concentration on reconstruction, especially the setting up of heavy industry, in the country's early years impeded a successful solution of the gigantic housing problem, although the changed national priorities were alleviating the situation by the 1970s. Within the family women enjoy full equality; families with many children, unwed mothers, and one-parent families receive special attention.

Of the total national income of the republic, about 23 percent is put by for capital accumulation, and the remainder is used for consumption. About 7 percent goes to national educational funds, the same amount to sciences, art, and culture generally, and about 20 percent for the social insurance plan. Even though private home ownership still plays a considerable role in the country, it is slowly declining as a result of state and cooperative housing developments. Rents vary regionally, with Berlin rents running 50 percent higher than those in localities of fewer than 100,000 people.

Changing consumer conditions are reflected in figures that show that between 1955 and 1974 automobile ownership (per 100 households) rose from 0.2 to almost 24, motorcycles from 11 to 20, radios from 77 to 96, television sets from 1.2 to 80, and refrigerators and washing machines from 0.5 to 70.

CULTURAL LIFE AND INSTITUTIONS

Much of the cultural life of the German Democratic Republic has been conditioned by three basic and inescapable factors: the rich German cultural heritage; the dismemberment of Germany and the Cold War era; and the introduction of a new cultural environment as one of the fundamental precepts of the Socialist society. The state now plays a prominent role in all cultural activities, including physical culture, sports, and tourism, all of which are regarded as components of Socialist culture.

The fine arts. Among the organizations founded with the new aim of creating a realistic art closely linked to the people was the Association of Artists (Verband Bildender Künstler) in 1950, while a decree on culture (Kulturverordnung) of the same year endeavoured to assure the material well-being of individual artists. Commissions for the creation of monumental works of art, notably at the former concentration camps of Buchenwald, Ravensbrück, and Sachsenhausen, influenced the development of the plastic arts, and ideological "guidance" has been constantly exercised.

Association of Artists

In the early postwar years, architecture also reflected Socialist ideological influence modelled on Soviet designs; several major showpieces were carried out regardless of cost, but sometimes exaggerated decorations and eclectic designs led to tasteless results, as, for example, the overall appearance of the Karl-Marx-Allee in Berlin. In an attempt to remedy the situation, principles of urban construction closer to contemporary Western forms were laid down to serve as the foundation for ensuing architectural design.

These principles perhaps found best expression in such entirely new planned cities as Eisenhüttenstadt and Hoyerswerda, as well as in the reconstructed parts of some of the older, historic cities such as Berlin, Dresden, and Leipzig.

Literature. Literature plays an important part in the cultural life of the republic. The publishing industry, centred in Berlin and Leipzig, produces many works stemming from the rich classical German tradition and also the works of a good number of modern writers. Representatives of the Communist tradition who are in the first rank internationally include Bertolt Brecht, who died in 1956 and whose austere poetry, sardonic humour, and biting social commentary left their mark on readers in many lands; the social-documentary novels of Anna Seghers, perhaps best illustrated by *Das siebte Kreuz* (1939; *The Seventh Cross*, 1942); and, possibly more significantly, Arnold Zweig, whose *Der Streit um den Sergeanten Grischa* (*The Case of Sergeant Grischa*, 1927) was a seminal work of the pre-Nazi era. The Bit-

terfeld Conference of 1959 formulated the role of the writer in the evolving Communist society and generated the movement known as the Movement of Writing Workers (Bewegung Schreibender Arbeiter) to encourage latent talent in the portrayal of "Socialist Realism" while at the same time allowing closer supervision and guidance by the authorities.

The theatre. All the theatres in the republic are owned by the state, a circumstance that, among other things, ensures an adequate subsidy. There are some 110 permanent theatres, almost 1,000 cultural centres, and almost 200 open-air seasonal theatres, including the Bergtheater Thale and the Felsenbühne in Rathen. The Deutsches Theater in Berlin opened as early as September 1945, being the first German theatre to perform following the Nazi collapse. Other historic theatres, including the Deutsche Staatsoper, the Komische Oper, and the Volksbühne—all in the capital—and the Schauspielhaus and the Oper in Leipzig, as well as the old Nationaltheater in Weimar, were rebuilt. Theatres have forged a strong functioning link between performers, audiences, and social organizations concerned with cultural affairs, and they perform a vital role in disseminating the ideological message.

The Berliner Ensemble

Berlin dominates theatrical life, and is the location of the Berliner Ensemble, long associated with Bertolt Brecht and probably the best known group internationally. Its often austere realism and disciplined professionalism have had a strong influence on contemporary theatre in many countries. Children's and youth theatres in Berlin, Halle, Leipzig, and Dresden are another new feature; their performances include not only productions of traditional favourites, such as fairy tales, but also productions that attempt to meet the problems of modern youth. Theatre, judging by the number of people attending performances, is highly popular.

Music. Concerts, too, are extremely well attended; the republic has more than 80 major orchestras of one kind or another, with the Leipziger Gewandhausorchester and the Staatskapelle in both Berlin and Dresden holding leading positions. The Thomaner Choir in Leipzig and the Kreuzchor of Dresden have a long and renowned tradition in the field of church music. There are also many amateur groups.

Sports and athletics. Sports occupy an extraordinarily large place in GDR life, under the aegis of the constitution, which invokes sport as essential to "development of a Socialist personality." Physical education and swimming are compulsory subjects in the schools, and around 5 percent of the labour force works at least part-time as coaches or sports officials. Members of state-supported sports clubs live on the club premises, and younger athletes even go to school on the club grounds, their classes being arranged around their training schedules. The German College of Physical Culture (Deutsche Hochschule für Körperkultur, founded 1950) in Leipzig has a renowned medical school that trains sports doctors. Women are trained as the men are, and women athletes, in consequence, have developed remarkably. Training emphasis is very much on Olympic sports, and its success was demonstrated at the summer Olympic Games in 1976, when the GDR took second place in gold medals won—40, surpassed only by the Soviet Union with 47; its women swimmers won 10 of 11 individual titles and broke eight world records.

The mass media. The state-owned film-making enterprise, DEFA (from Deutsche Film-Aktiengesellschaft), is located in Potsdam–Babelsberg and produces a wide range of cartoons, documentaries, and feature films, many of which are exported. Motion pictures continue to be a popular form of entertainment, especially in the rural communities. The highly developed radio network Deutscher Demokratischer Rundfunk is also government-owned and plays an important part in national life, while Radio Berlin International broadcasts on German subjects to many countries, including those of the developing world.

The Deutscher Fernsehfunk television network transmits through 10 channels, in two main program formats, from studios located in Berlin. It is a member of Intervision—the system linking east European countries—and, through this connection, of the west European Eurovision network.

Newspapers in the republic function as propagators of a Socialist viewpoint. There are some 40 dailies as well as many weekly, regional, and specialist publications. *Neues Deutschland*, the official newspaper of the Sozialistische Einheitspartei Deutschlands, is probably the best known internationally. (H.-J.K./R.E.H.M.)

THE OUTLOOK

The focal point of the future development envisaged for the German Democratic Republic is the economy. Up to the early 1960s, in the wake of the havoc wrought by World War II and in the light of the problems following the establishment of two German states, the main aim of economic policy was to ensure rapid growth in certain branches of industry, even at the expense of other industrial areas and sectors of the economy. More recently, steps have been taken to allocate investment funds more equitably, both within industry itself and among the various sectors of the economy. In the industrial field, the aim is to improve the technical level of production and move toward a new production pattern by concentrating on more sophisticated products, especially in engineering and electronics. It is felt that it is in these fields that the country has the greatest competitive advantage, since most other east European countries are not in the position to supply the required technological input. The German Democratic Republic is an enthusiastic member of Comecon, mainly because that body's specialization schemes have, on the whole, been helpful to the government's objective of rapid development in the more advanced industrial products.

Competitive advantages

The outlook for the economy is promising. The remainder of the 1970s is expected to see more economic reforms, which should lead to a further improvement in the system of economic management. This should help to make some progress in solving the country's principal problems, which Western observers interpret as the wasteful use of investment resources and the irrational price structures. This, in turn, is likely to have a beneficial effect on productivity, growth, and the advance of exports and should ensure a satisfactory trade balance, despite the need for large-scale food imports.

The Berlin Accord of 1971 seemed to reflect a changing climate of European affairs and some easing of regional tensions. The question of German unification, however, seems certain to occupy the republic and its citizens for some time to come. (E.I.U./Ed.)

BIBLIOGRAPHY. Comprehensive monographs concerning the physical and human geography of the German Democratic Republic are few in number in any language, but there is a wealth of periodical literature, especially in the magazines *Petermanns geographische Mitteilungen, Geographische Berichte*, and *Zeitschrift für den Erdkundeunterricht* (all published in the German Democratic Republic). The *Verfassung der Deutschen Demokratischen Republik*, 2nd ed., 2 vol. (1969), reflects the social conditions of the German Democratic Republic in official form. Political, demographic, economic, scientific, and cultural developments are reflected in great detail in the *Statistisches Jahrbuch der DDR* (annual). For economic geography, *Ökonomische Geographie der Deutschen Demokratischen Republik* (1969), a collective work, ed. by HORST KOHL, and *Die Bezirke der Deutschen Demokratischen Republik*, also ed. by HORST KOHL (1974), are standard reference sources. See also H.J. KRAMM, *Beiträge zur ökonomischen Geographie der Deutschen Demokratischen Republik*, 2 vol. (1962). English-language studies include ARTHUR M. HANHARDT, *The German Democratic Republic* (1968); and PETER C. LUDZ, *The German Democratic Republic from the Sixties to the Seventies: A Sociopolitical Analysis* (1970); a standard reference work is PETER C. LUDZ *et al.* (eds.), *DDR Handbuch* (1975).

(H.-J.K./R.E.H.M.)

Germanic Languages

The Germanic languages, a branch of the Indo-European language family, include a number of extinct languages as well as the earlier and present forms of German,

Netherlandic, Afrikaans, English, Frisian, the Scandinavian languages, Yiddish, and their many dialects.

In numbers of native speakers, English, with 320,000,000, clearly ranks second among the languages of the world (after Chinese); German, with 120,000,000, probably ranks sixth (after Hindi-Urdu, Spanish, and Russian). To these figures may be added those for persons with another native language who have learned one of the Germanic languages for commercial, scientific, literary, or other purposes. Though not even approximate statistics are available, English is unquestionably the world's most widely used second language.

Table 1 presents information on each of the modern standard Germanic languages.

Table 1: Modern Standard Germanic Languages

	where spoken	native speakers (1970 estimate)	use as a 2nd language
English	Great Britain, Ireland, United States, Canada, Australia, New Zealand, Republic of South Africa	320,000,000	extreme
German	Germany, Austria, Switzerland (part)	120,000,000	extensive
Netherlandic (Dutch-Flemish)	The Netherlands, Belgium (part)	19,000,000	moderate
Swedish	Sweden, Finland (part)	9,000,000	slight
Danish	Denmark	5,000,000	slight
Afrikaans	Republic of South Africa (part)	5,000,000	slight
Norwegian	Norway	4,000,000	slight
Yiddish	various countries	3,000,000	slight
Frisian	The Netherlands, Germany	311,000	—
Icelandic	Iceland	205,000	—
Faeroese	Faeroe Islands	35,000	—

The earliest historical evidence for Germanic is provided by isolated words and names recorded by Latin authors beginning in the 1st century BC. From *c.* AD 200 there are Scandinavian inscriptions carved in the 24-letter runic alphabet. The earliest extensive Germanic text is the (incomplete) Gothic Bible, translated *c.* AD 350 by the Visigothic bishop Ulfilas (Wulfila), and written in a 27-letter alphabet of the translator's own design. Although the Gothic alphabet was hardly used outside of this Bible translation, later versions of the runic alphabet were used sparingly in England, Germany, and particularly Scandinavia—in the latter area down to early modern times. All extensive later Germanic texts, however, use adaptations of the Latin alphabet.

The names and approximate dates of the earliest recorded Germanic languages are recorded in Table 2.

Table 2: Earliest Recorded Germanic Languages

	dates* (AD)
Early Runic	200–600
Gothic	350
Old English (Anglo-Saxon)	700–1050
Old High German	750–1050
Old Saxon (Old Low German)	850–1050
Old Norwegian	1150–1450
Old Icelandic	1150–1500†
Middle Netherlandic	1170–1500†
Old Danish	1250–1500†
Old Swedish	1250–1500†
Old Frisian	1300–1500†

*Indicates approximate range of dates.
†Cutoff date for beginnings of modern Germanic languages.

The Germanic languages are related in the sense that they can be shown to be different historical developments of a single earlier parent language. Although for some language families there are written records of the parent language (*e.g.*, for the Romance languages, which are variant developments of Latin), in the case of Germanic no written records of the parent language exist. Much of its structure, however, can be deduced by the comparative method of reconstruction (a reconstructed language is called a protolanguage; reconstructed forms are marked with an asterisk). For example, a comparison of Runic *-gastiR*, Gothic *gasts*, Old Norse *gestr*, Old English *giest*, Old Frisian *iest*, and Old Saxon and Old High German *gast* "guest" leads to the reconstruction of Proto-Germanic **gastiz*. Similarly, a comparison of Runic *horna*, Gothic *haurn*, Old Norse, Old English, Old Frisian, Old Saxon, and Old High German *horn* "horn" leads scholars to reconstruct the Proto-Germanic form **hornan*.

Reconstruction of parent language

Such reconstructions are, in part, merely formulas of relationship. Thus the Proto-Germanic **o* of **hornan* in this position gave *au* in Gothic and *o* in the other languages. In other positions (*e.g.*, when followed by a nasal sound plus a consonant) **o* gave *u* in all the languages: Proto-Germanic **dumbaz*, Gothic *dumbs*, Old Norse *dumbr*, Old English, Old Frisian, and Old Saxon *dumb*, Old High German *tumb* "dumb." What may be deduced is that this vowel sounded more like *u* in some environments, but like *o* in others; it may be written as **u~o*, indicating that it varied between these two pronunciations.

The above example shows that such reconstructions are more than mere formulas of relationship; they also give some indication of how Proto-Germanic actually sounded. Occasionally scholars are fortunate enough to find external confirmation of these deductions. For example, on the basis of Old English *cyning*, Old Saxon and Old High German *kuning* "king," the Proto-Germanic **kuningaz* can be reconstructed; this would seem to be confirmed by Finnish *kuningas* "king," which must have been borrowed from Germanic at a very early date.

By pushing the comparative method still farther back, it can be shown that Germanic is related to a number of other languages, notably Celtic, Italic, Greek, Baltic, Slavic, Iranian, and Indo-Aryan (Indic). All of these language groups are subsequent developments of a still earlier parent language for which there are, again, no written records but which can be reconstructed as Proto-Indo-European (see also INDO-EUROPEAN LANGUAGES).

This article is divided into the following sections:

I. Characteristics of the Germanic languages

The special characteristics of the Germanic languages that distinguish them from other Indo-European languages result from numerous changes, both phonological and grammatical.

PHONOLOGY

Consonants. Proto-Indo-European had 12 stop consonants: *p, t, k, k*^{w}; *b, d, g, g*^{w}; *bh, dh, gh, g*^{w}*h;* and one sibilant, *s*. (Stops are produced with momentary complete stoppage of the breathstream at some point in the vocal tract.) By a change known as the Germanic consonant shift (or Grimm's law, after the German scholar Jacob Grimm, who was one of the first to describe it), the 12 stops changed in Germanic to voiceless fricatives, voiceless stops, and voiced fricatives, as illustrated in Table 3. A few examples: (1) Proto-Indo-European *p, t, k*, and *k*^{w}, as in Latin *piscis, tenuis, centum*, and *quod*, became Proto-Germanic *f, þ, x*, and *x*^{w}, as in English "fish," "thin," "hund(red)," and "what." Proto-Germanic *x* and *x*^{w} early became *h* and *h*^{w} in some positions, giving the

Grimm's law

Table 3: Sound Changes in the Germanic Consonant Shift

Proto-Indo-European voiceless stops	p	t	k	k^w
Proto-Germanic voiceless fricatives	f	þ	x	x^w
Proto-Indo-European voiced stops	b	d	g	g^w
Proto-Germanic voiceless stops	p	t	k	k^w
Proto-Indo-European voiced aspirated stops	bh	dh	gh	g^wh
Proto-Germanic voiced fricatives	ƀ	ð	g	g^w

alternations of *h*∼*x* and h^w∼x^w. (2) Proto-Indo-European *d* and *g*, as in Latin *decem* and *genus*, became Proto-Germanic *t* and *k*, as in English "ten" and "kin." (3) Proto-Indo-European *bh*, *dh*, and *gh*, as in Sanskrit *bhū-*, *dhā-*, and *(g)hā-*, became Proto-Germanic *ƀ*, *ð*, and *g*, which later changed to the stops *b*, *d*, and *g* in some positions (*e.g.*, English "be," "do," and "go"), giving *b*∼*ƀ*, *d*∼*ð*, and *g*∼*g*. Proto-Indo-European *s*, as in Latin *sedeō*, was unchanged; Proto-Germanic kept *s*, as in English "sit."

In addition to these general changes, there were two special ones. (1) Proto-Indo-European *p*, *t*, and *k* remained voiceless stops when preceded by *s* or another stop; thus, Proto-Indo-European *sp*, *st*, *sk*, *pt*, and *kt* gave Proto-Germanic *sp*, *st*, *sk*, *ft*, and *xt*, respectively. For example, Proto-Indo-European *sp* and *st*, as in Latin *spuō* and *hostis*, remained *sp* and *st* in Proto-Germanic, as in English "spew" and "guest"; Proto-Indo-European *pt* and *kt*, as in Latin *captus* and *octō*, became Proto-Germanic *ft* and *xt*, respectively, in Old English *hæft* "captured" and *eahta* "eight." (By still another change, Proto-Indo-European *tt* gave Proto-Germanic *ss*; *e.g.*, Sanskrit *sattá-*, Old English *sess* "seat.") (2) By a change known as Verner's law (named for the Danish scholar Karl Verner, who first described it), early Germanic voiceless *f*, *þ*, *x*, x^w, and *s* (from Proto-Indo-European *p*, *t*, *k*, k^w, and *s*) were voiced to *ƀ*, *ð*, *g*, g^w, and *z*, respectively, when they followed an unaccented syllable, and the first four of these thereby merged with the already existing *ƀ*, *ð*, *g*, and g^w (from Proto-Indo-European *bh*, *dh*, *gh*, and g^wh). Thus, Proto-Indo-European **bhrā́tēr* became Proto-Germanic **brōþēr* (with *þ* after an accented syllable) and Old English *brōþor* "brother"; but by Verner's law Proto-Indo-European **mātḗr* became Proto-Germanic **mōðēr* (with *ð* after an unaccented syllable) and Old English *mōdor* "mother." (The *th* of modern English "mother" is the result of a subsequent change.)

Verner's law

These changes gave the following Proto-Germanic system of consonants: voiceless stops and fricatives, *p*, *f*, *t*, *þ*, *k*, *h*∼*x*, k^w, h^w∼x^w; voiced stops and fricatives, *b*∼*ƀ*, *d*∼*ð*, *g*∼*g*, (g^w∼g^w); sibilants, *s*, *z*; nasals, *m*, *n*; liquids, *l*, *r*; and semivowels, *w*, *j*(*y*). The sound alternation of g^w∼g^w is parenthesized because it early became either *g*∼*g* or *w*. The sounds k^w and h^w∼x^w occurred as such more or less clearly only in Gothic; elsewhere they became the sequences *kw* and *hw*∼*xw*, or the labial element ^{w} was lost. All remaining consonants except *z* occurred between vowels both singly and doubly (*e.g.*, *-p-* and *-pp-*, *-t-* and *-tt-*).

Vowels. In addition to the above consonants (12 stops and the sibilant *s*), Proto-Indo-European also had vowels and resonants. The vowel of any given root was not necessarily fixed but varied in an alternation called ablaut. Thus, the root that means "sit" was alternately **sed-*, **sod-*, **sd-*, **sēd-*, and **sōd-* (English "sit" is from **sed-*, "sat" from **sod-*, and "seat" from **sēd-*); and the root that means "do" was **dhē-*, **dhō-*, and **dhə-* (English "deed" is from **dhē-*, and "do" is from **dhō-*). Other Proto-Indo-European vowels were *a*, *ā*, *ī*, and *ū*. The Proto-Indo-European resonants, which functioned as vowels in some positions and as consonants in others, were *i*, *u*, *m*, *n*, *l*, and *r*. Thus, **bhṛtó-* (Sanskrit *bhṛtá-* "borne") had syllabic *ṛ* (*i.e.*, *ṛ* functioning as a vowel), but **bhéreti* (Sanskrit *bhárati* "he bears") had nonsyllabic *r* (*i.e.*, *r* functioning as a consonant).

Ablaut

This Proto-Indo-European system of vowels contrasting with resonants was reshaped in Germanic by a number of changes. Syllabic *i*, *u*, *ṃ*, *ṇ*, *ḷ*, and *ṛ* became in Proto-Germanic the vowels *i* and *u* and the sequences *um*, *un*, *ul*, and *ur*, respectively; nonsyllabic *m*, *n*, *l*, and *r* developed into the nasals and liquids *m*, *n*, *l*, and *r*, respectively; nonsyllabic *i* and *u* before vowels resulted in the semivowels *j* (also symbolized as *y*) and *w*, though after vowels they continued to form diphthongs (*ei*, *ai*, *oi*; *eu*, *au*, *ou*). The Proto-Indo-European vowels and diphthongs then changed into Proto-Germanic sounds as follows:

In this diagram the lines between two sounds indicate that the Proto-Indo-European sound developed into the corresponding Proto-Germanic sound; for example, Proto-Indo-European *i* became either *i* or *e*, and Proto-Indo-European *ə*, *a*, and *o* coalesced in Proto-Germanic as *a*. These changes gave the following vowels for early Proto-Germanic: short vowels, *i*, *e*, *a*, *u*∼*o*; long vowels, $\bar{\imath}$, $\bar{e}^1$, $\bar{u}$, $\bar{o}$; diphthongs, *ai*, *au*, *iu*∼*eo*. The vowel $\bar{e}$ is noted here as $\bar{e}^1$ because Proto-Germanic had (or developed) a second $\bar{e}^2$ of uncertain origin. In Gothic the two $\bar{e}$'s merged. Elsewhere $\bar{e}^2$ remained a midvowel, but $\bar{e}^1$ was lowered; thus, for example, $\bar{e}^2$ in Old Saxon *hēr* "here" but lowered $\bar{e}^1$ in Old Saxon *dād* "deed." In addition to the above oral vowels, Proto-Germanic also had three nasalized vowels: long $\tilde{\imath}$, $\tilde{a}$, and $\tilde{u}$, which arose when, in the sequences *inx*, *anx*, and *unx*, the *n* was lost with nasalization and lengthening of the preceding vowel.

Accent. Proto-Indo-European had a variable pitch accent that could fall on any syllable of a word (*e.g.*, on the first syllable in **bhrā́tēr* "brother" but on the last syllable in **mātḗr* "mother." This was replaced in Germanic by a fixed stress accent that always fell on the first syllable: **brṓþēr*, **mṓðēr*. One effect of this strong initial stress seems to have been the progressive weakening and loss of unstressed final syllables; *e.g.*, Proto-Indo-European *sodéionom*, Proto-Germanic **sátjanan*, Old English *settan*, Middle English *sette(n)*, and modern English (to) "set." Strong initial stress is also reflected in the basic unit of old Germanic poetry, which consisted of two half lines, each with one of a small number of stress patterns, linked by the alliteration of stressed initial consonants or vowels (*e.g.*, from *Beowulf: Béo-wùlf wæs bréme / blǽd wīde spràng* "Beowulf was famous; his renown went far").

Strong initial stress

GRAMMAR

Declensions. Proto-Germanic kept the Proto-Indo-European system of three genders (masculine, feminine, neuter) and three numbers (singular, dual, plural), though the dual was becoming obsolete. It reduced the Proto-Indo-European system of eight cases to six: nominative, accusative, dative, genitive, instrumental, and vocative, though the last two were becoming obsolete. In the adjective declensions there were two innovations: (1) To the Proto-Indo-European vowel types (*o*-, *ā*-, *i*-, and *u*-stems), it added some pronominal endings to give the Germanic "strong" adjective declension. (2) It extended the Proto-Indo-European *n*-stem endings to all adjectives to give the Germanic "weak" adjective declension. Contrast, in modern German, strong *gutes Bier* "good beer" with weak *das gute Bier* "the good beer."

Conjugations. The Proto-Indo-European verb seems to have had five moods (indicative, imperative, subjunctive, injunctive, and optative), two voices (active and mediopassive), three persons (1st, 2nd, and 3rd), three numbers (singular, dual, and plural), and several verbal nouns (infinitives) and adjectives (participles). In Germanic these were reduced to indicative, imperative, and subjunctive moods; a full active voice plus passive found only in Gothic; three persons; full singular and plural forms and dual forms found only in Gothic; and one infinitive (present) and two participles (present and past). The Proto-Indo-European tense-aspect system (present, imperfect, aorist, perfect) was reshaped to a single tense contrast between present and past. The past showed two innovations: (1) In the "strong" verb Germanic transformed Proto-Indo-European ablaut into a specific tense marker (*e.g.*, Proto-Indo-European **bher-*, **bhor-*,

Strong and weak verbs

**bhēr-*, **bhṛ-* in Old English *beran* "bear," past singular *bær*, past plural *bæron*, past participle *boren*). (2) In the "weak" verb Germanic developed a new type of past and past participle (*e.g.*, Old English *fyllan* "fill," past *fylde*, participle *gefylled*). Weak verbs fell into three classes depending on the syllable following the root (*e.g.*, Old High German *full-e-n* [from **full-ja-n*] "fill," *mahh-ō-n* "make," *sag-ē-n* "say"). Gothic also had a fourth class: *full-nō-da* "it became full."

Many Proto-Germanic strong verbs showed a consonant alternation between *f* and *ƀ*, *þ* and *ð*, *x* and *g*, and *s* and *z* that was the result, through Verner's law, of the alternating position of the Proto-Indo-European accent. The forms in Table 4 illustrate changes resulting from Verner's law. In this particular word, English has generalized the *s* (now *z*): "freeze," "froze," "frozen." German has generalized the *z* (now *r*): *frieren, fror, gefroren.* And Netherlandic still shows the alternation: *vriezen, vroor, gevroren.* English has kept the alternation in only one verb: singular "was," plural "were." Traces of it still survive, however, in a few now isolated forms: "seethe" (Proto-Germanic *þ*) and its old past participle "sodden" (Proto-Germanic *ð*); "lose" (Proto-Germanic *s*) and its old past participle "(for)lorn" (Proto-Germanic *z*).

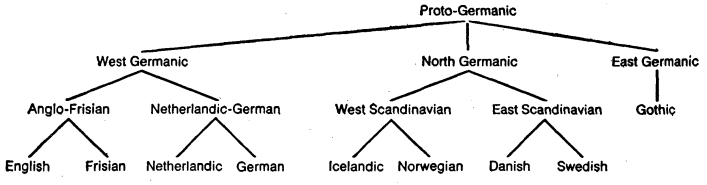
Table 4: Illustration of Verner's Law

Proto-Indo-European	Proto-Germanic	Old English	English translation
*préusonom	*freosanan	frēosan	"(to) freeze"
*próuse	*fraus	frēas	"(it) froze"
*prusṇt	*fruzun	fruron	"(they) froze"
*prusénos	*frozenaz	froren	"frozen"

*Unattested, reconstructed form.

BRANCHES OF GERMANIC

Like every language spoken over a considerable geographic area, Proto-Germanic presumably consisted of a number of geographical varieties or dialects, which, in the course of time, developed in different ways to give the different early and modern Germanic languages. Late-19th-century scholars used a family tree diagram to show this splitting into dialects and the relationships among the dialects:



Though there is much truth in such a diagram, it overemphasizes the notion of "splits" into separate "branches" and obscures the fact that the transition from one dialect to another may be gradual rather than abrupt. Modern Netherlandic and German, for example, constitute a single speech area at the level of local dialects; they have "split" only in the sense that they have developed different standard languages.

Dialect similarities

Mid-20th-century scholars, using the findings of archaeology and the methods of geographical linguistics, attempted to correct the distortions of this family-tree model by noting also the linguistic features shared by two or more dialect areas. Archaeological evidence suggests that a relatively uniform Germanic people at *c.* 750 BC were located in southern Scandinavia and along the North Sea and Baltic coasts from The Netherlands to the Vistula. Five hundred years later (*c.* 250 BC) they had spread south, and five general groups are distinguishable: North Germanic in southern Scandinavia, excluding Jutland; North Sea Germanic, along the North Sea and in Jutland; Rhine-Weser Germanic, along the middle Rhine and Weser; Elbe Germanic, along the middle Elbe; and East Germanic, between the middle Oder and the Vistula.

By *c.* AD 250 the division was much the same, though the Elbe group had spread southward to the Danube, and the East Germanic group moved southeast into the Carpathians and beyond. Then, toward the end of the 4th century, began the great Germanic tribal migrations. North Germanic speakers migrated into Jutland, approximately to the modern Danish–German language border; part of the North Sea group crossed the North Sea and conquered much of England; the Elbe group (the later Alamanni, Bavarians, and Langobardi) spread still farther south into part of Switzerland and into Austria and northern Italy; and the East Germanic group left the Oder-Vistula area to begin their many wanderings.

This five-way division of the Germanic peoples is based on archaeological evidence, but it agrees well with deductions that can be made from the earliest linguistic evidence. Five linguistic groups are indeed distinguishable, though they are linked into sets of two, three, or four through shared linguistic innovations.

Linguistic groups

1. North Germanic, North Sea Germanic, Rhine-Weser Germanic, and Elbe Germanic share the change of *z* to *r; e.g.*, Proto-Germanic **maiz-* "more," Gothic *maiza*, contrasting with Old Norse *meire*, Old English and Old Frisian *māra*, Old Saxon *mêro*, and Old High German *mēro.* In addition, they also show *i*-umlaut, as in the raising of *a* to *e* before *j* (pronounced as the *y* in "year"); *e.g.*, Proto-Germanic **satjanan* "set," Gothic *satjan* in contrast to Old Norse *setia*, Old English *settan*, Old Frisian *setta*, Old Saxon *settian*, and Old High German *setzen.* In certain strong verbs they share a new past tense form with *ē*[2] and without reduplication (the repetition of a part of a word)—*e.g.*, Proto-Germanic **le-lōt* "let," Gothic *lailot* in contrast to Old Norse, Old English, Old Frisian, and Old Saxon *lēt* and Old High German *liez.*

2. North Germanic, North Sea Germanic, and Rhine-Weser Germanic partly share the loss of nasal sounds before voiceless fricative sounds. As noted above, *n* was lost in Proto-Germanic before *x*. North Sea Germanic shows loss of nasals before the remaining fricatives *f*, *þ*, and *s;* thus, the nasals in Proto-Germanic **fimf* "five," **munþ* "mouth," and **uns* "us" are preserved in Gothic *fimf*, *munþs*, and *uns*, as well as in Old High German *fimf*, *mund*, and *uns*, but are lost in Old English *fīf*, *mūþ*, and *ūs* and Old Frisian *fīf*, *mūth*, and *ūs.* Rhine-Weser Germanic shows this same loss only sporadically; Old Saxon has *fīf*, *mūð*, and *ūs*, without the nasals, but also has *andar* (from Proto-Germanic **anþar-* "other"), with the nasal consonant, beside *āðar* and *ōðar*, without it. Old Norse, which is North Germanic, shows regular loss of a nasal sound only before *s* (*e.g.*, *oss* "us").

3. North Sea Germanic, Rhine-Weser Germanic, and Elbe Germanic (usually grouped together as West Germanic) share the change of *ð* to *d* in all positions (*e.g.*, Proto-Germanic **blōð-* "blood," and Gothic and Old Norse *blōð-* in contrast to Old English, Old Frisian, and Old Saxon *blōd* and Old High German *bluot*), the loss of *-z* after unstressed vowels (*e.g.*, Proto-Germanic **dagaz* "day," Gothic *dags*, and Old Norse *dagr* in contrast to Old English *dæg*, Old Frisian *dei*, Old Saxon *dag*, and Old High German *tag*), and a 2nd-person-singular past formation in strong verbs different from that of East Germanic and North Germanic (*e.g.*, Proto-Germanic **gaft* "[thou] gavest" occurs in Gothic and Old Norse *gaft*, but Proto-Germanic **gē*[1]*bi* appears in Old English *gēafe*, Old Saxon *gabi*, and Old High German *gābi;* Old Frisian has a new analogical form, *iefst*).

In addition, they share the doubling of most consonants in certain positions, especially before *j* (the *y* sound); *e.g.*, Proto-Germanic **satjanan* "set" appears in Gothic as *satjan* and in Old Norse as *setia* but in Old English as *settan*, in Old Frisian as *setta*, in Old Saxon as *settian*, and in Old High German as *setzen.* North Germanic also shows doubling of *g* and *k* before *j* (*y*); *e.g.*, Proto-Germanic **lagjanan* "lay" becomes Gothic *lagjan* but Old Norse *leggia*, Old English *lecgan*, Old Frisian *ledza*, Old Saxon *leggian*, and Old High German *lecken.*

4. North Sea and Rhine-Weser Germanic share a single ending for the 1st, 2nd, and 3rd persons plural of verbs (North Germanic, Elbe Germanic, and East Germanic

show two or three different endings), loss of the Proto-Germanic reflexive pronoun **sik*, and loss of *-z* in pronouns (*e.g.*, Proto-Germanic **wīz* or **wiz* "we," which appears in Gothic as *weis*, in Old Norse as *vēr*, and in Old High German as *wir*, appears in Old English as *wē* and in Old Frisian and Old Saxon as *wī*).

5. North Germanic, Elbe Germanic, and East Germanic share the addition of the Proto-Germanic nominative-accusative neuter singular pronominal ending **-at* in the strong adjective declension (*e.g.*, Proto-Germanic **hailan* "whole," Old English and Old Frisian *hāl*, and Old Saxon *hêl* in contrast to Gothic *heilata*, Old Norse *heilt*, and Old High German *heilaz*).

6. Elbe Germanic and East Germanic share the pronoun reconstructed for Proto-Germanic as **iz* "he": Gothic *is*, Old High German *ir* or *er*, instead of Proto-Germanic **h-* occurring in Old Norse *hann* and in Old English, Old Frisian, and Old Saxon *hē*.

7. North Germanic and East Germanic share the change of *jj* (pronounced as English *yy*) and *ww* to a long stop plus a semivowel (*e.g.*, from Proto-Germanic **twajj-* "of two" and *triww-* "true"—as in Old High German *zweiio* and *triuwi*—to Old Norse *tueggia* and *tryggr*, Gothic *twaddje* and *triggws*).

II. East Germanic

The East Germanic languages, all of which have long been extinct, developed from the dialects of the East Germanic group mentioned above; they were spoken by Germanic tribes located between the middle Oder and the Vistula.

HISTORY

According to historical tradition, at least some of the Germanic tribes migrated to the mouth of the Vistula from Scandinavia. Little is known of Gepidic, Rugian, and Burgundian; some knowledge of Vandalic, Visigothic, and, especially, Ostrogothic is provided by the names recorded in Greek and Latin writings. The only East Germanic language on which there is extensive information is the Gothic—more specifically, Visigothic—that was spoken along the western shore of the Black Sea around the middle of the 4th century AD. Its special importance lies in the fact that, except for a few scattered runic inscriptions, it is by far the oldest Germanic language preserved.

Gothic language

Knowledge of Gothic is derived primarily from the remains of a Bible translation made for the Visigoths living along the lower Danube by a Visigothic bishop of the Arian church named Ulfilas, who lived during the 4th century. The surviving manuscripts of this translation, which are not originals but later copies thought to have been written in northern Italy during the period of Ostrogothic rule (493–554), include considerable portions of the New Testament and parts of Nehemiah from the Old Testament. Although most of them are palimpsests, manuscripts in which earlier erased writings are found, a handsome exception is the famous Codex Argenteus, written in silver and gold letters on purple parchment and containing (in 188 leaves remaining from an original 330 or 336) portions of the four gospels. Closely related to these biblical manuscripts are eight leaves containing fragments of a commentary (called the

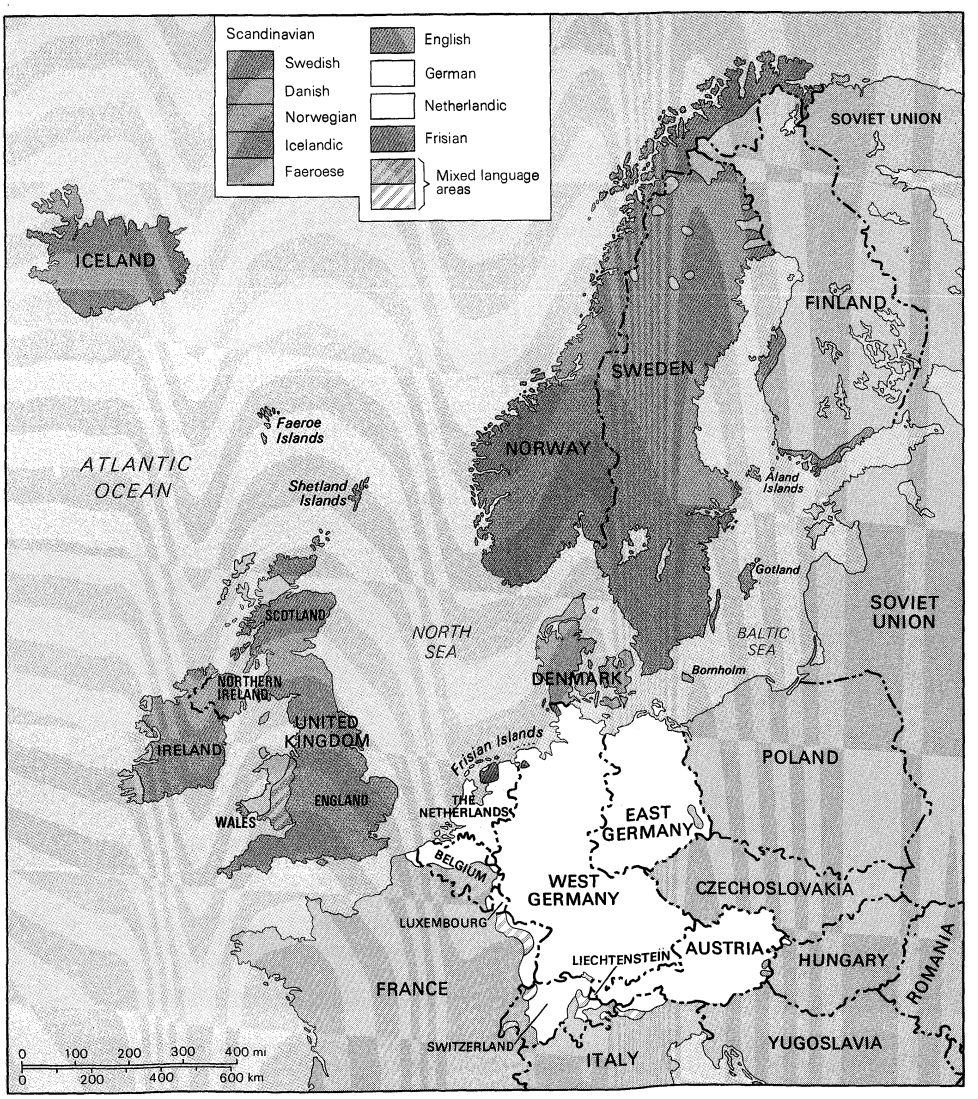


Figure 1: Distribution of the Germanic languages in Europe.

Skeireins in Gothic) on the Gospel According to St. John. Minor nonbiblical texts include a fragment of a calendar, two deeds containing some Gothic sentences, and a 10th-century Salzburg manuscript that gives the Gothic alphabet, a few Gothic words with Latin transliteration, and some phonetic remarks with illustrative examples.

In the 4th and 5th centuries, Gothic (Visigothic and Ostrogothic) must have spread, along with the conquering Goths, at least thinly over much of southern Europe; but there is no evidence for its survival in Italy after the fall of the Ostrogothic kingdom, and in Spain it is doubtful whether the Visigoths retained their language until the Arab conquest. In the 9th century the German monk Walahfrid Strabo mentions that Gothic was still being used in some churches near the lower Danube. After that time Gothic seems to have survived only among the Goths of the Crimea, who were last mentioned in the middle of the 16th century by a Flemish diplomat named De Busbecq, who, while on a mission to Constantinople in 1560–62, collected a number of words and phrases showing that their language was still essentially a form of Gothic.

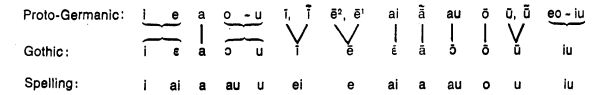
CHARACTERISTICS

Gothic alphabet

The Gothic alphabet, said to have been created by Ulfilas, contained 27 symbols, two of which functioned only as numbers, while the remaining 25 were used as both numbers and letters. The shape, numerical value, and ordering of the symbols show clearly that the alphabet was based primarily on that of Greek, though a few symbols seem to have been adapted from the Latin alphabet.

Phonology. *Consonants.* The Gothic consonant system seems to have been largely identical with that assumed above for Proto-Germanic: *p, t, k, k*^{w} (this last sound was probably much like the *qu* in "queen"); *f, þ, h, h*^{w} (this last sound was probably pronounced much like the *wh* in "white"); *b, d, g; s, z; m, n; l, r; w, j.* The nasal *n* was presumably velar before the velar consonants *k, q,* and *g;* in these positions it was usually written (as in Greek) as *g* or *gg.* Examples of this spelling include *dragk* "drank," *igqis* "you two," and *briggan* "bring," although *n* was occasionally used as in Latin (*e.g., þank* "thanks," *inqis* "you two," and *bringiþ* "bring ye").

Vowels. The Gothic alphabet contained the five simple vowel symbols, *i, e, a, o,* and *u,* from which four compound symbols, *ei, ai, au,* and *iu,* were also made; in addition, *w* was used to transliterate Greek *υ* and *οι* (both of which were pronounced as umlauted *u* [ü] in 4th-century Greek). The generally accepted development of the Proto-Germanic vowels in Gothic can be diagrammed as follows:



In this diagram straight lines indicate that the Proto-Germanic sound developed into the Gothic sound below. Brackets in the Proto-Germanic line indicate that the two linked sounds coalesced into one; brackets in the Gothic line indicate two variants of the same sound that are in different phonetic environments. Proto-Germanic *i* and *e* apparently first merged as a single vowel and then became Gothic *i* in most positions, but became *ai* before *h, h*^{w}, and *r.* Similarly, Proto-Germanic **o~u* became Gothic *u* in most positions, but *au* before *h, h*^{w}, and *r.*

Special characteristics. Gothic shows a number of archaic features that had been almost or entirely lost by the time the other Germanic languages began to appear in writing; among these are a passive voice and one type of past tense formed with reduplication, a dual number in the 1st and 2nd persons of its verbs and pronouns, and a special vocative case in one noun class. At the same time, Gothic also shows changes from Proto-Germanic, among which are the shortening of most long vowels in final unstressed syllables and the loss of most short vowels (*e.g.,* Proto-Germanic **erþō* "earth" became Gothic *airþa,* Proto-Germanic **stainaz* "stone" became Gothic *stains*). Finally, voiced fricatives that occurred or came to occur at the end of a word have been unvoiced (*e.g.,* nominative **hlaibaz,* accusative **hlaiban* "bread, loaf" changed to *hlaifs* and *hlaif,* respectively [but dative *hlaiba*]).

III. West Germanic

The West Germanic languages are those that developed from the North Sea, Rhine-Weser, and Elbe groups mentioned above. Out of the many local West Germanic dialects the following six modern standard languages have arisen: English, Frisian, Netherlandic (Dutch-Flemish), Afrikaans, German, and Yiddish.

ENGLISH

English and Frisian changes

English and Frisian are descended from North Sea Germanic. The most striking changes that distinguish them from the other Germanic languages are the loss of nasal sounds before the Proto-Germanic voiceless fricatives *f, þ,* and *s* (contrast the following pairs of words, in which English loses the nasal but German preserves it: before *f*—"soft"/*sanft;* before *þ*—"other"/*ander;* before *s*—"us"/*uns,* "goose"/*Gans*); palatalization of Proto-Germanic *k* before front vowels and *j,* giving modern English *ch* (English/German pairs: "chin"/*Kinn,* "birch" [Old English *birce*]/*Birke*); and palatalization of Proto-Germanic *g* before front vowels, giving modern English *y* (English/German pairs include "yield"/*gelten,* "yester[day]"/*gestern,* "yard" [Old English *geard*]/*Garten;* this palatalized *g* merged with the *j* [*y* sound] from Proto-Germanic *j:* "year"/*Jahr*).

Other changes include palatalization of *gg* before *j* to Old English *cg* (Proto-Germanic **brugjō,* pre-Old English **bruggju,* Old English *brycg* "bridge"; contrast the unpalatalized *ck* from *gg* of German *Brücke* "bridge"); fronting and raising of *ā* from Proto-Germanic *ē*^{1} (English/German pairs include "deed"/*Tat,* "seed"/*Saat,* "sleep"/*schlafen,* "meal"/*Mahl*); and backing and raising of nasalized *ā,* from Proto-Germanic *ā* and from Proto-Germanic *a* before nasal plus *f, þ,* and *s* (English/German pairs include "brought"/*brachte,* "thought"/*dachte,* "other"/*ander,* and "goose"/*Gans*).

For further information on English, see the article ENGLISH LANGUAGE.

FRISIAN

A thousand years or so ago, Frisian was apparently spoken throughout a North Sea coastal area extending from the modern Netherlands province of Noord-Holland (North Holland) on up to modern German Schleswig and the adjacent offshore islands. During the following centuries, the Frisian of much of this area was gradually replaced by local Netherlandic and Low German dialects, so that Modern Frisian is now spoken in only three remaining areas: (1) West Frisian, in the Netherlandic province of Friesland, including the island of Schiermonnikoog and two-thirds of the island of Terschelling (altogether some 300,000 speakers); (2) East Frisian, in the German Saterland (some 1,000 speakers; this area was apparently settled in the 12th or 13th centuries from the former East Frisian area to the north); and (3) North Frisian, along the west coast of German Schleswig and on the offshore islands of Sylt, Föhr, Amrum, the Halligen, and Helgoland (altogether some 10,000 speakers).

History. The earliest manuscripts written in Frisian date from the end of the 13th century, though the legal documents that they contain were probably first composed, in part, as early as the 11th century. This stage of the language, until about 1575, is known as Old Frisian. The last written document of this period dates from 1573, after which Frisian was hardly used at all as a written language for some three centuries, though it continued to be spoken.

From the start Old Frisian shows all of the features that distinguish English and Frisian from the other Germanic languages. These include loss of the nasal sound before Proto-Germanic *f, þ,* and *s* (*e.g.,* Proto-Germanic

**fimf*, **munþ-*, and **uns* became Old Frisian *fīf* "five," *mūth* "mouth," and *ūs* "us"), palatalization of Proto-Germanic *k* before front vowels and *j* (*e.g.*, Proto-Germanic **kinn-* and **lē¹kj-* became Old Frisian *tzin* "chin" and *lētza* "physician" [*cf.* English archaic "leech"]), and palatalization of Proto-Germanic *g* before front vowels (*e.g.*, Proto-Germanic **geldan-* became Old Frisian *ielda* "yield"). This merged with the *j* from Proto-Germanic *j*, as in Proto-Germanic **jē¹r-* or Old Frisian *iēr* "year." In addition, Old Frisian shows palatalization of *gg* from Proto-Germanic *g* before *j* (*e.g.*, Proto-Germanic **lagjan-*, with doubling **laggjan*, became Old Frisian *ledza* "to lay"); fronting and raising of *ā* from Proto-Germanic *ē¹*, as in Proto-Germanic **dē¹ð-*, lowered to **dād*, and raised again to Old Frisian *dēd* "deed"; and backing and raising of nasalized *ã* from Proto-Germanic *ã* and Proto-Germanic *a* before nasal plus *f*, *þ*, *s*, as in Proto-Germanic **brãxt-*, **anþar-*, and **gans-*, which became Old Frisian *brocht* "brought," *ōther* "other," and *gōs* "goose."

Around the beginning of the 19th century it appeared that the age-old replacement of Frisian by Netherlandic and German would continue unabated and that the language would soon become extinct. But with 19th-century Romanticism a new interest in local life arose, and societies were formed for the preservation of the Frisian language and culture. Very slowly, the aims of this "Frisian movement" came to be realized, especially in the Netherlands province of Friesland, where in 1937 Frisian was accepted as an optional course in elementary schools; a Frisian Academy was founded in 1938; and in 1943 the first Frisian translation of the Bible was published. Later, in 1955, Frisian was approved as the language of instruction in the first two years of elementary school (though only about one-fourth of all schools use it in this way), and in 1956 the use of Frisian in courts of law was approved.

Status of Frisian

Despite this gradual re-emergence of Frisian, Netherlandic still functions as the primary standard language of Friesland. Nearly all school instruction is given in Netherlandic; all daily newspapers are printed in Netherlandic (though they contain occasional articles in Frisian); and all television broadcasts and nearly all radio broadcasts are in Netherlandic. There is a small and enthusiastic Frisian literary movement, but its works are not widely read. Furthermore, though Frisian continues to be widely used as the language of everyday oral communication, it is increasingly a "Netherlandic" Frisian, with numerous borrowings from standard Netherlandic.

The status of Frisian in the East and North Frisian areas of Germany is far more tenuous. There German performs all the functions of a standard language, and Frisian serves only as yet another local dialect, comparable to the many surrounding local dialects of Low German. No standard North Frisian or East Frisian exists.

Characteristics. The following remarks refer to the more or less standard West Frisian that is developing in the province of Friesland.

Consonants. Frisian has the following system of consonants, given here in the usual spellings: stops, *p*, *b*, *t*, *d*, *k*, *g*; fricatives, *f*, *v*, *s*, *z*, *ch*, *g*; nasals, *m*, *n*, *ng*; liquids, *l*, *r*; and glides, *w*, *h*, *j*. Examples (given here in part to show the close relationship between Frisian and English) include *p*, *t*, and *k* (unaspirated) in *peal* "pole," *twa* "two," and *kat* "cat"; *b*, *d*, and the stop symbolized by the letter *g* in *boi* "boy," *dei* "day," and *goed* "good"; *f*, *s*, and *ch* in *fiif* "five," *seis* "six," and *acht* "eight"; *v*, *z*, and the fricative symbolized by the letter *g* in *tolve* "twelve," *tûzen* "thousand," and *wegen* "ways"; *m*, *n*, and *ng* in *miel* "meal," *need* "need," and *ring* "ring"; *l* and *r* in *laem* "lamb" and *reep* "rope"; *w*, *h*, and *j* in *wy* "we," *hy* "he," and *jo* "you." Word-finally, voiced *b*, *d*, *z*, and *g* are generally unvoiced to *p*, *t*, *s*, and *ch*.

Vowels. Frisian has the following system of stressed vowels and diphthongs. The symbols given in Table 5 refer to the actual sounds rather than to Frisian spellings, which are often irregular. Frisian also has an unstressed vowel *ə* (pronounced as the *a* in English "sofa"), which occurs only in unstressed syllables.

Table 5: The Vowel System of Frisian

short vowels	long vowels	rising diphthongs	falling diphthongs
i ü u	ī ǖ ū		ie üö uo
e ö o	ē ō ō	öi	eɛ öə oa
ɛ ɔ	ɛ̄ ɔ̄	ɛi ɔu	
a	ā	ai	

Dialects. The Frisian dialects of The Netherlands province of Friesland are, with three exceptions, relatively uniform, though it is customary to make a distinction between Wouden Frisian in the east, Klei Frisian in the west (the variety on which standard Frisian is largely based), and Southwest Corner Frisian in the southwest. The three exceptions are the island dialect of East and West Terschelling and the dialects of the city of Hindeloopen and of the island of Schiermonnikoog. These latter two differ so greatly that they are not intelligible to other speakers of West Frisian and are both dying out. Quite different from any of these is the so-called City Frisian (Stedfrysk, or Stedsk) spoken in the cities of Leeuwarden, Franeker, Harlingen, Bolsward, Sneek, Staveren, and Dokkum. Despite the name, this is not Frisian at all but a variety of Netherlandic strongly influenced by Frisian. Similar in nature are the dialects of Heerenveen and Kollum, of the middle section of the island of Terschelling, and of Het Bildt (a coastal area northwest of Leeuwarden, diked in and settled by Hollanders during the 16th century).

Dialects of Friesland

East Frisian survives today only in the German Saterland, consisting of the three parishes of Ramsloh, Strücklingen, and Scharrel, each with a slightly different dialect. The area to the north is called East Frisia (German Ostfriesland), and the local dialect East Frisian (German Ostfriesisch), although it is really not Frisian but the local variety of Low German.

Though North Frisian is spoken in only a small geographical area by only some 10,000 persons, it exists in an extraordinary number of local dialects, some of which are mutually unintelligible. Because of this, it would be almost impossible to develop a single standard North Frisian that could be used throughout this area. North Frisian dialects are customarily divided into Insular North Frisian (Sylt, Föhr-Amrum, Helgoland) and Continental North Frisian (the Halligen Islands and the coast of Schleswig), the latter in seven main varieties and further subvarieties. Because this whole area bordered until recently on Danish, it was extensively influenced by the neighbouring Danish dialects. In more recent times it has been heavily influenced by German, both standard German and the neighbouring Low German dialects. Today all speakers of North Frisian are probably bilingual or trilingual; all of them learn Frisian at home and standard German in school, and many also learn dialectal Low German.

NETHERLANDIC (DUTCH–FLEMISH)

Netherlandic is the national language of The Netherlands and one of the two national languages (beside French) of Belgium. Popular English usage applies the term Dutch to the Netherlandic of Holland and the term Flemish to the Netherlandic of Belgium, but in fact they are one and the same standard language. In its various forms, standard and dialectal, Netherlandic is the indigenous language of most of The Netherlands (all but the Frisian-speaking province of Friesland), of northern Belgium, and of a small part of France immediately to the west of Belgium. It is also used as the language of administration in the former Dutch colonies of Surinam and the Netherlands Antilles. A derivative of Netherlandic, Afrikaans, is one of the two national languages (with English) of the Republic of South Africa.

Identity of "Dutch" and "Flemish"

As a written language, Netherlandic is quite uniform; it differs in Holland and Belgium no more than written English does in the United States and Great Britain. As a spoken language, however, it exists in far more varieties than does the English of North America. At one extreme is Standard Netherlandic (Algemeen Beschaafd

Nederlands, "General Cultured Netherlandic"), which is used for public and official purposes and is the language of instruction in schools and universities. It is everywhere quite uniform, though speakers usually show by their accents the general area from which they come. At the other extreme are the local dialects, used among family and friends and with others from the same village.

History. Netherlandic is descended primarily from the language of the Rhine-Weser group, especially from the language of the Franks who entered much of this area during the 4th and 5th centuries AD. At the same time, it shows many forms descended from the speech of the North Sea Germanic inhabitants of the coastal areas. For example, modern *vijf* "five" (Proto-Germanic **fimf*) shows the typical North Sea Germanic loss of a nasal sound before *f*. Modern *mond* "mouth" (Proto-Germanic **munþ-*) and *ons* "us" (Proto-Germanic **uns*), on the other hand, show preservation of *n* before *þ* and *s;* but loss of *n* before *þ* appears in such place names as *IJmuiden* "mouth of the river IJ," and loss of *n* before *s* appears in the widespread dialectal forms *us* and *os* "us."

Documents written in Netherlandic do not begin to appear until toward the end of the 12th century, in the rich literature called Middle Dutch or Middle Netherlandic. From the preceding Old Netherlandic period there are only a few glosses, names, and isolated words appearing in Latin documents. Related to Netherlandic, though not ancestral to it, are the copyings—partly running text, partly isolated words—made from a lost manuscript that apparently contained an interlinear translation from Latin into Old Low Franconian of the book of Psalms.

The development of modern Netherlandic is closely tied to the political and economic history of the area. By the middle of the 16th century the speech of Brabant and its leading cities Antwerp and Brussels was well on its way to becoming standard for the whole Netherlandic speech area. Then came the revolt against Spain, in which the northern province of Holland was split off from the southern Netherlandic provinces.

Northern and Southern Netherlandic differences

This political split between the United Provinces of the Netherlands in the north and the Spanish Netherlands in the south had far-reaching linguistic consequences. In the prosperous and vigorous north a standard language rapidly developed, based on the speech of the big cities; it also showed the influence of the culturally important refugees from Brabant, who fled to the north, above all to Amsterdam, before and especially after the fall of Antwerp (1585). In the south, French came to prevail among the upper classes. The less privileged classes continued to use dialectal Netherlandic ("Flemish"), but no supradialectal standard was developed.

The cultural predominance of French in the south increased during the period of French rule (1795–1814), abated somewhat during the years when Belgium and Holland were united independently (1815–30), and rose again after the founding of the Kingdom of Belgium in 1830. At that time French was the only official language, used exclusively in government, courts, and schools. The long struggle to give Netherlandic equal status with French ended with the Language Act of 1938, which made Netherlandic the only official language of northern Belgium. There were numerous attempts to set up a standard Flemish different from the Netherlandic of the north, but in the end the standard Netherlandic that had become established in Holland was accepted for northern Belgium as well.

Characteristics. *Consonants.* Modern Standard Netherlandic has the following consonants, given here in the usual spellings: stops, *p, b, t, d, k;* fricatives, *f, v, s, z, ch, g;* nasals, *m, n, ng;* liquids, *l, r;* glides, *w, h, j.*

The voiced stops and fricatives *b, d, v, z,* and *g* are unvoiced to *p, t, f, s,* and *ch,* respectively, in word-final position. The spelling shows this in the case of *v* and *z* (plural *dieven* "thieves," *huizen* "houses," but singular *dief* "thief," *huis* "house") but does not show it in the case of *b, d,* and *g* (plural *ribben* "ribs," *bedden* "beds," *dagen* "days," but singular *rib* "rib," *bed* "bed," *dag* "day," pronounced *rip, bet, dach*).

Vowels. Netherlandic has three classes of vowels and diphthongs: (1) six checked vowels, which are short and always followed by a consonant; (2) ten free vowels and diphthongs, most of them usually long, which need not be followed by a consonant; and (3) a vowel that occurs only in unstressed syllables. They form the system shown in Table 6 (the traditional spelling is to the left, and to the right is a notation, used by some linguists, that indicates the distinctive sounds [phonemes] of the language). Unlike the English spelling system, which in its basic design has remained essentially unchanged since the days of Chaucer (died 1400), the Netherlandic spelling system has undergone a series of official reforms to keep it in line with changes in pronunciation. The principal inconsistencies in the spelling of vowels are the spellings *ij* and *ei,* which both symbolize the same diphthong, pronounced somewhat between the *ai* of English "aisle" and the *ai* of English "maid" (*bijt* "he bites" rhymes with *feit* "fact"), and the spellings *ou* and *au,* which both symbolize the same diphthong, pronounced somewhat between the *ow* of English "now" and the *ow* of English "low" (*bouw* "building" rhymes with *nauw* "narrow"). Free vowels are written with double letters in closed syllables (*vuur* "fire," *boot* "boat"), but with single letters in open syllables (*vuren* "fires," *boten* "boats"). In contrast the checked vowels are always written with single letters.

Table 6: Vowel System of Netherlandic

	a				aa			a			ā		
unstressed: e							unstressed: ə						

Netherlandic spelling

Dialects. Although the standard language changes abruptly at the political border separating Holland and Belgium from Germany (Netherlandic being used to the west, German to the east), in local dialect speech there is no such abrupt change. The entire Netherlandic–German territory from the North Sea to the Alps is a single dialect area with only gradual transitions from one village to the next.

In an area bounded roughly by Amsterdam, The Hague, and Rotterdam, rural dialects are very similar to Standard Netherlandic; there are marked differences only in urban dialects, especially those of Amsterdam and Rotterdam. As one travels from this area—the source of the standard language—in any direction, however, the difference between local dialects and the standard language becomes progressively greater; as a result, throughout most of Holland rural inhabitants in effect speak two closely related but distinct languages, Standard Netherlandic and a local dialect, in varying degrees of proficiency. Dialects are traditionally named after the provinces in which they are spoken (*e.g.,* Gronings in Groningen and Limburgs in Limburg).

In Netherlandic Belgium the use of Standard Netherlandic is more limited, and that of local dialects is more extensive. Some of the better educated people speak the standard language fluently and use it regularly, while others prefer French. The less well educated use a local dialect almost exclusively and are often able to handle the standard language only with difficulty.

AFRIKAANS

In 1652 a party of Netherlanders under the leadership of Jan van Riebeeck landed at the Cape of Good Hope to establish a station for the Dutch East India Company. In the immediately following years they were joined by a wide variety of other Europeans, in particular Germans and, after 1685, French Huguenots. By 1806, a century and a half after the original settlement, the national origins of the white inhabitants are estimated to have been 53 percent Dutch, 28 percent German, 15 percent French, and 4 percent of other nationalities. Shortly be-

fore this date, in 1795, the Cape Colony came under British control, and British settlers began to arrive around 1820.

History. From the start, the dialect of the province of Zuid-Holland (South Holland), which was spoken by Van Riebeeck and his large family, seems to have set the style for what was eventually to become modern Afrikaans. As might be expected in a language used by so many non-native speakers (white and black), some simplification of sounds and forms took place. For example, whereas Standard Netherlandic shows three forms in the present tense of most verbs—*ik loop, hij loopt, wij/zij lopen* "I run, he runs, we/they run"—Afrikaans shows only one form—*ek/hy/ons/sy loop* "I/he/we/they run" (with no ending). In addition, whereas Standard Netherlandic uses stressed *die man* "that man" in contrast to unstressed *de man* "the man," Afrikaans has only *die man* 'the man"; and, whereas Standard Netherlandic distinguishes *wij/we* "we" and *ons* "us," Afrikaans has only *ons* "we/us."

Afrikaans–Netherlandic differences

The relatively small numbers of white European speakers of Afrikaans borrowed place-names and names of such cultural novelties as African plants and the like from the immensely larger numbers of black speakers of various Bantu languages, with whom they were in intimate contact. For some two centuries the gradually developing Afrikaans language existed only as a spoken dialect, alongside Standard Netherlandic (by which it was constantly influenced) and, later, English. Then, around the middle of the 19th century, the effort to make Afrikaans a medium of literary expression and a standard written language began. It came gradually to be used in newspapers. It was adopted for use in schools in 1914 and was accepted for use in the Dutch Reformed Church in 1919. In 1925 the South African Parliament declared it to be an official language, replacing Netherlandic. The first complete translation of the Bible into Afrikaans was published in 1933. Thus it came to be recognized as one of the two standard languages (beside English) of the modern Republic of South Africa. Though clearly a separate language, Afrikaans is very similar to Netherlandic. A person who knows Netherlandic can read Afrikaans with little difficulty; and, with some practice, he can easily learn to understand it when spoken.

Characteristics. *Consonants.* Afrikaans has the following consonants, given here in the conventional spellings: stops, *p, b, t, d, k, gh/g;* fricatives, *f/v, w, s, z, g;* nasals, *m, n, ng;* liquids, *l, r;* glides, *h, j.* There are numerous differences between Afrikaans and Netherlandic. Netherlandic *-g-* (*-gg-*) is a voiced fricative, but Afrikaans *-g-* (*-gg-*) is a voiced stop. Unlike Netherlandic, Afrikaans also has this voiced stop initially in a few loanwords. Netherlandic has voiced fricatives initially (*v-, z-, g-*); corresponding words have voiceless initial fricatives in Afrikaans. Afrikaans, however, has voiced *z-* in loanwords: *Zoeloe* "Zulu." Netherlandic has initial *s* plus fricative *ch* as in *schoen* "shoe"; corresponding words have *s* plus *k* in Afrikaans: *skoen.* Netherlandic has *-ft, -st,* and *-cht* as in *gift* "poison," *nest* "nest," *nacht* "night"; corresponding words show loss of *-t* in Afrikaans: *gif, nes,* and *nag.*

Vowels. Afrikaans has the system of vowels shown in Table 7 (usual spelling to the left; notation used by linguists to indicate distinctive sounds to the right). As in Netherlandic, *uu, ee, oo,* and *aa* are written with single letters in open syllables, and single consonant letters are doubled in open syllables to show that the preceding vowel is short.

GERMAN

German is spoken throughout a large area in central Europe, where it is the national language of Germany and of Austria and one of the four national languages (beside French, Italian, and Romansh) of Switzerland. From this homeland it has been carried by emigration to many other parts of the world; there are German-speaking communities in North and South America, South Africa, and Australia. In the western world it is extensively used as a second language and in this respect is next in importance (along with French) only to English.

Dispersion of German

As a written language German is quite uniform, differing in Germany, Austria, and Switzerland no more than written English does in the United States and the British Commonwealth. As a spoken language, however, German exists in far more varieties than English. At one extreme is Standard German (Hochsprache), based on the written form of the language and used in radio, television, public lectures, the theatre, schools, and universities. It is relatively uniform, although speakers often show by their accents the areas from which they come. At the other extreme are the local dialects, which differ from village to village. Between these two extremes there is a continuous scale of speech forms that, in cities, are often close to the standard language and are called Colloquial German (Umgangssprache).

History. From the point of view of local dialects the territory within which German and Netherlandic are spoken is a single speech area. It is possible to travel from Austria, northern Italy, and much of Switzerland into Germany, eastern France (Alsace and part of Lorraine), Luxembourg, northern Belgium, and The Netherlands without encountering a village where the local speech is suddenly different. The only sharp breaks occur when one enters the French-speaking parts of France and Belgium or the Frisian-speaking parts of The Netherlands and Germany.

Table 8: Results of the High German Consonant Shift

p-	*pound*	*Pf*und	*pp*	ap*p*le	A*pf*el	*Vp*†	ho*p*e	ho*ff*en
t-	*t*en	*z*ehn	*tt*	si*tt*ing	si*tz*en	*Vt*†	bi*t*e	bei*ss*en
k-	*c*an	*kh*ann*	*kk*	li*ck*	le*kch*en*	*Vk*†	ma*k*e	ma*ch*en

**Khann* and *lekchen,* with affricates, are southern dialect forms; standard German has stops: *kann, lecken.* †*V* represents any vowel.

The most striking dialect differences within this large area are those that divide Netherlandic-Low German in the lowlands of the north from High German in the highlands of the south. When the Germanic tribes migrated into southern Germany during the early centuries of the Christian era, their speech had the voiceless stops *p, t,* and *k* in much the same distribution as in modern English. Then, probably during the 6th century, there occurred a change customarily called the "High German consonant shift." At the beginning of words and when doubled, *p, t,* and *k* came to be pronounced as affricates; after a vowel they came to be pronounced as long fricatives. The modern results, compared with related English words, are shown in Table 8.

High German consonant shift

These changes occurred in the south of the German speech area and then spread north, some extending far-

Table 7: Vowel System of Afrikaans

usual spelling										linguistic notation									
short vowels			long vowels			diphthongs				short vowels			long vowels			diphthongs			
ie	uu	oe	ie	uu	oe					i	ü	u	ī	ū	ū				
			ee	eu	oo	(ee	eu	oo)*					ē	ō	ō	(iə	üə	uə)*	
	i			î							ə			ə̄					
e	u	o	ê/e	û	ô/o	y/ei	ui	ou		ɛ	ö	ɔ	ɛ̄	ō	ō	əi	əü	əu	
	a			aa			ai				a			ā			ai		

*The spellings *ee, eu,* and *oo* are pronounced either as long vowels (ē, ō, ō) or as diphthongs (iə, üə, uə).

ther than others. The situation at the end of the 19th century was as indicated in Figure 2. Line 2, *maken/machen*, is generally chosen as the boundary between Low German and High German, because it is typical for the shift of *p*, *t*, and *k* after vowels to *ff*, *ss*, and *ch*, respectively (*hopen/hoffen*, *bīten/beissen*, *maken/machen*), and of *t* and *tt* to *z* and *tz*, respectively (*ten/zehn*, *sitten/sitzen*). The shift of *ik* "I" to *ich* is indicated by line 1, which

Figure 2: The Netherlandic–German dialect divisions. Numbers refer to isoglosses described in text.

shows that the shift of *k* to *ch* after a vowel in this particular word spread unusually far. Line 3, which indicates the shift of *Dorp* "village" to *Dorf* (*cf.* archaic English "thorp"), shows that shifted *p* after *r* and *l* spread less far north than did shifted *p*, *t*, *k* after a vowel. And line 4, indicating the shift of *dat* "that" to *das*, shows that the shift of *t* to *s* after a vowel spread still less far north in this word (and in a few others: *it/es* "it," *wat/was* "what"). The striking way in which these lines "fan out" in the west (in the area along the Rhine River) has led to their being called the "Rhenish fan."

The shift of *p* when doubled or at the beginning of a word occurred in a much smaller area. Line 5, showing the shift of *Appel* "apple" to *Apfel*, lies wholly within the High German speech area and is customarily used to subdivide it into Middle German (*Appel*) and Upper German (*Apfel*) areas. Line 6, which indicates the shift of *Pund* "pound" to *Pfund*, follows much the same course as does line 5 in the west, but it then runs north to join the *maken/machen* line; it is customarily used to distinguish West Middle German (*Appel*, *Pund*) from East Middle German (*Appel*, *Fund*—the latter being more common than Upper German *Pfund*).

Beginning of German

Preliterary period (to c. AD 750). As noted above (in the section on the branches of Germanic), during the early centuries of the Christian era there was only one "Germanic" language, with little more than minor dialect differences. Only after the consonant shift just described is there justification in speaking of a "German" (*i.e.*, High German) language distinct from the other Germanic languages. The fact that many early loans from Latin spread throughout all of Germanic makes it clear that the various dialects of early Germanic were mutually intelligible and that there was easy communication among them. At the same time, the modern German forms of these early loans show that they must have been borrowed before the consonant shift, because they show its effects. Examples include Latin *pondō*, English "pound," but German *Pfund;* Latin *piper*, English "pepper," but German *Pfeffer;* Latin *tegula*, English "tile," but German *Ziegel;* Latin (*via*) *strāta* "paved (road)," English "street," but German *Strasse;* Latin *catillus*, English "kettle," but German *Kessel;* and Latin *coquus*, English "cook," but German *Koch*.

Toward the end of the 4th century there began the great migrations (German *Völkerwanderung*) of Germanic tribes, resulting in an expansion of the Germanic-speaking territory. Angles, Saxons, and Jutes crossed the channel to England; Franks moved southwest into northern France and south into southern Germany; and Alamanni, Bavarians, and Langobardi moved south into southern Germany, Switzerland, Austria, and northern Italy. At the same time, the area east of the Elbe and Saale rivers was largely vacated by Germanic speakers, and Slavic speakers moved in.

Old period (c. 750–1050). In the southern area settled by Franks, Alamanni, and Bavarians, the first Old High German written records began to appear during the 2nd half of the 8th century. Their language is best described as a collection of monastery dialects; there is a certain uniformity in the writings of any given monastery, but little for the area as a whole. The first documents are translations into German of Latin word lists. Later documents include prose translations of St. Isidore of Seville (made *c.* 800) and of Tatian (*c.* 830), as well as a new verse form with end rhyme (Otfrid, *c.* 870). This literature reached its highest point in the able translations and interpretations of the Swiss monastery teacher Notker Labeo (died 1022). From the north (the Old Low German or Old Saxon speech area), the most extensive documents preserved are a life of Christ in alliterative verse (*Heliand*, *c.* 830) and a fragment of a similar Genesis translation.

In this period there were many borrowings from Latin, nearly all connected with Christianization of the Germans. Because they were made after the consonant shift, they do not show its effects. Examples of these borrowings include *predigōn* (modern German *predigen* "to preach"), from Latin *praedicāre;* *tempal* (modern German *Tempel* "temple"), from Latin *templum;* and *spiagal* (modern German *Spiegel* "mirror"), from Latin *speculum*. On the other hand, borrowings of this period reflect sound changes that had occurred in popular Latin, such as the change of Latin *c* before *e* from a *k* sound to *ts* in *ceïla* "ceil" and *crucem* "cross," Old High German *zella*, *krūzi*, modern German *Zelle*, *Kreuz* (the letter *z* in the German and Old High German examples represents the sound of *ts*); or the change of Latin medial *-b-* to *-v-* in *tabula* "table," borrowed into Old High German as *tavala*, modern German *Tafel*.

Middle period (c. 1050–1350). Several developments justify the usual assumption of a new period, the language of which is called Middle High German, beginning around 1050. First, there were changes in the language itself, among which were the unvoicing of final *b*, *d*, and *g* (*cf.* Old High German *grab* "grave," *rad* "wheel," and *tag* "day" with Middle High German *grap*, *rat*, and *tac;* in modern German these words are again spelled *Grab*, *Rad*, and *Tag* but are pronounced with final *p*, *t*, and *k*) and the reduction of the vowels of unstressed syllables to a *ə* sound, usually spelled *e* (*e.g.*, in the plural of the word for "day," the Old High German nominative-accusative form was *taga*, the genitive was *tago*, and the dative was *tagun*, but for these Middle High German had *tage*, *tage*, and *tagen*, respectively, and modern German has *Tage*, *Tage*, and *Tagen*). Second, there were great changes in the geographical area in which German was spoken. In the west the Franks of northern France had become romanized, and the French–German language border had assumed approximately its present location; in the east, on the other hand, German began to spread into Slavic territory, a process that was to continue for many centuries and to be reversed only at the end of World War II. Third, writing became independent of the monasteries, and the number of written documents soon increased greatly in both north and south. In the south, especially, a remarkable literature developed that included courtly epic and *Minnesang*. There is clear evidence of a trend toward a standard Middle High German literary language, though it seems to have had no influence on ordinary speech. Because this literature was based largely on French models, many French words were borrowed into German.

Geographical expansion

Early modern period (c. 1350–1650). Four events—the growth of trade, the rise of a middle class, the invention of printing, and the Reformation—had great influence on the development of the language. In the north, because of the prosperity of the Hanseatic League, a standard Low German written language began to develop, though it never reached full growth and probably had little influence on everyday speech. In the south the dialects that had arisen in the recently settled East Middle German area were relatively uniform and contained elements from both West Middle German and Upper German. Gradually these East Middle German dialects came to be used as the official languages of the chancelleries of the area, including that of Saxony; and on this latter Martin Luther based the language of his widely read Bible translation (1522–34). The growth of this type of German, which developed gradually into modern Standard German, was aided by the fact that printers preferred it as a means of making their books appeal to the widest possible audience.

Three striking vowel changes are characteristic of this period. In the southeast, as early as the 12th century, the long vowels *ī*, *ū*, and *ǖ* came to be diphthongized to *ei*, *ou*, and *öü;* this is called the "New High German diphthongization." By the 15th century these new diphthongs had spread to East Middle German, and in the standard language they merged with the old diphthongs *ei*, *ou*, and *öü*. Examples include Middle High German *mîn* "my," *hûs* "house," and *hiuser* "houses" with the monophthongs *ī*, *ū*, and *ǖ*, in contrast to *ein* "a," *troum* "dream," and *tröume* "dreams" with the diphthongs *ei*, *ou*, and *öü*, but modern Standard German *mein*, *Haus*, and *Häuser* appear with the same diphthongs (*ai*, *au*, and *oi*) as *ein*, *Traum*, and *Träume*. By a specifically Middle German development, the diphthongs *iə*, *uə*, and *üə*, still preserved in the southern dialects, were monophthongized to long *ī*, *ū*, and *ǖ;* this is the "New High German monophthongization." Examples include Middle High German *tief* "deep," *vuoz* "foot," and *vüeze* "feet" with the diphthongs *iə*, *uə*, and *üə*, contrasted to modern Standard German *tief*, *Fuss*, and *Füsse* with the monophthongs *ī*, *ū*, and *ǖ*. Short vowels remained short in closed syllables before long consonants but were lengthened in open syllables before a short consonant plus an unstressed vowel. This is called "lengthening in open syllables."

Modern period (c. 1650 to the present). The outstanding developments of the modern period have been the increasing standardization of High German and its increasing acceptance as the supradialectal form of the language. In writing, it is almost the only form used (except for small amounts of dialect literature); in speech, it is the first or second language of nearly the entire population.

Standard German

Although Standard German is clearly based on the East Middle German dialects, it is not identical with any one of them; it has accepted and standardized many forms from other areas, notably the Upper German sound *pf* (*Pfund*, *Apfel*) and also large numbers of individual words in the form of other dialect areas. Since it is the only type of German taught in schools, its spoken form is based to a large extent on its written form; and the spoken form that carries the greatest prestige (that of stage, screen, radio, and so on) uses a largely Low German pronunciation of this written form. As a result, the spoken form of modern Standard German has often been aptly described as "High German with Low German sounds."

Characteristics of modern Standard German. *Consonants.* German has the following consonants, given here in phonetic symbols because the spelling often varies: stops, *p*, *b*, *t*, *d*, *k*, *g;* fricatives, *f*, *v*, *ç*~*x;* sibilants, *s*, *z*, *š*, *ž;* nasals, *m*, *n*, *ŋ*; liquids, *l*, *r;* glides, *h*, *j*. German *ç*~*x*, spelled *ch*, is the voiceless velar fricative *x* after *a*, *ā*, *o*, *ō*, *u*, *ū*, and *au* but is the voiceless palatal fricative *ç* in other phonetic environments. The German sound *ž* occurs only in loanwords.

In the orthography, German *w* always indicates a *v* sound; German *v* spells an *f* sound in native words but a *v* sound in loanwords. German *sp* and *st* spell the sounds *sp* and *st* in most positions, but they spell *šp* (*shp*) and *št* (*sht*) at the beginnings of words or word stems. In other positions the *š* (*sh*) sound is spelled *sch*—*e.g.*, *Schiff* "ship." Medial *ss* marks a preceding vowel as short, medial *ß* marks it as long; medial *ss*, however, changes to *ß* at the end of a word and before a consonant. German *z* always indicates the sound *ts*. The spelling *tz* marks a preceding vowel as short, and the spelling *z* marks it as long.

Voiced *b*, *d*, *g*, *v*, and *z* do not occur at the ends of words, at the ends of parts of compound words, before suffixes beginning with a consonant, or before endings in *s* or *t*. In these positions they are replaced in pronunciation (though not in spelling) by the corresponding voiceless consonants, namely *p*, *t*, *k*, *f*, and *s*. For example, the *g* in *Tage* "days" is pronounced as English *g*, and the *g* in *Tag* "day" is pronounced as English *k*.

Vowels. The German vowel system is given in Table 9 in phonetic symbols.

Table 9: Vowel System of German

short and lax vowels	long and tense vowels	diphthongs	unstressed vowel
i ü u	ī ǖ ū		
e ö o	ē ō̄ ō	oi	ə
a	ā	ai au	

Though the spelling does not always indicate the difference between short and long vowels, the following devices are used more or less consistently: (1) A vowel is always short if followed by a double consonant letter—*e.g.*, *still* "still," *wenn* "if," *Rasse* "race," *offen* "open," *Hütte* "hut"—in contrast to the long vowels of *Stil* "style," *wen* "whom," *Straße* "street," *Ofen* "oven," *Hüte* "hats." (2) A vowel is always long if followed by an (unpronounced) *h*—*e.g.*, *ihnen* "to them," *stehlen* "to steal," *Kahn* "barge," *wohnen* "to dwell," *Ruhm* "fame"—in contrast to the short vowels of *innen* "inside," *stellen* "to place," *kann* "can," *Wonne* "bliss," *dumm* "dumb." (3) A vowel is always long if written double—*e.g.*, *Beet* "(flower)bed," *Staat* "state," *Boot* "boat"—in contrast to the short vowels of *Bett* "bed (for sleeping)," *Stadt* "city," *Gott* "god"; *ie* counts as the doubled spelling of *i*—*e.g.*, long *ī* in *Miete* "rent" but short *i* in *Mitte* "middle." (4) A vowel (except unstressed *e*) is always long when it stands at the end of a word.

The "plain" vowels—*a*, *o*, *u*, *ā*, *ō*, *ū*, *au*—often alternate with the "umlaut" vowels—*e*, *ö*, *ü*, *ē*, *ō̄*, *ǖ*, *oi*, respectively—as in the following examples with plain vowels in the singular but umlauted vowels in the plural: *Gast* "guest," *Gäste; Gott* "god," *Götter; Mutter* "mother," *Mütter*. As these examples show, the vowel sounds *e*, *ē*, and *oi* are spelled *ä*, *ǟ*, and *äu* when they are the umlaut of *a*, *ā*, and *au* sounds. *Gast–Gäste, Vater–Väter, Braut–Bräute.* Otherwise they are generally spelled *e*, *eh*, or *ee* (*beten* "to pray," *geht* "goes," *Beet* ["flower]bed"), and *eu* (*Leute* "people").

The sound *ai* is generally spelled *ei: Seite* "side," *nein* "no," though in a few words *ai: Saite* "string (of an instrument)," *Kaiser* "kaiser." The unstressed schwa sound (*ə*), as the *a* in English "sofa," is spelled *e: beginnen/bəgínən/*"to begin," *geredet/gərêdət/*"spoken."

(Wi.G.M.)

YIDDISH

Although there were about 11,000,000 speakers of Yiddish before World War II, approximately half of them were killed in the Nazi holocaust. There are perhaps 5,000,000 Yiddish speakers today, including native speakers and those who use it as a second language. Most speakers live in the United States, Latin America, Israel, and the Soviet Union. They are served by an active press, including 11 daily newspapers.

International nature of Yiddish

History. Yiddish, although Germanic, is not a typical Germanic language; it includes not only Germanic features but also elements from Romance, Hebrew-Aramaic, and Slavic languages. A cursory examination of the

German component of Yiddish indicates that no Yiddish dialect stands in a one-to-one relationship to any German dialect. The language had its beginnings in the 10th century when Jews from northern France and northern Italy settled in the Rhineland. These early Jewish settlements were dislocated by the Crusades and later by the persecutions that followed in the wake of the Black Plague. The subsequent move to Slavic territory had enormous influence on the development of the language.

Onomastic evidence (evidence from recorded proper names) for Yiddish is known from 1096, and glosses in biblical commentaries may be several decades older. The earliest known connected text is a rhymed couplet inscribed in a Hebrew holiday prayer book from Worms and bearing the date 1272–73. The earliest extensive manuscript, known as the Cambridge Yiddish Codex, is explicitly dated November 9, 1382. It excites the interest of Germanicists for its version of "Ducus Horant" (a poem from the Hildesage of the Gudrun epic known from the Ambross Manuscript written by Hans Reid, 1502/4–1515), which antedates the earliest extant manuscript of the Hildesage by at least 130 years. The documentary history of Yiddish is unbroken thereafter to the present day. Unique evidence for spoken Yiddish is incorporated in an extensive body of rabbinical Responsa (published rabbinical opinions on matters of religious law) beginning in the 15th century. Testimony before the rabbinical court, recorded verbatim, provides unusual insight into the colloquial language.

Scholars divide the history of Yiddish into four periods: Earliest Yiddish, to 1250; Old Yiddish, 1250–1500; Middle Yiddish, 1500–1750; and Modern Yiddish, 1750 to the present. The earliest literary tradition had a Western Yiddish dialectal base; writing in this literary dialect continued into the Modern Yiddish period long after the major population centres had shifted to the East. The establishment of the modern literary language on an Eastern Yiddish base occurred only in the early 19th century. At the same time a new style in the language of Yiddish Bible translation emerged, free from the constraints of the original Hebrew syntax and of the stricture against the use of Yiddish words of Hebrew-Aramaic origin in translating from Hebrew. The continuous contact of Yiddish speakers with Hebrew-Aramaic texts and, in the European language area, with one or another Germanic or Slavic language have been important factors in the development of the language.

Characteristics. Because of the conditions under which Yiddish developed (*i.e.*, the numerous contacts it has had with other languages), it is of great interest to scholars.

Alphabet. Yiddish uses all the letters of the Hebrew alphabet, including traditional word-final variants, which have only recently been reintroduced into the orthography of Soviet Yiddish. Several letters occur only in words of Hebrew-Aramaic origin, which retain their traditional spelling except in the Yiddish of the Soviet Union.

Phonology. The vowel system of Standard Yiddish consists of the simple vowels *i, e, a, o,* and *u* and the diphthongs *ej, aj, oj.* Under Slavic influence a palatal series of consonants has emerged. Unlike German, *x* corresponding to German *ch* has no palatal variant, the ŋ sound (the *ng* in English "sing") is simply a positional variant of *n*, there is no glottal stop (a sound made by closure of the vocal cords), and word final voicing is distinctive (phonemic—*i.e.*, it carries a change in meaning). Words of Hebrew–Aramaic and Slavic origin have introduced a rich variety of consonant clusters that do not appear in German. Intonation contours, apparently related to the chant with which the Talmud is studied, convey syntactic–semantic distinctions independently.

Grammar. Case inflections, preserved only in the singular, appear in noun modifiers but only rarely in nouns themselves. The dative and accusative cases have merged in the masculine; the nominative and accusative cases have merged in the feminine and neuter. All prepositions govern the dative case. The system of noun plural formation, basically of German origin, is enriched by word elements of Hebrew origin. Many nouns differ from their German cognates both in gender and plural form. A well-developed system of diminution uses word elements largely of German origin but on a Slavic grammatical model. A semantically significant distinction between inflected and uninflected predicate adjectives has emerged, while the difference between weak and strong adjectives, a characteristic of other Germanic languages, has effectively disappeared. The verb is inflected only in the present indicative. Other tenses and moods are expressed by means of auxiliary words. In normal word order the inflected verb immediately follows the subject; any remaining part of the verb phrase occurs as close to the inflected verb as possible. The special word order of the German subordinate clause is unknown, and verb initial constructions generally express consecutiveness rather than interrogation.

Hebrew influences

Vocabulary. In the vocabulary, words and word elements borrowed from a number of different languages co-occur and often combine freely in a manner unfamiliar to the languages from which they derive. Furthermore, when words borrowed from different languages are partially alike, one of them may be analyzed and inflected in terms historically appropriate to the other, thereby yielding blends of complex etymology. In addition, a highly productive system of prefixing yields verbs that are German in form but derive their meanings from an underlying Slavic model.

Dialects. The basic dialectal division is between Western Yiddish, which occurs largely within the German language area, and Eastern Yiddish in the Slavic-speaking areas. Eastern Yiddish is traditionally subdivided into Northeastern Yiddish and Southern Yiddish, the latter consisting of Central Yiddish and Southeastern Yiddish. The phonological criteria on which this division is based are typically reflected in the variants of the phrase "to buy meat": Western Yiddish *kāfn flāš*, Central Yiddish *kojfn flajš*, Southeastern Yiddish *kojfn flejš*, Northeastern Yiddish *kejfn flejš*. Other phonological and many lexical differences reinforce the distinctness of Western Yiddish. In the East, Central Yiddish is further distinguished by a full set of contrasts in vowel length, while the varieties of Southeastern Yiddish have made changes in vowel quality that have led to the types *hont* "hand," *huz* "house," and *rign* "rain." Northeastern Yiddish is characterized by the loss of the neuter gender. Standard Yiddish adheres more closely to Northeastern Yiddish in its sound system, and more closely to Southern Yiddish in its grammatical patterns. (M.I.H.)

IV. North Germanic (the Scandinavian languages)

HISTORY

Runes

About 125 inscriptions dated from AD 200 to 600, carved in the older runic alphabet (futhark), are chronologically and linguistically the oldest evidence of any Germanic language. Most of them are from Scandinavia, but enough have been found in southeastern Europe to suggest that the use of runes was also familiar to other Germanic tribes. Most inscriptions are brief, marking ownership or manufacture, as on the Gallehus (Denmark) golden horn (*c.* AD 400): *Ek Hlewagastiz Holtijaz horna tawido* "I, Hlewagastiz, son of Holti, made [this] horn." A number of inscriptions are memorials to the dead, while others are magical in content. The earliest were carved on loose wooden or metal objects, while later ones were also chiselled in stone.

The inscriptions retain the unstressed vowels that were descended from Germanic and Indo-European but were lost in the later Germanic languages; *e.g.*, the *i*'s in *Hlewagastiz* and *tawido* (Old Norse would have been **Hlégestr* and **táða*) or the *a*'s in *Hlewagastiz, Holtijaz,* and *horna* (Old Norse **Høltir, horn*). The scantiness of the material (fewer than 300 words) makes it impossible to be sure of the relationship of this language to Germanic and its daughter languages. It is traditionally known as Proto-Scandinavian but shows few if any distinctively North Germanic features and may reflect a stage, sometimes called Northwest Germanic, prior to the splitting of North and West Germanic (but after the separation of Gothic). Only after the departure of the Angles and Jutes for England and the establishment of

the Eider River in south Jutland as a border between Scandinavians and Germans is it reasonable to speak of a clearly Scandinavian or North Germanic dialect.

Common Scandinavian: 600–1050. Inscriptions from the 7th century show North Germanic as a distinct, fairly uniform, and recognizable dialect. Information about the language is derived from runic inscriptions, which became more abundant after the creation of the short runic futhark about AD 800, from names and loanwords in foreign texts and from reconstructions based on placenames and later dialects. The expansion of Nordic peoples in the Viking Age (*c.* 750–1050) led to the establishment of Scandinavian speech in Iceland, Greenland, the Faeroes, Shetlands, Orkneys, Hebrides, and the Isle of Man, as well as parts of Ireland, Scotland, England, France (Normandy), and Russia. Scandinavian languages later disappeared in all these territories except the Faeroes and Iceland through absorption or extinction of the Scandinavian-speaking population.

Viking expansion

During the period of expansion, all Scandinavians could communicate without difficulty and thought of their language as one (sometimes called "Danish" in opposition to "German"), but the differing orientations of the various kingdoms in the Viking Age led to a number of dialectal differences. It is possible to distinguish a more conservative West Scandinavian area (Norway and her colonies, especially Iceland) from a more innovative East Scandinavian (Denmark and Sweden), the former oriented to the Atlantic, the latter to the Baltic. There were no firm borders, however, and the sea lanes formed active channels of contact. An example of a linguistic difference setting off the eastern dialect area is the monophthongization of the Common Scandinavian diphthongs *ei*, *au*, and *øy* to *ē* and *ø̄* (*e.g.*, *steinn* "stone" became *stēn*, *lauss* "loose" became *løs*, and *høyra* "hear" became *hø̄ra*). The diphthongs remained on the island of Gotland and in most North Swedish dialects, however, while they were lost in some East Norwegian dialects. The pronoun *ek* "I" became *jak* in East Scandinavian (modern Danish *jeg*, Swedish *jag*) but remained *ek* in West Scandinavian (New Norwegian and Faeroese *eg*, Icelandic *ég*); in East Norwegian it later became *jak* (dialects *je*, *jæ*, Dano-Norwegian *jeg*) but remained *ek* (dialects *a*, *æ*) in Jutland.

Old Scandinavian: 1050–1450. The establishment of the Christian church in its Roman Catholic form during the 10th and 11th centuries had considerable linguistic significance. It helped to consolidate the existing kingdoms, brought the North into the sphere of classical and medieval European culture, and introduced the writing on parchment of Latin letters. Runic writing continued in use for epigraphic purposes and messages for the general population (several thousand inscriptions are extant, from 11th-century Sweden, especially, and also all the way from Russia to Greenland). For more sustained literary efforts, the Latin alphabet was used—at first only for Latin writings but soon for native writings as well. The oldest preserved manuscripts date from *c.* 1150 in Norway and Iceland and *c.* 1250 in Denmark and Sweden. The first important works to be written down were the previously oral laws; these were followed by translations of Latin and French works, among them sermons, saints' legends, epics, and romances. Some of these may have stimulated the extraordinary flowering of native literature, especially in Iceland. One can hardly speak of distinct languages in this period, although it is customary to distinguish Old Icelandic, Old Norwegian, Old Swedish, Old Danish, and Old Gutnish (or Guthnic, spoken in Gotland) on the basis of quite minor differences in the writing traditions. Some of these were merely scribal habits resulting from local usage, but others did reflect the growing separation of the kingdoms and the centralization within each. Literary Old Icelandic is often presented in a normalized textbook form under the name of Old Norse.

Roman influence

Culture words like *caupō* "merchant" (giving Old Norse *kaupa* "buy") and *vinum* "wine" (Old Norse *vín*) had been filtering into the North from the Roman Empire for a long time. But the first great wave of such words came from the medieval church and its translations, often with the other Germanic languages as intermediaries because the first missionaries were English and German. Some religious terms were borrowed from other Germanic languages; among these are Old Norse *helviti* "hell" from Old Saxon *helliwiti* or Old English *hellewite*, and Old Norse *sál* "soul" from Old English *sāwol*. East Scandinavian borrowed the Old Saxon word *siala*, from which come later Danish *sjæl* and Swedish *själ*. In the secular field the most profound influence on Scandinavian was that exerted by Middle Low German because of the commercial dominance of the Hanseatic League and the political influence of the North German states on the royal houses of Denmark and Sweden between 1250 and 1450. The major commercial cities of Scandinavia had large Low German-speaking populations, and the wide use of their language resulted in a stock of loanwords and grammatical formatives comparable in extent to that which French left behind in English after the Norman Conquest.

Reformation and Renaissance: 1450–1550. The many local dialects that exist today developed in the late Middle Ages, when the bulk of the population was rural and tied to its local village or parish, with few opportunities to travel. The people of the cities developed new forms of urban speech, coloured by surrounding rural dialects, by foreign contacts, and by the written languages. The chanceries in which documents of government were produced began to be influential in shaping written norms that were no longer local but nationwide. The Reformation came from Germany and brought with it High German influence through Martin Luther's translation of the Bible, which was quickly translated into Swedish (1541), Danish (1550), and Icelandic (1584). That it was not translated into Norwegian was one of the major reasons that no separate Norwegian literary language arose. Until the 19th century there was no distinct written Norwegian but only a Norwegian variety of Danish. With the invention of printing and the growth of literacy, all speakers of Scandinavian dialects gradually learned to read (and eventually write) the new standard languages.

The modern languages. The six standard languages of today, in the order of their emergence as languages of culture and prestige, are Danish, Swedish, Icelandic, Faeroese, New Norwegian (Nynorsk), and Dano-Norwegian (Bokmål).

Danish. The norms of the first printed books in Danish continued the norm of the royal chancery in Copenhagen, which was not based on any particular dialect and probably reflected a state of the language closer to 1350 than 1550. Because of the influence of the written language, many speech forms used even by the aristocracy at that time were eliminated or branded as vulgar. Danish is clearly the Scandinavian language that has undergone the greatest amount of change away from the Common Scandinavian norm. In the 18th century a mildly puristic reform led to the replacement of many French loans by their native equivalents (*e.g.*, *imagination* by *indbildning; cf.* German *Einbildung*), and, in the 18th and 19th centuries, Danish became the vehicle of a classical literature. There are regional differences in the cultivated speech norm, but upper-class Copenhagen speech probably has the highest prestige. A spelling reform in 1958 eliminated the capitalization of nouns and introduced the letter *å* for *aa*, thereby bringing the spelling closer to that of Norwegian and Swedish. Danish is spoken by most of the nearly 5,000,000 inhabitants of Denmark and in a few communities south of the German border; it is taught in the schools of the Faeroe Islands, Iceland, and Greenland.

Swedish. Before the Swedish revolt of Gustav Vasa in 1525, Danish influence on the Swedish language had been strong; the new government, however, made vigorous efforts to eliminate this. The written norm was based on one that had developed in the manuscripts of central Sweden, extending from the Vadstena monastery in east Götaland to Stockholm and Uppsala. In relation to the speech of the area, many of its features were conservative (*e.g.*, silent *-t* and *-d* in words like *huset* "the house" and *kastad* "thrown"). The written language was culti-

Swedish dominance

vated energetically as a symbol of national strength, and in 1786 the Swedish Academy was established by King Gustav III. The language expanded its area at the expense of Danish and Norwegian by the conquest of southern and western provinces in the 17th century. After Sweden lost Finland in 1809, the role of Swedish was gradually reduced in that country. Since independence (1917), Finland has accepted Swedish as one of its official languages and has taught it in its schools, but only about 7 percent of its population uses it. Except for small Lappish and Finnish minorities, the entire population of Sweden (about 8,000,000) has Swedish as its daily language, and there is a rich and distinguished literature.

Icelandic. Important factors in the survival of Icelandic during the period of Danish rule were its continued use for literary purposes, the geographical remoteness of Iceland, a scattered population, and the great linguistic differences between Danish and Icelandic. In the period when the Scandinavian languages in continental Europe became essentially uninflected, Icelandic preserved Old Scandinavian grammar almost intact. The native Bible became a basis for the further development of Icelandic. Nevertheless, the circumstances of the language were highly restricted until self-government developed in the 19th century, and Icelandic was rediscovered by Scandinavian scholars. A firm orthography along etymological lines was gradually established, and the policy of not adopting foreign words was confirmed, so that Icelandic today offers a strikingly different appearance from the other Scandinavian languages.

Faeroese. Prior to modern times literary activity in the Faeroe Islands was minimal, but the local dialects continued to develop, though Danish was the official language. The Danish language scholar Rasmus Rask, who wrote the first Faeroese grammar (1811), described the language as a dialect of Icelandic, but it is actually an independent language, intermediate between West Norwegian and Icelandic but containing many Danish loanwords. Traditional dance ballads were written down after 1773 before the establishment in 1846 of an independent orthography. This orthography is etymologizing and unphonetic and gives Faeroese a strong Icelandic appearance. The establishment of home rule in 1948 led to the introduction of Faeroese as the primary language taught in the schools. The language is now spoken by about 35,000 people.

New Norwegian. Old Norwegian writing traditions gradually died out in the 15th century, after the union of Norway with Denmark and the removal of the central government to Copenhagen. After independence was achieved in 1814, the linguistic union with Danish persisted, but the ideology of National Romanticism stimulated a search for a national standard language. In 1853 a young, self-taught linguist of rural stock, Ivar Aasen, constructed a language norm from the spoken dialects that would continue the Old Norwegian tradition and, hopefully, might eventually replace Danish. After long research and experimentation, he presented this New Norwegian norm (often called Landsmål, but now officially Nynorsk) in a grammar, a dictionary, and in numerous literary texts. New Norwegian was officially recognized as a second national language in 1885. Today all Norwegians learn to read and write it, but only a fifth of the school population and an even smaller percentage of the writers actually use it as their primary language. It has been cultivated by many excellent authors and has a quality of poetic earthiness that appeals even to nonusers. Its norm has changed considerably since Aasen's time in the direction of spoken East Norwegian or written Dano-Norwegian.

Work of Ivar Aasen

Dano-Norwegian. Most Norwegian literature in the 19th century was written in a superficially Danish norm, but it was given Norwegian pronunciation and had many un-Danish words and constructions. The spoken norm was a compromise Dano-Norwegian that had grown up in the urban bourgeois environment. In the 1840s Knud Knudsen formulated a policy of gradual reform that would bring the written norm closer to that spoken norm and, thereby, create a distinctively Norwegian language without the radical disruption envisaged by the supporters of Aasen's New Norwegian. This solution was supported by most of the new writers in the powerful literary movement of the late 19th century. The official reforms of 1907, 1917, and 1938 broke with the Danish writing tradition and adopted native pronunciation and grammar as its normative base; the resultant language form was called Riksmål, later officially Bokmål. Controversial efforts to bring Dano-Norwegian and New Norwegian together into an amalgamated Pan-Norwegian (Samnorsk) have not yet led to any definite result. In its current form Dano-Norwegian is the predominant language of Norway's population of nearly 4,000,000, except in western Norway and among the small Lappish minority in the North. It is the language usually taught abroad as "Norwegian."

Dialects. The teaching of the standard languages in the schools and the high levels of literacy have tended to spread the urban norms of speaking. Nevertheless, very diverse dialects, partially unintelligible to outsiders, are spoken in many rural communities; some of them are used occasionally for the writing down of local traditions or for giving local colour in plays and novels. Dialect institutes for their study exist in each country. Boundaries between dialect areas are gradual and do not always coincide with national borders, so that the following traditional divisions are somewhat arbitrary: in Denmark, West (Jutland), Central (Fyn, Sjælland), and East (Bornholm); in Sweden, South (especially Skåne), Götaland, Svealand, North (Norrland), Gotland, East (Finland); in Norway, East (Lowland, Midland), Trönder (around Trondheim), North (Nordland), West. In the Faeroese language there are minor dialectal differences between the southern and northern islands; minor dialectal differences occur in Icelandic as well, but there are no clearly defined regional dialects. In the larger cities there is a range of social dialects from the everyday speech of the working classes (often similar to nearby rural speech) to the more cultivated forms of middle- and upper-class speech, including the highly formal style of courts and legislatures. Speakers of Danish, Norwegian, and Swedish normally use their own languages in communicating with one another; Norwegian and Swedish have a common phonetic base, and Norwegian and Danish share many vocabulary items.

CHARACTERISTICS

Differences between North and West Germanic

Common and distinctly Scandinavian characteristics. North Germanic differs from West Germanic (but not East Germanic) in having *ggj* and *ggv* for medial *jj* and *ww*, respectively (Old Norse *tveggja* "two," *hoggva* "hew"), *-t* for *-e* in the 2nd person singular of the strong preterite (Old Norse *namt* "you took"; *cf.* Old English *næme*), and a reflexive possessive *sin*.

North Germanic differs from East Germanic (but not West Germanic) in that original *ē* becomes *ā* (Old Norse *máni* "moon") and original *z* becomes *r* (Old Norse *meiri* "more"); furthermore, there is a new demonstrative pronoun *þessi* "this" (Danish, Swedish, and Norwegian *denne*), back vowels are mutated to front vowels by the influence of a following *i* or *j* ("*i*-umlaut"—*a* and *ā* become *æ* and *ǣ*, *o* and *ō* become *ø* and *ø̄* [*ø* represents umlauted *o*], *u* and *ū* become *y* and *ȳ* [*y* represents umlauted *u*], *au* becomes *ey* or *øy*), and the number of unstressed vowels is reduced to three (*a*, *i*, *u*).

North Germanic differs from both West Germanic and East Germanic in the following ways: rounding of unrounded vowels by following *u* or *w* ("*u*-umlaut"—*a* and *ā* become *ǫ* and *ǭ* [*ǫ* represents a low back rounded vowel], *e* becomes *ø*, *i* becomes *y*, *ei* becomes *ey* or *øy*); loss of initial *j* and *w* in some positions (Old Norse *ungr* "young," *ár* "year," *Óðinn* "Wodan," *ull* "wool"); loss of final nasals (Old Norse *frá* "from," *fara* "fare, go"; *cf.* Old English *faran*, German *fahren*); diphthongization ("breaking") of short *e* to *ja* or *jǫ* (Old Norse *jafn* "even," *jǫrd* "earth"). It has new pronouns for the 3rd person singular (Old Norse *hann* "he," *hon* "she"); attaches the reflexive pronoun (*sik*) to the verb to make a new mediopassive in *-sk*, *-st*, or *-s* (*finna sik* "find oneself" became

Old Norse *finnast* "be found, exist," Danish *findes*); attaches the demonstrative *inn* "that" to nouns as a definite article (Old Norse *fótrinn* "the foot," Norwegian and Swedish *foten*, Danish *foden*), except in West Jutland (possibly a later development); and uses *-t* as marker of the neuter in pronouns and adjectives (Old Norse *hvítt* "white" from *hvít-*, *eitt* "one" from *ein-*). Furthermore, North Germanic employed *es* (which changed to *er*) and later *sum* as an indeclinable relative pronoun; and it lost some Germanic prefixes, such as *ga-* (German *ge-*), and contains a considerable number of words such as *hestr* "horse," *fær* or *fár* "sheep," *gríss* "pig," *gólf* "floor," and *ostr* "cheese" that do not occur in East or West Germanic.

Orthography. The five basic vowel symbols of the Latin alphabet are supplemented by a number of special symbols, mostly for umlauted vowels: thus, there is *y* (pronounced as German *ü*), *æ* (used in Danish, Norwegian, Icelandic, and Faeroese) and the corresponding *ä* (used in Swedish), *ø* (in Danish, Norwegian, and Faeroese) and the corresponding *ö* (in Swedish and Icelandic), and *å* (also written *aa*, used in Danish, Swedish, and Norwegian).

Their present-day values are not identical; Icelandic *æ* is pronounced as the diphthong sound *ai* (as the *i* in English "ice"). Icelandic also uses accents on vowels that were long in Old Norse but are now mostly diphthongs (*á, é, í, ó, ú,* and *ý*); Faeroese has the same system except for *é*. The consonant symbols are the usual Latin ones, except that *þ* (thorn) and *ð* (edh) are used in Icelandic for voiceless and voiced *th* (*ð* in Faeroese has a different value). Loanwords containing *c, q, w, x,* and *z* have generally been naturalized by substituting, respectively, *k* or *s, kv, v, ks,* and *s* (*e.g., kontakt* "contact" but Norwegian *sigar* "cigar" versus Danish and Swedish *cigar*).

Phonology. Stress is on the first syllable in native words, with sporadic exceptions for compounds. Stress on a later syllable reflects borrowing from other languages, except in Icelandic, which has stress on the first syllable of all words.

Influence of borrowing on stress

Pitch is usually high on the stressed syllable, falling at the end of a statement, rising for a yes-no question. An exception is East Norwegian and some Swedish dialects, in which the stressed syllable is low and the pitch is often rising at the end of statements. In most of Norway and Sweden and in scattered Danish dialects, there is a special word tone, by which old monosyllables have one kind of pitch while old polysyllables have another. The first pitch type is usually high or low pitch on the stressed syllable, like that in other Germanic languages, while the second is more complex and varies from region to region. In Danish the tones have been replaced by glottalization in instances in which Norwegian and Swedish have the first type.

Vowels are short before two or more consonants (with some exceptions) or when unstressed. Doubled consonants after short stressed vowels are pronounced long, except in Danish, which also does not double consonants in final position.

The Common Scandinavian vowel system contained ten vowels, each of which could be long, short, or nasalized: front unround (*i, e,* and *æ*), front round (*y, ø,* and *ø̨*), back round (*u, o,* and *ǫ*), and back unround (*a*). There were three falling diphthongs: front unround (*ęi*), front round (*øy*), and back round (*au*). While most of these are still present in some dialects, there have been many changes. The nasalized vowels disappeared, though they were still present in Icelandic around 1150. Diphthongs became long vowels in Danish and Swedish in the 10th century. Short low umlauted vowels coalesced with neighbouring vowels (*æ* became *e, ø̨* became *ø, ǫ* became *o/ø*). Long *ā* (Old Norse *á*) was rounded to *å* (pronunciation similar to the *o* in English "order"; in Icelandic and West Norwegian, pronunciation is like the *ow* in "now"). In Norwegian and Swedish the rounded vowels were shifted upwards and forwards, giving "overrounded" *o* and *u* that resemble *u* and *y* respectively. The unstressed vowels *a, i,* and *u* have remained in Icelandic and Faeroese but have been partially merged in New Norwegian and Swedish (written *a, e, o*), completely merged as *ə* (the schwa sound, as *a* in English "sofa") in Danish and Dano-Norwegian, and lost in Jutland and Trönder dialects. High round vowels (*y, ȳ, øy*) have been merged with the unround vowels in Icelandic and Faeroese (and in scattered dialects elsewhere) but are still distinguished in writing. Long vowels have been diphthongized not only in many dialects (*e.g.*, Jutland, Skåne, and West Norwegian) but also in standard Icelandic and Faeroese (Icelandic *é*, pronounced [je], *ó* [ou], *á* [au], *æ* [ai]; Faeroese *í* [ui], *æ* [æa], and so on). (Symbols in brackets are phonetic symbols designating actual pronunciation.) A quantity shift took place in the late Middle Ages, in which short vowels were lengthened before single consonants and long vowels were shortened before clusters, sometimes with qualitative changes that affected different dialects differently; thus, in Swedish *veta* "know" *i* became *e* (though all the other languages have *i*).

The Common Scandinavian consonant system contained voiceless stops (*p, t, k*), voiced stops (*b, d, g*), voiceless-voiced spirants (*f*/*ƀ*, *þ*/*ð*, *x*/*ɣ*), nasals (*m, n*), a sibilant (*s*), liquids (*l, r*), and glides (*w, j*). The chief changes were as follows: Short voiceless stops became voiced after vowels in Danish and neighbouring dialects and then partially opened to become spirants or glides (*tapa* became *tabe* "lose," *ūt* became *ud* "out," *kakur* became *kager* "cakes"). Velar stops (*k, g, sk*) were palatalized before front vowels to merge with *kj, gj,* and *skj,* as still occurs in Icelandic (and Jutland dialect); in Faeroese, Norwegian, Swedish, and many Danish dialects, these were fronted to *tj, dj, stj* or even opened to spirants [ç, j, š], while in Danish they reverted to *k, g,* and *sk*. Voiced *f* [*ƀ*] merged with *w* to become *v*, though it is still written *f* in Icelandic; in Danish both *f* and *w* have become pronounced as *w* after vowels. Voiceless *þ* became *t* (occasionally *h* in Faeroese) and voiced *þ* [*ð*] became *d*, except in Icelandic. Voiceless *x* became *h* initially before vowels, but was lost elsewhere; voiced *x* [*ɣ*] became *g*, except in Icelandic (in Danish it has become either [j] or [w] after vowels). The *r* sound was assimilated to following dental sounds (*l, n, s, t, d*) to make a series of retroflex consonants (*l̩, n̩, s̩, t̩, d̩*, pronounced with the tip of the tongue curled up towards the hard palate) in many Swedish and Norwegian dialects, including those of Oslo and Stockholm. In much the same area a "dark" *l* was merged with *rð* to make a new "thick *l*," defined as a "cacuminal flap" not acceptable in standard speech. The *r* sound became a uvular *r* in Danish and in the dialects of the nearest parts of Sweden and Norway in the last century or two.

Morphology. The Common Scandinavian system of inflections in nouns, adjectives, pronouns, and verbs is almost totally preserved in Icelandic, if allowance is made for some sound changes (*e.g.*, *-r* becomes *-ur* as in *situr* "sits," and *-t* becomes *ð* as in *húsið* "the house"). In Faeroese and New Norwegian the genitive case is replaced in speech by prepositional phrases or compounds. Declensions in Faeroese have been simplified in the plurals of nouns (all end in *-r*), verb plurals (*-a* in present, *-u* in preterite), verb singulars (*-i* in weak present for all persons), and the subjunctive (*-i* in the present, same ending as indicative in the preterite). In the remaining languages all case forms except the genitive (which invariably ends in *-s*) have been merged, as have markers of person and number in the verbs. This simplification began in Danish and spread to Norwegian and Swedish between 1200 and 1500, perhaps under the influence of Low German.

Loss of inflection

Major similarities. The present-day system of Danish, Dano-Norwegian, New Norwegian, and Swedish is basically identical. Nouns have singular and plural forms, to which the definite article may be suffixed; the plural suffixes vary, reflecting earlier stem, gender, and umlaut classes. Adjectives have neuter singulars marked by *-t*, plurals marked by a vowel (*-e* or *-a*), and weak forms used after determiners, usually identical in form with the plurals; the comparatives are marked by *r* and superlatives by the cluster *st*. Adverbs derived from adjectives are identical in form with the neuter singular forms

of the adjectives. Personal pronouns occur in three persons and in both singular and plural. In part, they still distinguish nominative and accusative (*e.g.*, Swedish *jag* "I"—*mig* "me"). There are polite pronouns of address that are either identical with the 2nd person plural (Swedish *ni*, Icelandic *þér*, Faeroese *tygum*, and New Norwegian *de* or *dykk*) or the 3rd person plural (Danish or Dano-Norwegian *De*); in Icelandic and Faeroese old duals have taken over the function of plurals (Icelandic *við* "we," *þið* "you"; Faeroese *vit* "we," *tit* "you"). Each personal pronoun has a corresponding possessive pronoun, the 3rd person being identical with the genitive of the pronoun and invariable. The possessive pronouns for the other persons and the reflexive *sin* are inflected for gender and number like most other pronouns and articles. Verbs inflect for tense only, with *-r* as the usual present marker (New Norwegian does not have an ending to indicate present tense in the strong verbs), while the preterites have stem-vowel ablaut changes in the strong verbs and a dental suffix in the weak verbs. Nonfinite forms of the verb have invariable suffixes (*-a* or *-e* for the infinitive, *-ande* or *-ende* for present participles, and *-at* or *-et* for perfect participles), except that Swedish and New Norwegian mark gender when the perfect participle is used adjectivally.

Major differences. New Norwegian, like Icelandic and Faeroese, and, in part, Dano-Norwegian preserve masculine, feminine, and neuter genders; Danish and Swedish combine masculine and feminine into a common (nonneuter) gender. Swedish and New Norwegian (in part) preserve non-neuter plurals in *-ar*, *-er*, and *-or*, which merged as *-er* in Dano-Norwegian; in Danish these have become *-e*, while a new plural in *-er* has arisen, primarily for loanwords. The preterite of first class weak verbs (Old Norse *-aði*) ends in *-a* in New Norwegian, *-et* in Dano-Norwegian, *-ede* in Danish, and *-ade* in Swedish (usually pronounced *-a*). In Norwegian and Swedish a new class of weak verbs with preterite ending *-dde* has arisen, including stems ending in *-d* or long vowels (Swedish *födde* "bore," *bodde* "lived"). The present tense form of strong verbs is umlauted in New Norwegian (as in Icelandic and Faeroese); it is monosyllabic in New Norwegian, has high or low pitch on the stressed syllable in Dano-Norwegian and Swedish, and glottalization in Danish (New Norwegian *kjem;* Dano-Norwegian, Swedish *kommer*, pronounced *'kåmmər;* Danish *kommer*, pronounced *kåmˀər*. New Norwegian has *-st* in the mediopassive (like Icelandic and Faeroese); Dano-Norwegian, Swedish, and Danish have *-s*.

Syntax. The reduction of morphological complexity has been accompanied by the emergence of a more rigid order of sentence elements. Normal order is subject–finite verb–indirect object–direct object. The verb must precede the subject in yes-no questions, or when any part of the predicate is put first. Contrary to German practice, the verb keeps its normal place in subordinate clauses, except that negatives and other lightly stressed adverbs usually precede the finite verb (except in Icelandic). Complex verb phrases are formed with modal auxiliaries (*e.g.*, *kan* "can") and infinitives or with the perfect auxiliaries *ha(ve)* "have" and *få* "get" (Icelandic *geta*) and the perfect participle. Instead of such durative aspect markers as the English progressive (*e.g.*, "is talking"), verbs indicating position are combined with the main verb (*e.g.*, Dano-Norwegian *han sitter* [*står, går, ligger*] *og prater* "he is sitting [standing, walking, lying] and talking."). Icelandic has special constructions for present and perfect aspects (*er að ganga* "is going" or *er buinn að ganga* "is through going").

Normal word order in sentences

Major differences in the Norwegian languages, Swedish, and Danish are few: (1) New Norwegian and Swedish use the nominative after a copula (*Det er eg/jag* "It is I"), Dano-Norwegian and Danish, the accusative (*Det er meg/mig* "It is me"). (2) A complex passive is formed either with Old Scandinavian *verða* (Swedish *varda*, New Norwegian *verta*) or Low German *bliven* (Danish *blive*, Dano-Norwegian *bli*) and the perfect participle. (3) Swedish supplements the polite pronoun of address with a pronominal use of titles: *Önskar professoren kaffe?* "Do you [professor] wish coffee?" (4) The reflexive pronoun *sin* is used with singular or plural subjects, except in Danish, in which it is used only with singular subjects. (5) A definite article is indicated by a form before the adjective and a suffix after the noun ("double definite"), except in Icelandic and Danish (*e.g.*, in Norwegian and Swedish *det store* [*stora*] *huset* "the big house," both *det* and *-et* in *huset* mean "the," in Danish the suffix *-et* is not used: *det store hus*). (6) A possessive may follow its noun in Icelandic, Faeroese, and Norwegian but not in Danish or Swedish (Icelandic *hesturinn minn* "my horse," literally, "horse mine," Swedish *min häst* "my horse"). (7) The numeral "one" is used (in unstressed form) as an indefinite article (*i.e.*. as "a," "an"), except in Icelandic, which has no indefinite article. (8) Swedish omits the auxiliary *hava* "have" in subordinate clauses (*Huset jag sett*. . . . "The house I [have] seen . . .").

Vocabulary. The everyday stock of Scandinavian words, including most of the high frequency words, is Indo-European and Germanic in its core. Of the 200,000 or more entries in the large dictionaries of each language, the vast majority are either compounds and derivatives of the simpler words or else borrowings from other languages—mostly of a scientific and cultural nature. At the present time the chief source of loanwords is English.

Borrowings

Icelandic preserved the creative powers of the older language by making it a policy not to accept new words in unassimilated form. Whenever possible, new compounds and derivatives have been created to avoid the borrowing of foreign terms. To some extent Faeroese and New Norwegian have followed the same policy but without the success of Icelandic. Danish, Swedish, and Dano-Norwegian have adopted numerous German words, along with their prefixes and suffixes; *e.g.*, Danish and Norwegian *betale* and Swedish *betala* "pay" from Low German *betalen* (*cf.* Icelandic and Faeroese *gjalda, borga*). A knowledge of German is very helpful in learning to read Norwegian, Swedish, and Danish, but this is less true for Icelandic and Faeroese, which even baffle fellow Scandinavians.

The borrowings of Danish, Swedish, and Norwegian reflect the varied contacts discussed above. Their vocabulary consists of a native core, a German middle layer (with words like Danish *skrædder* "tailor"; *cf.* Icelandic and Faeroese *klæðskeri*, literally "cloth-cutter"), and an international outer layer (with words like *psykologi* "psychology"; *cf.* Icelandic and Faeroese *sálfræði*, literally, "soul science"). While there are some differences among the languages in the exact composition of these layers, there is also considerable agreement. Differences occur especially in words of local origin (slang, humour, endearments, abuse) and in borrowings of different origin; *e.g.*, Norwegian *etasje*/Swedish *våning*/Danish *sal* "story" (in a hotel), from French *étage*, Middle Low German *woninge*, and Old Scandinavian *salr* (but with its meaning from North German *Saal*). (Ei.H.)

BIBLIOGRAPHY

History and classification of the Germanic languages: The reconstruction of Proto-Germanic and the derivation of Proto-Germanic from Proto-Indo-European are treated in FRANS VAN COETSEM (ed.), *Toward a Grammar of Proto-Germanic* (1972); EDUARD PROKOSCH, *A Comparative Germanic Grammar* (1939); HERMANN HIRT, *Handbuch des Urgermanischen*, 3 vol. (1931–34); ANTOINE MEILLET, *Caractères généraux des langues germaniques*, 7th ed. (1949); WILHELM STREITBERG, *Urgermanische Grammatik* (1896, reprinted 1963).

Yiddish: The main works up to 1958 are listed in URIEL and BEATRICE WEINREICH, *Yiddish Language and Folklore: A Selective Bibliography for Research* (1959). Significant recent works include: *For Max Weinreich on His Seventieth Birthday: Studies in Jewish Languages, Literature, and Society* (1964); *The Field of Yiddish: Studies in Language, Folklore and Literature*, 2nd collection, ed. by URIEL WEINREICH (1965); *The Field of Yiddish: Studies in Language, Folklore, and Literature*, 3rd collection, ed. by MARVIN I. HERZOG, WITA RAVID, and URIEL WEINREICH (1969); JOSHUA A. FISHMAN, *Yiddish in America: Socio-linguistic Description and Analysis* (1965); MARVIN I. HERZOG, *The Yiddish Language in Northern Poland: Its Geography and History* (1965); URIEL WEINREICH, *Modern English-Yiddish, Yiddish-English Dictionary* (1968), and "Yiddish Language," *Encyclopaedia Judaica*, vol. 16, col. 789–798 (1971).

Scandinavian (North Germanic): A survey of research on Scandinavian languages since 1918 by EINAR HAUGEN and THOMAS L. MARKEY is presented in THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics*, vol. 11 (forthcoming). Important recent contributions are treated in *The Nordic Languages and Modern Linguistics*, ed. by H. BENEDIKTSSON (1970). (*Histories*): Compact histories of all the languages are presented in ELIAS WESSEN, *Die nordischen Sprachen* (1968); and EINAR HAUGEN, *The Scandinavian Languages* (forthcoming). Detailed histories include: D.A. SEIP, *Norsk språkhistorie til omkring 1370*, 2 vol. (1955; German trans., 1971), for Old Norwegian; PETER SKAUTRUP, *Det danske sprogs historie*, 4 vol. and index (1944–68), for Danish; ELIAS WESSEN, *Svensk språkhistoria*, 3 vol. (1965), for Swedish; GUSTAV L. INDREBO, *Norsk målsoga* (1951), for Norwegian; and EINAR HAUGEN, *Language Conflict and Language Planning* (1966), for the modern Norwegian period. (*Grammars*): The classic grammars of the older languages are ADOLF G. NOREEN, *Altisländische und altnorwegische Grammatik*, 4th ed. (1923); and *Altschwedische Grammatik* (1904); and JOHANNES BRONDUM-NIELSEN, *Gammeldansk grammatik*, 5 vol. (1950–65). For introductory purposes the best grammar is E.V. GORDON, *An Introduction to Old Norse*, 2nd ed. (1957). Grammars of the modern languages are: PAUL DIDERICHSEN, *Elementaer dansk grammatik*, 2nd ed. (1957), for Danish, and Diderichsen's compendium *Essentials of Danish Grammar* (1964), as well as AAGE K. HANSEN, *Moderne dansk*, 3 vol. (1967); ADOLF G. NOREEN, *Vårt språk*, 9 vol. (1903–24), for Swedish; AUGUST WESTERN, *Norsk riksmåls grammatikk* (1921), for Dano-Norwegian; OLAV T. BEITO, *Nynorsk grammatikk* (1970), for New Norwegian; W.B. LOCKWOOD, *An Introduction to Modern Faroese* (1955), for Faeroese; STEFAN EINARSSON, *Icelandic: Grammar, Texts, Glossary* (1945). Introductory textbooks for English-speaking users are (beside the two just preceding) ELIAS BREDSDORFF, *Danish* (1956); EINAR HAUGEN and KENNETH G. CHAPMAN, *Spoken Norwegian*, rev. ed. (1964); NILS-GUSTAV HILDEMAN and ANN-MARI BEITE (eds.), *Learn Swedish*, 2nd ed. (1964); and volumes in the "Teach Yourself Series." (*Dictionaries*): There are many-volumed native dictionaries for each language. Only some bilingual dictionaries are listed here: HERMANN VINTERBERG and JENS AXELSEN, *Dansk-engelsk ordbog*, 7th ed., 2 vol. (1967); RICHARD CLEASBY and GUDBRAND VIGFUSSON, *An Icelandic-English Dictionary*, 2nd ed. (1957); W.E. HARLOCK, *Svensk-engelsk ordbok* (1944); the technical I.E. GULLBERG, *Svensk-engelsk fackordbok* (1964); and EINAR HAUGEN (ed.), *Norwegian-English Dictionary* (1965).

(Wi.G.M./Ei.H./M.I.H.)

Germanic Law

Germanic law is a designation that covers the laws of the various peoples of Germanic stock from the time that the earliest "barbarian" tribes came into contact with the Romans until their tribal laws developed into national territorial laws—a development that occurred at different times with different peoples. Thus some of the characteristics of Scandinavian legal collections of the 12th century are similar to those in the Visigothic laws of the 6th century.

Knowledge of the early Germanic period is derived mainly from the observations of tribal life contained in Julius Caesar's *Gallic War* and Tacitus' *Germania*. The first written collections of Germanic law are the so-called *Leges Barbarorum*, which date from the 5th century until the 9th century. They are all written in Latin and show Roman influence in the use of technical terms of Roman law. The Anglo-Saxon laws and the laws of the North Germanic group, on the other hand, are in the vernacular and owe their written form largely to the advent of Christianity.

For all of the Germanic peoples, law (West German, *reht, êwa;* High German, *wizzôd;* North German, *lagh*, from which the English word "law" is derived) was basically not something laid down by a central authority such as the king but rather the custom of a particular nation (tribe). It was essentially unwritten, being derived from popular practices, and was not sharply distinguished from morality; it was personal in the sense that it applied only to those who belonged to the nation. Each man thus followed his own law, a notion appropriate to a nomadic people who originally did not live in clearly defined territory. When, after the fall of the Roman Empire in the West, Germanic tribes took over former Roman provinces, they did not attempt to apply their laws to their Roman subjects, to whom Roman law was still applicable.

Thus the earliest Germanic code, that of Euric, king of the Visigoths in Spain and southwestern Gaul in the late 5th century, applied exclusively to Visigoths. The *Lex*

Visigothic Laws

Romana Visigothorum, or Breviary of Alaric, was issued in AD 506 for their Roman subjects. It was a compilation of "vulgar law"—Roman law adapted to fit the social and economic conditions of the late Roman Empire—and was later the main source of Roman law in the Frankish kingdom. Only in the 7th century was Visigothic law applied to Visigoths and Romans alike, the two peoples having by then substantially fused.

The *Leges Barbarorum*, then, are not legislation in the modern sense but rather the records of customs that were first collected and then declared as law. The prologue to the Salic Law (the law of the west or Salic Franks) recounts how four chosen men collected the original practices in particular cases after having discussed them with the presidents of the local popular assemblies. Nor did the *Leges* seek, as do modern codes, to set out all of the main rules of law. They were not concerned with what everyone took for granted but concentrated on matters that, perhaps as a result of migration or conquest, had become doubtful and needed authoritative exposition. They dealt with specific situations rather than general rules, particularly with court procedure, money compensation for acts of violence, and succession on death.

The initiative for declaring law usually came from the king, but the resulting laws normally required approval by the popular assemblies. Because of this collaboration between king and people, a compilation was sometimes referred to as an "agreement" or *pactus*. The Visigothic laws were an exception; they appear always to have been formulated by the king and chief landowners without popular participation. Gradually, in any case, first the Lombard and then the Frankish kings overcame their people's aversion to central government and legislated unilaterally. The Lombards, who invaded Italy in 568, had no single code of custom, but their kings issued edicts from the mid-7th century onward. In the Frankish kingdom, the Merovingian kings called their legislation *edicta* or *praecepta*, but the succeeding Carolingians characterized them as *capitularia; i.e.*, royal ordinances divided into articles (*capitula*). These included modifications of the *Leges* of the Franks or other nations in the Frankish kingdom; administrative orders to officials; and independent legislation. Charlemagne and his successors claimed the power of the Roman emperors to make laws for all their subjects, irrespective of nation, and without the consent of any assembly. The validity of the law depended solely on the oral act of the king in promulgating it.

Germanic institutions and legal organization. Germanic law recognized a distinction between free and unfree persons. Only the former had legal capacity, and they were subdivided into nobles and ordinary freemen. The nobles enjoyed a larger share in land distribution, were preferentially chosen for public office, and were protected by a larger money compensation if they were injured. Certain west Germanic tribes recognized an intermediate status of half-free persons, who could enter into legal transactions and marry but had no political rights.

Role of the king

Basically a Germanic tribe was a league of clans. Its main institutions of government were the king, his council, and the tribal assembly (*mallus, witan, mot, ding*, or *thing*). The king was military leader, chief priest, and president of the assembly, and he was assisted in the routine business of government by his council of elders and higher nobles. The assembly was composed of all free members of the tribe grouped in clans. It elected kings, declared war, outlawed freemen, and generally controlled the membership of the tribe by its supervision of the manumission of slaves, the emancipation of minors, and the adoption of strangers.

The dominant social institution was the "sib" (*sippe*), a term that could mean both a clan—the extended family composed of all those related by blood, however remotely, and subject to a clan chief—and also a household or narrow family, whose members were under the *mund* of the family head. A boy remained in his father's *mund* until he was emancipated on attaining physical maturity; a girl remained until she married, when she passed into the *mund* of her husband. Marriage commonly took the form of the sale of the bride to her groom for a price, which developed into a settlement for her benefit. The husband could divorce his wife at will but risked being penalized financially.

Laws of property

The main notion in the law of property was the *gewere* or power exercised by the owner, which did not clearly distinguish legal title and physical control. Various forms of limited ownership were recognized. Land was treated differently from movables. Originally it belonged to each family collectively; gradually family ownership developed into the private ownership of the family head, but for a long time he could alienate land only with the consent of the nearest heirs. Land transfer required much formality, and among the west Germanic peoples a glove or spear was handed over as a symbol of *gewere*.

On the death of the family head, his property passed to his descendants in the nearest degree of proximity, with a preference for males. (The declaration in the Salic Law that daughters could not inherit land was used by 16th-century French lawyers as additional support for the long-standing practice of excluding women or their descendants from succeeding to the crown.) In the absence of descendants, several *Leges* provided that property deriving from the father's side should return to that side and property from the mother's side to her side. The order of succession could not be altered by will.

When trade was still on a cash or barter basis, there was little need for formal contract law. A family could obligate itself to another either by pledging a thing as security (*wadium, gage*) or by surrendering a hostage (*gijzel, born*).

Later, a debt was guaranteed by formal oath accompanied by surrendering a staff to the creditor (*effestucatio*). Contractual obligation was then constituted either by oath, enforced by an action for perjury, or by delivery of a thing, in which case it was enforced by an action for theft.

Laws to control crime

Offenses against the community, such as treason, secret killing, and secret theft were punished by outlawry, pronounced by the tribal assembly. The convicted person could then be killed by anyone. Offenses against individuals, which included open killing and open robbery, became the subject of a blood feud if the criminal and victim belonged to different family groups. Peace could be bought by the payment of compensation, known as *wergild* in homicide cases and *bot* in others, which was at first voluntary and only later became obligatory. Even in the 7th century, Visigothic law still allowed retaliation in kind for all injuries except those to the head. The *Leges* contained elaborate tariffs of compensation for different kinds of injury, the amount varying according to the social status of the victim. The private feud was eventually restricted with the growth of royal authority in the Frankish period and the notion of the king's peace, breach of which was punishable by the king's court.

When the parties had appeared before a court and stated their case, the court decided the method of proof, which could be either by oath of the parties, supported by *compurgatores* (literally "oath-helpers"), the number required depending on the gravity of the case, or by ordeal or by battle. A successful claimant had to enforce judgment himself on the person or property of the defendant.

The abandonment of personal laws. With the division of the Frankish kingdom in the late 9th century, government became highly decentralized. Already before then the pattern of landholding, which determined the more important legal relationships, had begun to take on the characteristics of feudalism. Before the end of the Roman Empire much of the land had been concentrated in the hands of magnates, secular and ecclesiastical. But, unlike their predecessors under the Romans, the holders of secular land in the Germanic states became largely independent of the central government. By the 9th century, many lords had become strong enough to challenge the power of the Carolingian kings of the Frankish Empire and to make the inhabitants of their own areas their vassals. These vassals held their land from the lords as

tenants of a so-called feud or fee. Each feudal lord held a court for his tenants, and in the feudal court the lord applied the same law to all of his tenants, irrespective of their racial or national origin. Thus the old Germanic personal principle was abandoned in favour of the territorial principle, which meant the application of the custom of the region. This was usually based partly on Germanic law and partly on the Roman law of the *Lex Romana Visigothorum*, adapted in the interests of the feudal lords.

Influence of canon law

In the same period the Roman Church became the main unifying force in western Europe and began to claim jurisdiction over many matters that earlier had been considered secular rather than ecclesiastical. Church courts had existed since the Roman Empire, and their power in matters of faith was recognized by the secular authorities. The personal law of the church as an institution was always Roman, and indeed the law of the Ripuarian Franks on the Rhine expressly declared: "The church lives by Roman law." The canon law applied in the church courts was largely influenced by Roman law and contained very few Germanic elements. Now the church courts applied this law to matters that had previously been dealt with by the secular courts, such as marriage, adultery, wills, and succession. In many countries these matters remained withdrawn from Germanic law and subject to the church law even after the Reformation.

Merchants also found that the old Germanic customary law was inadequate to cope with the problems created by the rapid growth of commerce that had occurred by the 12th century. A special commercial law, based mainly on Roman law as developed by the Mediterranean seaborne traders, was developed to settle disputes between merchants, without regard to their nationality or place of residence.

These developments reduced the range of matters subject to the jurisdiction of the local county courts. In Germany some of the earlier codifications of customary law were forgotten, partly because the local judges were unable to understand the Latin in which they were written and partly because the rules that they contained were unsuited to the new social and economic conditions. The local courts applied an unwritten customary law based on the dominant tribal law of the area, and it was this that formed the basis of such codifications as the *Sachsenspiegel* ("mirror of the Saxons") in the 13th century.

Regional variations

In France the legal development in the North differed from that in the South. The regional customs in the North were made up of Germanic and Roman law, the Carolingian capitularies, and canon law, but Germanic elements predominated. In the South, the so-called *pays de droit écrit* ("land of written law"), where Gallo-Romans had been far more numerous than Franks, the custom of each district was based mainly on the vulgar law of the *Lex Romana Visigothorum*. In Italy this law existed side by side with Lombard law. In the 7th and 8th centuries that law had been subjected to a relatively sophisticated codification, whose form shows Roman influence.

In England the Norman conquerors continued the movement toward legal unity begun by the Anglo-Saxons and imposed on the country a centralized form of government more powerful than any on the Continent. In the 12th century, Henry II made the king's court a permanent court of professional judges, who assumed jurisdiction over many matters that earlier had been dealt with by other courts. The common law developed by this court was largely Germanic law.

Scandinavian developments. For several reasons—because they were isolated from the literate tradition of Rome, because their kingdoms were not unified until the 9th century, and because feudalism was less prevalent—the Scandinavian countries (including Iceland) developed forms of law distinct from the mainstream of Germanic law.

As elsewhere, the Scandinavian tribes originally had no written laws; indeed, customary laws were handed down by word of mouth until the 11th century or even later. Those learned in the traditional customs were known as "law men." They gave private counsel; advised the local assembly or *thing*, which had decisive authority to declare the law; and, in effect, acted as judges. In some areas they gave a periodic, public recital of the law (*laghsagha*, or "law-saying"). In Norway and Iceland they collectively retained this semi-official character for centuries, but in Sweden the law man became an elected public official who presided over the local *landsthing* and generally acted as the guardian of the *land*'s independence against the encroachments of the king's authority. Consolidation of several provinces under one king did not at first change this situation significantly, because cohesion was feeble and the central government's influence on legislation was restricted. A trend toward greater legal unity asserted itself, however, with the formation of more comprehensive regions with a common *thing*.

Between the 11th and the 13th centuries the provincial customary laws were first put into writing on private initiative and later officially codified, the most famous codification being the *Jydske Lov*, enacted for Jutland in 1241. Whereas the unwritten laws, in common with other early Germanic laws, had tolerated and regulated blood feuds, the new codes were in several respects more progressive. Thus, the code of the Norwegian King Magnus (1263–80) abolished private vengeance, declaring that the king's officials should initiate criminal proceedings and provide for the punishment of evildoers; crime was thus made a matter of public prosecution rather than of personal action. Further, presumably under the influence of Christianity, legal provisions were introduced for assisting paupers and the helpless. Landholding was allodial rather than feudal; that is, the ownership of the land was in the holder himself rather than in a lord from whom he held it. The freedom from outside influences, whether of Roman, canon, or other Germanic laws, largely prevailed in Scandinavia until the 18th and 19th centuries.

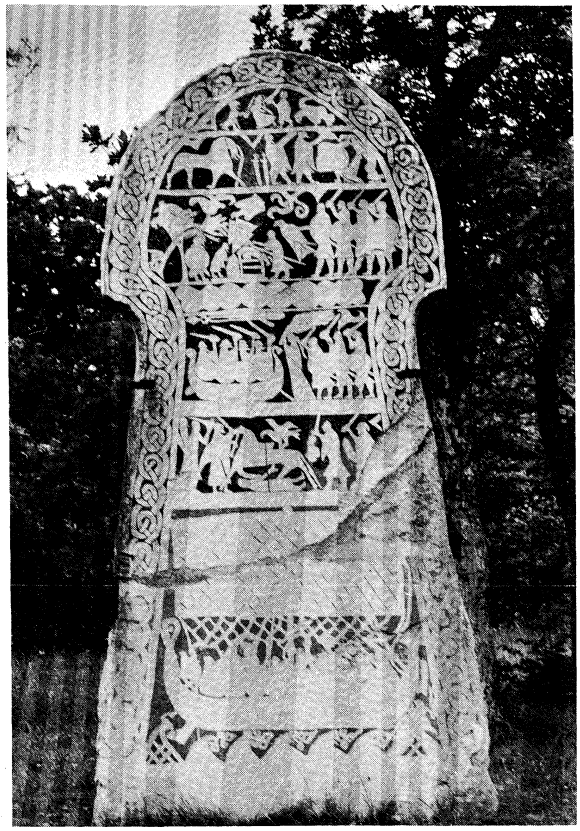
(P.G.S.)

Germanic Religion and Mythology

The term Germanic religion is used for the mythology, religious beliefs, and cults practiced by peoples who spoke one or another of the Germanic dialects before they were converted to Christianity. Germanic culture extended, at various times, from the Black Sea to Greenland, or even the American continent. Germanic religion played an important role in shaping the civilization of Europe. But since the Germanic peoples of the Continent and of England were converted to Christianity in comparatively early times, it is not surprising that little is known about the gods whom they used to worship and the forms of their religious cults. Vivid memories of Germanic religion have survived only in Scandinavia.

SOURCES

Classical and early medieval sources. The works of classical authors, written mostly in Latin and occasion-



Memorial stone from Gotland, Sweden, showing battle scenes and ships. In the third panel from the top, a warrior is being hanged in a tree as a sacrifice to Odin, whose cult is represented by an eagle and a twisted knot. Late 8th century.
Antikvarisk-Topografiska Arkivet

ally in Greek, throw some light on the religion of Germanic peoples; however, few authors showed interest in the religious practices of Germanic peoples. Tacitus, who wrote *Germania* c. AD 98, was an exception; he provided a lucid picture of customs and religious practices of continental Germanic tribes. He described some of their sacrifices, and occasionally named a god or a goddess. It is doubtful whether Tacitus had ever visited Germany; his book was based largely on older ones now lost.

Caesar (*De bello Gallico* VI, 21–4) made some remarks on the political and social organization of Germans, as well as cursory remarks on their religion. Contrasting Germans with the Celts of Gaul, Caesar was struck by the poverty of the German religion: they had no druids (*druides*), no zeal for sacrifice, and counted as gods only the sun, the fire god (Vulcanus), and the moon. For all his knowledge of the Celts, Caesar had no more than a superficial knowledge of Germans.

Early medieval records. As the power of Rome declined, records grew poorer, and nothing of great importance survives before *Getica* ("The History of the Goths"), written by the Gothic historian Jordanes c. 550; it was based partly on a larger work of Cassiodorus and partly on the work of Ablavius. The *Getica* is short and scrappy, but it incorporates valuable records of Gothic tradition, the origin of the Goths, and some important remarks about the gods whom the Goths worshipped and the forms of their sacrifices, human and otherwise.

Origin of the Lombards

A story about the origin of the Lombards is given in a tract, *Origo gentis Langobardorum* ("Origin of the Nation of Lombards"), of the late 7th century. It relates how the goddess Frea, wife of Godan (Wodan) tricked her husband into granting the Lombards victory over the Vandals. The story shows that the divine pair, recognizable from Scandinavian sources as Odin and Frigg, was known to the Lombards at this early time. A rather similar story about this pair is told in a Scandinavian source. Paul the Deacon, working late in the 8th or early in the 9th century, repeated the tale just mentioned in his fairly comprehensive *Historia Langobardorum* ("History of the Lombards"). Paulus used written sources available to him and seemed also to draw upon Lombard tradition in prose and verse.

The Venerable Bede, writing his *Historia ecclesiastica gentis Anglorum* (*Ecclesiastical History of the English People*) early in the 8th century, showed much interest in the conversion of the English, and some in the pagan religion practiced by the English before it. The lives of Irish and English missionaries who worked among Germanic peoples on the Continent (*e.g.*, Columbanus, Willibrord, Boniface) provide some information about heathens and their sacrifices.

The first detailed document touching upon the early religion of Scandinavia is the *Vita Anskarii* ("Life of St. Anskar of Rimbert"). St. Anskar (died 888) twice visited the royal seat, Björkö, in eastern Sweden, and noticed some religious practices, among them the worship of a dead king. Anskar was well received by the Swedes, but it was much later that they adopted Christianity.

Some two centuries later, c. 1072, Adam of Bremen compiled his *Gesta Hammaburgensis ecclesiae pontificum* (*History of the Archbishops of Hamburg-Bremen*), which included a description of the lands in the north, then part of the province of Hamburg. Adam's work is particularly rich in descriptions of the festivals and sacrifices of the Swedes, still largely pagan in his day.

German and English vernacular sources. Learned sources, such as those just mentioned, may be supplemented by a few written in vernacular in continental Germany and England. Among the most interesting are two charms, the so-called Merseburg Charms, found in a manuscript of c. 900, in alliterating verse. The charms appear to be of great antiquity, and the second, intended to cure sprains, contains the names of seven or perhaps eight gods and goddesses. While some of these are unknown from other sources, three or perhaps four are also known from Scandinavian records, viz., Wodan (Odin), Friia (Frigg), Volla (Fulla), Balder (Baldr). The last is somewhat doubtful. The charm also names two other deities, Phol and Sinthgut, who cannot be identified.

A manuscript of the 9th century contains a baptismal vow in the Saxon dialect, probably dating from the 8th century. The postulant is made to renounce the devil and all his works, as well as three gods, Thunaer (Thor), Woden (Odin), and Saxnot. The meaning of the last name is not clear but a Seaxnet, son of Woden, appears in a genealogy of the kings of Essex.

Old English sources

Vernacular sources in Old English are rich, but reveal little about the pre-Christian religion. The poem *Beowulf* is based upon heroic traditions, ultimately of Scandinavian origin, but it is thoroughly Christian. It does, however, retain something of Germanic morality, heroism, and defiance of death. The same might be said of minor historical poems, such as the *Battle of Brunanburh* and the *Battle of Maldon*. Old English literature also includes numerous charms, intended as safeguards against illnesses and misfortunes, but these can hardly be called religious. It is noticeable that Woden (Odin) is mentioned repeatedly in Old English sources; he is frequently named among ancestors of the royal houses.

Scandinavian literary sources. The greater part of scholarly knowledge of Germanic religion comes from literary sources written in Scandinavia. These sources are mostly written in the Old Norse language and, strange to say, they are nearly all preserved in manuscripts written in Iceland from the 12th to 14th centuries or in later copies of manuscripts written at that period. This implies a surviving tradition and an antiquarian revival in that distant outpost of Scandinavian culture.

The oldest of the sources found in the Icelandic manuscripts are in verse. Although remembered and written

down in Iceland, some of these verses originated elsewhere, some in Norway and a few in Denmark and Sweden. Some of them may well be older than the settlement of Iceland, which took place toward the end of the 9th century. The Icelanders remained pagan until the year AD 1000 (or 999).

The verse preserved in the Icelandic manuscripts may be divided broadly into two classes, the so-called Eddaic and the scaldic. The Eddaic is mostly composed in free alliterative measures, much like that of the Old English *Beowulf*. Much of the Eddaic poetry is preserved in a manuscript now called the *Elder Edda* or *Poetic Edda*, written in Iceland *c.* 1270 and containing material centuries older. The meaning of the name *Edda* is disputed; it was not originally applied to this book but to another mentioned below.

The *Elder Edda* consists of a number of lays, which may be divided into two classes, the mythological and the heroic. The mythological section contains stories about heathen gods; words of wisdom; and descriptions of the cosmos, the beginning of the world, and the Ragnarök, the end of the pagan world. The ages and places of origin of the various lays preserved in the *Edda* and minor collections are disputed. The first lay in the *Edda* is called *Völuspá* ("Sibyl's Prophecy") and, in comparatively few lines, covers the history of the world of gods from the beginning to the Ragnarök. Scholars detect the influence of Christian imagery in this poem. The scenery described is that of Iceland, and it is commonly thought that it was composed in Iceland about the year 1000, when Icelanders perceived the fall of their ancient gods and the approach of Christianity.

Hávamál

The *Hávamál* ("Words of the High One") is given as the words of Odin. It is not, in fact, one poem but consists of fragments of six or more. Some sections cannot be Icelandic, for the scenery and conditions described are rather those of Norway in the Viking Age, the 9th or 10th century. The *Hávamál* contains two interesting myths about the erotic affairs of Odin, his theft of the precious mead, and, most interesting of all, an account of how Odin hanged himself on the World Tree, Yggdrasill, a name apparently meaning "Odin's Horse."

In another poem the god Odin engages in a contest of wits with an immensely wise giant (Vafthrúdnir). The poem is in the form of question and answer, and is thus didactic; it tells of the cosmos, gods, giants, the beginning of the world and its end.

The second section of the *Elder Edda* tells of traditional Germanic heroes. Many of the stories told there are also known from continental Germany and England, but the Norse sources preserve them in an older and purer form. They are of some interest for the study of religion because the gods often intervene in the lives of heroes.

The Icelandic and, to a lesser extent, the Norwegian manuscripts of the 13th and 14th centuries contain a great bulk of poetry of a quite different kind. This is commonly, if unjustifiably, called scaldic poetry. The scaldic verse forms were perhaps devised in Norway in the 9th century. They differ fundamentally from the traditional Germanic and Eddaic forms in that the syllables are strictly counted and the lines must end in a given form. The scalds also used a complicated system of alliteration, as well as internal rhyme and consonance. Their strophes usually consist of eight lines, falling neatly into half-strophes of four lines. Scaldic poetry was often made in praise of chieftains of Norway and other Scandinavian lands. Its authors are frequently named and their approximate ages are known. The scalds allude to myths and pagan worship, and their testimony is the most reliable of all. The strict verse forms provided some safeguard against corruption, although the complex syntax and abstruse diction often make this professional poetry difficult to interpret.

After the Icelanders were converted to Christianity, much of their ancient poetry survived this religious change, as did traditions about pagan gods and their worship. Icelanders of the 12th century travelled widely and were perhaps the most lettered people in Europe, studying and translating homilies, saints' lives, and other learned literature of Europe. The 13th century saw a revival of the Icelanders' interest in the practices of their pagan ancestors, as well as in those of their kinsfolk in Norway and, to a lesser extent, in Sweden.

The *Edda* and other writings of Snorri Sturluson

The name chiefly associated with this revival is that of Snorri Sturluson (1179–1241). Snorri acquired great wealth and received the best education available in those days. He became a powerful man in Icelandic politics, and political intrigue led to his assassination in 1241. The first of Snorri's works and one of the most memorable was his *Prose Edda*, written *c.* 1220. It is to this book that the title *Edda*, whatever its meaning, originally belonged.

It is likely that Snorri wrote the various sections of this book in an order opposite to that which they now have. He began with a poem exemplifying 102 different forms of verse, addressed to Haakon, the young king of Norway, and his uncle Jarl Skúli. He then furnished a section on the speech of poetry, explaining the diction of the scalds and their abstruse allusions to gods and ancient heroes. After this, Snorri wrote the section of the *Edda* most widely read today, the *Gylfaginning* ("Beguiling of Gylfi"), which is an introduction to the mythology of the north. All the major gods and their functions are described. Snorri worked partly from Eddaic and scaldic poetry still extant, but partly from sources that are now lost. He presents a clear, if not altogether reliable, account of the gods, the creation of the world, and the Ragnarök. Another important work ascribed to Snorri is the *Heimskringla* ("Orb of the World"), a history of the kings of Norway from the beginning to the mid-12th century. The first section of this book, the *Ynglinga Saga*, is of particular interest, for in it, Snorri described the descent of the kings of Norway from the royal house of Sweden, the Ynglingar, who, in their turn, were said to descend from gods. Snorri used such written sources as were available, but he also used scaldic poems, in which he placed great faith, some of which are among the oldest known. Snorri visited Norway twice and Sweden once, and he probably used popular traditions that he heard in both countries.

About the beginning of the 13th century Icelanders began to write so-called Family Sagas; *i.e.*, lives of their ancestors who had settled in Iceland in the late 9th century, and lived through the 10th and 11th centuries. A good deal had already been written about these men in summary form by Ari the Learned (1067–1148) and other scholars of the early 12th century, but much more had been preserved in tradition handed down in verse and prose.

The reliability of Family Sagas as sources of history has long been debated and no simple answer can be given. Each saga has to be studied separately, and consideration must be given not only to the author's sources but also to his aims. Some of the authors were antiquarians and tried to relate faithfully the history of a district, a family, or a hero. Others aimed at re-creating the past by writing historical fiction.

Saxo Grammaticus

About the time when the first Family Sagas were written, the Dane Saxo Grammaticus, secretary of Archbishop Absalon (died 1201), was compiling in Latin a history of ancient gods and heroes, which formed the first nine books of his great history of the Danes (*Gesta Danorum*). These nine books deal with the prehistory of the Danes, and especially with pagan gods, whom Saxo regarded chiefly as crafty men of old. It may be that Saxo drew on Danish traditions and Danish poetry now lost, but much of his information came from vagrant Icelanders, of whom he speaks with some respect.

Material such as Saxo used was also used by Icelanders some generations later in the so-called Heroic Sagas (*fornaldar sögur*). Sagas of this kind describe the adventures of heroes who lived, or were supposed to have lived, in Scandinavia or on the Continent before Iceland was peopled. The gods, and particularly Odin, are frequently said to take part in the affairs of men, but since few of the Heroic Sagas were written before the 14th

century, and the aim of their authors was often entertainment rather than instruction, these sagas can be used as sources only with utmost discrimination.

Archaeology. The archaeological finds of Scandinavia are rich, and information about religious beliefs may be drawn especially from the grave goods and forms of burial. It may, in fact, be possible to trace continuity of belief from the Bronze Age to the Viking Age in the 9th and 10th centuries. Archaeological finds, however, are difficult to interpret from a religious point of view. Graves in which a ship or boat is found need not necessarily imply that the dead were believed, by those who buried or cremated them, to sail to the Other World. Such practices could have become simply conventional.

A number of small images in silver or bronze, dating from the Viking Age, have also been found in various parts of Scandinavia. One, found in Sweden, shows a fertility god with full erection, perhaps Freyr; another, found in Iceland, shows Thor with his hammer. Several silver images that appear to represent Thor's symbol, the hammer, have also been found in various places.

Runic inscriptions. The runic alphabet was used throughout the Germanic world beginning in about the 1st century AD. Occasionally one god or another is named; the god Thor may be called upon to hallow a grave. The runes had magical and sacral significance, as will be explained below.

Place-names. Theophoric place-names (derived from or bearing the name of a god) are found in all Germanic lands. Poor scholarly knowledge of pagan religion in continental Germany and England may be partly supplemented, especially in England, by the names of places with which gods' names are compounded. The theophoric place-names of Norway and Sweden are richer and have been carefully sifted. The names of numerous gods have come to light, but evidence drawn from them is treacherous. If scholars find a place called *Thorslundr* ("Thor's Grove") it need not necessarily mean that Thor was worshipped there, for names are often transferred by settlers from one place to another, as from England to America and, in the Viking Age, from the Scandinavian mainland to Iceland. Groups of theophoric place-names may, however, provide evidence of the cult of one god or another.

MYTHOLOGY

The beginning of the world of giants, gods, and men. The story of the beginning is told, with much variation, in three poems of the *Elder Edda*, and a synthesis of these is given by Snorri Sturluson in his *Prose Edda*. Snorri adds certain details that he must have taken from sources now lost.

Völuspa

The most rational of the older accounts is that of the *Völuspa*, defective as it is. The story is there told by a sibyl of such great age that she could remember the primeval giants who fostered her, although she does not disclose the origin of these giants. In the beginning there was nothing but Ginnungagap, a mighty void. Three gods, Odin and his brothers, raised up the earth, perhaps from the sea into which it will afterward sink. The sun shone on the barren rocks and the earth was overgrown with green herbage.

Later, Odin and two other gods came upon two figures, Askr and Embla, apparently lifeless tree trunks. They endowed them with breath, countenance, and the other qualities of life, evidently making them man and woman.

A very different story is told in the didactic poem *Vafthrúdnismál* ("The Words of Vafthrúdnir"). The poet speaks of a giant, Aurgelmir, who appears sometimes to be called Ymir. Drops of poison fell from the waters Elivagar (Élivágar; "stormy waves") and they grew into a giant. One of the giant's legs begat a six-headed son with the other leg, and under his arm grew a maid and a youth. The earth was formed from the body of the giant Ymir who, according to Snorri, was slaughtered by Odin and his brothers. Ymir's bones were the rocks, his skull the sky, and his blood the sea. Another didactic poem, *Grímnismál* ("The Words of Grímnir [Odin]"), adds further details The trees were the giant's hair and his brains the clouds. Snorri quotes the three poetic sources just mentioned, giving a more coherent account and adding some details. One of the most interesting and primitive is that about the primeval cow Audumla (Auðumla), formed from drops of melting rime. She was nourished by licking salty, rime-covered stones. Four rivers of milk flowed from her udders and thus she fed the giant Ymir. The cow licked the stones into the shape of a man; this was Buri (Búri), who was to be grandfather of Odin and his brothers. This story bears some resemblance to that of the Egyptian mother-goddess Hathor, who had the form of a cow. Parallels from other lands also have been noted.

A central point in the cosmos is the evergreen ash, Yggdrasill, on which the welfare of the world seems to depend. Its three roots stretch to the worlds of death, frost-giants and men. A hart (stag) is biting its foliage, its trunk is rotting, and a cruel dragon is gnawing its roots. When the Ragnarök approaches, the tree will shiver and, presumably, fall. Beneath the tree stands a well, the fount of wisdom. Odin got a drink from this well and had to leave one of his eyes as a pledge.

The gods. Old Norse sources name a great number of gods and goddesses. The evidence of place-names suggests that one cult succeeded another. Names, especially those in southeast Norway and southern Sweden, suggest that there was once widespread worship of a god Ull (Ullr). Indeed, an early poem reports an oath on the ring of Ull, suggesting that he was once the highest of the gods at least in some areas. Beyond that, little is known about Ull; he was god of the shield, the bow, and snowshoes.

Two tribes of gods: Aesir and Vanir

The gods can be divided roughly into two tribes, Aesir and Vanir. At one time, according to fairly reliable sources, there was war between the Aesir and the Vanir. Peace was made between them and hostages were exchanged. In this way, the specialized fertility gods, the Vanir, Njörd (Njörðr), his son Freyr, and presumably his daughter, Freyja, came to dwell among the Aesir and to be accepted in their hierarchy.

Odin (Óðinn). The foremost of the Aesir, according to literary sources, was Odin, although his worship, on the evidence of place-names and other records, does not appear to have been widespread. Probably Odin owes his pre-eminence in literary sources to the tradition that he was god of poetry. Various stories are told of the origin of poetry, but it was Odin who brought it to the world of gods. Poetry, called the sacred mead, was first brewed from the blood of a wise god, Kvasir, who was murdered by dwarfs. It later came into the hands of a giant and was stolen by Odin, who flew from the giant's fastness, apparently in the form of an eagle, carrying the sacred mead in his crop in order to regurgitate it in the dwelling of the gods. Because of this story, early poets refer to poetry as "blood of Kvasir" or "Odin's theft."

Odin is more than the god of poetry. He is god of occult wisdom, which, as he himself tells in the *Hávamál*, was acquired by hanging for nine nights on the World Tree. Odin was pierced with a spear; he was a sacrifice to himself. It was probably because of this story that the tree was called Yggdrasill; *i.e.*, "Odin's Horse." Odin was dead, or nearly dead, and seemed to acquire that wisdom that belongs only to the dead, as well as the runes that he carved and painted.

Odin, since he hanged himself, was god of the hanged, and stories are told of men hanged as a sacrifice to him; he was a necromancer, and could make hanged men talk. He is god of heroes and of war, promoting battle between princes. Those who fell in battle were said to go to his castle Valhalla (Valhöll), probably meaning "hall of the slain." There fallen warriors would live in bliss until the Ragnarök, when they would join Odin in his fight against a monstrous wolf. As god of the dead, Odin was accompanied by carrion beasts, two ravens, and two wolves. He had only one eye, for he had sacrificed the other for knowledge.

While place-names suggest that Odin was worshipped

from early times, especially in south Sweden and Denmark, his cult appears to have spread during the Viking Age. He is god of lawless men and vikings, boasting that he himself breaks the most sacred of oaths, the oath on the holy ring. Icelandic poets refer frequently to Odin, but it is doubtful whether he was ever worshipped in Iceland.

English and continental sources show that Odin (Woden, Wotan) was well known in the southern lands. His name is found as an element in many place-names, especially those of England and, as already mentioned, in the royal genealogies of England.

Tacitus describes a god, the *regnator omnium deus* (the god governing all), worshipped by the tribe Semnones in a forest. They would sacrifice a man to him in a horrifying ritual. There are reasons to believe that the *regnator* was Odin, often identified by writers in Latin with Mercury, to whom, according to Tacitus, human sacrifice was offered.

The name Odin is related to Icelandic, *óðr*, German *Wut*, meaning "rage, fury."

Silver image showing the integration of pagan (Thor's hammer) and Christian (cross) symbols; found in southern Iceland. In the National Museum, Reykjavik.

Thor (*þórr*). Thor is a god of very different stamp. Place-names, personal names, poetry, and prose show that he was worshipped widely, at any rate toward the end of the pagan period. Thor is called the son of Odin, but is in many ways his antithesis. He is god of order and chief antagonist of the giants, demons of chaos. Were it not for him, the whole of our world would be peopled by these monsters, and many stories are told of Thor's contests with them. His chief weapon was his short-handled hammer, of which several images have been found. Among his chief enemies was the World Serpent Jörmungand (Jörmungandr), symbol of evil, who surrounds the world. It is told how Thor failed to smash the skull of this monster; in the Ragnarök they will fight and kill each other.

The World Serpent: Jörmungand

The place-names of England suggest that Thor, or Thunor as he was called in English, was fairly well known, at any rate in Saxon and Jutish areas. As already noted, Thor was among the gods whom continental Saxons renounced on baptism.

Thor was sometimes equated with Jupiter, *dies Jovis* (Jove's day) becoming Thor's Day (Thursday). The name Thor is related to thunder (German *Donner*). Thor travelled in a chariot drawn by goats, and later evidence suggested that thunder was thought of as the sound of this chariot. As god of thunder Thor was god of rainfall and fertility, as is supported by place-names found in eastern Scandinavia and in England.

Balder (*Baldr*). The west Norse sources name another son of Odin, Balder, the spotless, innocent, suffering god. When Balder had dreams foreboding his death, his mother, Frigg, took oaths from all creatures, as well as from fire, water, metals, trees, stones, and illnesses, not to harm Balder. Only the mistletoe was thought too young and slender to take the oath. The guileful Loki tore up the mistletoe and, under his guidance, the blind god Höd (Höðr) hurled it as a shaft through Balder's body. The gods sent an emissary to Hel, goddess of death; she would release Balder if all things would weep for him. All did, except a giantess, who appears to be none other than Loki in disguise. There is another version of this story, to which allusion is made in a west Norse poem (*Baldrs draumar*). According to this Loki does not seem to be directly responsible for Balder's death but Höd alone.

Balder's name occurs rarely in place-names, and it does not appear that his worship was widespread.

The Danish historian Saxo gives an entirely different picture of Balder: he is not the innocent, Christlike figure of the west Norse sources but vicious and lustful, not a god but a demigod. He and Höd were rivals for the hand of Nanna, said in west Norse sources to be the wife of Balder. After many adventures, Höd pierced Balder with a sword. In order to secure vengeance, Odin raped a princess, Rinda (Rindr), who bore a son, Bous, who killed Höd.

Saxo's story has many details in common with the west Norse sources, but his views of Balder were so different that he may have been following a Danish rather than a west Norse tradition. Much of Saxo's story is placed in Denmark.

English sources show that Balder was known among the Scandinavian settlers in England, but there is no strong evidence that he was worshipped by the English themselves. The Merseburg Charm, mentioned above, may suggest that he was worshipped in continental Germany, but those lines are difficult to interpret.

Loki. There is no more baffling figure in Norse mythology than Loki. He is counted among the Aesir, but is not one of them. His father was a giant (Fárbauti; Cruel Striker). Loki begat a female, Angrboda (Angrboða; Distress-Bringer), and produced three evil progeny, the goddess of death, Hel, the evil serpent surrounding the world (Jörmungand) and the wolf Fenrir (Fenrisúlfr), who lies chained until he will break loose in the Ragnarök, to fall upon the dwellings of gods and men. Loki himself lies bound, but will break his bonds in the Ragnarök to join the giants in battle against the gods.

Origin of monsters

Loki deceived the gods and cheated them, but sometimes he got them out of trouble. He is seen in company with Odin and an obscure god Hoenir; he is called the friend of Thor. Loki is bisexual or homosexual; he was said to bear as well as to beget children. He was said to be mother, not father, of Odin's eight-legged horse, Sleipnir. According to one poem, Loki ate the heart of an evil woman and grew pregnant; many evil monsters are thus descended from him.

Like Odin, Loki was a changer of shape; he could take the form of a hawk and, apparently, that of a seal. According to an early poem, Odin and Loki had mixed their blood as foster brothers. It has been suggested that Loki was a hypostasis of Odin, or at least that he represents one side of Odin, the most evil side.

Minor Aesir. Though the Vanir form a major group, some minor gods and goddesses should be mentioned who do not, apparently, belong to the tribe of the Vanir. The god Heimdall (Heimdallr or Heimdalr) is interesting, though obscure. A scald of the 10th century described a struggle between Loki and Heimdall. Snorri relates that in the Ragnarök Loki and Heimdall will kill each other. Heimdall is of mysterious origin; he was the son of nine mothers, said to be sisters, all of whom are named. Heimdall was said to live in Himinbjörg ("Heavenly Rocks"?), merrily drinking his splendid mead. Snorri adds some details, which are supported by the older poetry; he is the watchman of the gods and, when the Ragnarök draws near, he will blow his ringing horn (Gjallarhorn).

There is another myth that, according to many scholars, makes Heimdall the father of men. He came to the world of man and called himself Rigr (Ríg̊r), a name probably derived from the Irish *rí* (king). He consorted with three women, from whom descend the three classes of men—thrall (serf), freeman, and prince.

Germanic religion is judged chiefly from poetry composed late in the pagan period and from remarks of outside observers, who generally had little interest in what they considered to be heathendom. There were many

gods whom these authors have nearly forgotten; Ull was mentioned earlier as one of these. Tyr (Týr) was probably a major god in early times, but memories of him have faded. He is the one-handed god, because one of his hands had been bitten off by the wolf Fenrir. He is brave and warlike; in the Ragnarök he will face the wolf Garm (Garmr), and they will kill each other. Like other gods, Tyr is said to be a son of Odin, but according to one early poem, he was the son of a giant. Tyr's cult is remembered in place-names, particularly those of Denmark. He was equated with Mars and hence *dies Martis* (Mars' day) became "Tuesday" (Icelandic *Týs dagr*).

Tyr

Bragi. Not only Odin but also Bragi was called god of poetry, at any rate in later sources. It is remarkable that the first recorded scald, living in the 9th century, was also called Bragi. Since there is no record of a cult of the god Bragi, some have suspected that the god and the poet are identical.

Frigg. Frigg is remembered as wife of Odin and mother of Balder. She is named as Friia in the second Merseburg Charm. Some writers describe her as unchaste, but more often she is depicted as the weeping mother of Balder. She was sometimes equated with Venus, and her name survives in "Friday" (Old English *Frigedæg*) from *dies Veneris*, Venus' day.

Idun (Iðunn). Idun was said to be wife of Bragi. Little is told of her, but one of the oldest Norwegian scalds refers to a myth that she kept the apples that prevented the gods from growing old. She was raped by a giant and was recovered with her apples by Loki. The story of the apples has many parallels in foreign sources, those in Irish being the closest.

Jörd (Jörð). Jörd, whose name means "earth," was mother of Thor and thus mistress of Odin. She appears under other names, Fjörgyn, which may also mean "earth," and Hlodyn (Hloðyn). A *dea Hludana* is also remembered in votive inscriptions of lower Germany and Holland. When one goddess has several names, it often means that several goddesses have been combined as one.

The Vanir. As mentioned above, the Vanir formed a tribe of gods distinct from the Aesir. If the Aesir were largely gods of battle, the Vanir were gods of fertility and riches, although they could fight too.

The best known Vanir, Njörd, Freyr, and probably Freyja, came as hostages to the Aesir. Njörd was father of the god Freyr and goddess Freyja. Tacitus, in his *Germania* (Ch. XL) described the worship of a goddess, Nerthus, on an island, probably in the Baltic Sea. Her idol was stored in a grove and conveyed in a chariot; when the goddess was present there was rejoicing and peace, and weapons were laid aside.

Although she was a goddess, *Terra Mater* (earth mother), the name Nerthus corresponds with that of the god Njörd (older Nerthuz). The change of sex is hard to explain. Some say that Nerthus was originally a hermaphrodite. Others point out that feminine nouns of the type Njörd practically died out in the Norse language and therefore the original goddess must be seen as a god.

Njörd

Njörd (Njörðr) had been married to his own sister before he came to the Aesir. Since such incestuous unions were not allowed among the Aesir, Njörd afterward married Skadi (Skaði), daughter of a giant. He was said to have immense wealth and, at least in western Scandinavia, he was god of the sea and its riches. Evidence from place-names shows that Njörd was worshipped widely in Sweden and Norway, and he was one of the gods whom Icelanders invoked when they swore their most sacred oaths.

Freyr. Much more is told of Freyr, the son of Njörd. His name probably means "Lord" (compare Old English *Frea*), but Freyr had other names as well; he was called Yngvi or Yngvi-Freyr, and this name suggests that he was the eponymous father of the north Germans whom Tacitus calls Ingvæones (Ingævones). Ing is also named in the Old English *Runic Poem*, where it is said that he was seen first among the eastern Danes; he departed eastward over a wave and his chariot went after him. It is remarkable how the chariot persists in the cult of the Vanir, Nerthus, Ing, Freyr. A comparatively late source tells how the idol of Freyr was carried in a chariot to bring fertility to the crops in Sweden. In an early saga of Iceland, where crops were little cultivated, Freyr still appears as the guardian of a sacred cornfield. Freyr's name often is found as the first element of a place-name, especially in eastern Sweden; the second element often means "cornfield, meadow."

The Eddaic poem *Skírnismál* ("The Words of Skírnir") relates a myth of Freyr taking his bride, Gerd (Gerðr), from the world of giants. Many have seen this story as a fertility myth. Gerdr (from *garðr*, "field") is held fast in the clutches of the frost-giant demons of winter. Freyr is thus the god of the sun.

Several animals were sacred to Freyr, particularly the horse and, because of his great fertility, the boar.

The centre of Freyr's cult was Uppsala, and he was once said to be king of the Swedes. His reign was one of peace and plenty. While Freyr reigned in Sweden a certain Frodi ruled the Danes, and the Danes attributed this age of prosperity to him. Frodi (Fróði) was also conveyed ceremoniously in a chariot, and some have seen him as no other than a doublet of Freyr. Freyr was said to be ancestor of the Ynglingar, the kings of the Swedes; many have regarded these kings as semidivine figures, although this view has lately been challenged.

Freyja. Freyja, the sister of Freyr, resembles her brother in many ways. She was goddess of love and fertility. One of her nicknames was *Syr* or "sow." She was goddess of wealth, owning the famous Brísing necklace mentioned in the *Thrymskviða* ("Lay of Thrym") and many other sources. It was said to be forged by dwarfs. Freyja wept tears of gold. She was also goddess of magic (*seiðr*) and taught this to the Aesir. Freyja has some of the qualities of a death goddess, taking half of those who fall in battle.

Guardian spirits. Besides gods and goddesses, medieval writers frequently allude to female guardian spirits called *dísir* and *fylgjur*. The conceptions underlying these two certainly differed originally, although some of the later writers used the words interchangeably.

Dísir and *fylgjur*

Reference is made several times to sacrifice to the *dísir*, held at the beginning of winter. The sacrifice seems generally to be a private one, suggesting that the *dísir* belonged to one house, one district, or one family. The *dísir* are sometimes described as "dead women," and in actuality they may have been dead female ancestors, assuring the prosperity of their descendants.

There is no record of a cult of the *fylgja* (plural *fylgjur*), a word best translated as "fetch, wraith." The *fylgja* may take the form of a woman or an animal that is rarely seen except in dreams or at the time of death. They may be the companions of one man or of a family and are transferred at death from father to son.

The elves (*álfar*) also stood in fairly close relationship to men. An Icelandic Christian poet of the 11th century described a sacrifice to the elves early in winter among the pagan Swedes. The elves lived in mounds or rocks. An old saga tells how the blood of a bull was smeared on a mound inhabited by elves.

A good deal is told of land spirits (*landvaettir*). The prosperity of the land depends largely upon them. According to the pre-Christian law of Iceland, no one must approach the land in a ship bearing a dragonhead, lest he frighten the land spirits. An Icelandic poet, cursing the king and queen of Norway, enjoined the *landvaettir* to drive them from the land.

Dwarfs. Dwarfs (*dvergar*) play a part in Norse mythology. Snorri says that they originated as maggots in the flesh of the slaughtered giant Ymir. This crude statement finds some support in the older poetic sources, obscure as they are. The dwarfs were very wise and expert craftsmen. Among the treasures they forged was Thor's hammer.

WORSHIP AND PLACES OF WORSHIP

Sacrifice often was conducted in the open or in groves and forests. As already noted, Tacitus speaks of a forest

in which men were sacrificed to the *regnator omnium deus* and gives other examples of groves dedicated to gods. Tacitus does, however, mention temples in Germany, although they were probably few. Old English laws mention fenced places around a stone, tree, or other object of worship. In Scandinavia, men brought sacrifice to groves and waterfalls.

A common word for a holy place in Old English is *hearg* and in Old High German *harug*, occasionally glossed as *lucus* ("a sacred grove") or *nemus* ("forest"). In Old Norse this word has the form *hörgr*. It seems to be applied to a pile of stones, or primitive altar, but was occasionally used for roofed temples. *Vé* (compare *vígja*, "to consecrate") was also applied to sacred places in Scandinavia, and forms an element in many place-names; *e.g.*, Odense (older Óðinsvé).

Temples

Although worship was originally conducted in the open, temples also developed with the art of building. Bede shows that some temples in England were built well enough to be used as churches and mentions a great one that burned.

The word *hof*, commonly applied to temples in the literature of Iceland, seems to belong to the later rather than to the earlier period. A detailed description of a *hof* is given in one of the sagas. It consisted of two compartments, perhaps analogous to the chancel and the nave of a church. The idols were kept in the chancel. If the description is valid, it implies that Icelandic temples of the 10th century were modelled on churches. A building believed to be a temple has been excavated in northern Iceland, and its outline agrees closely with that described in the saga.

Temples on the mainland of Scandinavia were probably built of wood, of which nothing survives, although some see the influence of pagan temples on the so-called stave-churches. At the close of the pagan period, the most splendid temple of all was at Uppsala. It was richly described by Adam of Bremen, though he knew it only by hearsay and may have been influenced in his description of it by the description of the temple of Solomon in the Bible. Idols of Thor, Wodan, and Fricco (Freyr) stood together within it. There were also famous temples in Norway, but detailed descriptions are not given.

Sacrifice took many different forms. Jordanes mentions the sacrifice of prisoners of war among the Goths. The idol of Nerthus was washed by thralls who alone were allowed to see her; immediately afterward they were drowned. A detailed description of a sacrificial feast is given in a saga about a king of Norway. All kinds of cattle were slaughtered, and blood was sprinkled inside and out; the meat was consumed and toasts were drunk to Odin, Njörd, and Freyr. The most detailed description of a sacrifice is that given by Adam of Bremen. Every nine years a great festival was held at Uppsala, and sacrifice was conducted in a sacred grove that stood beside the temple. The victims, human and animal, were hung on trees. One of the trees in this grove was holier than all the others and beneath it lay a well into which a living man would be plunged.

There also were sacrifices of a more private kind. A man might sacrifice an ox to a god or smear an elf mound with bull's blood.

ESCHATOLOGY AND DEATH CUSTOMS

No unified conception of the afterlife is known. Some may have believed that fallen warriors would go to Valhalla to live happily with Odin until the Ragnarök, but it is unlikely that this belief was widespread. Others seemed to believe that there was no afterlife. According to the *Hávamál*, any misfortune was better than to be burnt on a funeral pyre, for a corpse was a useless object.

More often people believed that life went on after death for a time, but was inseparable from the body. If men had been evil in life, they could persecute the living when dead; they might have to be killed a second time or even a third before they were finished.

The presence of ships or boats in graves, and occasionally of chariots and horses, may suggest that men were thought to go on a journey to the Other World, but this is questionable.

Some records show that the dead needed company; a wife, mistress, or servant would be placed in the grave with them. The famous Oseberg grave contained the bones of two women, probably a queen and her servant. Some stories suggest that there was an ancient belief that men might be born again, but this, says a medieval writer, is an old wives' tale.

On the whole, beliefs in death seem negative. Men pass, perhaps by slow stages, to a dark, misty world called Niflheim (Niflheimr).

Cosmic destruction: Twilight of the Gods

The word Ragnarök is found in two forms. The older is Ragnarök, meaning "Fate of the Gods"; the later form, used by Snorri and some others, is Ragnarøkkr, "Twilight of the Gods." Allusions to the Ragnarök, the impending disaster, are made by several scalds of the 10th and 11th centuries, but fuller descriptions of it are given chiefly in the *Völuspá* and the didactic poems of the *Poetic Edda*, which form the basis of Snorri's description in his *Edda*.

Only a brief summary of this rich subject can be attempted here. Through their own work, and especially because of the strength of Thor, gods have kept the demons of destruction at bay. The savage wolf Fenrir is chained, as is the guileful Loki, but they will break loose. Giants and other monsters will attack the world of gods and men from various directions. If we follow the *Völuspá*, the most rational of the sources, Odin will fight the wolf and lose his life, to be avenged by his son *Vidar* (Víðarr) piercing the beast to the heart. Thor will fight the World Serpent and they will kill each other. The sun will turn black, the stars vanish, and fire will play against the firmament. The earth will sink into the sea, but will rise again refreshed. Unsown fields will bear corn. Balder and his innocent slayer, Höd, will return to inhabit the dwellings of gods. There will be a hall, roofed with gold, in which just men will live throughout ages. It is as if men found it impossible to believe in a universe in which nothing at all is left.

Many have seen the influence of Christian thought, and especially of apocryphal Christian literature about the end of the world, in the description given in the *Völuspá* of the Ragnarök. According to another Eddaic poem, the wolf will swallow Odin and, in revenge, his son will tear the jaws of the beast asunder. Several more details are given in other sources, generally cruder than those of the *Völuspá*.

THE END OF PAGANISM

The Germanic peoples were converted to Christianity in different periods, many of the Goths in the 4th century, the English in the 6th and 7th centuries, the Saxons, under force of Frankish arms, in the late 8th century, and the Danes, under German pressure, in the course of the 10th century. The pagan religion held out longest in the most northerly lands, Iceland, Norway, and Sweden.

The story of the conversion of Iceland is known best because of the wealth of historical documents written in that country during the Middle Ages. Icelanders were, in many ways, the most international of northern Scandinavians. Among those who settled in Iceland in the late 9th century were men and women partly of Norse stock from Christian Ireland. Some of these were Christians; some were mixed in their beliefs, worshipping Christ and Thor at once. There were others who believed in no gods at all. Lack of faith in the heathen gods seemed to grow during the 10th century. Influence of Christian thought on some Icelandic poets is noticeable, as is a tendency toward monotheism. Occasional missions to Iceland in the later 10th century are recorded, but little progress was made until Olaf I Trygvason, king of Norway, sent out the German priest Thangbrand *c.* 997. Thangbrand was a ruthless, brutal man; he was outlawed and returned to Norway *c.* 999. But, unlike Norway and Sweden, Iceland was ripe for conversion. In the year after Thangbrand left (*c.* 1000) the Icelandic parliament (Althingi) resolved, at the instigation of King Olaf, that all should be

Conversions to Christianity

baptized, although concessions were made to those who wished to practice heathen rites in private. Many of the hereditary pagan chieftains became leaders of the church and, largely for this reason, tradition survived in Iceland as in no other Scandinavian land.

The conversion of Norway was far less peaceful, and much is known about it, chiefly from Icelandic records, which are highly coloured. Olaf Trygvason had come to Norway from England *c.* 995, and quickly overcame the arch-pagan ruler Haakon Sigurdarson. Paganism was deeply rooted in the minds of hereditary landowners, whose social system depended largely upon it. Olaf converted the whole of Norway in his short reign of five years. He used fire and sword rather than persuasion. When he died in a naval battle, *c.* 1000, many of Olaf's subjects were Christians only in name. When Olaf the Saint came to the throne, about 15 years later, some of the Norwegians were baptized and some not, and everyone believed whatever he liked. St. Olaf completed the work of his namesake, and his methods were of the same kind. He was such a tyrant that his own subjects, Christian though they were, drove him into exile in Russia. When he returned with a motley army, *c.* 1030, he met his death and was soon regarded as a saint. For all his faults, Olaf had established Christianity firmly in Norway.

Very little is known about the conversion of Sweden. It was a slow and complicated process. The people of West Gautland were, apparently, converted earlier than the rest, but public pagan sacrifice persisted in the temple of Uppsala until late in the 11th century. Kings who were Christian were driven out, probably because of their religious activities. Sweden was hardly a Christian country before *c.* 1100.

Germanic paganism was, in many ways, a vague religion. Some were devoted to one god, some to another. Religion was often a personal relationship between a man and his favourite god. Under pagan civilization in the north, the standard of morals was high, but this had little to do with religious belief. An offense against the god would be punished by the god. Other crimes—theft, adultery, seduction—could be prosecuted under the civil law. The law may have originated under pagan religion but, in the sources extant, religion had little to do with morals.

Paganism was a religion without force that could not resist the pressure of positive, monotheistic Christianity, a religion with forceful, definitive creed, embracing morals as well as faith.

Germans, Ancient

The Germanic, or Teutonic, peoples are a branch of the Indo-Europeans. Their origin is a problem of profound obscurity. A major cause of the difficulty is the paucity of archaeological finds relating to them in northern Germany and southern Sweden between the end of the Bronze Age (*c.* 500–400 BC) and the 2nd century BC. It may be supposed, however, that in the Late Bronze Age Germanic peoples inhabited southern Sweden, the Danish peninsula, and northern Germany between the Ems and Oder rivers and the Harz Mountains. The Vandals, Gepidae, and Goths migrated from southern Sweden in the closing centuries BC and occupied the area of the southern Baltic coast between the Oder and the Vistula and even beyond to the Passarge (Pasłęka) River. At an early date there was also migration toward the south and west at the expense of the Celtic peoples who then inhabited much of western Germany; the Helvetii, for example, who were confined to Switzerland in the 1st century BC, had once extended as far as the Main River.

By the time of Julius Caesar, Germans were established west of the Rhine and had reached the Danube in the south. Their first great clash with Romans came at the end of the 2nd century BC, when the Cimbri and Teutoni (Teutones) invaded southern Gaul and northern Italy and were annihilated by Marius in 102 and 101. Although individual travellers from the time of Pytheas onward had visited Teutonic countries in the north, it was not until the middle of the 1st century BC that the Romans learned to distinguish precisely between the Germans and the Celts, a distinction that is made with great clarity by Julius Caesar. It was Caesar who incorporated within the frontiers of the Roman Empire those Germans who had penetrated west of the Rhine, and it is he who provides the earliest extant description of Germanic culture. In 9 BC the Romans pushed their frontier eastward from the Rhine to the Elbe, but in AD 9 a revolt of their subject Germans headed by Arminius ended in the destruction of the occupying army of P. Quinctilius Varus in the Teutoburg Forest and in the withdrawal of the Roman frontier to the Rhine. In this period of occupation and during the numerous wars fought between Rome and the Germans in the 1st century AD, enormous quantities of information about the Germans reached Rome. When Tacitus published in AD 98 the book now known as the *Germania*, he had reliable sources of information on which to draw. The book is one of the most valuable ethnographical works in existence; archaeology has in many ways supplemented Tacitus' information but in general has tended only to confirm his accuracy and to illustrate his insight into his subject.

Tacitus' *Germania*

Tacitus relates that according to their ancient songs the Germans were descended from the three sons of Mannus (perhaps "Man") the son of the god Tuisto, the son of Earth. Hence they were divided into three groups: the Ingaevones, the Herminones, and the Istaevones. The first of these groups embraced the peoples of the northwest, the second those of the interior, and the third, probably, those near the Rhine. These names, which are also mentioned by the elder Pliny and in a 6th-century Frankish document, are clearly of great antiquity, but Tacitus gives no further information about them. What this grouping amounted to in practice or what it was originally based on is unknown. Indeed the historian records a variant form of the genealogy according to which Mannus had a larger number of sons,

who were regarded as the ancestors of the Suebi, the Vandals, and others. At any rate the existence of these poems suggests that in Tacitus' time the various Germanic peoples were conscious of their relationship with one another. Although individual Germans in Roman service would sometimes refer to themselves as Germani, the free Germans beyond the Rhine had no collective name for themselves until the 11th century AD, when the adjective *diutisc* ("popular," modern *deutsch*) came into fashion. A famous sentence in which Tacitus attempts to account for the origin of the word Germani as a generic term has been interminably discussed. Its general sense is that Germani was originally the name of one Germanic people, the people later known as the Tungri. The Tungri first crossed the Rhine at an unknown date into the Meuse Valley (hence the name Tongeren or Tongres, Belgium) and expelled the Gauls there from their habitations. Their name, which was Germani at that time, was applied to all their fellow countrymen. (Similarly, the Hellenes were called Graeci by the Romans, perhaps after a small people in Epirus, and the French call the Germans *les allemands* after the Alemanni.) The meaning of the word Germani and even of the language to which it belongs have never been determined.

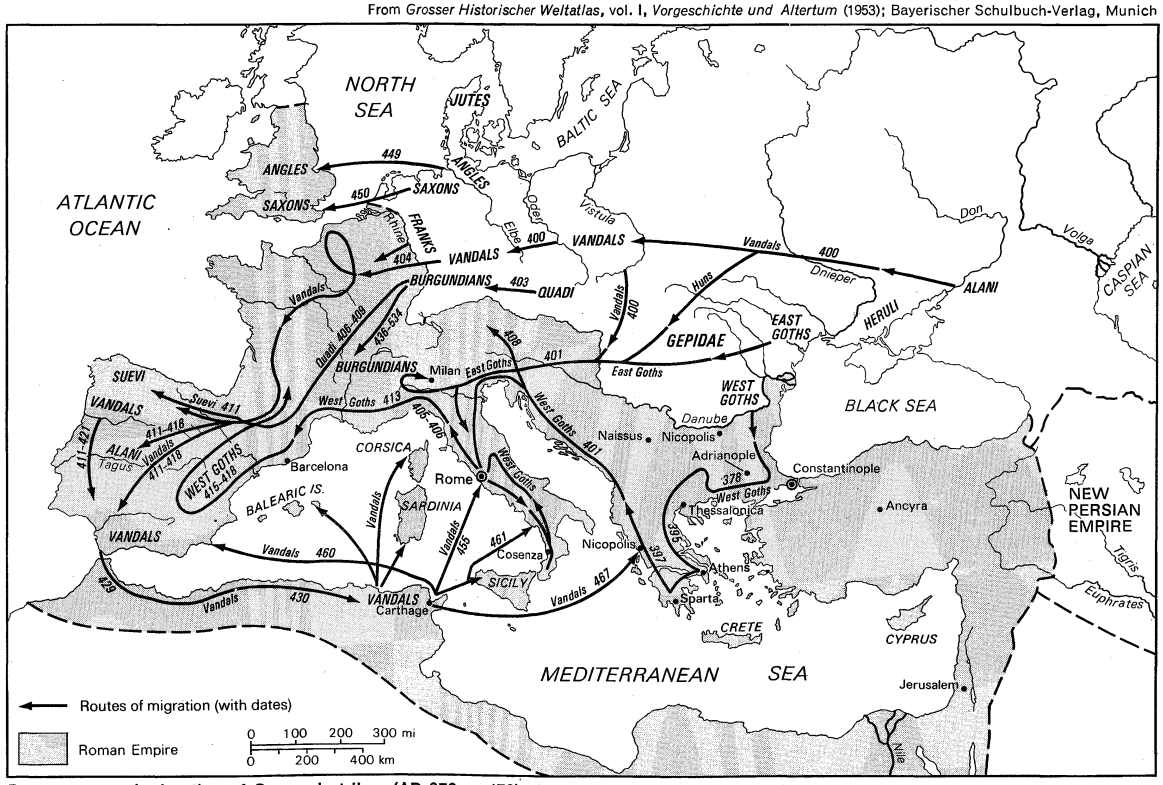
Distribution. The principal Germanic peoples were distributed as follows in the time of Tacitus. The Chatti lived in what is now Hesse. The Frisii inhabited the coastlands between the Rhine and the Ems. The Chauci were at the mouth of the Weser, and south of them lived the Cherusci, the people of Arminius. The Suebi, who have given their name to Schwaben, were a group of peoples inhabiting Mecklenburg, Brandenburg, Saxony, and Thuringia; the Semnones, living around the Havel and the Spree rivers, were a Suebic people, as were the Langobardi (Lombards) who lived northwest of the Semnones. Among the seven peoples who worshipped the goddess Nerthus were the Angli (Angles), centred on the peninsula of Angeln in eastern Schleswig. As for the Danubian frontier of the Roman Empire, the Hermunduri extended from the neighbourhood of Regensburg northward through Franconia to Thuringia. The Marcomanni, who had previously lived in the Main Valley, migrated during the last decade BC to Bohemia (which had hitherto been occupied by a Celtic people called the Boii). To the east were the Quadi in Moravia. On the lower Danube were a people called the Bastarnae, who are usually thought to have been Germans. The Goths, Gepidae, and Vandals on the Baltic coast have already been mentioned. Tacitus mentions the Suiones and the Sitones as living in Sweden. He also speaks of several other peoples of less historical importance than those listed here but he knew nothing of the Saxons, the Burgundians, the Franks, and others who became prominent after his time.

New tribes

By the end of the 3rd century AD important changes had taken place. East of the Rhine lived three great confederacies of peoples unknown to Tacitus. The Roman frontier on the lower Rhine now faced the Franks. The Main Valley was occupied from *c.* 260 by the Burgundians, while the *agri decumates* (the area south of the Main River and immediately east of the Rhine) were held by the Alemanni. The Burgundians appear to have been immigrants from eastern Germany. The Franks and the Alemanni may have been confederacies of peoples who had lived in these respective areas in Tacitus' day, though perhaps with an admixture of immigrants from the east. The peoples whom Tacitus mentions as living on the Baltic coast had moved southeastward in the second half of the 2nd century. The Goths now controlled the Ukraine and a large section of the present-day country of Romania; the Gepidae were in the mountains north of Transylvania with the Vandals as their neighbours on the west.

By the year 500 further striking changes had taken place. The Angles and Saxons were in England and the Franks controlled northeastern Gaul. The Burgundians were in the Rhône Valley with the Visigoths as their western neighbours. The Ostrogoths were established in Italy and the Vandals in Africa. In 507 the Franks expelled the Visigoths from most of their Gallic possessions, which had stretched from the Pyrenees to the Loire River, and the Visigoths thereafter lived in Spain until their extinction by the Muslims in 711. In 568 the Lombards entered Italy and lived there in an independent kingdom until they were overthrown by Charlemagne (774). The areas of eastern Germany vacated by the Goths and others were filled up by the Slavs, who ex-

From *Grosser Historischer Weltatlas*, vol. I, *Vorgeschichte und Altertum* (1953); Bayerischer Schulbuch-Verlag, Munich



Distribution and migration of Germanic tribes (AD 378–*c.* 470).

tended westward as far as Bohemia and the basin of the Elbe. After the 8th century the Germans recovered eastern Germany, lower Austria, and much of Styria and Carinthia from the Slavs.

Material civilization. According to Julius Caesar the Germans were not primarily agriculturists; they were pastoralists, and the bulk of their foodstuffs—milk, cheese, and meat—came from their flocks and herds. But agriculture was not unknown, and Caesar's description of their system of land tenure has been much debated. His words are:

Land tenure

> No one has a fixed measure of land as private property; but the magistrates and leading men distribute every year to the clans and groups of kinsmen [what follows in the Latin text is corrupt; the words further defined the kinsmen] as much land and in such place as has seemed right to them, and in the following year force them to move on.

It does not follow from this description that any given piece of land was tilled for one year only and was thereafter deserted by the community; it cannot be inferred that the entire community abandoned its dwellings and moved on each year to completely new habitations after reaping their crops. Such a type of migratory agriculture had almost completely disappeared from Europe at a far earlier date, and such a hypothesis could hardly be reconciled with the archaeological evidence, which shows German settlements continuously inhabited for very long periods of time. The correct inference would seem to be that the same piece of land was used by the same community indefinitely but that the arable land was redistributed annually so that the one kindred did not till the one piece of land for more than a year. A further inference is that land was not privately owned in the middle of the 1st century BC but was in some sense the property of the community: in the case of the Suebi, Caesar emphasizes this point. What exactly is to be understood by the "community" in this context, Caesar does not make clear. Is he speaking of villages or of *pagi* (these appear to have been adjacent groups of kindreds, but information about them is very meagre) or of some other unit? At all events, it seems certain that the leading men distributed each piece of arable land not to individual cultivators but to kindreds, which tilled their allotment in common. This system of annual redistribution ensured the general equality of the kindreds insofar as agriculture was concerned, and Caesar comments that it guaranteed that the masses of the warriors would be contented and disinclined to engage in factional strife and revolt.

As regards Tacitus' description of Germanic land tenure, it must be remembered that he is discussing the situation as it existed more than 100 years after Caesar had been on the Rhine and at a date when the proximity of Roman civilization had possibly brought about considerable changes in Germanic society. His words are:

> Lands proportionate in extent to the number of cultivators are occupied in turn by the whole body of them, and these they then divide among themselves according to social standing: distribution is easy owing to the wide expanse of ground. They change their arable every year and yet there is land in abundance.

Whatever is to be made of this, one point seems clear: although the annual redistribution mentioned by Caesar was still practiced, the arable land was now allotted not to kindreds but to individuals—the term social standing (*dignationem*) makes this certain. In other words, although the private ownership of land was not yet common in Germany, it had come perceptibly closer than it had been in Caesar's day and individual cases of private ownership undoubtedly existed. The kindred, at any rate in matters relating to agriculture, was no longer the basic unit of Germanic society; its place had been taken by the individual. When Tacitus goes on to say that grain alone was grown by the Germans, he is in error; a great variety of root crops and vegetables was known to them, though of fruits only the apple was cultivated by them in the Roman period. As for the techniques of agriculture, Caesar and Tacitus are silent on these, but even the Bronze Age rock carvings at Bohuslän in southern Sweden include a picture of an ox-drawn plow.

It must be stressed, however, that cattle were the main source of food for the Germans. There is no reason to think that in the historical period cattle were owned by the clan collectively; they were the private property of individuals, and a man's status was reckoned on the basis of the number of cattle he owned. Both the cattle and the horses of the Germans were of poor quality by Roman standards.

The Iron Age had begun in Germany about four centuries before the days of Caesar, but even in his time metal appears to have been a luxury material for domestic utensils, most of which were made of wood, leather, or clay. Of the larger metal objects used by them, most were still made of bronze, though this was not the case with weapons. Pottery was for the most part still made by hand and pots turned on the wheel were distinctly unusual.

Trade

The degree to which trade was developed in early Germany is very obscure. There was certainly a slave trade and many slaves were sold to the Romans. Such potters as used the wheel—and these were relatively few—and smiths and miners no doubt sold their products. But in general the average Germanic village is unlikely to have used many objects that had not been made at home. Foreign merchants dealing in Italian as well as Celtic wares were active in Germany in Caesar's time and supplied prosperous warriors with wine, bronze vessels, and so on. But from the reign of Augustus onward there was a huge increase in German imports from the Roman Empire. The German leaders were now able to buy whole categories of goods—glass vessels, red tableware, Roman weapons, brooches, statuettes, ornaments of various kinds, and other objects—that had not reached them before. These Roman products brought their owners much prestige, but how the Germans paid for them is not fully known. The amber trade, however, became important after the middle of the 1st century BC, though for the most part it affected eastern Germany alone.

Form of government. No trace of autocracy can be found among the Germans whom Caesar describes. The leading men of the *pagi* would try to patch up such disputes as arose but they acted only in those disputes that broke out between members of their own *pagus*. When disputes arose between persons belonging to different *pagi* there appears to have been no mediatory body at this date. In fact in peacetime there seems to have been no central authority that could issue orders to, or exercise influence over, all the *pagi* of which any one people (*civitas, Stamm*) was composed. Evidently the clans or groups of clans were more or less independent of one another in internal affairs, and on at least some occasions they could act independently even in their foreign relations. Some clans or *pagi* could, for example, negotiate with the Romans without reference to the other clans of which their people was composed. Caesar relates that in wartime a number of confederate chieftains were elected, but he gives no indication that any one of them had greater authority than the others; they were joint leaders and they held office only in time of war. It was still the case among some Germanic peoples in the 4th century AD and even later there was normally no one overall peacetime chieftain. Nor was the multiple war leadership quick to disappear in all parts of Germany; it could still be found among the Franks, Burgundians, and Alemanni in the 4th and 5th centuries.

Military chieftains

A new type of military chieftainship had come into being by the time Tacitus wrote. This type of chieftain was also elected, but not all the warriors were eligible for election. The office was confined to the members of a recognized "royal clan," such as is known to have existed among the 1st-century Cherusci and Batavians and the 6th-century Heruli. Any member of this royal clan was eligible for election and the chieftainship was in no way hereditary. There is no conclusive evidence that any Germanic chieftain of the 1st century AD was followed as leader of his people by his son. A chief of this type held

office for life and had religious as well as military duties, but he was in no sense an autocrat. He could be overruled by the council of the leading men, and the proposals he laid before the general assembly of the warriors might be rejected by them. On the battlefield, too, he had no powers of coercion; he could only set an example and give advice. The degree of his influence, in fact, depended largely on his own personal qualities. Among the peoples who retained the type of chieftainship described by Caesar, it became common to appoint two leaders to hold office simultaneously, but the chief of the type mentioned by Tacitus had no colleague.

The council of the leading men (*principes*) dealt with matters of minor importance affecting the people as a whole, while the most weighty business was decided by the general assembly of the warriors, though this too received preliminary consideration in the council of the leading men. Little is known of how these leading men were appointed or of their numbers or whether each *pagus* necessarily had one or more representatives on the council. As for the general assembly, all the warriors had the right to attend its meetings except those who had thrown away their shields in battle. The assembly could not initiate measures nor does it seem to have had the right to debate any proposals put to it by the chief or the leading men; it could only adopt or reject their proposals, but its decision was final. It is not known what happened when opinion was divided in the assembly, but certainly there were no means by which a substantial minority of the warriors could have been coerced into a course of action of which they strongly disapproved. The assembly exercised judicial functions in cases that were felt to affect the community as a whole. Tacitus lists treachery, desertion, cowardice, and homosexuality as examples, and for all these offenses the penalty was death.

As for the administration of justice in general, it has been seen that in Caesar's day the leading men of each *pagus* tried to settle disputes that arose within the *pagus*. There is no evidence that they could oblige the disputants to appear before them or that they could enforce their decisions; they could, it seems, only use their influence. But in Tacitus' time the general assembly elected a number of the leading men to act as judges and these judges travelled through the villages to hear private suits. Each of them was accompanied by 100 attendants to lend authority to his decisions. That is to say, the judge now came into the community often as a stranger to those among whom he was to adjudicate. A rudimentary judicial apparatus had come into existence. A person who was found guilty by these judges had to pay a number of horses or cattle proportionate to the gravity of his offense. But many disputes—*e.g.*, those arising from homicide, wounding, or theft—continued to be settled by the kindreds themselves, and the blood feuds to which they gave rise might continue from generation to generation. Long after the conversion to Christianity the German rulers found it difficult to stamp out the blood feud.

Growth of the *comitatus*

It is possible, then, to detect a considerable development in Germanic society between the time of Caesar and that of Tacitus. The rudiments of the state had now made their appearance. Power, insofar as it existed at all, was tending to become concentrated and wealth to accumulate in private hands. Perhaps the most remarkable development concerns the "retinue" (*comitatus*). In Caesar's day one of the leading men would announce in the assembly that he proposed to undertake a foray and would call for followers. Whoever was attracted by the proposal would volunteer his services and when he had done so public opinion would not allow him to withdraw. The relationship between the leader and his followers was a purely temporary one, lasting only for the duration of the raid, and the followers could not be described as dependents of the leader. But in the time of which Tacitus speaks the relationship between the leader and his "companions" (*comites*) had become a permanent one. The leader fed them and kept them about him in peacetime as well as in war. He supplied them with their weapons and horses and with a share in the booty taken during their raids, though in these early times he could not supply them with land, for full private ownership of land hardly existed as yet. The retinue leader thus acquired a military force over which the other warriors had little or no control, and his followers were prepared to fight for him to the death—it was a disgrace for them to survive their leader. The members of the retinues seem nearly always to have been drawn from among the more well-to-do warriors, so that in Tacitus' time the tribal aristocracy appeared to be well on the way to overthrowing the primitive democracy described above and to establishing something like state power among the various peoples. But in fact only one Germanic chieftain is known who was able before AD 100 to set up a personal tyranny over his people. This was Maroboduus, who led the Marcomanni from their homes in the Main Valley *c.* 9 BC and settled them in Bohemia. From there he conquered a considerable number of other Germanic peoples between the Elbe and the Vistula, including the Semnones, the Lombards, and the Lugii. But the Cherusci, joined by some of the king's subjects, attacked him in AD 17, overthrew him, and drove him into Roman territory. All other chiefs who attempted in this period to establish monarchies were, so far as is known, defeated.

Maroboduus' kingdom

Many of the peoples who had been prominent in western Germany in the days of Tacitus disappeared from history during the 2nd century and their place was taken by the Franks, Burgundians, Alemanni, and others. Sources for their internal and social history during the 3rd and later centuries are very fragmentary. In general it is not easy to detect any substantial difference in their material civilization or social organization from what Tacitus had described, except that there is little or no evidence for the existence of the general assembly of the warriors among any of the great peoples living along the Rhine and the Danube. Information about the Visigoths is more abundant than information about any of the other peoples and yet nothing is said by the ancient authorities about the Visigothic warriors having the right to assemble together in order to approve or veto the recommendations of their leaders. This suggests that in the 4th century the rank and file of the population had less control over their own affairs than they had had 300 years earlier. Even so, there are few reports in this period of the overthrow of such democratic institutions as still existed or of the establishment of monarchies. The only certain example is that of Ermanaric who ruled the Ostrogoths in the Ukraine as a king in the middle of the 4th century. The monarchy did not become fully established in the Germanic world until German peoples had settled as federates inside the Roman Empire, after which the leaders of the Ostrogoths in Italy, the Visigoths in Gaul and Spain, and the Vandals in Africa became the first Germanic kings. Other famous German chieftains in this period, such as Athanaric and Alaric who lived outside the Roman frontier or whose peoples were not federates settled in the provinces under a treaty (*foedus*) to defend the frontier, seem to have had little more personal authority than the war leaders described by Tacitus.

Weaponry

Warfare. In the period of the early Roman Empire German weapons, both offensive and defensive, were characterized by shortage of metal. The warrior, whether mounted or on foot, had as his chief weapon a long lance with one end hardened by fire or else fitted with a short, narrow iron point, which could be hurled or used for thrusting. Very few carried swords. Helmets and breastplates were almost unknown and the German went into battle naked or wearing a short cloak. His only defensive weapon was a light wooden or wicker shield, sometimes fitted with an iron rim and sometimes strengthened with leather. This lack of adequate equipment explains the swift, fierce rush with which the Germans would charge the ranks of the heavily armed Romans. Their only hope of overwhelming a Roman army in open country was to break it by the impetus of their first attack, for if they became entangled in a prolonged, hand-to-hand grapple, where their light shields and thrusting spears were confronted with Roman arms and armour, they had little

hope of success. Their best plan was to catch the Romans on an open plain surrounded by woods and then to launch incessant, short, sharp attacks on them from all sides, using the woods as cover.

In the period of the later Roman Empire the equipment of the German warriors does not seem to have improved very much. In the 3rd century they began to use bows and arrows extensively. Their armies were still mainly infantry forces though the tribal nobles, as previously, were mounted. Even in the 6th century there is no reason to think that helmets and breastplates were not something of a rarity in the armies of the Germanic peoples who were now living in what had been the Roman provinces. The Ostrogothic army in Italy, which fought against Belisarius, was an army of mounted spearmen supported by unmounted archers. Such, too, were the army of the Vandals in Africa in the 6th century and the army of the Visigoths in Spain in the 6th and 7th centuries. These peoples seem to have had a higher percentage of cavalry in their armed forces than the Germans had had in Tacitus' day, but in defensive armour little progress had been made. The main strength of the Frankish army lay not in mounted spearmen but in its infantry, whose characteristic weapon was a short-handled, double-headed ax used as a missile weapon. They, too, wore little defensive armour. None of these peoples evolved a military force adequate to deal with the heavily armed mounted archers of Justinian I. Nor did they master the art of siege warfare; throughout the first six centuries AD there is hardly a single report of a Roman town skillfully and successfully besieged by a German army (the Fall of Philippopolis in 250–251 was due to the treachery of the governor).

Conversion to Christianity. Christianity was first brought to the Visigoths by some of the prisoners whom they took during their raids on Anatolia in the mid-3rd century. The Visigoths do not seem to have been converted to Christianity until they were living as federates in the Roman province of Moesia (south of the lower Danube) in the years 382–395. The evidence suggests that before the fall of the Western Roman Empire in 476 none of the great Germanic peoples was converted to Christianity while still living outside the Roman frontier but that all the Germanic peoples who moved into the Roman provinces before that date were converted to Christianity within a generation. The Vandals seem to have been converted when in Spain in 409–429, the Burgundians when in eastern Gaul in 412–436, and the Ostrogoths when in the province of Pannonia *c.* 456–472. The only certain exception is the people known as the Rugii, who were already Christian before 482 while living north of the Danube in lower Austria; in what circumstances they had been converted is not known. In all these cases it seems likely that the conversion was carried through by German-speaking and not by Roman missionaries, and Visigothic priests are likely to have played a major part in the process.

In all these cases the Germans embraced the Arian form of Christianity; none of the major Germanic people became officially Catholic until the conversion of the Franks under Clovis (496) and of the Burgundians under Sigismund. The reason for their adoption of Arianism rather than Catholicism is very obscure. Unhappily, the books produced by the Arian Germans have all disappeared with the exception of the fragments of Ulfilas' Bible, some leaves of an anonymous Gothic commentary on St. John's Gospel, and a fragment of a church calendar written in Gothic. It is clear, however, that their theology depended on a literal interpretation of the Scriptures and refrained from drawing practical lessons from the texts. Although the pagan Germans living outside the Roman frontier once or twice persecuted the Christians in their midst, the Arian German kings, with the exception of the Vandal kings of Africa, were extraordinarily tolerant both of Catholics and of Jews.

The last Germanic people on the continent to be converted to Christianity were the Old Saxons (second half of the 8th century), while the Scandinavian peoples were converted in the 10th century, though several districts remained pagan until late in the 11th century. England had been converted in the 7th century, while Christianity obtained public recognition in Iceland in the year 1000.

BIBLIOGRAPHY. For the older archaeological evidence, see especially the excellent bibliography to G. EKHOLM, *The Cambridge Ancient History*, vol. 11, ch. 2, sect. 1–5 (1936); and for more recent finds, consult the periodical *Germania* (semi-annual). (E.A.T.)

Germany, Federal Republic of

Commonly referred to as West Germany, the Federal Republic of Germany (Bundesrepublik Deutschland) is a federation of 10 *Länder* (states) plus the territory of West Berlin. It is a self-governing republic created in 1949 through the amalgamation of the British, United States, and French zones of occupation that were established following the surrender of the German *Reich* in May 1945.

Location and boundaries of the Federal Republic

West Germany occupies the regions of northwest central Europe, extending from the upland approaches of the Northern Alps in the south to the North Sea, the Jutland Peninsula, and the western Baltic in the north. Except for a stretch of the Upper Rhine River extending south of Karlsruhe to form part of its border with eastern France and continuing due east of Basel to form a portion of its boundary with Switzerland, the republic is largely lacking in natural frontiers with the eight countries on which it borders. To these eight neighbours must be added the separate state created out of the former *Reich*, the German Democratic Republic (Deutsche Demokratische Republik), commonly known as East Germany, the former Soviet zone of occupation.

The Federal Republic is bounded at its extreme north on the Jutland Peninsula by Denmark. To its west it borders on The Netherlands, Belgium, and Luxembourg; to the southwest, with France. It shares its entire southern boundaries with Austria and Switzerland. Its eastern frontiers, continuing northward with Austria and past Czechoslovakia, recede to the west at the juncture of Czechoslovakia and East Germany and meander northward in a common border with its rival German state as far as the Baltic Sea.

Until recently, West Germany held itself to be the sole successor to the former *Reich* and alone entitled to act in the name of the latter's defunct government. It is linked politically to the three Western sectors of Berlin, the former capital of the *Reich*, technically under quadripartite occupation by the British, U.S., French, and Soviet forces since the end of World War II and at present an enclave within the German Democratic Republic. Connected to West Germany by precisely defined overland, railway, water, and air routes, West Berlin by treaty agreement is no longer claimed by the Federal Republic as a part of its constituent territory but rather as an administrative adjunct, whose inhabitants are counted for all purposes—except for their franchise to

vote in federal German elections—as citizens of West Germany.

Backgrounds of the federal *Länder*

The 96,094 square miles (248,882 square kilometres) of the German Federal Republic, including the 185 square miles of West Berlin, had a population of over 61,280,000 by mid-year 1971; the capital is at Bonn. The constituent *Länder* follow roughly the historic lines of the political divisions making up the former *Reich*. Most of these date back to consolidations brought about largely by the Napoleonic Wars and the founding of the *Reich* in 1871 out of an intricate maze of kingdoms, principalities, duchies, bishoprics, free cities, and the like that existed under the Holy Roman Empire. The *Länder* enjoy considerable political autonomy within the federative structure, especially in such areas as education, finance, and law enforcement; and each has its own equivalent of a prime minister, a parliament or diet, and its own provincial ministries. Their strong voice in the upper levels of the federal government is unique among Western republics.

The largest of the *Länder* is Bayern (English Bavaria), the wealthiest and most populous, Nordrhein-Westfalen (North Rhine-Westphalia). In the extreme north lies Schleswig-Holstein, south of which is Niedersachsen (Lower Saxony). The ancient free Hanseatic cities of Hamburg and Bremen rank as *Länder* in their own right. The states of Rheinland-Pfalz (Rhineland-Palatinate) and Hessen (Hesse) cover the central area of the Federal Republic; the mineral-rich Saarland (or often the Saar), a pocket in the southwestern corner of the Pfälzerwald, was an administrative unit of France after 1945 but reverted to Germany in 1957. In 1951 the small southwestern states of Baden and Württemberg with Hohenzollern were amalgamated into the *Land* Baden-Württemberg.

West Germany's recovery from its total economic and political prostration at the end of World War II and the devastation of its cities and capital industries have been of such dramatic proportions as to become a modern legend. The *Wirtschaftswunder* ("economic miracle") of the 1950s had by the early 1970s catapulted Germany into the position of the world's fourth-largest industrial power, after the U.S., the Soviet Union, and Japan. Its currency, the Deutsche Mark, had become so strong that by 1972 it had been revalued on four occasions, to an increase of almost 25 percent of its value in relation to the U.S. dollar.

Development of a national identity

Domestically, the fledgling West German state, with only the abortive 14 years of the Weimar Republic (1919–33) to serve as a precedent, developed into one of the most stable of the Western democracies. As it gradually relaxed its predilection inherited from the past for the authoritarian or, at best, paternalistic leadership of elderly statesmen, a younger and more heterogeneous cast of political leaders won the public confidence, rising to power through maturation in political service throughout the republic's postwar growth or, often, through their technical expertise. The three major political parties largely have overcome their origins along class, regional, or sectarian lines. In large measure because of the 5 percent of votes required for representation in the federal parliament and provincial diets, extremist parties of the right and left call forth little parliamentary representation or significant popular support.

A careful and intricate balance of power between the federal government and the historically divisive regional interests, now in the custody of the *Länder*, has all but eliminated the factionalism that for centuries was Germany's greatest obstacle to unity. The West Germans as citizens have moved far from their accustomed apathy or even perverse boast of being apolitical to becoming intensely involved and well informed on the issues, domestic and foreign, that affect their personal lives. Of the some 42,000,000 eligible voters, roughly 75 to 90 percent go to the polls in the national elections.

From the ignominy of its position in the early postwar years, the Federal Republic has grown from strength to strength and now commands a status of great respect and, through its economic might, of no small power in the councils of the world. It has undertaken a series of independent diplomatic initiatives, the most significant of which have been aimed at a political rapprochement not only with its adversary German state but also with the Soviet Union and other nations of the eastern European bloc.

The Federal Republic is a major force in the North Atlantic Treaty Organization (NATO), of which it became a member upon achievement of full sovereignty in 1955. Apart from the other intra-European organizations to which it belongs, it is a charter member of the European Coal and Steel Community (ECSC) of 1952, the European Atomic Energy Community (Euratom), and the European Economic Community (EEC), both dating from 1957. The anomalous position of both East and West Germany in international law has long prevented either from becoming a formal member of the United Nations, but it has sent a permanent observer and participates in the working agencies and organizations of the U.N.

The history of both West and East Germany is covered in GERMANY, HISTORY OF, while that of the region in the ancient world is in GERMANS, ANCIENT. The article EUROPE places West Germany in its geographical and cultural contexts, while separate articles focus more closely on the life and institutions of each of the West German *Länder* (see under their German spellings; *e.g.*, BAYERN). See also the articles BERLIN; COLOGNE; FRANKFURT AM MAIN; MUNICH; and GERMAN DEMOCRATIC REPUBLIC. German contributions to the arts may be found in such articles as LITERATURE, WESTERN; MUSIC, WESTERN; MODERN DANCE; and VISUAL ARTS, WESTERN.

This article is divided into the following major sections:

I. The natural and human landscape

FEATURES OF THE NATURAL ENVIRONMENT

In its major topographical features, West Germany shares with the countries on its eastern and western borders a profile that ascends in altitude from north to south. The North German Plain, or Lowland, comprising approximately the northern third of the republic, is but a segment of a vast lowland coastal area extending from extreme southwestern France across the Low Countries and throughout the Baltic areas to the Soviet Union. The central third of the territory, commonly known as the Central German Uplands, is a complex system of forested lowland mountain ranges, river basins, and plateaus. These follow a sequence of upland regions that range in a wide arc from the Massif Central of south central France, through Belgium and Luxembourg, across West Germany and the southern portion of East Germany, and through the entirety of Czechoslovakia to the Carpathian Mountains of eastern Europe. The southern third of Germany, although in its outer appearance often similar to the Central Uplands, is, in effect, a northeast-

ern extension of the Jura mountain system, which has its origins on the eastern bank of the Rhône Valley in southeastern France. Entering Germany at the juncture of the French and Swiss borders in the extreme southeast, the Jura branches into two ranges within Germany. South of the Jura Mountains and the basin of the Danube River, an undulating upland plateau forms the southernmost region of West Germany as it skirts the country's southern frontiers and terminates at the shores of Lake Constance, the mountainous Allgäu, and the precipitous rise of the Bavarian Alps south of Munich.

Topography and resources. *The North German Plain, or Lowland.* Embracing all of the *Länder* ("states") of Schleswig-Holstein, Hamburg, and Bremen, the greater portion of Niedersachsen and the northwestern areas of Nordrhein-Westfalen, the North German Plain has been graven by glacial action. It presents, in spite of some intimations of monotony, an area of considerable variety in topography—to say nothing of scenic beauty. Although great stretches of the coastal plain between the Weser River and the Dutch border are largely flat, the moraine-formed areas stretching southward down the Jutland Peninsula of Denmark include gentle, rolling terrain of low hills and broad valleys, woodland areas, lakes, marshland, and heaths. Of the last, the best known is the Lüneburger Heide (Lüneburg Heath), a plateau extending on a morainic belt between Hamburg and Hannover.

A northern morainic belt, only a small portion of which is in West German territory, extends along the Baltic from eastern Schleswig-Holstein. The coastline of Schleswig-Holstein and Niedersachsen along the North Sea is characterized by sandy dunes, tidal inlets, and marshland. Farther inland, the grassy dairylands are interspersed with the sudden rises of geest, oblong hills representing groups of old alluvial deposits.

Off the western peninsula, the Schleswig portion of the Jutland coast, lie the North Frisian Islands, popular as summer resorts; the best known of them is the isle of Sylt. Extending east to west off the coast of Niedersachsen lies the chain of the East Frisian Islands; their West Frisian extension belongs to The Netherlands. The tiny rocky island of Helgoland is located in the North Sea some 40 miles (65 kilometres) northwest of the mouth of the Elbe at Cuxhaven. The alluvial plain stretching from the eastern part of Holstein and the north portion of Nordrhein-Westfalen to the Dutch border is of great economic importance because of its rich soil and mineral wealth. Lignite and bituminous coal is found in areas west of the Elbe and in the Lower Rhine areas; iron ore, potash, and salt deposits are found in the plains north of the Harz Mountains, and, in addition, there are some oil and natural-gas deposits between the Ems, Weser, and Elbe rivers and up through Schleswig-Holstein.

Apart from its agricultural importance, particularly in grain, dairy products, and livestock, the plain's wealth of rivers and canals—largely a result of its glacial origin—is an important adjunct to Germany's intricate inland-waterway transportation system. The Elbe and Weser rivers flow through Germany's two great inland seaports, Hamburg and Bremen, respectively. The Ems, running parallel to the Dutch border, also empties into the North Sea. Farther to the south and moving to the northwest, the Rhine, Europe's greatest inland waterway, flows to the North Sea through The Netherlands after passing Cologne and Düsseldorf, just to the west of Europe's largest concentration of industrial and mineral wealth, the Ruhr. This district, taking its name from a river valley that constitutes only a portion of the area, represents a great industry–population complex roughly triangular in shape. At its southern tip lies Cologne, with Dortmund in the northeast and Duisburg in the northwest. Rich in coal and formerly in iron, it is Germany's greatest centre of heavy industry—steel, machinery, oil refining, chemicals, glass, ceramics, textiles, and many other manufactures.

Industrial concentration in the Ruhr

The Central Uplands. In general, the Central Uplands constitute an extremely intricate and geologically complex continuum of mountain ranges, separated in their larger divisions by river and stream valleys. They are rounded and of no great height, most less than 3,500 feet (1,100 metres) in elevation. At their upper levels they tend to be heavily forested; they are important sources of timber, and a number of these mountain districts are known as forestlands rather than mountain ranges. A number of areas, especially those formed by volcanic activity in relatively recent geological times, are important sources of minerals and centres of local industry. Valleys are utilized for crop raising and, where climatic conditions permit, for growing wine grapes. In other areas, a plentiful supply of hydroelectricity and easy access to water, rail, and road transport support mining, manufacturing, and processing industries.

This Central Upland district of West Germany—all of Hessen, Rheinland-Pfalz, and the Saarland and the southern portions of Nordrhein-Westfalen and Niedersachsen—is extremely variegated in character; sharing only its mountainous and hilly terrain as a common feature. It contains some of West Germany's most centrally located and wealthy industrial areas (in the Rhine–Main area of southern Hessen) and also some of the most remote and sparsely populated backwoods regions.

The high tier of the Central Uplands extends east of the Rhine and south of the Ruhr and the Lippe rivers and north of the Lahn River eastward to the upper reaches of the Weser. In this range, or bordering on it, are the Teutoburgerwald (Teutoburg Forest) in the north, the Siebengebirge and Sauerland in the west, and the rugged Westerwald in its south near the Lahn. Across the Weser and its tributary, the Werra, the range continues into the Harz region, south of Hannover and Braunschweig. The Harz Mountains, noted for their beauty and popular as a resort area, extend into East Germany. The Brocken, at 3,747 feet (1,142 metres) the highest peak in the Harz range, is known for its many associations with German heathen legend; its peak straddles the frontier of West and East Germany.

East of the Rhine and between the Lahn and Main rivers are the highland districts of the Taunus, also a favoured resort, and the Spessart, an extensive forest preserve in which the last of Germany's ancient oak trees

are found. To its south, between the Main and Neckar rivers, lies the fabled Odenwald, a remote forest near the populous Frankfurt am Main metropolitan area; in this wood the legendary Siegfried is said to have been slain.

To the northwest, west of the Rhine and north of the Mosel (Moselle), the vast tract of the Eifel Mountains continues into Belgium as the Ardennes. This range, together with the parallel mountain ridge south of the Mosel known as the Hunsrück, bears evidence of geologically recent volcanic action and is an important source of basalt. Semiprecious stones are mined in the vicinity of Idar-Oberstein. South of the Hunsrück, between the Franco-Luxembourg border, lie the highlands of the Pfälzerwald (Palatinate Forest). The Saar Basin, bordering French Lorraine in the extreme southwest of the Pfälzerwald, is, like the Ruhr, rich in coal and iron, though of an even higher quality than that of the northern mining regions.

The Rhine gorge cuts and winds through the plateau of lowland mountains that represents a continuum between the Eifel and the Hunsrück in the west and the Siebengebirge and Taunus in the east. This famed and most spectacular stretch of the Rhine, from about Andernach in the north to Bingen at its southern reach, is lined with hilltop castles, vineyards along its precipitous slopes, and a sequence of picturesque towns along its banks. The winding stretches near Sankt Goarshausen pass between all but vertical rocky cliffs, the most famous of which is the fabled Lorelei rock.

The Southern Highlands, or plateau region. The Main River, which, upstream from its mouth at the Rhine near Mainz, meanders in a westerly direction toward the juncture of the West German, East German, and Czechoslovakian borders, may be regarded as the dividing line between the Central Uplands and the mountainous and plateau region of southern Germany. The area lacks no one specific characteristic to distinguish it from the Central Uplands. In its topography, if not in its external appearance, it is rather similar to the central regions. Its mountains, however, are derived from different systems from those in central Germany, and its mean elevation above sea level, even in plateau regions, is considerably higher.

In an area of northern Baden-Württemberg and northeastern Bavaria framed by the basins of the Main and Neckar rivers and extending to the east is a region of low hills, plateaus, and valleys. It is both rich as an agricultural area and noted for its many ancient towns that, largely because of their remoteness from the main routes of transport, have remained in their outward appearance relatively untouched by modern development. This district includes the renowned "Romantic Road" from Donauwörth to Würzburg, passing through Rothenburg-ob-der-Tauber, a perfectly preserved walled city that has remained virtually unchanged since the 17th century.

The Jura range and the Black Forest

The northernmost reaches of the Jura range, entering Germany from Switzerland in the extreme southwest, branch into two forks. The western fork, moving in a northerly direction parallel with the Rhine River to a point just south of Karlsruhe, is commonly known as the Schwarzwald (Black Forest), popularly associated with the dark appearance of the area's giant fir trees. The Schwarzwald is rich in thermal water sources and abounds in resort areas, spas, and sanitoriums. West of the Schwarzwald is the wide, sloping eastern valley of the Rhine opposite Alsace, in which the lower and smoother Vosges Mountains on the French side run parallel to the Schwarzwald as part of the northern Jura.

The eastern fork of the Jura range branches off from the northern extension some 15 miles east of Freiburg im Breisgau, where the Danube River rises to meander 1,770 miles eastward past seven countries to the Black Sea. This branch extends due east some 320 miles to near the source of the Main, skirting to the south of Stuttgart and Nürnberg and following the northern basin of the Upper Danube as far as Donauwörth. It is known as the Schwäbische Alb (Swabian Jura), and portions of it evidence curious and often rugged geological formations.

From Donauwörth, the Jura swings in an arc almost due north to its terminal point near Bayreuth and just south of the mountain Schneeberg (3,455 feet). To the east, toward the Czechoslovakian border, lie the rolling wooded plains of the Böhmer Wald (Bohemian Forest); farther south, near Regensburg, the Bayerischer Wald (Bavarian Forest) lines the northern slopes of the Danube Valley.

Justly famed as they are for their dramatic beauty—and especially for the foothills in their immediate foreground—the Bavarian Alps represent, in effect, only the northern edge of two relatively minor extensions of the Austrian Alps, the Arlberg and Tirolean ranges. Germany's share in Alpine territory is, in fact, miniscule by comparison to that of Austria, Switzerland, Italy, and France.

Waters and soils. Because of Germany's steady upward incline from the coastal regions of the north to the Bavarian Plateau and Alpine regions of the southeast, the greater majority of its rivers and their tributaries flow north and empty into the North Sea via the Rhine, the Ems, the Weser, and the Elbe. While many of the tributaries to these major rivers meander east–west or west–east, only the Lahn flows in a southerly direction, emptying into the Rhine. The remainder of German waters—all of which are located in Bavaria—escape into the Danube on its eastward course through the Balkans; the main tributaries to the south of the Danube are the Iller, the Lech, the Isar, and the Inn; flowing southward from the north are the Altmühl, the Naab, and the Regen.

The lakes of West Germany

The Federal Republic has relatively few lakes. Most lakes across the German regions are the shallow lakes of the postglacial lowland of the north; the majority are in East Germany. In addition to the Dümmer Sae (Dümmer Lake) and the Steinhuder Meer in Niedersachsen, a few small lakes of glacial origin dot Schleswig-Holstein. The remainder of West Germany's lakes are concentrated at the extreme southeastern corner of Upper Bavaria, many of these in outstandingly beautiful surroundings. Germany shares Lake Constance (Bodensee), its largest lake (having the proportions of an inland sea), with Switzerland and Austria. Stretching 46 miles at its longest reach, Lake Constance is, in effect, an elongated basin filled by the Rhine River from its point of origin in eastern Switzerland; at its southwesternmost fork the lake reassumes the form of a river and flows eastward toward Basel.

Although practically all of Germany's arable land is under cultivation, comparatively few areas are highly fertile. The terrains thus unsuited for large-scale grain production—chiefly wheat, barley, rye, and oats, in addition to potatoes, sugar beet, and some tobacco—are given over to grazing land. In the lowlands of the north, the land overwhelmingly comprises sand and loam, though along the North Sea littoral up the western coast of Jutland the soil is predominantly sandy. The eastern half of the Jutland Peninsula and the tier of the Baltic coast extending southward to Hamburg is mostly the clay of the northern morainic belt, or Baltic Ridge.

An especially fertile area known as the *Börde* is covered with a siltlike loess; it extends in a wide belt from west of the Rhine near the Ruhr district eastward, following the southern edge of the Mittelland Kanal and extending into East Germany at the Elbe near Magdeburg. Other regions containing this richest of soil are found in scattered areas, particularly in the lowland regions west of the Rhine to the Dutch border and in three districts around the greater Frankfurt am Main area. Other loess-covered districts of considerable fertility are located in the north of Württemberg, in small portions of northern Bavaria, and in wide ranges to the southeast of Ulm and east of Munich. Some marshland is found both in the North German Plains and in the Alpine plateau.

The remainder of German soil types, because of the preponderance of mountainous and forested areas, range from sandy loam, from loam to clay, and from clay to rocky outcrops. Timber production thrives where the land is all but unarable, and viticulture in the southern regions flourishes in an otherwise inhospitable type of soil.

Climate. West Germany is favoured with a generally temperate climate, especially in view of its northerly latitudes and the distance of the larger portions of its territory from the warming influence of the Gulf Stream of the Atlantic. Excesses of extremely high temperatures in the summer or of deep, prolonged frost in the winter are rare. These conditions, together with ordinarily a more than abundant and well-distributed amount of rainfall, afford ideal conditions for crop raising. As throughout western Europe in general, however, Germany's climate is subject to quick variations when the warm westerly maritime climate emanating from the Gulf Stream collides with the more extreme climatic ranges moving in from northeastern Europe.

Progression of the seasons

The seasons, year by year, are subject to great variations: winters may be unusually cold or prolonged, particularly in the higher elevations in the south, or mild, with the temperatures hovering only two or three degrees above and below the freezing point. Spring may arrive early and extend through a hot, rainless, summer to a warm, dry autumn with the threat of drought. In other years, spring—invariably interrupted by a frosty lapse in May, popularly known as *die drei Eisheiligen* ("the three ice saints")—may arrive so late as to be imperceptible and be followed by a cool, rainy summer. One less agreeable feature of the German climate is an almost permanent overcast in the cool seasons, only infrequently accompanied by precipitation; it sets in toward the latter part of autumn and lifts as late as March or April. Thus for months on end virtually no sunshine may appear.

The intricate topography of the Central Uplands and Southern Highlands and their valleys causes infinite local variations in temperature, frequency of sunshine, humidity, and precipitation. For this reason Germany produces more vintages and varieties of wine than any other country, at least 10,000 registered for marketing purposes.

The northwestern and lowland portions of the republic are affected chiefly by the uniformly moist air, moderate in temperature, that is carried inland from the North Sea by the prevailing westerly winds. While this influence, on the whole, affords moderately warm summers and mild winters, it is accompanied by the disadvantages of high humidities, extended stretches of rainfall, and, in the cooler seasons, fog. The hilly districts of the central and southwestern regions and, to an even greater degree, the upland and plateau districts of the southeast are subject to the more pronounced ranges of hot and cold from the countervailing continental climate. Southeastern Germany may intermittently be the coldest area of the country in the winter; but the valleys of the Rhine, Main, Neckar, and Mosel rivers may also be the hottest in the summer. Winters in the North German Plains tend to be consistently colder, if only by a few degrees, than in the south, largely because of winds from Scandinavia.

One anomaly of the climate of Upper Bavaria in the warm seasons is the occasional appearance of warm, dry air passing over the northern Alps to the Bavarian Plateau. These mild winds, known as *Föhn*, not only create an optical phenomenon that makes the Alps visible from points where normally they would be out of sight but also are reputed to have a depressing psychological effect upon the inhabitants.

Annual mean precipitation varies according to region. In the North German Plain it ranges between 20 to 28 inches (510 to 710 millimetres); in the Central Uplands, from 28 to 59 inches; and in the Alpine districts, up to and exceeding 78 inches. The average temperature for January, the coldest month, varies from 27° to 34° F (−3° to 1° C) in the lowland areas of the north; in the upland regions, depending on altitude, temperatures in January will fall to an average of 21° F (−6° C). July temperatures average from 60° to 66° F (16° to 19° C) and run slightly higher in the sheltered river valleys.

Vegetation and animal life. In ancient times Germany was covered by preponderantly deciduous forests of oak, linden, beech, and birch. Only beech and birch remain evident in some abundance in the patchy forests of the North German Plains and Schleswig-Holstein; oak is found less frequently. After the felling of these primeval forests, Germany took the lead in systematic reforestation, mostly, however, by planting the faster-growing conifers. Thus, fir, spruce, and pine outnumber deciduous trees of all varieties by more than two to one. Because of a carefully regulated system of reforestation, the Federal Republic contains the greatest density of woodland of any larger region of western Europe exclusive of Scandinavia, and forestry and timber production are major facets of German agriculture. The heavily forested districts, nevertheless, are almost solely confined to the central and southern uplands.

Reforested areas

Fruit trees—apple, pear, peach, cherry, plum, apricot, and quince—and the walnut, chestnut, and hazelnut trees are widely distributed, but, like the vineyards, they thrive best in the western and southwestern regions. Strawberries, blueberries, blackberries, cranberries, and currants abound in the forests and meadows of all districts.

The vast tracts of forest and mountainous terrain, with only scattered habitation, contribute to a surprising variety of wildlife in so densely populated and highly developed a country. Game animals abound in all regions—several varieties of deer, quail, and pheasant and, in the Alpine regions, the chamois and ibex—and their numbers are protected by stringent game laws. The wild boar population, which soared after World War II because of restrictions on hunting, has now been reduced so that it no longer represents a danger to man and crops. The hare, a favoured game animal, is ubiquitous. Although the bear and the wolf are now extinct in the republic, the wildcat has had a resurgence in the postwar years, especially in the Eifel and Hunsrück regions and in the Harz. The lynx has reappeared in the areas near the Czechoslovakian border. The polecat, marten, weasel, beaver, and badger are found in the central and southern uplands. Among the reptiles are salamanders, blindworms, various lizards and snakes, of which only the adder is poisonous.

Threatened and reappearing animal species

Although the numbers of the white stork, the cormorant, the horned owl, the fishhawk, and the osprey have decreased to near the point of extinction, the golden eagle has gained in numbers in the Alpine districts, and the heron still holds forth in scattered areas over various parts of the country. The republic has established upwards of 50 natural parks and endowed five major resort areas, such as portions of the Schwarzwald, with the status of natural park. In addition, it has declared some 1,000 localities as wildlife preserves and 7,200 sites as protected scenic areas. A further 40,000 locations of unusual historical interest or natural beauty have been set aside as natural monuments.

CHARACTER OF THE TRADITIONAL REGIONS

The boundaries of the modern *Länder* of Germany were established in comparatively modern times. The more than 2,000 political units, large and small, that existed under the Holy Roman Empire gradually were consolidated through war, treaties, dynastic marriages, large-scale amalgamations effected under Napoleonic rule, further consolidations brought about by the establishment of the German Empire, or *Reich*, in 1871, and even, in the wake of World War II, by plebiscite. Transcending and often defying these modern political borders, however, are the traditional regions of Germany, the characters of which are chiefly ethnic in nature and often prehistoric in origin. These regions have persisted with remarkable tenacity throughout the turbulent history of the German territories and the radical social upheavals of recent times. In addition to what might be described as the "tribal" cohesion of the regions, the affinities of linguistic dialect, traditional political allegiances, and, often as not, religion will in different measure serve not only to set off one region from another but also to account for the various subdivisions within the major regions themselves.

Ingrained feelings for the regional homelands

Regional feelings are still very strong in Germany. Just as a Briton of Celtic stock may call himself a Scotsman or Welshman, even though his family has resided for years in England, or as an eighth-generation American will often describe himself as Scots-Irish or Dutch, a German will claim descent from the region of his ancestors no matter how remote the ties may be. To this per-

sistent consciousness of one's ancestral origins must be affixed the German's deeply felt sense of *Heimat*, his "homeland" (or often the homeland of his forebears), which connotes a much narrower sense of native region, viz., the valley or forestland, plain, mountain, or even village or town where one's ancestral ties run deep. These feelings prevail less strongly among the postwar generation, however, and have been dissipated by the enormous influx after World War II of German expellees and refugees from East Germany and the former provinces now incorporated into Poland.

Many of the regional names are no longer reflected in any formal political designation, but they are still used in everyday parlance. In many instances, political consolidations, especially in the south, have not only cut across the conventional boundaries of the ancient regions but also have brought together under a single political administration regions that were, at best, disparate and, at worst, disdainful or even hostile to one another.

Southern regions. In the south the major regions are largely within the *Länder* of Baden-Württemberg, Bavaria, and Rheinland-Pfalz. Baden extends from an area east of the Rhine River and north of Karlsruhe southward and along the Rhine and through the Schwarzwald to the Swiss border. The natives of Baden have close ties and affinities with the northwest area of German-speaking Switzerland and with Alsace, the former German province across the Rhine; like the Swabians, they are of ancient Alemannic stock. North of the Baden region, beginning south of Heidelberg and Mannheim and reaching across the Rhine is the region traditionally known as the Pfalz (Palatinate). The Saarland is a region unto itself, but it has characteristic aspects of both the surrounding Pfalz and the neighbouring French region of Lorraine, which used to be a province of Germany.

Schwaben (Swabia) is a notable example of a region the name of which no longer is affixed to any political entity (or component of a political division), yet its extent transcends *Länder* boundaries. It embraces most of the former states of Württemberg and Hohenzollern, but its eastern portion between the Iller and Lech rivers, roughly between the cities of Ulm and Augsburg, was ceded to Bavaria in 1806. The Allgäu district, in a pocket in the extreme southwestern corner of Bavaria, not only is Swabian in character but also has close historic ties with the Vorarlberg district of Austria, itself settled by Alemannic tribes. Schwaben may be roughly divided into Oberschwaben (Upper Swabia), the district south of Stuttgart leading to Lake Constance, and Niederschwaben (Lower Swabia), from Stuttgart northward to the area around Heilbronn.

The region popularly thought of as Bavaria—a land famed for its Alpine costumes, the *Dirndl* for women and *Lederhosen* for men, and fabled for gargantuan consumption of beer to the accompaniment of music from a brass band—is more correctly Upper Bavaria. It comprises only the southeastern quadrant of West Germany's largest *Land*—east of the Lech and south of the Danube eastward from Donauwörth. The northern and geographically larger portion of the *Land*, Bavaria is almost completely occupied by the region of Franken (Franconia)—its name deriving from its East Frankish settlers. Oberfranken (Upper Franconia) takes in the highland district near the East German and Czechoslovakian borders near Bayreuth; Mittelfranken (Central Franconia) is located in the areas surrounding Nürnberg, while Unterfranken (Lower Franconia) centres around Würzburg. Portions of northeast Baden-Württemberg are also Franconian in origin and character.

Northern regions. The regions north of the Main River, with certain exceptions, are larger and more homogeneous, except for the inroads of modern internal migration in such large urban districts as the Rhine–Main and Rhine–Ruhr metropolitan areas. Only the Rheinland, consisting of the areas of the west bank of the Rhine from Mainz to Cologne, differs notably from most of the regions north of the Main. As a region it enjoys an international fame surpassed only by that of Bavaria. The Mosel and Eifel districts to its west are of a perceptibly different cast. On the opposite bank of the Rhine, the state of Hessen, in spite of its relatively large size, is one of the few states that can claim an almost complete identity of *Land*, region, and ethnic origin; the Hessians are a branch of the Franks in the ancient land of the Chatti.

The Rheinland, by contrast, is politically wedded today to the very different regions of the Sauerland, east of the Rhine opposite Cologne, and to Westphalen, with its close affinities in character and outward appearance to the eastern provinces of The Netherlands. The Ruhr itself is sometimes called the *Kohlenpott* ("coal pot"), a derisive reference to the modern migration of workers from the German eastern provinces and Poland to tend its mines and factories.

Niedersachsen, apart from incidental subregions demarcated by landscape, such as the Lüneburger Heide (Lüneburg Heath) and the Harz, divides roughly into the regions of Hannover and Oldenburg, except for its coastal area, East Friesland, which has close ties to West Friesland in The Netherlands and North Friesland off the coast of Jutland. The slip of coastline extending from the Dutch border up around the shore of the North Sea to Schleswig-Holstein is also sometimes referred to by the Low German term *Waterkant*, "water's edge." The ancient Hanseatic cities of Bremen, Hamburg, and Lübeck may be ranked as separate regions in their own right; all have in common a sense of self-sufficiency, independence, and aloofness from the remainder of Germany. The amalgamated *Land* created from the provinces of Schleswig and Holstein, once duchies under the Danish crown, although not settled by tribes of Danish stock, retains obvious ties of kinship and culture that extend up the peninsula to its Jutlandic cousins across the border in Denmark.

Varieties of the people. Although such generalizations fail to account for the exceptions, it can be stated that the people of the regions north of the Main River tend more toward the popular notion of the blond, blue-eyed, sobersided, hard-working, and often dour German of legend. A conspicuous exception to this stereotype would be that of the Rhinelander, noted for his carefree disposition and almost Gallic affinities with Latin Europe. The Franconians in the south also share in the north German profile of being rather sturdily given to work and no nonsense, and they are rather conservative in the preservation of their traditional ways. A great contrast is found between the easy-going natives of Baden and their fellow Alemannians the Swabians, who among other Germans are thought to be the hardest working, the thriftiest, the most inclined to introspection, and one of the most self-sufficient of German peoples. No greater regional contrast could exist than that between the Swabians and the Bavarians, the latter noted for their garrulous and sometimes coarse temperament, rough humour, and vigorous pursuit of fleshly pleasures. But, if Schwaben has furnished Germany with its poets and great intellects, Bavaria is the home of its artists.

PATTERNS OF HUMAN SETTLEMENT

Rural West Germany. The manner in which land under cultivation in West Germany is divided and the major patterns that have prevailed in the utilization of crop-growing and grazing lands and timberland have been determined not only by the somewhat severe limitations of the soil but also by regional convention and historical circumstance and, especially in modern times, by economic expediency. The disposition of arable land and the structure of rural settlement have undergone steady change over the centuries, as circumstances have dictated, until the major land reforms and the onset of industrialization in the 19th century. But the most radical and abrupt adjustments in agriculture and the rural population have occurred since World War II.

Under the traditional patterns that prevailed throughout medieval and early modern times, to some degree even until the mid-20th century, the simplest structural form of farmland was that of the *Einödflur*, or *Einzelhof*, the individual farm unattached to a community or village. This type of farming in detachment has been rather

Historic methods of farming and land use

the exception in Germany, and it is widespread chiefly in the grazing lands of the northwest. Numerous variations are encountered in the more complex patterns, usually centred around a village, often in conjunction with a large estate. To these variations must be added the nature of tenancy—whether the land was the property of a *Gutsherr*, a large landholder, usually of the nobility; a *Grossbauer*, a peasant or farmer with large holdings; a *Kleinbauer*, a small farmer-proprietor; or a *Pächter*, a tenant farmer, large or small.

The ancient division of land, the *Hufe*, comprising 60 to 100 acres (25 to 40 hectares), was conceived of as the amount of land, arranged into one or several strips, that was necessary for growing enough crops or for maintaining sufficient livestock to sustain one farming operation. In the larger village enterprises and especially common in most of the regions now forming the Federal Republic, the *Hufen* were arranged into *Gewannfluren*, or the acreage surrounding a village to which the farmers went from their villages to tend their crops on the strips of land allotted to them or, in some instances, on the communal property of the village. Of this latter form, large tracts of forestland are still under the ownership of the *Gemeinde*, or "community."

The patterns of the *Hufenfluren*, or "acreage," differed widely, depending on the type of soil, the terrain, and the region. As often as not, a farmer's land would consist of several plots or strips frequently separated from one another. The divisions could also be quite irregular and uneconomically small. For this reason, a major reform in German agriculture in the postwar era has been the attempt to bring about a more efficient arrangement in the division of agricultural lands through a series of consolidations and redistribution of acreage. Along with this realignment of agricultural properties, largely accomplished by land sales and exchanges, has come the gradual disappearance of the small farmer and of multi-crop or self-sustaining farms in favour of the large-scale farmer concentrating on one or a few selected crops, the nature of which is likely to be determined by planning requirements at the *Land* or *Bund* (federal) level and adjusted to fit the crop quotas and price structures indicated by West Germany's membership in the European Economic Community. As in other industrial countries, the migration from the land continues: whereas in 1961, about 13 percent of the working population was engaged in agricultural pursuits, including fishing, by 1970 this figure had decreased to 8.9.

Village patterns

German rural settlement follows certain set patterns—from the relatively infrequent individual farm to the *Weiler*, a loose collection of farms found most frequently in the southwest and the Alpine forelands, to the many variations of the *Dorf*, or "village." By far the most common form of village in the Federal Republic, representing as it does the historically older portion of the German regions, is the *Haufendorf*, a conglomerate village of irregular pattern. Typically, it comprises a main thoroughfare and a square or village centre with such customary fixtures as a church, local administrative offices, marketing facilities, inns, shops, and the like and an assymetrical patchwork of streets and roads leading from the centre.

Other patterns of village structure include the *Rundling*, a round village (the form of which was determined by economic function and not, as was commonly supposed, by considerations of defense), and the *Reihendorf*, a linear village, the simplest form of which is the *Strassendorf*, in which the houses, buildings, and farm structures simply line the highway. These latter two forms are much more common in present-day East Germany, the lands of which were settled relatively later than those in West Germany. Among the minor variants found in all areas of West Germany and determined by terrain are villages formed in forest clearings, mountainous areas, drained marshland, or moors. The transition of a village to the rank of a town historically was betokened by its being granted the privilege of the *Marktfleckenrecht*, the privilege of holding a market. Today, however, a village may lose its essentially agricultural character by the sudden appearance of a factory or an urban housing tract on its outskirts, or, especially in the southern regions, through a reorientation of its economy toward tourism.

Urban West Germany. In the Federal Republic, as in other highly industrialized nations, well over one-half of the population reside in urban areas of 10,000 or more, while almost one-third of the remainder still live in communities of fewer than 5,000 inhabitants—many of which, nevertheless, are satellite or dormitory adjuncts to larger municipalities. Germany is essentially a country of small- to medium-size towns and cities, which, apart from the divided metropolis of Berlin, include only two cities, Hamburg and Munich, of more than 1,000,000 inhabitants. Nevertheless, almost 47 percent of the population live within the spheres of commercial and urban influence of only 10 major metropolitan centres: in approximate order, Rhine–Ruhr, Rhine–Main, Hannover–Braunschweig, West Berlin, Stuttgart, Hamburg, Munich, Bremen–Oldenburg, Mannheim–Ludwigshafen, and Saarland.

Metropolitan areas

The Rhine–Ruhr area, by far the greatest aggregate of heavy and light industry of almost every description, is Europe's greatest industrial and commercial complex. The Hamburg and Bremen metropolitan areas are primarily centres of shipping, trade, maritime industries, and manufacturing. The Hannover–Braunschweig region is largely a manufacturing and trading centre, as is West Berlin. The Rhine–Main area is important not only for certain heavy industries but also as a general commercial centre; because of its central location, it is also a crossroads of transport. The greater Stuttgart area, apart from a few key heavy-industrial firms, has West Germany's major concentration of small- to medium-size industries, mainly in the processing fields. Since World War II, Munich has grown considerably as a region of small manufacturers and processors, as well as being the urban focal point of the southeast. The Saarland is important primarily for its coal, iron, and steel industries. West Germany's two great centres of finance are Frankfurt am Main and Düsseldorf, and, with Munich and Hamburg, are favoured as headquarter cities for the German or European subsidiaries of the large international corporations.

Germany, Federal Republic of, Area and Population

	area		population	
	sq mi	sq km	1961 census	1970 census
States (*Länder*)				
Baden-Württemburg	13,803	35,750	7,759,000	8,895,000

II. The people of West Germany

DIVERSE GROUPINGS WITHIN THE POPULATION

The German-speaking peoples—to whom must be accounted not only the inhabitants of the Federal Republic and East Germany but also those of Austria, the major parts of Switzerland and Luxembourg, small portions of France and Italy, and the remnants of German communities in eastern Europe—are extremely heterogeneous in their ethnic origins, in their dialectal divisions, and in their political and cultural heritage, in which the split between Protestant and Catholic has played a significant role since the Protestant Reformation and Catholic Counter-Reformation in the 16th century.

The areas of central Europe called Germania by the Ro-

Interacting factors in cultural patterns

mans (for only one of numerous tribes in the regions north of the Alps) were known as Germany (Deutschland) only in an imprecise geographical sense until the founding of the *Reich* in 1871. Until that recent time, Germany had only the loosest bonds of a multidialectal language, certain cultural affinities, disjointed political affiliations, and, to an even lesser degree, ties of kinship upon which to form any sense of nationhood or national consciousness. Certainly Germany was far short of being a nation-state in the manner of France or England. The ethnic and linguistic subdivisions of today's Federal Republic of necessity transcend political boundaries, even though West Germany, by and large, embraces most of the territories that comprised the nucleus of the German nation—of both the Roman Germania and the Carolingian East Frankish kingdom.

The Germanic, or Teutonic, element represents only a portion of the ethnic profile of what are known as the German peoples. Account must be taken also of a considerable substratum of the pre-German Celtic inhabitants in the west and of numerous Slavonic strains in the east. Whatever internal cohesion existed in the past within the borders of present-day West Germany has been obscured to some extent by the absorption of some 13,000,000 expellees and refugees from the territories to the east. The Federal Republic has recently acquired a substantial non-German minority of over 2,300,000 *Gastarbeiter* ("guest workers"), migrant labourers most of whom are from six nations of southern Europe.

Ethnic divisions. The traditional ethnic divisions of West Germany, coinciding in their larger dimensions with the major regions, go back to tribes and branches of tribes that had settled mainly there by the time of the Roman occupation. Their ultimate origin is still a matter of speculation if not dispute, but it is commonly held that they moved into central Europe from the Baltic regions and either drove the resident Celtic tribes farther west or partly absorbed them. The Celtic strain is notably marked by one of the most enduring forms of evidence: the place-names of rivers, mountains, settlements, and other landmarks that have come into the German nomenclature most often from the Latin rendition of the original Celtic term. The names of the Rhine, Danube, and Neckar rivers, to cite only the best known, are derived from the Celtic.

Six major German ethnic groups have persisted in their historic regions from Roman and early medieval times to the present, and their numerous subdivisions are of no small historic, linguistic, and cultural importance. The southwest of the modern Federal Republic was settled by the Alemannic tribes, who occupy not only the German regions of Baden and Schwaben, but also the French province of Alsace, the German regions of Switzerland, and the Vorarlberg province of western Austria. The southeast, roughly south of the Danube River and east of the Lech River, was settled by the Bavarians, who share ties of kinship and linguistic dialect with the greater portions of modern Austria.

The central districts of West Germany were occupied by the Upper Franks—the Main, Rhine, Mosel, and Hessian Franks—as well as the Thuringians. The Lower Franks find their present-day descendants in portions of Westphalen, Flanders, and The Netherlands. The Thuringians, moving eastward, colonized the areas now in East Germany that formerly were known as Saxony.

The greater portion of the North German Plain, inhabited by the "original" Saxons, is preserved in the name of the *Land* of Niedersachsen. The descendants of these ancient Saxons, however, have few kinship ties with the people of the later and now defunct region of Saxony in East Germany. They comprised one of the several west Germanic tribes of the North Sea littoral, including the Angles, who invaded Britain in the 5th century—hence, "Anglo-Saxon."

The sixth major group, still intact if now small in number, is that of the Frisians in the islands off the coasts of Jutland and Niedersachsen. They are closely related to the West Frisians in the northern portions of The Netherlands.

The German ethnic groups of the east had their origin in later colonizations from the west, beginning in the 9th century; they are known generally as the Mecklenburgers, the Upper Saxons, the Brandenburgers, the Silesians, the Pommeranians, the Prussians, and the Baltic Germans. During these eastern colonizations, the indigenous Slavonic and Baltic peoples were absorbed and Germanized in great measure. To the south, Austria, in German Österreich (Eastern Realm, as both the Latin and German versions of its name indicate), represents an eastward colonization by the Bavarians, of whom the Tiroleans form an ethnic subgroup.

Minority groups in the population

Chief among the historical minority groups in Germany were the Jews, present in western Germany since early medieval times; they numbered about 800,000 in all of Germany prior to the genocide of World War II. Small cultural pockets of the original Slavic inhabitants of the regions colonized east of the Elbe still exist in East Germany, and their language, Wendish or Sorbian, still survives. The persecutions of the French Protestants in the late 17th century brought large numbers of Huguenots to the German lands, especially to the cities of the northwest and to Berlin. The provinces of Schleswig and Holstein, duchies of the Danish crown until the 1860s, were inhabited largely by peoples of west Germanic as opposed to north Germanic or Scandinavian stock; thus, only a small minority of Danes, estimated at 3 percent of the population, still live there.

Various other minorities, large and small, that may be noted in German territory in relatively modern times include the Polish workers who migrated to the Ruhr in the late 19th century; small groups of Russian émigrés who settled in Germany, especially in Berlin, after the October Revolution in Russia; the countless numbers of "displaced" or "stateless" persons from eastern Europe and the Balkans who were stranded in Germany at the end of World War II, and a minority that may well become permanent—the *Gastarbeiter*, their families, and descendants.

Linguistic diversities. The dialectal divisions of Germany, once of conspicuous significance for the ethnic and cultural distinctions they implied, persist in spite of such levelling and standardizing influences as mass education and communication and in spite of internal migration and the trend among the younger, better trained, better educated, and more mobile ranks of society to speak a standard, "accentless" German. The repository of dialectal differences thus lies more with the rural populace of the regions and the long-time native inhabitants of the cities.

Standard German itself is something of a hybrid language in origin, drawn from elements of the dialects spoken in the central and southern districts but with the phonetic characteristics of the north predominating. The pronunciation of standard German is, in fact, an arbitrary compromise that gained universal currency only in the late 19th century. Even today, the most "accent conscious" of the well educated will speak with the coloration of his native district's dialect and, if from the southern regions, all the more intently so.

The dialects of German

The three major dialectical divisions of Germany—as with the ethnic divisions—coincide almost identically with the major topographical regions of the North German Plains, the Central Uplands, and the southern Jura, Danube Basin, and Alpine districts. In reverse order, these dialectical divisions are known as Upper German, Central German, and Low German.

Of the Upper German dialects, the Alemannic branch in the southwest is subdivided into Swabian, Low Alemannic, and High Allemannic. The first, the most widespread and still-ascending form, is spoken to the west and north of Stuttgart and as far east as Augsburg. Low Alemannic is spoken in Baden, southern Württemberg, and Alsace, while High Alemannic is the dialect of German-speaking Switzerland. The Bavarian dialect, with its many local variations, is spoken in the areas south of the Danube River and east of the Lech River and throughout all of Austria, except in the Vorarlberg district, which is Swabian in origin.

The Central German, or Franconian, dialects and the Thuringian helped to form the basis of modern standard German. The present-day influence of Thuringian touches only partly upon West German territory, but it is of great significance in areas now in East Germany. East Franconian is spoken in northern Bavaria, South Franconian in northern Württemberg. The Rhenish Franconian dialect extends from approximately Metz, in French Lorraine, northwest through the Pfalz and Hessen. Mosel Franconian extends from Luxembourg through the Mosel Valley districts and across the Rhine into the Westerwald. Ripuarian Franconian begins roughly near Aachen, at the Dutch–Belgian border, and spreads across the Rhine between Düsseldorf and Koblenz into the Sauerland.

The dialect known as Low German, Plattdeutsch, historically covered all regions occupied by the Saxons and spread across the whole of the North German Plain. Although largely displaced in common usage by standard German, it is still widely spoken, especially among the elderly and rural inhabitants in the areas near the North Sea and the Baltic. Tiny dialectal pockets of Frisian, linguistically the most closely related of German dialects to English, still persist.

Religious profiles. Germany, ever since the Protestant Reformation and the ensuing Thirty Years' War, has notably been divided into the sectarian lines of Catholic and Protestant, though in ways that far transcend considerations of religious doctrine and practice. Following the precept formulated in the Peace of Augsburg (1555), whereby the inhabitants of a given region remained Catholic or became Protestant according to the choice of their temporal ruler, the matter of whether a person or a region is Catholic or Protestant has had the greatest effect not only on such subjective factors as culture and personal attitudes but also on the entire social and political profile of Germany. The very name of the numerically largest political party, the Christian Democratic Union, attests to the fact that it is a federation of an older middle class Catholic party with its Protestant counterparts. The Social Democratic Party, by contrast, owed much of its early orientation not only to Marxism but to antisectarianism.

Origin and political impact of religious division

In today's Federal Republic, without the overwhelmingly Protestant areas now comprising East Germany, the balance between Protestant and Catholic is almost equal. By a 1970 count, Protestants constituted about 49 percent of the population; and Roman Catholics, about 45 percent. A minute fraction of the German public belong to what are known as the free churches, such as independent Protestants (Lutherans or Calvinists), Old Catholics, Methodists, Jehovah's Witnesses, and Eastern Orthodox. The remainder, those people professing no religion (*Konfessionslose*), have been sharply on the increase in recent years, not only because of a slackening of religious loyalties but also as a means of avoiding the "church tax." That relic of Bismarckian Germany requires a citizen to pay a certain percentage of his net income tax to whatever church he acknowledges, despite the fact that there is no established state church. To become eligible for this tax exemption, a citizen must formally renounce his religious affiliation before a civil authority.

The predominantly Roman Catholic districts are found in the Rheinland and Upper Bavaria. The Rhine–Main, Pfalz, and southwestern districts are mixed, while north Germany is overwhelmingly Protestant. Germany now has 32,000 Jews, some 27,000 of whom are formally attached to Jewish communities. The greater number are concentrated in the cities of Berlin, Cologne, Düsseldorf, and Frankfurt am Main, as well as in Bavaria.

CONTEMPORARY DEMOGRAPHY

Vital statistics. The Federal Republic, like most comparable advanced industrial countries of western Europe, manifests a relatively low birth rate coupled with the expectancy of increasing longevity, with births barely outnumbering deaths each year. While the death rate has remained relatively constant in the years 1950–71, averaging around 11.5 deaths per 1,000 of population, the birth rate has varied in the same period from 16.2 in 1950 to a high of 18.3 in 1963 to a low in 1971 of 12.8. Between 1950 and 1971 the average net gain has been 5.2 per 1,000 of population, or an average annual gain of births over deaths of about 291,000 over the two decades.

Only in Hamburg and, to a much greater extent, in West Berlin does a net population loss occur through a preponderance of deaths over births. The reason is a disproportionately high percentage of elderly persons in both of those cities. West Berlin, because of its isolated situation, constantly is confronted with the problem of keeping or attracting younger residents. At the census of 1970, almost 47.5 percent of its population was aged 45 or more, and about 45 percent of that group was 65 or over.

Demographers expect that the population growth rate will be retarded in the immediate decades ahead. In 1972 the net gain in population dropped to an all-time postwar low to −0.2 net births per 1,000. Although the average age for first marriages has become steadily lower, the peaks of child-bearing years for German women were exceptionally late: around ages 29–30. One forecast for the population of the Federal Republic for the year 2000 is given at 67,000,000, as against 61,500,000 in 1970.

Migratory patterns. An additional factor of the population's composition is the presence of about 2,500,000 aliens, excluding foreign military personnel and their families. Of these resident aliens, two-thirds to three-quarters are migrant workers, the *Gastarbeiter* from southern Europe whose residence is mostly of limited duration. Because of West Germany's chronic labour shortage, it can be expected that, even with fluctuating rates of employment, they will constitute a steady if constantly changing minority. Relatively few of the *Gastarbeiter* bring their families to West Germany or marry during their stay in the country, and most will ultimately return to their home countries. It is apparent, however, that many will have settled permanently and will constitute a consistent minority. In descending order of numbers, these immigrant workers are drawn from Yugoslavia, Italy, Turkey, Greece, Spain, and Portugal.

Influx of the "guest worker"

The large numbers in this intrinsically mobile category somewhat distort the profile of internal migration in the Federal Republic, which during 1970 showed some 3,661,500 changes of residence. Among the native German population, however, two trends are discernible, both following the pattern of other comparable industrial nations: first, young Germans are more mobile than their elders and are more willing to move from one part of the country to another as their work requires. Second, the greater amounts of leisure time and disposable income tend to direct young Germans toward the southern regions, in which more attractive leisure-time amenities can be found and which are closer to the favoured holiday spots within the Federal Republic itself and in Austria, Switzerland, and the Mediterranean countries.

Since Germany's economic recovery in the 1950s, the net loss of population through emigration to such nations as the United States, Canada, Australia, New Zealand, South Africa, and, to a lesser extent, those of South America has shrunk to negligible proportions: about 15,000 to 25,000 a year. Declining overseas job opportunities as well as a growing reluctance to leave the excellent living conditions of West Germany and western Europe in general have contributed to this lowered rate of emigration.

Population distribution. Although almost one-half of West Germany's population live in 10 major metropolitan regions, the country still enjoys a highly favourable distribution of population. Other European countries are often dominated by a single metropolis or have only a few metropolitan regions that constantly grow at the further expense of the less populous or less prosperous districts. This rather even population spread is one beneficial dividend of Germany's traditional regionalism, a factor that has militated against the dominance of any one city or district. Nor is economic opportunity in the Federal Republic essentially confined to the great industrial or metropolitan regions. Upwards of one-third of the population still reside in villages of fewer than 5,000

persons and one-fourth in small- and medium-sized towns of from 10,000 to 100,000. The spread of light industry to previously sparsely populated and underdeveloped areas, along with the Federal Republic's continued improvement of its already excellent transport facilities, will probably maintain West Germany's comparatively even distribution of an otherwise dense population of 640 persons per square mile (247 per square kilometre).

(G.H.K.)

III. The national economy

West Germany is western Europe's greatest economic power in terms of total gross national product (GNP), ahead of both France and the United Kingdom. In terms of GNP per capita, however, West Germany trailed Sweden, Switzerland, and Denmark in the early 1970s. In the world, it stands fourth in terms of total GNP after the United States, the Soviet Union, and, since 1968, Japan. West German industrial production grew by 74 percent between 1960 and 1970, an average annual GNP growth, discounting inflation, of about 4.7 percent—below the growth rate of Japan, Italy, and France, above that of the United States and the United Kingdom.

Comparative standing in the international marketplace

If the post-World War II "economic miracles" of West Germany and Japan are compared, it appears that West Germany's economic growth has been the less spectacular and that its miracle ended at about the time of the first upward revaluation of the Deutsche Mark in 1961. The great immigration into West Germany from the German Democratic Republic and other parts of eastern Europe between the end of the war and 1961 was probably largely responsible for West Germany's extraordinary economic upsurge in the 1950s, whereas forces of a more dynamic nature produced Japan's rapid rate of growth.

Japan is a particularly troublesome rival for West Germany, for the two countries deal in many of the same industrial products. West Germany's export performance in the early 1970s, however, remained impressive. In 1970 it was the world's second-largest exporter by a wide margin. In 1971 West Germany was also the world's second-largest importer as well, followed by the United Kingdom, Japan, and France.

West Germany is a member of the European Economic Community (EEC). With increasing European economic and monetary integration, its economic strength will be affected increasingly by that of the other EEC members.

EXTENT AND DISTRIBUTION OF RESOURCES

Minerals. West Germany's most important mineral resources are coal, petroleum, natural gas, and iron ore. Deposits of hard coal are concentrated largely in the Aachen and Ruhr areas (Nordrhein-Westfalen) and in the Saar. The Ruhr deposits alone are estimated at about 65,000,000,000 tons; the seams are deep, often descending to more than 3,000 feet. Uneconomic mining methods, however, as well as the shift of consumer demand to oil and natural gas, caused a serious decline in the coal industry in the 1960s. West of Cologne and, to a lesser extent, in Hessen and Bavaria, deposits of lignite, a fuel intermediate between peat and soft coal, reach to a depth of 330 feet; they are usually surface mined. Total accessible reserves are estimated to be nearly 5,000,000,000 tons.

Coal, oil, and natural gas reserves

Petroleum deposits are located mainly in Emsland in Niedersachsen and on the coast of Schleswig-Holstein. Output in 1971 met about 8 percent of domestic demand, and reserves were estimated to be 89,000,000 tons. Deposits of natural gas occur mainly in the northwest, in the area between the Ems and Weser rivers and around the mouth of the Ems in Niedersachsen. Reserves of natural gas have been put at 507,000,000,000 cubic yards (388,000,000,000 cubic metres). According to unofficial estimates, however, as much as 520,000,000,000 cubic metres might become proved.

West Germany's best iron-ore deposits are located along the Lahn, Sieg, and Dill rivers in Nordrhein-Westfalen; low-grade ore is found in the Harz district near Salzgitter in Niedersachsen. Total iron reserves are estimated to be about 3,000,000,000 tons, low grade. In the 1960s output declined; total iron ore mined in 1971 amounted to 6,400,000 tons, with an iron content of 1,800,000 tons. Of great importance are West Germany's deposits of potash, its annual output accounting for about one-fifth of the world's production. Among other minerals mined in West Germany, in relatively small quantities, are copper, lead, zinc, and bauxite.

Biological and hydroelectrical resources. In 1970, more than one-half of West Germany's area was devoted to farming, although the cultivated area decreased slowly but steadily in the 1960s with continuing industrialization and urbanization. Arable land suited for temperate crops accounted for about 60 percent of this agricultural land, meadows and pastures for the remainder. The important dairying districts are in the northern coastal lowlands and in Bavaria. Orchards are mainly in the west; vineyards, in the Mosel, Rhine, Neckar, and Main valleys.

Between 1949 and 1965, reafforestation increased the woodland area by 4 percent, and, by the end of the decade, forests represented almost 30 percent of the nation's land area. Two-thirds of the forests are coniferous. The *Länder* with most woodland are Baden-Württemberg, Bavaria, Hessen, and Rheinland-Pfalz. About 30 percent of the total forest area is owned by the federal government and the *Länder*, another 30 percent by municipalities and corporations, with the remainder privately owned.

West Germany's hydroelectric stations are located mainly in the Bavarian Alps. In the late 1960s, output of hydroelectricity decreased slightly, but rose 21 percent in 1970. Long term trends favour increased production of nuclear energy, although output of hydroelectricity could be stepped up by inundating larger valleys.

SOURCES OF NATIONAL INCOME

Agriculture, forestry, and fishing. During the 1950s and 1960s the agricultural sector of West Germany's economy underwent a dramatic decline. One-third of all farms disappeared, and two-thirds of all persons employed in agriculture had to give up their jobs. During the 1960s the number of people employed full-time in all of these fields fell from 3,600,000 to 2,400,000. In all likelihood, this development will continue throughout the 1970s.

Decline in farming

In spite of the continuing drift of farmers into other sectors of economic activity, however, West Germany in the early 1970s was still a country of peasant-type farming. As a result of traditional partitioning among heirs, the land is divided up into a large number of relatively small units, though concentration took place in the 1960s. By 1971, farms totalled 1,200,000, more than 500,000 of which were less than 12 acres (five hectares) in size.

Since 1955, the federal government has drawn up an annual plan providing for structural improvements and for farm income subsidies to make up for low prices. The entire farm price system is governed by the EEC common agricultural policy. Decisions for promoting land reform were taken by the EEC in 1971; subsequently, the West German government laid down a program of supplementary national measures for structural reform and social aid.

From 1960 to 1969 the index of farm output rose by more than 18 percent. As a result of the surplus of labour and the increasing mechanization and improvement of farm structures, productivity also showed some increase during the 1960s. The agricultural sector was unable, however, to narrow the gap between its productivity level and that of the economy as a whole; farms, with less than 10 percent of the republic's workers, were producing less than 4 percent of the GNP. Such measures as retraining agricultural employees, offering incentives for retirement of farmers, and the merging of farming with other pursuits to reduce the number of full-time farmers might increase productivity in the long run.

West Germany must rely on food imports, but it is approaching self-sufficiency in a number of important commodities such as wheat, oats, and potatoes. The country is self-sufficient in rye. The main crops are rye, wheat, barley, oats, potatoes and sugar beets. Livestock farming, however, plays a more important role in the agricul-

tural sector than crop farming, and in most dairy products the nation is self-sufficient.

About one-third of West Germany's timber requirements are met by imports. In a European comparison, West Germany takes fourth place after Sweden, Finland, and France in timber production. Although the fishing catch is important, imports are still needed to satisfy consumption. The principal fishing grounds are in the North Sea, which supplies more than one-quarter of the catch, mainly herrings, and the North Atlantic, especially off Norway, Iceland, and Greenland. West German fishing vessels also ply waters off Labrador, Nova Scotia, and New England.

Mining. Mining and quarrying is a relatively unimportant sector of the West German economy, representing 4 percent or less of domestic product. The coal industry declined steadily throughout the 1960s, and a 1968 law provided for the closing of uneconomic pits. Thereupon all major coal companies joined in a giant holding company, Ruhrkohle AG, to facilitate, with financial help from the government, the orderly slowing down of coal output and diversification of industry in coal-producing areas. In all likelihood, EEC coal production in the future will be concentrated in the Aachen and Saar regions.

Contrary to developments in the coal sector, output of natural gas rose considerably in the second half of the 1960s and was likely to continue through the 1970s in view of the extent of proved reserves. Reserves of crude oil are more limited, and production has stagnated for years. Iron-ore mining is on the decline, and reserves of nonferrous metals are small, though potash mining remains important.

Manufacturing. Manufacturing accounted for about 43 percent of the domestic product in the early 1970s, virtually the same proportion as a decade earlier. With this contribution it represented the most important sector of the economy. The next most important, services, increased its share slightly during the decade. Between 1960 and 1970, manufacturing output increased by more than 75 percent, with production of capital goods rising faster than that of consumer goods. Growth leaders among important capital goods were electrical engineering, transport equipment, and machinery construction. Productivity increased during the 1960s in terms of both output per worker and output per man-hour.

Economic dominance of industry

This excellent industrial performance was to a large extent fuelled by a sustained high level of capital investment, even during periods of economic recession. Like Japan (but at a considerably lower level), West Germany devoted a considerable share of its national income to investment—in 1971, nearly 27 percent. During boom periods the labour market became extremely tight in spite of a continued shift of manpower resources from agriculture to industry and a strong influx of foreign workers. In 1971, almost 13,220,000 persons, nearly 50 percent of the work force, were engaged in the industrial sector, 9,800,000 of them in manufacturing. The largest industry in terms of employment and monetary income and expenditure was mechanical engineering, followed by electrical engineering, chemicals, textiles and clothing, and transport equipment. These industries—apart from textiles and clothing, which are declining—are also West Germany's leading export industries.

In the 1960s, a trend developed toward concentration of enterprises in a number of industrial sectors, especially in steel and petrochemicals. In spite of the government's plans in the early 1970s to frame a new cartel law prohibiting certain large-scale mergers, concentration will probably continue because of the force of world competition. In 1971, West Germany's largest enterprise, the partly state-owned automobile producer Volkswagenwerk, ranked as the fourth-largest company in Europe. With a few such exceptions of partial governmental ownership, West Germany's industry is mainly in private hands.

Foreign participation, especially investment from the United States, was of particular importance in the oil-refining, chemical, electronics, and motor industries. Of the total foreign investments in West Germany, about 90 percent was in manufacturing industries. The major part of West Germany's investment abroad was in other European countries, and to a lesser extent, in the United States and Canada.

Energy. Dramatic changes in the source of energy took place in the 1960s, when the share of hard coal dropped from 61 to 31 percent and that of lignite from 15 to 9 percent, while the share of oil rose from 21 to 52 percent. At the same time, energy consumption increased by 50 percent. With the Coal Adjustment Law of 1968, the government became committed to the gradual elimination of high-cost coal production. Thus, with the increasing importance of oil and natural gas, West Germany has become largely dependent on energy imports. Although domestic oil production seems stagnated, output of natural gas rose rapidly in the 1960s. It is estimated that by 1975 natural gas will supply 10 percent of energy, with imports from The Netherlands and the Soviet Union providing part of the supply.

Over 90 percent of electricity is produced by conventional thermal generators; small additional sources are waterpower and nuclear energy. It was planned to expand the capacity of nuclear-power plants about threefold by 1980. Most of the electric-power and gas plants are publicly owned, but a considerable part of the total volume of electricity and gas is produced by privately owned companies. Since the 1960s, the gas industry has been shifting to natural-gas sources, closing down local gasworks and constructing a pipeline network for the transport of natural gas.

Financial services. From 1948 to 1957, bank notes were issued solely by the Bank Deutscher Länder (Bank of German States), which was at the same time the bank of the federal government. Since then, the functions of central bank and bank of issue have been taken over by the Deutsche Bundesbank (German Federal Bank), which by law has the additional task of watching the stability of the currency. In exercising these tasks, the Bundesbank is not subject to any control by the federal government; as a result, repeated conflicts have taken place between the government and the Bundesbank over fundamental issues concerning the management of the national economy.

Banking and securities institutions

At the end of 1971 there were 311 commercial banks, including the "Big Three"—the Deutsche Bank AG, the Dresdner Bank AG, and the Commerzbank AG, which have a broad network of branches throughout the country. The fourth-largest bank, the Bank für Gemeinwirtschaft AG, is run on a cooperative basis by West Germany's major trade-union confederation. The major German banks not only dominate the financial sector but also have a long history of direct participation in the industrial sector.

There are also more than 100 *Land* and local banks, over 172 private banks, and 23 foreign banks. Of the credit institutions, the state-owned Kreditanstalt für Wiederaufbau (Reconstruction Loan Corporation) is the channel for public aid to developing countries. The banking system also includes over 800 savings banks, for which 12 central *Giro* institutions act as clearinghouses. There are several thousand small industrial and agricultural credit co-operatives and allied institutions; and in addition, private and public mortgage banks, installment-credit institutions, the postal-check and postal-savings schemes.

A characteristic feature of banking business in West Germany is the large amount of long-term finance provided to industry, the government, and local authorities. The public sector's long-term borrowing is controlled, however, while industrial and business borrowing is regulated by the Konjunkturrat (Business Cycle Council).

Although the government had encouraged the purchase of securities by the public, by the early 1970s the results were relatively modest. Investments in savings deposits and similar instruments were growing faster than in securities. The largest part of the securities held were shares of government-owned concerns that had been offered to the small investor at attractive terms; saving and treasury certificates were less popular.

Stock exchanges are located in Bremen, Düsseldorf, Frankfurt am Main, Hamburg, Hanover, Munich, Stuttgart, and West Berlin. In the 1960s share prices were subject to heavy fluctuations, and as a result of the general economic recession a serious stock-market slump occurred in 1966. Share prices recovered, to reach a record level in 1969, but they dropped again in 1970.

Foreign trade. In the 1960s, foreign trade played an increasingly important role in West Germany's economy. Imports of goods and services accounted for 20 percent of the GNP in 1971, exports of goods and services for 21.5 percent. West Germany's competitiveness on foreign markets remained strong throughout the 1960s; even after the upward revaluation of the Deutsche Mark in October 1969, it was hardly impaired, partly because of the readiness of exporters to accept lower profits.

The average annual export growth rate between 1960 and 1970 was 11.1 percent. The outstanding feature of the export pattern is the large proportion of manufactured goods, which in a recent year made up over 85 percent of all exports. The most important export industries are machinery construction, transport equipment, chemicals, electrical engineering, iron and steel, iron and metal products, textiles, precision and optical instruments, and shipbuilding. Although West Germany remains Europe's leading exporter, in the 1960s it lost ground to Italy in such exports as refrigerators and clothing. Japanese competition is most dangerous for key products such as automobiles, cameras, and electronic equipment.

Balance of trade

About one-half of West German exports go to EEC countries, with France the largest national market, followed by The Netherlands, the United States, Italy, and Belgium–Luxembourg. More than 10 percent of its exports go to developing countries, about 5 percent to eastern European nations. The average annual growth rate of imports in the 1960s was of the same order as that of exports. The commodity composition of imports changed to give greater weight to manufactures, less to raw materials. West Germany's best customers were also often its largest suppliers. Of total imports, about 45 percent originated from EEC countries, 16 percent from developing countries, and 4 percent from the Eastern bloc.

Trade with the German Democratic Republic is classified as "interzonal" trade and is not included in the external trade accounts. West German exports to the German Democratic Republic usually exceed imports.

MANAGEMENT OF THE ECONOMY

The public and private sectors. West Germany's system of economic management has undergone a number of shifts since the end of World War II. In 1948, the system of a planned economy, inherited from wartime, was abolished, and until 1965 the government pursued the principle of "social market economy." That principle gave virtually unlimited scope to free enterprise, except to restrict certain practices that restrained competition (though the growth of monopoly power as such was not forbidden). After 1965 a trend toward a more interventionist economic policy developed. Plans for stricter legislation to regulate competition, however, were only a minor part of that trend, when the government began consideration of a stability law the primary aim of which would be to coordinate the fiscal policies of the federal government and those of the *Länder*. The resulting Stabilization and Growth Law of 1967 not only gave the federal government far-reaching control of overall public spending, including that of the *Länder* and municipalities, but also some new weapons with which to influence private demand without introducing supplementary budgets. Under this law, the government in 1970 temporarily suspended investment depreciation allowances and imposed a temporary and repayable surcharge on income and corporation taxes. It also instituted a procedure by which the minister of economics meets at regular intervals with employer and union representatives to persuade them to exercise restraint in price increases and wage demands. In 1970 the government reaffirmed, however, that it would not impose price or income controls. In view of the income gap between persons employed in agriculture and industry, the government is involved in regulating private economic activity in the farm sector, justifying its actions as an instrument of adjustment to Common Market conditions.

Taxation. Responsibility for raising tax revenues is divided among the federal government, the *Länder*, and the municipalities. The federal government draws its revenue mainly from duties on customs and excise (except for the tax on beer) and sales taxes; it also had a share in income and corporation tax revenues, which were at the disposal of both the federal government and the *Länder*. Besides their share in those tax revenues, the *Länder* receive income from property, vehicle, and beer taxes. Municipal revenues are derived mainly from taxes on tradesmen's profits and taxes on real property. Legislation in 1969 provided that revenue from income and corporate, as well as sales, taxes was to be shared by the federal government and the *Länder* in proportions to be fixed annually; in addition, income taxes were to be shared with the municipalities. Special grants were made to the poorer *Länder*. A further reform, placing stronger emphasis on indirect taxation, was scheduled to be implemented at the beginning of 1974.

Divisions of tax sources and revenues

The financial structure is undergoing other changes as a result of EEC policies: the government's revenue from agricultural levies has been flowing into the EEC budget since 1971; its customs duties gradually will be made over to the EEC budget by 1975; and up to 1 percent of its sales-tax revenue also may have to be paid into the EEC budget as of 1975. In accordance with EEC decisions, West Germany switched to a tax-on-value-added system in 1968.

Tax receipts more than doubled during the 1960s, with the most significant development the growing share of revenue from income taxes. During the same period, the share from corporation taxes decreased, while sales taxes changed little in their contribution.

Trade unions and employer associations. Labour relations in West Germany have a strong legal bias. At the federal level, the Federal Labour Court and the Federal Constitutional Court have had considerable influence by defining the limits of the unions' and employer associations' freedom of collective bargaining and by settling important legal and industrial disputes. At the *Länder* level, the labour ministries are in charge of implementing federal labour and social legislation; they also supervise labour courts and social-security institutions. The trade unions and employer associations are represented, however, in the labour courts, labour exchanges, and social-security institutions.

In the early 1970s, somewhat less than one-third of the 27,200,000-man work force belonged to West German trade unions. The major union, the Deutsche Gewerkschaftsbund (DGB; German Labour Federation) is one of the three largest and most powerful union federations in the non-Communist world. Its several affiliated single-industry unions combined in a rigid organizational structure in 1949. The DGB executive board represents the interests of the affiliates in social, economic, educational, and cultural matters. The most influential member within the DGB is the metal-workers' union, IG Metall.

At the federal level, the employers' interests are represented by the Bundesvereinigung der Deutschen Arbeitgeberverbände (BDA; Confederation of German Employers' Associations), grouping 43 large federations and some 800 local federations in West Germany, representing about 90 percent of all privately owned enterprises. For the defense of their interests in fields other than labour policy, employers are grouped in federal organizations, of which the most important one is the Bundesverband der Deutschen Industrie (BDI; Federation of German Industries).

Contract and conciliation procedures between unions and employer associations are complicated. Postwar legal decisions have tended to restrict the right to strike. Before a strike can be called legally, the industry must be without a collective agreement because of the expiration of the old one and a breakdown of talks on a new one;

Restrictions on strikes

both sides must have observed a compulsory three-week period of mediation; and the union must ballot its members and obtain a 75 percent majority in favour of a strike. Serious strikes occurred legally in 1956–57 and 1963, while a series of illegal strikes alarmed the government and the unions alike in 1969. On the whole, the number of working days lost was considerably smaller in the 1960s than in most other industrialized countries. In spite of the 1969 strikes, statistics convey a picture of relatively peaceful relations between labour and management, with working days lost by strikes well below 1 percent of the figure in the United States and Italy and only a fraction of those in the United Kingdom, Japan, and France.

The DGB is a strong advocate of workers' participation in company management. In 1951 it obtained a law on co-determination of policy, which applied to major firms in the coal and steel industries; in the early 1970s it still was seeking an extension of this law to other important industries.

CONTEMPORARY ECONOMIC POLICIES

The Stabilization and Growth Law of 1967 marked a turning point in West Germany's economic policy making. The earlier uncompromising application of the principle of a social market economy created conditions under which market processes ran their course. The federal government had control over only part of public spending, since the budgets of the *Länder* and municipalities were operated completely independently, with the result that all budgets became completely out of control in 1965.

The Stabilization and Growth Law was designed to provide a framework of economic decision making at federal level, especially the coordination and federal supervision of public spending, with a view to achieving price stability, full employment, external equilibrium, and growth. Under the psychological impact of the 1966–67 economic recession, the *Länder* and municipalities accepted the curtailment of their financial autonomy. One of the most important features of the law is that it obliges the government to draw up a medium-term finance plan, and since 1969 an official finance council composed of representatives of local government has played a part in forming this plan.

Contacts with local-government representatives are also cultivated within the framework of the Business Cycle Council, which advises the federal government on bond issues but, in turn, is held to support the government in its attempts to control economic cycles. Almost for the first time since World War II, the government's fiscal policy in 1967 and 1968 was intentionally countercyclical. The periodic meetings with trade unionists and employers initially looked successful, when the unions, under the shock of the 1966–67 recession, kept their wage claims at a very modest level. During the boom years of 1968–69, however, company profits soared at a rate disproportionate to that of wages, leading to the illegal strikes of 1969. Subsequently, the pace of wage increases began to accelerate, accompanied by substantial price increases.

In 1970 both the ministry of economics and the Bundesbank took a series of measures to check inflationary pressures. The ministry of economics pursued a policy of restraint on public expenditure; in addition, in 1970 it introduced a temporary and repayable surcharge on income and corporation taxes and temporarily suspended investment depreciation allowances. In the same year, the Bundesbank raised the discount rate to the then record level of 7.5 percent and introduced measures to keep credit as tight as possible. Subsequently, however, the Bundesbank had to cut the discount rate, in several stages, in view of cuts in interest rates abroad and a heavy influx of foreign money, especially United States dollars, into West Germany.

ECONOMIC PROBLEMS AND PROSPECTS

In international comparisons, West Germany's economic situation in the early 1970s seemed less worrisome than it was viewed at home. The inflation it had to combat in the early 1970s was not an isolated, domestic inflation but a worldwide one. The weakness of the economy, however, is that all of its booms up to 1970 were led by exports, and for that reason the nation's economic development has depended largely on that of its major markets. The most obvious solution, a shift of resources from exports into the improvement of the domestic infrastructure, is difficult to put into practice, however. The government has increased spending to realize part of its promised reform program to raise the standard of schools, hospitals, and social services, but it seems doubtful that a far-reaching reform can be carried out without substantial tax increases. According to estimates, annual budget deficits will occur until 1975. It is also most doubtful whether public spending, which is slower to take effect than private investment spending, will be a fast-acting stimulus to the economy.

At the same time, it is evident that a real need for social reform exists and the call for a more equitable distribution of the country's wealth is likely to become more intensive. In particular, more measures will have to be taken to narrow the income gap between the farm sector and other economic sectors, which is often part of complex regional problems. Thus, in the framework of a regional program drawn up by the government in the late 1960s, official efforts are to be undertaken to attract industry to the large farming areas. In view of these domestic problems, it is almost certain that West Germany's economic growth, at least in the first half of the 1970s, will continue to hinge upon the general development of world trade. (E.I.U.)

IV. Transportation

The Federal Republic not only must serve its own extremely complex needs as a densely populated and highly industrialized nation, but, because of its central location in Europe, it must also function as Europe's principal nation of transit for the passenger and freight traffic. In consequence, its system of overland transport—highways, railways, and waterways—and, to a lesser but adequate degree, of air transport—are among the most intricate and highly developed of any nation. Elaborate plans, made in coordination with neighbouring countries and partners in the EEC, call for further improvements and ambitious long-range programs to expand and improve existing facilities and to incorporate the most advanced concepts in transport engineering to handle the growing volume of traffic anticipated in the decades ahead. More limited-access motorways and widened highways will lessen the present immense burden on Germany's labyrinthine road system, while the continuing modernization of existing rail facilities will be augmented by the construction of new lines to relieve the most heavily travelled routes.

PATTERNS OF TRAFFIC MOVEMENT

Predominance of north–south routes

Although throughout history Germany has served as a crossroads for European traffic, both from north to south and from east to west, the geographic contours of West Germany and its inherited overland routes, as well as existing political conditions, make the north–south and northwest–southeast routes of greater significance than those running from east to west. By its location, it is the one Western country with the greatest number of points of access to the Communist nations of the eastern European bloc, but the volume of passenger and goods traffic to and from these nations, including Germany's estranged sister-state, the German Democratic Republic, amounts to only a small fraction of the volume hauled across its frontiers.

The notable exceptions are the freight and passenger routes to West Berlin, a political and economic adjunct to the Federal Republic: access to the city, except for two of the three air corridors and the Elbe River, is direct east–west. Until the partition of the *Reich* in 1945, Berlin was the focal point of the nation's railway system, but today this function is all but vestigial, even within East Germany.

National routes. West Germany's major overland routes follow parallel patterns in both the highway and rail systems. From north to south, traffic gathering from the direction of Scandinavia focusses at Hamburg and moves largely in two directions. It may follow a course roughly due south via Hannover and Würzburg to Stuttgart and the southwest or from Würzburg eastward toward Nürnberg or southeastward toward Munich. Alternatively, it may go from Hamburg southwestward toward Bremen, whence it veers south and then west to the Rhine–Ruhr district, from which area the major routes of transport follow the Rhine Valley, past the Rhine–Main district to all points south.

Major intermediary routes are the rail and highway links from Hamburg and Hannover to Kassel and Frankfurt am Main; from the Rhine–Ruhr district to Hannover; from Frankfurt am Main to Würzburg, Nürnberg, and Munich; from the Mannheim–Ludwigshafen area westward to the Saar and northern France; and from the Mannheim–Heidelberg area to Karlsruhe or, further eastward, to Stuttgart, Ulm, Augsburg, and Munich. Munich is the great highway and rail terminal point for traffic to and from Austria, Italy, and the Balkans. The major routes to southwestern Europe run south past Karlsruhe and up the Rhine Valley—with a major access to eastern France at Strasbourg—or south past Freiburg, im Breisgau, to the juncture of the German, Swiss, and French borders at Basel.

Germany's unexcelled system of overland transport is complemented by its great endowment of navigable rivers and their interconnections by means of an intricate system of canals. Apart from the Danube River and its tributaries, which flow eastward toward the Balkans but eventually will be linked by canal to the northern water routes, these rivers have access to the North Sea and, via a link with the Elbe, to the Baltic. Although three of West Germany's major rivers—the Elbe, the Weser, and the Ems—empty into the North Sea, a major portion of freight to or from overseas passes through The Netherlands and Europe's largest port, Rotterdam, for the Rhine route via Rotterdam is closer by almost half the distance to the North Sea and the Atlantic than even the Ems. As a corollary, The Netherlands' extensive motor-freight fleet has been developed to service goods passing through the port of Rotterdam, and a major portion of this fleet is deployed to and in transit through the Federal Republic via Nordrhein-Westfalen.

Local and interurban services. West Germany's systems of passenger transit are among the most thoroughly developed and efficient in the world. A dense network of mainline railways not only provides frequent and speedy service in long-distance passenger traffic but also serves simultaneously for local commuter traffic.

Local urban transport is no less intensely structured: local bus systems operate in even the smallest towns, and all communities have access to the regional interurban bus lines. German cities, far from abandoning streetcar and tram services in the post-1945 era in favour of municipal bus lines, continue to rely heavily upon urban rail service; and in the larger cities, municipal buses are usually ancillary to the streetcar and tram lines. Although Berlin and Hamburg have maintained both underground and elevated train services for decades and Wuppertal constructed an 8.3-mile-long elevated monorail in 1900, several other West German cities have begun to construct similar rapid-transit facilities. Most of these rapid-transit systems, in such cities as Frankfurt am Main, Cologne, Stuttgart, and Hannover, represent essentially a submerging of the surface rail lines in the central portions of the city. Only Munich has built an underground rapid-transit system independent of the surface lines, complemented by an independent fast-rail service linking communities within a 25-mile radius of the city centre.

Problems and prospects of municipal services

Interurban bus transport, most of it operated by the federal postal service as a relic of the ancient postal coaches, is limited in most instances to localized suburban and nearby interurban services. Because of the superior train service available, long-distance coach runs play a relatively minor role in passenger transport.

COMPONENTS OF THE SYSTEMS

Of the major forms of long-distance freight carriage of all kinds, including transshipments, the railways haul well over one-third of all goods; inland shipping accounts for almost one-quarter; overseas shipping, for upwards of 15 percent; and motor-freight carriers, for slightly over 15 percent. The remainder of freight transport is conveyed by pipeline (chiefly oil and natural gas), now at some 8 percent, plus a relatively minute fraction of goods shipped by airfreight. The latter two forms of haulage showed the greatest growth (virtually fourfold) during the 1960s. At the same time, water and road transport increased slightly in the proportion of goods carried over that of the railways.

Highways. Approximately 75,000 miles of roads and highways of all categories remained in West Germany after World War II. Even the best of these were antiquated in terms of early postwar traffic demands, and few exceeded more than two lanes in width. Superimposed on the older highway system was the badly damaged system of limited-access motorways, then some 1,330 miles in length, known as the *Autobahn*, begun under the Nazi regime in the mid-1930s and considered the marvel of the world in its time. It was in operation well before comparable superhighways in the United States. But though the *Autobahn* complex linked the major industrial and population centres, many important segments had not been completed by the war's end, and its relatively narrow dual lanes, impeded by war-damaged or incomplete sections, were soon overtaxed by the mounting volume of traffic. Improvements and extensions of the *Autobahn* network were begun in the early 1950s, and by the early 1970s it covered over 3,000 miles. The Federal Republic's present highway system comprises some 100,000 miles (exclusive of municipal street systems), but only about 23,000 miles of these are major arteries. By 1985, the long-distance highway system will have been expanded to approximately 36,500 miles.

The *Autobahn*

Since neighbouring countries have developed most of their own limited-access highway systems to complement the *Autobahn* routes, it is possible to cross directly into the motorways of The Netherlands, Belgium, and Austria. Similar links are in preparation for expressway transit into Denmark, France, and Switzerland. Plans for overhauls that will run into the 1980s involve a trans-European highway system coordinated by the federal and *Länder* governments as well as those of neighbouring countries.

Railways. Germany's first train service operated over a five-mile line between Nürnberg and Fürth in 1835. The privately owned railway corporations formed throughout the late 19th century were transferred to public ownership through the individual states, and by 1920 the entire network was owned and operated by one national corporation. Some minor lines—for the most part narrow-gauge, resort, or excursion lines—survived under private ownership. Prior to territorial annexations from Austria and Czechoslovakia before the outbreak of World War II, Germany had some 35,000 miles of railway lines. About 19,000 miles of this network, much of it heavily damaged during the war, devolved to the Federal Republic, which by 1951 had taken over operation of service from the occupying powers. (Its counterpart in East Germany lost almost all of its dual-track routes to the Soviet Union, as reparation, and only minor portions have so far been restored to multitrack operation.)

As with so many facets of West Germany's infrastructure, widespread wartime destruction called for an almost complete overhaul or replacement of capital stock and equipment, so that the new rail network was rebuilt with the benefit of the latest technology and stocked with new equipment. By 1970 the network had increased its total length to 18,500 miles, over 5,300 miles of which were electrified.

A major innovation since 1967 has been the rapid addition of containerized-freight facilities, facilitating the speedy transfer of cargo between ship, rail, and motor transport. In addition to rapid long-distance passenger

service, the Deutsche Bundesbahn (German Federal Railway), in conjunction with other countries of western Europe, operates luxurious high-speed trains known as the TEE's (Trans-European Expresses) and the Inter-City routes. Attaining cruising speeds of about 90 miles per hour and higher, these express services enable passengers to travel, for example, from Hamburg to Munich, a rail distance of 522 miles, in seven hours. Considerable progress also has already been made toward perfecting revolutionary forms of rail transport in superspeed monorail motor trains, as well as other still experimental innovations in rail transport.

Waterways. Germany's intricate system of inland waterways, of which the Rhine is the very symbol, assumes a vital economic importance in the inexpensive haulage of bulk goods, raw materials, and fuels. Of the 3,700 miles of navigable waterways, about 2,500 are represented by rivers, most of the rest by canals, and a few by lake routes, especially on Lake Constance. About 75 percent of internal water transport is on the Rhine, whose density of ships, barges, freighters, and other vessels from the fleets of five nations is comparable to that of a heavily travelled highway.

The river and canal systems

The most important of Germany's canals is the 200-mile-long Mittelland Kanal, which connects Berlin with the Elbe within East Germany, extends westward across the West German frontier into Niedersachsen and the Greater Hannover industrial region, leads to the Weser at Minden, and continues westward with the Dortmund-Ems-Kanal leading to the North Sea port of Emden. The Kiel Canal (also known as the Nord-Ostsee-Kanal), 61 miles long, has linked the Baltic and the North seas since 1895. Intensified improvements to inland waterways are actively in progress. Both rivers and canals are constantly being deepened and channels widened to increase capacities; lock facilities are undergoing widespread remodelling and enlargement. The most important development in inland shipping both for Germany and all Europe will be the linking of the northern river and canal system with that of the Danube and its tributaries and canals, a project contemplated since the reign of Charlemagne in the 9th century AD. This trans-European link between the North Sea and the Black Sea is expected to be opened by the 1980s.

Although having only limited access to the open sea, Germany long has ranked high as a maritime power: its merchant marine was the fifth largest in the world at the outbreak of World War II. As with other leading shipping nations, however, the Federal Republic's position among the merchant fleets of the world tends to be obscured by the intricacies of postwar patterns of ownership and through ship registration under flags of convenience. Discounting, thus, the ships under, for example, Liberian and Panamanian registration, the Federal Republic held eighth position in the early 1970s. Of its major seaports, Hamburg, noted for its excellent modern and swift facilities for docking and the transfer of cargo, accounted for the greatest number of arrivals and departures. As in other comparable maritime nations, however, passenger traffic to and from overseas dwindled to insignificant proportions because of the ascendancy of airline transportation. On inland waterways, passenger carriers are limited mainly to ferry transport and excursion traffic.

Airways. Germany, apart from its many technical contributions to aeronautics, was one of the great pioneers of commercial aviation in the years between World Wars I and II. The original Deutsche Lufthansa AG, founded in 1926, whence the Federal Republic's state-controlled airline Lufthansa takes its name, was an early leader in operating regular passenger service throughout Europe and by 1936 was flying the North Atlantic route. In 1938, this airline offered nonstop passenger service between Berlin and New York. Since the re-establishment of German commercial aviation in the mid-1950s, Lufthansa has become one of the leading international carriers, with routes around the world.

It is, in fact, in international rather than in domestic aviation that West Germany's role is important, not the least reason for which is the nation's central location and, thus, convenience as a point of arrival and departure in Europe. Because of the relatively short distances between the cities of Germany and the availability of fast and less expensive train service, domestic passenger service represents less than 1 percent of the traffic on public air carriers of all types. Only on the traffic to and from West Berlin do most persons prefer to fly—to avoid passing through East German controls. Air freight represents only a tiny fraction of the total of long-distance goods hauled in the Federal Republic, though its volume grows significantly each year.

Eleven commercial airports serve the major cities of West Germany, of which Frankfurt's Rhine-Main—Europe's third largest in volume after the airports serving London and Paris—far exceeds all others in numbers of passengers and total air freight handled. Because upwards of 1,000,000 visitors fly in to Frankfurt am Main each year to attend its numerous international trade fairs, an underground railway connection links Rhine-Main airport with the fairgrounds. Major new airports are being opened for Munich and Hamburg.

V. Administration and social conditions

The structure and authority of West Germany's government is derived from the *Grundgesetz*, or Basic Law, which was signed and proclaimed on May 23, 1949, after formal consent to the formation of the republic had been given by the military governments of the Western occupying powers and on the assent of the parliaments of the *Länder* to form the *Bund*. The extension of full sovereignty was achieved only gradually: many powers and prerogatives, including those of direct intervention, were retained by the Western powers and devolved to the Federal Republic only as it was able to grow in economic and political stability and to be integrated into the Western community of nations. The tripartite offices of military governor were replaced upon the creation of the Federal Republic by those of high commissioners, and upon its achievement of full sovereignty on May 5, 1955, the high commissioners became ambassadors, accredited to the president of the republic. Since its founding, the West German government, representing the older and more populous of the traditional Germanic territories, has looked upon itself as the legitimate heir to the Wilhelmian (or Bismarckian) *Reich* that united the German states from 1871 until 1945.

Overview of the political and social environments

In the days of Imperial Germany, the society of the nation was among the most intricately hierarchical in all Europe. With certain notable exceptions, the social upheaval of two major wars and economic change, though loosening this rigidity, left the basic class structure intact. West German society is far from plagued by class consciousness, but a sense of one's station in life is implicitly understood. Education still commands a greater awe in Germany than elsewhere; and the professor is held in an esteem incomprehensible to foreigners, and the title "doctor" is an all but essential credential for advancement not only in the upper echelons of the professions and the civil service, where a certain erudition is not inappropriate, but also—even more baffling to outsiders—in the ranks of business. The greatest loss of prestige has been suffered by the military; the German officer, who in the imperial era could snub bank directors with impunity, now commands mere apathy from the public. The older authoritarianism still lurks, but it has been enfeebled beyond repair. As in other advanced nations, the basis of true power has passed to the younger technical and managerial meritocracy.

STRUCTURE OF GOVERNMENT

The constitutional framework

The Basic Law has many affinities with the Anglo-American democracies and the predecessor Weimar Constitution (upon which it drew heavily). The parliamentary form of government incorporated many features of the British system, but since West Germany, unlike Great Britain, is a federation, many features were incorporated from the models of the United States and other federative governments. Because of Germany's heritage of par-

ticularism, however, the individual *Länder* were given and rigorously maintain greater autonomy than, for example, state governments in the United States. The Basic Law also exhibits two features similar to the Constitution of the United States: (1) its formal declaration of the principles of human rights and of bases for the government of men and (2) the strongly independent position of the courts, especially in the right of the Federal Constitutional Court to declare a law unconstitutional and void.

Executive and legislative power. The formal chief of state is the president. Intended to be an elder statesman of stature, he is chosen for a term of five years by an assembly specially convened. His functions are far from being honorific. Apart from representing West Germany among other nations and signing all federal legislation and treaties, he nominates the federal chancellor and the chancellor's cabinet appointments, whom he may dismiss upon the chancellor's recommendation. He cannot, however, dismiss the federal chancellor or the Bundestag, the federal parliament. Among his other important functions are those of appointing federal judges and certain other officials and the right of pardon and reprieve.

The government in power is headed by the chancellor, who is elected by a majority vote of the Bundestag upon nomination by the president; in practice, the chancellor is always the chairman of his party. He is vested with considerable independent powers and initiates government policy. His cabinet and its ministries also enjoy extensive autonomy and powers of initiative. The chancellor can be deposed by an absolute majority of the Bundestag but only after a majority has been assured for the election of his successor. Thus it is unlikely for a chancellor and his government to be unseated, however much his working majority may have dwindled. The cabinet may not be unseated by a vote of no confidence by the Bundestag. The president may not dismiss a government or, in a crisis, call upon a political leader at his discretion to form a new government, the latter constitutional provision being based on the experience of the manner whereby Adolf Hitler—against the better judgment of the *Reichspräsident*—became chancellor in 1933.

Ministries of the cabinet

The number of cabinet ministers may vary. Under the government formed in 1969, there were 14, whereas under the preceding coalition government there had been 19. Most cabinet members are delegates to the Bundestag and are drawn from the majority party or proportionally from the parties forming a coalition, but the chancellor may appoint persons without party affiliation from a certain area of technical competence. These nondelegate members speak or answer questions during parliamentary debates.

The chancellor is immediately assisted by his secretaries of state, who administer various aspects of foreign and internal affairs or the conduct of press and information services; they may exercise wide powers of discretion in carrying out the instructions of the chancellor. The cabinet ministries—apart from the major areas of foreign policy, finance, defense, internal affairs, justice, and commerce—are responsible for such technical and social functions as transport and telecommunications (including the post office, the telephone system, and certain aspects of broadcasting); youth, family, and health; economic cooperation; education; nutrition; labour; and housing and urban planning. A ministry peculiar to the German situation is that devoted to All-German Affairs, which deals with matters pertaining to the Federal Republic's tenuous relations with the German Democratic Republic.

Certain individual organs of government administer such areas as internal security, intelligence, press and information, and statistics; they operate under the direct authority of the chancellor. The Federal Audit Office, independent of both chancellor and Bundestag, is charged with the accounting and budgetary control of all governmental functions.

The Bundestag, the cornerstone of the West German system of government, consists of 518 members (subject to slight variation), including 22 nonvoting delegates from West Berlin. Its delegates are chosen either in general elections held every four years or in special by-elections. In addition to the members elected by each district, a set of *Länder* delegates at large are elected simultaneously both as a means of ensuring stability and continuity of representation by the major parties in the lower chamber and as a corollary to look to the interests of nation, *Land*, party, or bloc of voters at large. In this latter function the delegates at large serve as a counterbalance to the parochial tendencies inherent in strict representation by district constituency mandate.

Methods of constituting the parliamentary chambers

The Bundestag exercises much wider powers than does the upper chamber, known as the Bundesrat, or Federal Council. In the Bundesrat, the *Länder* themselves exercise authority to protect their rights and prerogatives. Its 45 members are appointed by the governments of the *Länder*, each *Land* sending from three to five members, depending on size and population; West Berlin sends four nonvoting members. The delegations are bound by the instructions of their provincial governments. All legislation originates in the Bundestag, and the Bundesrat's consent is necessary only on certain matters directly affecting the interests of the *Länder*, especially in the area of finance and administration, and for legislation in which questions affecting the Basic Law are involved. It may exercise a restraint on the Bundestag by rejecting certain routine legislation passed by the lower chamber, but unless the bills fall within certain categories, its vote may be overridden by a simple majority in the Bundestag. Should the president be absent abroad for long periods or withdraw from office, the speaker of the Bundesrat deputizes for him.

The powers of the Bundestag are kept in careful balance with those of the Landtage, the provincial parliaments. Certain powers are specifically reserved to the republic—foreign affairs, defense, currency and minting, post and telecommunications, customs and problems of international trade, and matters affecting citizenship. The Bundestag and the *Länder* may pass concurrent legislation in such matters when it is necessary and desirable, or the Bundestag may set out certain guidelines for legislation; drawing from these, each individual Landtag will pass appropriate legislation in keeping with the particular needs and circumstances of its own *Land*. In principle, the Bundestag initiates or approves legislation in matters in which uniformity is essential, but the Landtage otherwise are free to act in areas in which not expressly restrained by the Basic Law.

Provincial and municipal government. Certain functions are specifically the province of the *Länder*, notably education and law enforcement; yet even here an attempt is made to maintain a degree of uniformity among the 10 *Länder* and West Berlin through joint consultative bodies. The governments of the *Länder* are generally parallel in structure to that of the Bund but need not be. In eight of the *Länder* the head of government has his own cabinet and ministers; each has its own parliamentary body, but in the city-state *Länder* of Hamburg, Bremen, and Berlin, the mayor is simultaneously the head of government of the *Land*. The municipal senates serve also as provincial parliaments, and the municipal offices assume the nature of provincial ministries.

The administrative subdivisions of the *Länder* (exclusive of the city-states) are known as *Kreise* or, in parts of North Germany, as *Grafschaften*, roughly equivalent to counties. Larger communities enjoy the status of what in Great Britain would be a county borough. The *Kreise* themselves are further subdivided into the *Gemeinden*, roughly "boroughs" or "parishes," which through long German tradition have considerable local autonomy and responsibility in the administration of schools, hospitals, housing and construction, social welfare, public services and utilities, and cultural amenities.

Justice. German law is based on two ancient systems: German law, deriving from the Germanic tribal conventions of antiquity (of which the Salic Law of the Franks, dating from Merovingian times, was the pre-eminent form), and Roman law, the principles of which gained in favour in Germany from the Renaissance to during and after the Napoleonic era. Laws were codified, unlike

Anglo-Saxon common law, in three great civil, criminal, and commercial codes after the founding of the *Reich* in 1871.

Levels and operations of the judicial system

The Federal Constitutional Court, located in Karlsruhe, is the highest court of the land. It enjoys complete independence in its principal tasks of determining the constitutionality of all laws and monitoring the administration of justice and the legality and propriety of administrative and political procedures. The court of highest instance, it admits for deliberation only cases of major import. Immediately below it are 19 high *Land* courts, then the *Land* courts of the first and second instance. The lowest court is the equivalent to a county or district court, which hears cases involving minor offenses or smaller claims. When acting as criminal courts or in cases involving manslaughter, both the *Land* and *Kreis* employ both professional judges and jurors. Certain serious cases such as high treason or conspiracy against the state will be heard in the first instance by the high *Land* court. The Federal Republic has also established a system of labour, social, administrative, and finance courts, appeals from which go to the appropriate federal courts.

While the structures and conventions of Anglo-American and German law, court systems, and procedures are so very different in their provenience and practical workings both systems seem, nevertheless, to arrive at roughly the same conclusions by entirely different routes. By comparison to the general tenor of Anglo-American law, German law often seems to combine a curious mixture of assets—painstaking care, a tendency toward leniency and lighter sentences, and certainly greater consistency and uniformity in the administration of justice—with the faults of a more conservative outlook, especially in the assertion of individual grievances against larger and more powerful organizations and authorities. Claims for damages, substantive or physical, are very difficult to assert. Though German law may fall short of the common law on these counts, the German legal system is far less bound by tradition than the English and American systems and more open to reform and the incorporation of modern procedures.

In the late 1960s a sweeping law reform was begun, some of whose components were the introduction of modern concepts of penology and criminal rehabilitation, the removal of certain matters of moral conduct (such as homosexuality, abortion, and pornography) from the realm of criminal offenses, and the beginning of improvements in the treatment of juvenile offenders. The death penalty is expressly forbidden in the Basic Law.

POLITICAL INSTITUTIONS

The voting age was reduced from 21 to 18 in 1970. Both the quadriennial general and provincial elections as well as local elections are attended with the greatest interest and involvement on the part of the electorate. The electorate is kept informed on political issues through saturation coverage in the press, television, and radio, and political affairs provide a topic for frequent debate among German citizens. The pride with which many Germans once asserted that politics held no interest for them is an attitude of the past. Although voting is not compulsory, an extremely high percentage of citizens participate: in the 1972 general election, 91.1 percent of registered voters went to the polls. Since elections in the *Länder* are staggered throughout the life of each Bundestag, they act as weather vanes of public response to the policies of the incumbent federal government.

Germany's political parties, the sheer proliferation of which contributed to the downfall of the Weimar Republic in 1933, have shown an increasing tendency toward consolidation since the early days of the Federal Republic. Smaller parties have either allied themselves to the larger ones, have shrunk into insignificance, or simply have vanished. Germany in the 1970s has, in effect, only two major parties, though neither can easily attain a parliamentary majority. Most governments, therefore, to date, have held power in coalition with a third party.

The party of the middle and the right—the "bourgeois" party in older European terms—is the Christian Democratic Union (CDU), which headed every Bonn government, often in coalition, from 1949 to 1969, when the Social Democratic Party (SPD) succeeded in forming a government. It functions in all *Länder* except Bayern, where the more conservative Christian Socialist Union (CSU) functions as its counterpart in quasi-permanent coalition.

Political parties and their constituencies

In its origins, the CDU represents a merger of the old Catholic Centre Party with kindred bourgeois parties, either Protestant or nonsectarian. In a nation in which one's religion had also often been one's politics, its strongest constituencies are still in the Catholic districts, although the sectarian Christian aspect is of only incidental emphasis, chiefly among older voters. Its policies emphasize Germany's place in the Western community and NATO, its free-market economy, skepticism if not hostility toward negotiations and a rapprochement with the Communist bloc, and the reunification of Germany on the basis of free elections. Historically the successor to the Marxist parties dating from the 19th century, the SPD under its early postwar leadership maintained a rigorous policy of adherence to classic Marxist doctrine, vehement opposition to the Communist movement from which it had split in the early 20th century, and rejection of rearmament for West Germany and its integration into the Western military defense system. In 1959, however, the SPD discarded is doctrinaire approach: the call for nationalizing large industries was foresaken in preference to gradualist reform, and appeals to class warfare were abandoned. The SPD was able, thereby, to broaden its base to attract greater segments of the middle class, whether these persons were liberal or intellectually Marxist or merely seeking an alternative to the tenure of CDU leadership. Current SPD policies call for social and industrial reform, a rapprochement with the nations of the Eastern bloc (a coming-of-age for the nation in foreign affairs that caused more consternation at home than abroad) while remaining politically and militarily allied with the West, and western European unity through EEC; and it was not hostile to the free-market system.

The third party, minute in comparison but wielding power because it can and will join in coalition with either of the two major parties when no clear parliamentary majority has been obtained, is the Free Democratic Party (FDP). Existing since the 19th century, it was formerly of a conservative, pro-business, and anti-sectarian cast.

Many smaller parties and some older regional parties have disappeared, their members realigned with the larger parties. Both the radical right and left have been reduced to small, dissident groups. Few have been able to get the 5 percent of the votes required by the Basic Law before a party may send delegates to legislative bodies of government. A resurgence of alleged Nazi sentiment under the National Democratic Party (NDP) in the mid-1960s was short-lived, before being fragmented into a shattered collection of elderly unteachables and youthful romantics.

THE ARMED FORCES

A wave of shock spread through war-weary West Germany when in 1950, in view of the likelihood of a long-term Soviet threat to western Europe and the fact that the Soviet Zone of Occupation was rearming, the Western allies reversed the policy—taken at the end of World War II—that Germany should and must never fight again in a European war. A special task force scrupulously strove to create the foundations for an army that would be all but completely purged of the former German military traditions in matters of discipline and of outer appearance—the end effect of which was a positively liberal and democratic cast. To combat the previous blind obedience to orders, members of the Bundeswehr (Federal Army) are indoctrinated in their role as citizen-soldiers and in the range of discretion allowed in conflicts between orders and personal conscience.

Conscription

The Bundeswehr at its inception sought to raise 12 divisions, a goal achieved not without difficulty. Conscription is uniform for males between 18 and 45 years of age; conscientious objectors must perform a term of non-

combatant service in socially useful work, and the sole surviving sons of fathers killed in military service in World War II are exempt. The period of service for conscripts is presently set at 18 months, but plans are underway for a widely based reserve army and a long-term reserve obligation to offset this relatively short period of active duty. Approximately three-quarters of the Bundeswehr's officer corps but less than one-third of its noncommissioned officers are career soldiers. A smaller air force and navy are maintained by the Bundeswehr, along with such other military or quasi-military services as the territorial army, an independent border patrol, and a coast guard.

The German armed forces operate in close coordination with their partners in the North Atlantic Treaty Organization (NATO), of which West Germany became a full member in 1955. The Federal Republic helps to support the presence of some 360,000 Allied troops on its soil, the majority of which (over 200,000) are from the United States. The continued presence of these troops is a frequently reaffirmed objective of German national policy. In 1969 the nation signed the nuclear nonproliferation pact.

THE SOCIAL MILIEU

Education. Schooling is free and compulsory for all Germans from the sixth through the 18th year of age; through age 15 the time must be spent in classroom study. Although each *Land* is absolutely sovereign in matters of education, a permanent conference strives for uniformity in curriculum, requirements, and standards. Primary and secondary education, although presently subject to far-reaching reform, still largely follows the traditional pattern of a common elementary school for the first through fourth years, after completion of which a determination is made as to whether a pupil will terminate his education after a further five to six years of elementary schooling and subsequently be apprenticed to a trade or trained in a special industrial vocation at age 15 or 16; will attend a school essentially geared to clerical, administrative, and commercial careers; or will receive a lengthy academic training in preparation for entry to university or the higher ranks of business and the civil service.

Thus, all children attend the *Grundschule* ("basic school") until about age 10. The majority of children then go on to the *Hauptschule* (roughly, "main school"), usually for five more years, after which they will be assigned to a *Berufsschule* ("vocational school"), usually attended part-time in conjunction with practical apprenticeship. Children to be given training with a practical commercial emphasis attend the *Mittelschule* ("middle school") or *Realschule* (*Real-* implying "practical"). About 14 percent of all children will be chosen for study at the *Gymnasium*, in which a rigorous program lasting from seven to nine years will prepare them—with emphasis variously on the classics, modern languages, mathematics and natural science, or the fine arts—for the *Abitur* degree, the holding of which until recently forthwith entitled a student to matriculation at any German university.

Tradition and change in German universities

The German universities, famed in history and noted for their enormous contributions to learning, especially in the 19th and early 20th centuries, are undergoing profound upheavals. Since their inception in the late Middle Ages and until recently, the traditions of *Lehrfreiheit* and *Lernfreiheit*—the freedom of what to teach as well as the freedom of how a student could go about his studies and preparations for examinations—were sacred. But the expansion of higher learning, as in other Western countries, and the burgeoning number of students and changing social conditions have taxed the traditional structures of the universities beyond their capacities or their accustomed functions. Today it has become all but impossible for a student to take as long as he wished, often eight to 10 years, to complete his studies with the privilege of moving from university to university as he pleased. Lecture rooms, seminars, and libraries are disastrously overburdened, and the higher education explosion and the knowledge explosion in the past generation have undermined the usefulness of original research as well as the solitary authoritarian position of the one professor who stood at the pinnacle of each discipline in each university.

A general reform of higher education long has been under discussion, but little progress has been made. An attempt to limit enrollments—despite the opening of new universities and enlargement of staffs—has been received with violent hostility by the student population. Ironically, the introduction of patterns inherent in the ancient English model and common throughout the English-speaking world runs so contrary to German academic tradition as to have provoked riots. The student unrests of the late 1960s apparently had subsided by the early 1970s, but how the universities are to be reformed remains not only an open but also a volatile question.

By the late 1970s West Germany will have some 40 institutions of university rank, of which over a dozen are or will be institutes of technology or specialized in medicine, economics, or agriculture. Little or no difference in prestige and no social distinction attach to whether a student studies at Heidelberg, founded in 1386, or at Saarbrücken, founded in 1948. The doctorate is the only degree offered as such (although the *Magister*, or Master of Arts, abandoned in the 17th century, has been partially revived); the state examination, roughly equivalent to the master of arts or a good honours degree, is the level at which most students complete their studies.

An extensive range of possibilities exists for extended education or extramural studies. Upward of 1,500 *Volkshochschulen* ("people's universities") enroll almost 2,000,000 adults for complete courses or individual subjects, whether in preparation for or furtherance of a career or out of personal interest.

Welfare and health. West Germany's system of social benefits is one of the most elaborate and all-embracing in the world. The country's pioneer work in social legislation initiated in the 1880s to cover health and accident insurance, workers' and employees' benefits and pensions, miner's insurance, and the like long anticipated and served as a model for similar programs in other countries.

Compulsory national and private insurance plans

Health and retirement insurance are compulsory for all workers and employees earning below a certain level of income geared to the cost of living. Under German labour law, a categorical distinction is made between workers and clerical and managerial employees, and differing rules and rates apply to each group. Employees above a certain salary level or self-employed persons are generally exempt from most obligatory systems; however, although the former will usually participate in a firm's retirement plan, almost all persons in the upper salary brackets or the self-employed will be covered by private insurance as comprehensive as the government-sponsored plans. With increasing prosperity, an increasing percentage of the population is subscribing to these somewhat more expensive but also more generous private plans. Nearly 90 percent of the population is covered by compulsory health insurance, and West Germany ranks highest among comparable nations of continental western Europe in the proportion of money allowed toward health costs—about 90 percent of medical costs incurred. Contributions range from about 8 to 13 percent of wages or salaries.

Medical personnel and facilities

Medical care is of a high standard, and rural areas are well served. Hospitals, no less plagued by runaway costs and staff shortages than in other industrial nations, are usually operated by the municipalities, religious bodies, or as proprietary operations by one or more physicians. There was one physician in 1970 for every 612 inhabitants, of whom very slightly more than one-half were in private practice; of almost 32,000 dentists, nearly 30,000 were in private practice. The nearly 3,600 hospitals hold upward of 680,000 beds. Public health standards are high. Great inroads have been made in the control of tuberculosis, formerly a disease especially endemic to Germany, and free and quasi-obligatory X-rays are offered by local public health authorities. Compulsory medical checks are made on all immigrants, the majority

of whom are drawn from the Mediterranean countries. The standards of public sanitation are among the highest of any nation.

Accident and retirement insurance are tied in with the health- and medical-care plans. The rate of compulsory accident insurance rises with the risks involved in one's job. The three major pension plans cover miners (the oldest, dating from Bismarck's introductory social legislation), the workers, and employees. In general, men are eligible for retirement at 65 and women at 60, but both sexes may be allowed to retire earlier under special circumstances.

In addition, several special systems of coverage are available for such special groups as war widows, orphans, and farmers. Unemployment insurance is provided through deductions from wages and salaries. Allowances are made for families having more than two children, though a grant in some cases may be made for the second child born. Additional public allowances are granted to persons suffering disabilities from wartime injury, whether as military personnel or as civilians. Some small indemnification has been made to property owners whose holdings lay in the territories now under Polish authority, in the Sudetenland (which reverted to Czechoslovakia after 1945), and (by the early 1970s) in East Germany.

Reparations to the Jewish people and Israel

The Federal Republic, consistent with the role it asserted as the one legitimate successor to the defunct *Reich*, has assumed the immense financial responsibility of making restitution to the Jewish and non-Jewish victims of National Socialism. Claims for properties confiscated under the Nazi regime have been honoured, and Jewish refugees and expellees, the vast majority of whom reside abroad, have been paid indemnifications and pensions. Massive reparations have been paid to the State of Israel in the name of the Jewish people at large. (In contrast, East Germany has failed to make any restitution whatsoever to Jewish victims of Nazi persecution and has made no contributions to the State of Israel, with which it holds no ties.)

Housing. In World War II some 20 percent of all dwelling units in what is now the Federal Republic were either destroyed or rendered uninhabitable; almost half of all housing suffered some damage. The immense job of providing replacements had been largely overcome by the mid-1950s, and by 1965 8,800,000 dwelling units had been built to accommodate some 25,000,000 persons. In the early postwar years, the greater amount of funds for housing construction came from government sources, including foreign aid, and relatively little money could be raised in the capital market. By 1965, however, over two-thirds of the funds emanated from private capital, the remainder from funds set aside by the *Bund*.

Assistance is provided by the *Bund* to every citizen wishing to avail himself of a building savings policy. After a certain minimum contribution by the indivdual has been deposited over a determined period of years, the government provides a housing loan on generous terms for those wishing to build their own house or buy a flat.

West Germany still suffers, nonetheless, from a serious housing shortage. Rents and house prices on the private market are high; the great majority of city dwellers live in blocks of flats or multiple housing units, and until recently private rental property was subject to relatively little control over rents or arbitrary imposition of conditions of rental by the landlords.

Law enforcement. No nationwide police force exists, and law enforcement remains a function reserved to the *Länder*. Each *Land* maintains its own force, the *Landespolizei*, which is charged with all phases of enforcement throughout each *Land* except where their function is assumed by a municipal police force. In a state of national emergency the *Bund* may commandeer the services of the various Landespolizei units, together with the standby police reserve that is trained and equipped by each *Land* for action during civil emergencies. Federal offices investigate certain actions, however, notably those inimical to the security of the state or criminal actions that transcend the confines of the *Länder*, and one assists the provincial and municipal units as a clearing agency, the Bundeskriminalamt (Federal Crime Agency), on criminals and criminal actions.

Standards of living. Despite recent sharp rises in the cost of living, the German wage earner still enjoys a relatively high and stable standard of living. As in most countries of EEC, food prices are high in relation to income. The average German consumer, if not the large exporter or farmer, benefitted to a small extent when the value of his mark increased during and after 1969—by some 10 percent in relation to the currencies of neighbouring countries and by almost 25 percent in relation to the United States dollar.

The distribution of wealth in Germany compares favourably with that of other advanced nations. Wages in the lower paid occupations are adequate if not high, while salaries in the medium range are only moderately higher. Thus, no exaggerated discrepancy exists between the rewards of blue-collar versus white-collar workers. The salary range may rise precipitously, however, above a certain level of management, and since, as in other EEC countries, a major portion of tax revenue derives from excise levies and valued-added tax, the low- and medium-income earners bear the greatest burden.

VI. Cultural life and institutions

The Federal Republic of Germany, as heir to the older regions of the *Reich*, is custodian to the greater portion of its rich cultural legacy. The major wealth of Germany's architectural monuments—of Roman Germany, of medieval Romanesque, of south German Baroque—fell within the borders of West Germany, as did many of the great libraries and archives, art treasures, and facilities for the performing arts. Much of incalculable value in the tangible heritage of the past lies in the trusteeship of the German Democratic Republic, which contains the Wartburg of Luther, the Weimar of Goethe, the Leipzig of Bach; a large share of prewar Berlin's art treasures now rests in the Eastern Sector, notably the Pergamon Museum and its archaeological holdings; and the Baroque monuments of Dresden savagely destroyed in World War II have undergone restoration. It would be untrue and unfair to assert that East Germany has been negligent in sustaining, within its resources, its share of the older Germany's cultural monuments and institutions. The archives, buildings, and museums pertaining to Germany's golden age of literature have been carefully restored at Weimar; the choir of St. Thomas' Church at Leipzig still continues in unbroken continuity since the days of Bach and before; Leipzig's Gewandhaus Orchestra, Dresden's Kreuzchor, and the German State Opera in East Berlin all maintain the high standards of the past.

But after the division of Germany, many of the cultural assets originally in the East were removed to the West. Many of its artists and writers and also entire institutions, such as a number of illustrious publishing houses, transplanted themselves or set up successor organizations in the Federal Republic. Although the older cultural traditions have been well served in East Germany, it has become virtually sterile ground for any great contributions to the arts—with the notable exception of Berliner Ensemble, the theatrical company founded and once directed by Germany's pre-eminent modern playwright, Bertolt Brecht, and his wife, Helene Weigel. In the Federal Republic, the German cultural tradition has been unimpeded by the strictures of political doctrine and flourishes with vigour and in abundance.

THE CULTURAL MILIEU

Governmental and audience support. For four centuries, Germany has enjoyed a tradition of governmental support of the arts. Before the founding of the *Reich*, the many small kingdoms, principalities, duchies, bishoprics, and free cities that preceded modern Germany—as well as Austria and German-speaking Switzerland—supported the arts; established theatres, museums, and libraries; and acted as patrons to poets, writers, painters, and performers. The institutions thus founded and the convention of generous public support has continued uninterrupted.

The quantitative dimensions of Germany's cultural life

astound foreigners. In the Federal Republic alone some 195 theatres are subsidized, about 85 by the Bund and the *Länder* and about 110 by the cities, in addition to upwards of 70 privately financed theatres. Within this system of theatres are over 50 opera companies. Unlike the United States, Britain, and France, in which theatre is more often than not centred in one city, no one city in Germany dominates over the others. Productions in Vienna or Zürich are significant to the artistic life of the Federal Republic, and artists and resources move easily and freely among the theatrical and operatic companies within the German-speaking regions. Only in Vienna, in which capital the arts arouse passions far more intense than those of politics, does theatre have a broader audience base than in Germany. Audiences in Germany are not limited to a small intellectual or social elite but are drawn from all ranks of society. Season tickets, group arrangements, bloc tickets bought by companies, and theatre clubs constitute the major part of the regular patronage of such production companies as the Theater der Freien Volksbühne (Free People's Theatre), dating from 1890 in Berlin. Going to the theatre or opera in Germany is about as inexpensive and as commonly done as attending the films would be elsewhere.

Theatrical and musical traditions

The same is true of concert music. Every major city has one or more symphony and chamber orchestras offering many concerts and recitals each week; the music and concert fare is less well provided for in the smaller cities and towns only in terms of quantity and, perhaps, professional quality. Musical festivals are a prominent feature in the calendar of the performing arts in Germany. The most renowned, the annual Wagner Festival held each summer in Bayreuth, is still under the direction of Wagner's descendants. Others of note are the autumn Berlin Festival, the May Festival in Wiesbaden, the Beethoven Festival in Bonn, the Mozart Festival in Würzburg, and the Festival of Contemporary Musical Art in Donaueschingen.

Music festivals

The greatest annual event in German music, the Salzburg Festival, is held across the Bavarian border in Austria. But in German, the adjective *deutsch* ("German") implies no strict nationality when referring to the arts, whether German, East or West, Austrian, or Swiss. Unlike the usage of the English-speaking world, the German-speaking nations will refer to Friedrich Dürrenmatt, a playwright of Swiss nationality, as a German writer or to the Austrian Mozart as a German composer, for they are all in the German cultural tradition.

Museums, libraries, and publishing. West Germany has more than 500 museums of all descriptions, ranging from some of the world's great collections of paintings and sculpture or of archaeological and scientific displays to exhibitions of minutiae such as those in the playing-card museum in Stuttgart. The western portions of Germany contain the greater amount of the nation's prewar art treasures. In addition to West Berlin's museum, museums and art galleries of great note are the Alte Pinakothek in Munich, with its unrivalled Rubens collection, the German Museum in Munich, the Roman-Germanic Museum in Mainz, the Senckenberg Museum of Natural Science in Frankfurt am Main, and the Alexander König Museum of Zoology in Bonn. Important individual art treasures are scattered in the scores of smaller museums, libraries and archives, cathedrals, churches and monasteries, and castles throughout the country. Special exhibitions are frequently held, one of the most outstanding of which was the 500th-anniversary celebration in Nürnberg in 1971 of Albrecht Dürer, which displayed almost every accessible work of the great Renaissance master.

Among the great libraries in Germany are the Bavarian State Library in Munich, the nation's largest, and portions of the former Prussian State Library that were removed to Marburg and are known as the West German Library. The German Library at Frankfurt am Main is the country's bibliographical centre; the Technical Library at Hannover is the most important for science, technology, and translations of works in the sciences and the engineering field. Apart from the great university libraries at Heidelberg, Cologne, Göttingen, Tübingen, and Munich, a wealth of ancient manuscripts, early printed works, manuscripts, and documents are in diverse collections. The great research libraries are complemented by an extensive system of lending libraries operated by the *Länder*, the municipalities, the library associations of the Roman Catholic and Evangelical Churches, and other public associations and institutes; virtually no citizen is out of easy reach of a free lending library.

Germany is a major publishing nation, with nearly 2,500 publishing houses. Few of these are on the scale of the giant houses known in British and American publishing, and most quality titles are published by prestige houses of small to moderate size. Academic and educational publishing is undertaken by scores of smaller houses. Over 900 publishing enterprises serve also as retail booksellers. In 1971, over 47,000 books were published in the Federal Republic, almost 39,000 of which were new titles.

CURRENT STATE OF ARTISTIC PRODUCTION

In no country in the world are the arts so lavishly cultivated as in the Federal Republic in terms of the proliferation of cultural amenities, the funds allotted to them, and the attendance upon them. Notwithstanding this abundance and generous support, relatively few major talents of international renown have emerged in the major fields of the fine arts in the postwar years, especially in comparison to the era of the Weimar Republic, when Germany (especially Berlin) experienced a resurgence in the arts and a proliferation of innovative talents unparalleled since the ages of German classicism and romanticism in the late 18th and early 19th centuries.

Sparsity of contemporary artistic contributions

Literature and theatre. German literature holds less than its deserved status in world literature in part because the lyrical qualities of its poetry and the nuances of its prose are ill served by translation. Even the most sublime of figures in German literary history such as Goethe and Schiller are doomed to remain known to the world largely by reputation. In the 20th century perhaps four German poets and writers have won a permanent niche in world literature—Franz Kafka, Thomas Mann, Rainer Maria Rilke, and Bertolt Brecht, all of whose works date from the early decades. Of German novelists since the war, only two have been published widely in translation abroad—Heinrich Böll and Günter Grass; among the playwrights (apart from Brecht and Carl Zuckmayer, whose major plays extend from the 1920s to the mid-1950s), the works of Siegfried Lenz and Peter Weiss have been well received abroad.

The German theatre today is thus presented with the dilemma of either relying on the rich repertory of German classics from the 18th and 19th centuries, along with a restricted number of truly great modern dramatic works, or of producing plays, in not always the most successful of translations, of leading British, American, and French authors. Small experimental theatres enjoy a lively and hazardous existence in the major cities and supplement and often closely resemble Germany's long-lived and still lively convention of political cabaret.

A major innovation to the German stage has been its adoption of the American musical. Ever since a game and gingerly attempt was made at Cole Porter's *Kiss Me Kate* (*Küss mich Kätchen*) in Berlin in 1955, this most indigenously Broadway of genres is now widely enjoyed throughout Germany; four separate productions of *Hair* (*Haar*) played to fully booked audiences concurrently from 1969 until 1971.

Music and dance. The performance of both operatic and concert music in the Federal Republic, as elsewhere, is faced with the dilemma of the public's preference for 18th- and 19th-century composers as opposed to the producers' and artists' wish to give contemporary works a better hearing. The works of Hans Werner Henze, whose opera *The Young Lord* is widely performed abroad, the symphonic works of Gottfried von Einem, and the avant-garde electronic music of Karlheinz Stockhausen have established these men as the most widely known of contemporary German composers. The Berlin Philharmonic, the Bamberg Symphonic Orchestra, and the Stuttgart

Chamber Orchestra continue to rank with the leading world ensembles. Innumerable German operatic voices have gained world renown, but an interesting phenomenon in recent decades has been the many North American and British voices who, lacking suitable outlets for their careers at home because of the few opera companies there, have trained in Germany and Austria and stayed on to perform on their stages. A refreshing trend in contemporary opera is the fading of the old insistence that the librettos be sung in German translation.

A conspicuous international success in the performing arts has been that of the Stuttgart Ballet under the direction of the South African-born John Cranko. German ballet, so often overshadowed by the Russian and English conventions, has been thrust into pre-eminence by the Württemberg State Theatre's company, which performs frequently in the major cities of the West and also has won acclaim by Russian audiences—the world's most critical—on its visits to the Soviet Union.

The visual arts. Contemporary painting has moved from under the dominance of the Expressionist mode dating back to the Dresden school known as Die Brücke (The Bridge) of the early 20th century and such successor movements as Die neue Sachlichkeit (Neo-Objectivity) of the 1920s, in which an emotive or subjective suggestion of reality was achieved by contorting or exaggerating natural forms. The greater number of younger painters have turned to the problems of abstraction and the eclectic experiments preoccupying artists in other Western countries; many concern themselves principally with graphic design or drawings. In sculpture, a similar nonparochially German trend is apparent in the drift from the conservatism of the older national sculpture to experiments in abstraction and the use of unconventional materials.

Increasing internationalism of painting and architecture

German architecture today—indeed world architecture today—is still very much the creature of the Bauhaus school, originating in Dessau in the 1920s. The basic ideals of its leading exponents, such as Walter Gropius and Mies van der Rohe, a spartan harmonizing of function with design, still prevails. This has been profoundly mitigated, however, by a less puritan decorativeness, by the social dictates of harmonizing the new with the old in rebuilding the cities and restoring old monuments, and by the exigencies of soaring building costs. Contemporary architecture—especially as evident in major commercial and public projects or housing estates on the outskirts of the larger cities, which are freed from an obligatory conformity with the existing architecture of the inner city—reflect a marked cosmopolitanism no longer identifiably German or even northern European in cast.

Traditional arts and crafts. The incursions of modern patterns of life have done much to weaken the traditional arts, entertainments, and customs of regional and rural Germany. In southern Germany the older arts and usages have persisted concurrently with a gradual adaptation to a modern, urban pattern of life; the old and the new coexist in an incongruous compatibility. The young still dance around the village maypole, but they also dance to rock. The woodcarvers, violin makers, and gunsmiths of Upper Bavaria continue, with increasing economic hardship, to follow their trades, not because it is quaint but because they still believe in them; the rural women in the Black Forest still wear elaborate costumes known as *Tracht* on festival days, not to amaze tourists but because they have always done so—yet these are the areas in which the tourist industry is most highly developed. Some usages have all but disappeared in the villages: older women now seldom wear black dresses and scarves, and the village men no longer appear in top hat and cutaway for a funeral procession.

Popular festivals still abound. Near-heathen usages such as the elaborate wooden masks that surround the pre-Lenten celebrations in southwestern Germany remain unaffected in spite of being televised; hundreds of smaller towns and larger villages in the south still commemorate an anniversary from the Thirty Years' War by a parade in 17th-century costume or, in Catholic areas, march in full procession on Corpus Christi Day. What is remarkable is not merely that these usages survive but also that the homelier and less celebrated of them remain truly genuine and naïve in the observance.

Popular culture. In contrast to the situation after World War I, when Germany helped set the pace in many of the popular forms of art and entertainment, most conspicuously in developing the film as a genre in its own right, modern West Germany has never been able to regain a métier of its own—with the exception of the political satires presented in scores of cabarets. In the cinema, the important pioneer films of Georg Wilhelm Pabst, Fritz Lang, and others were succeeded in the postwar years by farces and romances of so meagre a substance as to defy explanation in a nation so given to the performing arts. Television entertainment is of mixed quality, relieved in part by the occasional original play written for the medium or adapted from the stage. Many foreign imports are carried, mostly American and British television series and older films, the sound tracks dubbed into German.

Films and television

Styles in popular music have found no indigenously German vehicle of expression—nothing to compare, for example, with the world-weary and vaguely wicked Berlin chanson of the 1920s. Only slavish (if technically competent) copies of contemporary styles from abroad are heard along with the never-changing fund of conventional dance music. The tango still lives; no revival of the so-called big band sound of the 1930s was required in West Germany, since it never had waned.

CULTURAL INSTITUTIONS

Great importance has been attached in the Federal Republic to the support of the nation's cultural, educational, and scientific resources through institutions supported in whole or part by public funds. A prodigious complex of organizations are devoted to acquainting the public with the culture, life, and language of the German peoples and of making the culture and life of other nations more familiar. Cultural representation abroad and cultural exchanges are maintained in abundance with the advanced industrial nations of the West and, increasingly, with eastern Europe, but special emphasis is laid upon the development of cultural ties with the developing nations of the world. West Germany not only has assumed a major role in lending reserves of technological skill and capital to developing the resources of the lesser or non-industrialized nations; it also has become a major centre for the education and training of students from these countries in the professions, the sciences, and technology.

International cultural activities

Prominent among these groups is Inter Nationes, a nationwide organization devoted to the higher levels of cultural representation abroad through the media of books and films and to fostering a better understanding of the arts and education in the Federal Republic by sponsoring the visits of leading persons in these fields from abroad. A similar task is performed by the Institute for Foreign Relations and several bodies devoted to academic exchanges.

The massive task of making the German language and literature accessible to peoples abroad and of introducing them to German life and civilization falls in largest measure to the Goethe Institute in Munich. Through its 21 schools within the Federal Republic and more than 120 branches abroad, it sponsors intensified courses in German, with a practical emphasis on its use in daily life, and operates libraries and German cultural centres in the host countries. Its work is complemented by more than 70 German cultural institutes of various sponsorship abroad, prominent among them the jointly German–American-subsidized Goethe House in New York City.

Learning, the arts, the social sciences, and the natural sciences and technology are fostered by a proliferation of foundations, academies, and institutes. A series of learned journals published in Tübingen records the progress made in German research in all branches of learning. A great variety of major social projects and research, both in the Federal Republic and abroad, is sponsored by foundations established by the larger commercial and industrial corporations.

THE COMMUNICATIONS MEDIA

Newspapers and magazines. West Germany is very much a land of newspaper and periodical readers. Freedom of the press is guaranteed under law, and the economic state of its some 430 daily and 60 weekly newspapers and more than 870 magazines and journals, by comparison to the situation in similar nations, is enviably healthy. Most major cities support two or more major newspapers in addition to community periodicals, and few towns of any size are without their own daily. Although rising costs are endangering this abundance and consolidations and takeovers are narrowing the basis of ownership, few nations are so prodigiously served by the press. A national press similar to that in England has developed through such newspapers not identified with any one city as *Die Welt* and the weeklies *Die Zeit* and *Deutsche Zeitung*, in addition to certain municipal newspapers read throughout the nation—some of ranking international stature—such as the *Frankfurter Allgemeine Zeitung*, the *Süddeutsche Zeitung* of Munich, the *Stuttgarter Zeitung*, and Koblenz's *Rheinischer Merkur*. An important and enormously influential segment of the press is under the proprietorship of Axel Springer Verlag. Its empire includes five newspapers complemented by a wide spectrum of popular magazines. The Springer newspapers account for over one-fourth of all newspaper sales in the Federal Republic.

The genre of the *Illustrierte* dominates the German magazine market. Some few of these popular glossies, on a par with *Paris Match*—*Stern* foremost among them —feature investigative reporting of a high calibre; most, however, cater to the public's appetite for the escapades of celebrities, especially members of royal families and entertainers, and for bizarre crime, gracious living, and other trivia. Apart from a wealth of specialized journals and quality business-oriented magazines, the Federal Republic lacks prestigious magazines of opinion, a function served in some measure by the weighty weekend editions of the quality press.

A solitary power in political journalism, the weekly news magazine *Der Spiegel* has performed a unique function in the shaping of West German public opinion through its posture of the skeptical, nonaligned observer and guardian of the public conscience. Exhaustive in its coverage and invariably polemic in tone, it features in-depth muckraking investigations of the distant past and of contemporary affairs.

Broadcasting. Radio and television operate as public corporations under the authority of the Federal Ministry of Post and Telecommunications, which tenders broadcast licenses, assigns frequencies, and collects public revenues from fees levied on owners of radio and television sets. The individual corporations are otherwise free to establish their own broadcasting policies. Attempts to control these policies, which often are hostile to incumbent governments, have been rebuffed repeatedly, so that German television, in practice more than radio, is able to assert remarkable latitude and independence in the tenor and content of its broadcasts.

Radio is arranged along regional lines, with some 10 corporations engaged in local broadcasting. Each may operate two or more separate programs on various frequencies. Each corporation is independent of the other, but programs and facilities are shared. In addition, the Deutsche Welle broadcasts around the world in 30 languages. The *Deutschlandfunk* is a national program beamed at all Germany and Europe.

Two television networks, operating through two separate channels, transmit nationwide programs incorporating the full range of news, documentaries, and entertainment through the facilities of the regional broadcasting corporations, each of which appends its own television coverage and has full responsibility for programming on a third channel intended to function region by region as an educational and fine-arts medium. The uneven quality of the entertainment fare in both radio and television is offset by high-quality news coverage and political and social reporting.

VII. Prospects

Over the centuries, Germany has been a name in search of a nation, a nation in search of a state, a state in search of a role. Even Bismarck's creation of the *Reich* in 1871 only lasted a generous lifespan of 74 years of the two millennia of recorded German history, and it was accomplished only by excluding Austria, the once-dominant state among the lands once known as Germany. The German peoples, who in recent generations have had to come to grips more than once with what had been the unthinkable, may never succeed in realizing a precisely defined, geographically tidy concept of Germany. But if by analogy to the Anglo-Saxon nations and the Hispanic lands there may be several German states—not only the German Democratic Republic but also Austria, much of Switzerland, even Luxembourg and Liechtenstein—the Federal Republic of Germany, as the mainspring of the German peoples' language and culture, as heir to the oldest portions of the country, and as custodian of the title, seems best entitled to bear the ancient name.

Reunification, a hope that had already dimmed by the mid-1950s, later appeared impossible. The Socialist government's 1969 submission that there were two German states within one German nation appeared unlikely to satisfy either portion of a country that had been fully divided since 1949. The Federal Republic is firmly integrated into the Western political system, the German Democratic Republic into the Eastern. Their economic, political, and legal structures appear to have grown too far apart to be mutually compatible; notwithstanding the strongest ties of kinship and the bitter personal hardships of separation, the two societies have moved so far apart with the passage of time that the estrangement scarcely can be reversed.

From its beginnings, the Federal Republic has implicitly proceeded on these assumptions of a harsh political reality. Whatever its people may hold of the past, they cherish no fond hopes that it will be recouped, assuredly not in terms presently imaginable. Instead, they have devoted the considerable human resources of the nation into building not merely what many believe to be one of the sturdiest of the world's democracies but also one of the mightiest of the world's national economies. In so doing, the Federal Republic has seemingly laid a firmer and more lasting basis for a rightful German role in the world than its predecessor state could have sustained by military might. In 1830 the Prussian military theorist Karl von Clausewitz wrote that war is a continuation of diplomacy by other means. In its reaffirmed goals of working toward a united Europe, of using its offices to strengthen the cause of peace, and of lending its formidable assets to relieve imbalances in the potentials of the weaker nations, the Federal Republic of Germany, many believe, may prove itself an example to the world—a paradoxical turn of von Clausewitz's dictum of how to extend a nation's policy through truly "other means."

BIBLIOGRAPHY. The best general geography of Germany in English is THOMAS H. ELKINS, *Germany* (1968), while MICHAEL WINSCH, *Introducing Germany*, new ed. (1967); MARGARET WIGHTMAN, *The Faces of Germany* (1971); and the *Nagel Travel Guide to Germany*, 3rd ed. (1968), are readable and informative for their detailed descriptions region by region, city by city, and for the treatments of such ancillary topics as German history, geography, cultural life and folklore, the news media, and the economy. The definitive source for figures and details on population, infrastructure, and the economy is the annual edition of the *Statistisches Jahrbuch* published by the Federal Republic's *Statistiches Bundesamt* in Wiesbaden; details of all major public institutions are reflected in ALBERT OECKL (ed.), *Taschenbuch des öffentlichen Lebens* (annual). West Germany's standard reference book is *Der Grosse Brockhaus*, a revised edition of which has been appearing serially since 1966.

Of the prolific body of works on the Federal Republic, an abundance of titles dating from the late 1960s serves well to complement or supplant treatments available in English that rapid changes have in large measure superseded. For informative general accounts of the country, the people, the regions, and the historical, political, economic, and cultural background, see J.P. PAYNE (ed.), *Germany Today: Introductory Studies* (1971); and, with scholarly emphasis on the current

state of institutions and the arts, MALCOLM PALSEY (ed.), *Germany: A Companion to German Studies* (1972), intended as a successor volume to JETHRO BITHELL's classic of the same title (1932), never revised but ever valuable for its historical perspectives. RUDOLF LEONHARDT's perennially successful collection of observations and speculations about his country, *X-Mal Deutschland*, 11th ed. (1971), is available in English as *This Germany* (1964). TERENCE PRITTIE, long a senior foreign correspondent in Bonn, has contributed the volume *Germany* (1965) in the "Time-Life Series."

An intimate view of modern Germany and its people as recalled from the author's own career, together with insights into the historic and philosophic background seldom emphasized by foreign commentators, may be found in GEORGE BAILEY, *Germans: The Biography of an Obsession*, new ed. (1972). A further authoritative summation of the history and institutions of the Federal Republic since its founding, with comparisons to developments in East Germany, is offered in ALFRED GROSSER, *L'Allemagne de notre temps, 1945–1970* (1970; Eng. trans., *Germany in Our Time*, 1971). The U.S. journalist ADOLPH SCHALK gives a comprehensive view of contemporary German life in *The Germans* (1971).

A trenchant critique of German democracy, marred by its neglect of accomplished political fact, is notable for the reputation of its author, the philosopher-theologian KARL JASPERS, in *Wohin treibt die Bundesrepublik*, pt. 3 (1966; Eng. trans., *The Future of Germany*, 1967); RALF DAHRENDORF, the German sociologist and statesman, has contributed an account of especial interest to foreigners in *Gesellschaft und Demokratie in Deutschland* (1968; Eng. trans., *Society and Democracy in Germany*, 1969). Other works with particular attention to West German government and politics are R.B. TILFORD and R.J. PREECE, *Federal Germany: Political and Social Order* (1969); OTTO SIEGNER, *Germany* (1970); GWENDOLEN M. CARTER and JOHN H. HERZ, *The Government of Germany*, 5th ed. (1967); GERHARD LOEWENBERG, *Parliament in the German Political System* (1967); JOHN C. LANE and JAMES K. POLLACK (comps.), *Source Materials on the Government and Politics of Germany* (1964); ELMER PLISCHKE, *Contemporary Governments of Germany* (1969); and KARL KAISER and ROGER MORGAN (eds.), *Britain and West Germany* (1971).

German popular culture and folkways are discussed in MARION ADAMS, *The German Tradition* (1971); and LAVERN RIPPLEY, *Of German Ways* (1970). One major aspect of German popular arts is treated in ROGER MANVELL and HEINRICH FRAENKEL, *The German Cinema* (1971).

(G.H.K.)

Germany, History of

This article traces the history of Germany from the breakup of the Carolingian Empire in the mid-9th century to the present. For the early history of the Germanic peoples, see GERMANS, ANCIENT; for the history of Germany from the 6th to the 9th centuries, see MEROVINGIAN AND CAROLINGIAN AGE.

The article is divided into the following sections:

I. Germany until c. 1250

THE DISINTEGRATION OF THE CAROLINGIAN EMPIRE

The kingdom of Louis the German. Louis I the Pious, Charlemagne's successor as emperor, was not unpopular with his German subjects; on two occasions he owed his restoration to power largely to their support. In 825 one of his sons, Louis the German, was entrusted with the government of Bavaria, whence he was gradually to extend his power over all Carolingian Germany. This was

the first time that the German nations had had a ruler whose authority was confined to their own lands and whose time was largely taken up with defending them from Slav penetration; but this was by no means the sum of ambition for Louis the German, who tended, like all his house, to regard the whole of Franconia as a divisible family inheritance of which each member in each generation should take for himself and his followers what he could get. Louis was thus satisfied neither with the partition treaty of Verdun (843), by which he obtained the bulk of the lands east of the Rhine together with the districts around Mainz, Worms, and Speyer on the left bank, nor with that of Mersen (870), by which he and his half brother the West Frankish king Charles the Bald came to terms over Lotharingia, the middle kingdom of their nephew Lothair that generally comprised the Low Countries, northwest Germany, and northeast France. Under the Treaty of Mersen Louis's dominions reached almost the proportions of medieval Germany. On the east they were bounded by the Elbe and the Bohemian mountains; on the west, beyond the Rhine, they included the districts afterward known as Alsace and Lorraine. Ecclesiastically, they included the provinces of Mainz, Trier, Cologne, Salzburg, and Bremen. But Charlemagne's capital at Aachen and the rich family estates in Lotharingia were never finally abandoned by either branch of the Carolingian dynasty, although the bulk of the lands that they controlled increasingly assumed the separate outlooks of France and of Germany. An example of this increasing separation is provided by the oaths sworn at Strasbourg in 842 by Louis and Charles, the former swearing in his brother's language, Romance, the latter, conversely, in German; but this drifting apart is in some ways less significant than the ties that still held France and Germany together.

Partition treaty of Verdun

The ceaseless external blows from Danes, Saracens, and Magyars that fell upon the Carolingian world in the 9th century did not have the effect of uniting it in resistance. Not only the Carolingians themselves but their followers also were prepared to take advantage of each other, to compromise with the enemy and to carve out even more dominions from each other's lands. The motives that led them to behave that way, however, were not so simple as they may now at first appear. For instance, in 887, Arnulf, an illegitimate son of Louis the German's son Carloman, led an army of Bavarians against Charles the Fat, in part because Charles was not defending the Rhineland from the ravages of the Danes, in part because his aim was the full Carolingian inheritance. But Arnulf was not equally successful in defending his eastern possessions. After his death in 899, the German kingdom came under the nominal rule of his young son, Louis the Child, and in the absence of strong military leadership became the prey of the Magyar horsemen and other invaders from the east.

Barbarian invasions

Rise of the duchies. The rise of the German duchies was a direct outcome of the Carolingian decision, avoidable or not, to leave defense in the hands of those who were attacked; in other words, to decentralize military command and with it, inevitably, something else of the royal authority. The new *duces* were neither, as was once thought, appointed by the peoples concerned, nor were they the descendants of the tribal chieftains of the post-migration period. It seems more likely that they were Carolingian counts who took the initiative in organizing defense on a local basis, without thereby seeking to shake men's loyalty to the house of Charlemagne, of which the German church was a natural champion. All the same, their initial success established them in the hearts of those whom they protected. This was particularly true of the Saxons, whose dukes, the Liudolfings, were descended from the military commanders first sent by Louis the German to defend eastern Saxony. Similarly, the Swabian dukes began with a military title (*duces Raetianorum*), as did the Bavarian ducal family of Liutpold. The origins of the short-lived duchy of Thuringia are less easy to determine. Franconia naturally remained the German duchy most intimately associated with the East Frankish kingship. How, in practice, the lives of the German land-owning or land-renting freemen were affected by these changes is a matter largely of guesswork. Perhaps it is true that political insecurity and its economic consequences tightened the lord–vassal relationship, as in France and elsewhere (see MIDDLE AGES). Nothing is more striking, however, than the region-to-region variety of German social organization. Perhaps much more of tribal ways of local government survived the Carolingians and the Magyars than had once been thought possible.

Development of lord–vassal relationship

(Ed.)

THE 10TH AND 11TH CENTURIES

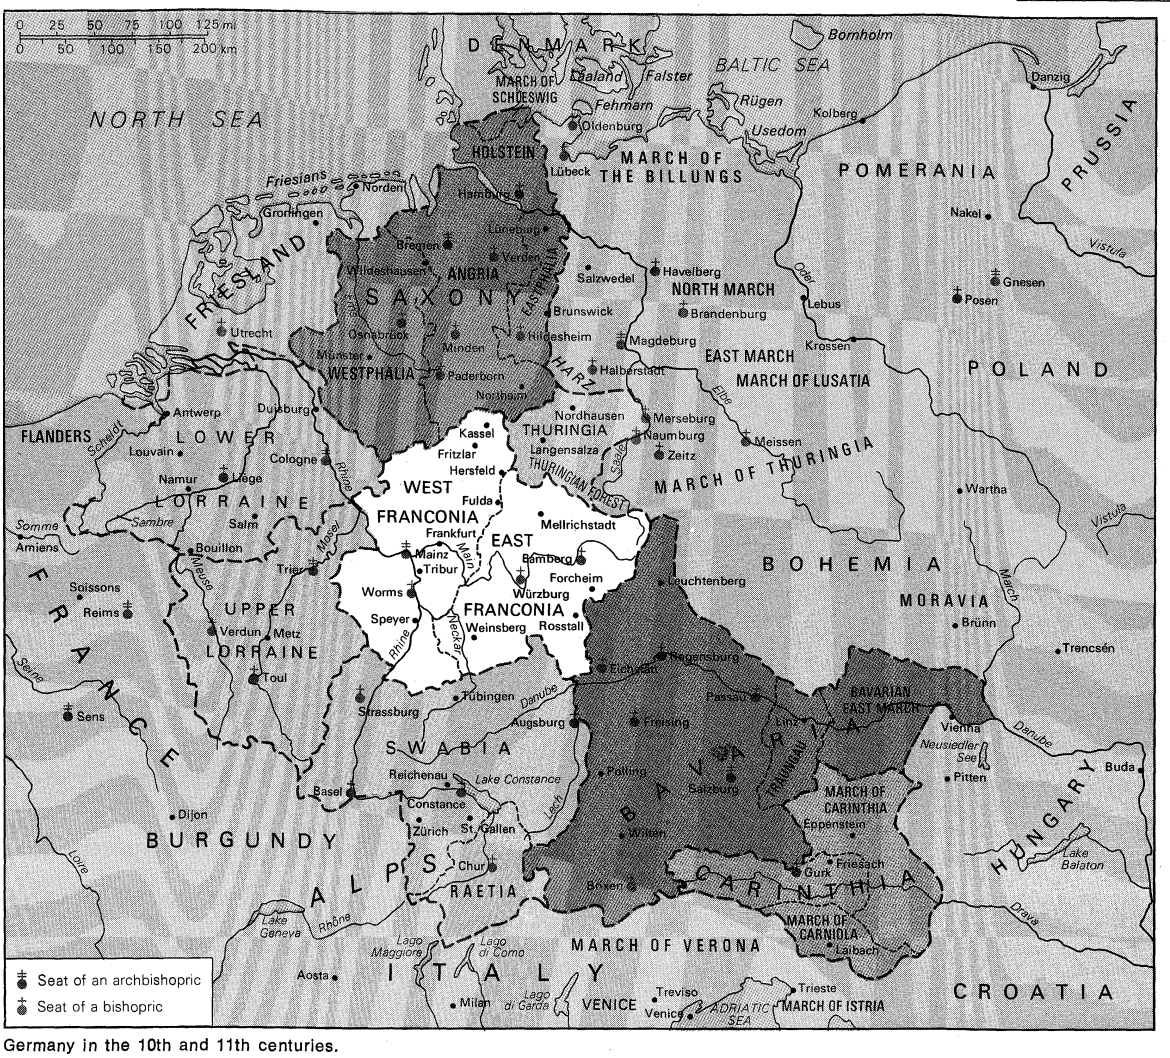
Conrad I (911–918). When in 911 Louis the Child, last of the East Frankish Carolingians, died without leaving a male heir, it seemed quite possible that his kingdom would break into pieces. In at least three of the four stem lands, Bavaria, Saxony, and Franconia, the ducal families were established in the leadership of their tribes; in Swabia (Alemannia) two houses were still fighting for hegemony. Only the church, fearing for its endowments, had an obvious interest in the future of the monarchy, its ancient protector. Against the growing authority of the dukes and the deep differences in dialect, in customs, and in social structure between the tribes there stood only the Carolingian tradition of kingship; but, with Charles the Simple as holder of the West Frankish kingdom, its future was certain and not very hopeful. Only the Lotharingians put their faith in the ancient line and did homage to Charles, its sole reigning representative. The other component parts of the East Frankish kingdom did not follow suit.

One can only guess at the motives of the Saxon and Frankish tribal hosts who on November 10, 911, elected Conrad, duke of the Franks, as their king at Forchheim in Franconia. At the opening of the 10th century the Germanic peoples in the lands east of the Rhine and west of the Elbe, the Saale, and the Bohemian forest—as rude and as thinly spread as their settlements were—had to face even more savage and pagan races pressing in from farther east, especially the Magyars. The Saxons, headed by their duke Otto of the house of the Liudolfings, were threatened by more enemies on their frontiers than any other tribe; Danes, Slavs, and Magyars simultaneously harassed their homeland. A king who commanded resources farther west, in Franconia, might therefore prove to be of help to Saxony. The Rhenish Franks, on the other hand, did not wish to abdicate from their position as the leading and kingmaking people, which gave them many material advantages.

Struggle against the Magyars

Conrad of Franconia, elected by Franks and Saxons, was soon recognized also by Arnulf, duke of Bavaria, and by the Swabian clans. In descent, honours, and wealth, however, Conrad was no more than the equal of the dukes who had accepted him as king. To gain a lead over them, to found a new royal house, and to acquire those wonder-working attributes that the Germans venerated in their rulers long after they had been converted to Christianity, he had yet to prove himself able, lucky, and successful. In this period, political affairs became the monopoly of the German kings and a few score families of great magnates. The reason for this concentration of power was that, at the very foundation of the German kingdom, circumstances had long favoured those men whom birth, wealth, and military success had raised well above the ranks of the ordinary free members of their tribe. Their estates were cultivated in the main by half-free peasants—slaves who had risen or freemen who had sunk. The holdings of these dependents fell under the power of the lord to whom they owed service and obedience. Already they were tied to the lands on which they laboured and were dependent on their protectors for justice. For many reasons ordinary freemen tended generally to lose their independence and had to seek aid from their more fortunate and powerful neighbours; thus, they lost their standing in the assemblies of their tribe. Everywhere, except in Friesland and parts of Saxony, the nobles wedged themselves between king or duke and the rank and file. They alone could become prelates of the church, and they alone could compete for the possession

Development of serfdom



Germany in the 10th and 11th centuries.

and enjoyment of governmental rights. At the level below the dukes, the bulk of administrative authority, jurisdiction, and command in war lay with the margraves and counts, whose hold on their charges developed gradually into hereditary right. The commended men and the half free disappeared from the important functions of public life. In the local assemblies they came only to pay dues and to receive orders, justice, and penalties. Their political role was passive. Those lords whose protection was most worth having also had the largest throng of dependents and thus became more formidable to their enemies and to the remaining freemen. Lordship and submission to it were hereditary, and thus the horizon of the dependent classes narrowed until eventually the lord and his officials filled the place of all secular authority and power in their lives. Military strength, the possession of arms and horses, and tactical training in their use were decisive. Most dependent men were disarmed; that became part of their degradation.

The accession of the Saxons. Conrad I was quite unequal to the situation in Germany. According to the beliefs of contemporaries, his failure meant that his house was luckless and lacked the prosperity-bringing virtues that belonged to true kingship. On his deathbed in 918, he therefore proposed that the crown, which in 911 had remained with the Franks, should now pass to the leading man in Saxony, the Liudolfing Henry (later called the Fowler). Henry I was elected by the Saxons and Franks at Fritzlar, their ancient meeting place, in 919. With a monarch of their own race, the Saxons now took over the burden and the rewards of being the kingmaking people. The centre of gravity shifted to eastern Saxony, where the Liudolfing lands lay.

The election of Henry I the Fowler

The transition of the crown from the Franks to the Saxons for a time enhanced the self-sufficiency of the south German tribes. The Swabians had kept away from the Fritzlar election. The Bavarians believed that they had a better right to the Carolingian inheritance than the Saxons (who had been remote outsiders in the 9th century) and in 919 elected their own duke Arnulf as king. They, too, wanted to be the royal and kingmaking people. Henry I's regime rested in the main on his own position and family demesne in Saxony and on certain ancient royal seats in Franconia. His kingship was purely military. He hoped to gather authority by waging successful frontier wars and to gain recognition in the first place by concessions rather than to insist on the sacred and priestlike status of the royal office that the church had built up in the 9th century. At his election he refused to be anointed and consecrated by the Archbishop of Mainz. In settling with the Bavarians, he abandoned the policy of supporting the internal opposition that the clergy offered to Duke Arnulf, a plank to which Conrad had clung. To end Arnulf's rival kingship, he formally surrendered to him the most characteristic privilege and honour of the crown: the right to dispose of the region's bishoprics and abbeys. Arnulf's homage and friendship entailed no positive obligations toward Henry, and the Bavarian duke pursued his own tribal interests—peace with the Hungarians and expansion across the Alps—as long as he lived.

From these unpromising beginnings the Saxon dynasty not only found its way back to Carolingian traditions of government but soon got far better terms in its relations with the autonomous powers of the duchies, which had gained such a start on it. But the constitution that it bequeathed to its Salian successors was self-contradictory; while seeking to overcome the princely aristocracies of

Reliance on the clergy

the stem lands by leaving them to themselves, the Saxon kings came to rely more and more, both for the inspiration and for the practice of government, on the prelates of the church, who were themselves recruited from the ranks of the same great families. They loaded bishoprics and abbeys with endowments and privileges and thus gradually turned the bishops and abbots into princes with interests not unlike those of their lay kinsmen. These weaknesses, however, lay concealed behind the personal ascendancy of an exceptionally tough and commanding set of rulers up to the middle of the 11th century. Thereafter, the ambiguous system could not take the strain of the changes fermenting within German society and even less the attack on its values that came from without—from the reformed papacy.

The Liudolfing kings won military success, and with it they gained that respect for their personal authority that counted for so much at a time when the great followed only those whose star they trusted and who could reward services with the spoils of victory. In 925 Henry I brought Lotharingia back to the East Frankish connection. Whoever had authority in that half-French-speaking, half-German-speaking region could treat the neighbouring kingdom of the West Franks as a dependent. The young Saxon dynasty thus won for itself and its successors a hegemony over the west and the southwest that lasted at least until the mid-11th century. The Carolingian kings of France, as well as the great feudatories who sought to dominate if not to ruin them, became, in turn, petitioners and even vassals of the German court during the reign of the Ottos. The kings of Burgundy—whose suzerainty lay over the valleys of the Saône and the Rhône, the western Alps, and Provence—likewise fell under the tutelage of the masters of Lotharingia. Rich in ancient towns, this region, once the homeland of the Carolingians, was more thickly populated and wealthier than the lands east of the Rhine. Lotharingian merchants controlled the slave trade from the Saxon marches to Córdoba.

The eastern policy of the Saxons. Greater prestige still and a claim to imperial hegemony fell to the Saxon rulers when they broke the impetus of the Hungarian invasions, against which the military resources and methods of western European society had almost wholly failed for several decades. In 933, after long preparations, Henry routed a Hungarian attack on Saxony and Thuringia. In 955 Otto I (reigned 936–973), at the head of a force to which nearly all the tribes had sent mounted contingents, annihilated a great Hungarian army on the Lech River near Augsburg. The battle again vindicated the efficiency of the heavily armed man skilled in fighting on horseback.

Defeat of the Hungarians at the Lech

With a Saxon dynasty on the throne, Saxon nobles gained office and power, with opportunities for conquest along the eastern river frontiers and marches of their homeland. Otto I indeed had an eastern policy that aimed at getting more than slaves, loot, and tribute. Between 955 and 972 he founded and richly endowed an archbishopric at Magdeburg, which he intended to be the metropolis of a large missionary province among the heathen Slavs beyond the Elbe. This would have brought their tribes under German control and exploitation in the long run; but the ruthless methods of the Saxon lay lords clashed with the church's efforts at more peaceful penetration.

In the 10th century there was little or no German agricultural settlement beyond the Elbe. Far too much forest clearing remained to be done in all the regions of western and southern Germany. The Saxon conquests up to the Oder were secured by military strongholds, called burgwards, and were held only as long as their garrisons had the upper hand. Beyond the Slav peoples of Brandenburg and Lusatia, moreover, new powers rose: the Poles under Mieszko I and, to the south, the Czechs under the Přemyslids received missionaries from Passau and Magdeburg without falling permanently under the political and ecclesiastical domination of Bavarians and Saxons. The heathen Elbe Slavs, subjugated by the Saxon margraves, rose in 983 when the military occupation collapsed along with the missionary bishoprics that had been founded at Oldenburg, Brandenburg, and Havelberg. Farther south the defenses of the Thuringian marches between the Saale and the middle Elbe remained in German hands, but only after a long and fierce struggle against Polish invaders early in the 11th century. The northern part of the frontier reverted to what it had been before Otto's trustees, Hermann Billung and Gero, opened their wars. Missionary enterprises directed from Bremen and Magdeburg achieved little before the 12th century. The Saxon ruling class, bishops, and margraves must bear the responsibility for the fiasco of eastward expansion in the 10th century. The prelates, too, saw their missions as means to found ecclesiastical empires with subject dioceses and tithes on Slav soil. The tribes across the Elbe therefore remained unconverted and implacable foes, a standing menace to the nearby churches. The wars also left a legacy of savagery on both sides so that from *c.* 1140 onward the substitution of German settlers for the native Slavs became the common policy of both the church and the princes.

Legacy of savagery

Dukes, counts, and advocates. Conrad I's and Henry I's kingships rested on the will of the tribes—or rather on that of their leaders and of the higher aristocracy. It was in the first place an arrangement between the Franks and the Saxons that the Bavarian and Swabian dukes recognized at a price by acts of personal homage. But the German kings, of whatever dynasty, had to live under Frankish law. After the death of Conrad I's brother Eberhard in 939, Otto I kept the Franconian dukedom vacant and the Franconian counts henceforth stood under the immediate authority of the crown. In Saxony, too, Otto kept in his hands the dukedom of his ancestors. The march-duchy of the Billungs, a bulwark raised against the Danes and the northern Slav tribes, did not give that family authority over all the other Saxon princes.

In the south the Ottonians sought to turn the dukedoms of the stem lands into royal fiefdoms and to supplant native dynasties by aliens and members of their own clan. When even that policy did not stop rebellions under the banner of tribal self-interest, they began to break up the ancient Bavarian stem land by creating a duchy in Carinthia to cut off the spearhead of Bavarian expansion southward. The first two Salians, Conrad II (reigned 1024–39) and Henry III (reigned alone 1039–56), also bestowed vacant duchies quite freely on their own kin and on men from outside the stem boundaries. They competed against ducal power but could neither abolish nor replace it. In the 11th century as before, the dukes held assemblies of their folk, led the tribal host in war, and enforced peace.

The counts, who were the ordinary officers of justice in serious, criminal cases, obeyed the ducal summons; but, for the most part, they received their "ban," the power to do blood justice, from the king himself. The fiefs and the customary rights attached to their office, and indeed the office itself, not only became hereditary but also came to be treated more and more as a patrimony to which they had an inherent right against all men, king and duke included. Even so, however, a good many lines died out and their counties fell back into the king's hands. From Otto III's reign (983–1002) onward, it became not at all unusual to bestow these counties on bishoprics and certain great abbeys rather than to grant them out again to other lay magnates. The bishops, however, could not perform all the functions of the counts; in particular, their holy orders forbade them to pass judgments of blood. They needed officials called advocates (*Vögte;* singular *Vogt*) to take charge of the higher jurisdiction in the counties and franchises that their churches possessed by royal grant. In the 10th and 11th centuries these advocates had to be recruited from the aristocracy, the very class whose greed for hereditary office was to be checked, because ordinary freemen could not enforce severe sentences or defend the privileges of the church against armed intrusion. Dangerous neighbours of bishoprics and abbeys in any case, the nobles as advocates and protectors of ecclesiastical possessions were anything but reliable servants of their ecclesiastical overlords.

The rise of the advocates

Thus, there arose in nearly all German lands, whether

the ducal office survived or not, powerful lines of margraves, counts, and hereditary advocates who enriched themselves at the expense of the church (which meant also the crown) and in competition with one another. From the abler, more fortunate, and long-lived races among these dynasts sprang the territorial princes of the later 12th and 13th centuries, absorbing and finally inheriting most of the rights of government.

Power of the kings

The king was the personal overlord of all the great. His court was the seat of government, and it went with him on his long journeys. The German kings, even more than other medieval rulers, could only make their authority respected in the far-flung regions of their kingdom by travelling ceaselessly from duchy to duchy, from frontier to frontier. Wherever they stayed, their jurisdiction superseded the standing power of dukes, counts, and advocates, and they could collect the profits of local justice and wield some control over it. As they came into each region, they summoned its leaders to attend their solemn crown wearings, deliberated with them on the affairs of the *Reich* and the locality, presided over pleas, granted privileges, and made war against peacebreakers at home and on enemies abroad.

The promotion of the German Church. The royal revenues came from the king's demesne lands and from his share of the tributes that Poles, Czechs, heathen Slavs, and Danes had to pay whenever he could enforce his claims of overlordship. The king's demesne was his working capital. He and his household lived on its produce during their wanderings through the *Reich*, and it also served to provide for his family, to found churches, and to reward faithful services done to him, especially in war. To swell the hosts, vassals had to be enfeoffed, and alienations were inevitable. The Salians, though they inherited the remains of Ottonian wealth as imperial demesne, brought little of their own to make up for its diminution. Already the last Saxon, Henry II (1002–24), and after him Conrad II accordingly took to enfeoffing vassals with lands commandeered from the monasteries. But the beneficiaries often enough were already powerful and wealthy men in their own right, so that no class of freeborn, mounted warriors linked permanently with the crown sprang from the loyalties and rewards of one or two reigns. In any case, the lion's share of grants went to the German Church.

The growth of central government

From the Carolingians, the German kings inherited their one and only institution of central government: the royal chapel, with the chancery that does not seem to have been distinct from it. Service there became a recognized avenue of promotion to the episcopate for highborn clerks. In the 11th century, bishops and abbots conducted the affairs of the *Reich* much more than the lay lords, even in war. They were its habitual diplomats and ambassadors. Unlike Henry I, Otto I and his successors sought to free the prelates from all forms of subjection to the dukes. The king appointed them, and to him alone, as to one sent by God, they owed obedience.

Thus, there arose besides the loose association of stem lands in the German kingdom a more compact and uniform body with a far greater vested interest in the *Reich:* the German Church. By ancient Germanic custom, moreover, the founder of a church did not lose his estate in the endowment that he had made; he remained its proprietor and protecting lord. The bishoprics, it is true, and certain ancient abbeys, such as Sankt Gallen, Reichenau, Fulda, and Hersfeld, did not belong to the king; they were members of the kingdom but under his guardianship. The greater churches therefore had to serve the rulers with mounted men, money, and free quarters. Gifts of royal demesne to found or to enrich bishoprics and convents were not really alienations but pious reinvestments, as long as the crown controlled the appointments of bishops and abbots. But the church did not merely receive grants of land, often waste, to settle, develop, and make profitable: it was also given, as has been shown, powers of jurisdiction over its dependents. Nor did the kings stint the prelates in other regalian rights, such as mints, markets, and tolls. These grants broke up counties and to some extent even duchies, and that was their purpose: to disrupt the secular lords' jurisdictions that had escaped royal control.

This policy of fastening the church, a universal institution, into the *Reich*, with its well-defined frontiers, is usually associated with the name of Otto I. But it gathered momentum only in the reigns of his successors. It reached a climax under Henry II, the founder of the see of Bamberg in the Upper Main Valley; but Conrad II, though less generous with his grants, and his son Henry III continued it. Bishops and abbots became the competitors of lay princes in the formation of territories, a rivalry that more than any other was the fuel and substance of the ceaseless feuds, the smoldering internal wars in all the regions of Germany for centuries. The welter and the confused mosaic of the political map of Germany until 1803 is the not-so-remote outcome of these 10th- and 11th-century grants and of the incompatible ambitions that they aroused.

The Ottonian conquest of Italy and the imperial crown. Otto I's marriage with Adelaide (Adelheid), daughter of Rudolph II of Burgundy, and the Italian rivalries between his brother Henry, duke of Bavaria, and Otto's son Liudolf, duke of Swabia, drew him southward. After 951, expeditions into Italy were a matter for the whole *Reich* under the leadership of its ruler and no longer just an outlet for the expansion of the south German tribes. For the Saxon military class, too, the south was more tempting than the primeval forests and swamps beyond the Elbe. With superior forces at their back, the German kings gained possession of the Lombard kingdom in Italy. There, too, their overlordship in the 10th and the 11th centuries came to rest on the bishoprics and a handful of great abbeys.

The formation of the Holy Roman Empire

After his victory over the Magyars in 955, Otto I's hegemony in the west was indisputable. By the standards of one chronicler, the Saxon Widukind, he had already become emperor because he had subjected other peoples and enjoyed authority in more than one kingdom. But the right to confer the imperial crown, to raise a king to the higher rank of emperor, had fallen to the papacy, which had crowned Charlemagne and most of his successors. The Carolingian order in the west was still the model and something like a political ideal for all Western ruling families in the 10th century. Otto had measured himself against the political tasks that had faced his East Frankish predecessors and more or less mastered them. To be like Charlemagne, therefore, and to clothe his newly won position in a traditional and time-honoured dignity, he accepted the imperial crown and anointment from Pope John XII in Rome in 962. The substance of his empire was military power and success in war; but Christian and Roman ideas were woven round the Saxon's throne by the writers of his own and the next generation. Although the German kings as emperors did not give the law to the Roman Church in matters of doctrine and ritual, they became its political masters for nearly a century. The imperial crown enhanced their standing even among the nobles and knights who followed them to Italy and can hardly have understood or wanted all its outlandish associations. Not only the king but also the German bishops and lay lords thus entered into a permanent connection with an empire won on the way to Rome and bestowed by the papacy.

Otto II (reigned alone 973–983) and above all Otto III (983–1002) were strongly drawn toward their new Mediterranean sphere of action, but Henry II returned to a sober regime centred on Germany and contented himself with three brief Italian expeditions.

The Salians, the papacy, and the princes, 1024–1125. Under Conrad II (reigned 1024–39), the first member of the Rhine–Frankish house known as the Salians, the kingdom of Burgundy fell finally under the overlordship of the German crown, and this tough and formidable emperor also renewed German authority in Italy. His son and successor, Henry III (reigned 1039–56), treated the empire as a mission that imposed on him the tasks of reforming the papacy and of preaching peace to his lay vassals. Without possessing any very significant new resources of power, he gave to his authority an exalted and

strained theocratic complexion. Yet, under him, the last German ruler to maintain his hegemony in western Europe, the popes themselves seemed to become mere imperial bishops. He deposed three of them, and four Germans held the Holy See at his command; but lay opposition to the Emperor in Germany and criticism of his regime over the church were on the increase during the last years of his reign.

The papal reforms and the German church. More than any other feudal society in early medieval Europe, Germany was divided and torn by the revolutionary ideas and measures of the reformed papacy. Beginning with the pontificate of Leo IX—one of Henry III's nominees—the most determined and inspired spokesmen of ecclesiastical reform placed themselves at the service of the Holy See. Only a few years after Henry III's death (1056), they agitated against lay authority in the church, founded on proprietary rights. They regarded the laity as passive partakers of the sacraments and denied the supernatural status of kingship. Priests, including bishops and abbots, who accepted their dignities from lay lords and emperors at a price, according to the reformers, committed a sin; for these earthly powers could not rightly confer churches at all, nor could they own them. They believed, moreover, that thorough reforms could only be brought about by the exaltation of the papacy so that it commanded the obedience of all provincial metropolitans and was out of the emperor's and the local aristocracy's reach.

Effects of the reformed papacy

The endless repetition of the reformers' teachings in brilliant pamphlets and at clerical synods spread agitation in Italy, Burgundy, and Lotharingia—all parts of the empire. Their new program committed the leaders of the movement to a struggle for power because it struck at the very roots of the regime to which the German church had grown accustomed and on which the German kings relied. The vast wealth that Henry IV's predecessors had showered on the bishoprics and abbeys would, if the new teaching prevailed, escape his control and remain at the free disposal of prelates whom he no longer appointed. Under Roman authority the churches were to be freed from most of the burdens of royal protection without losing any of its benefits. The most fiery spirits in Rome did not flinch from the consequences of their convictions. Their leader Hildebrand, later Pope Gregory VII (reigned 1073–85), was ready to risk a collision with the empire.

Henry IV was not yet six years old when his father died in 1056. The full impact of the Gregorian demands—coming shortly after a royal minority, a Saxon rising, and a conspiracy of the south German princes—has often been regarded as the most disastrous moment in Germany's history during the Middle Ages. In fact, the German church proved thoroughly unreliable as an inner bastion of the empire even before Rome struck. Its leaders, Anno and Adalbert, archibishops of Cologne and of Hamburg–Bremen, respectively, shamelessly exploited their hold over the young king by hunting for spoils out of the imperial demesne. In 1074 Gregory proceeded against simony (the buying and selling of church office) in Germany, humiliated the aristocratic episcopate by summonses to Rome and sentences of suspension, and, a year later, forbade rulers to invest bishops and abbots with their churches. These papal actions demoralized and shook the German hierarchy. The prelates' return to their customary support of the crown was not disinterested, nor whole hearted, nor unanimous.

Decrees of Gregory VII

The discontent of the lay princes. Henry IV's minority also gave elbowroom to the ambitions and hatreds of the lay magnates. The feeble regency of his mother, Agnes of Poitou, faltered before the throng of princes, who respected only authority and forces greater than their own. The ruling influence of the higher clergy at the court of Henry III and the renewed flow of grants to the church had estranged them from the empire. It is likely also that these eternally belligerent men were lagging behind the prelates in the development of their agrarian resources. The prelates had a vested interest in peace, and under royal protection they improved and enlarged their estates by turning forests into arable land and also by offering better terms to freemen in search of a lord. The bishops' market and toll privileges brought them revenues in money, which many of the lay princes lacked. So far, however, the princes' military power, their chief asset, had remained unchallenged. Now, for the first time, they also had to face rivals within their own sphere of action. Henry III and the young Henry IV began to rely on advisers and fighting men drawn from a lower tier of the social order—the poorer, freeborn nobility of Swabia and, above all, the class of unfree knights, known as *ministeriales*. Those knights had first become important as administrators and soldiers on the estates of the church early in the 11th century. Their status and that of their fiefs was fixed by seignorial ordinances, and they could be relied on and ordered about, unlike the free vassals of bishops and abbots. Beginning with Conrad II, the Salian kings used *ministeriales* to administer their demesne, as household officers at court and as garrisons for their castles. They formed a small army, which the crown could mobilize without having to appeal to the lay princes, whose ill will and antipathy toward the government of the *Reich* grew apace with their exclusion from it.

Having come of age, Henry IV used petty south German nobles and his *ministeriales* to recover some of the crown lands and rights, which the lay princes and certain prelates had acquired during his minority, particularly in Saxony. His recovery operations went further, however, and a great belt of lands from the northern slopes of the Harz Mountains to the Thuringian Forest was secured and fortified under the supervision of his knights to form a compact royal territory, where the King and his court could reside almost continuously. The south German magnates were thus kept at a distance when Henry and his advisers struck at such neighbouring Saxon princes as Otto of Northeim and the Billung family.

Formation of a royal territory

The storm broke in 1073. A group of Saxon nobles and prelates and the free peasantry of Eastphalia, who had to bear the brunt of statute labour in the building of the royal strongholds, revolted against the regime of Henry's Frankish and Swabian officials. To overcome this startling combination and to save his fortresses, the King needed the military strength of the south German princes Rudolf of Rheinfelden, duke of Swabia; Welf IV, duke (as Welf I) of Bavaria; and Berthold of Zähringen, duke of Carinthia. Suspicious and hostile at heart, they took the field for him only when the Eastphalian peasantry committed outrages that shocked aristocratic caste feeling everywhere. Their forces enabled Henry to defeat the Saxon tribal rebellion near Langensalza in June 1075. But, when the life-and-death struggle with Rome opened only half a year later, the south German malcontents deserted Henry and, together with the Saxons and a handful of bishops, entered into an alliance with Gregory VII. Few of them at this time were converted to papal reform doctrines, but Gregory's daring measures against the King gave them a chance to come to terms with one another and to justify a general revolt.

The civil war against Henry IV. On February 22, 1076, the Pope absolved all men from their oaths to Henry and solemnly excommunicated him. In October Gregory's legates met the German lords at Tribur (modern Trebur) to decide on the future of the King, whom his last adherents now abandoned. Although Henry was absolved by Gregory at Canossa in January 1077, the princes two months later nonetheless elected Rudolf of Rheinfelden to rule in his place.

The war that now broke out lasted for almost 20 years. A majority of the bishops, most of Rhenish Franconia (the Salian homeland), and some important Bavarian and Swabian vassals sided with Henry. He thus held a central position, dividing his south German from his Saxon enemies, who could not unite long enough to destroy him. With the death in battle of Rudolf of Rheinfelden (1080) and the demise of another anti-king, Hermann of Salm (1088), the war in Germany degenerated into a number of local conflicts for the possession of bishoprics and abbeys. It almost died down in 1098, when the south German adherents of the papacy came to terms with Henry

Division of Henry's enemies

for the time being, though without recognizing his antipope Clement III. Throughout these years the crown, the churches, and the lay lords had to enfeoff more and more *ministeriales* in order to raise mounted warriors for their forces. Though this recruitment and frequent devastations strained the fortunes of many nobles, they knew how to recoup themselves by extorting more fiefs out of neighbouring bishoprics and abbeys. The divided German Church thus bore the brunt of the costs of civil war, and it needed peace almost at any price.

Henry V and results of the conflict. The Salian dynasty and the rights for which it fought were saved because Henry IV's son and heir himself seized the leadership of a last rising against his father (1105). This manoeuvre enabled Henry V (reigned 1106–25) to continue the struggle for the crown's prerogative over the empire's churches against the inexorable demands of the papacy. The conflict now shrank into a legalistic dispute over the right to invest bishops and abbots with their dignities and the secular possessions attached to them. As the struggle continued, the princes became the arbiters and held the balance between their overlord and the Pope. In 1122, acting as intermediaries and on behalf of the *Reich*, they forced the temporary concessions known as the Concordat of Worms out of the Holy See and its German spokesman, Archbishop Adalbert of Mainz, the bitter personal enemy of Henry V and the territorial rival of the Hohenstaufen sons of Henry's sister Agnes. But by then the princes had for the most part defeated efforts to restore royal rights in Saxony and to stem the swollen jurisdictions and territorial powers of the aristocracy elsewhere.

German loss of power after the death of Henry V

When Henry V, the last Salian, died childless in 1125, Germany was no longer the most effective political force in Europe. The brillant conquest states of the Normans in England and in Sicily and the patient, step-by-step labours of the French kings were achieving forms of government and concentrations of military and economic strength that the older and larger empire lacked. The papacy had dimmed the empire's prestige, and Rome became the true home of universalistic interests. When Pope Urban II preached the first crusade in 1095, Henry IV, cut off and surrounded by enemies, was living obscurely in a corner of northern Italy. The Holy See, by its great appeal to the militant lay nobility of western Europe, thus won the initiative over the empire. At this critical moment the *Reich* also lost control in the Italian bishoprics and towns, just when their population, trade, and industrial production were expanding fast. Germany did not even benefit indirectly from the crusaders' triumphs, although some of their leaders (*e.g.*, Godfrey of Bouillon and Robert II of Flanders) were vassals of the Emperor. The civil wars renewed for a time the relative isolation of the southern and central German regions.

Internally, the crown had saved something of the indispensable means of government in the control over the church; but it was a bare minimum, and its future was problematic. The ecclesiastical princes henceforth held only their temporal lands as imperial fiefs, for which they owed personal and material services. As feudatories of the empire, they came to represent the same interests toward it as did the lay princes; at least, their sense of a special obligation tended to weaken. The king's jurisdiction continued to exist side-by-side and in competition with that of the local powers. The great tribal duchies survived as areas of separate customary law. Each developed differently, and the crown could not impose its rights on all alike or change the existing social order. The most tenacious defenders of this legal autonomy had been the Saxons; but it also prevailed in Swabia, where distinct territorial lordships grew fast.

The Gregorian reform movement therefore aggravated the age-old contradictions in Germany's early medieval constitution. But its monastic culture and its intellectual interests were anything but barren. Both sides fought with new literary weapons to work on public opinion in cathedrals and cloisters and perhaps also in the castles of the lay aristocracy. In their hard-hitting polemical writings they attempted to expound the fundamental theological, historical, and legal truths of their cause. The agitation did something to disturb the cultural self-sufficiency of the German laity. It drove many of the south German nobles to maintain direct connections with the Holy See, and, whether they wanted it or not, they had to fall in with the aspirations of the religious leaders. The reform movement of the 11th and 12th centuries, it might almost be said, very nearly completed the conversion of Germany that had begun five centuries before.

GERMANY AND THE HOHENSTAUFEN, 1125–1250

Dynastic competition, 1125–52. The nearest kinsmen of Henry V were his Hohenstaufen nephews—Frederick, duke of Swabia (1105–47), and his younger brother Conrad, the sons of Henry's sister Agnes and Frederick, the first Hohenstaufen duke of Swabia. Some form of election had always been necessary to succeed to the crown, but, before the great civil war, nearness to the royal blood had been honoured whenever a dynasty failed in the direct line. By 1125, however, the princes, guided by Archbishop Adalbert of Mainz, no longer respected blood right. Affinity with Henry V was no recommendation to them, and hereditary succession seemed to lower their authority in the government of the *Reich*. Instead of Frederick they chose the duke of Saxony, Lothair of Supplinburg (reigned as king 1125–37, reigned as emperor 1133–37). Like the Hohenstaufen, he had risen by a lucky marriage and a successful career of continuous fighting into the first rank of dynasts; but, unlike them, he had served the cause of the Saxon opposition to the Salians.

Disregard for blood right

With the enormous Northeim and Brunonian inheritances behind him, Lothair III (sometimes called Lothair II) could humble the Hohenstaufen brothers (1134) after marrying his only daughter and heiress to a Welf, Henry the Proud. Even without his dazzling alliance, the Welfs, already dukes of Bavaria and possessors of vast demesnes, countships, and ecclesiastical advocacies there and in Swabia, were somewhat better off than their Hohenstaufen rivals. On the death of Lothair in 1137, however, the fears of the church and a few princes turned against the Welfs. Instead of Henry the Proud, who now held the duchies of Saxony and Bavaria and the Matildine lands in Italy, they chose Conrad (reigned 1138–52), who had been Lothair's unsuccessful Hohenstaufen opponent.

The battle against the Welfs, which Conrad III put foremost on his political program, was abandoned with his death in 1152, when an election once again decided the succession and the political situation in Germany for the next 30 years. The princes then chose Frederick I Barbarossa (reigned as king 1152–90), the son of Conrad's elder brother Frederick and the Welf princess Judith. Frederick I agreed to share power in Germany with his Welf cousin Henry the Lion. The price of his election was dualism. In 1156 the duchy of Bavaria, which Conrad had tried to wrest from the Welfs, was restored to Henry the Lion, already undisputed duke of Saxony. The Babenberg margrave of Austria, Henry's rival, had to be compensated with a charter that raised his margravate into a duchy and gave him judicial suzerainty over an even wider area. Taken out of the Lion's duchy, it was to be held as an imperial fief that might descend both to sons and daughters. A perpetual principality, it served as a model for the aspirations of many other lay princes.

Colonization of the east. The history of Germany in the 12th and 13th centuries is one of ceaseless expansion. A conquering and colonizing movement burst across the river frontiers into the swamps and forests from Holstein to Silesia and overwhelmed the Slav tribes between the Elbe and the Oder. Every force in German society took part: the princes, the prelates, new religious orders, knights, townsmen, and peasant settlers. Agrarian conditions in the older lands of Germanic occupation seem to have favoured large-scale emigration. With a rising population, there was much experience in drainage and wood clearing but a diminishing fund of spare land to be attacked in the west. Excessive subdivision of holding impoverished tenants and did not suit the interests of their

The conquering and colonizing movement of the 12th and 13th centuries

lords. Sometimes also, seignorial oppression is said to have driven peasants to desert their masters' estates. They certainly found a better return for their labour in the colonial area: personal freedom, secure and hereditary leasehold tenures at moderate rents, and, in many places, quittance from services and the jurisdiction of the seignorial advocate.

The colonists brought with them a disciplined routine of husbandry, an efficient plow, and orderly methods in siting and laying out their villages. Very soon, even the Slav rulers of Bohemia and Silesia, were competing for immigrants. First and foremost, however, the princes of the Saxon and Thuringian marches sought to attract settlers for the lands that they had conquered and the towns that they had founded to open up communications and trade routes. The older regions of the *Reich*, moreover, had not only peasants but also men of the knightly class to spare —soldiers who needed fiefs and lordships to uphold their rank. Both could be gained beyond the Elbe under the leadership of successful princes. The Germanized east thus became the home of fair-sized principalities in the 13th century, while all along the Rhine River Valley the rights of government were tending to be scattered over smaller and less compact territories. The Ascanian dynasty, for instance, which under Albert the Bear began to advance into Brandenburg, by 1250 not only ruled over a broad belt of land up to the Oder River but had already established itself on the eastern banks ready for further advances. Farther south the Wettin margraves of Meissen busied themselves with settlements and town foundations in Lusatia.

For a time Henry the Lion, as duke of Saxony (1142–80), overshadowed all these rising powers, and the Welf profited as much by the ruthless use of his resources against weaker competitors as by his own efforts in Mecklenburg. As his protection was alone worth having in northeastern Germany, the newly established Baltic bishoprics were at his mercy, and he alone could attract the traders of Gotland to frequent the young port town of Lübeck, which he extorted from one of his vassals in 1158.

The *Reich*, too, possessed demesnes in the east, notably the Egerland, Vogtland, and Pleissnerland in the Thuringian March. The Hohenstaufen kings therefore took some part in opening up these regions. They, too, founded towns and monasteries on their thickly wooded lands and established their *ministeriales* as burgraves and advocates over them. But, in this, as in many other things, they only competed with the princes. They did not and could not control the eastward movement as a whole.

German expansion to the east, 800–1400.

Hohenstaufen policy in Italy. In the other great field of German expansion in the 12th century—Lombardy and central Italy—the emperors and their military following alone counted. The rural population of Germany had no direct interest in the wars waged to recover and exploit ancient regalian rights over the growing Lombard city communes. The connection between the German crown, the empire, and dominion over Italy has indeed been regarded as a disaster for Germany, and the ever-increasing concern of the Hohenstaufen dynasty with the south as its most tragic phase. But, although Frederick Barbarossa's policy was opportunistic, he had really very little choice. Having bought off the Welfs and reconciled other great families with yet more concessions and lastly endowed his own cousin, Conrad III's son Frederick, with Hohenstaufen demesnes in Swabia, he had to try to mobilize their goodwill for the empire while it lasted. He now aimed to set up a regime of imperial officials and captains who were to exact dues and to control jurisdiction that the communes had usurped from the failing grasp of the bishops. The Germans in Italy did not bring valuable accomplishments to poor and savage tribesmen, but they attacked economically advanced and better developed communities, to which they had nothing to offer in return for the rights and taxes they demanded. Military power was their chief asset in Lombardy, and they used it ruthlessly.

The disastrous Italian policy

For the Hohenstaufen *ministeriales* the rule of their masters in northern and central Italy was a career. Because they could be deployed continuously, they became the backbone of the imperial occupation. A handful of minor dynasts also served Barbarossa for many years in the powerful and profitable commands that he established. The German bishops and certain abbots still had to supply men and money, and some of them threw themselves wholeheartedly into the war: for instance, Rainald of Dassel and Philip of Heinsberg, archbishops of Cologne from 1159 to 1167 and from 1167 to 1191, respectively, who, as archchancellors for Italy, had a vested interest in it. But the support of the lay princes was fitful and sporadic. Even at critical moments they could not be counted on unless they individually agreed to serve or to send their much-needed contingents for a season. The refusal of the greatest of them, Henry the Lion, in 1176 brought about the Emperor's defeat at the Battle of Legnano and spoiled many years' efforts in Lombardy.

The fall of Henry the Lion and the estate of princes. Forced to retreat before the Lombard League in 1177, Barbarossa cooled toward his Welf cousin, whom he could justly blame for some of his setbacks. Dualism in Germany had outlived its purpose. Hitherto, the enemies of Henry—the princes, bishops, and magnates of Saxony—had been unable to gain a hearing against him at the Emperor's court days. By 1178, however, the Emperor was ready to help them. Outlawed (1180), beaten in the field and deserted by his vassals, Henry had to surrender and go into exile in 1182. His duchies and fiefs were forfeited to the *Reich*.

Surrender and exile of Henry the Lion

His fall left a throng of middling princes face-to-face with an emperor whose prestige, despite reverses, stood high and whose resources had greatly increased since he began to reign. The princes were nonetheless the chief and ultimate gainers from the events of 1180. The final judgment by which Henry the Lion lost his honours was not founded on folk law but on feudal custom. The princes who condemned him regarded themselves as the first feudatories of the empire, and they decided on the redistribution of his possessions among themselves. During the 12th century the stem duchies of the Ottonian period finally disintegrated. Within their ancient boundaries not only bishops but also lay lords succeeded in eluding the authority of the dukes. In their large immunities they themselves wielded stem-ducal powers. To enforce the imperial peace-laws became both their ambition and their justification. Everywhere, the greater lay dynasties and even some bishops tried to acquire a ducal or an equivalent title, that would enable them to consolidate their scattered jurisdictions and, if possible, to force lesser freelords to attend their pleas.

These highest dynasts had interests in common, and they closed their ranks not only against threats from above but also against fellow nobles who had been less successful in amassing wealth, counties, and advocacies and who did not possess the superior jurisdiction of a duke, a margrave, a count palatine, or a landgrave. They and they alone were now called princes of the empire. To lend a certain cohesion to their varied rights, they were willing to surrender their houselands to the *Reich* and receive them back again as a princely fief. For the emperor it was theoretically an advantage that men so powerful in their own right should owe their chief dignity and most valued privileges to his grant. It opened the possibility of escheats, or land seizures, for in feudal custom the rules of inheritance were strict. But in Germany the political misfortunes of rulers succeeded, by and large, in ensuring that ancient caste feeling and notions of inalienable right conquered the principles of feudal law. By 1216 it was established that the emperor could neither abolish principalities nor create princes at random.

The "heirs" of Henry the Lion had to fight a ceaseless battle to establish and maintain themselves. In Bavaria the Wittelsbachs had received the vacant duchy, but they were not recognized as superiors by the dukes of Styria or by the dukes of Andechs-Meran. In Saxony the Archbishop of Cologne was enfeoffed with Henry the Lion's ducal office and with all his rights in Westphalia, while an Ascanian prince, Bernard of Anhalt, received the eastern half of Henry's duchy. Neither Bernard nor the Archbishop, however, could make much out of their dukedoms, except in the regions where they already had lands and local jurisdictions. All over the *Reich* these and regalian rights, such as mints, fairs, tolls, and the right of granting safe-conducts, were the substance of princely power. To possess them as widely as possible became the first goal of the abler bishops and lay lords.

The Hohenstaufen conflict with the papacy, 1159–1215. The attempt to establish a direct imperial regime in Italy antagonized the papacy once again and led to a new struggle with Rome, the ally of the Lombard communes. Political and territorial rather than ecclesiastical interests were at stake; but the popes could only fight as heads of the universal church, defending its liberty against a race of persecutors, and they had to employ their characteristic weapons—excommunication, propaganda, and intrigue. Nonetheless, the German bishops stood by Barbarossa and, for the most part, followed him in maintaining a prolonged schism against Pope Alexander III. Unsuccessful in Lombardy, the centre of Hohenstaufen ambitions after 1177 shifted to Tuscany, Spoleto, and the Romagna. This redoubled the fears and the resentment of the popes, particularly when Frederick's son and chosen successor, Henry VI (reigned 1190–97), became after 1189 the legitimate claimant to the Sicilian kingdom through his wife Constance, the sole surviving legitimate heiress.

With their backs to the wall, the popes had to make what use they could out of any opposition to the Hohenstaufen. Their chance came in 1197 when Henry VI died prematurely, leaving a three-year-old son, Frederick, to succeed him. To escape the chaos of a minority regime, the bulk of the German princes and bishops in 1198 elected the boy's uncle Philip of Swabia; but an opposition faction in the Lower Rhenish region, led by the Archbishop of Cologne and financed by Richard I of England, raised an anti-king in Otto IV, a younger son of Henry the Lion. Pope Innocent III had to enlarge on his rights over imperial coronations and become a partisan in the German electoral feud if he wished to defend his recovered holdings in Italy against Hohenstaufen claims. Territorial interests in the Romagna tempted the papacy to exploit the weaknesses of the empire's constitution, the uncertainties of electoral custom, and the lack of strict legal norms in Germany. During the war for the crown, much hard-won demesne and useful rights over the church had to be sacrificed by the rivals to bribe their supporters.

Frederick II and the princes. Henry's son Frederick II entered Germany to regain his own against Otto IV in

1212 and secured the crown in 1215. Despite promises to divide his inheritance, he kept the Kingdom of Sicily and the empire together, and thus he also became locked in the inevitable life-and-death struggle with the papacy. The Hohenstaufen demesne in Swabia, Franconia, and Alsace and on the Middle Rhine was still very considerable, and Frederick even recovered certain fiefs and advocacies that had been lost during the earlier civil wars. Their administration was improved, and they provided valuable forces for his Italian wars. An edict of imperial peace in 1235, moreover, showed that the Emperor had not become a mere competitor in the race for territorial gain. But, except for brief intervals, the princes and bishops were left free to fight for the future of their lands against one another and against the intractable lesser dynasts who refused to accept their domination. The charters that Frederick had to grant to the ecclesiastical princes (the so-called *Confoederatio cum principibus ecclesiasticis*, 1220) and later to all territorial lords (*Constitutio*, or *Statutum in favorem principum*, 1232) gave them written guarantees against the activities of royal demesne officials and limited the development of imperial towns at the expense of episcopal territories. But the charters were not always observed, and until 1250 the crown remained formidable in southern Germany, despite the anti-kings Henry Raspe and William of Holland, whom the papacy caused to be elected by the Rhenish archbishops in Germany in 1246 and 1247.

The Reich after the Hohenstaufen catastrophe. Frederick II died in 1250, in the midst of his struggle against Pope Innocent IV. His son Conrad IV left the north in 1251 to fight for his father's Italian possessions. William of Holland, anti-king from 1247 to 1256, was thus without a rival in an indifferent Germany, which had lost interest in its rulers. The bishops' cities and the towns, many of them founded on royal demesne, could not be absorbed. Their economic power challenged the age-old aristocratic order in German society, and, deprived of royal protection, they banded together to defend their autonomy. Within the nobility each rank tended to acquire some of the personal rights of its betters. The Hohenstaufen breakdown after 1250 left a gap in Swabia that no rising territorial power was able to fill. Countless petty lords and imperial *ministeriales* of the southwest succeeded in holding their seigniories as immediate vassals of the *Reich*. Their independent territories often survived for centuries.

The *ministeriales* elsewhere, too, ceased to be the dependable servants that they once had been. Many free nobles voluntarily joined their ranks, and the knights thus assimilated the rights of the free aristocracy. They became the governing class of the territorial principalities, the standing councillors of their masters, whose household offices and local justice they monopolized and held in fee for many generations. Without the consent of this territorial nobility, the princes could neither tax nor legislate. Even the less important *ministeriales*, who only administered manors for their lords, entrenched themselves as hereditary bailiffs, who kept surplus produce for themselves and usurped seignorial dues, so that it paid the owners to commute the labour services of their villeins into money rents and to lease out those portions of the demesne that the unfree peasants had cultivated for them. Even then, however, the hereditary officials could not be easily dislodged. Finally, the ambitions of the princes themselves did not aim above the patrimonial policies of the past. They were acquisitive and attemped to build up their territories by usurpation, inheritance, marriage treaties, and escheats. They also tried, where possible, to administer their lands with officials whom they could depose at will. Yet, they did so not to found sovereign states but chiefly to provide for their families. Again and again, they divided their dominions among sons, who, in turn, founded cadet lines and set them up on a fraction of the principality.

By 1250 there was thus no really effective central authority left in Germany. The prince-bishoprics had become fiercely contested prizes between neighbouring dynasties, often vassals of the see (*i.e.*, the bishopric). But constant feuds, disorder, and insecurity did not, by any means, frustrate the immense energies of the Germans in the 13th century. Eastward expansion continued under the leadership of the princes and, above all, of the Knights of the Teutonic Order. Their advance into Prussia went hand in hand with the opening up of the Baltic by the merchants of Lübeck. It is possible that three centuries of complete security from foreign invasion made it unnecessary for the German aristocracy to learn the virtues of political self-discipline and subordination; but it would be a great mistake to judge Hohenstaufen Germany solely by its failure to achieve political and administrative unity. (K.J.L.)

The loss of effective central authority

II. Germany from 1250 to 1493

1250 TO 1378

The extinction of the Hohenstaufen dynasty and the rise of the Habsburgs and Luxembourgs. The death of Frederick II in 1250 and of his son Conrad IV in 1254 heralded the irreversible decline of Hohenstaufen power in Germany and in the conjoint kingdoms of Naples and Sicily. Conrad's infant son Conradin, heir to Naples and Sicily, remained in Germany under the guardianship of his Bavarian mother. His uncle Manfred seized the reins of government in both Italian kingdoms and in 1258 formally supplanted Conradin by engineering his own coronation in Palermo. Manfred's defiance of papal claims to suzerainty over the kingdoms impelled the French-born Pope Urban IV to grant them to Charles of Anjou, brother of Louis IX of France. Papal taxation of the French clergy and loans from Florentine bankers enabled Charles to raise a large mercenary army for an expedition to Italy. Manfred, deserted by his barons, was defeated and slain near Benevento in 1266. Conradin then rallied his German supporters and led them across the Alps. But Conradin's financial resources were inadequate; unpaid troops deserted, and his depleted following was routed by Charles near Tagliacozzo (1268). Conradin was captured as he fled toward Rome, convicted of lese majesty (a form of treason), and beheaded in the public square at Naples.

Decline of Hohenstaufen power

The Great Interregnum. In Germany, the death of Frederick II ushered in the Great Interregnum (1250–73), a period of internal confusion and political disorder. The anti-kings Henry Raspe (landgrave of Thuringia, 1246–47) and Count William of Holland (ruled 1247–56) were elected by the leading ecclesiastical princes at the behest of the papacy. William's title was recognized initially only in the lower Rhineland, but his marriage to Elizabeth of Brunswick in 1252 ensured his acceptance by the interrelated princely dynasties of north Germany. The death of the Hohenstaufen Conrad IV left William without a rival in Germany. His growing strength and independence enabled him to escape from the tutelage of his ecclesiastical electors and to devote himself to purely dynastic policies. He pursued his feud with Margaret, countess of Flanders, over their conflicting territorial claims in Zeeland at the mouth of the Rhine. He renewed the attempts of his dynasty to obtain complete mastery of the Zuider Zee by thrusting eastward at the expense of Friesland; he died at the hands of the Frisians in 1256.

Pope Alexander IV forbade the election of a Hohenstaufen but interfered no further with the succession. Hence the initiative was taken by a small group of influential German princes, lay and ecclesiastical, acting out of self-interest and personal advantage. None desired the election of a ruler powerful enough to threaten their growing independence as territorial princes; nor did they single out a German candidate, who might prove to be as uncontrollable as William. Archbishop Conrad of Cologne approached Richard, earl of Cornwall, brother of Henry III of England. Richard's bribes and assurances of future favour bought him the votes of the archbishops of Cologne and Mainz, the count Palatine of the Rhine, and Otakar II of Bohemia. He was formally elected in 1257 and crowned king at Aachen (Aix-la-Chapelle). Three months after Richard's election, Alfonso X of Castile, who aspired to the empire in order to strengthen his foothold in Italy, was chosen in equally corrupt fashion by

Initiative of the German princes

the Archbishop of Trier, the Duke of Saxony, the Margrave of Brandenburg, and the devious Otakar.

The candidates were distracted by the turbulence of the aristocracy in their respective countries—Richard paid four fleeting visits to Germany; Alfonso failed to appear at all. Both appealed to the papacy for confirmation of their election. Their claims were summarized in Urban IV's bull *Qui coelum* (1263), which assumed that the exclusive right of election lay with the seven leading princes involved in the double election of 1257.

The rise of the Habsburgs and Luxembourgs. *Rudolf of Habsburg.* When Richard died in 1272 the electoral princes were spurred into action by Pope Gregory X, who desired the election of a German monarch sympathetic toward a crusade for the recovery of the Holy Land. The princes, dreading an overly powerful king, rejected the advances of Philip III of France and Otakar. They chose instead Rudolf of Habsburg (1273), a minor count of Swabia who lacked the strength to regain the crown domains the electors had usurped during the Interregnum. Papal diplomacy persuaded Alfonso X to abandon his pretensions to the throne; but Otakar denounced the election on the ground that the Duke of Bavaria had voted as lay elector in his stead. Rudolf allied himself with the Wittelsbach family of Bavaria and with other envious neighbours of Otakar, who was defeated and slain (1278). The duchies of Austria and Styria, overrun by Otakar during the Interregnum, were declared vacant and conferred jointly on Rudolf's sons Albert and Rudolf (1282). These acquisitions placed the Habsburgs in the first rank of the German territorial princes and lent impetus to a gradual shift in the political centre of gravity from the Rhineland to east Germany. But the growing Habsburg power disquieted the electoral princes, who frustrated the King's attempts to secure the election of his elder son Albert in 1287 and of his younger son Rudolf in 1290.

Growing Habsburg power

Adolf of Nassau. On the death of Rudolf in 1291, the electors averted the danger of a hereditary Habsburg monarchy by choosing Count Adolf of Nassau as his successor. Adolf, possessing only a small patrimony to the south of the river Lahn, strengthened himself financially by promising military aid to and receiving subsidies from both sides in the current Anglo-French war. He took possession of Meissen when the cadet branch of the Wettin dynasty died out, and he used his foreign subsidies to purchase Thuringia in 1295. He was thus able to adopt a more independent attitude toward his electors. On June 23, 1298, five of the electors pronounced Adolf unfit to rule and deposed him; on the following day they elected Albert of Austria in his stead. Albert marched westward from Austria at the head of a large army, and in a battle at Göllheim, Adolf was slain and his supporters fled.

Albert I of Habsburg. By restoring the Habsburg Albert I (ruled 1298–1308) to the kingship, the electors placed themselves in jeopardy. The new ruler, backed by the ample resources of his Austrian dominions, was more powerful and unscrupulous than his predecessor. The electors regarded his treaty of friendship with Philip IV of France (1299) as a move to enlist French support for the election of his son Rudolf as his successor in Germany. His attempt to seize Holland and Zeeland as a vacant fief of the empire was rightly interpreted by the electors as an effort to establish Habsburg influence on the lower Rhine (1300). The four prince-electors of the Rhineland (the archbishops of Mainz, Trier, and Cologne and the count Palatine) conspired to depose Albert. But Albert wrecked the design by decisive military action (1301–02), and he sealed his victory over the electors by obtaining confirmation in 1303 of his election from Pope Boniface VIII in return for an unprecedented oath of fealty and obedience to the papacy. Albert subsequently renewed Adolf's claims to Meissen and Thuringia, but his authority there was still disputed when he died by assassination in 1308. Albert temporarily tamed the electoral princes, placated the papacy, and renounced intervention in Italy; but this policy foundered at his death, and the electors were given a fresh opportunity to reassert their influence over the German monarchy.

Oath of fealty and obedience to the papacy

Henry VII of Luxembourg. The princes, released from Albert's heavy hand, sought a servant, not a master. Archbishop Baldwin of Trier sponsored the candidature of his brother, Count Henry of Luxembourg, who was elected at Frankfurt (modern Frankfurt am Main) in 1308 as Henry VII. The house of Luxembourg (Luxemburg) was not a major territorial power, and Henry lost no time in exploiting his new status to extend its possessions. Under his direction the Diet of Frankfurt (1310) closed the long-disputed question of the Bohemian succession by awarding the kingdom, with the consent of the Bohemian estates, to Henry's son John. Thus, in common with the Habsburgs, the main weight of Luxembourg interests gravitated eastward. But Henry, unlike his Habsburg predecessors, dreamed of a restoration of the ancient authority of the empire in Italy. His Italian expedition (1310–13) opened brilliantly, and in 1312 he was crowned Holy Roman emperor at Rome. But the old fear of German domination stiffened the resistance of the Italian states. Pope Clement V was alarmed by Henry's preparations to invade the kingdom of Naples, a papal fief, and threatened excommunication. A renewed collision of empire and papacy seemed imminent when Henry died in 1313.

The growth of territorialism under the princes. The decline of Hohenstaufen influence in Germany, the Interregnum, and the rapid alternation of dynasties on the German throne created favourable conditions for the territorial princes, lay and spiritual, to gain power. Frederick II had purchased the support of the princes by lavish grants of crown lands, chiefly in the Rhineland and Thuringia; in 1220 he procured the cooperation of the ecclesiastical princes in the election of his son Henry as king and eventual heir to the empire by renouncing his regalian rights of building castles, issuing coinage, and imposing tolls on merchandise in their territories. Henry himself had extended similar concessions to the lay princes in 1231.

Thenceforth the direct action of royal authority was virtually precluded in the princely domains. The princes were at liberty to multiply castles and toll stations, establish mints, exploit mineral deposits, and settle all judicial cases except those transferred on appeal to the court of the emperor. But the machinery of administration under the prince and his council (*Hofrat*) was still rudimentary. Public taxation was intermittent and restricted to emergency occasions, and it was subject to the consent of the three estates of the principality (clergy, nobles, townspeople), which were consulted separately by the prince. The estates grasped the opportunity to ventilate their grievances and to press their advice upon the prince. The emerging territorial state was thus under the dual government of the prince and the estates, and its development was to be heavily influenced by a shifting balance of power between them.

Downfall of royal authority in princely domains

Constitutional conflicts in the 14th century. The death of Henry VII led to a disputed election and a civil war in Germany. The electors' impulse to choose another lesser count as king was checked by the houses of Habsburg and Luxembourg, which pressured the prince-electors to choose between their candidates. The pro-Habsburg majority elected Frederick the Handsome, duke of Austria. The minority withdrew their support from Henry VII's son John and transferred it to a more formidable candidate, the Bavarian duke Louis of Wittelsbach, who had recently broken an Austrian invasion of his duchy.

Electoral custom did not yet acknowledge the majority principle. The papacy, which had claimed the right to adjudicate disputed elections since 1201, was vacant. Hence the two claimants settled their differences by the sword. In 1322 Louis defeated and captured his rival at Mühldorf, but his triumph in Germany merely raised the curtain on a long and bitter dispute with the papacy.

Pope John XXII, guided by canon law and precedent, affirmed that Louis might not legally rule until confirmed by the papacy; thus the disputed election of 1314 and the absence of papal approbation invalidated Louis's royal title and his right to govern. Louis contended, however, that election by a majority conferred a legitimate title

and administrative power and did not require papal confirmation. His defiance of the Pope exposed him to excommunication (1324) and to the procedures of canon law, whereby he was required to submit entirely to the papal terms before absolution could be granted. Louis warned the electors that their rights were endangered by the subjection of the elections to papal confirmation. Six electors responded in the Declaration of Rhens (1338), proclaiming as an ancient custom of the empire that election by a majority was valid and that the king-elect assumed his administrative power immediately, without the intervention of papal approbation. Under Louis's direction the declaration was repeated at the subsequent Diet of Frankfurt as an imperial law, and offenders against it were declared guilty of lese majesty.

The Declaration of Rhens

John XXII and his successors were unyielding. In 1343 Pope Clement VI made diplomatic overtures to Charles of Luxembourg, heir to the Bohemian throne, with the object of procuring his election to the German kingship in Louis's stead. The electors, led by Baldwin of Luxembourg, archbishop of Trier, began to desert Louis one by one. The Pope thereupon urged a new election. Charles assured the Pope secretly that he would await papal confirmation of his forthcoming election before exercising governmental power in the Italian possessions of the empire, but, despite intense pressure by Clement, he would accept no such restriction with regard to Germany. In 1346 only two electors remained faithful to Louis: his son Louis of Brandenburg and his kinsman Rudolf, count Palatine of the Rhine. The other five assembled at Rhens on July 11 and elected Charles under the title of Charles IV. The new king was spared a lengthy conflict with his rival, who died of apoplexy in 1347.

Charles IV and the Golden Bull. Charles IV (ruled 1346–78) readily perceived that disputed elections exploding into civil war had been a standing malady of the German body politic since 1198 and that the stability of the German monarchy depended largely upon the degree of cooperation achieved with the territorial princes, more especially with the prince-electors. On his return from his imperial coronation as Holy Roman emperor (1355) he promulgated, with the consent of the German assembly of estates or diet (1356), a basic constitutional document—known as the Golden Bull from its pendant gold seal (*bulla*). Charles's double objective was to minimize areas of dispute in future elections and to strengthen his ties with the electors. Unanimity among the electoral princes had always been difficult to attain; hence the validity of election by majority vote, a principle already set forth in the Declaration of Rhens, was reaffirmed. The territories of the lay electors were declared indivisible and heritable only by the eldest son. Thus, partitions of land by family agreement and consequent uncertainty concerning the holder of the electoral vote were eliminated. In conformity with ancient custom the archbishop of Mainz was to convene the electors and to request them to name their favoured candidate. He was to announce his own choice after the other electors had given their vote verbally, and so he could cast the deciding vote in the event of a tie. The election was to be held in Frankfurt, the royal coronation in Aachen (Aix-la-Chapelle).

Provisions of the Golden Bull

The membership of the electoral body was fixed at the traditional number of seven: the archbishops of Mainz, Cologne, and Trier, the count Palatine of the Rhine, the king of Bohemia, the margrave of Brandenburg, and the duke of Saxony. When the throne was vacant the count Palatine would be regent in south Germany and the duke of Saxony in the north; thus the long-standing papal claim to govern the empire during a vacancy was tacitly rejected. The question of papal confirmation of elections was ignored; neither Charles nor his electors were prepared to yield, but an open affirmation of their position would have been ill-received by the papacy, which had played a leading role in Charles's election.

The Golden Bull consolidated and extended the territorial power of the electors. Their right to construct castles, issue coinage, and impose tolls was confirmed. They could judge without appeal. Conspiracy or rebellion against them was deemed high treason. They were to meet the ruler once yearly as supreme advisory council on affairs of state. The formation of city leagues against them was specifically prohibited. On the basis of these enactments the Golden Bull has been called the Magna Carta of German particularism. The electors in their capacity of territorial lords were its chief beneficiaries; the rest of the princes were envious and strove thenceforth to acquire an equally large measure of territorial sovereignty.

Rudolf IV of Austria ordered his chancery to fabricate a series of imperial charters, including two from Julius Caesar and Nero, as evidence of his virtual independence of the empire. Charles IV submitted them for examination to the Italian humanist Petrarch, who declared the charters to be spurious. Rudolf took up arms and was bought off by the recognition of his claim to Tirol (1364).

The election of Charles's son Wenceslas (Wenzel) as king in 1376 (two years before Charles's death) was a striking example of the Emperor's skill in securing the cooperation of the electors for his dynastic purposes. The election of an emperor's son as king of the Romans during the father's lifetime had not occurred since 1237; the prince-electors, in their anxiety to prevent any single dynasty from strengthening its grip on the succession, had checked all subsequent attempts. But unprecedented bribes, concessions, and a renewed prohibition of city leagues by Charles overcame the opposition of the electors. Pope Gregory XI had previously announced that the election would be invalid without papal confirmation. Charles, in concert with the electors, speeded the election and subsequent coronation of his son and then submitted an antedated request for confirmation to the Pope, who countered these devious tactics by delaying confirmation; it was still under consideration at Gregory's death in 1378. The decline of the papacy during the Great Schism (1378–1417) precluded the vigorous assertion of its right of confirmation, which became a mere formality and was subsequently tacitly abandoned.

Election of Wenceslas

Decline of the German monarchy. Charles IV's power was based primarily upon the territorial possessions of the house of Luxembourg, which he greatly extended by the purchase of the electorate of Brandenburg (1373). The German monarchy was a source of dignity and influence, but in terms of land and revenue it was outranked by Charles's hereditary domains in the east and northeast. The Golden Bull, replete with privileges to the electors, attacked none of the fundamental problems of the monarchy: dwindling crown lands, slender revenues, lack of an army and of an expert bureaucracy.

The financial problem was acute and of long standing. The succession of disputed elections between 1198 and 1257 had compelled the various claimants to purchase support by grants of royal land and revenues; the attempt by Rudolf of Habsburg to recover possession of crown lands alienated since 1245 had been opposed by his electors, who were unwilling to set an example by surrendering their own considerable acquisitions. At every election the votes of the princes had been bought by the grant or pledge of royal rights and property; thus, every king began his reign with a financial millstone round his neck and could attain freedom of action only by the possession or acquisition of extensive dynastic territories. The system of pledging crown lands involved the transference of the land and its revenues to the creditor. These revenues did not reduce the original debt, and the alienation tended to become permanent. The imperial cities (*Reichsstädte*) had been heavily taxed by Rudolf, and before his acquisition of Austria they had furnished the bulk of his revenue. His less provident successors had pledged them in a few cases to the local territorial princes and had thus lost the right of taxation. Charles IV carefully cultivated his dynastic revenues from Bohemia, but he lavishly expended crown assets in Germany to expand his family possessions. His financial exploitation of the cities for purely dynastic purposes naturally stiffened their resistance to taxation. By 1400 the annual revenues from all the German crown possessions averaged only 30,000 florins.

Financial problems

The enforcement of the public peace, a taproot of royal

power in other countries, also slipped gradually from the hands of the German monarchs. The German monarchy possessed no executive officials comparable with the English sheriff or justice of the peace, and it was diverted from its guardianship of law and order by recurrent conflicts with the papacy and by its absorption in purely dynastic matters. Consequently, the proclamation and enforcement of the peace fell into the hands of regional associations of cities and of the individual territorial princes. Thus the monarchy was prevented from using its function as defender of the public peace as an entering wedge to invade the jurisdiction of the municipalities and the territorial lords.

In sum, the German rulers were being gradually deprived of their triple role of feudal suzerains, defenders of the church, and keepers of the peace. The sweeping privileges granted to the princes in 1220 and 1231 had undermined their position as feudal suzerain. Their bitter struggles with the papacy cast doubt on their credibility as protectors of the church. They allowed their powers as guardians of the public peace to slip into the hands of others.

The continued ascendancy of the princes. By Charles IV's death in 1378, the division of Germany into loosely defined territorial principalities had reached an advanced stage.

Division into territorial principalities

Southern Germany. In south Germany, the dissolution of the Hohenstaufen duchy of Swabia gave territorial predominance to the Habsburgs, whose original possessions lay in Alsace, Breisgau, the Vorarlberg, and Tirol. Rudolf's acquisition of Austria and Styria (1282) had more than doubled the Habsburg patrimony and established its centre of gravity in eastern Germany. The Habsburg's rivals and neighbours to the north, the counts of Württemberg, had combined with the Swabian nobles to foil the attempt of Rudolf to revive the defunct duchy of Swabia for one of his sons (the counts, insatiably acquisitive and the inveterate enemies of the cities of the region, were finally raised to ducal status in 1495). The margraves of Baden were chiefly preoccupied with the southward expansion of their territory on the upper Rhine at the expense of the independent small nobles and cities of Swabia.

These three large entities contained lesser lordships, which were in constant danger of absorption by marriage, purchase, or feud. Bavaria, granted to the house of Wittelsbach as a duchy in 1180, was strengthened by the acquisition of the Palatinate in 1214; but subsequent testamentary partition restricted this important gain to the Upper Palatinate.

Central Germany. In central Germany, the margraves of Meissen of the Wettin dynasty thrust steadily eastward and received the electorate of Saxony in 1423, when the Ascanian line of electors died out; in the west they obtained Thuringia (1263) and clung to it tenaciously despite repeated royal attempts to oust them by claiming it as a vancant fief. The landgraves of Hesse, though surrounded by powerful neighbours, contrived to make modest territorial gains at the expense of the Wettin dynasty and the archbishops of Mainz. East and south of Hesse, the Rhine–Main region was a land of great ecclesiastical princes: the archbishops of Mainz, Trier, and Cologne; the bishops of Speyer, Worms, Würzburg, and Bamberg; and the wealthy abbots of Fulda and Lorsch. It abounded in counts of the second rank, dominated by a great secular prince, the count Palatine of the Rhine. The area contained four electorates and was therefore of crucial political importance.

Northern Germany. In north Germany, the dukes of Brunswick dissipated their strength by frequent divisions of their territory among heirs. Farther east the powerful duchy of Saxony was also split by partition between the Wittenberg and Lauenburg branches; the Wittenberg line was formally granted an electoral vote by the Golden Bull of 1356. The strength of the duchy lay in the military and commercial qualities of its predominantly free population. But the vigour of its eastward expansion into the Slav lands beyond the Elbe tended to diminish its involvement in the internal politics of the *Reich*.

Eastern Germany. In east Germany, the duchy of Mecklenburg, Germanized by a steady stream of immigrants, was drawn deeply into Scandinavian affairs and in 1363 provided Sweden with a new royal dynasty in the person of Albert of Mecklenburg. The electorate of Brandenburg, purchased by Charles IV and bequeathed to his second son, Sigismund, was dominated by a disorderly and rapacious nobility. Sigismund granted this dubious asset in 1415 to his faithful ally Frederick, burgrave of Nürnberg. The kingdom of Bohemia remained the durable territorial core of the Luxembourg dominions, and its silver mines at Kuttenberg, under German supervision, vastly increased crown revenues. The Slav population resented increasingly the economic and cultural influence of the German minority, and this created antagonisms profoundly disturbing to the monarchy.

Continued dispersement of territory. Inside the various territories the consolidation of the princely authority was far from complete. The principalities were often ragged in outline and territorially dispersed because of the accidents of inheritance, grant, partition, and conquest. Everywhere lesser nobles disputed the power of the prince and formed associations in defense of their rights and fiefs. In the ecclesiastical princedoms the ascendancy of an archbishop or a bishop was contested by the cathedral chapter, which had become a preserve of the nobility. The self-governing cities fought to protect their chartered liberties and drew together in formidable leagues to resist princely encroachments. Thus the princes, trying to enforce their authority, tended to consolidate the opposition and to excite potential or open hostility.

Opposition to princely power

In this crucial struggle the great secular potentates impaired their own strength by persisting in the Germanic custom of dividing their territory among their sons instead of transmitting it intact to the eldest. By 1378 the Bavarian lands of the house of Wittelsbach were shared between three grandsons of Louis IV. In 1379 the wide possessions of the Habsburgs were partitioned by family agreement between Albert III and his younger brother Leopold.

The ecclesiastical princes, dedicated to celibacy and elected by their cathedral chapters, could not hand on their lands to their descendants. But their policies and aspirations were no less worldly than those of the secular princes, and most of them contrived to install their relatives in rich canonries and prebends.

1378 TO 1493

Internal strife among cities and princes. The electors had voted for Wenceslas reluctantly during Charles IV's reign, fearful that the monarchy might become a perquisite of the house of Luxembourg. Most of the other princes shared their concern over the continued ascendancy of the dynasty.

Wenceslas. Wenceslas (ruled 1378–1400) inherited a variety of problems, which grew after his father's statesmanlike hand had been removed. Wenceslas' habitual indolence and drunkenness, vices that increased as he grew older, excited the pious indignation of his critics. His prolonged periods of residence in Bohemia betrayed his lack of interest in German affairs and allowed the continuous friction between princes, cities, and nobility to develop into open warfare.

Conflict between princes and cities

The collision of princes and cities was prompted by vital issues of long standing. The flight of the rural population from servile tenures on the land to the free air of the cities reduced the labour force and impaired the revenues of territorial lords. Others who stayed on the land accepted the protection and jurisdiction of the neighbouring city as "external" citizens (*Ausbürger, Pfahlbürger*) and thus withdrew themselves and their land from seignorial control. Only the most powerful cities (*e.g.*, Nürnberg, Rothenburg) were able to extend their extramural territory to a substantial degree by force. But all strove to expand the area of their jurisdiction at the expense of local lords, partly to prevent village industries from competing with the city guilds.

A second major issue was the insistence of territorial lords on imposing tolls on city merchandise in transit

through their possessions. In theory, tolls on road and river traffic were exacted in return for the protection of merchants and their goods. But the multiplication of toll stations without legal warrant hampered trade and provoked innumerable disputes, which often culminated in the seizure of merchants and merchandise by exigent lords.

The third and immediate cause of the crisis lay in the financial policy of Wenceslas himself. His Bohemian revenues, though large, were strained by the great sums payable to the electors in return for his elevation to the kingship. Hence he attempted to tap the resources of the imperial cities by demanding heavy taxes, and he threatened to mortgage recalcitrant cities to the neighbouring princes, their capital enemies.

On July 4, 1376, an alliance of 14 imperial cities of Swabia was formed under the leadership of Ulm and Constance for mutual protection against unjust taxes and alienation from the empire. The Swabian League counted 40 members by 1385 and was linked with similar coalitions in Alsace, the Rhineland, and Saxony. Wenceslas' initial hostility to the league faded as its membership increased, and in 1387 he gave it his verbal and unofficial recognition. He feared to offend the territorial princes by extending full recognition; further, a clause of the Golden Bull had declared all city leagues to be illegal. Thus he temporized and awaited the outcome of the approaching trial of strength between cities and princes. On August 28, 1388, the princes of Swabia and Franconia routed the largely mercenary forces of the Swabian League at Döffingen, near Stuttgart. The stipendiaries of the Rhenish League were put to flight by the count Palatine Rupert II near Worms on November 6.

The cities triumphantly withstood the ensuing siege operations, but their economy was injured by the forays, ambuscades, and blockades instituted by the princes. The protracted campaigns also exhausted the financial resources of the princes. When Wenceslas intervened in 1389, both parties were ready for peace. At the Diet of Eger (May 2) he ordered them to desist and declared the city leagues to be dissolved. The contestants complied. The princes were satisfied with the prospective disbandment of the cities, and the cities feared the consequences of further resistance. But Wenceslas' opportunism was relished by neither side; the princes disliked his political flirtation with the cities, and the cities resented his final championship of the cause of the princes.

Wenceslas' alienation of cities and princes

Wenceslas' early gestures of support for the cities rankled with the electors, who in 1384 and 1387 discussed the advisability of replacing him by an imperial vicar or regent. But Wenceslas learned of the plan and conveyed his opposition; nor could the electors unite on their choice of a regent. Some electors turned to a more drastic solution: his deposition. In 1394 Rupert II and the archbishop Frederick of Cologne considered the election of Richard II of England but failed to win the support of their electoral colleagues. In the following year, however, Wenceslas' elevation of Gian Galeazzo Visconti, imperial vicar of Milan, to the status of duke was assailed as a dismemberment of the empire and enabled the electors to pose as the indignant defenders of the integrity of the *Reich* against a wasteful and profligate king. Wenceslas attempted to conciliate the princes by appointing his younger brother Sigismund as German regent (1396). But the Milanese issue enabled Rupert and Frederick to enlist the support of the archbishops of Mainz and Trier for their proposed deposition of Wenceslas. The death of Rupert in 1398 occasioned some delay. But at length the electors compiled a lengthy series of charges against the King, and in September 1399 they openly proclaimed their intention of deposing him.

At this critical stage further proceedings were temporarily checked by serious differences concerning the choice of Wenceslas' successor. The favoured candidate of the Rhenish electors was the count Palatine Rupert III, himself an elector. But another elector, Duke Rudolf of Saxony, and a powerful group of north German princes contended that the electors could not raise one of their own members to the kingship. The Golden Bull had declared otherwise, but Rudolf held his ground and declined to participate in the subsequent proceedings. On June 4, 1400, the four Rhenish electors invited Wenceslas to Oberlahnstein to consider measures for the reform of the empire and threatened to release themselves from their oath of allegiance if he failed to appear. The King's efforts to rally support for his cause were utterly fruitless, and he decided to stay in Bohemia. On August 20 Archbishop John of Mainz, on behalf of the four electors, publicly proclaimed the deposition of Wenceslas as an unfit and useless king and freed his German subjects from their allegiance to him. On the following day the three archbishops elected Rupert in Wenceslas' stead. Rupert's consent to his election was presumed to furnish the necessary majority required by the Golden Bull.

Deposition of Wenceslas

There was no solid constitutional basis for the electors' claim that they possessed the right to depose their king: the dethronement of Frederick II in 1245 had been effected by the papacy. Their political purpose was to disentangle the monarchy from the grip of the house of Luxembourg and to repatriate it to the Rhineland. They succeeded because Wenceslas could exercise no leverage in German affairs after alienating both the princes and the cities.

Rupert. Rupert (ruled 1400–10) lacked the skill and resources necessary to revive the drooping power of the German monarchy. His title was not beyond dispute while Wenceslas lived, and the territorial princes and cities were therefore slow to acknowledge him. Pope Boniface IX, maintaining that only a pope might legally depose a German monarch, withheld his approbation of Rupert. An expedition against Wenceslas (1401) failed before the walls of Prague. Rupert then embarked upon an Italian expedition (1401–02), hoping to obtain the imperial crown from the pope and thus dispel the cloud of uncertainty that hung over his title. The enterprise was crippled by lack of financial means, Boniface's conditions were exorbitant, and Rupert returned to Germany without the coveted imperial coronation. Fortunately, he had little to fear from Wenceslas, who was fully occupied in protecting his Bohemian throne from the machinations of his ambitious younger brother Sigismund. Far more dangerous was the degeneration of Rupert's relations with the Rhenish electors. In 1405 he offended Archbishop John of Mainz by refusing him military aid in his war against Hesse and Brunswick. Consequently the Archbishop united all the enemies of Hesse and Brunswick in the League of Marbach, which included 18 imperial cities. Rupert contended that coalitions of cities were prohibited by the Golden Bull, and he denounced the league as illegal. The dispute was arrested by the mediation of the Archbishop of Cologne, but the memory rankled. Rupert's prospects darkened still further in 1408, when he lent his support to Pope Gregory XII against the cardinals who wished to summon a general council to end the Great Schism in the church. The archbishops of Mainz and Cologne and the vast majority of the German prelates favoured the conciliar solution and strongly approved the policy of the cardinals. Wenceslas shrewdly followed suit and in return received assurances from the cardinals that the future general council would recognize him as German king. The powerful proconciliar party in the German Church proceeded to agitate openly for the restoration of Wenceslas to the throne. But the threat of civil war was averted by Rupert's death on May 18, 1410.

Sigismund. On the death of Rupert the movement for the reinstatement of Wenceslas immediately lost headway. The Rhenish electors, having deposed Wenceslas ten years previously on ground of his unfitness, could not re-elect him without admitting their inconsistency. But the House of Luxembourg was powerful and would assuredly throw its full weight against any non-Luxemburg candidate to the German throne. The four electors agreed on the expediency of selecting Rupert's successor from the Luxembourg dynasty but disagreed on the choice of candidate. Rupert's successor, the count Palatine, and the archbishop of Trier elected Wenceslas' brilliant but unreliable brother, Sigismund, at Frankfurt on September 20, 1410. Eleven days later, the archbishops

of Cologne and Mainz elected Wenceslas' turbulent and treacherous cousin, Jost of Moravia. Jost died the next year, and Wenceslas agreed to accept Sigismund on condition that he himself retained the title of German king. But Sigismund ignored the reservation and assumed the disputed title. Wenceslas' protests were greeted with indifference in Germany and quickly died away. A second election of Sigismund at Frankfurt (July 21, 1411) gave him an ample majority and removed all doubt concerning the validity of the previous election.

Sigismund's character

Sigismund was energetic, versatile, and intelligent; but long experience never blunted his rashness in rushing into new projects, and his financial incapacity never ceased to astonish his contemporaries. His pursuit of personal power and dynastic possessions was unceasing and was conducted with complete unscrupulousness. His kingdom of Hungary and his later acquisition, Bohemia, were his primary concerns, and the interests of Germany were constantly set aside in their favour. The disastrous reigns of his predecessors, Wenceslas and Rupert, had emphasized Germany's basic problems: the weakness of the monarchy, the friction between princes and cities, and the unchecked growth of lawlessness and disorder. During his long reign (1410–37) Sigismund appeared less and less frequently in Germany and, as a largely absentee ruler, did little to correct these evils.

The Hussite controversy. Sigismund's prolonged absences were caused in great part by the explosive Hussite controversy in Bohemia. The Czech Church in Bohemia had long retained a marked individuality and much autonomy in its liturgy. This independent temper in ecclesiastical affairs was being slowly fused in the late 14th century with a rising sentiment of nationality among the Czechs. The upsurge of feeling took the negative form of a growing hatred of the German minority, which dominated the towns by virtue of its economic power and cultural influence. The luxury and immorality of the Bohemian clergy were castigated by a series of religious reformers such as Conrad of Waldhauser, Thomas of Štítný, John Milíč of Kroměříž (Kremsier), and Matthew of Janov. The teachings of Conrad and Milíč assumed a strongly puritanical tinge: in opposition to the wealthy sacramental church with its external means of grace they held up the ideal of the primitive church in a condition of apostolic poverty and the exclusive authority of the Bible as the foundation stone of faith and belief. These three movements met and intermingled in the person of Jan Hus.

Jan Hus. A graduate in divinity of Charles IV's foundation of the University of Prague, Hus was appointed incumbent of the Bethlehem Chapel in Prague (1402) and immediately attracted wide attention by his sermons, which were delivered in Czech in accordance with the foundation charter of the chapel. In 1403 he strongly defended a number of extracts drawn from the religious writings of the Englishman John Wycliffe. Czech opinion in the university solidly supported Hus. But the more numerous German masters carried the day, and the teaching of the controversial extracts was forbidden. Similarly, when Pope Gregory XII's cardinals rebelled against the Pope and demanded a general council to terminate the schism in the papacy (1408), the Czech members of the university aligned themselves with the cardinals, while the Germans stood with the Pope. On matters of general policy the masters of the university voted by "nations," of which there were four: Bohemian, Bavarian, Saxon, and Polish, the last consisting in fact largely of Germans. Thus the Germans controlled three votes, the Czechs only one. King Wenceslas reversed the proportion by decree, the German masters and students seceded to found their own university at Leipzig, and the mutual enmity deepened.

Hus's excommunication

In 1410 Hus was excommunicated by Archbishop Zbyněk of Prague but refused to appear at the papal court for judgment and continued to preach. Two years later he protested against the sale of indulgences, was placed under papal sentence of excommunication, and the city of Prague was subjected to a papal interdict. Hus left the capital at Wenceslas' request but preached throughout the land and vastly enlarged his following. From the lower Czech clergy who popularized Hus's doctrines, the masses learned that the German minority were intruders, foes of Bohemia and of the true religion. Lesser nobles who had lost their lands by mortgage or purchase to the prosperous German burghers of the cities were readily converted. The more self-interested members of the upper nobility were attracted by Hus's proposed reduction of the Czech Church to apostolic poverty, which would bring the rich territorial possessions of the higher clergy within their grasp.

The rising ferment in Bohemia disquieted the heir apparent, Sigismund, and he intervened with the suggestion that Hus should expound and justify his opinions to the Council of Constance (1414–18), recently convened to heal the schism in the papacy. Hus accepted, and Sigismund furnished him with a comprehensive safe conduct. The conciliar commission that examined Hus focussed the debate on two issues: the unauthorized Bohemian practice of extending communion in both kinds (bread and wine) to the laity, and the points of agreement between Wycliffe and Hus. Hus declined to retract his Wycliffite opinions until they were refuted by Holy Writ, and thus he defied the authority of the council in matters of doctrine. He was arrested on November 28, 1414, and died courageously at the stake on July 6, 1415. Sigismund's protests against the breach of his safe conduct were silenced by the argument that pacts with convicted heretics were not binding.

The Council of Constance

The Hussite wars. The death of Hus enshrined him at once as a martyr and a national hero in the memory of his followers. They raised a storm of denunciation against Sigismund and expressed their resentment by widespread attacks on orthodox priests and churches. The Catholics retaliated in kind, and Bohemia was in a state of civil war when the death of Wenceslas (August 16, 1419) brought Sigismund to the tottering throne. The new king's talent for conciliation and compromise was useless in the heated religious atmosphere. Pope Martin V urged him on against the Hussites and promised him imperial coronation as his reward. Under his prompting, Sigismund raised a motley host in Germany and launched it into Bohemia under the banner of a papal crusade (March 1, 1420). But the invaders were thrown back from the walls of Prague, and on July 7, 1421, Sigismund was declared deposed by the Bohemian assembly of estates. The shock of defeat forced Sigismund to attempt a fuller mobilization of German resources. Under the traditional system, princes and cities had been allowed to fix at their own discretion the quota of men provided by each when a royal campaign was in prospect. Naturally, both estates used their discretionary power to reduce contributions to a minimum. In 1422, however, Sigismund himself fixed the strength of the contingents demanded from the individual princes and cities throughout Germany. The response was disappointing. In 1426 the King raised his requirements, but to no effect. Hence the yearly campaigns against the Hussites were waged largely by mercenary armies. To meet the rising costs, the Diet of Frankfurt was persuaded in 1427 to vote a general tax, the so-called Common Penny. But there was little enthusiasm in Germany for the crusade, massive evasions of payment occurred, and the strength of local feeling hampered the coercion of defaulters.

Hussite raids into Germany

In 1429–30 the irrepressible Hussites swept through Saxony, Thuringia, and Franconia in a destructive foray. Sigismund, exploiting the general alarm, reverted to the older system and demanded contingents from each prince and city. The response improved, and a large army invaded Bohemia, only to meet complete disaster at Taus (Domažlice in modern Czechoslovakia) in 1431. It was evident that the veteran Hussites could not be crushed by force. Sigismund therefore welcomed the opportunity to transfer the problem of reconciling the Hussites with the church to the Council of Basel (1431–49). The Hussite extremists, the Taborites, were inflexible. They condemned the hierarchical system of church government and affirmed the priesthood of all true believers. Hence the council conducted its long and arduous negotiations

with the majority party among the Hussites, the Calixtines or Utraquists, who were prepared to accept the grant of communion in both kinds as a basis of settlement. The Utraquist nobles annihilated the protesting Taborites at the Battle of Lipany (May 30, 1434), made peace with the council by the Compact of Iglau (July 5, 1436), which conceded them communion in both kinds, and reunited with the Roman Catholic Church. The Utraquist nobles extracted far better terms from Sigismund as the price of their recognition. He agreed to accept the guidance of Czech councillors in governmental affairs, to admit only Czechs to public office, to grant an amnesty for all offenses committed since the death of Wenceslas, and to allow the Czechs a large measure of autonomy in their civil and religious life. It is unlikely that the slippery Sigismund intended to honour these pledges, but they cleared the way for his triumphant return to Prague in August 1436.

Effects of the wars on Germany

In Germany, the Hussite threat had clearly revealed the inadequacies of the existing financial and military systems. But the incentive to press Sigismund's reforms to a successful conclusion faded when the Hussite peril was scotched by negotiation. The general apathy was demonstrated in 1434, when Sigismund proposed to the princes a land peace embracing the whole of Germany. The abolition of private wars and feuds by such a peace was undeniably a paramount necessity. But the princes themselves were among the chief offenders against law and order, and their nominal approval of the plan deceived no one. Sigismund himself, increasingly absorbed in crucial negotiations with the Hussites, did not persevere, and the project gathered dust in the imperial archives. The impulse he gave to the cause of reform did not, however, fade entirely, though Sigismund did not live to see the sequel. His death on December 9, 1437, terminated the tenure of the German throne by the House of Luxembourg and opened the door of opportunity to the Habsburg dynasty.

The Habsburgs and the imperial office. *Albert II.* In the absence of a male heir, Sigismund had named his son-in-law Albert of Habsburg, duke of Austria, as his successor. Albert was able and vigorous, and the union of the territories of the two dynasties enabled him to exert considerable leverage in German politics. Albert declared his neutrality in the current dispute between Pope Eugenius IV and the Council of Basel on the subject of conciliar sovereignty and thereby evaded an issue on which the electors were strongly divided; thus, on March 18, 1438, he was unanimously elected at Frankfurt. The electors attempted to elicit from the new king an undertaking that he would grant privileges to his subjects only with their advice and consent. They also submitted a project for the division of Germany into four new administrative units (*Kreise*) in which the enforcement of the land peace would be entrusted to captains of princely rank. Albert judged that the princes were seeking to enlarge their power and influence under the guise of introducing reforms for the common good. The German cities also doubted the impartiality of the princes as custodians of law and order. Both proposals were therefore stillborn. The King hastened from Frankfurt to defend his kingdom of Hungary, endangered by Turkish raids on Siebenbürgen (Transylvania in modern Romania). The campaign was brought to a premature close by the death of the King on October 27, 1439.

Frederick III. Albert II had left only an infant son, and the leadership of the House of Habsburg passed to his cousin Frederick, duke of Styria. Inside the electoral college the Duke was vigorously supported by his brother-in-law Frederick of Saxony and was elected unanimously on February 2, 1440. The choice of Frederick tightened the hold of the Habsburgs on the German kingship. It also brought to the throne a ruler who, absorbed in dynastic concerns and in astrology, had no more than a passing interest in Germany. Under the absentee government of Frederick III, the feuds among the princes and the collisions between the princes and the cities developed into savage wars accompanied by widespread ravaging and pillage. All paid lip service to the need for peace; but who was to enforce it? Was it to be enforced by the monarchy, which lacked power and executive machinery? Was it to be enforced in the courts of the princes, whose judicial impartiality was suspect? Were complaints against the princes to be heard and decided in the king's court (*Hofgericht*)? Or must they be adjudicated by the council (*Hofrat*) of the prince concerned? The right to enforce peace effectively was a major source of power to the holder: hence the struggle between Frederick and the princes was long, bitter, and inconclusive.

The Turkish threat

These issues were brought to a head by the rapid westward progress of the Ottoman Turks after their victories at Varna on the Black Sea (1444) and at Kossovo in Serbia (1448). The Habsburg kingdom of Hungary and Frederick III's own duchy of Styria lay full in the path of the invaders. In 1453 the fall of Constantinople extinguished the Eastern Empire and aroused fears in Germany that the Western Empire would meet with the same fate. The King used the opportunity to demand financial aid against the Turks from the diet, the German assembly of estates. Under the leadership of the princes, the diet reminded him that Germany's capacity for defense was weakened by the current internal anarchy. In 1455, six electors proposed to the King the establishment of an imperial court of justice in which all three estates (electors, princes, and cities) should be represented. Frederick dismissed the scheme as an attempted invasion of his authority and stubbornly maintained his disapproval in a series of stormy interviews.

In time an increasing number of princes became convinced that reform would make no significant progress until Frederick was removed. As early as 1460 the Wittelsbach princes urged his deposition in favour of George of Poděbrady, the able and resourceful king of Bohemia. To check the danger, Frederick began to dole out reforms with a sparing hand. In 1464 he consented to make the court of the treasury (*Kammergericht*) independent of his person, to staff it with representatives of the three estates, and to extend its jurisdiction into fields other than financial. It was the acquisition of Austria in 1463 on the death of his brother Albert that finally proved his undoing. The unruly Austrian nobility early took the measure of Frederick and thereafter disregarded his authority. On the east and south the duchy was imminently threatened by the expanding kingdom of Hungary under its land-hungry ruler Matthias Corvinus. The southern borders of the Habsburg lands were also ravaged by the Turks. Frederick's continuing irresolution and passivity encouraged Matthias Corvinus, who had already seized a portion of Bohemia, to launch a campaign against Austria. The Austrian nobility made no move against him, and Vienna fell to him in 1485. Frederick fled to Germany and made pitiful appeals for help to the princes. His misfortune provided the party of reform with a long-awaited opportunity. Led by Berthold of Henneberg, the able and resolute archbishop of Mainz, they pressed the aging and afflicted Frederick to relinquish the kingship in favour of his son Maximilian. Solaced somewhat by the assurance of a Habsburg succession, he gave a reluctant acquiescence, and Maximilian was elected on February 16, 1486. Frederick retained the title of emperor, held since his imperial coronation at Rome in 1452. But he played no part in the government of Germany, and his death on August 19, 1493, passed almost unnoticed.

Loss of Austria

Developments in the individual states to c. 1500. *The princes and the Landstände.* In the various principalities the outcome of the struggle between the territorial princes and the assembly of estates (*Landstände*) was not fully decided by 1500. The vigour of the conflict arose partly out of the contrasting conceptions of government held by the protagonists. The secular princes looked upon their lands as private possessions that could be divided by agreement among their sons and drew little distinction between their private and their public revenues. The three estates regarded themselves as the corporate representatives of the whole territorial community and maintained that actions by a prince affecting their interests and privileges should be subject to their con-

sent. They therefore opposed the partition of the territory by family pact among the princes' sons. The inadvisability of breaking up the principalities into petty territorial lordships was at length conceded by the more prudent princes. By 1500 the rulers of Bavaria, Brandenburg, Saxony, and Württemberg had accepted the principles of territorial indivisibility and primogeniture.

Dispute over taxation

In financial matters the imposition of extraordinary taxes (*Notbeden*) remained the crucial issue between the princes and the estates. The mounting cost of war and administration outstripped the ordinary revenues of the ruler, plunged him deeply into debt, and compelled him to seek financial aid from the estates with increasing frequency. In the absence of a clear distinction between public and private revenue, the estates often contended that the deficit was a private debt of the prince and disclaimed responsibility. Needy princes were thus forced to buy temporary solvency by concessions that later shackled them in their dealings with the estates. The estates regarded the *Notbede* strictly as an occasional emergency tax and insisted that it should be reasonable in amount. Indeed, the estates of Bavaria and Brunswick extracted from their respective princes in the course of the 14th century a formal recognition of their right of armed resistance to extortionate taxation. Similarly, any prince who broke his agreements with the estates was subject to the right of resistance. Thus the aims of these territorial assemblies were in part negative. They sought to preserve the privileges of the three orders, to restrain the power of the prince, and to limit taxation. But they were also actively interested in good government, and the more enlightened rulers usually issued their ordinances only after consultation with the estates.

The princes proceeded against these powerful and often turbulent bodies with great caution. They persistently demanded that territorial assemblies convene only at the summons of the prince. They discountenanced the widespread conviction that absentees from the assembly were not bound to pay the taxes that it voted. In consequence, the peasants, who were not represented except in the Swiss cantons Baden, Friesland, and Tirol, remained in the grasp of the princes' tax collectors. In these directions the princes had generally made notable advances by 1500. But in the vital matter of the *Notbede* they were still obliged to bargain with the estates as equals. They had nowhere attained their ultimate objective: to transform the tax into a regular imposition voted automatically by the estates on demand.

Beyond the confines of the assembly of estates the attempts of the princes to curb their overmighty subjects aroused vigorous resistance. The noble vassals, proud and unruly, readily combined against any prince who sought to tamper with their liberties. Wise rulers deflected the nobles' energies into useful channels by employing them as stipendiaries. Hence even the most powerful princes—the Habsburgs in Austria and the Hohenzollerns in Brandenburg—proceeded circumspectly, and the difficult task of bringing the nobility to heel was far from completed in 1500. The cities of the princely territories defended their independence no less stubbornly. The princes revoked their charters, influenced municipal elections, and forbade the cities to associate in self-defense. The struggle was most intense in the north and east, where the Hohenzollern dynasty of Brandenburg emerged as the chief foe of municipal freedom. In 1442 the elector Frederick II ("Iron Tooth") crushed a federation of Brandenburg cities and deprived its leader, Berlin, of its most valued privileges. In the Franconian possessions of the dynasty, Albert Achilles of Hohenzollern waged a destructive war (1449–50) against a city league headed by Nürnberg. He suffered a resounding defeat in a pitched battle near Pillenreuth (1450). The elector John Cicero took up the battle 38 years later, when the cities of the Altmark in west Brandenburg refused to pay an excise tax on beer voted by the assembly of estates.

The "Beer War"

He discomfited the cities in the ensuing "Beer War" and radically revised their constitutions to his own advantage. On the other hand, the great cities of south Germany, enriched by the Italian trade, were more than a match for the local princes: the Wittelsbach dukes of Bavaria were decisively worsted by Regensburg in 1488.

The growth of central governments. Between 1300 and 1500 the organs of central government in the territorial states became more specialized and diversified. The parent body was the advisory council (*Hofrat*) of high nobles and ecclesiastics, whom the prince consulted at his discretion. Its business was not differentiated, and there was no division of labour among the councillors. It met at the summons of the prince and did not convene at regular intervals. Its membership was not fixed, and some advisers did not attend except at special invitation. Others were regional councillors who attended the prince only when he appeared in their locality. A body so unspecialized and fluctuating was ill-adapted to cope with the increasingly complex problems of central government. Hence in the 14th and 15th centuries a professional element of "daily" or permanent councillors was introduced. They were usually legists, trained in Italy or in the newly founded universities of Prague (1364), Vienna (1365), Heidelberg (1386), Rostock (1419), and Tübingen (1477). They were well versed in Roman law, which, with its centralizing and authoritative precepts, provided a congenial climate for the growth of the powers of the territorial princes everywhere save in Saxony and Schleswig-Holstein, where the ancient customary codes were deeply rooted. Financial administration, which required specialized skills, was placed under the direction of a separate department of government, the chamber (*Hofkammer*). An inner ring of favoured advisers, the privy council (*Geheimrat*), was also instituted to counsel the prince on affairs of state. The besetting weakness of the new administrative structure was financial. Few princes followed the example of the Hohenzollern dynasty in drawing up an annual budget and requiring financial officials to submit regular accounts to the government.

German society, economy, and culture in the 14th and 15th centuries. *Transformation of rural life.* Despite the impressive advance of trade and industry in the later Middle Ages, German society was still sustained chiefly by agriculture. Of an estimated population of 12,000,000 in 1500, only 1,500,000 resided in cities and towns. Agriculture exhibited strong regional differences in organization. The more recently settled areas of the north and northeast were characterized by great farms and extensive estates that produced a surplus of grain for export through the Baltic ports. The south and southwest was a region of denser population, thickly sown with small villages and the "dwarf" estates of the lesser nobility. In the northeast the great landlords, headed by the Knights of the Teutonic Order, tightened their control of the originally free tenants, denied them freedom of movement, and ultimately bound them to the soil as serfs. In the south the heavy urban demand for grain chiefly benefitted the larger peasant proprietors, who sold their surplus production in the nearest town and used their gains to acquire more land. The lesser peasantry, with their smaller holdings, practiced chiefly subsistence farming, produced no surplus, and therefore failed to benefit from the buoyant urban demand. The frequent division of the patrimony among heirs often reduced it to uneconomically small fragments and encouraged an exodus to the cities. On the other hand, landless day labourers who survived the Black Death in the mid-14th century were able to command higher wages for their services.

Serfdom in the north

In south Germany, the strain of transition in rural society was heightened by the policies of the landlords, lay and ecclesiastical. Confronted by labour shortages and rising costs, many landlords attempted to recoup themselves at the expense of their tenants. By means of ordinances passed in the manorial courts they denied to the peasantry their traditional right of access to commons, woods, and streams. Further, they revived their demands for the performance of obsolete labour services and enforced the collection of the extraordinary taxes on behalf of the prince. The peasants protested and appealed to custom, but their sole legal recourse was to the manorial court, where their objections were silenced or ignored. Ecclesiastical landlords were especially grasping,

and peasant discontent assumed a strong anticlerical tinge and gave rise to the localized disturbances in Gotha (1391), Bregenz (1407), Rottweil (1420), and Worms (1421). Disturbances recurred with increasing frequency in the course of the 15th century on the upper Rhine, in Alsace, and in the Black Forest. In 1458 a cattle tax imposed by the archbishop of Salzburg kindled a peasant insurrection, which spread to Styria, Carinthia, and Carniola. In Alsace, the malcontents adopted as the symbol of revolt the *Bundschuh*, the wooden shoe usually worn by the peasants. They also formulated a series of specific demands, which included the abolition of the hated manorial courts and the reduction of feudal dues and public taxes to a trifling annual amount. On these fundamental points there was little room for compromise, and the outbreaks were stifled by the heavy hand of established authority. But the rigours of repression added fuel to peasant discontent, which finally burst forth in the great uprising of 1524–25 (see below).

Peasant discontent in south Germany

The nobility. The lesser nobility included two distinct elements. The imperial knights (*Reichsritter*) held their estates as tenants in chief of the crown. The provincial nobility (*Landesadel*) had lost direct contact with the crown and were being compelled by degrees to acknowledge the suzerainty of the local prince. The imperial knights had been extensively employed by the Hohenstaufen emperors in military and administrative capacities and were chiefly concentrated in the Hohenstaufen possessions in Swabia, Franconia, Alsace, and the Rhineland. With the extinction of the Hohenstaufen dynasty they lost their function and rewards as a nobility of service. Their revenues from their small estates sank in purchasing power as prices rose. Caste prejudice prevented them from seeking an alternative role in trade or industry. Resentful of the decline in their fortunes and fiercely independent, they clung grimly to their remaining privileges: exemption from imperial taxes and the right to indulge in private war. They stubbornly resisted the persistent attempts of the princes to reduce them to subject status, and in Trier and Württemberg especially they were given valuable aid by the provincial nobles. For purposes of defense or aggression the imperial and provincial knights combined freely in powerful regional leagues, usually directed against the local princes or cities. In the course of their chronic feuds with the cities, many knights became mere highwaymen. Many others, who had been forced to sell their estates or who were encumbered with debts, took service in Germany or Italy as mercenaries (*Soldritter*). In east Germany the knights, though equally unruly, were far more affluent. The knightly estate (*Rittergut*) was larger and produced a profitable surplus for export. The knights sat in the assembly of estates, and taxation by the prince required their consent. They were therefore well entrenched against the encroachments of princely power.

Urban life. Urban society in 15th-century Germany was concentrated in some 3,000 cities and towns. About 2,800 of the total were extremely small, with populations varying from 100 to 1,000. Of the remainder, no more than 15 cities contained more than 10,000 inhabitants. In this restricted group three were pre-eminent. Cologne reached its peak in the 13th century with a population of 60,000, but sank to 40,000 by 1500 following internal disputes, expulsions, and steady emigration. In 1500 Augsburg was the most populous German city, with a resident population of 50,000. Third place was held by fast-growing Nürnberg, which counted 30,000 souls. The social unity of the citizen body had been most marked in the 13th century, when the guilds joined the dominant patrician families (*Geschlechter*) in wresting the right to form an independent city council (*Stadtrat*) from the lord of the city. In the 14th century the guild masters, methodically excluded from the council by the patrician oligarchy, broke into open revolt in Speyer (1327), Strassburg (1332), Nürnberg (1348), and elsewhere. In its economic aspect the ensuing conflict embodied an attempt by the guildsmen as industrial producers to free urban industry from the tight control exercised by the merchant patriciate. By 1500 the guilds almost everywhere had gained varying degrees of representation in the city council.

The guild system

In the meantime the guilds themselves had become increasingly oligarchical and exclusive as the established masters restricted the entry of new members in order to reduce competition. The ascent of journeymen and apprentices to the rank of master was obstructed by the imposition of excessive fees, and in many guilds membership became virtually hereditary. In consequence, the journeymen began to associate in fraternities of their own to press their demands for higher wages and a shorter working day. The masters denounced the fraternities as illegal, compiled blacklists of leading agitators, and formed intercity associations to enforce low wage rates. The day labourers and casual workers outside the guild structure had no protective organization and suffered heavily in periods of economic depression. The surviving tax records of the German cities, though not wholly reliable guides, nevertheless suggest wide extremes of wealth and poverty. In late 15th-century Augsburg, 2,985 of a total of 4,485 households (66 percent) were recorded on the tax rolls as exempt from taxation on the ground of insufficient means. At the other extreme stood the enterprising and prosperous business dynasties of the Fugger and the Welser. But not all wealthy citizens lacked public spirit: hospitals, almshouses, and charitable foundations multiplied within the city walls. The spreading evil of mendicancy was combatted by stringent legislation against able-bodied beggars in Esslingen (1384), Brunswick (1400), Vienna (1442), Cologne (1446), and Nürnberg (1447).

The decline of the church. The vigour and assertiveness of secular society in Germany was exercised increasingly at the expense of the clergy and the church. Among the upper clergy more than 100 archbishops, bishops, and abbots were temporal rulers. The prelates were usually sons of the nobility and did not allow election to church office to interfere with their aristocratic ardour for war and territorial acquisition. They were expert in the accumulation of benefices and were notoriously lax in the performance of their spiritual duties. Their influence was freely used to advance their kinsmen and partisans among the greater and lesser nobles, who poured into the cathedral chapters and ruled the abbeys. Thus the monasteries were filled with unspiritual persons, who were distinguishable from the lay aristocracy only by a nominal celibacy. Among the secular princes, the rulers of Austria, Brandenburg, and Saxony wrested from the papacy, gravely weakened by the conciliar movement of the 15th century, a right of appointment to a fixed number of bishoprics and lesser church offices. All the lay princes, in defiance of canon law, imposed their extraordinary taxes on the clergy. The steady invasion of the church by secular interests was also exemplified by the moral and material condition of the lower clergy. The Black Death of 1348–49 had decimated the ranks of the more dedicated priests, who ministered to their plague-stricken flocks instead of seeking safety by flight. The new recruits who rushed into holy orders were often self-seeking and spiritually unqualified. As the inflow continued, the problem of clerical unemployment and inadequate stipends attained greater proportions. Many were compelled by need to accept ill-paid livings. Others obtained no benefice at all and lived precariously as chantry priests or as itinerant chaplains. Their moral and intellectual defects were bitterly assailed by church reformers and by an increasingly well-informed laity. Pious Christians, especially in the cities, began to turn away from the priesthood in their search for spiritual comfort and to seek relief in mysticism or in lay associations practicing a simple, undogmatic form of Christianity.

Trade and industry. The most impressive achievements of the German economy between 1200 and 1500 lay in trade and industry. German trade benefitted from the Hundred Years' War between France and England, which diverted northbound Mediterranean merchandise from the customary Rhône valley route to the eastern Alpine passes; by the fierce internal warfare between the Italian city-states, which weakened their supremacy in

long-distance trade; and by the rapid economic development of "colonial" eastern Europe between the Baltic and the Danube. The north German trade was chiefly based on staple commodities such as grain, fish, salt, and metals. But the south German merchants, in their capacity as middlemen between Italy and the rest of Europe, had taken the lead by 1500. They combined trade and industry in the great Ravensburg Trading Company (1380–1530), which produced and exported Swabian linen and laid the foundation of the fortunes of the Höchstetter, Herwart, Adler, Tucher, and Imhof families. The most important independent concern was that of the Fugger, whose founder, Hans Fugger, began his career as a linen weaver in Augsburg. The Fuggers' accumulated profits provided capital for moneylending and banking, which they conducted with the aid of business techniques borrowed from the more advanced Italians.

The Ravensburg Trading Company

Cultural life. In the absence of a strong centralized monarchy to act as a focus, German culture continued to be regional in character and widely diffused. The mysticism of Meister Eckehart, Johann Tauler, and Heinrich Suso, which commanded all men to look for the kingdom of God within themselves, flourished chiefly in the cities of the Rhineland, where lack of diligent pastoral care forced Christians to call upon their own inner resources. In the same region social and moral satire attained an urgent and vivid realism. Sebastian Brant (1458–1521), born at Strassburg, spared no class in his epic on human stupidity, the *Narrenschiff*, or *Ship of Fools*. But it was in the thriving cities of south Germany, as yet little affected by Italian Humanism, that late Gothic culture reached magnificent heights in art, architecture, and sculpture. Albrecht Dürer, born in Nürnberg in 1471, challenged his generation with his evocative engraving of "Melencolia I" in which a brooding figure with closed wings sat idly amid a chaos of scientific instruments and meditated on the futility of human endeavour. In architecture, the hierarchical elaboration of the late Gothic style maintained its ascendancy and even made a notable conquest in Italy with the construction of the great cathedral of Milan, begun in 1387. The sculptured carvings of Tilman Riemenschneider (1468–1531) in the castle of Würzburg revealed the anxiety, the deep piety, and the religious sensibility of Christian men engaged upon a spiritual pilgrimage that was to continue to the Reformation and beyond. (C.C.B.)

III. Germany from 1493 to c. 1760

THE REFORMATION, TO 1555

Imperial politics

Maximilian I. Maximilian I, emperor from 1493 to 1519, the "last knight," has exercised German imagination as few other emperors have done. Dignified, affable, and showy, famous as a leader of the mercenary *Landsknechte* (infantry), as a hunter, and as a patron of the arts, he hatched fantastic plans to escape his unceasing financial embarrassment. In spite of all his failures, chance continued to deal him winning cards. His favourite project was to lead a European army against the Turks, but this could not be realized. Charles VIII of France invaded Italy in 1494; and this endangered not only the imperial fief of Milan but also the communications with Rome, which the Emperor valued, as he considered himself the protector of Christendom. Maximilian was not able to maintain his rights, despite the long series of wars and the continually changing alliances with the Italian states, the papacy, Switzerland, Spain, England, or France against whomever held Milan at the time. The German princes refused to follow Maximilian, as they feared that he would use them only to strengthen Habsburg interests. It is true that the estates in the Diet of Worms, guided by the archbishop of Mainz, Berthold von Henneberg, in 1495, granted a uniform and general tax, the "common penny," for the establishment of an imperial army and agreed to the erection of a supreme court to supervise the execution of the "permanent public peace" forbidding private feuds; but, in return, Maximilian had to agree to the setting up of a council of regency that was to supervise the Emperor. The estates, however, were neither organized nor resolute enough to impose their will for long on the Emperor, while the empire, without an imperial civil service, was too weak to secure its own revenue by taxation. The war with the Swiss Confederacy, which refused to tolerate Habsburg territorial possessions on its soil, virtually severed the connection between Switzerland and the empire in 1499, though Swiss independence was not formally recognized until the Peace of Westphalia in 1648.

Dynastic politics

In order to strengthen the material basis of his power, Maximilian was forced to expand the hereditary Habsburg territories. He never forgot this necessity, not even when he had to mortgage important sources of income, such as the Tirolese silver mines, to his creditors, the main creditor being the banking house of Fugger. By his new marriage to Mary of Burgundy (1477), daughter of Charles the Bold, he had brought to his house the possessions in the Netherlands. The marriages (1496 and 1497) of his son Philip I the Handsome to Joan the Mad and of his daughter Margaret to Joan's brother John, heir to the Spanish crowns (who died, however, within a few months of his marriage), brought about that linking of Spain, the Netherlands, and Austria that formed the basis for the worldwide empire of Charles V. Similarly, the betrothal of his grandson Ferdinand in 1516 to the Jagiello princess Anna created a claim on the succession not only to Hungary (where the rule of the Jagiello dynasty was weakened militarily and financially by the wars with the Turks and by the opposition of the Magyar nobles) but also to Bohemia, since her father was king of both. In return, however, Maximilian had to agree that the Knights of the Teutonic Order should do homage for Prussia to Anna's uncle Sigismund I the Old of Poland. Maximilian's arbitration between Bavaria-Munich and the Palatinate for the disputed succession to Bavaria-Landshut was paid for by his acquisition of the towns of Kitzbühel, Rattenberg, and Kufstein and the bailiwicks of Hagenau and Ortenau (1504). The territory around Lienz, which escheated to him after the death of the last count of Görz, linked Tirol and Austrian Swabia in the west with Austria proper in the east.

Beginning of the Reformation. Maximilian's reign saw the beginning of the Reformation. Criticism of the church had continued unabated since the great reforming councils of the 15th century. The states of western Europe had long ago made concordats with the Holy See permitting them to draw on the rich property of the church for government expenditures and forming, in fact, state churches largely independent of Rome. Similar moves on behalf of the *Reich* were unsuccessful as long as its rulers did not give up their pretension to the secular universal empire and, therefore, were not able to afford to renounce the power of the universal church. The only gainers were the territorial princes and the towns; they used the emergency powers of all secular authorities to reform the church in their territories but still allowed the papacy's complicated financial demands. Hence, from 1456, the imperial and territorial diets repeatedly formulated the "grievances (gravamina) of the German nation." They complained bitterly that the church was but an enormous financial institution that administered the means of salvation only with an eye to material profit. Complaints were also made against the privileged social and economic position of the clergy. In its higher ranks the church had become a welfare organization for the younger sons and daughters of the nobility. In some districts one-third of the soil was ecclesiastical property. Although the radical sermons of the mendicant friars glorified the ideal of a poor church, many prebendaries, monks, and nuns lived the pleasant life of drones, enjoyed special legal status, and were free of all civic burdens. This criticism found new food as the lives of high and low ecclesiastics became more secular and less edifying.

Luther's Theses

Martin Luther gave to this public criticism of the church a voice that could not be quieted and thus compelled a complete reconstruction of the church. The young monk and theologian, after many solitary struggles, had learned from his study of the Bible that men are justified not by the accumulation of pious works but by trusting in the mercy of God. His opposition to the traditional customs

of the church became public because of the abuses connected with the sale of indulgences. Albert of Brandenburg (1490–1545), son of the elector Johann Cicero, was a pluralist, holding the archbishopric of Magdeburg and Mainz and the administration of the bishopric of Halberstadt; this breach of canon law had to be paid for by increased dues to Rome. In order to reimburse the Fuggers and to obtain some additional income, he permitted a clever salesman, the Dominican Johann Tetzel, to sell indulgences in his dioceses by every dirty trick; the indulgence in question had been promulgated by Pope Julius II in 1506 on the occasion of the papal jubilee and had been renewed by Pope Leo X to obtain funds for the rebuilding of St. Peter's Cathedral in Rome. It is not quite certain that Luther, a professor of theology in Wittenberg, affixed his Ninety-five Theses to the door of the palace church on October 31, 1517. This was the usual way of inviting an academic discussion concerning a doctrine that was not yet a dogma of the church and that, according to Luther, endangered the sacrament of penance. Nevertheless within a few weeks the theses were printed and distributed all over Germany; against Luther's wish they were interpreted as an attack on the Roman Catholic Church. The papacy opened proceedings against him, but he was protected by his territorial prince, the elector Frederick III the Wise of Saxony, a key figure in the contemporary struggle for the imperial crown.

The election of Charles V. Maximilian's succession as an emperor was contested by his grandson Charles I of Spain, by Francis I of France, and for a short period by Henry VIII of England. Charles had been in Spain since 1517; after the death of his father, Philip the Handsome (1506), he united Burgundy with the Kingdom of Castile and its newly discovered lands in America; after the death in 1516 of his maternal grandfather, Ferdinand II of Aragon, Charles joined Aragon, Naples, and Sicily to his realms; and, after the death of Maximilian (1519), he and his brother Ferdinand I shared the Austrian hereditary lands together with claims on Bohemia and Hungary. Francis I of France, threatened by this extension of Habsburg power into the area of the Meuse and Scheldt and across the Pyrenees, did not intend to give up France's claim to lead Europe. Pope Leo X, as the temporal ruler of the papal states, wished neither for a renewal by the Habsburgs of the Hohenstaufen combination of the empire and Naples nor for the foundation by Francis I, who held Milan, of a French imperial line. He therefore advocated the candidacy of Luther's protector, Frederick the Wise, who was, however, too clearly aware of his own limitations and those of his power to agree to this. Both the French and the Habsburgs offered enormous bribes to the electors, but the contest was decided unanimously in favour of Charles, who became emperor as Charles V. German public opinion was also in his favour. The princes insisted on a series of solemn promises on the Emperor's part, contained in a "capitulation," both in order not to be drawn into the imminent war between him and France and in order to limit his rights by means of an oligarchic constitution for the *Reich*. If he broke the capitulation, the estates were to have the right to oppose him by force. For the remainder of his life Charles tried to fuse the dynastic and the imperial ideals, but he was pushing both ideas beyond their limit in the very period that saw the rise of the national states in western Europe.

The Diet and Edict of Worms (1521). In the meantime, the Lutheran affair assumed the proportions of a national movement. Luther became increasingly confirmed in his opinion that the Christian Church, according to Holy Writ, was not a visible external organization but a small group of people separated from the mass of nominal Christians by their belief in the divine revelation witnessed by the Bible. Luther felt called to a reform of the existing church, not to its complete reconstruction.

Support for Luther

The Humanists, fighting against the Schoolmen and the friars, believed him to be their partisan. The great Dutch Humanist Erasmus counselled moderation, but Ulrich von Hutten hoped to win both Luther and the young emperor over to his fight against Rome after the Swabian League had driven the quarrelsome Duke Ulrich from Württemberg and transferred the administration of Württemberg to Austria. Public opinion felt certain that the long-awaited reform of church and state would at last be realized. Luther, the most popular professor at the University of Wittenberg, where he allied himself with Philipp Melanchthon in an attempt to reform the curriculum, symbolized his formal separation from the church by burning a copy of the papal bull excommunicating him.

Charles came from Spain to be crowned at Aachen in October 1520 and to open his first Diet at Worms in 1521. He left Spain in a state of revolt. The regency, led by Cardinal Adrian of Utrecht (the future Pope Adrian VI), managed only slowly to gain the upper hand. Charles's aim was to renew the universal empire on the basis of the universal Habsburg power. At the Diet the estates obtained the agreement of the self-confident emperor to the establishment of a Reichsregiment, or Governing Council. The council, however, was to function only during his absence from the *Reich*, was to be led by an imperial viceroy, and was to be barred from dealing with foreign affairs. Since the capitulation that had secured Charles's election had stipulated that no subject of the empire could be declared an outlaw—a procedure that normally followed papal excommunication—without public trial, Luther's case had to be heard. When Luther steadfastly refused to recant his doctrines, the Edict of Worms was promulgated outlawing him and forbidding the reading and sale of his books. On his way home to Wittenberg, Luther, for his own protection, was secretly taken to the Wartburg Castle on the elector Frederick's order.

Immediately after the Diet of Worms, Charles made alliances against France, first with Pope Leo X, then with Henry VIII of England. He reconquered Milan and Genoa and defeated and captured Francis at Pavia in 1525. The Treaty of Madrid, which the imprisoned king signed to secure his release, did not last long, since the new pope, the vacillating Clement VII, formed the League of Cognac with Milan, Venice, and France in order to obtain small territorial gains. The sack of Rome by German and Spanish mercenaries in 1527 forced the Pope and France to make peace (treaties of Barcelona and Cambrai, 1529). Charles received the imperial crown at the Pope's hand in Bologna before he left again for Germany, the last elected king to be so crowned.

Lutheran church organization and the Peasants' Revolt (1524–25). Germany had seen far-reaching changes while Charles was absent. Luther's doctrines of the priesthood of all believers and of the Bible as the sole norm of life had shaken the bases of society as it had formerly been constituted. Wherever the authorities did not interfere, Evangelical congregations, independent in doctrine and discipline, sprang up throughout Germany. For, while Luther stayed in the Wartburg, his Wittenberg congregation listened to the "Zwickau prophets" led by Nickolaus Storch, who taught, as did Thomas Müntzer in Thuringia, that the true authority was not the Bible but the "inner light" given by God to the faithful. Other men, appealing to Luther's writings as their authority, used the general insecurity to further their own ends. The wealthy Franz von Sickingen, a friend of Hutten and, like all knights, hemmed in between the rising cities and the territorial princes, hoped that the impending changes would bring him a principality between the Nahe River and Alsace. He made war against the Archbishop of Trier but was himself besieged and killed in his castle of Landstuhl with the assistance of Philip the Magnanimous of Hesse. The Swabian League razed the castles of the knights allied with him throughout Franconia and the Odenwald (1523). The greatest upheaval was caused by the Peasants' Revolt that began in 1524 in the southern area of the Black Forest and spread in 1525 through southern Germany (except Bavaria), Hesse, Thuringia, Saxony, and Tirol. Citing Luther's plea for the "liberty of Christian men," the peasants demanded the restoration of their customary rights and destroyed abbeys and manor houses. Luther, however, attacked them in passionately worded pamphlets. The individual peasant bands, badly

The Knights' War

led, were easily defeated, with enormous loss of life by the armies of the territorial princes.

The experience of the Peasants' Revolt proved that the Reformation could not advance by itself outside the cities. Ecclesiastical visitations of rural parishes showed that the common man was rude and hostile to all religiosity, while the clergy were ignorant, negligent wasters of church property. With Luther's encouragement each territory now established its own state church; they all differed according to the character of the prince concerned and according to the changing political circumstances. Unsuitable priests were dismissed; inventories of ecclesiastical property were drawn up; consistories supervised the clergy, with the prince as *summus episcopus* ("supreme bishop") and judge of appeal; the monasteries were made to bear the cost of schools and churches; and provision was made for education, for church discipline, and for a uniform development of dogma. As none of the rulers wanted to give up uniformity of public service or of dogma, their subjects who differed from them on grounds of conscience had to emigrate.

The Diets of Speyer (1526 and 1529) and Augsburg (1530). During the long absence of the Emperor, the estates tried to find a political solution to the religious differences, but Charles refused to call a German national council. The governors of both the Reformed and Roman Catholic territories were convinced that in one territory there should be only a unanimous faith; otherwise new revolts would arise. Some of the Roman Catholic territories, united in the Regensburg Convention (1524) and in the Dessau League, promised one another mutual succour in the execution of the Edict of Worms, but this provoked the formation of the Torgau League of Evangelicals. At the Diet of Speyer of 1526, Luther's followers were willing to uphold the union with Rome if they were permitted to treat institutions and ceremonies based on the Bible as essential but to regard those that were man-made as not essential and only to be tolerated until the calling of a general council. Charles objected again, for he wished all ecclesiastical changes only to be settled by a council called by both the Emperor and the Pope. He needed them both for the realization of his idea—a universal Christian empire. As these two powers were actually in a state of war, the estates bound themselves to follow only their conscience until the next council.

The Zwinglian movements

Besides the state churches based on Lutheran doctrines, there arose another type of reformed organization, the Zwinglian, in which the civil community was itself identified as the legal embodiment of the church and in which the citizen was equated with the Christian. Huldrych Zwingli had abolished the mass and removed the sacred images in the Swiss city of Zürich. Zürich thus had to face the hostility of neighbours who had remained Roman Catholic and, for economic reasons, were not prepared to follow Zürich's example in cancelling their treaty for the provision of Swiss mercenaries to France. In Switzerland also there arose the radical Anabaptists, whose congregations also rapidly spread throughout southern Germany, Thuringia, Hesse, Silesia, and Moravia, into the Alpine valleys and down the Rhine into the Netherlands; everywhere they were cruelly persecuted by both Roman Catholic and Reformed authorities; a general war of religion was avoided only with difficulty. The Diet of Speyer of 1529 failed to produce any recess to which all the estates could agree: the Roman Catholic majority resolved to leave the solution of the religious quarrel to a future council, to oppose Zwingli's doctrines, and to keep the Edict of Worms; but the "protesting" minority appealed to the Emperor and to the council and, in the meantime, did not wish to do anything against their conscience. Philip the Magnanimous, landgrave of Hesse, invited Luther and Zwingli to Marburg, on the river Lahn, in the hope of reconciling their differences about the Eucharist so as to make possible a political alliance with the Swiss, but the attempt failed. Lutherans and Zwinglians presented to the Emperor different formularies of faith at the Diet of Augsburg (1530). Though drawn up in a conciliatory spirit, they did not lead to any compromise, since the Evangelicals remained firm on all questions of conscience. Yet the calling of a council could not be expected from the contemporary papacy, which could only foresee a diminution of its power as the likely result. Thus failed the attempts to reform the church in the empire. Those who wanted to recover the lost areas for Roman Catholicism had to use force. To be prepared against force, Philip of Hesse and the elector of Saxony, John the Steadfast, formed, in 1531, the Schmalkaldic League, consisting of the north German Protestant princes, Strassburg, and a number of south German cities. It proved impossible to form a counterleague, as the political interests of the Roman Catholic princes concerned were too divergent.

Protestant and imperial politics after Augsburg. Ferdinand, Charles V's brother, had been made his successor in the Austrian hereditary lands in 1522 and had become king of part of Hungary in 1526, after the death of his brother-in-law King Louis II in the Battle of Mohács against the Turks in 1529; and in 1526 a quarrel about the succession to Louis II's other kingdom, Bohemia, had ended with Ferdinand's election as king against his rivals, the Bavarian dukes. In 1531 Charles saw to it that Ferdinand was elected king of the Romans, or successor designate to the empire, despite strong Roman Catholic and Lutheran opposition. In the same year, the south German cities lost their Swiss backing when Zwingli was killed in the Battle of Kappel against the Roman Catholic cantons. When the Turks invaded Hungary again in 1532, Ferdinand was forced to buy the indispensable Protestant support by the Religious Peace of Nürnberg; a truce was called in doctrinal matters until the meeting of a council (now very far distant) or the next Reichstag. Philip of Hesse succeeded, with the help of French subsidies, in restoring Duke Ulrich to Württemberg, where he immediately introduced the Reformation (1534). Such successes gained new members for the Schmalkaldic League. The Reformation, in the form of strictly regulated state churches, spread along both shores of the Baltic, into Silesia, and to the lower Rhine.

Charles against the Turks

Charles, full of the dream of a universal empire, held it his highest duty to fight infidels and heretics. He was victorious against the Barbary corsairs of North Africa who had been harassing the coastal cities of Spain and ruining Spanish commerce in the Mediterranean, but this led to a renewal of hostilities with France. After futile campaigns in Provence and in the Netherlands, the ten-year Truce of Nice was mediated by Pope Paul III (1538). Paul, however, refused Charles's demand for a council. Consequently, Charles extended the religious truce to all the new adherents of the Augsburg Confession (Frankfurt Agreement, 1539), for he needed the aid of the Protestants against the Turks and now, moreover, had to compete not only with France but also with William, duke of Cleves-Jülich-Berg, heir to the rich duchy of Gelre. Religious colloquies at Hagenau, Worms, and Regensburg came to nothing. King Ferdinand had to watch impotently while the Ottoman sultan Süleyman I occupied Hungary.

In 1542 Francis I of France felt strong enough to make his fourth war against Charles V. The Schmalkaldic League remained inactive while Charles occupied Cleves and reintroduced Roman Catholicism; but Philip of Hesse and the elector, John Frederick I of Saxony, together expelled the Emperor's firmest partisan, Henry II of Brunswick-Wolfenbüttel, from his duchy and proceeded to evangelize it. At the same time Herman of Wied, archbishop-elector of Cologne, attempted to introduce Protestantism in his diocese with the advice of Melanchthon and the Strassburg reformer Martin Bucer. The Protestant faith was openly accepted in the bishoprics of Münster, Osnabrück, Paderborn, and Minden and was professed by Maurice, of the then ducal line of Saxony, and by Otto Heinrich of the Palatinate Neuburg.

The Schmalkaldic War. The Peace of Crépy (1544) between Charles V and Francis of France created the preconditions for a thorough overhaul of German affairs. While the Protestants were fooled by renewed religious talks at Regensburg, Charles got ready for war. The papacy had called a general Council to Trent for 1545

but hoped to escape this irksome promise by actively supporting the Emperor with money and troops. Charles obtained the neutrality of Bavaria and of Duke Maurice by vague promises. There was no doubt about the Emperor's purpose, yet the Schmalkaldic League proved unable to reform its cumbersome organization. The Emperor took the field against the league in the summer of 1546. Hesse and electoral Saxony could not bring themselves to risk the effective army they and their allies had quickly assembled; consequently, the Emperor was able to reinforce himself from Italy and the Netherlands. Impatient, Duke Maurice brought the decision when he, together with King Ferdinand, invaded unprotected Saxony in order not to lose the electoral dignity that had been promised to him. John Frederick fled but was caught near Mühlberg on April 24, 1547, and Philip of Hesse was made prisoner in July. Charles V had reached the zenith of his power, ready, with the help of the council, to lead back the strayed sheep into the fold of the church.

Charles V at the height of his success

The Augsburg Interim. The papacy, however, was not willing to see the Emperor all-powerful. Charles V had asked the Pope to consider and redress first the "grievances," but, when the long-awaited council had at last met, it had begun by redefining the creed and the apostolic traditions of the church. Indeed, Paul III had withdrawn his troops even before the Battle of Mühlberg and transferred the Council to Bologna in order to withdraw it from imperial influence. Thus, it was without papal backing that Charles V forced the Interim on the estates at the Diet of Augsburg (1547–48). This conciliatory formula restored Roman Catholic ritual in general but conceded the eucharistic cup to the laity and allowed priests who were already married to keep their wives pending the final decision of the general council. The Roman Catholic princes refused to accept this before the council had actually decided, and Roman Catholic priests were reintroduced by force in the Protestant areas and towns of southern Germany; but the common people either remained faithful to the expelled ministers (unless they went into exile) or renounced sermons and sacraments altogether where the authorities did not find a means of circumventing the Interim.

Pope Julius III recalled the Council to Trent in 1551, but the Protestant envoys, now admitted to its sessions, had to limit themselves to the mere presentation of their confessions of faith and to protests against decrees that could no longer be revised. Deeply disappointed, the Emperor had to recognize that the general council was unable to provide a viable solution for the religious conflicts in Germany.

Maurice of Saxony's war (1552). All the estates agreed in opposing the imperial absolutism, the "beastly Spanish servitude," as long as the Emperor, contrary to his election capitulation, kept Spanish troops in the *Reich*. The soul of the resistance movement was the ambitious Maurice of Saxony, whose Protestant faith was chiefly a means of affirming his princely independence and rise to power. His Treaty of Chambord with Henry II of France (1552) provided him with large subsidies for his war against the Emperor in exchange for the cession to France of the imperial cities of Metz, Toul, Verdun, and Cambrai. Taken by surprise, the Emperor fled from Innsbruck to Villach, pursued by the troops of Saxony, Hesse, and Brandenburg-Kulmbach; the council of Trent disintegrated out of fear of the approaching army. Yet, in the negotiations at Passau, the opposition achieved only a renewed truce until the calling of the next Diet, which was to decide whether the religious conflict was to be ended by decision of the Council, by a recess of the Diet, or by a religious colloquy. Maurice was killed in the Battle of Sievershausen in July 1553, against Albert II Alcibiades of Brandenburg–Kulmbach, who had continued the war on France's order, burning and killing as he pleased.

Charles V's abdication and the Peace of Augsburg (1555). Charles besieged Metz unsuccessfully, but his hopes for a universal empire were revived in 1554 by the marriage of his son Philip with the English queen Mary I; by combining the resources of the Netherlands, England, Spain, and the *Reich*, Charles hoped to encircle and defeat France. The marriage, however, remained childless, so that the Emperor's expectations came to nothing. When Henry II of France found a supporter in the new pope, Paul IV (elected 1555), Charles abdicated, worn out by all his failures. He handed over the Netherlands to his son Philip in 1555, Spain to Philip in 1556, and his imperial authority to his brother Ferdinand in 1556. He then withdrew to Estremadura, near the monastery of San Yuste. Thus, he admited that the medieval ideal of the unity of Christendom was no longer valid.

Division of the Habsburg dominions

In 1555, despite Charles's protests, the Diet of Augsburg sanctioned the existing state of affairs. The Peace of Augsburg renounced the idea of uniformity of doctrine within the empire, acknowledged the coexistence of Roman Catholicism and Lutheranism, and promised no toleration for Zwinglians, Calvinists, or Anabaptists. Lawyers later elaborated the formula *cujus regio ejus religio* ("the prince's religion is the religion of his dominions"), to be applied to the individual territories. The so-called ecclesiastical reservation stipulated that, if an ecclesiastical prince became Lutheran, he had to renounce his office; thus his change of religion would not affect his subjects as a secular prince's change would. Church property secularized before 1552 was to remain so. The cities that had accepted the Interim had to tolerate both Roman Catholicism and Lutheranism within their boundaries. The Peace of Augsburg was a deep disappointment to the high hopes entertained at the beginning of the Reformation. Its authors held it to be only a temporary solution, but nobody could really believe that a final religious reconciliation would be brought about in the future. The idea of one Christian Church had to be given up now that two creeds were legally established side-by-side.

The recess of the Diet of 1555 also decided the conflict between emperor and estates in favour of the estates. By its "executive ordinance" the "imperial circles" (administrative districts established by Maximilian) were given powers to administer law and to maintain order within their areas and to execute the decisions of the Imperial Chamber, or Reichskammergericht. In the southern and western areas, where there were the greatest number of quasi-independent authorities, this "circle" organization provided at least some safeguard against the religious wars threatening to spill over into Germany from the west. The vital forces making for a renewal of political life were now to be found in the individual territories of the empire rather than in the empire as a whole. They were not active in foreign affairs. Within the territories, however, newly created administrative organizations, centrally directed and staffed with trained lawyers, began to issue numerous laws covering every aspect of life. The subjects were treated as uniformly as possible within the boundaries of each state, and the habit of obedience to orders was instilled; the territorial estates, composed of nobility and towns, gradually saw their rights severely curtailed, especially that of deciding taxes. As regards ecclesiastical policy, the territorial princes, "viceregents of God," felt responsible for maintaining uniformity of belief: whatever their momentary belief might be, it was to be the only truth recognized, upheld, and propagated in their states. Regarded by contemporary opinion as an essential safeguard against heresy and revolution, the doctrinal unity thus enforced was used as an instrument of state policy to strengthen the unity of the territory and so to augment its power. The religious struggles in Germany came to be settled on the territorial plane, and the resultant territorial distribution of the various creeds survived, by and large, into the 20th century.

Powers of the "imperial circles"

The independence of the numerous though varied states was hardly called into question any more, so that emperor and empire faded into the background, having shed their universal claims. The emperors had to cooperate with independent institutions of the *Reich* and to reach an agreement with the diets and the representatives of imperial circles. The emperors' power was not enough to stop the centrifugal forces nor to inaugurate a development toward the formation of a national state.

The emperor and the *Reich*

THE COUNTER-REFORMATION AND THE THIRTY YEARS' WAR

Ferdinand I and Maximilian II. The partition of Charles V's dominions meant that henceforth there were two Habsburg lines—the Austrian and the Spanish—but both were still Roman Catholic, and they were closely linked with one another despite occasional tension and opposition. Ferdinand I was no less devoutly Roman Catholic than Charles V had been, but reasons of state found him readier to make necessary concessions. His son and successor, Maximilian II, emperor from 1564 to 1576, was still readier for compromise as he leaned toward Protestantism, though he never confessed it publicly. During their reigns, however, the leadership in the world of ideas, which Luther and the proponents of universal empire had combined to give to Germany, passed to the spiritual forces, which took advantage of the peace that now prevailed in the *Reich*.

The aims of the Counter-Reformation

The Roman Catholic Counter-Reformation, inaugurated by the Council of Trent and promoted by Spain, Rome, and Italy, put forward the idea of the hierarchical structure of the church, led by the papacy, against the Protestant doctrine of the priesthood of all believers. The reformed papacy, moreover, possessed in the Society of Jesus its most reliable army, which turned its attention immediately to the most threatened spot, Germany; Jesuit settlements had been founded as early as 1544 in Cologne, Vienna, Ingolstadt, and Prague—that is, in areas where the religious decision was still in the balance. Moreover, the relationship between the Habsburgs and the Bavarian dukes created a Roman Catholic bloc in southern Germany with its political and intellectual centre in Munich. Though support from the rest of Germany was always most readily forthcoming for the defense of the empire against the Turks, who bore most heavily on Austria, Ferdinand and Maximilian, nevertheless, avoided offensive war in order to prevent further religious concessions to the Protestant Austrian estates.

The Lutheran princes east of the Weser River, meanwhile, received effective help from Denmark. Electoral Saxony, Brandenburg, and Pomerania not only secularized ecclesiastical property and established Lutheran state churches within their territories but also began, from 1555, to absorb neighbouring bishoprics and abbeys. Despite endless disputes, which paralyzed the diets, this proved a successful method of circumventing the ecclesiastical reservation that had been meant to protect such ecclesiastical principalities. Disunity, however, grew among the German Protestants when French and later Dutch refugees brought Calvinism first to the Palatinate (1559) and then to Nassau, Hesse, and the Lower Rhine Valley. Soon after Luther's death (1546), doctrinal strife had broken out between the followers of the old radical Lutheranism and those who preferred Melanchthon's compromise formulas. As the princes could decide what form of religion they wished to establish, this theological quarrel had political consequences. Electoral Saxony, Württemberg, and Brunswick-Wolfenbüttel were eventually to end the constant doctrinal disputes among the Lutherans by accepting, after a long struggle, the *Formula concordiae* of 1577, after Rudolf II's accession as emperor. This did not prevent them from regarding the Calvinists as more serious opponents than the Roman Catholics. When the Calvinist John Casimir of the Palatinate tried to form a Protestant league, Saxony wrecked the plan. John Casimir was the foremost of the German princes to intervene on the Hugenot side in the wars of religion in France.

Calvinism in Germany

Wherever Austrian power proved ineffective, the empire suffered great losses. As the Teutonic Order had been secularized as early as 1525, its calls for help were ignored, so that Courland became a Polish fief in 1562, while Livonia was divided between Poland and Russia, and Estonia passed under Swedish rule. On the western frontier the French kept the cities of Metz, Toul, and Verdun and extended their influence over Lorraine. When the revolt of the Netherlands broke out against Spanish rule, the empire did not intervene, though the Netherlands belonged to the Burgundian circle of the empire and though the leader of the revolt, William I the Silent, was a prince of the empire (Nassau and Orange). Only the Calvinist Palatinate gave William support; otherwise, the Protestant estates merely appealed for Maximilian II's mediation, which Spain rejected.

Rudolf II, the Cologne War, and Matthias. Maximilian was succeeded by his eldest son, Rudolf II, emperor from 1576 to 1612. By this time the conflict in the Netherlands was having its effect on the strife of the creeds in the Rhineland. The fluctuating religious position there was decided by events in the archbishopric of Cologne (Köln), where Archbishop Gebhard wanted to marry and so, in order to circumvent the ecclesiastical reservation, tried to secularize the diocese (1582–83). Cologne's conversion to Protestantism would have given the Protestants a two-thirds majority in the electoral college, with far-reaching repercussions on the election of an emperor. Ernst of Bavaria, bishop of Freising, Hildesheim, and Liège, was consequently put forward by Bavaria, Spain, and the papacy to take Gebhard's place. Gebhard put his troops under the leadership of John Casimir of the Palatinate but received no help from the Lutheran princes. Defeated in 1584, he withdrew to the Netherlands and then to Strassburg. The Spaniards and the Dutch, however, continued the war for years, devastating the country; Münster and the other Westphalian bishoprics fell to Ernst of Bavaria, along with Cologne.

Rudolf II had been educated in Spain; he was devoutly Roman Catholic, interested in intellectual matters, of good political judgment, but of an odd nature. He fled from human contact, was afraid to act, and lived alone in his castle in Prague until his reason gave way and he became incapable of making political decisions. The violent means by which Catholicism was being restored in all the Austrian territories and in Hungary provoked the opposition of the Protestant territorial estates everywhere and fanned the discord between Rudolf and his brother Matthias, who in 1606 was declared the head of the House of Habsburg in Rudolf's place. It seemed as if the Habsburg dominion would disintegrate into separate small territories, each controlled by its estates, thus paralyzing Austria's capacity for action. As Rudolf, the wearer of the imperial crown, was thus incapacitated, imperial institutions slowly ceased to function.

The absolute paralysis of Emperor and empire revived the old plan to form religious associations. Two such groupings soon opposed one another: the Protestant Union, led by the Palatinate (1608); and the Catholic League, led by Maximilian I of Bavaria (1609). The former looked for help to France, the latter to Spain; and both armed themselves, as France and Spain seemed about to begin a European war over the succession to Cleves-Jülich-Berg and its undecided religious allegiance. The assassination of Henry IV of France (1610) prevented the outbreak of war, and Matthias (emperor from 1612 to 1619) tried to ease the tension by his policy of "compositions"—that is, of small concessions. Finally, in 1614, the duchy of Cleves-Jülich-Berg was peacefully partitioned, without imperial mediation, by the late duke's heirs: John Sigismund of Brandenburg, who had just turned Calvinist, and Wolfgang William of Palatinate Neuburg, who had just turned Catholic.

The Catholic League and Protestant Union

Ferdinand II and Bohemia. Since neither Matthias nor his surviving brothers had legitimate heirs, it was planned that the Habsburg and the imperial succession should pass to their cousin Ferdinand of Styria, a pupil of the Jesuits and a convinced champion of the Counter-Reformation who had just re-Catholicized inner Austria by force. Philip III of Spain renounced his own claims and offered help to Ferdinand in exchange for the cession of the Austrian territories in Alsace and Ortenau, which would link the Spanish Netherlands with the Spanish Franche-Comté and the routes to Italy and thus extend the arc of encirclement around France. The Protestant Bohemian estates, however, objected strongly to recognizing Ferdinand as their future king, and in 1618, during a dispute over local grievances, some radical nobles in Prague threw the imperial governors out of the windows of the Hradčany Castle. The Bohemians then pre-

pared for war, and in 1619, after the death of Matthias, proceeded to elect the Calvinist Frederick V, elector palatine, as king of Bohemia on August 26, two days before the Habsburg candidate was elected emperor as Ferdinand II. Ferdinand had the support of Spain, Poland, the papacy, and, especially, the Catholic League.

Bohemian defeat at White Mountain

Their combined armies defeated the isolated Frederick at the Battle of the White Mountain near Prague in November 1620. Draconic measures destroyed Protestantism in Bohemia and the remaining Austrian territories, and the influence of the estates was abolished. The army of the Catholic League pursued the last partisans of Frederick, the "winter king," on their flight to the Netherlands. Maximilian of Bavaria was granted the electoral dignity, which had been the condition of the help that he gave to the Emperor.

The Thirty Years' War. The Bohemian revolt and its suppression are conventionally regarded as the beginning of the complex European struggle designated as the Thirty Years' War (*q.v.*). The surprising resuscitation of the power of the German Habsburgs, the occupation by the Spaniards of the Rhenish Palatinate, and the resumption of war in 1621 between Spain and the United Provinces after a 12-year truce called the European powers into the arena, for they did not wish a revival of the empire of Charles V. Thus, the warfare in Germany became a general European war. Christian IV of Denmark wished to acquire the bishoprics of Verden, Bremen, Osnabrück, and Halberstadt, which were under Protestant administrators and surrounded by secular principalities. Against him Ferdinand put a new army into the field under the leadership of Albrecht Wenzel von Wallenstein (*q.v.*). This soldier of fortune had acquired an enormously compact mass of lands in Bohemia by a rich marriage and augmented it from the confiscated estates of Protestant nobles. After his elevation to the dukedom of Friedland (1625), he turned this property into a huge armaments factory. Because of his enormous wealth, Wallenstein became independent of the imperial treasury and was thus, at first, indispensable to Ferdinand. Johann Tserclaes, Graf von Tilly, the general of the Catholic League, defeated Christian near Lutter (1626); Wallenstein occupied Jutland, Mecklenburg, and Pomerania; Christian was forced to make peace at Lübeck (1629), regaining his lands but renouncing his alliances with the north German princes and his claims on the bishoprics in Lower Saxony.

The rise of Wallenstein

Now at the height of his power, Ferdinand issued the Edict of Restitution (1629), enforcing again the ecclesiastical reservation and ordering all bishoprics and abbeys secularized since 1552 to be restored to the Roman Catholic faith. This edict showed the Emperor determined to revolutionize all existing political conditions; the independent and aggressive spirit that he revealed provoked even the opposition of the Catholic League and especially that of Maximilian of Bavaria. At a meeting at Regensburg (1630) the electors, backed diplomatically by France, forced Ferdinand to dismiss Wallenstein, to reduce the imperial army, and to accept the electors' control of foreign and military policy. Wallenstein's dismissal made it easier for the Swedish king Gustavus II Adolphus to decide to land in Pomerania. The King of Sweden was brought to this decision by Sweden's struggle for the *dominium maris Baltici* (supremacy in the Baltic sea), and Gustavus' intervention was also by his desire, based on his deep religious convictions, to liberate the north German Protestants and to obtain the large subsidies offered by France. Of the Protestant states only Hesse-Kassel voluntarily joined the Swedish king; Saxony was forced into an alliance because of counterpressure from Vienna. The princes feared for their freedom and dreaded the Emperor's revenge. In 1631, in the first of the battles of Breitenfeld, Gustavus Adolphus defeated Tilly, who had taken Magdeburg; the victory was so complete that the Catholic party collapsed completely in northern Germany and the Catholic League dissolved itself. The Swedes now occupied Munich and threatened Vienna.

Entry of Sweden into the war

In this danger, Ferdinand asked Wallenstein to recruit another army. Wallenstein, however, proceeded very cautiously, since he wanted both to demonstrate his indispensability and to avoid jeopardizing his new army. Gustavus Adolphus restored Protestantism in large areas of Germany but fell mortally wounded in the Battle of Lützen (1632). The Swedes, however, under the chancellor Axel Oxenstierna, continued the war, united the south German estates in the League of Heilbronn, and again threatened the Austrian hereditary lands. The Vienna court began to distrust Wallenstein because of his hesitant strategy. He negotiated with Saxony and Sweden without, however, following a clear line of policy. Suspected of high treason, he was murdered in 1634 at Ferdinand's instigation by some of his officers. The imperial army, still intact, and the newly arrived Spanish auxiliary troops defeated the Swedes at Nördlingen and again occupied southern Germany to the Rhine. Peace was made at Prague between the Emperor and Saxony (1635), and most German states agreed to its terms in time. The Peace of Prague fixed the religious divisions as they had existed in 1627 (an arrangement originally limited to 40 years and not applicable to Calvinists), renounced the Edict of Restitution, and gave the emperor command over a new imperial army to be provided by the estates and to be used against the foreign powers.

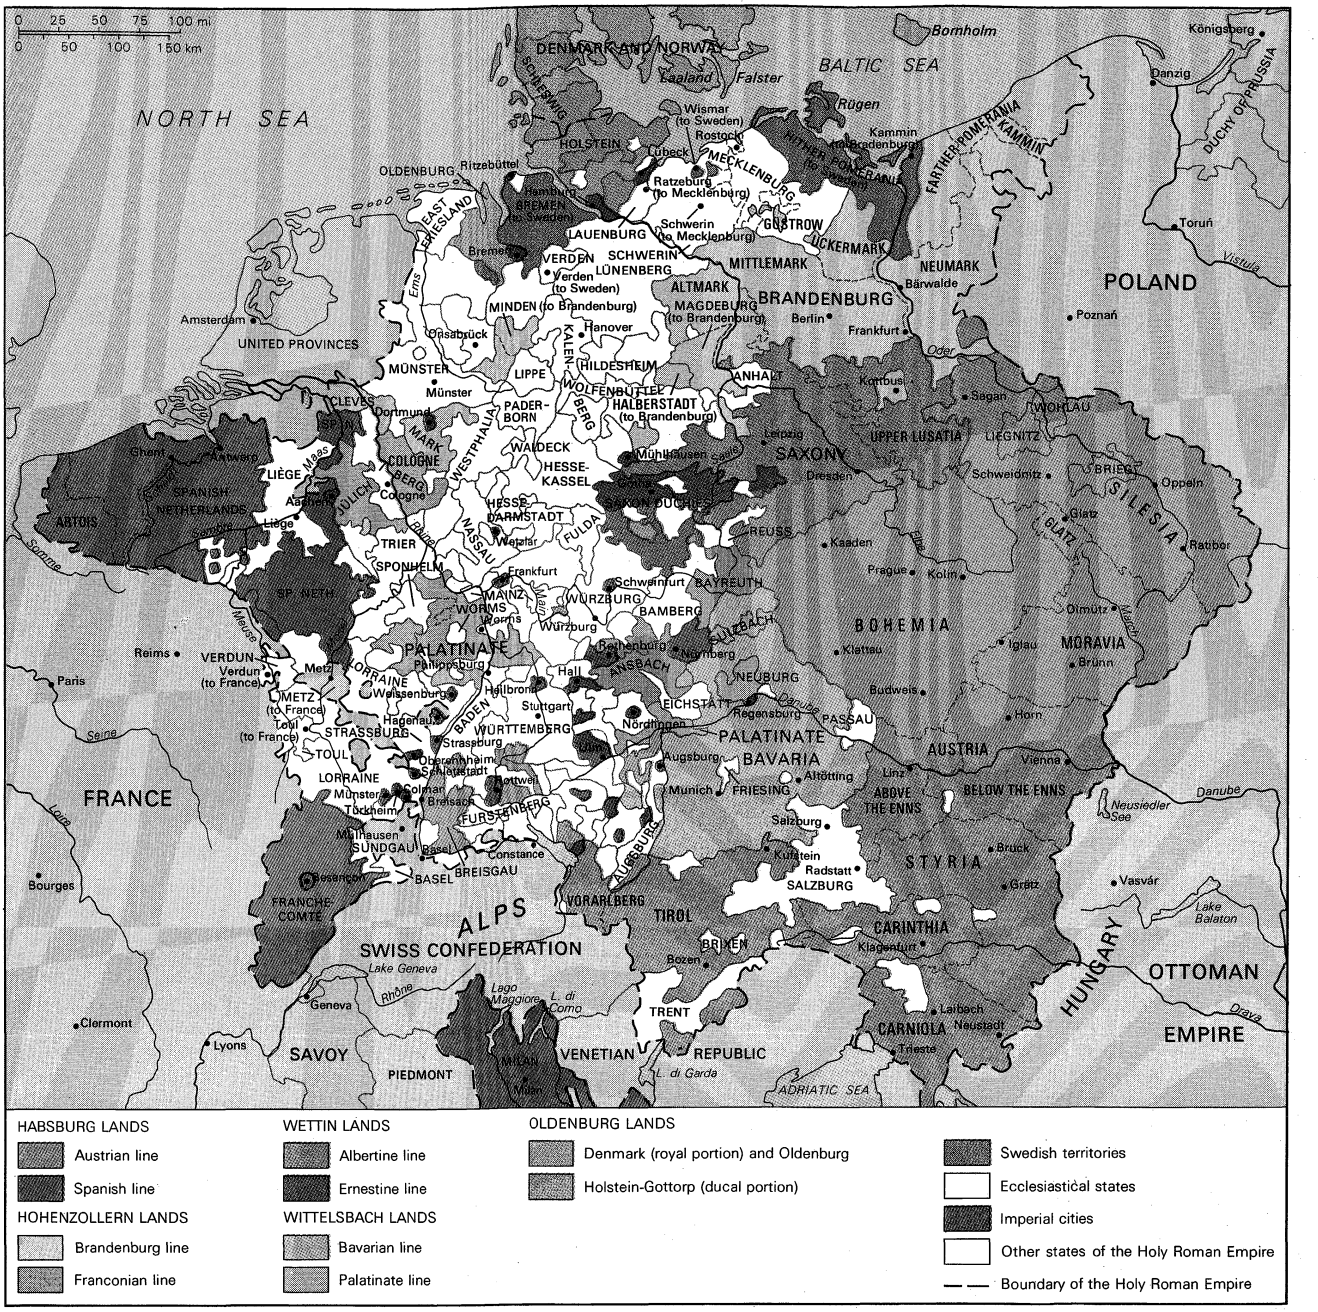
Despite this renewed effort, German strength did not suffice to enforce peace. War ravaged the country for another 13 years; it was no longer fought for German questions but to divide the spoils between Sweden and France. A renewed France under the Cardinal de Richelieu declared war against the Spanish world power on all fronts in 1635, regardless of doctrinal considerations but simply following the dictates of French reason of state. France gained footholds in Savoy, Mantua, and Parma and thus controlled Spanish Milan and the passes over the Alps into southern Germany. The United Provinces and those states of the empire that stood aside from the war were strengthened by subsidies from France. Along the western frontier of Germany, Richelieu occupied Lorraine and pushed his occupation troops through Alsace to the Rhine. In order to keep the Swedish army in the German theatre of war, Richelieu mediated a prolongation of the Swedish–Polish truce for another 26 years and granted annual subsidies for the Swedish armies fighting in the empire. There were meetings of the electors and of the Diet, but neither the Emperor nor the estates were able to bring about a general pacification. One prince after another made separate treaties with the foreign powers.

Continuation of the war

The Peace of Westphalia (1648). Ferdinand II was succeeded by his son Ferdinand III, emperor from 1637 to 1657. Nine years after his accession, with Spain's power sapped by internal revolts, the enemies of the House of Habsburg won the upper hand in Germany. In 1648 the French had crossed Bavaria and reached the Inn River, and the Swedes were again attacking Prague when the news of the Peace of Westphalia at last arrived.

Earlier peace feelers had been in vain, but, from 1644 onward, serious negotiations had been taking place among the interested powers. First, Spain concluded a separate peace with the United Provinces of the Netherlands, the sovereignty of which was recognized (though the Franco-Spanish war was to go on for 11 more years until the Treaty of the Pyrenees in 1659). The conditions offered by the Emperor and the states of the empire to the Swedes at Osnabrück and to the French at Münster were accepted, and peace was signed in October 1648. In addition to 5,000,000 thalers to pay off their troops, the Swedes obtained the archbishopric of Bremen, the bishopric of Verden, the town of Wismar, and Hither Pomerania; the French obtained the Habsburg rights in Alsace and the Lorraine bishoprics of Metz, Toul, and Verdun, together with the fortress of Breisach and the right to occupy the fortress of Philippsburg. The Swiss and the Dutch, now sovereign powers, severed all links with the empire.

Within the empire, Bavaria retained the electoral dignity and the Upper Palatinate; the Elector of Brandenburg received the bishoprics of Kammin, Halberstadt, and Min-



Germany in 1648.

den, with the reversion to that of Magdeburg, in compensation for what he had had to cede to Sweden; and the dukes of Mecklenburg received the bishoprics of Ratzeburg and Schwerin, also in compensation. Otherwise, the territorial status quo of 1618 was restored. The religious status quo of 1624 was acknowledged, except for the Austrian hereditary lands and Bavaria, and Calvinism was recognized as one of the creeds of the empire. Constitutionally, the Emperor's power was considerably reduced in favour of the estates or members of the empire, even in matters of foreign policy. To prevent majority decisions in denominational disputes, the estates were divided between a Corpus Evangelicorum, or Protestant group, and a Corpus Catholicorum, both of which had to be in agreement if a decision was to be valid for the empire as a whole. Finally, the fact that France and Sweden were guarantors of the peace laid Germany open to foreign intervention.

THE EMPIRE IN DECAY, 1648–1721

Emperor and empire after 1648. After the Peace of Westphalia, the expression emperor and empire (*Kaiser und Reich*) ceased to mean the whole body politic with its monarchical head but emphasized the contrast between the emperor, who had no power in the empire, and the empire, which had little use for the emperor. Free to form associations among themselves or with foreign princes (provided that they were not directed against empire or emperor), the rulers of the member states had become nearly fully sovereign and independent in international law. The emperor was reduced to the rank of an honorary president of an aristocratic republic; he was unable either to make laws or to levy taxes for the *Reich* without the consent of the Imperial Diet, or Reichstag. On the other hand, the territorial diets declined nearly everywhere—with the special exceptions of Mecklenburg and Württemberg, where the dukes were almost powerless. Therefore, the territorial princes could now build up their military power and finances without interference from above or below and so consolidate the basis not only for increasing independence but also for absolute government within their own territories.

Division into small principalities

As a result of the Peace of Westphalia, Germany was divided into about 300 entities with practically sovereign

rights and the quality of *Reichsstandschaft—i.e.*, that of being represented in the Reichstag as an estate of the empire. In addition to these quasi-sovereignties, there were nearly 1,500 other minor lordships that, without having *Reichsstandschaft*, enjoyed *Reichsunmittelbarkeit*, or "immediate" dependence on the *Reich*, with no suzerain other than the emperor. With no direct power over the *Reich*, the emperor was little more than the nominal guardian of law and order (which he could scarcely enforce) and the fountain of honour (for elevations in rank and the granting of privileges).

The territorial powers in the 17th century. The greatest of the secular powers in the *Reich* was the House of Habsburg, which ruled over a vast area in the southeast comprising Bohemia, Austria, Styria, Carinthia, Carniola, Istria, Trieste, and Tirol and also held numerous hereditary possessions in southern Swabia extending to the banks of the Rhine (in the area of Breisgau). These lands, however, had from time to time been distributed among various branches of the house and were not finally reunited until 1665 (after the extinction of the Tirolese branch). Moreover, the central authority for the Habsburg possessions, which Maximilian I had tried to set up, exercised little control, as many of the component territories kept their own administrations and diets. The Kingdom of Hungary was a Habsburg territory outside the *Reich*.

The decades after the Thirty Years' War saw the beginning of the rise of Brandenburg-Prussia to pre-eminence among the territorial powers of the *Reich*. From the middle of the 17th century, the House of Hohenzollern was outpacing the houses of Wittelsbach and Wettin in the struggle for the second place in the *Reich*. The Hohenzollern margraves of Brandenburg had inherited Cleves in western Germany, together with Mark and Ravensberg in Westphalia, in 1614, and the duchy of Prussia, which was a Polish fief outside the *Reich*, in 1618. The union of Ducal Prussia with Brandenburg was fundamental to the rise of the Hohenzollern monarchy to the rank of a great power in Europe. John Sigismund's grandson Frederick William, the Great Elector of Brandenburg, by military intervention in the Swedish–Polish War of 1655–60 and by diplomacy obtained the ending of Poland's suzerainty over Ducal Prussia at the Treaty of Oliva (1660). This made the Hohenzollerns sovereign over Ducal Prussia, whereas Brandenburg and their other German territories were still nominally parts of the *Reich* under the theoretical suzerainty of the Holy Roman emperor. Frederick William was also able to set up a centralized administration in Prussia and to secure control of the duchy's financial resources, thus reducing the power of the Prussian *Landstände*, or estates. These estates, comprising the landowning nobility and the oligarchies of the towns, among which Königsberg was paramount, had previously run the duchy's affairs.

The rise of the Hohenzollerns

When Frederick III of Brandenburg succeeded his father, the Great Elector, in 1688, Brandenburg-Prussia consisted of four separate groups of lands, scattered across Europe from the lower Rhine in the west to the Memel River in the east and unconnected by any territorial link. The central and largest group comprised Electoral Brandenburg (Altmark, Mittelmark, and Neumark), with the secularized bishoprics of Magdeburg and Halberstadt adjoining it in the southwest and Hinterpommern (Farther Pomerania) in the northeast; the second group comprised the duchy of Cleves, on the lower Rhine, and the countship of Mark, on the Ruhr River (these two territories were not contiguous); the third group comprised the countship of Ravensberg and the secularized bishopric of Minden, between the upper Ems and the middle Weser; and finally there was Ducal Prussia in the east, independent of the *Reich*.

The most significant achievement of the Great Elector's son was to secure the royal dignity for himself, as Frederick I, king in Prussia; he crowned himself at Königsberg on January 18, 1701, after the emperor Leopold I had consented to his assuming this new status in order to ensure his goodwill in the forthcoming War of the Spanish Succession. Ducal Prussia thus became the basis of his rank as sovereign king; and the other Hohenzollern possessions, though theoretically they remained within the German *Reich* and under the ultimate overlordship of the emperor, came to be treated in practice as part of the Prussian kingdom rather than as distinct from it.

Among the other territorial powers, the House of Wettin was divided into so many branches that its head, the elector of Saxony, ruled only a portion of its lands. The same was true of the House of Wittelsbach: its largest and most compact territory was Bavaria, whereas its scattered lands in the Palatinate were distributed among junior branches of the family. The House of Welf, which had the leading role in northwestern Germany, also divided its lands in Brunswick and Hanover among various branches (seven or sometimes even more); and the House of Hesse was similarly divided. In the extreme southwest, the House of Zähringen, with the margraviate of Baden, and the House of Württemberg were the most important dynasties.

Most of these great princes in the course of the 17th and 18th centuries succeeded in reducing the old-established powers of the diets in their territories, though they did not dare to suppress them outright. Government and justice, however, in the hands of paid officials, were far more efficiently administered in the greater principalities than they were in the lesser ones. The lesser secular princes ruled their subjects patriarchally but employed quantities of officials out of all proportion to the size of their miniature territories and maintained sumptuous courts, for the upkeep of which they were ever preoccupied with devising new taxation. The ecclesiastical princes, in general, governed no better than the secular ones, since their lack of legitimate issue made them sometimes careless of the future well-being of their countries. Elected by the chapter with which he was to share the administration and which was composed largely of younger sons of the local nobility, a bishop or abbot would often use his position to further the interests of his family by settling his brothers, cousins, and nephews on church property or bringing them into the chapters.

The major imperial cities

Some of the imperial cities were towns of major importance with a long-standing commerce, among them Lübeck, Hamburg, Bremen, Nürnberg, Augsburg, Ulm, Frankfurt am Main, and Strassburg. Most, however, were little country towns in southwestern Germany, with 3,000 inhabitants or less, which had long ago lost any significance. Overshadowed by the capitals rising around the princely residences, the imperial cities were for the most part governed by a few patrician families who monopolized all positions of influence and profit and used them to their personal advantage.

Finally, there were the dominions of the "immediate" knights of the empire (not to be confused with the knights of orders, whose master was an ecclesiastical prince), nearly all in southwestern Germany. These knights were large landowners who exercised sovereign rights over their manor and perhaps some adjacent village.

In the first decade after the Peace of Westphalia, the primary concern of all the estates was the maintenance of peace. As the war between France and Spain lasted until 1659 and as grave issues were arising in the north and in the east, Germany could easily have been involved again in a general war. As no one believed in the ability of the emperor to safeguard the empire from this danger, there grew up a network of alliances between the different territories for mutual defense. The elector of Mainz, Johann Philipp von Schönborn, succeeded in uniting the most important Catholic and Protestant princes in a great defensive alliance. This first Rheinbund, or League of the Rhine, was signed in August 1658 for three years and had for its object the full execution of the Peace of Westphalia, the prevention of foreign wars, and the defense of its members' own territories; but, in fact, the alliance, which the emperor regarded as directed against his authority, soon became largely dependent on France. It was frequently renewed and lasted until 1667.

During the First Northern War (1655–60), Emperor Leopold, in the Catholic interest, supported the Catholic king of Poland, John Casimir; the elector of Branden-

burg, Frederick William the Great, who at the outset had supported Sweden, later entered into an understanding with Poland and the Emperor. This warfare, however, was waged, for the most part, outside the territory of the empire. Germany was far more deeply distrurbed by the course of events on its western frontier, where Louis XIV of France was preparing to invade the United Provinces. When Louis induced the archbishop of Cologne, Maximilian Heinrich of Bavaria, and the bishop of Münster, Christoph Bernhard of Galen, to cooperate with his invasion of the United Provinces, the neighbouring German states, fearing that they would be involved in the war, invoked the assistance of the Emperor and the empire. Moreover, Louis XIV had, without any legal grounds, driven the duke of Lorraine, Charles IV, who was a prince of the empire, out of his duchy. The empire, thus, had good cause to intervene.

Rise of Louis XIV

Yet Leopold hesitated to take any action against Louis XIV. Foreseeing the extinction of the Spanish branch of the Habsburgs, his main policy was to assure its succession for his own branch. This would require the French king's acquiescence, for which Louis let him hope, so that Leopold did not feel himself at liberty to oppose him. Hence, the Dutch found their sole support in the elector of Brandenburg, Frederick William, who had grown up in Holland and whose first wife had been a princess of Orange. By cutting the dikes and flooding their country, the Dutch were able to avert the French attack in 1672. At the urgent request of the estates, Leopold determined to send an army, under Raimondo Montecuccoli, for the defense of the imperial frontier on the Rhine but with instructions to maintain the defensive. Finally, having allied himself with Spain, the Emperor secured the declaration of war by the *Reich* against France in 1674.

The war was waged chiefly in the Austrian Netherlands and on the Rhine. The Swedes, in alliance with Louis, invaded Brandenburg from Pomerania to restrain Frederick William, who was participating personally in the war against France. At the same time, Louis entered into relations with Poland, with Turkey, and also with Hungary, which was discontented with Habsburg rule. The Emperor then found himself threatened in the rear. By his victory at Fehrbellin on June 28, 1675, Frederick William drove the Swedes out of his territory and occupied nearly the whole of Swedish Pomerania. The French, on the other hand, were for the most part victorious on the western front, and, eventually, Louis was able to induce first the Dutch and then Spain to conclude a separate peace (1678). When the Emperor could no longer hope to win anything by continuing the war, he acceded to the Treaty of Nijmegen in February 1679.

Convinced by these experiences that the *Reich* was too weak to withstand encroachments on its territory, Louis next proceeded to set up special courts, the so-called chambers of reunion, for the purpose of determining what lands had at any former time belonged to districts already ceded to him. On the strength of these investigations, he declared that the countship of Mömpelgard (Montbéliard), the whole of Alsace, and certain districts in the Palatinate and in the electorate of Trier belonged, by right, to France. French armies occupied the territories, and the imperial city of Strassburg was seized on September 28, 1681, and at once erected into a powerful French fortress. The Emperor and the Reichstag contented themselves with ineffectual protests.

The Emperor's failure to safeguard the integrity of the *Reich* at this crisis is partly to be explained by his preoccupation with the dangers threatening his own territories. The Turks in Hungary were planning an invasion of Austria, and in the summer of 1683 they appeared with a powerful army before the walls of Vienna. The imperial generals, however, managed to hold off the attack; and, finally, John III Sobieski of Poland and the electors Maximilian II Emanuel of Bavaria and John George III of Saxony arrived with an army to defeat the Turks and free the city.

When Louis XIV sought to bring the Palatinate within his grasp, claiming it as the inheritance of his sister-in-law Elizabeth Charlotte of Orléans, war once more broke out in the west. French armies invaded the Palatinate, and the Emperor allied himself with England and the Dutch. The War of the Grand Alliance inflicted severe losses on the French but did not result in any decisive victory. Once more Louis was able to sow dissension among his enemies and isolate Germany, and the Emperor had to conclude the Treaty of Rijswijk in 1697, with but small gain to himself. Louis restored Lorraine to the rightful duke, Leopold Joseph, and abandoned his claims to the Palatinate and to the districts outside Alsace that had been declared to have once formed part of it. But he retained the whole of Alsace and also Strasbourg.

The War of the Spanish Succession (1701–14). The last Habsburg king of Spain, Charles II, died childless on November 1, 1700. The question of succession, which had already occupied the European diplomats for decades, had now to be settled. Both Leopold I and Louis XIV each supported a different candidate for the Spanish throne. Louis supported his grandson Philip, while Leopold maintained the right to the Spanish inheritance of his son, the archduke Charles; this conflict erupted in 1701 in the War of the Spanish Succession. The English and the Dutch, led by William III of Orange, stadtholder of the Netherlands and from 1689 also king of England, supported the Archduke's claim, while the French had the help of the Hungarians, of the English Jacobites, and of a number of German princes, chief of whom was Maximilian Emanuel of Bavaria. In the first years of the war, the advantage lay with the French, who might have struck a deadly blow at Austria by a concerted attack from the Rhine and Italy. This danger was averted by the great Anglo-Austrian victory in the Battle of Blenheim on August 13, 1704. Bavaria was occupied by the imperial troops, and Maximilian Emanuel fled to Brussels.

Battle of Blenheim

Leopold I died in May 1705. His eldest son, Joseph I, succeeded him as emperor (1705–11). The war against France was pursued with great successes throughout Joseph's reign. The archduke Charles landed in Catalonia and by the summer of 1706 was in Madrid. After French defeats in the Netherlands and in Italy, Louis XIV, in 1708 expressed his readiness to renounce on behalf of his grandson all claims to the Spanish throne and to agree to a restoration of the Franco-German frontier on the line laid down in the Peace of Westphalia in 1648, which would have meant restoring Strasbourg. The allies, however, demanded that French troops should help them to expel Philip V from Spain. When Louis refused this, they broke off negotiations. Similarly, after the Battle of Malplaquet (1709), when Louis even offered to give up his acquisitions in Alsace and the bishoprics of Metz, Toul, and Verdun, together with money to be used for driving Philip V out of Spain, the allies stood by their former demands, so that negotiations once more broke down.

The death of the emperor Joseph I (April 1711) changed the situation. As he left no son, his younger brother the Archduke succeeded him as the emperor Charles VI (1711–40). Now, if Austria, the empire, and the Spanish inheritance were all to be united under one ruler, there was danger that such a disproportionate concentration of power would threaten the European balance of power more seriously than would the establishment of a French dynasty in Spain; and neither England nor the Dutch nor Savoy felt disposed to prosecute the war for such an objective. A peace congress met at Utrecht in 1712, and the chief treaties were signed in 1713. These awarded only a portion of Lombardy, the Neapolitan mainland, and the former Spanish Netherlands to Charles VI; and no mention was made of a restoration of the old Franco-German frontier. Meanwhile, the Emperor and the *Reich* were still at war with France, but, when Landau and Freiburg im Breisgau had been lost, they were forced in the treaties of Rastatt and Baden (March and September 1714) to assent to the terms of Utrecht. The frontiers of the German *Reich* remained as laid down in the Treaty of Rijswijk; the Elector of Bavaria recovered his

territories; and the prospect of winning back the old German territories in the southwest had completely vanished. Thus, the War of the Spanish Succession had overthrown the supremacy enjoyed by France in Europe without yielding any profit to Germany.

The Great Northern War (1700–21). At the same time, another long-standing quarrel was being fought out in the north and the east. In 1697 the elector Frederick Augustus I of Saxony, after conversion to Catholicism, had been elected king of Poland as Augustus II the Strong. In alliance with Denmark and with the Russian tsar Peter I the Great, he began a war against Charles XII of Sweden in the summer of 1700, with the object of breaking the power that the Swedes had been exercising in the Baltic area since the Thirty Years' War. By the spring of 1706, however, Charles XII was in possession of the greater part of Poland and, in agreement with a section of the Polish nobility, had set up Stanisław (Leszczyński) I as king in opposition to Frederick Augustus. He then marched through Silesia into his enemy's German territories, occupied a great part of Saxony, and established his headquarters, during the winter of 1706–07, in Altranstädt near Leipzig. But the peace that Frederick Augustus had to sign, renouncing the Polish throne, did not long remain in force. When Peter the Great of Russia threatened to occupy Poland, Charles marched against him and was defeated at Poltava (1709). The Swedes were driven from Poland, and their allied enemies invaded Swedish territory on all sides. The elector Frederick III of Brandenburg, who with the emperor Leopold I's consent had assumed the title of king in Prussia as Frederick I in 1701, also took part in the attack. Pomerania, Bremen, and Verden, Sweden's possessions in Germany, were seized.

The treaties of Stockholm and Nystad

After Charles XII's death (1718), the conclusion of peace was possible. Sweden had to surrender Bremen and Verden to Hanover (1719) and western Pomerania south of the Peene to Prussia (Peace of Stockholm, 1720). Of greater importance for future Russo-German relations, however, was the Treaty of Nystad (1721), whereby Sweden ceded Estonia, Livonia, and Ingria to the Tsar, thus giving Russia a firm foothold on the shores of the Baltic and thereby a position that became more and more threatening to Germany. Sweden, meanwhile, retained the northern part of western Pomerania and Rügen.

AUSTRO-PRUSSIAN RIVALRY IN THE 18TH CENTURY

Charles VI and the Pragmatic Sanction. From his youth the emperor Charles VI had been regarded by the emperor Leopold as a future king of Spain and had been brought up in the spirit of Spanish Jesuitism. In his reign (1711–40) Austrian policy became more and more obviously inspired by the desire to strengthen Habsburg influence in Italy and also to win more territory along the lower reaches of the Danube. In this latter aim Charles was at first successful through the war that he entered in 1716 in support of Venice against the Turks. By the Treaty of Passarowitz (1718), thanks to Prince Eugene's victories, Austria obtained the Banat, Little Walachia, northern Serbia (with Belgrade), and part of Bosnia.

Imperial authority in Germany, meanwhile, was based both on the imperial constitution and on the territorial power of the Emperor and his house. As the various Austrian lands grew into a political organism, the interests of the *Reich* and the interests of the House of Habsburg diverged more and more. This is clearly visible in the disputes between the Aulic Council, led by Ludwig Phillipp, Graf von Sinzendorf, and the Imperial Chancery under Friedrich Karl, Graf von Schönborn, nephew of the archbishop of Mainz, Lothar Franz von Schönborn. The smaller secular and ecclesiastical states of the *Reich* were concerned to retain and to strengthen imperial power, but the larger states, especially Hanover and Brandenburg, which wanted to expand, were opposed to this. Four of the most powerful electors were now sovereign rulers: the Elector of Brandenburg was king in Prussia; the Elector of Hanover was king of Great Britain; the Elector of Saxony was king of Poland; and the Emperor himself was king of Hungary. Moreover, the kings of Denmark and of Sweden were also princes of the empire. Whereas the smaller states regarded the imperial power as the only guarantee of their "liberty" against aggression, the greater states regarded that power as a danger to their own liberty, fearing that the Emperor might erect a "despotic" or truly monarchical regime. Whenever the interests of the more powerful states were involved, the Emperor found few means at his disposal to render effective legal and constitutional decisions. Indeed, the evolution of the territorial states undermined the imperial constitution and the feeling for the unity of the *Reich*. There was no common political history for Germany in this period, though Germany's destiny as a whole was to be deeply influenced by international affairs.

Attempts to keep the dynasty intact

When Charles had gone to Spain to enter into his inheritance there, a secret family compact had been made to regulate the succession, the *Pactum mutuae successionis* (1703). After Spain had been lost and Charles had succeeded to Austria, it became necessary to adapt the precedence of the heirs and the order of their succession to the changed circumstances if Austria was to remain a unitary state and to be saved from partition among the various claimants. This was done not only in the interest of Austria and of the dynasty but also in that of Germany and, indeed, of Europe, since the European balance of power depended on the survival of the undivided Austrian state. Charles spared no effort to ensure that after his death his wishes respecting the succession would be carried out. These wishes he embodied in a special law, the Pragmatic Sanction, for which he secured the approval of the diets in all his territories.

Charles did not consider this security enough; he sought to have the Pragmatic Sanction recognized by the great powers and approved by the Reichstag. The approval of the Reichstag was especially difficult to obtain, because two of the most important princes in Germany, the future electors Frederick Augustus II of Saxony and Charles Albert of Bavaria, had, in 1719 and 1722, respectively, married Emperor Joseph I's daughters and so had an immediate personal interest in frustrating the execution of Charles VI's wishes. In these circumstances, the Emperor particularly desired Prussia's consent to his plan. Frederick William I of Prussia was quite willing to fall in with the Emperor's wishes but demanded in return that the Emperor should help him to pursue his claim to part of the inheritance of the duchies of Jülich and Berg on the Lower Rhine. The Emperor appeared to assent to this and so secured Frederick William's agreement to the Pragmatic Sanction by the Treaty of Berlin (December 23, 1728). Soon, however, it became clear that the Emperor had made contrary promises to the rival claimants to Jülich and Berg. This estranged Prussia from Austria, and Frederick William allied himself with the Emperor's enemies.

The War of the Polish Succession (1733–35). In 1733 Augustus II of Poland (that is, Frederick Augustus I of Saxony) died. While Austria and Russia declared themselves in favour of the succession of his son Augustus III (Frederick Augustus II), a number of Polish nobles chose Augustus II's former opponent, Stanisław Leszczyński, whose daughter was married to the young French king, Louis XV.

When the War of the Polish Succession broke out, the French used the opportunity to acquire at last the long-disputed Duchy of Lorraine. The Spanish Bourbons also entered the war in order to realize their claims to the Italian duchies of Parma and Piacenza. Though the *Reich* as a whole took the Emperor's side, the Wittelsbach rulers of Bavaria, the Palatinate, and Cologne refused to do so. Old and ill, Prince Eugene of Savoy could only hold the defensive with a small army, and he advised the Emperor to make peace. As the French minister Cardinal André-Hercule de Fleury also wanted peace, the preliminary agreements of 1735 became the basis of the final Treaty of Vienna (1738). The Emperor had to abandon Sicily and Naples, which were placed under the rule of one of the Spanish princes, Don Carlos, though the duchies of Parma and Piacenza were ceded to Austria. Of special significance to Germany was the Em-

peror's consent to the cession of Lorraine, which was made over to Stanisław Leszczyński as compensation for his renunciation of the Polish crown but which was to revert to France after his death. The reigning duke of Lorraine, Francis Stephen, who was married to Charles VI's heiress, Maria Theresa, was compensated with the Grand Duchy of Tuscany. France, in return, recognized the Pragmatic Sanction—with the important reservation that it only did so insofar as it did not conflict with established third-party rights.

The War of the Austrian Succession (1740–48). When Charles VI died on October 20, 1740, his daughter Maria Theresa at once assumed the government of the countries belonging to the House of Habsburg. The interests of power politics, however, proved stronger than the treaties by which her father had sought to secure the succession for her. Though Germany and even Europe required that the integrity of her inheritance should be maintained, the electors Frederick Augustus II of Saxony (Augustus III of Poland) and Charles Albert of Bavaria protested against her accession and were supported by the French, who desired to see a partition of the Austrian territories; a still more pressing danger threatened Maria Theresa when the new Prussian king joined her opponents. Frederick II the Great of Prussia at first offered Maria Theresa his help against her enemies if she would cede to him a part of Silesia to which Prussia had some claim by virtue of old dynastic agreements. When she rejected his proposal, he determined to occupy the disputed Silesia territory by force.

The aggression of Frederick II of Prussia

Frederick crossed the Silesian frontier in December 1740, advanced as far as Breslau, and defeated an advancing Austrian Army near Mollwitz in April 1741. At the same time, the Bavarians, supported by a French Army, advanced as far as Linz and even seized Prague with the help of the Saxons. Next, the German electors, under French and Prussian influence, elected as emperor not Maria Theresa's husband, Francis Stephen, but the elector Charles Albert of Bavaria (January 24, 1742), who assumed the name of Charles VII. When Frederick, having occupied all Silesia and invaded Moravia, won the Battle of Chotusitz against an Austrian army, Maria Theresa thought it prudent to open negotiations—though her troops had regained Linz and even invaded Bavaria. England, also at war with France over colonial questions, acted as intermediary, and, thus, the Treaty of Breslau (June 11, 1742) was concluded between Austria and Prussia. Austria ceded the greater part of Silesia along with the Countship of Glatz (now Kłodzko, Poland) to Prussia and retained only the principalities of Troppau (now Opava, Czechoslovakia) and Teschen. In return, Frederick promised his neutrality. The First Silesian War, which ended with this peace, established the military reputation of Frederick the Great. It was the first armed contest between the two greatest German states that had developed out of the old *Reich*—states that had long regarded each other with distrust and jealousy.

The struggle for the inheritance of Charles VI continued. The Austrian Army captured Prague, freed Bohemia from the invaders, and even captured Munich, the Bavarian capital. A British Army defeated the French at Dettingen and advanced from Hanover as far as the Rhine. Then, when the Austrians, led by Prince Charles of Lorraine, were advancing from southern Germany with the intention of crossing the Rhine, Frederick the Great decided to intervene again, lest Maria Theresa, after a complete victory over her other enemies, should try to wrest back Silesia. Having signed a new alliance with France, he invaded Bohemia in August 1744 but had to withdraw, because the expected simultaneous advance of the French Army did not take place. Then, Charles VII died (January 20, 1745), and his son, the elector Maximilian III Joseph of Bavaria, at once made peace with Maria Theresa, recovering his ancestral domains in return for renunciation of all his claims to the Austrian inheritance. Frederick Augustus II of Saxony had already abandoned his claims and made peace with Austria, and, as the French were fully occupied in Flanders, Frederick found himself alone opposed to the main force of Austria. Strengthened by Saxon troops, the Austrians attacked Silesia but were defeated near Hohenfriedeberg on June 4, 1745. Once more Frederick invaded Bohemia, and, by the end of the year, a great part of Saxony was in his possession. On December 15, his chief general, Leopold of Anhault-Dessau, won a fresh victory over the Austrians and Saxons at Kesselsdorf, near Dresden.

The majority of the electors had, in the meantime, elected Francis Stephen of Lorraine as emperor. As Francis I, he was nominal head of the *Reich* from 1745 to 1765. Maria Theresa, who now saw that it would not be so easy to retake Silesia and who laid great stress on the recognition of her husband as emperor by Frederick, was ready to reopen negotiations. On December 25, 1745, the Second Silesian War was brought to a close by the Treaty of Dresden, by which Frederick retained Silesia and recognized Francis I as emperor.

The election of Francis

The war against France lasted nearly three years more, but French victories on land were more than offset by the British victories at sea. Finally, by the Treaty of Aix-la-Chapelle (1748), Maria Theresa was recognized as her father's sole heiress but gave certain frontier districts in Lombardy to Savoy and the Duchy of Parma to the Spanish prince Philip. Maria Theresa had to come to terms mainly because Great Britain wanted to end the war.

The Seven Years' War (1756–63). Though peace was, thus, outwardly restored, tension between Austria and Prussia remained, since Maria Theresa had never abandoned her hopes of regaining Silesia. These hopes were shared by her chief minister, Wenzel Kaunitz, Fürst von Kaunitz-Rietberg, who looked on Prussia as the natural enemy of Austria. Neither party, however, wished to resume the contest without the help of powerful allies. Kaunitz had already established relations with Russia, and his special concern was to induce France, Austria's old enemy, to support his schemes. The French, meanwhile, despite their Prussian alliance, viewed the growing power of Prussia with dislike. Frederick, for his part, was convinced that he would have to defend Silesia against an Austrian attack and so was anxious to detach the British from their traditional support of Austria if he could do so without impairing his formal friendship with France, Great Britain's principal rival.

In 1755, when French and British settlers in North America had already come to blows and the Austrian government showed itself unwilling to undertake the protection of Hannover in the event of Anglo-French hostilities in Europe, the British government sought a promise of help from Prussia. Since it was to be a purely defensive agreement, Frederick considered that he could enter into it without breaking faith with France and, on January 16, 1756, concluded the Convention of Westminster, which stipulated that Prussia should help Great Britain if the French attacked Hanover and that Great Britain should support Frederick if the Austrians attacked Silesia. The French, however, saw this convention as a defection by Frederick from his French commitments, and, on May 1, 1756, at Versailles, the defensive alliance for which Kaunitz had so long laboured was concluded between France and Austria.

The Convention of Westminster

Kaunitz, with the zealous support of Russia, set to work in Paris to turn the Austro-French defensive alliance into an offensive one for the complete destruction and partition of Prussia; and Frederick the Great learned that an attack on Prussia by Austria, Russia, and France was being planned for the following spring. Frederick, resolved to anticipate his enemies, gave the order to his troops to cross the Saxon frontier. Thus began the Seven Years' War (*q.v.*), in which Prussia fought against Austria, France, Russia, Saxony, and Sweden. Frederick's sole ally was Great Britain–Hanover, the support of which consisted mainly in a subsidy of 4,000,000 thalers a year. It was only his generalship and his determination not to consent to any dimunition of his territory that made it possible for him to survive.

In the autumn of 1756 Frederick occupied Saxony and compelled the Saxon army to surrender at Pirna. In 1757 he invaded Bohemia and besieged Prague but was him-

self defeated at Kolín on June 18 and forced to withdraw. At the same time Russian troops threatened East Prussia, one French Army overran Hanover, and a second French Army, in conjunction with an imperial army, advanced on Berlin. Frederick defeated the French and imperial forces at Rossbach on November 5 and then hastened to Silesia, where, by the Battle of Leuthen (December 5), he recovered Breslau from the Austrians. The moral effect of Rossbach was even greater than its military effect, for it brought many members of the *Reich* to "a Fritzian way of thinking" (Goethe): it was not only a victory over the French but also a victory over the *Reich*, which, notwithstanding the smaller states' leadership in cultural matters, had declined in political importance while Austria and Prussia rose to power.

The following years, however, brought Prussia to the verge of disaster. While the French advanced as far as the Weser, Austrian and Russian armies together defeated Frederick at Kunersdorf on August 12, 1759. With his army well-nigh exterminated, Frederick thought that Prussia was bound to fall; however, disunity among leading Russian and Austrian commanders gave him time to recruit a new army. The imperial army entered Dresden and occupied a part of Saxony, but the illness of the empress Elizabeth hindered the operations of the Russians, since it was common knowledge that the sympathies of the heir apparent, the future Peter III, were with Frederick. Nevertheless, it became daily more difficult for Frederick to obtain reinforcements and money. After the fall of the elder William Pitt's ministry, the British government began to negotiate for peace with France and ceased its financial support of Prussia from April 1762.

By this time, however, Frederick's position had been decisively improved by the death of Elizabeth of Russia on January 5, 1762: her successor, Peter III, made peace with Frederick and entered into an alliance with him. Though Peter was murdered a few months later, his successor, Catherine II the Great, also thought that neither a strengthening of Austria nor the destruction of Prussia would serve Russia's true interests. She withdrew her military support from Frederick but did not renew the alliance with Austria.

Furthermore, after signing the preliminaries of peace with Great Britain (November 1762), the French lost all interest in the war with Prussia and withdrew their troops from Germany. Hence, Maria Theresa gave up all hope of a decisive victory and entered into negotiations. Peace was signed at Hubertusburg on February 15, 1763. Frederick evacuated Saxony but retained Silesia.

The importance of the Seven Years' War in German history lies in the failure of Austria's attempt to destroy Prussia before Prussian power was consolidated. The hostility between the two greatest German states continued to exist and to influence powerfully the whole future political development of Germany. (Ed.)

IV. Circa 1760–1871

GERMANY FROM C. 1760 TO 1815

Germany in the middle of the 18th century was a country that had been drifting in the backwaters of European politics for more than a hundred years. The decisive roles in the affairs of the continent were played by those great powers, such as France, England, and Spain, whose economic resources and commercial connections provided a solid foundation for their military might. The states of central Europe, on the other hand, floundered in a morass of provincialism and particularism. All the forces that had contributed to the rise of powerful national monarchies west of the Rhine were lacking in the east. In the Holy Roman Empire the central government was losing rather than gaining strength, the princes were enlarging their authority at the expense of the crown, and business initiative was being discouraged by the lack of political unity and by the remoteness of the major trade routes.

The Holy Roman Empire in the late 18th century

Civic power became increasingly concentrated in the hands of local governments controlled by aristocratic overlords, ecclesiastical dignitaries, or municipal oligarchs. The history of Germany between the Thirty Years' War and the French Revolution is largely the sum total of the histories of dozens upon dozens of small political units, each enjoying virtually full rights of sovereignty. The rulers of these gingerbread principalities, copying the example of the royal court of France or Austria, built costly imitations of the palaces of Versailles and Schönbrunn, which today are the delight of tourists but which were once the curse of an impoverished peasantry. The tradition of princely authority, an instrument of national greatness in western Europe, encouraged national divisiveness in central Europe. The petty rulers of Germany legislated at will, levied taxes, concluded alliances, and waged wars against each other and against the emperor. Policies pursued in Munich, Stuttgart, Dresden, or Darmstadt reflected policies originating in Paris, Vienna, London, or Madrid, but without seeking a goal greater than the promotion of particularistic interests.

Political institutions designed theoretically to express the will of the nation continued to function, yet they had become an empty shell. The Holy Roman emperor was still elected in accordance with a time-honoured ritual that proclaimed him to be the successor of Caesar and Augustus. The splendid coronation ceremony in Frankfurt am Main, however, could not disguise the fact that the office conferred on its holder little more than prestige. Since all the emperors except Charles VII were Habsburgs by birth or marriage, they enjoyed an authority that had to be respected. But that authority rested not on the prerogative of the imperial crown but on the possession of hereditary lands stretching from Antwerp in the west to Debrecen in the east. The sovereigns of the Holy Roman Empire, in other words, were able to play an important role in German affairs by virtue of their non-German resources. And since Germany was not the main source of their strength, Germany was not the main object of their concern. The emperors tended to regard the dignity bestowed upon them as a means of furthering the interests of their dynastic holdings. The imperial Diet meeting in Regensburg had also become an instrument for the promotion of particularistic advantage rather than national welfare. It continued in theory to express the will of the estates of the realm meeting in solemn deliberation. In fact it had degenerated into a debating society without authority or influence. The princes had ceased to attend the sessions, so that only diplomatic representatives were left to discuss questions for which they were powerless to provide answers. The other central institutions of the empire, such as the imperial cameral tribunal in Wetzlar, languished in indolence. Constitutionally and politically Germany around 1760 resembled Poland in that a once vigorous and proud state had become weakened by internal conflict to the point that it invited the intervention of its more powerful neighbours.

What saved Germany from the fate of Poland was the ability of one of the member states to defend the empire against aggression. For 200 years Austria acted as the bulwark of central Europe against French expansion. Its possessions, forming a chain of protective bases extending between the North Sea and the Danube, had time and again borne the brunt of attacks by Bourbon armies. The frontiers of France kept moving closer to the Rhine, but the Holy Roman Empire was at least spared the tragedy of partition that befell the Polish state. It was partly in recognition of the vital role that the Habsburgs played in the defense of Germany that the electors chose them emperors with such regularity. The Austrian monarchy, moreover, endowed with resources comparable to those of the western nations, was able to pursue a policy of political rationalization with greater success than the principalities. The rulers in Vienna succeeded in improving the administration, strengthening the economy, and centralizing the government. Until the middle of the 18th century Austria remained the only great power east of the Rhine.

Traditional role of the Austrian Habsburgs

Further rise of Prussia and the Hohenzollerns. The emergence of the Hohenzollerns as rivals of the Habsburgs and the beginning of the Austro-Prussian dualism created the possibility of reversing the process of civic

decentralization that had prevailed in central Europe since the late Middle Ages. The interests of the territorial princes of the Holy Roman Empire inclined them toward a policy of particularism, while the government of Austria, with its Flemish, Italian, Slavic, and Magyar territories, could not perforce become the instrument of German unification. Prussia, on the other hand, was militarily strong enough and ethnically homogeneous enough to make national consolidation the main object of statecraft. But though the creation of a united Germany became its mission, this mission was not from the outset one that it accepted willingly or even consciously. The intention of Frederick the Great and of his successors Frederick William II and Frederick William III was to pursue dynastic rather than national objectives. Like the lesser princes of central Europe, all they sought was to maintain and enlarge their authority against the claim of imperial supremacy. Far from wanting to end the disunity of Germany, they hoped to prolong and exploit it. The patriotic Prussophile historians who a hundred years later argued that what Bismarck had achieved was the consummation of what Frederick had sought were letting the present distort their understanding of the past. In fact, the greatest of the Hohenzollerns had remained as indifferent to the glaring political weaknesses of his nation as to its great cultural achievements. His attitude toward the constitutional system of the Holy Roman Empire was similar to that of the self-seeking princelings who were his neighbours and from whom he was distinguishable only by talent and power. He may have scorned their sybaritic way of life. But politically he wanted what they wanted: the freedom to seek the advantage of his dynasty without regard for the interests of Germany as a whole.

The interests of Frederick the Great and his successors

His preoccupation with the welfare of his state rather than with that of his nation is apparent in the strategy by which he tried to check Habsburg ambitions after the Seven Years' War (1756–63). During the first half of his reign he had relied primarily on military force to restrict and undermine imperial authority. In the second half he preferred to employ the weapons of diplomacy to achieve the same end. In 1777 the ruling dynasty of Bavaria came to an end with the death of Maximilian Joseph. The elector of the Palatinate, Charles Theodore, now became ruler over the territories of both branches of the House of Wittelsbach. Without legitimate offspring to whom to leave his state and without affection for his newly acquired eastern possessions, he agreed to a plan proposed by Emperor Joseph II according to which part of the Bavarian lands would be ceded to Austria. But any increase in the strength of the Habsburgs was unacceptable to Frederick the Great. With the tacit approval of most of the princes of the empire, he declared war against Austria in 1778, hoping that other states within and outside central Europe would join him. In this expectation he was disappointed. Yet Joseph also became discouraged by the difficulties encountered in what he had believed would be an easy success. The War of the Bavarian Succession dragged on from the summer of 1778 to the spring of 1779, with neither side enhancing its reputation for prowess on the field of battle. There was much marching back and forth, while hungry soldiers scrounged for food in what came to be called the "potato war." The upshot was the Treaty of Teschen (May 1779), by which the Austrian government abandoned all claims to Bavarian territory except for a small strip along the Inn River. The conflict had brought Frederick no significant military victories, but he had succeeded in frustrating Habsburg ambition.

War of the Bavarian Succession

Joseph II, however, was a stubborn adversary. In 1785 he once again advanced a plan for the acquisition of Wittelsbach lands, this time on an even more ambitious scale. He suggested to Charles Theodore nothing less than an outright exchange of the Austrian Netherlands for all of Bavaria. The Emperor, in other words, proposed to surrender his distant possessions on the North Sea, which were difficult to defend, for a territory that was contiguous and a population that was assimilable. The scheme went far beyond that which Prussia had defeated seven years before, and Frederick opposed it with equal determination. He hoped to enlist the diplomatic aid of France and Russia against what he regarded as an attempt to upset the balance of power in central Europe. But more than that, he succeeded in forming a Constitutional Association of Imperial Princes, which 17 of the more important rulers in Germany joined. The members pledged themselves to maintain the fundamental law of the empire and to defend the possessions of the governments included within its boundaries. The growing opposition to the absorption of Bavaria by Austria persuaded Joseph that the risks inherent in his plan outweighed its advantages. The proposed exchange of territories was dropped, and Frederick could celebrate yet another triumph of his statecraft, the last of an illustrious career. But the association of princes that he founded did not survive its author. Its sole purpose had been the protection of princely prerogative against imperial authority. Once the danger had passed, it lost the only justification for its existence. Those nationalists who later maintained that it foreshadowed the creation of the German Empire misunderstood its origins and objectives. It was never more than a weapon in the struggle for the preservation of a decentralized form of government in central Europe.

The subordination by the Hohenzollerns of national to dynastic interests was even more apparent in the role they played during the partitions of Poland. Frederick the Great was the chief architect of the first partition, that of 1772, by which the ill-starred kingdom lost about a fifth of its inhabitants and a fourth of its territory to Prussia, Russia, and Austria. His successor, Frederick William II, helped to complete the destruction of the Polish state by the partitions of 1793 (between Prussia and Russia) and 1795 (between Prussia, Russia, and Austria). The result was bound to be an enhancement of Prussia's role in Europe but also a diminution of its role in Germany. The Hohenzollerns willingly embarked on a course that would in time have transformed their kingdom into a binational state comparable to the Habsburg empire. The German population in the old provinces would have been counterbalanced by the Slavic population in the new; the Protestant faith of the Prussians would have had to share its influence with the Catholicism of the Poles; the capital city of Berlin would have found a competitor in the capital city of Warsaw. In short, the centre of gravity of the state would have shifted eastward, away from the problems and interests of the Holy Roman Empire. Yet the rulers of Prussia did not shrink from a policy that was likely to have such far-reaching consequences. They never contemplated sacrificing the advantage that their state would gain from an enlargement of its resources in order to assume the role of unifiers of their nation. Such a political attitude would have been an anachronism during the age of princely absolutism in central Europe. It was not design but accident that before long led to the abandonment by Prussia of most of its Polish possessions and that thereby allowed it to continue to play a vital part in the affairs of Germany.

Contingent results of the Polish partition

The cultural scene. Whereas in England the great literary epoch of Queen Elizabeth I had coincided with commercial and naval expansion, and in France the golden age of classicism had added lustre to the military glory of Louis XIV, German arts and letters flourished amid tiny principalities and somnolent towns that could only envy the powerful national monarchies west of the Rhine. Moreover, whereas in France and England, where public opinion could exert a significant influence on government, the debate over issues of state and society was conducted with a vigour that reflected its importance, in Germany the debate was bound to remain purely theoretical. No Voltaires, Rousseaus, or Burkes were likely to emerge out of such an environment. The thinkers of central Europe tended to emphasize introspection and spirituality. Culture became an escape from the narrow world of princely absolutism. Intellectual energies that could not reform the community fought to emancipate the individual through self-purification and self-perfection.

This was the background of German Idealism, a philosophic movement seeking to liberate ethics and aesthetics

German Idealism

from the shackles of empirical knowledge. Armed with the weapons of Kantian thought, it attempted to prove that there was a realm of experience lying beyond the categories of scientific investigation, the realm of the good, the true, and the beautiful. There were realities of the spirit and the mind, in other words, that were inaccessible to the practicality of the British Empiricists or the intellectualism of the French Rationalists. The disciples of Idealism hoped to transcend the barriers created by nation, class, and religion. They spoke in the name of humanity as a whole, which manifested its underlying harmony through the infinite variety of its political, social, and theological categories. Gotthold Ephraim Lessing pleaded for religious toleration on the basis of a common system of ethical values to which all men of good will could subscribe. Johann Gottfried Herder preached that the unique character and meaning of each culture contributed to the richness of common humanity that defied state boundaries. Johann Joachim Winckelmann deified the classical ideal of beauty that he found in Greek art as an eternal standard, immune to the vicissitudes of time and history. These were views that offered an escape from the narrowness of everyday life. Men who found no scope for their talents in the petty world of princely authority could turn to the liberating spirituality of the Idealist philosophy. Thought in central Europe gradually acquired a metaphysical coloration that distinguished it from the more robust Pragmatism of philosophy in the west. It was during the second half of the 18th century that the Germans began to consider their country "the land of thinkers and poets."

The introspection of arts and letters

The literary revival of the age displayed the same quality of introspective Idealism as the philosophic movement. Johann Wolfgang von Goethe, the greatest genius of German letters, willingly accepted the existing system of civic and social values. He regarded the disunity of his nation as an expression of its historic character, and he defended the authority of the petty princes as an instrument of good government. He urged his countrymen to seek greatness not in collective action but in individual perfectibility. After a period of youthful rebellion against traditional canons of literary propriety, he turned to a classicism in which a serene acceptance of life harmonized with his own sympathy for the established order. Friedrich Schiller, a man of more turbulent temperament, felt a sense of resentment against political injustice and weakness. In his plays and poems there are occasional outbursts of indignation and appeals for reform. Yet there is also a pessimistic mood of resignation induced by the burden of civic ineffectualness that history had imposed on his people. Ultimately, he too sought refuge from the world in the poet's private vision. The *Sturm und Drang* ("storm and stress") was a movement of literary innovation through which a group of young writers in the last decades of the 18th century sought to throw off the yoke of accepted standards of composition. But it remained confined to problems of prosody and taste, refusing to grapple with political or social issues.

The cultural achievements could not alter the harsh realities of national fragmentation and princely autocracy. They supported, however, the ideals of rational reform and social progress that the Enlightenment had introduced throughout the Continent. In Germany as elsewhere the 18th century became the age when the monarchical principle advanced the loftiest justification of its claim to power. The authority of the prince, so the argument went, was to be exercised not for his private advantage or gratification but for the greatness of his state and the welfare of his people. His power had to be unrestricted so that his benevolence might be unlimited. Absolute government was the only effective instrument for achieving the general good. Impressed by the scientific discoveries and material advances that they saw about them, men began to believe that the prejudices and injustices that had plagued society would gradually disappear before the steady march of reason.

Enlightened reform and benevolent despotism. The main source of enlightened reform was to be the crown, but many well-intentioned people of means and education also began to apply a new standard of conduct in their dealings with their fellow man. This change in attitude was apparent in the decline of religious resentments and discriminations. Never before had the relationship between Catholics and Protestants among the well-to-do classes of central Europe been as free of rancor as on the eve of the French Revolution. It was at this time also that the Jews first began to emerge from the isolation to which a deep-seated intolerance had consigned them. The idea of assimilation held out to them the prospect of escape from the ghetto on the condition that they identify themselves in thought, speech, and attitude with the Christian society in which they lived. That prospect was to attract the Jewish minority in Germany more and more during the next 150 years. Religious toleration, however, was not the only article of faith of the Enlightenment. Its vision of a happier future included the reform of education, the abolition of poverty, the alleviation of sickness, and the elimination of injustice. Men of good will established schools, founded orphanages, built hospitals, improved farming methods, modernized industrial techniques, and tried to raise the standard of living of the masses. While the hopes of the enlightened reformers of the 18th century far outstripped their accomplishments, the practical results of their efforts should not be underestimated.

Growing religious toleration

According to the doctrines of benevolent despotism, however, the chief instrumentality for the improvement of society was not private philanthropy but government action. The state had the primary responsibility for preparing the way for that golden age which, in the opinion of many intellectuals, awaited mankind. The extent to which official policy conformed to rationalist theory depended, in central Europe as elsewhere, on the personality and ability of the ruler. Both of the leading powers of the Holy Roman Empire followed the teachings of benevolent despotism, but with substantially different results. The emperor Joseph II, a well-meaning though doctrinaire reformer, attempted to initiate a revolution from above against the opposition of powerful forces that continued to cling to tradition. In the course of a single decade he tried to centralize the government of his far-flung domains, reduce the influence of the church, introduce religious toleration, and ease the burden of serfdom. His uncompromising program of innovation, however, alienated the landed aristocracy, whose support was essential for the effective operation of the government. The emperor encountered mounting unrest that did not end until his death in 1790 and the subsequent abandonment of most of the reforms that he had promulgated. Frederick the Great was more successful as an enlightened autocrat, but only because he was more cautious. His reorganization of the government was not as drastic, his belief in religious toleration remained less profound, and his assistance to the peasants did not go beyond a prohibition against the absorption of their holdings by the nobility. He invited settlers to cultivate reclaimed lands, and he encouraged entrepreneurs to increase the industrial capacity of Prussia. Among his most important accomplishments, although it was not completed until after his death, was the Prussian Legal Code, which defined the principles and practices of an absolute government and a corporative society. Yet Frederick was also convinced that the Prussian landed noblemen, the Junkers, were the backbone of the state, and he continued accordingly to uphold the alliance between crown and aristocracy on which his kingdom had been built.

Attempts at social and political reform

The achievements of benevolent despotism among the minor states of the Holy Roman Empire varied considerably. Some princes employed their inherited authority in a serious effort to improve the lot of their subjects. Charles Frederick of Baden, for example, devoted himself to the improvement of education in his margravate, and he even abolished serfdom, though without eliminating manorial obligations. Carl August of Saxe-Weimar-Eisenach was a hard-working administrator of his small Thuringian principality, whose capital he transformed into the cultural centre of Germany. Charles Eugene of Württemberg, on the other hand, led a life of profligacy and licentiousness in defiance of protests by the estates

of the duchy. Frederick II of Hesse-Kassel was another princely prodigal whose love of pleasure impoverished his subjects and forced his soldiers into mercenary service for England. The record of enlightened autocracy in central Europe was as uneven as in western Europe. Yet the ideas of the Enlightenment even at their best were unable to transform the basis of political life in the Holy Roman Empire. They could palliate, reform, and improve. But they could not alter a system of particularistic sovereignty and absolutistic authority resting on a hierarchical structure of society. They could not become an instrument of national consolidation or representative government. Only some great creative disruption of existing civic institutions could break through the crust of habit and tradition sanctified by history. Germany lacked the vital energies required for a process of political reconstruction. The galvanizing forces of rejuvenation and regeneration were to come from the outside.

The French Revolutionary and Napoleonic era. The French Revolution, transforming the Bourbon kingdom into a constitutional state, aroused intense excitement east of the Rhine. Most German intellectuals were at first in sympathy with the new order in France, hoping that the defeat of royal absolutism in western Europe would lead to its decline in central Europe as well. The princes, on the other hand, were from the outset fearful of the Revolution, which they regarded as a serious danger; for the example of unpunished insubordination by the French might encourage demands for reform among the Germans. The result was a growing hostility between the government in Paris and the rulers of the Holy Roman Empire, which led in the spring of 1792 to the outbreak of war (the War of the First Coalition, 1792–97). The immediate occasion of the conflict was a quarrel over the rights of German princes with holdings in France and over the propagandistic activities of French émigrés in Germany. But the underlying cause was the clash of two incompatible principles of authority divided by profound differences regarding the nature of political and social justice. The course of hostilities soon revealed that the civic ideals and military tactics of the Revolution were more than a match for the decrepit Holy Roman Empire. After 1793 the left bank of the Rhine remained under the control of France, and for the next 20 years its inhabitants were governed from Paris. Yet there is no evidence that they were dissatisfied with French rule or at least that they strongly opposed it. Devoid of a sense of nationalism and accustomed to submission to authority, they accepted their new status with the same equanimity with which they regarded a succession to the throne or a change in the dynasty. The Prussians, moreover, discouraged by defeats in the west and eager for Polish spoils in the east, concluded a separate peace at Basel in 1795 by which they in effect recognized the French acquisition of the Rhineland. The Austrians held out two years longer, but the brilliant successes of the young Napoleon Bonaparte forced them to accept the loss of the left bank in the Treaty of Campo Formio (October 17, 1797).

War of the First Coalition

War of the Second Coalition

End of the Holy Roman Empire. The peace proved short-lived, however, for at the end of 1798 a new coalition directed against France was formed (the War of the Second Coalition, 1798–1802). This time Prussia remained neutral. Frederick William III, a conscientious and modest but ineffectual ruler, was distinguishable from his father by private morality rather than political skill. The government in Berlin drifted back and forth, dabbling in minor economic and administrative reforms without introducing a significant improvement in the structure of the state. A decade of neutrality was frittered away, while the army commanders rested on the laurels of Frederick the Great. Austria, on the other hand, played the same leading role in the War of the Second Coalition as in the War of the First Coalition, and with the same unfortunate result. The French victories at Marengo (June 14, 1800) and Hohenlinden (December 3, 1800) forced Emperor Francis II to agree to the Treaty of Lunéville (February 9, 1801), which confirmed the cession of the Rhineland. More than that, those rulers who lost their possessions on the left bank under the terms of the peace were to receive compensation elsewhere in the empire. In order to carry out this redistribution of territory, the imperial Diet entrusted a committee of princes, the Reichsdeputation, with the task of drawing a new map of central Europe. The major influence over its deliberations, however, was exercised by France. Napoleon had resolved to utilize the settlement of territorial claims to achieve a fundamental alteration in the structure of the Holy Roman Empire. The result was that the Final Recess (*Hauptschluss*) of the Reichsdeputation of February 1803 marked the end of the old order in Germany. In their attempt to establish a chain of satellite states east of the Rhine, the French diplomats brought about the elimination of the smallest and least viable of the political components of central Europe. But thereby they also furthered the process of national consolidation, since the fragmentation of civic authority in the empire had been a mainstay of particularism. That it was not Napoleon's intention to encourage unity among his neighbours goes without saying. Yet he unwittingly prepared the way for a program of centralization in Germany that helped to frustrate his own plans for the future aggrandizement of France.

The chief victims of the Final Recess were the free cities and the ecclesiastical territories. They fell by the dozens. Too weak to be useful allies of Napoleon, they were destroyed by the ambition of their French conquerors and by the greed of their German neighbours. They could still boast of their ancient history as sovereign members of the Holy Roman Empire, but their continued existence had become incompatible with the establishment of effective government in central Europe. The principal heirs to their holdings were the larger secondary states. To be sure, Napoleon could not keep Austria and Prussia from making some gains in the general scramble for territory that they had helped make possible. But he was especially solicitous for the welfare of those German rulers, most of them in the south, who were strong enough to be valuable vassals but not strong enough to be potential threats. Bavaria, Württemberg, Baden, Hesse-Darmstadt, and Nassau were the big winners in the competition for booty that had been the main object of the negotiations. Napoleon's strategy had been in the classic tradition of French diplomacy, the tradition of Richelieu and Mazarin. The princes had been pitted against the emperor in order to enhance the role that Paris could play in the affairs of central Europe. Yet neither the states that gained nor those that lost territory felt any resentment at being used as pawns in a political game to promote the interests of a foreign power. Whatever objections they raised against the settlement of 1803 were based on expediency and opportunism. The most serious indictment of the old order was that in the hour of its imminent collapse none of the rulers made the least attempt to defend it in the name of the general welfare of Germany.

The Final Recess was the next to the last act in the fall of the Holy Roman Empire. The end came three years later. In 1805 Austria joined the third coalition of Great Powers determined to reduce the preponderance of France (the War of the Third Coalition, 1805–07). The outcome was even more disastrous than its participation in the first and the second coalitions. Napoleon forced the main Habsburg army in Germany to surrender at Ulm (October 17, 1805); then he descended on Vienna, occupying the proud capital of his enemy; and finally he inflicted a crushing defeat on the combined Russian and Austrian armies at Austerlitz in Moravia (December 2, 1805). Before the year was out Francis II had been forced to sign the humiliating Treaty of Pressburg (December 26), which signified the end of the dominant role his dynasty had played in the affairs of cental Europe. He had to surrender his possessions in western Germany to Württemberg and Baden, and the province of Tirol to Bavaria. Napoleon's strategy of playing off princely against imperial ambitions had proved a brilliant success. The rulers of the secondary states in the south had supported him in the war against Austria, and in the peace that ensued they were richly rewarded. Not only did they share in the booty seized from the Habsburgs but they

War of the Third Coalition

were permitted to absorb the remaining free cities, petty principalities, and ecclesiastical territories. Finally, in an assertion of the rights of full sovereignty, the rulers of Bavaria and Württemberg assumed the title of king, while the rulers of Baden and Hesse-Darmstadt contented themselves with the more modest rank of grand duke. The last vestiges of the imperial constitution had now been destroyed, and central Europe was ready to receive a new form of political organization reflecting the power relationship created by the force of arms.

Confederation of the Rhine

In the summer of 1806, 16 of the secondary states, encouraged and prodded by Paris, announced that they were forming a separate association to be known as the Confederation of the Rhine. Archbishop Karl Theodor von Dalberg was to preside over the new union as the "prince primate," while future deliberations among the members were to establish a college of kings and a college of princes as common legislative bodies. There was even talk of a "fundamental statute" that would serve as the constitution of a rejuvenated Germany. Yet all these brave plans were never more than a facade for the harsh reality of alien hegemony in central Europe. Napoleon was proclaimed the "protector" of the Confederation of the Rhine, and a permanent alliance between the member states and the French Empire obliged the former to maintain substantial military forces for the purpose of mutual defense. There could be no doubt whose interests these troops would serve. The secondary rulers of Germany were expected to pay a handsome tribute to Paris for their newly acquired sham sovereignty. On August 1 the confederated states proclaimed their secession from the empire, and a week later, on August 6, 1806, Francis II announced that he was laying down the imperial crown. The Holy Roman Empire thus came officially to an end after a history of a thousand years.

Period of French hegemony in Germany. The long conflict between emperors and princes in Germany had concluded with the triumph of the latter. Yet the victors soon discovered that instead of achieving independence they had merely exchanged one master for another. Indeed, they were more subordinate now to the wishes of Paris than they had been to those of Vienna. Napoleon gradually induced or forced all the states of Germany except Austria and Prussia, 36 states in all, to join the confederation. The inclusion of the two leading powers of central Europe might have proved troublesome for him or even dangerous. The participation of the secondary states, on the other hand, provided him with reliable mercenaries who owed him too much and feared him too much to oppose his wishes. He was free to do as he liked in the region between the Rhine and the Elbe. In order to enforce his embargo on continental trade with England, he annexed the entire coastline along the North Sea. When that was not enough, he added Lübeck on the Baltic to the French Empire. He carved out the Kingdom of Westphalia for his brother Jérôme and the Grand Duchy of Berg for his brother-in-law Joachim Murat. He was the undisputed master of all of middle Germany.

After the formation of the Confederation of the Rhine there was only one state in central Europe that had not yet been forced to submit to France. But the leaders of Prussia hesitated and wavered in their policy until they lost the opportunity of profiting from the War of the Third Coalition. Had they joined Austria and Russia against Napoleon, they might have kept him from gaining hegemony over Germany. Or had they become the allies of Napoleon, they might have established a sphere of influence in the region north of the Main River. As it was, they waited until they fell between two stools. They finally declared war against the French in October 1806, after Austria had been forced to surrender, Russia had decided to retreat, and the secondary states had become the vassals of Paris. Yet public opinion in the Prussian capital remained confident that the army of Frederick the Great would prove a match for the conqueror of Europe.

The subjection of Prussia

The result of such self-deception was a military disaster of unparalleled magnitude. In the two simultaneous battles of Jena and Auerstädt (October 14, 1806) the Hohenzollern armies were completely routed, and the road to Berlin lay open before the French invaders. The city was occupied on October 27.

More disastrous than the military defeat, however, was the moral collapse of a state that had taught its citizens that obedience to authority was the supreme political virtue. The civilian population never thought of offering resistance to the advancing enemy. Even many army officers were so disheartened by Napoleon's success that they surrendered one fortified position after another without a fight. Frederick William III had to pay a terrible price for the policy of his ancestors, who had built efficient government at the expense of civic initiative. He tried to hold out in East Prussia, hoping that the Russian armies, which were still at war with Napoleon, would help him regain the rest of his kingdom. But when in July 1807 Alexander I concluded peace with France at Tilsit, the unfortunate Hohenzollern had no choice but to follow suit. The treaty that he was forced to sign was a catastrophe. Prussia lost almost half its territory and population, including most of the Polish possessions in the east as well as all of the territories west of the Elbe. Subsequent agreements, moreover, imposed a heavy indemnity, a military occupation, and a reduction in the size of the army. The proud monarchy of Frederick the Great had been reduced to a secondary state in Germany.

Germany in 1807 after reconstruction by Napoleon.

Napoleonic reforms and the birth of German nationalism

Central Europe remained under the dominant influence of France for more than a decade. That influence was at first limited and indirect, then pervasive and overpowering. Yet it was during this period of alien preponderance that Germany for the first time felt the stirrings of liberalism and nationalism. The regions that had become part of the French Empire experienced at first hand the advantages of efficient centralized government in which equality before the law and freedom of opportunity were accepted principles. Those states that retained a pseudo-independence as satellites of Napoleon, moreover, sought to imitate the example of their master, partly in order to gain his favour, partly in order to emulate his success.

One government after another began to remove religious disabilities, relax economic restrictions, eliminate servile obligations, and centralize administrative functions. Above all, constitutional rule and popular representation ceased to seem utopian to men of property and education who had witnessed the stirring events of the years since 1789. The French hegemony also led to the birth of nationalism in central Europe. For one thing, the achievement of political unity became a distinct possibility, once the territorial fragmentation of the Holy Roman Empire had come to an end. The presence of foreign invaders, furthermore—arrogant, overbearing, and avaricious—aroused among the Germans a sense of nationality that they had never felt in the tranquil days of the old order. Finally, an example of what great deeds the love of fatherland could inspire lay before all who admired or envied the triumphs of Napoleon. The ideal of cosmopolitan individualism that had been generally accepted in the 18th century began to give way before a growing consciousness of national identity. Yet the fact that the concepts of constitutional freedom and national unity were not indigenous but arose in response to foreign domination had an important effect on the form they assumed in central Europe.

Every German state felt the influence of the new principles of government and economy that the period of French hegemony had introduced. But nowhere was that influence more profound or fruitful than in Prussia. For only in the hour of deepest humiliation did the Hohenzollern kingdom finally make an effort to adapt its structure to the changing political and social conditions that it had stubbornly ignored during the years of greatness. Between 1806 and 1813 the statesmen in Berlin initiated a revolution from above in order to transform a rigid despotism into a popular monarchy supported by the loyalty of a free citizenry. Out of the disasters of Jena and Tilsit emerged a group of gifted reformers who sought to prepare the way for the regeneration of their country. The leading figures in this movement for civic reconstruction were the civil servants Karl vom Stein and Karl August von Hardenberg and the military commanders Gerhard von Scharnhorst and August Neithardt von Gneisenau. Among their most important achievements was the abolition of serfdom, a measure designed to create dedicated citizens out of human beasts of burden. Yet while it gave the peasant personal freedom, the government failed to provide him with economic independence. Most of the land remained in the hands of the aristocracy, which therefore continued to dominate the countryside politically as well as socially. More successful was the law establishing municipal self-government. Thereafter, the cities of the kingdom were to be administered by officials chosen not by the central bureaucracy but by the propertied inhabitants of the cities themselves. The autonomy of the urban communities, it was hoped, would help train a politically conscious and active middle class. The most effective reforms, however, were those introduced in the armed forces. After the officers who had shown themselves incompetent during the war were dismissed or retired, the high command carried out a thoroughgoing reorganization of the military system. Discipline became more humane, promotion was made a reward for merit, the method of recruitment was improved, and the training in tactics was modernized. Most important of all, the army's leaders sought to instill in the soldiers a new spirit rooted in inner conviction rather than unquestioning obedience. Defeat had changed Prussia from a garrison state into a centre of political and intellectual ferment.

The Prussian reformers: Stein and Hardenberg

Liberalism and nationalism became increasingly vehement in Germany as the burden of French domination grew progressively heavier. The financial sacrifices occasioned by the subordination to Napoleon reinforced the personal resentments aroused by his ruthless statecraft. Before long a network of secret organizations had sprung up in central Europe seeking the expulsion of the foreign invaders. Yet it would be a mistake to think that all Germans regarded the hegemony of France as an unmitigated evil. There were in fact wide differences of opinion among them. The rulers of the secondary states and their supporters in the army and the bureaucracy saw in Napoleon the instrumentality of their new importance. Many reformers in the south—the Bavarian statesman Maximilian von Montgelas, for example—believed that only French influence had made possible the modernization of government in Germany. Some publicists continued to argue, moreover, that the political disunity of central Europe was a natural result of its historic experience and reflected its essential character. To be sure, those who opposed alien domination outnumbered those who accepted it. But even among the former there was no agreement regarding the future political structure of the nation. Many of them dreamed of a liberal and united fatherland that would take its place among the great powers of Europe. Others were willing to settle for a loose association of governments, similar to the Confederation of the Rhine, which could safeguard the interests of the secondary states against Prussia and Austria. Still others hoped for a complete restoration of the old order in which they had grown up and to which they longed to return. And then there were the broad masses of the population of central Europe, exploited, illiterate, and uninformed. They remained by and large indifferent to the crosscurrents of political thought, seeking nothing more than an improvement in their standard of living and the preservation of their way of life. Germany was beginning to move toward new norms of civic and social value, but the transformation of political attitudes was gradual and intermittent.

The defeat of Austria

That the growth of the ideals of unity and freedom was slow became apparent during the first serious effort to throw off the yoke of foreign domination in central Europe. The Austrian government concluded in 1809 that the reverses that Napoleon had been encountering in Spain presaged a general uprising against the French hegemony on the Continent. The result was an ill-fated attempt at a war of liberation, in which the Habsburg troops challenged Napoleon for the fourth time, only to go down in defeat once again. Appeals from Vienna to the people of Germany found little response except in the Tirol and among a few nationalist hotspurs in the north. The princes refused to risk French wrath until they could be sure of ultimate victory, while their subjects refused to rise against French oppression without princely approval. The result was that the war in central Europe, unlike the one in the Iberian Peninsula, was waged primarily by regular forces rather than by guerrilla bands. Archduke Charles gained important successes for the Austrian Army at Aspern and Essling (May 21–22, 1809), an indication that the strategic mastery of the French was drawing to a close. But at Wagram (July 5–6) Napoleon was able to work the last of his military miracles. Vienna had to sue for peace once more, the Treaty of Schönbrunn (October 14) ceding Salzburg to Bavaria, West Galicia to the Grand Duchy of Warsaw, and the Adriatic coastland to France. The defeat finally persuaded the Emperor, who had exchanged the title Francis II of the Holy Roman Empire for Francis I of the Austrian Empire, that resistance would be as futile in the future as it had been in the past. He therefore adopted a policy of collaboration with France signallized by the marriage of his daughter Marie-Louise to Napoleon. Germany continued to languish in the grip of foreign domination.

The wars of liberation. A new struggle for liberation opened three years later with the defeat of Napoleon's *grande armée* in Russia. As the tsarist armies began to cross their western frontiers in December 1812, the crucial question became what reception they would find among the rulers and the inhabitants of central Europe. The first state to cut its ties to Paris was Prussia. It was not the King, however, but one of his generals, Ludwig Yorck von Wartenburg, who decided on his own initiative to cooperate with the Russians. Only hesitatingly and fearfully did Frederick William III then agree in February 1813 to a war against France, although public opinion in his kingdom greeted the outbreak of the conflict with enthusiasm. The other rulers of central Europe refused initially to follow the Prussian example. The members of the Confederation of the Rhine were still convinced of Napoleon's invincibility, while Austria pre-

ferred to see the combatants exhaust each other to the point at which it could play the role of mediator and arbiter. The foreign minister in Vienna, Clemens Lothar von Metternich, was afraid that the hegemony of France in central Europe might be replaced by that of Russia. He tried, therefore, to pursue a strategy of armed neutrality, hoping that he could persuade the opposing sides to accept a compromise by which an equilibrium would be maintained between Alexander I and Napoleon. This plan failed because of the obstinacy of the latter, who feared that concessions in foreign affairs would weaken his control over internal politics in France. The upshot was that in August 1813 Austria entered the conflict on the side of Russia and Prussia, and the balance of military power shifted in favour of the anti-French coalition. The faith of the secondary states in Napoleon's star began to weaken and Bavaria became the first member to secede from the Confederation of the Rhine (October 8). One great allied victory would now suffice to bring all of Germany into the struggle against France.

The anti-French alliance of Russia, Prussia, and Austria

That victory came on October 16–19, 1813, at the Battle of Leipzig. After four days of bitter fighting the French Army was forced to retreat, and its domination of central Europe was finally at an end. Before the year was out, Napoleon had withdrawn across the Rhine. Of all his conquests in Germany, only the left bank was still under the effective control of Paris. The Confederation of the Rhine promptly collapsed, as its members rushed to go over to the winning side before it was too late. The Rhineland was also reconquered early in 1814, after the allies had launched their invasion of France. In the course of the spring the capture of Paris, the restoration of the Bourbons, and the conclusion of peace in the first Treaty of Paris (May 30) ended the war of liberation except for the episode of the Hundred Days, when Napoleon briefly returned to power and was ultimately and finally beaten at Waterloo. The western frontier of central Europe was to remain essentially the same as at the time of the initial outbreak of hostilities more than 20 years before. New state boundaries within Germany would still have to be determined, to be sure, and the problem of a new political organization of the nation awaited the victorious statesmen. But the period of foreign hegemony was over at last. The rulers of central Europe, relying partly on the forces of innovation, partly on those of tradition, had succeeded in freeing themselves from alien domination. Now they had to decide what use they would make of their freedom. Would they create a new polity of unity and liberty, which many reformers demanded, or would they re-establish the old order of absolutism and particularism, which the conservatives advocated? As the statesmen began to gather in Vienna in the fall of 1814 to restore peace to a continent ravaged by two decades of war, they pondered the problem of devising an enduring form of government for Germany.

Results of the Congress of Vienna. The men who, in the course of the nine months from September 1814 to June 1815, redrew the map of Europe were diplomats of the old school. Francis I and Prince Metternich of Austria, Frederick William III and Prince Hardenberg of Prussia, Alexander I of Russia, Viscount Castlereagh of England, Prince Talleyrand of France, and the representatives of the secondary states were all intellectual heirs of the 18th century. They feared the principles of the French Revolution, they scorned the theories of democratic government, and they opposed the doctrines of national self-determination. But they also recognized that the boundaries and governments of 1789 could not be restored without modification or compromise. There had been too many changes in attitudes and loyalties that the rigid dogmas of legitimism were powerless to undo. The task before the peacemakers was thus the establishment of a sound balance between necessary reform and valid tradition capable of preserving the tranquillity that the Continent desperately needed. The decisions regarding Germany reached during the deliberations in Vienna followed a middle course between innovation and reaction, avoiding extreme fragmentation as well as rigid centralization. The Confederation of the Rhine was not maintained, but neither was the Holy Roman Empire restored. Although the reforms introduced during the period of foreign domination were partly revoked, the practices of enlightened despotism were not entirely re-established. Despite the bitter complaints of unbending legitimists and the dire predictions of disappointed reformers, the peacemakers succeeded in creating a new political order in central Europe that endured for half a century. The long years of war and unrest that had convulsed the Continent during the era of the French Revolution and Napoleon were followed by even longer years of stability and tranquillity.

The German Confederation, 1815.

The Germany that emerged in 1815 from the Congress of Vienna included 39 states ranging in size from the two great powers, Austria and Prussia, through the minor kingdoms Bavaria, Württemberg, Saxony, and Hanover; through smaller duchies such as Baden, Nassau, Oldenburg, and Hesse-Darmstadt; through tiny principalities such as Schaumburg-Lippe, Schwarzburg-Sondershausen, and Reuss-Schleiz-Gera; to the free cities Hamburg, Bremen, Lübeck, and Frankfurt am Main. The new boundaries in central Europe bore little resemblance to the bewildering territorial mosaic that had been maintained under the Holy Roman Empire, but there were still many fragments, subdivisions, enclaves, and exclaves, too many for the taste of ardent nationalists. Yet the overall pattern of state frontiers represented a significant improvement over the chaotic patchwork of sovereignties and jurisdictions that had characterized the old order. The peacemakers not only created more integrated and viable political entities but also altered the role that these entities were to play in the affairs of the nation. Without design or even awareness on the part of Frederick William III, his kingdom of Prussia assumed a pivotal position in Germany. The victorious powers, on guard against a revival of French aggression, decided to make Berlin the defender of the western boundary of central Europe. The Rhineland and Westphalia, a region destined to develop into the greatest industrial centre on the Continent, became Hohenzollern provinces. More than that, the King agreed at the urging of Alexander I to cede the bulk of his Polish possessions to Russia in return for a substantial part of Saxony. Prussia, which at the end of the 18th century had

The new Germany of 39 states

Germanic Prussia and the polyglot Austrian Empire

been in the process of becoming a binational state, was thrust back into Germany and given a strategic position on both frontiers of the nation. The centre of gravity of Austria, on the other hand, shifted eastward. Francis I had decided to abandon the historic role of his state as protector of the Holy Roman Empire against the Bourbons for the sake of greater geographic compactness and military defensibility. The possessions in southern and western Germany were surrendered along with the Austrian Netherlands in return for Venetian territory on the Adriatic. The Habsburg empire thus became less German in composition and outlook, as its focus shifted in the direction of Italy and the Balkans. The consequences of this territorial rearrangement were to be far-reaching.

THE AGE OF METTERNICH AND THE ERA OF UNIFICATION: 1815–71

Reform and reaction. In place of the Holy Roman Empire the peacemakers of the Congress of Vienna had established a new organization of states of central Europe, the German Confederation. This was a loose political association in which most of the rights of sovereignty remained in the hands of the member governments. There was no central executive or judiciary, only a federal Diet meeting in Frankfurt am Main to consider common legislation. The delegates who participated in its deliberations were representatives appointed by and responsible to the rulers whom they served. The confederation was in theory empowered to adopt measures strengthening the political and economic bonds of the nation. In fact it remained a stronghold of particularism, unwilling to sacrifice local autonomy in order to establish centralized authority. It was designed essentially to defend the interests of the secondary states and the Habsburgs. The former, jealously guarding the independence and importance they had gained during the period of French hegemony, were opposed to any reform that might limit their sovereignty. The latter believed that only a decentralized form of political union in Germany would give them enough freedom of action to pursue their non-German objectives. The confederation was thus from the outset an ally of localism and traditionalism. To the nationalists, whose hopes had risen so high during the war of liberation, it seemed to be an instrument of blind reaction. Yet the truth is that the confederal system established in 1815 accurately reflected the slow development of civic consciousness and economic integration in central Europe. The militant reformers who demanded the centralization of government were a vocal but small minority. The lower classes accepted the territorial and constitutional decisions of the Congress of Vienna without a murmur of protest. The weakness of the peace settlement was not its failure to embody present realities but its inability to adjust to future changes. What had been a reasonable adaptation to the political needs of an agrarian and rural society became a hopeless anachronism 50 years later in the age of factories and railroads. This was the fatal flaw in the German Confederation.

Yet the reform movement that had begun under the impact of the French hegemony did not end with the downfall of Napoleon. It continued to exert influence over affairs of state for another few years, before the forces of authoritarianism and particularism crushed it. That influence was strongest in southern Germany, where the political example of western Europe had made the deepest impression. There, many civil servants, court officials, army officers, and even aristocratic landowners came to believe that the future of the state depended on its readiness to reform civic institutions in accordance with liberal theories. In the years following Waterloo one government in the south after another promulgated a constitution, Bavaria and Baden in 1818, Württemberg in 1819, and Hesse-Darmstadt in 1820. These constitutions established representative assemblies, elected by the propertied citizens, whose assent was required for the enactment of legislation. Their purpose was not only to win for the crown the support of the educated classes of society but also to engender a sense of unity in a heterogeneous population that still had diverse allegiances and traditions. To the north there were also persistent echoes of the reform movement.

The followers of Karl vom Stein were still influential in the councils of state, and Frederick William III of Prussia at first seriously considered ways of fulfilling the promise he had made in 1815 to establish constitutional government. The agitation for political reorganization was loudest, however, among university students, who formed patriotic groups known as *Burschenschaften*. They demanded the abandonment of the confederal system, the establishment of greater unity, and the achievement of national power. Gathering in 1817 at the Wartburg, a castle near Eisenach, they listened to veiled denunciations of the existing order and consigned to flames various symbols of traditional authority. The rulers of Germany began to stir uneasily at this bold display of defiance of legitimate government.

The chief strategist of the forces hostile to reform was Metternich. Not only did he reject the teachings of liberalism and nationalism in principle, but, as the leading statesman of the Habsburg empire, he recognized that the establishment of centralized authority in Germany would seriously impede the policies his government was pursuing in Hungary, Italy, and the Balkans. When on March 23, 1819, an unbalanced student, Karl Ludwig Sand, assassinated the conservative playwright and publicist August von Kotzebue, Vienna persuaded the princes of the German Confederation that they were facing a dangerous attempt to overthrow the established order in central Europe. The result was a series of repressive measures called the Carlsbad Decrees, which the federal Diet adopted on September 20, 1819. General censorship was introduced, and the *Burschenschaften* were outlawed. This first major success of the conservative counteroffensive had an important effect on the struggle within the state governments between the advocates and the opponents of reform. In Prussia, the liberal members of the ministry were forced to resign, and the plan to promulgate a constitution for the kingdom was rejected. This shift to the right by Berlin encouraged authoritarian tendencies among the secondary states of the north, which soon abandoned their own constitutional projects. By the end of 1820 the reform movement, which had begun some 15 years before, came to a complete halt. It had succeeded in altering the political and economic structure of society, but it had been unable to establish a tradition of liberal government and national loyalty in central Europe. The forces of particularism and legitimism, deriving their chief support from the landowning nobility and the conservative peasantry, remained strong. The foundation of bourgeois civic consciousness and material prosperity on which England and France had built their representative institutions was still lacking beyond the Rhine. The ideal of free government was introduced in Germany not as the fruit of an industrial or a political revolution but as the imitation of a foreign example and the reaction against a foreign oppression.

Repression and the Carlsbad Decrees

The established order was once again threatened briefly in the wake of the July days of 1830 in France. The news that there had been a successful insurrection against the Bourbons in Paris had an electrifying effect throughout the Continent. In central Europe there were sympathetic uprisings in some of the secondary states of the north. The rulers of Brunswick, Saxony, Hanover, and Hesse-Kassel, seeking to forestall more extreme demands, agreed to promulgate liberal constitutions. A mass meeting of southern radicals at Hambach Castle in the Palatinate (May 1832), moreover, expressed its approval of national unification, republican government, and popular sovereignty. A group of militant students even launched a foolhardy attempt to seize the city of Frankfurt am Main, dissolve the federal Diet, and proclaim a German republic. The effect of such harebrained schemes was predictable. As the princes of the German Confederation gradually recovered from their initial fear of the revolutionary movement, they began to oppose with increasing vigour plans to alter the existing system of government. Again, Metternich took the lead in the effort to crush liberalism and nationalism. Under his direction the fed-

Effects of the July Revolution of 1830

eral Diet adopted additional repressive measures reinforcing the position of the crown in state politics, limiting the power of the legislature, restricting the right of assembly, enlarging the authority of the police, and intensifying the censorship. Within a few years the opposition had been subdued, and the German Confederation could continue to vegetate in its cozy provincialism. Not until the middle years of the century did a new and more violent outburst of political disaffection shake the foundations of the system of authority that the Congress of Vienna had erected.

Evolution of parties and ideologies. Although the critics of the established order could be defeated, they could not be silenced. The struggle between the supporters and the adversaries of the existing form of government led to the emergence of a rudimentary party system in the German Confederation. In the legislative assemblies of the secondary states the proponents of reform began to meet, plan, organize, and propagandize. The defenders of legitimism were thereby forced in turn to concert their strategy and to publicize their program. Even in Prussia and Austria, where there were as yet no constitutions or parliaments, political criticism could be expressed obliquely through clubs, meetings, newspapers, pamphlets, and petitions. The result was the gradual development of amorphous civic associations held together by common convictions regarding the nature of state and society. These primitive groupings were only the raw material out of which disciplined political parties were slowly fashioned in the course of the century. They still lacked a clear sense of purpose and the systematic propagation of belief characteristic of a fully mature system of parliamentary politics. Yet they became the instrumentalities by which disaffected groups in the community could express their opposition to the established order. They reflected the fact that the civic attitudes of the period of the Restoration were no longer those of the age of enlightened despotism. There were men in central Europe now who refused to submit without question to princely authority, seeking freedom only in the inner recesses of the soul. The change in the form of economy and the structure of society produced by the beginnings of industrialization led to an alternation in the system and organization of politics.

The liberals and moderates

The most important opponents of legitimism and particularism were the liberals and moderates. Deriving their support primarily from industrialists, merchants, financiers, mineowners, railroad promoters, civil servants, and university professors, they represented the opposition of the well-to-do bourgeoisie to a form of government in which an aristocracy of birth rather than of talent predominated. Their political principles favoured a monarchical system of authority, but the crown was to share its powers with a parliament elected by the propertied classes. Influence in public affairs should be accessible to all citizens who had demonstrated through the acquisition of wealth and education that they were capable of exercising the franchise intelligently. While the liberals resented the inherited privileges of the nobility, they also feared the wild passions of the proletariat. The man who lived in poverty and ignorance, they reasoned, was ripe for demagoguery and insurrection. The path of civic wisdom was therefore the *juste-milieu* between royal absolutism and mob rule, which had been established in England by the Reform Bill of 1832 and in France by the regime of Louis-Philippe. In economics, the teachings of liberalism advocated a policy of unrestrained competition by which wealth would become the reward of business acumen rather than the perquisite of corporative privilege. Guild monopolies, government regulations, and entailed estates were to be abolished as violations of that freedom of enterprise that alone could ensure the well-being of all society. As for the problem of unification, the liberals favoured the transformation of the German Confederation into a national monarchy in which the states' rights would be curtailed but not destroyed by a central government and a federal parliament.

Farther to the left stood the democrats or radicals, whose following was made up largely of small businessmen, petty shopkeepers, skilled workers, independent farmers, publicists, journalists, lawyers, and physicians. They looked with scorn on the golden mean between autocracy and anarchy that the liberals were seeking. They preferred an egalitarian form of authority in which not parliamentary plutocracy but popular sovereignty would be the underlying principle of government. Their supporters drew inspiration from the French rather than the English or the American Revolution. Their ideal of petty bourgeois democracy was the Jacobin republic of 1793 as an instrument to shape the energies and aspirations of the people into a disciplined force for political and social reform. The spokesmen of this ideal could not openly demand the overthrow of monarchical institutions without risking imprisonment. Yet while they were forced to accept the crown as a political institution, they sought to transfer its power to a parliament elected by equal manhood suffrage. The masses would thereby become the ultimate arbiter of politics. The democrats were also willing to accept government regulation of business activity as a means of improving the economic position of the lower classes, although their belief in the sanctity of private property was as firm as that of the liberals. In their advocacy of national unification, however, they were less solicitous about royal prerogatives and state rights. While not as numerous as the moderates, the radicals remained an important source of opposition to the established order.

The democrats and radicals

The growth of criticism directed against the political system of the Restoration forced its supporters to define their ideological position with greater precision. The old theories of monarchy by divine right or despotic benevolence offered little protection against the assaults of liberalism and democracy. Legitimism, whose defenders came mostly from the landed nobility, the court aristocracy, the officer corps, the upper bureaucracy, and the established church, began therefore to advance new arguments based on conservative assumptions regarding the nature of man and society. The relationship between the individual and his government, so the reasoning went, cannot be determined by paper constitutions founded on a doctrinaire individualism. Human actions are not motivated solely by rational considerations, but by habit, feeling, instinct, and tradition as well. The impractical theories of visionary reformers fail to take into account the historic forces of organic development by which the past and the present shape the future. To assert that all men are equal is to ignore differences in rights and duties expressing differences in birth, class, background, education, and tradition. The dogmas of constitutional authority and parliamentary government are merely a facade behind which a self-seeking bourgeoisie seeks to disguise its lust for power. An enduring form of government can be built only on the traditional institutions of society that men have learned in the course of time to accept: the throne, the church, the nobility, and the army. Only a system of authority legitimated by law and history can protect the worker against exploitation, the believer against godlessness, and the citizen against revolution. According to these tenets, the political institutions of the German Confederation were valid, because they represented fundamental convictions deeply embedded in the spirit of the nation.

The conservatives or legitimists

Economic changes and the Zollverein. The struggle of parties and ideologies during the Restoration reflected far-reaching changes in the structure of the economy and the community. The most significant of these changes was the rise of large-scale industry in central Europe. Techniques of mechanization, introduced in textile mills and coal mines, spread to other branches of manufacture and exerted pressures that influenced the entire economic life of the nation. The transportation network improved with the construction of railroads, steamships, bigger highways, and better canals. Banking institutions and private investors began to transfer their funds from government bonds and commercial ventures to manufacturing enterprises. Millowners, ironmasters, railroaders, financiers, and stockbrokers gradually formed a new middle class whose wealth was derived primarily from

The growth of large-scale industry

industrial activity and whose growing economic importance encouraged among its members a demand for greater political influence. Skilled handicraftsmen, constituting the bulk of the urban working class, could not compete successfully with the factories. The conflict between industrial and pre-industrial forms of output was aggravated, moreover, by important demographic changes in the period following the Congress of Vienna. Population began to shift from country to city, although a majority of the inhabitants of the German Confederation continued to live in rural communities.

The reorganization of agriculture

Agriculture also went through as difficult a period of reorganization and rationalization as industry. The end of serfdom had led in the regions east of the Elbe to the establishment of large estates belonging to aristocratic landowners but cultivated by a propertyless rural proletariat. Peasant emancipation in Prussia allowed the Junkers to enlarge their lands by absorbing the holdings of small farmers. The result was the continuing economic, social, and political domination of the village by the nobility in the eastern provinces of the Hohenzollern kingdom. The squirearchy entrenched in Pomerania, Brandenburg, Silesia, and East Prussia controlled agriculture, commanded the army, directed the bureaucracy, and influenced the court. It constituted a powerful force for conservatism and particularism.

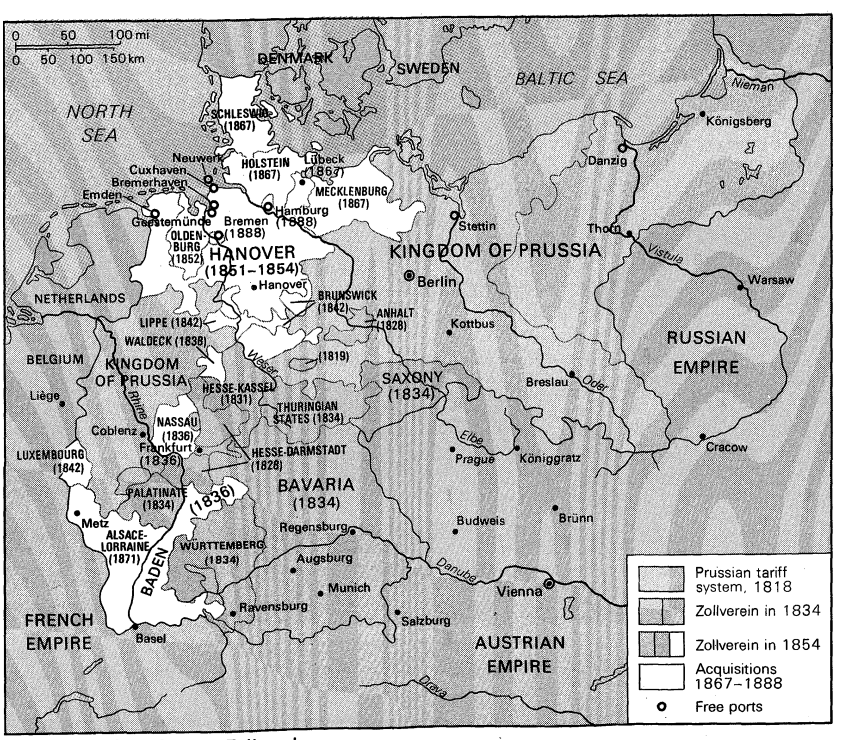
West of the Elbe the basic problem was not landlessness but overpopulation. The aristocracy along the Rhine and the Danube was often willing to give the peasantry possession of the soil in return for a substantial payment. The farmer was thereby saddled with heavy financial obligations. Many rustics tried to escape poverty by emigrating to the New World; those who remained faced swift demographic expansion and often had to subdivide small holdings until they yielded no profit. Civil discontent mounted among impoverished villagers who lacked employment in industry.

The system of authority in the German Confederation was thus being undermined by the struggle of artisans against industrial mechanization, by the disaffection of peasants hungry for land, and above all by the criticism of businessmen groaning under the shackles of particularism. Industrialists and financiers had to overcome the barriers created by a variety of monetary systems, commercial regulations, excise taxes, and state boundaries. It is little wonder that the bourgeoisie of central Europe turned increasingly to the teachings of liberalism and nationalism. Yet the established order did make a major attempt to meet the needs of the business community. Before long, several of the more important secondary governments also concluded agreements with Berlin by which a sizable free-trade area was established in the heart of central Europe.

The Zollverein

In 1834 the Zollverein, or "customs union," including most of the states of the German Confederation, came into existence. Only Austria and the northwest coastland remained aloof. The industrialists of the Habsburg empire, who wanted their products protected against outside competition, felt that the tariff rates of the new association were too low for their needs; whereas the merchants and bankers of the coastal region, who depended on imports, thought that they were too high. Yet for some 25,000,000 Germans the Zollverein meant in effect the achievement of commercial unification without the aid of political unification. The Prussian government, moreover, acquired a powerful new weapon in the struggle against Austria for the dominant position in central Europe. Still, although the customs union helped meet the most pressing demands of the middle class for economic consolidation, it could not surmount all the material disadvantages of a particularistic form of government. Men of means and education continued to grumble about the confederal system under which they lived, while the masses became increasingly restless under the pressure of social dislocation.

The revolutions of 1848–49. The hard times that swept over the Continent in the late 1840s transformed widespread popular discontent in the German Confederation into a full-blown revolution. After the middle of the decade a severe business depression halted industrial expansion and aggravated urban unemployment. At the same time, serious crop failures led to a major famine in the entire area from the Irish Sea to Russian Poland. In central Europe the hungry '40s drove the lower classes, which had long been suffering from the economic effects of industrial and agricultural rationalization, to the point of open rebellion. There were sporadic hunger riots and violent disturbances in several of the states, but the signal for a concerted uprising did not come until early in 1848 with the exciting news that the regime of the bourgeois king Louis-Philippe had been overthrown by an insurrection in Paris (February 22–24). The result was



The growth of the German Zollverein.

a series of sympathetic revolutions against the governments of the German Confederation, most of them mild but a few, as in the case of the fighting in Berlin, bitter and bloody. When on March 13 Metternich, the proud symbol of the established order, was forced to resign his position in the Austrian cabinet, the princes hastened to make peace with the opposition in order to forestall republican and socialistic experiments like those in France. Prominent liberals were appointed to the state ministries, and civic reforms were introduced safeguarding the rights of the citizen and the powers of the legislature. But even more important was the attempt to achieve political unification through a national assembly representing all of Germany. Elections were held soon after the spring uprising had subsided, and on May 18 the Frankfurt National Assembly met to prepare the constitution for a free and united fatherland. Its convocation represented the realization of the hopes that nationalists had cherished for more than a generation. Within the space of a few weeks, those who had fought against the particularistic system of the Restoration for so long suddenly found themselves in power with a popular mandate to rebuild the foundations of political and social life in central Europe. It was an intoxicating moment.

The Frankfurt National Assembly

The forces that had defeated the establishment order, however, soon discovered that they were in disagreement regarding the use to be made of their common victory. There were, first of all, sharp differences between the liberals and the democrats. While the former had comfortable majorities in most of the state legislatures as well as in the Frankfurt parliament, the latter continued to plead, agitate, and conspire for a more radical course of action. There were also bitter disputes over the form that national unification should assume. The Grossdeutsch (Great German) movement maintained that only Austria, the state whose rulers had worn the crown of the Holy Roman Empire for 400 years, could successfully guide the united fatherland. The Kleindeutsch (Little German) party, on the other hand, argued that the Habsburgs had too many Slavic, Magyar, and Italian interests to work single-mindedly for the greatness of Germany. The natural leader of the nation was Prussia, whose political vigour and geographic position would provide efficient government and military security for central Europe. Finally, there was a basic conflict between the proletariat, which wanted protection against mechanized production and rural impoverishment, and the bourgeoisie, which sought to use the political power it had gained in order to promote an industrial capitalism based on freedom of enterprise. Once the spring uprising was over, the parties and classes that had participated in it began to quarrel about the nature of the new order that was to take the place of the old. Popular support for the revolution, which had made the defeat of legitimism during the March days possible, began to dwindle, discouraged by the realization that the liberals would do no more to solve the problems of the masses than the conservatives had done. While the Frankfurt parliament was debating the constitution under which Germany would be governed, its following diminished and its authority declined. The forces of the right, recovering from the demoralization into which they had been plunged by the revolution, began to plan a counterrevolution.

Suppression of the revolutions

Their first major victory came in Austria, where the young emperor Francis Joseph found an able successor to Metternich in his prime minister Prince Felix zu Schwarzenberg. In the course of the summer of 1848 the Habsburg armies crushed the uprising in Bohemia and checked the insurrection in Italy. By the end of October they subjugated Vienna itself, the centre of the revolutionary movement, and now Hungary was still in arms against the imperial government. At the same time in Prussia, the irresolute Frederick William IV had been gradually persuaded by the conservatives to embark on a course of piecemeal reaction. Early in December he dissolved the constituent assembly that had been meeting in Berlin, promulgated by his own authority a middle-of-the-road constitution for the kingdom, and proceeded little by little to reassert the prerogatives of the crown. Among the secondary states there was also a noticeable shift to the right, as particularist princes and legitimist aristocrats began to regain their courage. By the time the Frankfurt parliament completed its deliberations in the spring of 1849, the revolution was everywhere at ebb tide. The constitution that the National Assembly had drafted provided for the creation of a federal union at the head of which was to stand a hereditary emperor with powers limited by a popularly elected legislature. Since the Austrian government had already indicated that it would oppose the establishment of a centralized system in Germany, the imperial crown was offered to the King of Prussia. Frederick William IV hesitated, brooded, and agonized, but in the end he refused the dignity whose authority was in his opinion too restricted. This rejection of political consolidation under a liberal constitution destroyed the last chance of the revolutionary movement for success. The moderates, admitting failure, went home to mourn the defeat of their hopes and labours. The radicals, on the other hand, sought to attain their objectives by inciting a new wave of insurrections. Their appeals for a mass uprising, however, were answered mostly by visionary intellectuals, enthusiastic students, radical politicians, and professional revolutionaries. The lower classes remained by and large indifferent. There was sporadic violence, especially in the southwest, but troops loyal to princely authority had little difficulty in defeating petty bourgeois democracy. By the summer of 1849 the revolution, which had begun a year earlier amid such extravagant expectations, was completely crushed.

The 1850s: years of political reaction and economic growth. The attempt to achieve national unification through liberal reform was followed by an attempt to achieve it through conservative statesmanship. Frederick William IV had refused to accept an imperial crown vitiated by parliamentary government, but he was willing to become the head of a national federation in which the royal prerogative remained unimpaired. While the Austrian armies were still engaged in the campaign against the revolution in Hungary, Berlin began to exert diplomatic pressure on the secondary governments to join in the formation of a new federal league known as the Prussian Union. If Frederick William IV had acted with enough determination, he might have been able to reach his goal before Francis Joseph could intervene effectively in the affairs of Germany. But he allowed his opportunity to slip away. Though he succeeded through threats and promises in persuading most of the princes to accept his proposals, no irrevocable commitments had been made by the time the Hungarians were defeated in August 1849. Vienna could now proceed to woo the secondary governments, which had in most cases submitted to Prussia only out of weakness and fear. Basically they remained opposed to sacrificing their sovereignty in order to exalt the Hohenzollern dynasty. When Schwarzenberg suggested the re-establishment of the old federal Diet, he won the support of many rulers who had agreed to follow Berlin against their will. The nation was now divided into two camps, the Prussian Union on one side and the revived German Confederation on the other. It was only a question of time before they would clash. When both Austria and Prussia decided to intervene in Hesse-Kassel, where there was a conflict between the supporters and the opponents of the prince, Germany stood on the brink of civil war. But Frederick William IV decided at the last moment to back down. His fear overcame his pride, especially after Nicholas I of Russia indicated that he supported Vienna in the controversy. By the Punctation of Olmütz of November 29, 1850, the Prussians agreed to the restoration of the German Confederation, and the old order was fully re-established in all its weakness and inadequacy.

Revival of the German Confederation

The years that followed were a period of unmitigated reaction. Those who had dared to defy royal authority were forced to pay the penalty of harassment, exile, imprisonment, or even death. Many of the political concessions made earlier, under the pressure of popular turmoil, were now restricted or abrogated. In Austria, for example, the constitution that had been promulgated

in 1849 was revoked, and legitimacy, centralization, and clericalism became the guiding principles of government. While in Prussia the constitution granted by the King remained in force, its effectiveness was reduced through the introduction of a complicated system of election by which the ballots were weighted in accordance with the income of the voters. The consequence was that well-to-do conservatives controlled the legislature. The secondary states returned to the policies of legitimism and particularism that they had pursued before the revolution. In Frankfurt am Main, where the federal Diet now resumed its sessions, diplomats continued to guard the prerogatives of princely authority and state sovereignty. The restoration of the confederal system also served the interests of the Habsburgs, who stood at the pinnacle of their prestige as the saviours of the established order. In Berlin, on the other hand, the prevailing mood was one of confusion and discouragement. The King, increasingly gloomy and withdrawn, came under the influence of ultraconservative advisers who preached legitimism in politics and orthodoxy in religion. The government, smarting under the humiliation suffered at the hands of Austria, was as timid in foreign as it was oppressive in domestic affairs. The people, tired of insurrection and cowed by repression, were politically apathetic. The German Confederation as a whole, rigid and unyielding, remained during these last years of its existence blind to the need for reform that the revolution had made clear.

Growth of industrial capitalism in central Europe in the 1850s

Yet the 1850s, so barren in politics, were of the highest importance in economics. For it was during this period that the great breakthrough of industrial capitalism occurred in central Europe. The national energies, frustrated in the effort to achieve civic reform, turned to the attainment of material progress. The victory of the reaction was followed by an economic expansion as the business community began to recover from its fear of mob violence and social upheaval. The influx of gold from America and Australia, moreover, generated an inflationary tendency, which in turn encouraged a speculative boom. Not only did the value of industrial production and foreign trade in the Zollverein more than double in the course of the decade, but new investment banks based on the joint-stock principle were founded to provide risk capital for factories and railroads. The bubble burst in 1857 in a financial crash that affected the entire Continent. For many investors the price of over-optimism and speculation turned out to be misfortune and bankruptcy. Yet Germany had now crossed the dividing line between a pre-industrial and an industrial form of economy. Although the rural population still outnumbered the urban, the tendency toward industrialization and urbanization had become irreversible. And this in turn had a profound effect on the direction of politics. For as wealth continued to shift from farming to manufacturing, from the country to the city, and from the aristocracy to the bourgeoisie, the pressure for a redistribution of political power also gained strength. While the reactionaries were solemnly proclaiming the sanctity of traditional institutions, economic change was undermining the foundation of those institutions. By the end of the decade a new struggle between the forces of liberalism and conservatism was in the making.

The 1860s and the triumphs of Bismarck. The revival of the movement for liberal reform and national unification at the end of the 1850s came to be known as the "new era." Its coming was heralded by scattered but distinct indications that the days of the reaction were numbered. In 1859 the defeat of Austria in the war against France and Piedmont had a profound effect on central Europe. For one thing, the maintenance of the authoritarian regime in Vienna depended on respect for its military strength. Now that the Habsburg armies had shown themselves to be vulnerable, popular unrest in the empire began to increase. Since autocracy was no longer an effective principle of government, Francis Joseph decided to experiment with a parliamentary form of authority. On October 20, 1860, he promulgated a constitution (the October Diploma) for his domains, setting up a bicameral legislature with an electoral system favouring the bourgeoisie; and Austria ceased to be an absolutist state. The achievement of political consolidation in Italy, moreover, aroused hope and envy north of the Alps. If the Italians could overcome the obstacles of conservatism and particularism, why not the Germans? National sentiment in central Europe, dormant since the revolution, suddenly awoke. Patriotic organizations like the Nationalverein (National Union) and the Reformverein (Reform Union) initiated an agitation for a new federal union, the former advocating Prussian, the latter Austrian, leadership. Liberal publicists and politicians began to advance plans for the reconstruction of the German Confederation. Some of the states, detecting a shift in the trend of public opinion, decided to change their course accordingly. Here and there the conservative ministers of the reaction were retired or dismissed, and their place was taken by statesmen with more moderate views.

The most significant portent of a new age in politics, however, appeared in Prussia. In 1857 Frederick William IV, crushed by memories of the mass insurrections and diplomatic defeats that he had been forced to endure, had suffered a mental breakdown. A year later his brother had become regent, and the government in Berlin immediately began altering the direction of its policy. Prince William, although a man of conservative inclination, had little sympathy with the mystical visions and pious dogmas prevailing at the court during the period of reaction. He dismissed the cabinet that had served his predecessor, announced a program of cautious reform in Prussian as well as German affairs, and won a popular endorsement of his course in the elections that gave the liberals control of the legislature. After a long period of discouragement, the advocates of civic reconstruction could once again look to the future with hope and expectation.

Yet there was an important difference between the political attitude of the liberals in 1858–59 from that of 1848–49. They came to feel during the new era that their defeat ten years before had been due to an excess of idealism and exuberance. The fatal mistake of the revolution, they reasoned, had been the assumption that enthusiasm and selflessness could be translated into power and substituted for statesmanship. Now a more calculating policy, a policy of *Realpolitik*, must be adopted. Not theory and rhetoric but negotiation and compromise would lead to the attainment of unity and freedom. The liberals therefore pursued at first a strategy of conciliation, anxious not to frighten the established order into blind resistance against all reform. In Prussia, for example, they waited patiently for the regent to move against the forces of disunity and oppression, confident that if they only gave him enough time he would obtain for them by royal authority what they could not seize through revolutionary violence. Yet it gradually became apparent that their hopes would not be realized. Prince William, who in 1861 became king in his own right, was a moderate conservative, but a conservative nevertheless. As the advocates of reform grew increasingly restless, the more militant among them formed the Progressive Party, which sought to hasten the introduction of liberal legislation by exerting pressure on the government. The monarch, afraid that he was being pushed farther to the left than he wanted to go, became more adamant and uncompromising. Sooner or later a conflict between crown and parliament was bound to arise.

The Prussian policy of *Realpolitik*

It came in connection with the question of army reform, although if that issue had not developed there would undoubtedly have been another. The King wanted to strengthen the armed forces by increasing the number of line regiments and decreasing the size of the popular militia. The legislature, reluctant to enhance the power of the conservative officer corps, demanded a modification of the plan. The King refused, convinced that the politicians were attempting to gain control of the army, which he considered subject only to royal authority. The legislature responded by withholding approval of the budget to pay for the cost of army reform. A complete deadlock ensued. In the spring of 1862 the liberal minis-

ters who had been appointed after the establishment of the regency were dismissed, and a conservative cabinet took office. But the new leaders of the government were as unsuccessful as the old in resolving the crisis. William I began to think about abdicating in favour of his son, who was believed to have political views close to those of the parliamentary opposition. He was persuaded, however, to consider first the possibility of naming a new ministry led by Otto von Bismarck, the Prussian ambassador to Paris. There was a momentous interview between the monarch and the envoy, as a result of which the former abandoned all thought of retirement, and the latter became head of a cabinet pledged to continue the struggle against the legislature. The battle between crown and parliament, which the liberals had been on the point of winning, was now to be waged without regard for constitutional provisions concerning the budget. On September 23, 1862, the nation was startled by the news that a statesman with a reputation for unyielding conservatism had become the prime minister of Prussia. It meant that the established order, having successfully defended its interests against the forces of reform after 1815 and after 1848, was determined to fight to the bitter end against the new challenge to its predominance.

Advent of Otto von Bismarck

The constitutional conflict in the Hohenzollern kingdom continued for another four years. The legislature refused to approve the budget until its wishes concerning military reform had been met. Bismarck's government, after carrying out the controversial reorganization of the army, continued to collect taxes and disburse funds without regard for parliamentary authorization. The liberals condemned the prime minister as a violator of the law, while the prime minister denounced the liberals as blindly doctrinaire. Although the electorate remained on the side of the opposition, the cabinet declared that it would not be swayed by party politics or parliamentary majorities. The broad masses of the population, it maintained, were still loyal to the crown. And so the struggle went on without prospect of alleviation or resolution. There were even dark prophecies of a violent uprising against a regime that was so indifferent to its constitutional obligations. Yet in fact Bismarck was not blind to the need for a reconciliation between crown and bourgeoisie. Despite his reputation as a fire-eating legitimist, he had a supple mind and recognized that the political principles of Frederick the Great could not solve the problems facing William I. He hoped, therefore, for an eventual reconciliation between the government and the legislature, but a reconciliation in which the prerogative of the monarch and the influence of the nobility would remain undiminished.

What Bismarck sought in essence was an alteration in the form of government that would create a facade of parliamentary institutions disguising the continuation of authoritarian policies. The middle class wanted to end the domination of the traditional forces in society, he calculated, but it also wanted to achieve national unification in central Europe. Here was the key to a solution of the constitutional conflict. Unity could be used to restrict freedom; nationalism could become the means of taming liberalism. Bismarck had concluded that the political integration of Germany was, in the long run, inevitable. If the established order did not effect it, the reformers, democrats, and revolutionaries would. Thus, it was in the interest of conservatism to take the task of centralization in hand, bring it to a successful conclusion, and create a new system of authority compatible with the preservation of royal and aristocratic preponderance. Such a policy would make possible a compromise between crown and bourgeoisie by which the latter obtained the benefits of economic consolidation, while the former retained the advantages of political domination. Through this strategy the prime minister hoped to end the constitutional conflict.

The defeat of Austria. The international situation was favourable to a program of unification in the German Confederation. Since its defeat in the Crimean War (1853–56), Russia had ceased to play a decisive role in the affairs of the Continent. England remained preoccupied with the problems of domestic reform. And Napoleon III was not unwilling to see a civil war east of the Rhine that he might eventually use to enlarge the boundaries of France. Bismarck could thus prepare for a struggle against Austria without the imminent danger of foreign intervention that had faced Frederick William IV. His first great opportunity came in connection with the duchies of Schleswig and Holstein, which were ruled by the king of Denmark but which were politically and ethnically tied to Germany. When the government in Copenhagen sought to make Schleswig an integral part of the Danish state in 1863, nationalist sentiment in central Europe was outraged. William I proposed to Francis Joseph that the two leading powers of the German Confederation should occupy the duchies in order to prevent the violation of an international agreement that had guaranteed their separate status. Afraid to let the Prussians act on their own, the Emperor agreed, and in 1864 there was a brief war against Denmark that demonstrated the strength of the reorganized army of the Hohenzollerns. Danish hopes for foreign assistance proved illusory, and by the Peace of Vienna (October 30) the duchies became the joint possession of Prussia and Austria.

The Danish War and the issue of Schleswig-Holstein

The easy victory of the allies, however, was only the prelude to a bitter conflict between them. Vienna would have liked to see Schleswig-Holstein become an independent secondary state in the German Confederation, committed to a policy of particularism. Berlin, on the other hand, hoped for the outright annexation of the duchies or at least the indirect control of their government. Even more important than the disposition of the spoils of war, however, was the mounting rivalry between the two great powers for hegemony in central Europe. Bismarck would probably have been willing to collaborate with Austria in the division of Germany into two spheres of influence, a northern under the Hohenzollerns and a southern under the Habsburgs. But Francis Joseph was reluctant to restrict his authority and ambition to the region below the Main River. The result was a steady deterioration of relations between Vienna and Berlin. In 1865 their differences were papered over by the Convention of Gastein, which placed Schleswig under Prussian and Holstein under Austrian administration, but which also reaffirmed the joint sovereignty of the two governments over the duchies. Still, this was only a temporary solution, and before long the danger of civil war in the German Confederation began to grow once again.

In the course of the spring of 1866 both sides stepped up their preparations for a military solution to the Austro-Prussian dualism. Bismarck concluded an alliance with Italy by which the latter was to receive Venetia as a reward for participating in a war against the Habsburg empire. He also sought to gain the support of public opinion in the German Confederation by introducing a motion in the federal Diet for the convocation of a national parliament elected by equal manhood suffrage. The Austrians in the meantime secured a promise of French neutrality in the event of hostilities and tried to win the adherence of the secondary states in the impending struggle. The last desperate attempts to preserve peace collapsed in June. Vienna announced that it would submit the question of the duchies to the federal Diet. Berlin, condemning this step as a violation of the Convention of Gastein, ordered its troops in Schleswig to expel the Austrians from Holstein. Francis Joseph in reply called on the other states of the confederation to mobilize their armies against the Prussian threat to domestic tranquillity, and central Europe trembled on the verge of civil war. The only question now was what the position of the secondary states would be. Most of them lined up behind Austria, which they regarded as the defender of their independence against the ambitions of Berlin. Bismarck's attempt to enlist the aid of the national movement by advocating reform of the confederal system thus failed. It alarmed the particularists without propitiating the centralists. Public opinion remained frightened and confused, distrusting one side and fearing the other. The future of the nation was decided not by popular insurrec-

Prussia's defeat of Austria in the Seven Weeks' War

tions or parliamentary deliberations but by the force of arms.

The Seven Weeks' War between Prussia and Austria (June–August) produced a diplomatic revolution in Europe, destroying the balance of power that had been established 50 years before by the Congress of Vienna. Yet this momentous alteration in the international equilibrium was accomplished so swiftly that foreign diplomats had barely begun to grasp its implications before the struggle for hegemony in Germany ended. The Hohenzollern armies had a brilliant strategist in Helmuth von Moltke and a deadly weapon in the breech-loading needle gun. The Austrian high command, on the other hand, became irresolute and demoralized before a decisive encounter had even taken place. The Prussians succeeded in dividing and defeating the forces of the secondary states, and on July 3 they routed the Habsburg troops as well at the Battle of Sadowa (Königgrätz). The war was thus decided within a few weeks after its outbreak. Bismarck, refusing to be dazzled by the brilliance of the victory, urged the swift conclusion of an honourable peace. Not only did he feel that the preservation of a strong Austria was essential for the maintenance of stability on the Continent, but he feared that a prolongation of hostilities would enable Napoleon III to intervene in the affairs of Germany. By the preliminary Peace of Nikolsburg (July 26) and the definitive Treaty of Prague (August 23), Francis Joseph was permitted to retain all of his possessions except Venetia, which had been promised to the Italians. There was to be no occupation and only a modest indemnity. The Emperor had to acquiesce, however, in the Prussian annexation of Hanover, Nassau, Hesse-Kassel, Schleswig-Holstein, and Frankfurt am Main, in the dissolution of the German Confederation, and in the formation under Hohenzollern leadership of a new federal union north of the Main River. The contest between Berlin and Vienna that had determined the history of central Europe for more than a century was now over.

Bismarck's national policies: the restriction of liberalism. Bismarck's triumph in the military struggle led directly to his victory in the constitutional conflict. Before the outbreak of hostilities he had tried to reach an understanding with the liberal opposition, but the liberals hesitated to make peace with a statesman who had so flagrantly violated the fundamental law of the kingdom. The defeat of Austria changed all that. While the war was still in progress, general elections resulted in important gains for the right. Many voters, elated over the successes of the Prussian armies, expressed their confidence in the government by supporting its adherents at the polls. Some of the ultraconservatives hoped that the Cabinet would now capitalize on its triumph by suspending the constitution and establishing an authoritarian regime. Yet the prime minister recognized that such reactionary schemes would prove futile in the long run. What he wanted was not the suppression of liberalism but an accommodation with it. As soon as peace was concluded, he introduced in the legislature a bill of indemnity granting the government retroactive approval for its conduct of affairs of state without a legal budget. The consequence, as Bismarck had foreseen, was a split in the ranks of his adversaries. Those who argued that there could be no compromise with the principle of constitutional government rejected a reconciliation between crown and parliament based on mutual concessions. But many members of the opposition, who eventually formed the National Liberal Party, decided to accept the settlement offered by the prime minister. Their reasoning was that an obstinate resistance against the cabinet would only condemn them to sterile dogmatism, whereas a willingness to accept what could not be prevented would enable them to influence official policy in the direction of greater freedom. This view prevailed, and on September 3, 1866, the legislature approved the Bill of Indemnity, 230 to 75. By dividing the forces of reform and weakening their sense of purpose, Bismarck won as important a success in domestic affairs as the victory on the field of battle.

His subjugation of liberalism was made possible by the triumph of nationalism. It had long been the prime minister's belief that the achievement of unity could appease the demand for freedom. The success of the Prussian armies provided him with an opportunity to test this assumption. Once Austria had been subdued, he cajoled and bullied the secondary governments above the Main into joining Berlin in the establishment of the North German Confederation. It was the union of a giant and 21 pygmies, for the Hohenzollern kingdom comprised about four-fifths of the territory and population of the confederation. Executive authority was vested in a presidency held in accordance with hereditary right by the rulers of Prussia, who were to exercise the powers of their office with the assistance of a chancellor responsible only to them. The legislature was composed of a federal council or Bundesrat, whose members were appointed by the state governments, and a lower house or Reichstag, elected by equal manhood suffrage. Since Berlin had 17 votes in the Bundesrat out of 43, it could easily control the proceedings with the support of a few of its satellites among the small principalities. Although the Reichstag could theoretically exercise considerable influence over legislation by granting or withholding its approval, parliamentary authority and party initiative were weak and untested, and Bismarck had little difficulty in piecing together a workable majority for his program by a strategy of divide and rule. His support came largely from a combination of moderate liberals and moderate conservatives willing to sacrifice theory for expediency. The federal constitution provided no bill of rights, no ministerial responsibility, and no civilian supervision over military affairs. But it introduced uniformity in currency, weights, measures, commercial practices, industrial laws, and financial regulations. In short, it created the economic unity that the middle class had long demanded and that helped reconcile it to the defeat of its hopes for greater political freedom.

Establishment of the North German Confederation

Franco-Prussian conflict and the new German Reich. The Seven Weeks' War, by creating a powerful new state in the heart of central Europe, abruptly altered the system of international relations on the Continent. Every government now had to re-examine its diplomatic and military position in the light of the establishment of the North German Confederation. No nation, however, was affected by the victory of the Hohenzollern armies as directly as France. Emperor Napoleon III had encouraged the outbreak of hostilities between Austria and Prussia on the assumption that both combatants would emerge from the struggle exhausted and that the Second Empire of France could then expand eastward against little resistance. The outcome of the war revealed how shortsighted such calculations had been. Instead of profiting from the conflict between Francis Joseph and William I, Paris suddenly confronted a strong and united German state that presented a serious threat to French interests. The imperial government was bound to regard this turn of events with suspicion and hostility. It sought to mitigate its discomfiture by seeking compensation in the Rhineland, Luxembourg, or Belgium. But Berlin succeeded in frustrating these plans, and the conviction began to grow in France that sooner or later a struggle with Germany would be unavoidable. The prospect of a new armed conflict was not unwelcome to Bismarck. He wanted to see national unification consummated by the entry of the southern states into the North German Confederation. Yet public opinion below the Main remained distrustful. Only a common patriotic struggle against foreign aggression might overcome the reluctance of the south to unite politically with the north. Thus in Berlin as well as in Paris there were reasons for seeking a test of strength. The immediate occasion came in the spring of 1870 with the candidacy of Prince Leopold, a relative of William I, for the throne of Spain. The ensuing controversy was cleverly exploited by Bismarck to provoke the French into initiating hostilities which both sides had wanted but for which the French government received the blame.

When France learned of Leopold's acceptance of the offer of the Spanish crown, there were wild protests in Paris and an immediate demand that Leopold be ordered to

withdraw. On July 12 Leopold's father renounced the Spanish candidature on his behalf. This was not enough for the French government; it insisted that William I, as head of the Hohenzollern family, should promise that the candidature would never be renewed. This demand was presented to William at Ems by the French ambassador. Though William refused to give a promise, he dismissed the ambassador in a friendly enough way. But when the "Ems telegram," a report of what was happening, reached Bismarck, he shortened it for publication in such a way as to imply that William had refused to see the French ambassador again. The French used this as an excuse to declare war on Prussia on July 19.

Franco-German War

Bismarck's calculation that a struggle waged ostensibly against the expansionist designs of Napoleon III would overcome particularism below the Main proved correct. The southern states joined the north in the Franco-Prussian War, and the sense of unity engendered by the brotherhood of arms was soon enhanced by the intoxication of victory. The German troops won one battle after another in hard fighting along the frontier, until on September 1 they forced a large French Army, headed by the Emperor himself, to surrender at Sedan. The result was the establishment of a republican government in France, which continued to wage the struggle in the name of the old revolutionary ideals of 1793. But the generalship of Moltke was too much for the fierce determination of the new regime. Paris capitulated on January 28, 1871, after a long and bitter siege, and on May 10 the Treaty of Frankfurt brought the war officially to a close. The Third Republic had to cede Alsace-Lorraine, pay an indemnity of 5,000,000,000 francs, and accept an army of occupation. It was a Carthaginian peace designed to crush a dangerous rival. The work of national unification in Germany, in the meantime, was successfully completed even before hostilities had ended. Bismarck had entered into negotiations with the southern states soon after the outbreak of war, determined to use patriotic fervour as an instrument for achieving political consolidation. The enthusiasm aroused in central Europe by the victory over France proved too much for the defenders of particularism. On January 18, while Prussian guns bombarded Paris, William I was proclaimed emperor of a united nation at military headquarters in Versailles. The governments below the Main joined the North German Confederation to form a powerful new *Reich* under the Hohenzollerns. Within a single lifetime central Europe had completed the transition from cosmopolitanism to nationalism, from serfdom to industrialization, from division to union, from weakness to preponderance, from the Holy Roman Empire to the German Empire. (T.S.H.)

V. Germany from 1871

THE SECOND REICH, 1871–1918

Bismarck as imperial chancellor, 1871–90. *The making of the German Empire.* During the Franco-Prussian War, negotiations were pushed on for the uniting of all Germany outside Austria. Bismarck gave some political concessions to the southern German states, and eventually both Bavaria and Württemberg made separate treaties of union with Prussia. The princes were persuaded to offer the imperial crown to King William I of Prussia, and he was proclaimed German emperor on January 18, 1871. A Reichstag elected from all Germany accepted as the imperial constitution that of 1867, with certain minor concessions allowed to Bavaria. The new *Reich* consisted of four kingdoms, five grand duchies, 12 duchies and principalities, and three free cities (Hamburg, Lübeck, and Bremen). Alsace-Lorraine was treated as a conquered province, ruled by an imperial governor. The weakness of the constitution was its inadequate definition of the powers of the Reichstag over the executive. The chancellor was defined as "responsible," but it was not stated to whom; Bismarck contended that his responsibility was to the emperor, while the politicians asserted that it was to the Reichstag. The question of effective control of the army through authorization of expenditure was also not clear. Bismarck failed to get provision for a permanent grant to be written into the constitution and had to agree to a compromise, the Septennat, by which finance for the army was to be voted every seven years. As a result, artificial alarm had to be created every seven years in order to get the army grant renewed.

Bismarck's liberal period and the Kulturkampf. From 1871 to 1879, the National Liberals acted almost as a government party in the Reichstag, and their predominance made the first period of the empire an age of great liberal reform. Germany acquired a uniform legal procedure, uniform coinage, and uniform administration. An imperial bank was created, most restrictions on freedom of enterprise and of movement were removed, and limited companies and trade combinations were allowed. Freedom of the press was secured in 1874, and work was begun on an imperial civil code that was in universal operation by 1900. Particularly important was the establishment of municipal autonomy in 1873; towns were freed from control of the *Landrat* (usually a large landowner), and the way was clear for the development of local government, in which Germany led the world.

Distrust of political Roman Catholicism, which Bismarck shared with liberals, grew stronger in 1871 when a confessional party, the Centre, gained 58 seats in the Reichstag and drew support from all the elements that had opposed Bismarck's work. Believing that unity was more easily created when there was some object to attack, Bismarck vigorously denounced the party, and a dispute over the clerical control of education extended his policy into a general attack, known as the *Kulturkampf*, on the independence of the Roman Catholic Church. The recent defection of the so-called Old Catholics, who could not accept the doctrine of papal infallibility proclaimed in 1870, caused the church to seek to expel all Old Catholics from teaching positions. Bismarck in turn attacked the Catholic teaching orders, expelling the Jesuits and insisting that the state should train and license priests. Priests and bishops who would not conform were imprisoned, and sees were left vacant. These penal measures were expressed in the May Laws passed by the Prussian Landtag (state assembly) in 1873. But, by about 1875, it was clear that Bismarck would not achieve victory; the Old Catholics carried no weight, and even many Protestants disliked the attack on religious teaching.

The *Kulturkampf*

Bismarck's breach with the National Liberals. From 1877 fiscal, economic, and political factors turned Bismarck against the National Liberals. The question of raising money to meet deficits in the armed forces' budgets created dissension, the Liberals wanting it to be done by direct taxation that would be controlled by the Reichstag but Bismarck obtaining some grants of indirect taxes voted for an indefinite period. His attempt to silence the Liberals' opposition on this issue by offering to make their leader virtually his deputy was foiled. Soon afterward the breach was widened, when Bismarck introduced protectionist measures designed to safeguard German agriculture from the new competition provided by American wheat. Regarding agricultural workers as potentially good soldiers, Bismarck wished to keep German agriculture prosperous. He also took steps to protect the German iron and steel industry. The Liberals, traditionally supporters of free trade and laissez-faire policies, were further alienated. By 1879 Bismarck was ready to form an alliance with the Centre. Gradually he reversed the measures taken against the Catholic Church, in 1880 suspending the May Laws for individual cases and abolishing the secular examinations that had been required for candidates for the priesthood. By 1887, when peace was finally restored, the church had regained complete control of seminary education; in return, the Centre Party agreed to support all of Bismarck's nonreligious policies.

In the early 1870s, the Roman Catholic Church had been Bismarck's scapegoat; from the time of his alliance with the Centre, his attacks became directed against the Social Democrats, particularly after an attempted assassination of the Emperor in 1878. The Social Democratic Party was declared illegal, although its members still sat in the Reichstag; but the uproar produced a conservative majority in an election later in 1878, and in 1879 the Septennat was renewed almost without opposition.

Social security measures

During the early 1880s, Bismarck promoted measures of social security in order to attach the workers to the state. A Sickness Insurance Law was passed in 1883, a scheme of compulsory accident insurance in 1884, and old age pensions were also introduced.

Nevertheless, Bismarck's alliance with the Centre was never completely firm. At any time in the period from 1879 to 1890, they could have defeated him by alliance with the Radicals and the Social Democrats. So he continued to create artificial panics, in 1884 colonial disputes and in 1887 foreign dangers, in order to stampede the electorate to his support.

Bismarck's foreign policy, 1871–90. Once the empire was founded, Bismarck's sole aim was peace and security, pursued at first through neutrality and later through a complicated network of alliances. Resolutely impartial during the great Near Eastern crisis of 1875–78, when war nearly broke out between Great Britain and Russia, he decided thereafter to pursue a more active role, concluding, in 1879, a defensive alliance with Austria-Hungary. This, while guaranteeing Austria-Hungary's survival as a great power, specifically gave it no support for its Balkan ambitions. Russia, which might have been antagonized by the alliance, felt that there was now less danger of Austria working with Britain and was persuaded to renew (1881) the Dreikaiserbund, or League of the Three Emperors (of Russia, Austria-Hungary, and Germany), a vague alliance that Bismarck had first established in 1873. Bismarck also concluded (1882) the Triple Alliance of Germany, Austria, and Italy; Italy was guaranteed support against France in return for a promise of neutrality in the event of a war between Austria and Russia. A crisis in which Russo-Austrian rivalries were aroused over Bulgaria in 1885 caused Bismarck to strengthen his ties with both sides in order to maintain a balance between them. By the Reinsurance Treaty (1887) he promised Russia diplomatic support in the Near East and German neutrality in any Russian war except one with Austria; by promoting a Mediterranean naval agreement between Italy, Britain, and Austria, he established virtually the Triple Entente opposing Russia in the Near East. These apparently contradictory policies have caused Bismarck to be charged with duplicity; in fact, Germany's position in the centre of Europe necessitated a two-faced policy. On this occasion, at least, a Balkan war was averted.

Bismarck occasionally pursued other issues in order to satisfy the aspirations of German nationalism. Thus, between 1883 and 1885, he deliberately encouraged colonial rivalry with Great Britain; and, in the 1870s and again after 1886, he encouraged resentment against the Poles. In 1887, when a new army grant was needed, he raised the alarm that the French would try to regain Alsace-Lorraine. Although the Reichstag threw out his army bill, he was able in the subsequent general election to win sufficient support to get it passed (March 1887) in the new house.

The fall of Bismarck. Bismarck's position had always depended on the emperor's support; during the reigns of William I (died March 1888) and Frederick III (died June 1888) this was assured, but the position was entirely changed with the accession of William II. The new emperor had no reasons, as had his predecessors, for gratitude to Bismarck; moreover, he represented a new, self-confident Germany and was impatient with Bismarck's social conservatism, which seemed to prevent the emperor from establishing a demagogic relation with his subjects. Lacking imperial support, Bismarck's position became untenable after his political allies lost the general election of 1890. His attempt to engineer a strike of Prussian ministers failed, and he was forced to resign on March 18, 1890.

Accession of William II

Chancellors Caprivi and Hohenlohe, 1890–1900. The chancellorships of Leo, Graf von Caprivi (1890–94), and of Chlodwig Karl Victor, Fürst zu Hohenlohe-Schillingsfürst (1894–1900), represented, respectively, an official attempt at alliance with left-wing elements and a disillusioned return to conservatism. Caprivi's abandonment of old conservative policies was shown in every field. In foreign policy, he refused to renew the Reinsurance Treaty with Russia, thus breaking the traditional partnership between tsardom and the Prussian monarchy. He gave encouragement to Austrian ambitions in the Balkans and hoped to persuade Britain to join the Triple Alliance (of Germany, Austria-Hungary, and Italy). A step in this direction was the agreement (1890) by which Britain gave the North Sea island of Heligoland to Germany in return for colonial concessions in East Africa. At home, Caprivi promoted social security measures and wooed the parties of the left. But, like Bismarck, he was confronted with the perennial problem of achieving the passage of the Septennat. He eventually got the army grant passed in 1893, after having conceded that its renewal should in future occur every five instead of seven years. By representing Russia as the "enemy," he drew his support for the renewal from the left rather than the right. But the political manoeuvres involved split the German Radical Party, a serious event of decisive future importance.

Meanwhile, the Emperor had become disillusioned with Caprivi's social policies. Failure of the Chancellor's pro-British policy, occurring when a colonial dispute (1894) with the British caused them to repudiate their promises of support for Austria-Hungary, further weakened his position. A quarrel between Caprivi and the Prussian prime minister (Caprivi had given up the Prussian premiership in 1892, in order to appear less conservative) gave William II the opportunity to dismiss both ministers (October 1894).

Caprivi's successor, Hohenlohe-Schillingsfürst, an old man (75), was intended to revive the glories of the Bismarckian era without engendering its troubles. He got on well with the Conservatives and, as a former prime minister of Catholic Bavaria, was acceptable to the Centre Party and agreed to many of their confessional demands. Hohenlohe returned to a policy of alliance with Russia and refused to support Austria-Hungary in the Balkans. One of the most striking events of his chancellorship was the dispute with Britain over the Boer republics in South Africa, which culminated in the telegram sent (January 3, 1896) by the Emperor, congratulating Paul Kruger, president of the Transvaal, on the defeat of the British Jameson raid. The telegram did not affect British policy, but it had a lasting effect on German national sentiment, which, for the first time, came to regard Britain as Germany's principal rival in imperial greatness.

The Kruger telegram

Chancellorship of Bülow, 1900–09. Appointed secretary of state in June 1897, Bernhard, Fürst von Bülow, wielded the real political power in Germany during the last years when Hohenlohe was chancellor and succeeded him in that office in October 1900. He founded his power on the support of the Conservative Prussian landowners, bought, with the aid of the Prussian finance minister, Johannes von Miquel, by granting easy credit facilities and high tariffs to protect agricultural produce. Thus the landowners became economically dependent on the *Reich* as a whole, obliged to support Pan-German policies.

With this assurance behind him, Bülow launched on a policy of achieving grandeur abroad in order to stave off reform or conflict at home. The popular desire for imperial greatness was ripe for exploitation, and, indeed, the strength of Germany's iron and steel industry in the Ruhr had already made Germany Europe's greatest industrial power. At a time when Britain, France, and Russia appeared occupied with their own rivalries in Africa and in the Far East, it seemed desirable to Bülow to keep Germany free from involvements, apart from a protective relationship with Austria-Hungary. He rejected alliances offered by Britain in 1898 and 1901, but he retained a friendly relationship by participating in a hypothetical plan to carve up the Portuguese colonial empire and by maintaining official neutrality during the war between Britain and the Boers in South Africa.

A major cause of the decline in good relations with Britain was the rapid development of the German Navy as a result of the Navy laws of 1898 and 1900, promulgated by Alfred von Tirpitz, secretary for the navy from 1897 to 1916. The supporters of the project felt that a great navy was essential for a great power; moreover, its

construction would provide steady work for the iron and steel industry. The plans were grandiose in scale, and the Navy Law of 1900 laid down details of annual development up to the year 1917. The naval program had two main effects. First, by 1909, when parity with the Royal Navy was almost achieved, Britain became seriously alarmed; but, even had it been desired, it would have been difficult then to reverse such carefully laid plans. Second, the problem of paying for the navy caused serious splits between the Conservatives, who supported indirect taxation, and the Centre Party, which wanted direct taxation. The Centre was not successful, and the navy, in fact, was paid for largely by state borrowing, thus inaugurating the inflationary trends that later notably characterized German finance during World War I.

The policy of international detachment received a blow in 1902 when the Anglo-Japanese alliance and the subsequent Russo-Japanese War of 1904–05 enabled Britain to check the Russians in the Far East without becoming involved itself. Germany then began to seek to effect a continental bloc opposed to Britain; France, which in 1904 had concluded the entente with Britain, seemed to need coercion in order to join it. Germany's attempt at such coercion resulted in the first Moroccan Crisis.

William II landed at Tangier on March 31, 1905, and announced German support for Moroccan independence of France. The French sought to negotiate but, under the threat of war, gave in to Germany's demand that Théophile Delcassé, the foreign minister, resign. Germany's stand seemed quite justified, and Bülow was created a prince. But the sequel was less satisfactory. Britain rallied to France's support, and, at the Algeciras Conference (January–April 1906), Germany was obliged to acquiesce in the continuation of French influence in Morocco. The Tangier triumph had not appealed overmuch to the German public; and an important effect of the Algeciras reversal was the resignation from the German foreign ministry of the undersecretary Friedrich von Holstein, who had largely influenced policy since the 1870s.

A change in the political basis of Bülow's power occurred in 1906, when the Centre Party, on which, with the Conservatives, he had hitherto relied, withdrew its support when its ever increasing demands for concessions to the Catholic Church were resisted. The Centre members of the Reichstag voted against a resolution providing finance for the suppression of a native revolt in southwest Africa, and Bülow at once sought other political allies. He gained the support of a variety of non-Socialist left-wing parties, including the two branches of the old Radical Party. His allies won a handsome majority in the election of 1907 but were still not strong enough in the Reichstag to outvote Conservative opposition to the introduction of direct taxation. Nevertheless, his new alliances enabled Bülow to pose as a liberal statesman; and the zenith of this phase of his chancellorship was reached in October 1908 when, after an indiscreet and bombastic interview granted by William II to the English newspaper *The Daily Telegraph*, Bülow was able grandly to announce that in future the Emperor would "respect his constitutional obligations."

William II's *Daily Telegraph* interview

The logical consequence of the swing toward liberalism in home affairs should have been a rapprochement with Britain and an estrangement from Russia, as in the days of Caprivi. But Anglo-German relations worsened and reached a crisis in 1909 when Britain, in reply to Germany's expanded naval program, inaugurated a hasty increase in its naval building schedules. Bülow, however, did fall out with Russia when, in 1908, he supported Austria-Hungary's annexation of Bosnia-Hercegovina.

Bülow, like Bismarck, could survive in power only with imperial or adequate parliamentary support. The Conservatives resented his quarrel with Russia and resented still more a proposed introduction of death duties on landed estates. Tiring of their strange alliance with the left, they made common cause with the Centre Party, defeated the death-duties proposal by a narrow majority, and caused him to resign. The Emperor, bitterly inimical to him since the *Daily Telegraph* affair, accepted his resignation (July 1909). Bülow was the last effective chancellor of the Second Reich; his successors were mere administrators.

The prewar years, 1909–14. Theobald von Bethmann Hollweg, Bülow's successor as chancellor, was the first to be appointed to that office from the purely administrative grade of the civil service. Essentially a bureaucrat, he lacked the force to pursue any policies of his own and, although of high character, constantly gave in to the dubious counsels of Tirpitz, the Emperor, and the secretary of state, Alfred von Kiderlen-Wächter.

The second Moroccan Crisis, of 1911, was almost entirely Kiderlen-Wächter's responsibility. He believed that the recent French occupation of Rabat and Fez meant the end of Moroccan independence and decided to try to coerce France into making concessions to Germany. The gunboat "Panther" was sent to the port of Agadir, and Germany demanded part of the French Congo in return for alleged (but nonexistent) German "rights" in Morocco. On this occasion, German public opinion was more belligerent than the government had expected; Germany had to create an artificial war crisis but was outmanoeuvred by the British and French, acting in close cooperation. Although Germany acquired a portion of the Congo to add to its territory in the Cameroons, Bethmann and Kiderlen were furiously attacked in the Reichstag for their timidity.

This crisis had seriously aggravated international tension. In the remaining years before the outbreak of World War I, Bethmann made sincere efforts to reduce it, but he was always pushed by ministers such as Tirpitz and the German military general staff and was influenced by an aggressive public opinion. He could postpone but not avert war.

In his home policy Bethmann Hollweg was even less effectual than in foreign affairs, and the years immediately preceding the war saw a complete stalemate in German domestic politics, culminating in near farce over the affair of the arrogant officers garrisoning Saverne in Alsace. It was unfortunate for German politics at this time that no genuine democratic majority could be arrived at, because the Social Democrats clung to revolutionary theories that prevented other left-wing parties, which otherwise would have been their natural allies, from joining with them. In fact, the Social Democrats became in 1912 the largest single party in the Reichstag; but in the face of their victory, Bethmann maintained his customary inertia, neither attacking nor wooing them. When, in November 1913, the officers at Saverne provoked, and then illegally arrested, a number of the townsfolk, Bethmann, although privately disapproving of their action, defended them in the Reichstag. For so doing, he was defeated in a vote of censure, by 293 votes to 54. German politics had reached such a low ebb that he neither resigned after this defeat nor were steps taken to punish the soldiers whose action the Reichstag had so vigorously condemned. In fact, the same assembly shortly afterward voted a capital levy in order to increase and further equip the army. Thus, right up to 1914, the German people tried to combine the rule of law at home with the rule of German military power abroad.

The Saverne affair

World War I. There is little or no evidence that the Germans deliberately planned war in the summer of 1914. The crisis of July 1914, caused by the assassination of the Austrian archduke Francis Ferdinand, caught the German statesmen unawares, forcing on them a decision whether or not to stand by Austria-Hungary. In authorizing Austria to act against Serbia and promising support if Russia tried to intervene (July 5), they did not at first realize that they had chosen war; they supposed that a firm line would lead the other powers to give way. Three weeks later Germany vainly warned Russia against mobilization. At this point, Helmuth von Moltke, chief of the general staff, believing that Germany's only chance of victory lay in defeating France before Russia was ready, insisted that, in view of Russia's mobilization, Germany must immediately declare war on both France and Russia. Bethmann could not effectively answer this military argument and gave in, finally himself defending the German march through Belgium, which brought

Great Britain into the war against Germany.

The outbreak of war achieved something that social concessions had failed to do; it brought the Social Democrats over to the support of the imperial government. The German Socialists had always been the leading spokesmen in the Socialist International of the general strike against war. When it came to the point, they were won over by the argument that Germany was being attacked by reactionary tsarist Russia. At the meeting of Socialist members, a minority opposed the war; but when the Reichstag met, the entire Socialist Party voted for war credits, in the name of party unity. The Socialists went further. They joined the other parties in declaring *Burgfrieden*, a civil truce, by which they agreed to criticize neither each other nor the government. Thus the members of the Reichstag abdicated to the imperial government, though it remained unchanged and beyond their control.

Truce among political parties

For Germany, as for other belligerent countries, World War I fell into two distinct phases: the first, that of conventional warfare, which lasted until 1916; the second, a war of desperate expedients when both sides struggled for their very existence. The German High Command had envisaged a short war in which France would be overrun in six weeks and Russia in six months. In the west, this plan was disrupted by the First Battle of the Marne (September 1914), as a result of which the Germans failed to capture Paris and were obliged to occupy long miles of trenches across Belgium and northern France. Yet the defeat of the Russians at Tannenberg had given Germany the security that was its ostensible war aim, and, at any time up to the summer of 1917, it could have negotiated peace on a status quo basis. But such a peace was not then acceptable to Germany, since it would have arrested the expansion of German industry and brought about political revolution at home.

After the Marne, Moltke was succeeded as chief of the general staff by Erich von Falkenhayn, whose plan to remain defensive on the western front, while attacking in the east, achieved some success. Anglo-French offensives on the west achieved nothing, while Germany drove the Russians from Galicia, overran Serbia (autumn 1915), and, by the entry of Bulgaria into the war as its ally, secured a land route to Turkey and beyond to the Persian Gulf.

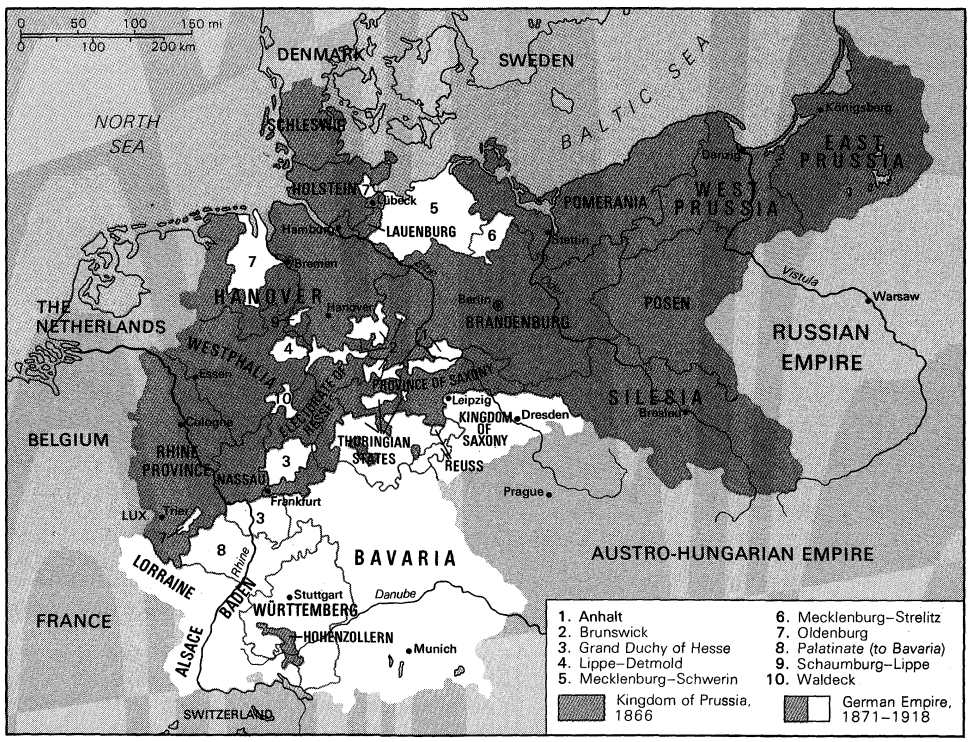
The second year of war saw the first serious efforts to mobilize and organize German resources; this was largely the work of an industrialist, Walter Rathenau, who convinced the government of the need for economic planning. Gradually, despite the success of Falkenhayn's strategy, it became clear that German interest had shifted to the west, mainly because control of the industrial resources of Belgium and of northeastern France became a major preoccupation of the German steel magnates. Annexation, or at least partial control, of Belgium began to be regarded as an essential condition for peace. Some Liberal elements continued to think that peace could be made without excessive demands, while a minority group of the Social Democrats became virtually pacifist.

In 1916 Falkenhayn's attempt to "bleed the French white" by the prolonged Battle of Verdun (February–June) proved almost as exhausting for the Germans. At the same time, an attempt to break British naval power by direct assault failed at the Battle of Jutland (May 31, 1916), and two months later William II dismissed Falkenhayn, appointing Paul von Hindenburg chief of staff, with Erich Ludendorff as his quartermaster general.

These appointments, reflecting a general desire for more vigorous policies, brought to an end any chances of a compromise peace and resulted in a major German political crisis. Bethmann had been negotiating with tsarist Russia for a peace without victory, but his moderation became unpopular, and in October 1916 the Reichstag passed a motion declaring that it had confidence in Bethmann so long as he possessed the confidence of the High Command. Thus Bethmann could oppose none of Hindenburg's and Ludendorff's policies. Ludendorff's insistence on the proclamation (November 1916) of an independent kingdom of Poland brought the Russian peace negotiations to an end. The decision (January 1917) to inaugurate unrestricted submarine warfare was made against Bethmann's judgment; the attempt to blockade Britain by this means was ultimately defeated by the British convoy system, while such warfare had the far graver consequence of bringing the United States into the war against Germany.

Unrestricted submarine warfare

There was a shortage of food during the winter of 1916–17, and war-weariness developed. The first Russian Revolution (March 1917) encouraged left-wing feeling, and soon afterward Matthias Erzberger, leader of the Centre, decided that it would be politically opportune to secure for it the position of most prominent anti-war



The German Empire (1871–1918).

party. In July he attacked Bethmann for advocating the policies of conquest that Ludendorff had, in fact, forced on him. Ludendorff, for quite opposite reasons, regarding Bethmann as too pacific, also wanted to oust the Chancellor and so welcomed Erzberger's attack. The politicians wanted to replace Bethmann by Bülow; but William II, remembering his humiliation by Bülow over the *Daily Telegraph* interview, refused to appoint him. Since the politicians could put forward no alternative candidate, Ludendorff then nominated an unknown official, Georg Michaelis, who would be a mere puppet.

Having failed to make a chancellor, the Reichstag was, however, allowed to dabble in policy making. On July 19 it passed a "peace resolution," which was little more than a string of innocuous phrases and lacked concrete proposals. Further apparent concessions were made to the Reichstag in October when, after dismissing Michaelis for incompetence, Ludendorff appointed as chancellor Georg, Graf von Hertling, who, as a Catholic, was particularly acceptable to the Centre Party. But Hertling, an old man, was allowed no influence on policy.

The German Empire was to have one last year of illusory success before its final collapse. Allied offensives on the western front were routed (1917) and Russian forces disintegrated, especially after the Bolshevik Revolution in November 1917. The Bolsheviks' belief that by offering a peace "without indemnities or annexations" they could induce the German workers to revolution proved unfounded; although a wave of strikes occurred in Germany early in 1918, they produced no political effect. The Social Democrats, who had declared themselves to be fighting against Russian tsardom, continued to fight after tsardom had disappeared. Thus, the Bolsheviks had to sign (March 1918) the Treaty of Brest-Litovsk, by which Russia lost 56,000,000 inhabitants, 79 percent of its iron, and 89 percent of its coal production. In May, Romania had to agree to a peace treaty that made Germany its economic master. Thus, for a few months, Germany had all of Europe east of the Rhine under its economic domination.

Treaty of Brest-Litovsk

The decisive battle remained, however, to be fought in the west. Ludendorff launched what he called "the emperor's battle" (much against the Emperor's wish) in March 1918, winning a battle against the British in April and against the French at the end of May. But these were not decisive, and in July the French struck back. The British broke through on August 8. The collapse of Bulgaria late in September and the imminent collapse of Austria-Hungary caused Ludendorff to decide to seek an immediate armistice. Approaches were made to the United States, whose president, Woodrow Wilson, had enumerated in January 1918 a list of Fourteen Points that he regarded as essential for a just and lasting peace. In order to make Germany's position more acceptable to the Allies, Ludendorff ordered that it should become a constitutional monarchy, and Prince Max of Baden, noted internationally for his liberalism, was made chancellor (October 3). The same day the political leaders were told that the war was lost. Ludendorff, who had not studied the Fourteen Points, wished to continue the war when he realized their implication, but he was overruled and resigned (October 26). Hindenberg remained at the head of the general staff.

The situation deteriorated in November, with the capitulation of Turkey and of Austria (November 3). The next day revolution broke out in Germany, and, on November 9, Prince Max ceded the chancellorship to the Socialist Friedrich Ebert. On the same day the abdication of William II was announced, and he fled to The Netherlands. The German delegates had already left Berlin and, with revolution at home as well as an untenable military position, were obliged to sign the Armistice on November 11.

Defeat of revolutionaries, 1918–19. A republic was hastily proclaimed on November 9 by a Social Democrat, Philipp Scheidemann, in order to forestall the proclamation of a soviet republic by Karl Liebknecht, leader of the extreme left-wing group known as Spartacists. The next day Ebert became chairman of the Council of People's Representatives, a body dominated by so-called Majority Social Democrats, who were opposed to revolution. Ebert made a bargain with Hindenburg, by which it was agreed that Ebert would resist revolution and Hindenburg would retain his command. Ebert then arranged for elections for a constituent assembly to take place on January 19. In the intervening period, the government survived various disorders and attacks, culminating in several days of street fighting in Berlin (January 6–15). Liebknecht and another prominent Spartacist, Rosa Luxemburg, were arrested and murdered. Thus the forces of social revolution were defeated, and the way was clear for the establishment of a democratic republic to preserve the economic order and military values of imperial Germany.

THE GERMAN REPUBLIC, 1919–33

The Weimar constitution. The new National Assembly met at Weimar on February 6, 1919. Ebert was elected president of the *Reich*, and Philipp Scheidemann as chancellor formed a ministry based on support from his own party, the Social Democrats, allied with the Centre and Democratic parties. The new constitution, promulgated in August, retained for the republic a federal basis, but the central government was much stronger than in imperial times, controlling all taxation and its laws overriding those of the separate *Länder*, or states. There were 17 *Länder* in all, ranging from Prussia, with a population (in 1925) of 38,000,000, to Schaumburg-Lippe, with 48,000. The only new *Land* was Thuringia, formed from the amalgamation of seven small principalities. The *Länder* were represented in the Reichsrat, but this chamber was subordinate to the Reichstag, to which alone the chancellor and his government were responsible. The Reichstag was to be chosen on a system of proportional representation, by all men and women over the age of 20.

As a counterweight to the Reichstag, the president as the chief executive was endowed with strong powers. He was to be elected by direct national vote for a term of seven years and was eligible for re-election. He was to make alliances and treaties, was the supreme commander of the armed forces, and could dissolve the Reichstag and submit any law enacted by it to a referendum. Finally, under the famous Article 48, he had the right to suspend civil liberties in case of emergency.

Powers of the president

The new German Republic was democratic but not Socialist. German industry continued to be marked by cartels and combines, control of which was increasingly concentrated in the hands of a very small group. The fact that there were no far-reaching plans for securing public control of industry or for breaking up the big landed estates had two serious consequences. The working class, although improving its political and economic status, remained resentful and increasingly supported the left-wing opposition, thus weakening both the Social Democratic Party and the republic. Meanwhile, economic power remained in the hands of those who either opposed the republic outright or, giving it nominal support, preferred more authoritarian forms of government.

The Treaty of Versailles. To many Germans, the break with the past was complete, and they imagined the program of self-determination and equality of rights originally set out in Pres. Woodrow Wilson's Fourteen Points to be binding on both sides. In the event, the Allies refused them the right to negotiate, and the terms presented on May 7, 1919, provoked bitter indignation throughout Germany.

Germany was to cede Alsace-Lorraine to France; Upper Silesia, most of Posen, and the so-called West Prussia to Poland; North Schleswig to Denmark; and three small frontier districts to Belgium. Danzig was to become an independent, free city; East Prussia was separated from the rest of the *Reich* by Polish Pomorze (modern Pomerania); and Memel was handed over to Lithuania. The union of Austria with the *Reich*, which was advocated in both countries, was expressly forbidden. All German colonies were to be handed over to the Allies. The left (German) bank of the Rhine and the right bank to a

depth of 30 miles (50 kilometres) were to be permanently demilitarized. The rich area of the Saar was to be governed by the League of Nations for 15 years and its coalfields administered by France. At the end of that time a plebiscite was to determine the Saar's future status. To ensure execution of the treaty's terms, Allied troops would occupy the left bank of the Rhine for a period of five to 15 years. The German Army was to be limited to 100,000 officers and men; the general staff was to be dissolved; vast quantities of war material were to be handed over and the manufacture of munitions rigidly curtailed. The navy was to be similarly reduced, and no military aircraft were allowed.

Reparations

A decision on financial reparations was deferred until 1921, but Germany was to make a provisional payment of 20,000,000,000 marks in gold, as well as deliveries in kind. Prewar commercial agreements with other countries were cancelled; German foreign financial holdings were confiscated, and the German merchant marine was reduced to less than one-tenth of its prewar size. As justification for these reparation claims, the Allies inserted into the treaty the famous war-guilt clause, Article 231, by which Germany and its allies were named the aggressors in the recent war and were held responsible for all loss and damage suffered by the Allies.

All the German political parties protested against these terms, and the belief that Germany had been tricked into signing the Armistice became widespread. But in June the Allies presented an ultimatum, and the German government faced the alternatives of either signing the treaty or suffering military invasion. Scheidemann, who opposed acceptance, resigned when his cabinet failed to agree. He was succeeded by Gustav Bauer, who formed an administration supported by Social Democrats and the Centre, but without the Democrats, most of whom joined the Nationalists (Deutschnationale Volkspartei) and the People's Party (Deutsche Volkspartei) in opposition. On June 23 the majority of the Reichstag, seeing no alternative, voted for acceptance of the terms, and the treaty was signed on June 28.

The Allies' insistence on terms so humiliating seriously weakened the republican regime. The legend that the German Army had never been defeated but was stabbed in the back by the Republicans, the Socialists, and the Jews was assiduously repeated by enemies of the republic and, in the mood of resentment created by the treaty, was increasingly accepted.

Years of crisis, 1920–23. The "Weimar coalition" of Social Democrats, Centre, and Democrats was re-established when the Democrats joined Bauer's government in October 1919 and was maintained under Hermann Müller, who succeeded Bauer as chancellor in March 1920. But, in the elections of June 1920, these parties lost heavily in favour of some more to the left and others more to the right. A Centrist, Konstantin Fehrenbach, became chancellor, leading a coalition of the Centre, the Democrats, and the right-wing People's Party.

There were some workers' risings in 1920 and 1921, but the danger to the republic from the left gradually became less. After the left wing of the Independent Social Democrats joined the Communists in December 1920, the remaining Independents drew closer to the Social Democrats, and a union of the two parties was achieved in September 1922. By far the greater danger to the republic came from the right. A coup d'etat, attempted in March 1920 by the conservative politician Wolfgang Kapp, was only defeated by a solid working class resistance and the organization by the trade unions of a general strike. Inside the Reichstag the Nationalists kept up an unrestrained attack upon the republic and its leaders, but even they were not sufficiently extreme to satisfy such groups as the German Racist Freedom Party in the north and Adolf Hitler's National Socialist German Workers Party in Munich, which combined anti-Semitism, anti-Communism, and inflammatory nationalism with open demands for the overthrow of the republic. Closely linked with these groups were various paramilitary organizations, drawing their membership largely from former servicemen and in close touch with army officers who provided them with arms. From this underworld of conspiracy, which was the breeding ground of the Nazi movement, were recruited gangs such as the notorious Organisation Konsul, responsible for several political assassinations. The stronghold of these counter-revolutionary forces was Bavaria, also the home of the Catholic Bavarian People's Party, which made no secret of its anti-republican and particularist views.

On April 27, 1921, the Allied Reparation Commission fixed the total to be paid by Germany at 132,000,000,000 gold marks. Regarding this sum as far in excess of what the country could pay, Fehrenbach and his government resigned, but, in face of an Allied ultimatum based on a threat of occupation of the Ruhr, the new chancellor, Karl Joseph Wirth (Centre), secured a reluctant vote from the Reichstag in favour of paying. It proved, however, impossible to pay the sums required on time, and the French, who had already engaged in frontier harassment, made a technical default by Germany in timber deliveries the pretext for occupying the Ruhr (January 1923).

One way of breaking the hostile ring with which the Germans felt themselves encircled was to ally with the other European outcast, the Soviet Union. Economic negotiations proved successful in 1921, and in April 1922 a treaty of friendship between Germany and Russia was signed at Rapallo. Reparation claims by both sides were abandoned, and the expansion of Russo-German trade was planned. The most important practical consequence of the treaty was the conclusion of secret agreements between the German and Russian armies, by which German units obtained experience with the Red Army in the use of weapons and aircraft forbidden to Germany by the Treaty of Versailles.

The Treaty of Rapallo

During these immediate postwar years, the value of the German mark steadily deteriorated, largely as a result of reparation payments and the savage penalties imposed on German trade. Faced with budgetary deficits, governments followed a practice already begun during the war, that of issuing more money to meet expenses. The result was a runaway inflation more severe than that experienced in any other part of Europe. During the year 1922, the value of the mark in terms of the U.S. dollar fell from 162 marks to more than 7,000 marks (the pre-1914 relation had been 4.20 marks to the dollar).

This serious situation was vastly worsened as a result of the French occupation of the Ruhr. The government of Wilhelm Cuno (Centre, People's Party, and Democrats), which succeeded that of Wirth in November 1922, ordered passive resistance to the French and Belgian attempts to get the mines and factories working and a ban on all reparation deliveries. The occupation forces replied with mass arrests and an economic blockade that cut off not only the Ruhr but the greater part of the occupied Rhineland from the rest of Germany. This was a devastating blow to the German economy, especially after the final loss in 1921, as a result of a plebiscite and a League of Nations' ruling, of the coal-mining and industrial areas of Upper Silesia. As a result, by July 1, 1923, the mark had fallen to 160,000 to the dollar; by November 20, 1923, it was down to 4,200,000,000,000 to the dollar. Barter replaced other commercial dealings, and food riots broke out. The heaviest losers were the middle classes and pensioners; but the drop in real wages also hit the workers hard. On the other hand, many businessmen made large profits, and everyone with debts to pay off gained immensely.

The extremist parties hastened to exploit this dire situation. Communists were active in Saxony and Thuringia and led a rising in Hamburg (October 1923). At the same time, the *Land* government in Bavaria openly defied the central government, while Hitler and the small National Socialist movement were urging the Munich authorities to stage a march on Berlin. In face of these troubles, Social Democratic pressure for a stronger policy led to the replacement of Cuno (August 1923) by Gustav Stresemann of the People's Party, who was supported by the Centre, the Democrats, and (until November) the Social Democrats. Stresemann courageously called off the cam-

paign of passive resistance in the Rhineland and lifted the ban on reparation deliveries. Declaring an emergency, he used the army to suppress the leftist governments in Saxony and Thuringia, put down the Hamburg rising, and took a strong line with the Bavarians. An attempted coup by Hitler (the Beer Hall Putsch) in Munich (November 8–9) failed to influence the authorities there, who suppressed the Nazis and hastened to make their peace with Berlin.

Attempts to stabilize the republic, 1923–30. The history of Germany in the mid-1920s is of a gradual return to normality, shown at home by the surmounting of the inflation problem and abroad by the establishment of friendly relations with the Allies, the withdrawal of the occupying forces from the Ruhr and the Rhineland, and the acceptance of Germany as a full member of the League of Nations. The election of Hindenburg as president of the republic on Ebert's death in February 1925 at first aroused concern among republicans and abroad, because of his monarchist and right-wing views; in fact, by his loyalty to the constitution during his first five years of office, he made an important contribution to the republic's stability.

Coalition governments

Throughout the years 1924 to 1928, Germany was governed by a succession of coalition cabinets, based on the support of the three bourgeois parties, the Centre, the Democrats, and the People's Party. Stresemann, defeated on a vote of confidence by an alliance of his enemies on the extreme left and right, had resigned in November 1923; his successor, Wilhelm Marx (Centre), was chancellor until January 1925. Marx was followed by Hans Luther, a former finance minister, but returned to a further term of office as chancellor from May 1926 to June 1928. The election of 1928 showed a swing to the left, and Hermann Müller, a Social Democrat, became chancellor, receiving additional support from the Democrats, the People's Party, and the Centre. During these years opposition, apart from that of extremists, came mainly from the Social Democrats before their accession to power and from the Nationalists. The former supported current foreign policy but criticized the continued concentration of economic power in the hands of a few industrialists and businessmen; the latter steadily criticized all attempts by German governments to comply with the terms of the Treaty of Versailles.

Before he fell from power as chancellor, Stresemann tackled the problem of inflation, introducing (November 1923), in strictly limited amounts, a new Rentenmark, for which cover was provided by mortgages on the entire industrial and agricultural resources of the country. Financial stability gradually returned; and in August 1924 the national bank (Reichsbank) was made independent of government control, and a new Reichsmark currency worth 1,000,000,000,000 original marks was issued. Foreign investment, mostly in the form of short-term loans, flowed back into Germany; industry was re-equipped, production boomed, and unemployment declined.

Relations with the Allies became easier, and, largely with the help of United States financiers, final decisions were reached on reparations. An interim arrangement, the Dawes Plan (1924), provided for a resumption of payments by Germany on a scale beginning at 1,000,000,000 gold marks a year, rising to 2,500,000,000 in 1928 and subsequent years. To help the German government at this stage, a foreign loan of 800,000,000 Reichsmarks was floated. The Dawes Plan had not tackled the question of Germany's total liability; this was studied in February 1929 by a committee, on which Germany was represented, presided over by the American Owen D. Young. As a result of its recommendations, it was finally agreed that the total amount payable by Germany in reparation would be 121,000,000,000 Reichsmarks, payable in 59 annual installments.

The Dawes and Young plans

Germany's acceptance of this liability was the occasion of particularly violent but unsuccessful criticism by the Nationalists, under their leader Alfred Hugenberg, and by the Nazi Party, which now, for the first time, made its mark in national as opposed to purely Bavarian politics.

The gradual removal, during these years, of foreign troops and controls and Germany's international rehabilitation were largely the work of Stresemann, foreign minister from November 1923 until his death in October 1929. His policy of "fulfillment" of Germany's obligations under the Treaty of Versailles was often attacked, but he always obtained other concessions for Germany and did a vast amount to restore his country to international prestige. He was particularly prominent in League of Nations disarmament discussions. In return for Germany's acceptance of the Dawes reparation plan, he secured French withdrawal from the Ruhr in 1924. Improved relations with France led to the conclusion of the Locarno Pact in December 1925, in one of the clauses of which Germany reaffirmed its renunciation of Alsace-Lorraine and undertook not to attempt by force any alteration of its frontiers with France and Belgium. These frontiers were also guaranteed by other signatory powers, including Britain and Italy. The signing of these treaties was followed by the Allies' evacuation of the first (Cologne) zone of the occupied Rhineland and by Germany's entry into the League of Nations (September 1926).

Finally, the Allied Military Control Commission withdrew from Germany in January 1927, and, as a result of agreements connected with the Young committee's decisions on reparations, the Allies promised final evacuation of the Rhineland by June 1930.

The end of the republic. German prosperity in the late 1920s, although real, was largely dependent on foreign credit. This was already being withdrawn early in 1929, and, with the crash of the New York Stock Exchange in October and the beginning of the world Depression, Germany was plunged into a slump more severe than that experienced by any other country. The Depression had immediate political repercussions, producing a notable increase in the support given to extremist parties, both of the right and of the left. Within two years the Nazis became the largest, and the Communists the third largest, of the parties. The Depression was the indispensable condition for the Nazis' rise to power.

The Depression

The immediate consequence of the slump was the breakup and resignation of Müller's coalition cabinet. The new chancellor, Heinrich Brüning, unable to get his budget through the Reichstag because of combined opposition from the Social Democrats, Communists, Nationalists, and Nazis, resorted to the emergency powers available under Article 48 of the constitution and put his economic program into effect by decree (July 1930). Such a development had been envisaged by the group of advisers to Hindenburg, prominent among whom was Gen. Kurt von Schleicher, head of the Ministry of Defense, who had suggested Brüning as chancellor. Defeated anew in the Reichstag, Brüning dissolved it and ordered fresh elections (September 1930). These were conducted in an atmosphere of public disorder, created largely by the Nazis and Communists, and resulted in a sensational rise in the vote for these two extremist parties.

Brüning decided to remain in office, nevertheless, and obtained sufficient support because the Social Democrats, alarmed at the advance of the extremists, now voted for him. His measures failed to check the slump, which was a worldwide phenomenon. A plan to create an Austro-German customs union (March 1931), which would have been a move in the breaking down of tariff barriers and also would have placated those in both Germany and Austria who wanted the countries combined, was wrecked by French and Italian opposition.

In July 1931, the big Darmstätter und Nationalbank failed, and, early in 1932, the number of unemployed rose to more than 6,000,000. In these circumstances, the prospect of a presidential election when Hindenburg's term of office expired was alarming. Attempts to extend the existing term were rejected, and, in an election held in March 1932, Hindenburg was opposed by Hitler and three other candidates. Hindenburg failed to obtain the absolute majority necessary, and, at a second election in April, he polled 19,359,642 votes against 13,417,460 cast for Hitler. In the same month, the increasing power of

the Nazis was shown when they became the largest single party in the Prussian Landtag.

Once Brüning had secured the re-election of Hindenberg, his usefulness in Schleicher's eyes had been exhausted. Hindenburg was persuaded to withdraw his confidence from Brüning (May 1932), who was replaced as chancellor by Franz von Papen, who, nominally a member of the Centre, was repudiated by his party and formed a nonparty cabinet in which Schleicher held office as minister of defense. Although unpopular in the country, Papen had presidential and army support and, in foreign policy, achieved a success for which Brüning had vainly striven; at a conference held in Lausanne, in Switzerland, in June 1932, reparations were virtually abolished in return for a payment of 3,000,000,000 Reichsmarks into a fund for European conservation.

Nazi rise to power

Elections held in July 1932 gave the Nazis 230 seats in the Reichstag. When it met in September, they outvoted Papen, and he dissolved the chamber, deciding to govern by emergency decree. In fresh elections held in November, the Nazis lost nearly 2,000,000 votes, but the prospect of deadlock continued. Schleicher decided to supersede Papen (December 1932), but, when he too failed to win support from moderate parties and did not pursue a course he had earlier advocated, of bringing the Nazis into the government, Hindenburg refused to allow him to dissolve the Reichstag. Meanwhile, Papen had made contact with Hitler and with the Nationalists and was able to offer the President the prospect of a coalition that could command a majority in the Reichstag.

In this bargain, Papen thought he had tied Hitler's hands by creating a coalition in which Nazi ministers were heavily outnumbered and held no key posts. Hitler was forced by the declining fortunes of his party to accept considerably less than he had demanded earlier in 1932. But he secured the chancellorship for himself, attaining this office (January 30, 1933) legally, as he had been determined to do, and not by revolution.

THE THIRD REICH, 1933–45

The Nazi revolution. Hitler's first step was to persuade the cabinet to agree to new elections, in order to achieve a majority in the Reichstag; he promised that, whatever the result, the composition of the coalition would remain unaltered. The elections were fixed for March 5, 1933, and the Nazis made full use of all the power they now possessed to launch an overwhelming campaign. The radio was extensively used for Nazi propaganda, and the meetings of other parties were broken up, and their newspapers suppressed. Hermann Göring, a *Reichsminister* without portfolio and Prussian minister of the interior, carried through a purge of the Prussian police force, bringing it effectively under Nazi control. The police were forbidden to interfere with the actions of the Nazi Sturmabteilung (SA, the Nazi militia), who were given the "freedom of the streets."

The Reichstag fire

On the night of February 27, the Reichstag building was burned down, and, on the pretext of a Communist plot to seize power, the *Reich* government assumed emergency powers. Despite this atmosphere of insecurity, the Nazis failed to gain an overall majority in the elections, both the Centre Party and the Social Democrats maintaining their strength. It was only with the support given by the 52 Nationalist members, in addition to that of the 288 Nazis, that Hitler achieved a bare majority in a Reichstag of 647 deputies.

Hitler's next step was to pass the Enabling Act, which would allow the government to issue decrees independently of Reichstag or president. For this he needed a two-thirds majority in the Reichstag. By arresting or excluding the 81 Communist deputies and by buying with promises and assurances the support of the Nationalist and Centre parties, he easily achieved this; the Social Democrats, sole opponents of the bill, were outvoted by 441 to 94. The Enabling Act remained the constitutional basis of Hitler's dictatorship in the Third Reich (*i.e.*, "empire"; the Second Reich was that created by Bismarck in 1871, while the first denoted the Holy Roman Empire of 962–1806).

Thus armed with overriding powers, Hitler proceeded to carry through a revolution with the authority of the state on his side. A series of decrees abolished the *Land* diets, transferring their sovereign powers to the central government. In May 1933, trade unions were suppressed, and their organizations merged in a German Labour Front. Soon afterward all political parties other than the National Socialist (Nazi) Party were suppressed. Cabinet opposition to these various measures crumpled before the wave of violence that swept the country. Official Nazi power was strengthend by the inclusion of Joseph Goebbels in the cabinet as minister of public enlightenment and propaganda, and Göring replaced Papen, who had been commissioner for Prussia. But in fact the cabinet had already ceased to matter, since all decisions were taken by the Nazi leaders on their own authority. The National Party was unable to retain its identity, and its leader, Hugenberg, resigned.

Hitler, for the sake of the country's economy, could not afford to quarrel with the industrialists and financiers and appointed as Hugenberg's successor at the Ministry of Economy the director of the largest insurance company in Germany. He was also anxious to enlist the support of conservative forces in resisting attempts by the more radical section of the Nazi movement to bring about a so-called second revolution. Hitler needed an accommodation with the army, still the most powerful independent institution of the country. He was anxious for its help in carrying through the rearmament of Germany and knew that he needed its support for his plan of succeeding to the presidency, which included the Supreme Command of the armed forces, when Hindenberg, now in his 87th year, should die. There was already conflict between the generals and the radical Nazis, whose leader, Ernst Röhm, chief of staff of the Nazi SA, was pressing for the SA to be incorporated into the army.

The tension and animosities came to a head in June 1934 when Hitler, visiting the dying Hindenburg, was met by an uncompromising demand from Gen. Werner von Blomberg, minister of defense, that, unless the government achieved a relaxation of the tension forthwith, Hindenberg would hand over power to the army. Hitler therefore reluctantly decided to act against Röhm and the SA; Röhm's most notable enemies, Göring and Heinrich Himmler (the leader of the SS, the party's special guard), planned the purge. On the weekend of June 30, 1934, Röhm and his chief lieutenants were seized and executed without trial. The opportunity was also taken to eliminate other enemies, including Schleicher. Thus the army's demands were satisfied, and, when Hindenburg died on August 2, it concurred in the merging of the offices of president and chancellor. Hitler assumed the title of *Führer und Reichskanzler* (literally "leader and state chancellor") and was confirmed in his new office by a plebiscite held on August 19.

The purge of June 1934

The totalitarian police state. The period 1934 to 1939 saw the steady elaboration of a totalitarian police state in Germany. The principal instrument of control was the unified police, security, and Schutzstaffel (SS) organization, run by Himmler. All educational and artistic institutions and media were forced into the pattern of Nazi regimentation, and, through schools and the compulsory Hitler Youth movement, determined efforts were made to indoctrinate the young. A concordat that the Vatican had signed with the German government in July 1933 did not protect German Catholics from constant harassment, and the refusal of German Protestants to accept a Nazi-sponsored German Christian movement brought them into an equally bitter conflict with the state.

The regime showed particular hostility toward the Jews. In April 1933 they were dismissed from government service and the universities and were debarred from entering the professions. The Nürnberg Laws of September 1935 forbade marriages between Jews and persons of German blood, and the Jews virtually lost all civil rights. Their persecution reached its climax in the pogrom of November 9–10, 1938, carried through by the SS. The greater part of all Jewish property was confiscated, and the surviving Jews were restricted to ghettos until World War

II, when they were systematically exterminated. Altogether, in German-occupied Europe, 6,000,000 out of a total of about 8,300,000 Jews were killed or died in concentration camps.

Hitler dealt with unemployment through a major program of public works, such as afforestation and road building; and, from 1935 onward, massive rearmament rapidly changed the problem to one of acute labour shortage. All other considerations were sacrificed to Hitler's demand for the rearmament of Germany at double the rate that the military and economic experts considered feasible. The four-year plan that Hitler proclaimed in September 1936 and that Göring was commissioned to carry out was regarded as unduly reckless by Hjalmar Schacht, minister of economic affairs and president of the Reichsbank; he resigned the former office in November 1937 and the latter in January 1939. Germany's expenditure on armaments rose from less than 2,000,000,000 Reichsmarks in 1933–34 to 16,000,000,000 in 1938–39.

In 1939 Hitler finally managed to bring under his control the two German institutions that had so far retained their independence—the army and the foreign service. By attacking circumstances of their private lives, he secured the removal of Blomberg from the office of commander in chief and of Gen. Werner von Fritsch from the Ministry of Defense. Hitler himself became commander in chief of the armed forces and replaced the Ministry of Defense by a separate high command that in fact acted as his personal staff. Sixteen senior generals were retired. Henceforth until the end of the war, Hitler's arbitrary power over Germany was complete.

Foreign expansion and defeat. *Hitler's early foreign policy.* Hitler's unswerving aim was to overthrow the 1919 peace settlement and establish a German hegemony in Europe. The principles of the League of Nations were quite alien to such an aim, and in October 1933 Germany withdrew from the League, ostensibly in disgust at the member nations' slowness in pursuing its disarmament policies. Although Hitler declared, after the reunion of the Saar with Germany as the result of a 90 percent plebiscite vote in favour of return, that Germany had no further cause of dispute with France, he avoided participation in schemes for a general European settlement. His announcement (March 1935) that Germany was reintroducing conscription in order to create an army of 36 divisions, a flagrant breach of the Treaty of Versailles, aroused nothing beyond protests from the other powers, and Hitler was encouraged to take bigger risks in the future.

Conscription reintroduced

During subsequent years Hitler played off the rivalries between other powers. A naval treaty made with the British (June 1935) annoyed the French, and he soon became the principal beneficiary of the quarrel between Italy and the Western powers over Ethiopia. The outbreak of the Spanish Civil War in 1936 enabled him to establish close working relations with Benito Mussolini, the Italian dictator. Meanwhile, while ratifying the treaty of mutual assistance with Soviet Russia, he had denounced the Locarno Pact made ten years earlier and remilitarized the Rhineland (1936). International acquiescence in this second open breach of the Versailles Treaty not only further increased his confidence but also weakened the complex system of alliances that France had built up in eastern Europe. When, in November 1937, Hitler's anti-Comintern (Communist International) Pact (1936) with Japan was joined by Italy, and German rearmament had made considerable progress, Hitler felt able to take the offensive in foreign policy. He was convinced that France and Britain would never fight; moreover, he had won the close cooperation of Italy and had driven a powerful wedge between the Soviet Union and the Western powers.

Annexation of Austria, Czechoslovakia, and Poland, 1938–39. Hitler's first objective was the annexation of Austria. An attempted Nazi coup there had been unsuccessful in 1934, but his alliance with Italy had now removed the major external support that those Austrians opposed to a union could have found. Kurt von Schuschnigg, the Austrian chancellor, was bullied by Hitler into acceding to far-reaching demands (February 12, 1938) but subsequently decided to conduct a plebiscite in Austria on the issues. Hitler acted quickly to avert this, German troops occupying Austria on March 12, 1938, the day before the plebiscite was to be held. Once again, the other powers merely protested, and Hitler turned rapidly to his second objective, Czechoslovakia. The demands of the Sudeten German minority in Czechoslovakia were skillfully used by Hitler to cause France and Britain to help him by bringing pressure on the Prague government. At the Munich Conference (September 29–30, 1938), the British prime minister, Neville Chamberlain, secured the cession of Sudetenland to Germany by the Czechoslovaks. But this was not all that Hitler wanted, and, in March 1939, he used the smoldering quarrel between Slovaks and Czechs as a pretext for occupying the whole of Bohemia and Moravia. In the same month he secured the return of Memel from Lithuania to Germany.

Hitler then turned to Poland, renewing demands for the return to Germany of the free city of Danzig and for the construction across Polish Pomerania of a German road and railway to link East Prussia with the rest of Germany. The demands were uncompromisingly rejected, and the British government, which had abandoned its policy of appeasement after the occupation of Bohemia-Moravia, guaranteed support for Poland in the event of aggression, and France followed suit. In the face of this diplomatic move, Hitler in May strengthened his alliance with Italy. Finally, he disrupted negotiations the British and French were trying to conduct with the Russians by making secret counterproposals that resulted in the signing of the German–Soviet Nonaggression Pact on the night of August 23–24. To the public pact of nonaggression was appended a secret treaty dividing the whole of eastern Europe into spheres of influence and partitioning Poland.

The Nazi–Soviet pact

Hitler had assumed that his Moscow pact would cause the British and French to withdraw their guarantees to Poland. When, on the contrary, Britain signed a pact of mutual assistance with Poland (August 25), Hitler tried to inaugurate negotiations. But the British would not bring pressure on the Poles as Chamberlain had done on the Czechoslovaks, and on September 1 the German Army invaded Poland. Hitler did not respond to the British and French ultimatum demanding withdrawal of the invading army, and on September 3 Great Britain and France declared war on Germany.

World War II, 1939–45. Hitler intended merely to wage a localized war against Poland and then make a peace settlement. But the speed and ease of his conquest tempted him to extend the war to the west. No fighting took place during the winter of 1939–40, but in April the Germans occupied Norway and Denmark, partly to safeguard their vital iron-ore supply route from northern Sweden through the Norwegian port of Narvik and partly to secure the Baltic Sea. The invasion of The Netherlands, Belgium, and France began on May 10, 1940. Breaking through the Ardennes sector of the Allies' front toward the English Channel coast, the German troops cut off the French and British fighting in Belgium. The Dutch and Belgian armies surrendered before the end of May, the British had to evacuate from Dunkirk, and in mid-June the French requested an armistice. Although he had had no plans to do so, Hitler then ordered preparations for an invasion of Britain. But the defeat of his air force in the Battle of Britain meant that the essential prerequisite, control of the air, was lacking, and in October 1940 the project was postponed indefinitely.

Encouraged by German successes, Italy had entered the war in June. Its attack on Greece in October 1940 complicated the situation for Hitler because it created a Balkan front of which the British might take advantage. Moreover, the Italians were totally unsuccessful, and Hitler had to help them in both North Africa and the Balkans. In the spring of 1941, with Hungary and Romania already satellites, Germany took over key posi-

tions in Bulgaria and invaded and occupied both Yugoslavia and Greece, including Crete.

In the view of Adm. Erich Raeder, commander in chief of the navy, and of other service leaders, these successes should have been followed by an all-out attack on the whole British position in the Middle East. But Hitler had already determined to attack the Soviet Union. The invasion began in June 1941, and at first the Germans drove deep into Soviet territory. But, at the end of the year, the horrors of Russian winter and an unexpected counteroffensive brought to a head the strained relations between Hitler and the army leaders. He assumed direct control of the field armies, and his success at any rate in holding the Soviet attacks during the winter increased his belief in his own military genius.

The Japanese attack on the United States' base at Pearl Harbor in December 1941 had made the war worldwide, and Germany declared war on the United States. Hitler failed to grasp the importance of sea power, and it was only in 1942 that Karl Dönitz, who was to succeed Raeder as naval commander in chief in January 1943, was able to persuade him to concentrate on submarine warfare. Allied shipping was hard pressed, and it was not until the end of 1943 that the Allies could be said to have won the Battle of the Atlantic. Meanwhile, in Russia a German drive to the Volga turned into a desperate contest for the city of Stalingrad (Volgograd), where Hitler's obstinate refusal to withdraw in time led to the encirclement and capitulation of the German armies in January 1943. At the same time, the British had renewed their Mediterranean offensive, and in May 1943 more than 250,000 German and Italian troops surrendered in Tunisia. This double defeat represented the turning point of the war.

Battle of Stalingrad

At the height of his success, Hitler was the master of the greater part of the European continent, with most states either directly occupied or in the position of subservient satellites. German exploitation of these territories was ruthless. Persons likely to provide leadership were, together with the Jews, exterminated, and vast numbers of people were deported to work in Germany. By the end of 1944, about 4,795,000 foreign workers had been recruited in this way, mainly Russians, Poles, and French. In certain occupied countries, the Germans encountered partisan guerilla warfare; almost everywhere there was some form of resistance movement.

In Germany itself the impact of war was not sharply felt until 1942, when casualties in Russia had first reached the scale of World War I. The effects of the Allies' naval blockade were reduced by the plundering of the occupied countries. Total mobilization was introduced early in 1942, and war production was maintained and even stepped up despite heavy air attacks on industry and communications. Göring, originally Hitler's second in command and named successor, had become completely eclipsed as a result of the failure of the air force, for which he was responsible, adequately to check or counter Allied air raids. His place was taken by Himmler, who extended the functions of the SS until it became virtually a state within a state, creating, with the *Waffen* (armed) SS divisions, a rival to the traditional army (*Wehrmacht*).

By the end of 1943 at the latest, Germany's defeat seemed certain to many of its military leaders. But Hitler would not admit it. During the year 1943, Mussolini was overthrown, Anglo-United States forces invaded Italy, and the Russians assumed the offensive. In June 1944 the British and Americans landed in Normandy. Meanwhile, Allied bombing of Germany became more and more extensive and did enormous damage. Hitler, who since mid-1941 had made his headquarters in a remote part of East Prussia, was now completely cut off from the life of the nation; he was scarcely ever seen in public and rarely spoke or broadcast.

Realizing the harm being done by Hitler's refusal to consider surrender, a group of patriots had for some time been plotting to assassinate him. The only institution capable of staging a successful coup d'etat was the army, and one of the principal centres of the plot had been the Abwehr, the army counterintelligence unit. Although the Abwehr was broken up by Himmler in 1943, a small group in the command headquarters of the reserve army became the new conspiratorial centre. On July 20, 1944, one of its members, Colonel Claus von Stauffenberg, placed a bomb carefully concealed in his briefcase under a table during a conference at Hitler's headquarters. But Hitler, although injured, was not among those killed. Attempts by the conspirators to seize power in Berlin and Paris were suppressed.

By late 1944, the Western Allies had reached the Rhine. The Russians swept through the Balkans and, by December 1944, were threatening East Prussia. Early the next year, they launched an attack from the Baltic to the Carpathian Mountains and broke into Germany. In March 1945 the British and Americans crossed the Rhine and entered from the west. At Hitler's command Germany was turned into a battlefield in a senseless campaign to delay the inevitable defeat. Despite talk of fleeing to an underground fortress in Bavaria, Hitler finally refused to leave Berlin. He appointed Admiral Dönitz his successor as head of state and Goebbels chancellor and, so far as is known, shot himself on the afternoon of April 30. Goebbels committed suicide the following day, and Himmler soon afterward. Most of the other Nazi leaders were captured and subsequently tried by the Allies as war criminals. Dönitz tried to negotiate with the Western powers, but the Allies insisted on unconditional surrender, and this was signed on May 7, 1945, to take effect at midnight on May 8–9.

Death of Hitler

GERMANY AFTER WORLD WAR II, 1945–49

With the unconditional surrender the German state ceased to exist, and responsibility for government was assumed by the four occupying powers, the United States, Great Britain, the Soviet Union, and France. Each power occupied a specific zone of Germany; Berlin, although situated in the Soviet zone, was to be occupied by all four powers and was to be governed by an inter-Allied authority. The Allies announced that they would determine the frontiers and status of Germany.

At the Potsdam Conference (July 17 to August 2, 1945), attended by the United States, British, and Soviet leaders, but not by the French, it was agreed that, although a program of decentralization should be carried out, Germany must be treated as a single economic unit. The British and Americans agreed to support at the settlement the Soviet annexation of the northern half of East Prussia; and, for the time being, the "former German territories" east of the Oder and Neisse rivers (Pomerania, Swinemünde, Silesia, and the southern half of East Prussia, as well as Danzig) should remain under Polish administration. These changes involved the loss of 23 percent of German territory as constituted by the Treaty of Versailles.

The Allies' plans for a common policy in Germany proved abortive because of their own divergent interests, and increasing deadlock characterized the meetings of the Allied Control Council. Between 1945 and 1947, attempts to heal the widening rift between Britain and the United States, on the one hand, and the Soviet Union, on the other, proved totally unavailing. Increasingly the British and United States authorities acted on their own initiative in dealing with problems in their own zones of occupation. In 1946 the British accepted an American proposal that their two zones should be merged for economic purposes, and the bizone came into existence on January 1, 1947. In both zones much administrative responsibility had already been handed over to the Germans, and state (*Länder*) governments had been set up. State parliaments (Landtage) were elected in the United States' zone (June 1946), in the British zone (April 1947), and in the French zone (May 1947). The three largest parties to emerge were the Christian Democratic Union, the Free Democratic Party, and the Social Democratic Party, the last named being closely bound up with the revived trade-union movement.

The Allies had undertaken the occupation of Germany with the purpose of rooting out the Nazi regime and de-

stroying the basis of German military power. Hence their original directives laid great stress on political and economic decentralization, disarmament, the arrest of war criminals, and the dismantling of German war industries. They rapidly found themselves forced to deal with quite a different set of problems: economic stagnation, the dislocation of communications, famine, a desperate housing shortage, an unstable currency, and a rampant black market. The problems were rendered much more acute by the influx into Germany of millions of refugees expelled from eastern Europe, partly as the result of decisions made at Potsdam. These problems, together with the sense of insecurity caused by dissension among the allies, added to German demoralization and apathy.

Postwar problems in Germany

The turning point in the postwar history of Germany was the year 1948. In January, the powers and composition of the German Economic Council for the Anglo-American bizone were changed to create the nucleus of a future German government. The council itself was expanded to 104 members, and a second chamber, a Länderrat, consisting of two representatives from each state, was set up. In June a plan of development that would include the French zone was agreed upon. It provided for a federal German government for all three zones and the summoning of a constituent assembly. Relations with the Allies were to be regulated by an occupation statute; an Allied military security board would enforce demilitarization; and an international Ruhr authority would control the coal and steel industries of the area. The Saar, which at the end of 1947 had become an autonomous territory economically attached to France, was excluded from this arrangement.

The Soviet government reacted strongly to these developments and began to interrupt communications between western Germany and Berlin. After a much-needed currency reform in the western zones (June 1948), the Soviet authorities blockaded the Allied garrisons and about 2,500,000 inhabitants of West Berlin, intending to drive out the Western powers. These powers counterblockaded the Soviet zone and organized an airlift to keep West Berlin supplied. The Soviet Union finally lifted the blockade in May 1949, but further disputes made it necessary for the airlift to be continued until September. Finally a tacit working agreement was reached that left Berlin divided into western and eastern sectors under separate administrations, but with the garrisons of the Western Allies still present.

Meanwhile, the plans for development of German government in the western zones had proceeded. A Parliamentary Council of 65 members, elected by the Landtage, met at Bonn on September 1, 1948, to draft a constitution. Their work went on while final attempts to achieve a unified policy for Germany among all four occupying powers again proved unsuccessful. In April 1949 the United States, British, and French foreign ministers published a new occupation statute governing their three respective zones. This guaranteed full powers of self-government to the new West German state, except for certain reserved subjects, such as the question of Berlin. If the political outlook for the new state remained difficult, its economic condition was encouraging. Currency reform and economic aid from the United States under the Marshall Plan had led to a remarkable recovery. In the second half of 1948, industrial production had risen from 45 percent to nearly 75 percent of the 1936 level, while steel production doubled during that year. Although the policy of free competition pursued by the German authorities led to steep price rises and consequent hardship for the poorer classes, in general the revival in German confidence was marked.

THE FEDERAL REPUBLIC OF GERMANY

The Basic Law

The Basic Law of the new state was passed by the Parliamentary Council on May 8, 1949, and four days later was approved by the Western Allied military governors with certain reservations, notably the exclusion of West Berlin, which had been proposed as the 12th *Land* of the federation. The 11 *Länder*, then, were Schleswig-Holstein, Hamburg, Bremen, Lower Saxony, North Rhine-Westphalia, Rhineland-Palatinate, Hesse, Bavaria, Baden, Württemberg-Baden, and Württemberg-Hohenzollern (the last three were merged in 1952 to form Baden-Württemberg, and in 1957, the Saar became the tenth *Land*). When the Occupation Statute came into force in September, the Allied military government was replaced by an Allied High Commission. In November the Petersberg Agreement made further concessions on dismantling industries and allowed the building of a merchant fleet. The Federal Republic became a direct member of the Ruhr Authority and the Council of Europe, and was able to establish consular and commercial relations abroad.

The constitution drawn up for the Federal Republic was not unlike that of Weimar, but it provided far greater democratic safeguards and established by law certain basic individual rights. The positions of president and chancellor were virtually reversed; in the new constitution the president was elected for a five-year term by a federal assembly (Bundesversammlung) made up of both legislative houses. The emergency powers available to the president under the Weimar constitution were now to be wielded by the chancellor and his cabinet. The chancellor, nominated by the president, had then to be elected by absolute majority in the Bundestag, or lower house. This house was elected by direct universal suffrage for a four-year term. The Bundesrat, or the upper house, represented the *Land* governments: no change could be made in the Basic Law without its consent.

The first federal election was held on August 14, 1949. Led by Konrad Adenauer, who had been chairman of the Parliamentary Council, the Christian Democrats won 139 seats out of 402 in the Bundestag. The Social Democrats won 131 seats. Of the other eight parties represented in the Bundestag, the most important were the Free Democratic, with 52 seats, followed by the conservative German Party and by the federalist Bavarian Party, with 17 seats each. The Communists obtained 15 seats. An alliance with the Free Democrats and the German Party enabled Adenauer to be elected chancellor by an absolute majority of one vote in the Bundestag and to form a coalition government. Theodor Heuss, of the Free Democratic Party, was elected president of the republic in September.

Chancellorship of Adenauer. *Foreign policy under Adenauer, 1949–63.* Adenauer, long a strong champion of European cooperation, regarded foreign policy of the greatest importance, and, when (March 1951) the Allied High Commission allowed the Federal Republic to establish a Foreign Office, Adenauer became foreign minister himself, as well as chancellor. Even when, in 1955, Heinrich von Brentano was made foreign minister, important decisions remained reserved to the Chancellor.

Adenauer's avowed aim was the reunification of Germany, but he regarded this as the Allies' responsibility, and continued differences between the Western and the Communist powers made its achievement unlikely. In this situation Adenauer supported the Western alliance under United States leadership and worked to establish a federal relationship between the countries of western Europe. The Social Democrats sharply opposed this order of priorities until 1956 and also opposed the idea of German rearmament, pressed on the Federal Republic by the United States. To prevent the re-emergence of a German national army, Sir Winston Churchill and René Pleven (of France) proposed the setting up of a European army, in which German units would be integrated under European command. The Social Democrats consistently opposed this project, until the elections of 1953 gave the government a two-thirds majority in both houses, which meant that, had they needed to amend the constitution on the rearmament issue, they could have done so. But the European Defense Community project was turned down by the French in August 1954, and, following agreements made in Paris in October 1954, the Federal Republic became, in May 1955, a sovereign state and a full member of the North Atlantic Treaty Organization (NATO), pledged to establish its own armed forces. Great Britain joined with

Membership in NATO

the six member countries of the European Coal and Steel Community (established in 1951) in a Western European Union, which was both to supervise German rearmament and to ensure the maintenance of sufficient British forces on the continent.

Adenauer still worked for closer European integration, and in 1955 Germany was prominent in the discussions that led in 1957 to the signing of the Rome Treaties establishing the European Atomic Energy Community and the European Economic Community (EEC). The Social Democrats voted for their ratification.

A meeting between Pres. Charles de Gaulle and Adenauer in September 1958 inaugurated a period of cooperation between the two men, which was crowned by a further increase in cordiality in 1962 and resulted in the signing of a Franco-German treaty of cooperation in 1963. The late 1950s also saw some coolness between the Federal Republic and Britain. Adenauer distrusted the approaches that the British prime minister, Harold Macmillan, was making to Moscow. Britain, on its side, was anxious about the number of former Nazis holding government and judicial office in Germany. Some cordiality was re-established in the early 1960s.

Outside Europe, Germany tried hard, especially among the emergent nations of Africa and Asia, to establish itself as a noncolonial power able to aid their economic development. Israel was a special case, receiving more than 3,000,000,000 Deutsche Marks in material reparation for Germany's treatment of the Jews. Throughout the 1950s Germany was on excellent terms with the United States, especially after the 1956 involvement of France and Britain in the Suez. A peak of cordiality was reached in 1963 when President John F. Kennedy visited West Germany and West Berlin.

Adenauer went to Moscow in 1955 and agreed to establish diplomatic relations with the Soviet Union, in return for the repatriation of nearly 10,000 German prisoners of war still held in the Soviet Union. A constant problem was the two countries' divergent views about East Germany (the Democratic Republic). Moscow considered that there were two German states, but the Federal Republic would not recognize the legal existence of the East German government. Although a trade agreement was signed with the Soviet Union in 1958, a crisis developed over Berlin later in that year, when the Soviets demanded the withdrawal of Western troops and wanted to declare Berlin a free city. A series of international meetings failed to solve the conflict, and in 1961 the Soviets authorized the building of the Berlin Wall, separating the eastern from the western sectors.

Domestic affairs under Adenauer, 1949–63. The most urgent internal problem for Adenauer's first administration was the resettlement of refugees. At the end of the war, about 8,000,000 Germans had been expelled from Polish territories or from the Sudeten lands; there were others from the Balkans, and each year tens of thousands of additional refugees were arriving from East Germany. The presence of these refugees put a social burden on the Federal Republic, but their assimilation proved surprisingly easy. Many of the refugees, indeed, were skilled, enterprising, and readily adaptable, and their labour proved an important factor in the "economic miracle" of West Germany's speedy recovery.

German refugees

The first legislative period (1949–53) was marked by the struggle over the Law of Codetermination demanded by the Trade Union Federation. As a result, "labour directors" nominated by the unions were made compulsory in the coal and steel industries. But, in spite of their strongly held views about the distribution of the nation's wealth, in the matter of wage demands the German unions were extremely moderate throughout the postwar decade, thereby facilitating economic growth. German industry was rapidly re-equipping itself, and the business community was thought to have a powerful influence on politics behind-the-scenes.

In the elections of September 1953, the Christian Democrats won 243 seats out of 487 in the Bundestag. Economic progress, Adenauer's personal prestige, and the desire to remain close to the protection of the West were the chief reasons for this success. The Social Democrats won only 151 seats. The Free Democrats, who as junior partners in Adenauer's coalition could neither attack its record nor claim much credit for its achievements, dropped to 48 seats. While the German Party obtained 15 seats, the All-German Bloc, a specifically refugee party, won 27. Adenauer formed a second coalition government with the Free Democrats, the German Party, and the All-German Bloc. Heuss was re-elected president in July 1954.

Conflicts soon developed. The trade unions and the Social Democrats launched a campaign against proposals for rearmament and conscription, although they were not able to prevent the passage in the Bundestag in July 1954 of a law authorizing the formation of a volunteer army. The Conscription Bill was passed two years later, and the first recruits were called up in 1957.

During this term of office, Adenauer lost the effective support of some of the smaller parties in his coalition. Most of the All-German Bloc went into opposition in 1955, and the next year, after a bitter quarrel over an electoral law, the Free Democrats also left the government. But any further erosion of Adenauer's power was averted by external events. The brutal suppression of the Hungarian rising by the Soviet Union in 1956 caused a swing back to the support of a government firmly in alliance with the West, while showing up as impractical various plans for reunification with East Germany that some of the Social Democrats and Free Democrats had been entertaining. Government popularity was also enhanced by the social security system in 1957; in future, pensions were to be tied not only to the cost of living but to the growth in national income. Thus, the government was able to point to impressive achievements when launching its campaign for the elections of 1957; it also claimed much of the credit for Germany's phenomenal economic progress under Ludwig Erhard, the minister of economics. As a result, the Christian Democrats increased their proportion of seats in the Bundestag to 270 out of 497. Adenauer formed his third coalition in alliance only with the German Party, which had won 17 seats in the election.

Again, rearmament proved a bone of contention, the Social Democrats and the trade unions this time protesting against the possible equipment of the German army with nuclear weapons. They also called for the withdrawal of foreign (that is, those of the North Atlantic Treaty Organization) troops from German soil. But the trade unions refused to call a strike over the issue; the constitution allowed no referendum on it; and in 1958 the federal armed forces received dual-purpose missiles capable of carrying atomic warheads. By the end of 1960, there were more than 290,000 men in the German forces.

The year 1959 saw the first attempt to challenge Adenauer's power from within the Christian Democratic Union. The crisis was provoked when, as Heuss's second term of office was drawing to an end, Adenauer proposed to have Erhard nominated to succeed him as president, thereby eliminating him from any contest for the chancellorship. Erhard refused to stand, and, in a surprise move, the party induced Adenauer himself to accept nomination for the presidency. But when he saw that the party would go on and make Erhard chancellor, Adenauer reversed his decision. Though, in the course of the crisis, Adenauer had cast grave aspersions on Erhard's political experience and reliability, he was able easily to crush the revolt in the party. The candidate finally elected president, in July 1959, was Heinrich Lübke, a Christian Democrat.

Adenauer's attempt to exclude Erhard

A notable change in the policy of the Social Democrats began in November 1959, with their adoption of the Bad Godesberg Program. This policy document showed them to have completely abandoned Marxism, while even socialization was scarcely mentioned. Roughly a year later, at Hannover, the party conference confirmed Willy Brandt, the mayor of West Berlin, as its candidate for the chancellorship. Brandt reversed the party's policy on the only major issue that now separated it from the government by accepting both conscription and the possibility

that German troops might be armed with nuclear weapons. The party now differed little in policy from the Christian Democrats and fought the electoral campaign of 1961 chiefly by contrasting Brandt with the octogenarian Adenauer.

The elections of 1961 returned only three parties to the Bundestag: the Christian Democrats with 242 seats, the Social Democrats with 190, and the Free Democrats with 67. Having lost their absolute majority, the Christian Democrats allied themselves with the Free Democrats. Although that party's leader, Erich Mende, wanted a new chancellor, Adenauer was in fact re-elected, after the Free Democrats had elicited an understanding that he would retire before the parliamentary term expired.

Chancellorships of Erhard and his successors. *Erhard.* Adenauer resigned in October 1963, and Erhard was elected chancellor, forming a coalition Cabinet very similar to Adenauer's but including Mende as vice chancellor and minister for all-German affairs. Lübke was re-elected president in July 1964.

Germany's relations with the West were complicated by the problem of reconciling "Atlanticism," European unity, and the Franco-German treaty—particularly as France under Pres. Charles de Gaulle became more estranged from NATO and insisted on the exclusion of Britain from the Common Market. Further difficulties arose over Germany's status in any plan for a "multilateral nuclear force" within NATO; France wished to restrict control of its nuclear deterrent to itself, while Britain did not want to allow Germany authority in decisions about the use of nuclear weapons. The whole plan, however, was abandoned in December 1965 when Erhard had talks in Washington with Pres. Lyndon B. Johnson. German–French relations remained at a stalemate, and relations with Britain, temporarily improved by a state visit from Queen Elizabeth II in May 1965, were clouded by disputes about liability for the financial upkeep of British troops stationed in Germany.

Although the results of the election of September 1965, when the Christian Democrats won an unexpected 245 seats against 202 won by the Social Democrats (the Free Democrats won 49), were regarded as a personal victory for Erhard, his government was running into difficulties. For the first time since the currency reform of 1948, the growth rate of the German economy slackened, and in 1967 industrial production actually fell. Widespread fear of economic recession, coupled with the lack of clear political leadership, led to two developments. In the country at large, the National Democratic Party—a neo-Nazi right-wing group—won some support, especially in Bavaria and Hesse, and in October 1966 the Free Democrats, worried about their own future as junior partners in a government in difficulty, withdrew from Erhard's Cabinet.

Economic difficulties

Kiesinger. The withdrawal of the coalition partner left the Cabinet without a parliamentary majority and the Christian Democrats without a leader who could command adequate parliamentary support. In November Kurt Georg Kiesinger, previously minister-president of Baden-Württemberg, became the candidate for the chancellorship and, after complicated negotiations, effected an unprecedented political alliance with the Social Democrats. Kiesinger was elected chancellor, and Brandt became vice chancellor and foreign minister.

Kiesinger sought a détente with the East and an improvement of relations with France. But, although ambassadors were exchanged with the Soviet Union in 1967, the Soviet occupation of Czechoslovakia in 1968 caused renewed tension. Friction with France not only continued but was increased by Brandt's warm endorsement of Britain's application to join the EEC, which was vetoed in December 1967 by President de Gaulle. Fresh conflict arose over the currency crisis of November 1968, when the Germans not only resisted pressure from France and other countries to revalue the Deutsche Mark but recommended the devaluation of the French franc, a step de Gaulle refused to take.

Despite the fact that the Kiesinger government presided over a return to economic growth and full employment, it encountered vociferous opposition from both right and left. In June 1969 the problem of trials of "war criminals" had to be faced again, since the regulations extended in 1965 would soon run out. A time limit for the bringing of charges of genocide was abandoned, and the limit for murder was extended to 30 years from the end of the war.

Early in 1969, President Lübke announced his resignation, and the decision to hold the new presidential election in West Berlin provoked reprisals from the East German authorities. The elections were held, nevertheless, and the new president was Gustav Heinemann, a Social Democrat.

In elections for the Bundestag held in September 1969, the Christian Democrats won 242 seats, the Free Democrats only 30, and the Social Democrats 224. With these results, Brandt made his bid for the chancellorship.

Brandt. On October 21, 1969, Willy Brandt became West Germany's first Social Democratic chancellor. His coalition government was made possible by the support given by the Free Democrats, who, despite their small showing, were in the position of offering an alliance to give power to either of the major parties. Later, in 1970, the fortune of the Free Democrats declined in local elections, and a split in the party weakened the coalition, reducing Brandt's majority in the Bundestag.

As a left-wing government, the Social Democrats had planned a program of domestic reform. In practice, however, much of their time was occupied in combatting inflation. Their first action on achieving power was to devalue the Deutsche Mark by 9.29 percent; in May 1971 they had to float the Mark against international currencies.

Brandt's most important work, and that which caused the most debate, was his *Ostpolitik,* his attempt to come to terms with Germany's Communist neighbours, notably the Soviet Union, Poland, the German Democratic Republic, and Czechoslovakia. In August 1970 he signed a treaty with the Soviet Union confirming the existing frontiers and pledging the renunciation of force to achieve political ends. It was to be ratified by the Bundestag upon the successful conclusion of talks on Berlin by the four Allied occupying powers—the Soviet Union, the United States, Great Britain, and France. They reached agreement in August 1971, and talks with the East Germans about improving facilities for communications between West Germany and West Berlin, which formed a part of the agreement, began. Brandt had had two meetings in 1970 with the East German premier, Willi Stoph, although little had been achieved; but now talks began in earnest. In October 1972 the two Germanies reached a transportation agreement, and that November they initialled a pact that made possible formal relations and cooperation; as a result, families were reunited, visits allowed, prisoners released, and relations formalized between the two Germanies. Meanwhile, in December 1970, West Germany had signed a treaty with Poland ratifying existing borders, and in December 1973 a similar treaty with Czechoslovakia was signed, thus completing the foundations of the *Ostpolitik.*

Brandt's *Ostpolitik*

Although Brandt's *Ostpolitik* was a major issue in the elections of November 1972, his coalition was re-elected with a majority of 46 seats in the 496-seat Bundestag. Brandt resigned as chancellor in May 1974 after accepting responsibility for negligence in a scandal involving one of his personal aides who was accused of spying.

Resignation of Brandt

Schmidt. It was taken for granted that Helmut Schmidt would succeed Brandt as chancellor, and he did so on May 16. In July Walter Scheel became the fourth president of the republic, succeeding Gustav Heinemann on his retirement. Both Schmidt and Scheel were returned to office in the federal elections of 1976.

The change of leadership in both West Germany and France in 1974 brought to power two men who had become friends as their countries' finance ministers, Schmidt and Valéry Giscard d'Estaing. This friendship formed a new basis for German–French relations. Schmidt's foreign policy emphasized European unity, and his domestic policy stressed economic stability.

THE GERMAN DEMOCRATIC REPUBLIC

For the East German zone a Soviet Military Administration was formed in June 1945, with the dual aim of providing a pro-Soviet regime in Germany and of collecting war reparations. The blocking of all bank accounts reduced everyone to an equal need to find work; on July 26 all private banks were closed, and all companies and individuals were ordered to surrender all currency, bullion, deeds, and valuables. Factories were dismantled, and rolling stock and even the rails themselves were transferred to the Soviet Union. All estates of more than 100 hectares (250 acres) were expropriated without compensation.

Thus, about one-third of the country's agricultural land, previously owned by about 3,000 landlords, passed into the hands of about 544,000 farm workers, smallholders, and refugees.

Political parties

The Soviet Zone was divided into five *Länder:* Saxony, Brandenburg, Mecklenburg (including part of Pomerania), Saxony-Anhalt, and Thuringia. The political freedom of all "anti-Fascist" parties was proclaimed (June 1945), and, besides the Communist Party of Germany (KPD), three other parties emerged: Social Democrats (SPD), Christian Democrats (CDU), and Liberal Democrats (LDPD). In April 1946 the Communists and Social Democrats merged to form the Socialist Unity Party of Germany (Sozialistische Einheitspartei Deutschlands, or SED); Wilhelm Pieck and Otto Grotewohl were elected joint chairmen, and Walter Ulbricht became secretary general (later first secretary). Later in 1946, the Socialist Unity Party won the largest number of votes in municipal elections and in elections for the Landtage, or provincial councils.

In 1948, when the United States and British authorities set up the German Economic Council in their bizone, the Soviet Union created a similar 25-member Economic Commission. At a People's Congress held by the Socialist Unity Party (March 1948), a Volksrat, or People's Council, of 400 members was set up and, later in the year, began to draft a constitution for the German Democratic Republic. The constitution was adopted on May 30, 1949, by another People's Congress of 1,525 elected members. A new Volksrat of 400 was appointed and transformed into a Volkskammer (People's Chamber) in October. A Länderkammer (Chamber of States) was also set up, and the two houses elected Pieck president of the republic; but the upper house disappeared on July 23, 1952, when the five *Länder* were subdivided to form 15 *Bezirke,* or districts. A government was formed, with Grotewohl as premier and Ulbricht as first deputy premier. The Soviet Military Authority formally transferred power to the government and was replaced by a Soviet Control Commission.

In July 1950 a treaty was signed with Poland, recognizing the Oder–Neisse line as the permanent frontier between the two countries.

Gradually Soviet claims became less harsh, and the GDR moved toward autonomy. In May 1950 Joseph Stalin announced a 50 percent reduction in reparations still held to be due. In October that year, the republic was admitted to the Council for Mutual Economic Assistance (Comecon), composed of the Soviet Union and its European allies.

In 1953 the Control Commission was replaced by a single high commissioner, as part of a new policy of concessions to German public opinion. Already, however, the Germans had been exasperated by persecution of the churches, by a serious food shortage, and by collectivization in 1952 of the smaller farms not involved in the agricultural expropriations of 1945.

When the production requirements of workers were raised, a wave of strikes culminated in an uprising on June 17, 1953, and Soviet troops were called in to restore order. Collection of reparations by the Soviet Union ceased in 1954, and on March 25 of that year it was announced that the GDR was a sovereign state. Soon afterward it became a founder-member of the Warsaw Treaty Organization, the unified military command established by the Soviet Union and its eastern European allies.

When Pieck died in September 1960, the presidency was abolished, and a Council of State was formed, with Ulbricht as chairman. He remained the first secretary of the Socialist Unity Party.

As early as 1952, the GDR took steps to isolate its territory from West Germany; a police-guarded cordon of land, three miles wide, was created along the whole frontier.

This action left Berlin as the easiest aperture through which persons dissatisfied with the East German regime could leave the country. Between 1945 and 1961, about 3,500,000 people left East Germany for the West. Though it is estimated that 500,000 of these eventually returned, the loss of 3,000,000 people, many of whom were highly trained technical specialists, severely damaged the East German economy.

The Berlin Wall

To deal with this crisis, the Volkskammer in August 1961 adopted a decree for sealing off West Berlin by building a barbed-wire barrier that was later replaced by a concrete wall.

This closing of the "Berlin gap" marked the beginning of an economic revival in East Germany. Rebuilding of East Berlin, Leipzig, Dresden, Magdeburg, Halle, and other cities was rapid and spectacular. In external affairs, the GDR's position also improved, and it made headway in its struggle for international recognition outside the Communist world. A bilateral treaty of alliance with the Soviet Union was signed in 1964, similar treaties with four other Soviet-allied countries in 1967. On October 15, 1971, the German Democratic Republic submitted to the United Nations a memorandum claiming that its membership in that institution would help to solve the outstanding problems between the two German states. At that time the German Democratic Republic maintained normal diplomatic relations with 30 states, as well as consular or commercial official relations with 32 other states.

The East German claim to recognition by West Germany had long been rejected by West German statesmen, but, from 1966 onward, positive attempts at improved relations were made, especially after Willy Brandt became chancellor of the Federal Republic in 1969. In 1970 Willi Stoph, who had succeeded Grotewohl as premier in 1964, had two meetings with Brandt. In 1971 Walter Ulbricht resigned as party chairman and was replaced by Erich Honecker, who also was named chairman of the Council of State in 1976. The question of mutual recognition between East and West Germany was solved with the treaty signed by the two countries on December 21, 1972. The treaty paved the way for them to be admitted to the United Nations in September 1973, and in June 1974 they exchanged diplomatic representatives. In September of that year the U.S. was the last member of the NATO alliance to grant formal recognition to East Germany. (Ed.)

BIBLIOGRAPHY

Medieval Germany to 1250: GEOFFREY BARRACLOUGH, *The Origins of Modern Germany,* 2nd ed. rev. (1947, reprinted 1966), probably the best history of medieval Germany available in English, its perspective enhanced by the author's study of the Middle Ages as an integral part of German history as a whole; and (ed. and trans.), *Mediaeval Germany, 911–1250,* 2 vol. (1938, reprinted 1967), a collection of essays by notable German scholars that presents a kaleidoscopic picture of political and constitutional developments of the medieval German state in addition to providing a concise history of the period; WILLIAM STUBBS, *Germany in the Early Middle Ages, 476–1250* (1908, reprinted 1969), an excellent analysis of the early medieval period, though dated in some respects; JAMES WESTFALL THOMPSON, *Feudal Germany,* 2 vol. (1928, reprinted 1962), the most thorough examination of the German system of feudalism as well as a competent general history; FRANZ H. BAUML, *Medieval Civilization in Germany, 800–1273* (1969), a somewhat simplified yet richly illustrated investigation of German medieval arts, architecture, culture, and social life; KARL BOSL, *Herrscher und Beherrschte im deutschen Reich des 10.–12. Jahrhunderts* (1963), a short statement of the power relationships in medieval German political and ecclesiastical life.

From 1250 to 1493: WILLY ANDREAS, *Deutschland vor der Reformation,* 6th rev. ed. (1959), a broad survey of German

society on the eve of the Reformation; GEOFFREY BARRACLOUGH (*op. cit.*), valuable for political trends and constitutional issues; LEO JUST (ed.), *Deutsche Geschichte bis zum Ausgang des Mittelalters* (1957), a cooperative work by various specialists in the period; HEINZ ANGERMEIER, *Königtum und Landfriede im deutschen Spätmittelalter* (1966), a critical analysis of the various means employed to preserve the public peace; OTTO BRUNNER, *Land und Herrschaft*, 4th ed. (1959), an original study of the growth of territorial lordship; FRANCIS L. CARSTEN, *Princes and Parliaments in Germany, from the Fifteenth to the Eighteenth Century* (1959), an analysis of the relationship between the territorial princes and the assemblies of estates; FRIEDRICH LUTGE, *Deutsche Sozial- und Wirtschaftsgeschichte* (1952), a wide-ranging work on social and economic conditions in late medieval Germany; MICHAEL SEIDLMAYER, *Currents of Mediaeval Thought* (1959), a thoughtful elucidation of general intellectual trends.

From 1493 to c. 1760: HAJO HOLBORN, *A History of Modern Germany*, vol. 1, *The Reformation* (1964), the best general history of Germany for the period from 1500 to 1648, focussing on political and intellectual developments of the Reformation and Counter-Reformation and the severe conflicts they provoked; JOHANNES JANSSEN, *Geschichte des deutschen Volkes seit dem Ausgang des Mittelalters*, 4 vol. (1883–86; Eng. trans., *History of the German People at the Close of the Middle Ages*, 17 vol., 1896–1925), by far the most exhaustive and all-inclusive examination of Germany from the later 15th century to the outbreak of the Thirty Years' War (1618)—still provides an almost unsurpassed wealth of detailed information about the period; RICARDA OCTAVIA HUCH, *Das Zeitalter der Glaubensspaltung* (1937), a German classic on the era of the Reformation to the end of the Thirty Years' War (1648), which contains much valuable material on social and intellectual life during this period; JOSEPH LORTZ, *Die Reformation in Deutschland*, 5th ed., 2 vol. (1965; Eng. trans., *The Reformation in Germany*, 2 vol., 1968), one of the most thorough studies of the German Reformation during the first half of the 16th century, the first volume focussing on Luther's life and historical impact and the second dealing with the resulting Protestant struggles against a conservative ecclesiastical and political establishment; MANFRED BENSING and SIEGFRIED HOYER, *Der deutsche Bauernkrieg, 1524–1526* (1965), an excellent examination of the German Peasants' War of the early 16th century, should be read with care, as the author's analysis is strictly Marxist, drawing heavily on Friedrich Engels' classic work on the subject; KARL BRANDI, *Kaiser Karl V*, 7th ed. (1964; Eng. trans., *The Emperor Charles V*, 1939, reprinted 1963), probably the best biography of the first man to rule a truly world-wide empire—succinctly documents his immeasurable role in the course of European history; LEOPOLD VON RANKE, *Zur deutschen Geschichte vom Religionsfrieden bis zum dreissigjährigen Krieg . . .* (1868), a classic German treatise on the period from 1555 to the beginning of the Thirty Years' War (1618), which still retains much of its validity today, though it is limited by its focus on political history; C.V. WEDGEWOOD, *The Thirty Years War* (1938, reprinted 1961), the standard work on this conflict that was fought almost exclusively in Germany, emphasis on political history; WILHELM TREUE, *Deutsche Geschichte von 1648 bis 1740* (1956), a short history of Germany for the century following the Thirty Years' War, provides an excellent general account of the developing Austro-Prussian and Franco-German rivalries but lacks detailed analysis due to its brevity; W.H. BRUFORD, *Germany in the Eighteenth Century* (1935, reprinted 1965), a well-rounded portrait of Germany in the century before the French Revolution emphasizing cultural and literary developments.

From c. 1760 to 1871: For a good account of Central Europe during the period of the Enlightenment, see W.H. BRUFORD (*op. cit.*). FRANCIS L. CARSTEN (*op. cit.*), deals with the form of government, while HANS ROSENBERG, *Bureaucracy, Aristocracy, and Autocracy* (1958), describes the nature of authority. The transformation of civic ideals is the theme of FRIEDRICH MEINECKE, *Weltbürgertum und Nationalstaat* (1962; Eng. trans., *Cosmopolitanism and the National State*, 1970). GERHARD RITTER, *Friedrich der Grosse*, 3rd ed. (1954; Eng. trans., 1968), analyzes the achievements of the famous king. The prevailing attitudes in the Holy Roman Empire toward the fall of the old order are examined by G.P. GOOCH, *Germany and the French Revolution* (1920, reprinted 1966). REINHOLD ARIS, *History of Political Thought in Germany from 1789 to 1815* (1936, reprinted 1965); and EUGENE N. ANDERSON, *Nationalism and the Cultural Crisis in Prussia, 1806–1815* (1939, reprinted 1966), depict the intellectual effects of the French hegemony. For political developments, see H.A.L. FISHER, *Studies in Napoleonic Statesmanship: Germany* (1903, reprinted 1968); and GUY S. FORD, *Stein and the Era of Reform in Prussia, 1807–1815* (1922). ENNO KRAEHE, *Metternich's German Policy* (1963), describes the War of Liberation, while HAROLD G. NICOLSON, *The Congress of Vienna* (1946, reprinted 1970), deals with the reconstruction of Europe. For the period of the German Confederation, see the vigorous but opinionated account by HEINRICH G. VON TREITSCHKE, *Deutsche Geschichte im neunzehnten Jahrhundert*, 5 vol. (1890–96; Eng. trans., *History of Germany in the Nineteenth Century*, 7 vol., 1915–19). THEODORE S. HAMEROW, *Restoration, Revolution, Reaction* (1958), stresses the connection between politics and economics. JOHN H. CLAPHAM, *The Economic Development of France and Germany, 1815–1914*, 4th ed. (1936); and WILLIAM O. HENDERSON, *The Zollverein* (1939), examine the transformation of the economy of Central Europe. VEIT VALENTIN, *Geschichte der deutschen Revolution von 1848–49* (1930–31; Eng. trans., *1848: Chapters of German History*, 1940), emphasizes the political events of the Revolution; WERNER E. MOSSE, *The European Powers and the German Question, 1848–71* (1958), looks at the diplomatic aspects. The achievement of national unification is described from the Prussian point of view by HEINRICH VON SYBEL, *Die Begründung des deutschen Reiches durch Wilhelm I*, 7 vol. (1889–94; Eng. trans., *The Founding of the German Empire by William I*, 7 vol., 1890–98, reprinted 1968); while HEINRICH FRIEDJUNG, *Der Kampf um die Vorherrschaft in Deutschland, 1859 bis 1866*, 10th ed. (1916–17; Eng. trans., *The Struggle for Supremacy in Germany, 1859–1866*, 1935, reprinted 1966), looks at it from the Austrian side. EUGENE N. ANDERSON, *The Social and Political Conflict in Prussia, 1858–1864* (1954), deals with the constitutional struggle in the Hohenzollern kingdom. OTTO PFLANZE, *Bismarck and the Development of Germany: The Period of Unification, 1815–1871* (1963); and ERICH EYCK, *Bismarck and the German Empire* (1950), portray the architect of the new Germany. The origins of the Franco-Prussian War are traced by HERMANN ONCKEN, *Die Rheinpolitik Kaiser Napoleons III* (1926; Eng. trans. from vol. 1, *Napoleon III and the Rhine*, 1928, reprinted 1967).

From 1871 to the present: HAJO HOLBORN, *A History of Modern Germany*, vol. 3, *1840–1945* (1969), perhaps the best one-volume work on recent German history, which, while focussing on political developments, provides valuable insights into the cultural and intellectural life that has made modern German history such an enigma; KOPPEL S. PINSON, *Modern Germany*, 2nd ed. (1966), another standard work on German history from the French Revolution to the present, provides a concise yet comprehensive analysis that includes much neglected material on the post-World-War II period; ARTHUR ROSENBERG, *Die Entstehung der Deutschen Republik, 1871–1918* (1928; Eng. trans., *Imperial Germany, The Birth of the German Republic, 1871–1918*, 1928, reprinted 1966), one of the best analyses of the German Second Empire (the author's socialist views are readily apparent); ERICH EYCK, *Bismarck and the German Empire*, 2nd ed. (1960), perhaps the best one-volume study of imperial Germany's greatest statesman and his decisive impact on the European balance of power; S. WILLIAM HALPERIN, *Germany Tried Democracy* (1946, reprinted 1965), still the most satisfactory one-volume history of the Weimar Republic (1918–33), most of whose arguments remain valid today despite the availability of new primary evidence since the book's publication more than 25 years ago; ARTHUR ROSENBERG, *Geschichte der Deutschen Republik* (1935; Eng. trans., *A History of the German Republic*, 1936, reprinted 1965), a valuable companion volume to Halperin, which views the Weimar period from a socialist perspective; WILLIAM L. SHIRER, *The Rise and Fall of the Third Reich* (1960), one of the most detailed one-volume accounts of the Hitler era beginning with the dictator's political career after World War I, but focusses on political and military events; ALAN BULLOCK, *Hitler: A Study in Tyranny*, rev. ed. (1962), an excellent comprehensive biography of Adolf Hitler indispensable for an understanding of the Third Reich; ALFRED GROSSER, *L'Allemagne de notre temps* (1970; Eng. trans., *Germany in Our Time*, 1971), traces Germany's history from the collapse of the Third Reich in 1945 to the present focussing mainly on West Germany—almost exclusively political history; MICHAEL BALFOUR, *West Germany* (1968), places the postwar Federal Republic in historical perspective while concentrating on the conservative Adenauer era during which West Germany developed close ties to the Western Allies, recovered economically, and began its rearmament program; JOHN DORNBERG, *The Other Germany* (1968), one of the few serious studies of the German Democratic Republic available in English but unfortunately concentrates on the post-1961 period, providing only a very limited account of the origin and development of Germany's socialist state.

(H.D.S./C.C.B./T.S.H.)

Germfree Life

Germfree life refers to plants and animals living in the absence of living micro-organisms. Concepts equivalent to germfree, including axenic and sterile, are included in the word gnotobiotic (the *g* is silent), which is derived from a Greek word meaning "known biota." Gnotobiology comprises the study of germfree plants and animals, as well as living things in which specific micro-organisms, added by experimental methods, are known to be present. When one or more known species of micro-organisms are added experimentally to a germfree plant or animal, the host, of course, is no longer germfree; both the host and the introduced species are gnotobiotic, however, since all added species are known to the investigator.

Definition of gnotobiology

Neither germfree nor conventional animals should be thought of as abnormal; each reflects a "normal state." Diseases may occur, for example, in either germfree or conventional animals. In most comparisons, the major differences between the animal types are the micro-organisms associated with conventional animals and the absence of all detectable living micro-organisms in germfree animals. Precise comparisons between germfree and conventional animals cannot be made unless both are isolated from the environment and fed the same sterile diet.

Gnotobiotic research seeks to explore the effects of micro-organisms in aging and in physiological diseases, the specific causative agent in infectious diseases, and the role of bacteria in protozoan and viral infections. Germfree research currently is directed toward studying the reactions of germfree animals after they have been inoculated with specific known micro-organisms. The vigorous activity now in progress in germfree research is reflected in an increasing number of publications on germfree life and gnotobiology, in the thousands of germfree animals raised each year, and in the laboratories that are contributing knowledge to interactions between micro-organisms and their hosts (which range from plants, flies, and silkworms to mice, rats, guinea pigs, rabbits, pigs, dogs, cats, chicks, turkeys, Japanese quail, monkeys, goats, sheep, and horses). Research, especially with invertebrate animals, may advance the knowledge of basic principles concerning host–microbe interactions.

GENERAL BACKGROUND

Germfree plants

Before methods for obtaining germfree animals had been developed, germfree plants were being used to resolve a controversy concerning the fixation of nitrogen into chemical compounds by leguminous plants. In 1858 it was found that nitrogen fixation occurred in plants grown on nonsterile soil but not in those grown on sterile soil. The fixation process was thought to occur in organic corpuscles (or nodes) found on the roots of plants grown in nonsterile soil. These nodes were shown to contain bacteria when the experiment was repeated in 1888.

After he presented a student's paper on germfree peas to the French Academy of Science in 1885, Pasteur commented that animals should not exist without bacteria to help digestion; in opposition, others argued that life would be better in the absence of bacteria. The first attempts to grow germfree animals, however, were not performed until 1895, with guinea pigs at the Hygiene Institute of Berlin; experiments were continued with chicks for more than a decade with no success. The first successful germfree vertebrate experiments (with chicks) were begun around 1912; shortly thereafter, germfree goats were kept alive for two months.

Progress in modern germfree research may be attributed to a few important developments. Methods developed at the University of Notre Dame in the United States have advanced the systematic exploration of germfree life so that it has become a useful tool in biological research. Work directed at the Kungliga Karolinska Institute in Stockholm, Sweden, pioneered the development between 1960 and 1970 of several centres for germfree research in Europe. Notable work also is carried out in France, Belgium, the Netherlands, and England. From beginnings at Kyoto University, work in government, university, and private laboratories in Japan includes germfree research centres at Nagoya Tokyo, Chiba, and Gifu universities. The Tokyo Sericulture Experiment Station is developing a germfree silkworm industry.

IMPORTANCE OF GERMFREE LIFE RESEARCH

Human health. The addition of one or two specific micro-organisms to germfree animals can clarify cause and effect relationships that are important in human disease. Sometimes, germfree animals become infected and die after they have been inoculated with bacteria commonly found in the intestines of conventional animals. Such bacteria include *Escherichia coli* and *Bacillus subtilis*. In contrast, inoculation of pathogenic (*i.e.*, disease-causing) organisms such as *Entamoeba histolytica* (which causes amebic dysentery) into guinea pigs, or *Shigella flexneri* (which causes enteritis) into rats and mice, kills conventional animals and has almost no effect on germfree ones. In some diseases caused by bacteria and viruses (*e.g.*, rabies), specific bacteria normally found in the intestinal tracts of conventional animals collaborate with pathogens to produce the usual clinical symptoms of disease and death; *E. coli* often collaborates in such cases.

Gnotobiotic research involving the simultaneous introduction of more than two micro-organisms may ultimately allow man to control his microflora (*i.e.*, the types of micro-organisms in his body). Experiments in which some germfree animals are inoculated with a pathogen and others are inoculated with both a pathogen and another micro-organism reveal that the apparent strength of the pathogen changes in the presence of different microfloral environments. Such results provide direct evidence for an increasingly popular concept that the microflora (in the alimentary tract of a conventional animal) are important in defending an animal from many potentially pathogenic micro-organisms frequently found in various parts of the alimentary tract.

Tooth decay

The techniques of gnotobiology have been used to clarify the causes of certain common human health problems. Gnotobiotic studies have shown, for example, that tooth decay is caused by certain infectious bacteria. Only a few of many microbial species added to germ-free rats have produced decay. It appears that tooth decay in man is an infectious disease caused by a few bacteria.

Germfree animals are used in toxicology, pollution control, and vaccine tests. The effects of an external force (*e.g.*, radiation or a noxious gas) are easy to distinguish because there is no interference from infection. Sterile surgery is another application of gnotobiotic procedures. Surgical entry into a patient can be made by a single incision through a sterile isolator and the skin which have been glued together. Both patient and surgeon are outside the isolator, while the sterile instruments and the area of the patient that is to be operated on cannot be contaminated by micro-organisms from the field of operation.

Patients with underdeveloped or suppressed immunological defenses against bacteria can be placed in complete biological isolation using gnotobiotic techniques. Babies suspected of lacking the ability to synthesize gammaglobulins (blood proteins that include antibodies) have been delivered into germfree isolators and maintained there until laboratory tests have shown that they could synthesize gammaglobulins. Some hospitals for cancer patients can maintain patients in an environment containing greatly reduced numbers of bacteria, particularly pathogens. Such facilities for humans are comparable to research facilities in which animal colonies are maintained free of specific pathogens. Precautions that precede heart transplants may include elaborate gnotobiotic rooms and procedures to prevent an immune-suppressed patient from coming into contact with pathogenic micro-organisms. Increasing success in antibiotic treatment of biologically isolated patients may culminate in gnotobiotic hospitals.

Biological research. Germfree animals are used to determine the effects of specific micro-organisms that are

added to a germfree host. Knowledge of the characteristics of germfree animals, therefore is important. The effects of the microbial population, which lives in the human alimentary tract and on the skin (every human harbours several hundred billion micro-organisms), can be inferred if experimental animals without micro-organisms are compared with those to which one (or more) species of micro-organisms has been added. The total numbers of each added microbial species in any part of an animal can be counted with standard microbiological techniques. Such qualitative and quantitative estimates permit the assessment of the biological component of the host environment with an exactness equivalent to that regarding physical and chemical components of the environment.

Except in ruminants (*e.g.*, cows), micro-organisms have been taken for granted in the ecology of healthy animals. In nature, however, ruminants cannot live without micro-organisms which digest cellulose and synthesize essential amino acids and vitamins. One challenge to germfree research, therefore, is to determine which of the specific nutrients produced by alimentary tract microflora are needed for the survival of a host. Many germfree species cannot survive if their diets are not fortified with vitamins that are synthesized in conventional animals by their microflora.

Other subtle interactions between host and microflora are studied with gnotobiotic techniques; for example, a balanced microflora is a defense mechanism that helps to prevent the accumulation of pathogenic micro-organisms within the alimentary tract of a host. Prolonged isolation of an animal may result in changes in its normal intestinal flora; these may lead, in turn, to complications generally termed microbial shock. Isolation of humans for transplantations, for immunological deficiencies at birth, for cancer treatments, or for prolonged space flights raises as yet unanswered questions about the functions, maintenance, and reconstitution of the normal alimentary microflora of humans.

Germfree research provides information about biologically pure animals. Life now is possible in the absence of the ubiquitous micro-organism, which was an important environmental component during vertebrate evolution. Germfree research provides a comparative basis for evaluating conventional life, which is intimately associated with micro-organisms. Aging processes, physiological activities, diseases, and specific nutritive requirements can be studied with gnotobiotic techniques in order to determine important aspects of host-microbe relationships. Experiments performed on germfree animal embryos, for example, provide insight into the development of organs, biochemical systems, physiological mechanisms, and immunological responses.

Outer space research. The germfree animal is a useful tool in the continuing search for life on the moon and other planets and in protecting life on Earth from possible extraterrestrial life forms. Space rockets, sterilized to avoid contaminating other planets with micro-organisms from Earth, can be used to bring materials from other planets back to Earth. Moon dust and moon rock samples, for example, have been examined physically, chemically, and biologically using gnotobiotic procedures. Moon dust has been fed to (and inoculated into) germfree animals to test its toxicity and to determine if it contains any moon micro-organisms that could grow or cause infection.

Industry. Industries exist that produce germfree animals, isolators, and other equipment. Germfree animals provide an ideal source for the culture of epithelial tissue (*e.g.*, skin) because skin removed from conventional animals is always contaminated with micro-organisms. Gnotobiotic techniques also provide stock animals that can be used to start disease-free colonies. After laboratory animals are used to start a new colony, the new colony can be maintained free of specific pathogens (and the animals then are known as specific pathogen-free animals) and are free from all common pathogenic micro-organisms. With animals such as these, better disease control and greater uniformity of animals used in research and drug assays can be maintained. Clean room procedures and isolation equipment also are being developed and improved continuously.

Possible Interactions of major components of ecology (see text).

GENERAL FEATURES OF GERMFREE LIFE

Germfree life is an extension of the pure culture concept in microbiology, in which one species can be isolated from all other species. Manipulation and description of the biological component of the environment of an animal are the objectives of gnotobiology. Gnotobiology provides a way to understand the ecology of interactions between host and micro-organisms.

Interaction of ecological components

Germfree research utilizes scientific methods, in which a complex subject is separated into its component parts and then studied in any desired combination. The component parts of a living system may be treated as units after the host (also called the macrobe) is separated from its normal complement of micro-organisms (also called the microbes). Interaction of major ecological components (*e.g.*, physical, chemical, and biological aspects of the environment) may be studied in a variety of ways (see drawing). A mammalian embryo in the uterus of its mother, for example, is in state 1*; that is, normally, no micro-organisms are present, and the environment of the embryo is the same as that of the mother. State 2* can be represented by a chick embryo. In this case, temperature regulation (a component of the physical environment) originates outside the egg; chemicals, including air and water vapour, must pass through egg membranes before entering the embryo. A newborn mammal is in state 2* until the amnion (the sac that encloses the fetus) is broken; then it passes to state 3*, and both chemical and physical environmental components act directly on it. State 3* usually lasts only a short time, because the first contacts of a newborn animal with the outside world contaminate it with many types of micro-organisms that immediately establish themselves on the skin, in the nose, and in the alimentary tract of the animal. The newborn animal then passes to state 4* and enters state 5 when it eats.

An animal may be born or hatched into a germfree isolator, and since there are no micro-organisms present, the animal will remain in state 3* until it is fed. Germfree piglets kept in this state for one or two days have been used as antigen-free animals in immunochemical studies. When it is fed, such an animal enters state 4**,

which is the usual state of the germfree animal. If a germfree animal is inoculated with one or more pure cultures of micro-organisms, both animal and micro-organisms enter state 5. Micro-organisms, for example, may be studied as they exist in various states, including the effect of the host upon the microbe in state 5.

Research may eventually show that most of the effects now attributed to microflora can be duplicated by the administration of certain compounds; *e.g.*, antigen (a substance that stimulates formation of antibodies) injection is known to cause changes in lymph node size, cell numbers, and antibody production. In this sense the germfree animal becomes an experimental base, or control animal; animals containing micro-organisms are in a more complex experimental condition.

METHODS

Isolation. Physical methods of isolating a desired organism from a group of micro-organisms (*i.e.*, the microbiological techniques developed for pure culture of micro-organisms) usually are not used with vertebrates. Although antibiotics and germicides are used routinely by some investigators to decontaminate animals, most germfree animals are transferred from microbe-free environments in nature into a sterile isolator by aseptic (*i.e.*, sterile) transfer. If, for example, a seed or an egg contains no internal microbial contaminants, germfree plants and egg-laying animals may be obtained from seeds or eggs whose surfaces have been sterilized. Germfree chicks, turkeys, and Japanese quail can be obtained by passing such surface sterilized eggs through a temperature controlled, germicidal trap and into a sterile isolator in which they are incubated and hatched. The eggs must be obtained from flocks free of micro-organisms that can invade the egg before it leaves the oviduct of a hen. The fetus of mammals, normally free of micro-organisms, can be removed from the mother and transferred to a sterile isolator. The young animal must be fed by hand in order to avoid contamination from its mother. When a hand-reared germfree mammal is allowed to reproduce, germfree colonies of that species are obtained. Germfree rats or mice can now be purchased commercially. In this case, the animals are shipped under sterile conditions and then transferred (also under sterile conditions) to an experimental isolator.

Eggs and seeds

Isolator. The isolator, a barrier that prohibits the passage of living micro-organisms, may be small or large, and usually is constructed of glass and steel, or plastic. The physical barrier to contamination may be a flow of sterile air from inside the isolator to the outside; *e.g.*, an air outlet in the isolator. The isolator has a sterile entry for placement of the animal and its food; a source of air with exhaust; and, usually, armlength rubber gloves. Special attachments may include a liquid dip tank, a transfer cage, a bacterial filter for liquids, or a second isolator. Transfers are made aseptically after the entry is sterilized with a dilute peracetic acid fog. The most widely used isolator is a soft plastic sack-like container that is available in many shapes and sizes. A simplified shipping cage for small germfree animals is a large plastic, screw-cap bottle with screening and a glass wool filter at the cap end. Isolators are usually maintained with a slight positive internal pressure. Steel isolators are used if a negative pressure is needed to prevent the escape of pathogenic micro-organisms or viruses inside the isolator. Plastic isolators are designed to surround the equipment needed for an experiment; for a given experiment, a standard commercial isolator can be modified or a special isolator constructed. Convenience and freedom from contamination are important characteristics of isolators.

Sterilization. Sterilization of metal isolators and most utensils is accomplished with steam under pressure. Germicidal vapour sterilization is used for plastic isolators that cannot withstand the heat of steam sterilization. Air filters are usually sterilized with dry heat. Air is sterilized by filtering it through a bed of fine glass wool; electrostatic forces trap particles too small to be stopped by the glass wool. Eggs and seeds are surface sterilized with compounds such as mercuric chloride, peracetic acid, or formalin. Food and water can be sterilized by steam, irradiation, filtration, or chemical agents.

Nutrition. Lack of knowledge about the exact nutritional requirements of specific animals has been the major obstacle to the successful development of germfree animal colonies. Special nourishing formulas, based upon analyses of colostrum and milk, have been used to hand feed rats, mice, guinea pigs, and rabbits removed surgically from their mothers. Once a germfree species has been reared and has reproduced, new strains can be raised by using foster germfree mothers with milk to suckle young animals removed from their mothers under sterile conditions. Germfree hamsters, however, cannot yet be reared either by hand feeding or by cross suckling to another species; apparently they require an unknown nutrient or environmental factor, which has not yet been discovered.

Cross suckling

The diets of germfree animals are generally comparable to those of conventional animals. Extra vitamins are added to the diets of germfree animals to compensate for losses during sterilization procedures and for vitamins originally supplied to the animal by microbial synthesis in the alimentary tract. Fibrous materials are added to diets for germfree rodents and rabbits to help reduce distention of the cecum, a pouch in the large intestine, in these species. Antigen-free diets fed to germfree animals provide a base for immunological studies; such chemically defined diets, which have maintained germfree mice through three generations, provide confirmatory evidence that all the nutrients required by mice are known.

Determination of absence of microbes. Microbiological tests for the presence of living micro-organisms in the germfree animal and its isolator are essential in germfree research. The criterion of germfreeness (*i.e.*, lack of contaminating living micro-organisms) is established by direct examination and exhaustive laboratory tests. In addition, two weeks of data from an organism may be required to establish that a plant or an animal is germfree. Dead micro-organisms or microbial products are permissible in a germfree experiment. Standard microbiological methods are used to detect viruses, rickettsiae, bacteria, fungi, protozoans, worms, and arthropods that could live in intimate association with a germfree host. The experimental base of the germfree concept varies according to the adequacy of methods used to detect viable (*i.e.*, capable of becoming active) organisms intimately associated with the host; for example, the virus-

free status of germfree animals can be questioned since radiation is known to activate viruses in all germfree mice and in some strains of germfree rats.

Inoculation of germ-free animals

Oral inoculation of germfree animals with one or more pure cultures of micro-organisms is used to study host-microbe interrelationships. Although the gnotobiotic animals are no longer germ free when this is done, the methods used to maintain them are comparable to those used for germfree animals. A drop of a uniform suspension of a pure culture of micro-organisms (called an inoculum) usually is placed in the mouth of each germfree animal in an isolator. The drop usually contains between one thousand and one million micro-organisms. If these micro-organisms become established in the alimentary tract (or some other area) of the inoculated animal, it is called a "gnotophoric" animal; *i.e.*, it carries one or more known species of microbes and no other species can be found by microbiological tests.

GENERAL CHARACTERISTICS OF GERMFREE ANIMALS

Appearance. Germfree chickens, turkeys, Japanese quail, guppies, flies, dogs, cats, calves, burros, sheep, pigs, goats, and monkeys are normal in appearance. On the other hand, germfree rodents and rabbits often appear to have an overfull abdomen; this is caused by cecal distension. When reared under conditions in which they remain clean, most germfree animals can be differentiated from conventional animals only by the lack of a characteristic odour in the former.

Classes of organs and tissues

Macroscopic characteristics. Laboratory comparison of gross morphological characteristics of germfree and healthy, non-infected conventional animals reveals five classes of organs and tissues, depending on the type of contact the organ or tissue has with the microflora or its products. First, organs and tissues remote from any physical or chemical activity of external microbes show no gross differences under germfree and conventional conditions. Brain, bone, cartilage, skeletal muscle, most organs, eyes, tongue, nose, lungs, and peripheral vascular system (alimentary tract excluded) have similar gross morphology under germfree and conventional conditions. Organs that act together with defense mechanisms comprise a second group. Liver and heart function, the intestinal vascular system, and perhaps the adrenal glands may be less prominent in germfree animals. The liver detoxifies compounds absorbed from the intestine. Since less blood flows to the liver and there is less inflammation of the intestine in germfree animals, cardiac output also decreases. Tissues that are targets for invasion by micro-organisms, as well as tissues that maintain function and integrity for reasons other than microbial defense are different in subtle ways in germfree animals. Skin, teeth, and mucosa of the respiratory tract, sinuses, pharynx, and gastrointestinal tract, for example, are more complex when they exist in animals containing micro-organisms than they are in germfree animals. These tissues have less blood circulation in germfree animals than in conventional animals. The intestinal wall of a germfree animal is somewhat lighter in weight and colour than that of a conventional animal. The mouth, urogenital tract, and eyelids have yet to be studied extensively. Organs and tissues of the specialized defense systems of the host comprise the fourth class. The lymphatic system (lymph nodes, thymus, spleen, white blood cells) generally is underdeveloped in the germfree animal that has not been stimulated by antigens to form antibodies. In general, the defense systems are very poorly developed in germfree animals. Special features that result from the state of germfreeness, (*i.e.*, the cecal wall of rodents) is the last class of morphological distinctions between germfree and conventional animals.

Although cecal distension is not common in most germfree species, the cecum may constitute up to 25 percent of the body weight of germfree rodents. This physically inert mass causes the animal to be lethargic, reluctant to breed, and susceptible to premature death. Since the weight of the cecal wall does not change, cecal distension is caused primarily by a flabby intestinal wall, in which muscle tone is decreased. Although the addition of fibrous materials to the diet reduces cecal distension in rats and mice, germfree guinea pigs and rabbits are not helped much by the dietary supplement. The compounds that cause the decrease in muscle tone may be decomposed by certain intestinal bacteria; therefore, such compounds, present in greater concentration in germfree animals than in conventional ones, may cause the condition.

Microscopic characteristics. Microscopic examination of the tissues of a germfree animal, particularly the lower intestine and lungs, reveals a lack of inflammation; the clarity of germfree tissues contrasts with the mildly inflammatory digestive and respiratory tissues of conventional animals. Germfree tissues, therefore, are particularly valuable for studying the first lesions produced by a respiratory or an alimentary toxin. Germfree guinea pigs, for example, have been valuable in studying lung lesions caused by air pollution. Microscopic examination of the small intestine shows fewer damaged absorptive surfaces in germfree animals; in addition, the villi (projections that line the small intestine) are more free and uniform, and there is less fibrous tissue in the intestinal wall. Peyer's patches, small lymph nodes associated with the intestinal wall, are reduced in numbers and size in germfree animals.

Functional characteristics. *Defense mechanisms.* A variety of immunological studies can be carried out on germfree animals for several reasons: the lymphatic system is poorly developed, and there is negligible antibody production. The blood of germfree animals has only one third as many white cells as that of conventional animals and few gammaglobulins (blood proteins that include antibodies). No gammaglobulins are present in germfree pigs until they are given antigen to stimulate antibody production. Plasma cells and other defense centres, absent in lymphatic and thymic tissues of germfree guinea pigs, are present in decreased numbers in other species. Since the defense mechanisms can be activated, however, it is known that they are not defective; rather, they act only when they are needed.

Nutrition and growth. Growth rates of most species of germfree animals are equal to, or faster than, those of conventional animals. Nutritional studies have shown that germfree animals use food more efficiently than do conventional animals. Apparently the germfree animal, which uses no energy to defend itself from invasion by undesirable micro-organisms, has more energy available for growth. Intestinal micro-organisms produce some vitamins that are utilized by the conventional animal. Since they lack such microbial synthesis, germfree rats require folic acid, biotin, and vitamin K in their diets. On the other hand, germfree rats may require smaller quantities of amino acids than do conventional rats, suggesting that the intestinal microflora may compete with the host for certain nutrients. Iron salts are poorly absorbed by the intestines of germfree rodents; calcium is more readily absorbed. Germfree mice and rats have more calculi ("stones") in the kidney and bladder than do conventional mice. Dietary antibiotics stimulate growth to a lesser extent in germfree chicks and turkeys than they do in conventional animals; most important in this case is the indirect action of the antibiotics on the intestinal micro-organisms. Germfree animals have more digestive enzymes in the lower digestive tract and excreta than do conventional animals; apparently intestinal bacteria degrade these products in conventional animals.

Reproduction and tumour growth. Germfree mice, rats, rabbits, guinea pigs, chicks, Japanese quail and dogs have reproduced. The average number of young mice at birth and at weaning is high in germfree colonies. With the exception of infections that end in death, both germfree and conventional animals have similar symptoms and pathology in several stress reactions (*e.g.*, radiation sickness, hemorrhagic shock, anal block). Cancer follows a similar route when chemical carcinogens are applied to germfree and conventional animals; tumours sometimes grow faster in germfree animals. Spontaneous tumours are rare in germfree animals; transmissible tumours

(*e.g.*, Bittner mammary tumour) do not occur spontaneously in germfree mice. Temperature, respiratory exchange, and cardiac output may be lower in germfree rats than in conventional ones. Although longevity has not yet been studied systematically, the lifespan of germfree mice appears to be about 25 percent longer than that of conventional mice. Male mice have been shown to survive longer than females.

Gesner, Conrad

A Swiss physician and naturalist, honoured as one of the founders of modern zoology and of bibliography and as a pioneer in both botany and mountaineering, Gesner is best known for his bibliography *Bibliotheca universalis*, which provides a checklist of European authors and their works in Latin, Greek, and Hebrew up to the Renaissance; for his *Historiae animalium*, which summarizes European knowledge and belief in his time of the Earth's animal life; and for his collection of notes and wood engravings on plant life.

Gesner, portrait by an unknown artist, second half of the 16th century. In the Schweizerisches Landesmuseum, Zürich.

Education

Gesner was born in Zürich on March 26, 1516. Noting his learning ability at an early age, his father, an impecunious furrier, placed him for schooling in the household of a great-uncle, who augmented his income by growing and collecting medicinal herbs. There young Conrad acquired a basic knowledge of plants and their medicinal uses that led to a lifelong interest in natural history.

Gesner's progress at school, largely concerned with gaining facility in reading the classic works of Latin and Greek authors, so impressed his teachers that a number of them sponsored his continued education. One acted as his foster father after his own father had been killed in 1531 during one of the many religious conflicts of the times; another fed and sheltered him for three years; and a third saw him through upper school at Strassburg. Together they promoted a scholarship for him to study at Bourges and Paris. Even when Gesner committed what his sponsors considered the fatal mistake at the age of 19 of marrying a young lady who had no dowry, his sponsors did not forsake him but rather found a teaching position for him in Zürich and then managed to persuade the authorities to grant him a leave of absence with pay so that he could undertake formal study of medicine in the city of Basel.

The first fruits of such faith was a Greek–Latin dictionary Gesner published in 1537, having prepared it in his spare time at Basel. At the age of 21, he was appointed professor of Greek at the Lausanne Academy. Three years of teaching brought him enough money for another year of studying medicine, and in 1541 he received his doctoral degree. Gesner spent the rest of his life practicing medicine in Zürich, serving also as a lecturer in Aristotelian physics at the Collegium Carolinum and, after 1554, as city physician.

During the years that followed, he continued to read prodigiously while at the same time, despite his many professional duties and recurring poor health, making field trips, starting a museum, organizing medical instruction, and publishing the 70 or so books that he either wrote or edited.

In an early work, a medical tract on the virtues of milk, *Libellus de lacte et operibus lactariis* (1545), he included a letter to a friend in which he extolled mountains as one of the greatest wonders of nature. This reference and a later account of his scaling of Mt. Pilatus (1555) provide one of the first records of mountain climbing.

In 1545 Gesner published his *Bibliotheca universalis*, the first bibliography of its kind, listing about 1,800 authors alphabetically with the titles of their works, annotations, evaluations, and comments on the nature and merit of each entry.

This monumental reference was followed in 1548 by the encyclopaedic work *Pandectarum sive Partitionum universalium Conradi Gesneri . . . libri xxi*, in which Gesner attempted to survey the recorded knowledge of the world under 21 headings. The first 19 books were published in 1548; the last, devoted to theological thought, was published in 1549, while the 20th, on medicine, was never completed.

Contributions to zoology and botany

Gesner's next monumental achievement was a compendium of recorded knowledge concerning animal life, the *Historiae animalium*, in which he sought to distinguish observed facts from myths and popular errors. The first volume (1551), a generously illustrated work of 1,100 folio pages, dealt with viviparous quadrupeds (four-footed animals that bear living young). Later volumes on oviparous quadrupeds (those that hatch the young from eggs), birds, and fishes and other aquatic animals followed in 1554, 1555, and 1556; the partially completed fifth volume, on serpents, was published posthumously in 1587.

Gesner never completed a similarly comprehensive survey of plant life, but his notes and about 1,500 wood engravings including the important flowers and seeds were used by other authors for two centuries after his death. In his own lifetime, he was best known for his botanical work.

Gesner also published *Mithridates: De differentis linguis* (1555), an account of about 130 then-known languages, and an edition (1556) of the works of the 3rd-century Roman miscellaneous writer Claudius Aelian.

Gesner died on December 13, 1565, from plague contracted during an epidemic in Zürich. By the standards of his time Gesner as a scientist showed good judgment and industry. His use of woodcuts was significant in fixing the accuracy of his data and made possible the eventual emergence of a scientific zoology and botany. His writ-

ings about his mountain excursions further helped to emphasize the importance of the empirical study of nature. Few in his time did so much to comprehend and extend the range of man's knowledge of his natural surroundings.

BIBLIOGRAPHY. Major biographies are: WILLY LEY, *Konrad Gesner* (1929), a summary in German of his life and contributions in zoology, botany, paleontology, and medicine, with a catalog of his publications and a bibliography of source materials; and *Dawn of Zoology* (1968), the most extensive discussion in English on Gesner's place in the history of zoology, with reproductions of his wood engravings of animals and birds; and JOHANNES HANHART, *Conrad Gessner* (1824), the first definitive and still valuable biography (in German), based on materials in the Bibliotheca Carolina and the Collectio Simmleriana in Zürich, the Kirchen-archive von Zürich and Basel, and the Collectio Vadiana in St. Gallen. See also JOSIAS SIMLER, *Vita Conradi Gesneri* (1566), a biography in Latin by the executor of his scientific papers, and a translation of this work into German: DAVID RICHTERN, *Des Welt-berühmten Medici . . .* (1711). Particular aspects of this work are discussed in the following: DIETHELM FRETZ, *Konrad Gessner als Gartner* (1948), based on Zürich records, details his early life in the home of his great-uncle, who was interested in herbal medicine, with a survey of his contributions to botany; J. CHRISTIAN BAY, *Conrad Gesner (1516–65) the Father of Bibliography: An Appreciation* (1916), discusses how Gesner's *Bibliotheca universalis* brought to public attention the existing sources of knowledge, thereby stimulating learning in the Renaissance; SIR WILLIAM JARDINE (ed.), "Memoir of Gesner," *The Naturalist's Library*, vol. 20, pp. 1–58 (1866), cites his contributions to natural history; and J.M. THORINGTON, *On Conrad Gesner* (1937), assesses his contributions to mountaineering, with an English translation of his 1543 letter on mountain climbing, and his account of scaling Mt. Pilatus in the Swiss Alps in 1555.

(G.A.P.)

Geysers and Fumaroles

Geysers and fumaroles are both manifestations of hot springs, which disperse groundwater from the upper parts of the Earth's crust after it has been heated by magma (molten silicate material) and its vapours from below. The thermal energy and part of the material in the hot springs are derived from volcanic activity. As magmas begin to solidify to form crystalline rocks, their gases become concentrated under ever-increasing pressure in the residual, uncrystallized liquid. In the last stages of crystallization, this liquid consists largely of hot water and contains gases and many soluble substances in solution. When the pressure becomes sufficiently high, the liquid is forced into cracks in the surrounding solid rock. If a crack extends upward and opens at the surface, then a fumarole, or a steam vent, is formed. If no surface opening exists, the liquid percolates upward, mixes with groundwater, and eventually emerges as a hot spring, possibly showing geyser action. The distinctions among geysers, fumaroles, and kindred phenomena are as follows:

Geysers (Icelandic *geysir*, from *geysa*, "to rush forth," or *gjósa*, "to gush") are spouting hot springs that throw forth intermittent jets of water and steam. Many hot springs that are not geysers may exhibit periodicity: some show periods of agitation or of violent boiling, and some alternately discharge water and gas. A sharp distinction between geysers and other hot springs cannot always be drawn.

Definitions and interrelationships

Fumaroles are steam vents (Latin *fumus*, "smoke"); the "smoke" is water vapour, the dominant constituent, but acid gases, such as carbon dioxide and hydrogen sulfide, characteristically occur.

Solfataras (Italian *zolfo*, "sulfur") are fumaroles that yield hot vapour and sulfurous gases. The temperature of fumaroles varies widely and in any one fumarole is subject to great variations over time. In the famous Valley of Ten Thousand Smokes, which was formed by the tremendous eruption of the volcano Katmai, Alaska, in 1912, temperatures up to 645° C (1,193° F) were measured. In the dying volcano La Solfatara (or Forum Vulcani) at Pozzuoli, Italy, known from antiquity, the temperature of the steam oscillates between 100° and 165° C (212° and 329° F).

With this group are included the paint pots, porridge pots (Figure 1), and mud volcanoes, all of which are hot springs of limited water supply and acid reaction. Their immediately adjacent surface rocks are undergoing active chemical attack from magmatic steam and acid gases to provide the porridge, whereas the iron content of the rocks provides the paint.

Figure 1: Porridge pots in the Solfatara Crater, Pozzuoli, Italy.

Mofettes (German *Muff*, "musty smell") are vents, issuing carbon dioxide, some methane and other hydrocarbons, nitrogen, and oxygen at low temperature; they mark the last stage of volcanic activity.

The intimate connection between fumaroles and simple hot springs is obvious in areas in which there exists a strong contrast between dry and wet seasons. During the dry season, hot springs are transformed into fumaroles, which in turn, during the wet seasons, become hot springs again. Growler Spring, in Yellowstone National Park, is a good example: its temperature is at a boiling point appropriate to its elevation (93° C or 199° F), but after long-continued dry weather it becomes a fumarole with a temperature of 103° C (217° F). Such seasonal variations indicate that hot-spring waters are derived from groundwater that is heated by magmatic gases and that hot springs are essentially "drowned fumaroles." Recent studies of water chemistry support this view and indicate that all thermal waters are essentially of meteoric (atmospheric) origin. This includes high-temperature fumarolic steam that contains such magmatic matter as sulfates, borates, and arsenates that are not present in the rock through which the water has passed.

Treated in this article are the physical and chemical characteristics of hot-spring waters and their deposits and the nature of geysers and geyser activity. For additional information on magmas and the water in the ground that is heated, see VOLCANOES; IGNEOUS ROCKS; and GROUNDWATER. See also SPRINGS AND WELLS and, for information on the transfer of heat within the earth, EARTH, HEAT FLOW IN.

PHYSICAL AND CHEMICAL CHARACTERISTICS OF HOT SPRINGS

Hot springs are fed by ordinary groundwater heated by magmatic steam. The development of various types of

hot springs, such as fumaroles, acid or alkaline springs, geysers, and tepid pools, is therefore dependent on the groundwater conditions at the locality. Such factors as topography, porosity and other rock properties, and local meteorologic conditions, particularly rainfall, are all important. The development of hot springs requires a source of local volcanic heat.

Water composition. The waters of hot springs fall roughly into three groups: (1) waters carrying calcium carbonate in solution, (2) siliceous acid waters, and (3) siliceous alkaline waters. The acid springs are of low volume and contain hydrochloric or sulfuric acid.

Calcium carbonate (or bicarbonate) lends the water special properties that are easily observed, particularly the ability to precipitate large quantities of travertine, or hard tufa (sedimentary rocks formed by precipitation from springwaters), consisting predominantly of the mineral calcite but also of aragonite, on the surface. Huge terraces of exquisite beauty may develop from this process. In Yellowstone National Park the Mammoth Hot Springs (Figure 2) provide an outstanding example. A unique scenic aspect is the deposit form of cones and basins; the high terraces were deposited along a steep slope by small rushing streams of springwater and now resemble the successive billows of a frozen cataract. In order for this type of springwater to develop, the source water must pass through limestone or other calcite-bearing rocks. In volcanic regions that are underlain by limestone or dolomite, as in Italy and Greece, extensive deposits of travertine are common.

Siliceous water types and their evolution

Siliceous types of springwater form an evolutionary series from acid to alkaline and throw much light on the chemical reactions taking place underground. There is no doubt that steam prevails among the gases given off by a magma. But, in addition, acid gases, such as carbon dioxide and hydrogen sulfide, characteristically occur. If oxygen is available, then sulfur dioxide forms, and the waters carrying the emanations will be highly acid. On the pH scale, a measure of the hydrogen-ion content, which ranges from 1 (extremely acid) to 14 (extremely alkaline), a pH of 7 is neutral, but these waters typically exhibit a pH of 4.

In the early evolutionary stages, hydrogen sulfide in acid solution will effectively precipitate silver, mercury, lead, bismuth, copper, cadmium, arsenic, antimony, and tin supplied by the magma. The acid solutions attack the rock minerals and mix with large quantities of groundwater; thus, they become neutral or alkaline, the pH value increasing from 4 to perhaps 10. The resulting alkaline waters then remove silica in colloidal solution (a very fine grained suspension). Thus, the general relation produced is one of increasing pH values with increasing distance from the mother magma to the place of eruption of a particular spring.

Many elements are precipitated as the solutions become alkaline. Iron and aluminum are the commonest of these elements; they are present only in springwater more acid than that with a pH of about 5. Calcium and magnesium are present in waters with a pH of about 7. Sodium and potassium are not affected by acidity, but sodium is always present in great excess over potassium. Except where there is a surplus of calcium carbonate, the issuing waters thus contain silica in great relative excess over all other rock constituents except sodium. The relative contents of the spring gases also evolve. Hydrogen and hydrogen sulfide in acid waters gradually diminish; they are still less abundant in neutral waters and are completely absent in alkaline waters.

Incrustations and deposits. High-temperature deposits from vapours around acid fumaroles and hot-gas vents are dominantly sal ammoniac. Sulfate-bearing incrustations and efflorescences (mainly of ammonia, magnesium, iron, and aluminum) occur in deposits of somewhat lower temperature, and large amounts of native sulfur and gypsum are deposited around acid hot springs at the boiling temperature. Minor amounts of other sulfates and of pyrite, limonite, and opal also occur.

Siliceous sinter deposits

Siliceous sinter (a variety of opal) is the deposit typically formed by alkaline hot springs. In some areas it comprises extensive deposits of domes, terraces, or flats. The most distinguished example was the great "White Terrace" beside Lake Rotomahana, in New Zealand, which was destroyed in a volcanic eruption in 1886. Alkaline springs are almost always deep and are often distinguished by the brilliant, bluish colouring of the water, which contrasts beautifully with their white sinter deposits. The sinter is white or grayish, scaly to massive, and sometimes porous, filamentous, or cauliflower-like. Chemical analyses show 80–90 percent silica and about 10 percent water; the remainder is mostly aluminum, iron, and small amounts of magnesium, calcium, and sodium.

Rather unusual and related to travertine deposits are small globules of mercury and cinnabar (a mercury sulfide mineral) deposited as coatings on calcareous tufa of some boiling springs in Idaho and California.

Another special occurrence is a salt crust on Lake Magadi, Kenya, which is a natural evaporation pan, fed by four copious hot springs (aggregate flow is about 750 gallons per second). This crust yields 80,000 tons of soda ash and 40,000 tons of salt annually, but the inflow of sodium salts far exceeds the rate of exploitation. Mineral-spring brines are worked at many places in the world.

Hot springs and fumaroles in Larderello, Italy, also have been the subject of considerable attention. Boric acid, ammonium sulfate, and carbon dioxide are recovered.

Discharge and thermal energy. Large amounts of hot groundwater emerge in alkaline hot-spring areas, whereas acid hot springs, solfataras, and fumaroles characteristically occur in drier areas and have a much smaller discharge. Indeed, observations indicate that acid waters make up 1 or 2 percent of the total hot-water discharge in Iceland and in Yellowstone National Park, although the acid-hot-spring areas are more extensive than those of the alkaline springs.

Because of the great porosity of rocks in Iceland, much hot water runs off as overland flow and subsurface discharge to be lost to the sea (Figure 3). Drilling has raised the yield considerably; the surface discharge in low-temperature areas of Iceland amounts to 300 gallons per second, but the additional discharge from drill holes is 400 gallons per second. The surface discharge in Yellowstone National Park is 800 gallons per second, and the total discharge in all of Japan is 4,400 gallons per second.

A conspicuous example of the copious water supply of alkaline springs can be seen at Deildartunguhver, 30 miles north of Reykjavík, Iceland. Cascades of boiling water belch forth from several rents and fissures in a steep wall of hardened boulder clay of red, blue, and yellow colours; they meet to form a steaming river, the

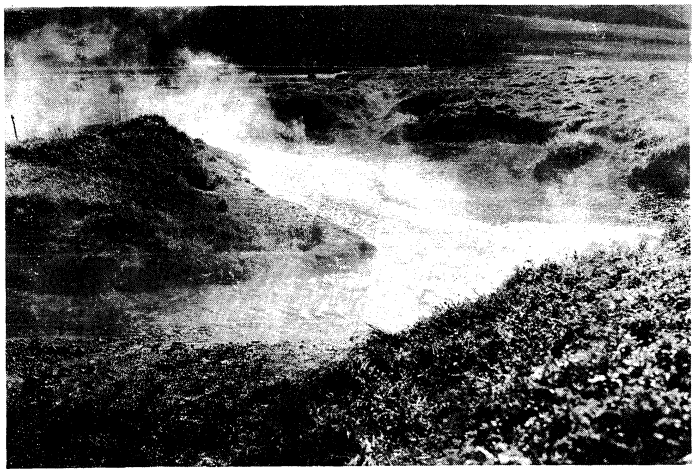

Figure 3: Deildartunguhver River, north of Reykjavík, Iceland.
By courtesy of T.F.W. Barth

largest "boiling river" in the world, yielding approximately 65 gallons per second. The temperature at the place of issue is approximately 99° C (210° F); at the confluence with Reykjadalsá, about 130 yards downstream, the temperature is 82° C (180° F).

Utilization of thermal energy

Although a tremendous amount of heat is released at the surface by the activity of hot springs, the utilization of this energy has been relatively slight.

Thermal energy is used only for home heating, greenhouses, and the drying of such substances as seaweed and diatomaceous earth. Leaky underground chambers and other technical difficulties have restricted the use of the mechanical energy (pressure) of fumaroles and geysers. Only at Larderello, southwest of Florence, have larger energy projects been developed. In 1904 the first generating station operated on natural pressurized steam was installed. Subsequently, a great number of additional borings were made, and the energy output increased from 3,000 kilowatt-hours in 1916 to 2,694,000,000 kilowatt-hours in 1968. This was approximately 2.6 percent of the total energy consumption of Italy in 1968.

Some electricity is generated from wells in the geyser region of Sonoma County, California, and the utilization of hot springs also has been accomplished in New Zealand.

GEYSERS AND GEYSER ACTIVITY

There are three major areas of geyser action in the world: Yellowstone National Park contains at least 200 geysers, or about 10 percent of the total number of hot springs in the park; Iceland has about 30 active geysers, or less than 1 percent of the total number of hot springs; and New Zealand has fewer geysers than Iceland but is famous for having had the greatest one in the world, the Waimangu Geyser, which played daily to heights above 300 metres (1,000 feet) between 1902 and 1905.

True geyser action, one of the rarest phenomena in nature, is one of the most beautiful and conspicuous to behold. Geysir, in Iceland, is the most famous geyser in the world. It was known to science centuries before Waimangu, in New Zealand, had been heard of or before the performances of Old Faithful, in Yellowstone National Park, had been seen by Western men. The behaviour of Geysir had attracted tourists as well as learned men, and the notes and descriptions of this geyser from the 17th century to the present are legion.

Eruption patterns. The magnitudes of geyser eruption range from insignificant (throwing the water a few inches high) to those of famous fountains that playfully attain heights of many hundred feet. Each geyser has its individual performance pattern; some are regular and rhythmical, whereas some are unpredictable. This is because no two geyser edifices and water paths are alike, and the precise causes of eruption cannot always be followed in detail.

Some geysers have negligible discharge, but the larger geysers disperse an amount of water that is many times greater than the volume of their accessible tubes during eruption. One or more storage basins of considerable size are therefore necessary to account for the volume of the visible eruptions. This fact was ascertained for many geysers of Yellowstone National Park and for the Geysir, in Iceland, which in a single 24-hour period (including numerous eruptions) may eject an amount of water equal to at least 100 days' normal or customary discharge.

Discharge and temperature of geysers

Most geysers erupt close to the boiling point, 100° C (212° F) at sea level, and some also will boil between eruptions; others will cool considerably. In the upper part of a geyser vent, the temperature often increases with depth, whereas in the lower part it is constant or decreases. This is a general pattern for all hot springs. Many geysers exhibit very irregular temperature—depth curves, but one important point should be emphasized: boiling temperatures are attained only in the uppermost parts of a geyser system; at greater depths the temperature recedes from the boiling point for that depth.

In Yellowstone National Park, the changing behaviour of geysers is well-known. Contrary to common belief, most geysers do not erupt with regularity, nor are they constant in the intensity of water jets or the heights attained. Even Old Faithful (Figure 4)—which in all tourist brochures during the 1920s and '30s was said to erupt at intervals of precisely one hour and five minutes—when under continuous observation was actually shown to erupt at intervals varying between 30 and 90 minutes. The highest measured eruption, originating in Beehive Geyser, was 67 metres (219 feet). It is possible that the great Excelsior Geyser, active in the 1890s, may have attained greater heights.

Crater Hills Geyser differs in pattern from most geysers: an eruption lasts for about 30 minutes, followed by a quiet interval of only two minutes. In most geysers the eruption period is shorter than the quiet period. There is no discharge, even during an eruption (all water falls back into the basin), and this is another unique characteristic. The eruption starts when the water level in the basin is low, whereas most geysers erupt only when the basin is full. And, finally, the maximum temperature during eruptions in August 1947 was 73° C (163° F); most geysers erupt when their water temperature is close to the boiling point.

Geyser eruptions have been compared to volcanic eruptions. The dimensions are usually different, but, when a

UPI Compix

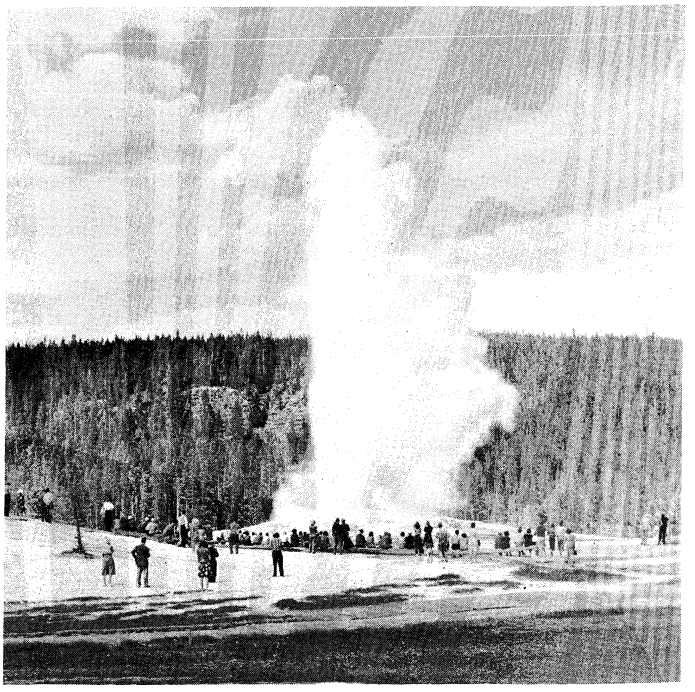

Figure 4: Old Faithful geyser, Yellowstone National Park, Wyoming.

geyser throws steam and water 300 metres (1,000 feet) into the air, it approaches the activity of a small volcano. The peculiar volcano Siretoko-Iô-Zan, in Japan, acts in some ways as if it were a tremendous irregular geyser. After a dormancy of 46 years, it sustained a continuous eruption for several months in 1936, during which it successively developed the following stages: (1) liquid-sulfur eruptions, (2) explosive emissions of hot water and steam, and (3) intermittent gushing of boiling water and steam.

Seawater geysers and *nagawakis*

A geyser spouting seawater, situated at the southwestern tip of Iceland, probably first erupted in 1906 and was said to be an active geyser at flood tide, quiet at ebb. In 1927 it was a true geyser with a regular period of 15 minutes, and the splashes were between three and six metres (ten to 20 feet) high. But in July 1928 the spring underwent a marked change. The period became irregular and, on the average, somewhat longer; after 20 to 25 minutes the water jets became lower. Eventually, the geyser action ceased, and in 1937 the spring became an incessantly boiling pot.

A real geyser, manifestly spouting seawater, is certainly one of the rarest phenomena of the natural world. The former geyser at Atami, Japan, situated 1,000 metres (3,300 feet) from the sea at an altitude of 18 metres (60 feet), is the best example. In many respects it was a peculiar spring. It dispersed diluted seawater, and in 1906 it threw small water jets 0.5 metre (1.5 feet) high, at regular intervals of about five hours. The rhythmic activity was broken by irregularly occurring eruptions, called *nagawaki*, that would go on for 12 hours, discharging large amounts of water and vapour. *Nagawakis* were known to occur at irregular intervals of from one to six months.

Age and history of geysers. Within the three principal geyser regions of the world, clusters of geysers form local areas, and these undoubtedly correspond to situations particularly favourable for geyser action. Although the life of an individual geyser may be ephemeral, geyser areas have persisted for centuries. Hveragerdhi, just east of Reykjavík, Iceland, has been known as a famous geyser area from the earliest historical records (Figure 5),

By courtesy of the Carnegie Institution, Washington, D.C

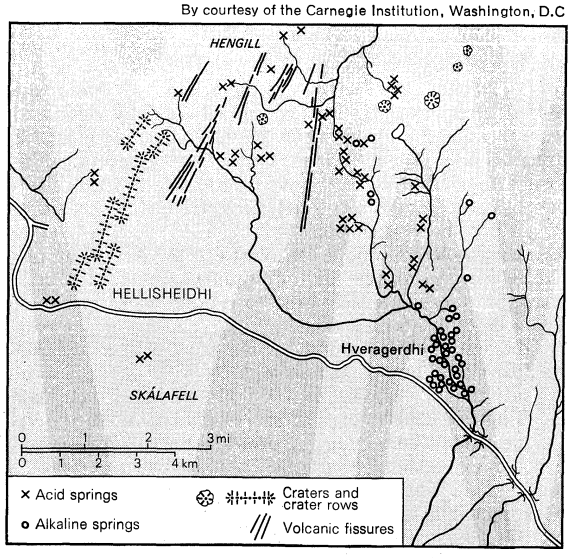

Figure 5: Distribution of hot springs in the Hveragerdhi area, Iceland.

but individual geysers have suffered radical changes; some have ceased spouting and have become ordinary hot springs, and new geysers have replaced the old. When the birth of a geyser was observed here in 1896, it was accompanied by much noise and the rush of great quantities of steam, mixed with dirt, clay, and rock fragments, which were shot 180 to 210 metres (600 to 700 feet) into the air. The force of the geyser decreased very soon, and after two days the jets were only ten feet high. After ten days the geyser activity ceased.

The most famous geyser area in Iceland, first mentioned in 1294, is an extensive plain of silica sinter at Haukadal, about 30 miles east of Reykjavík. About 50 individual hot springs occur here, ten of which are active or dead geysers, among them the Geysir. Steam escapes by seepage over the whole area, and the name Geysir was first applied in 1647; all spouting springs are now called geysers for this reason. The probability ratio of a hot spring being a geyser is low elsewhere in Iceland (less than 1 percent) but is much higher (about 25 percent) within the several local geyser areas.

History of the Icelandic Geysir

The Geysir has been known as a spouting geyser for 350 years, but it may be older. Its orifice is probably several thousand years old. It is surrounded by a regular dome-shaped eminence of silica sinter topped by a flat basin or crater 14 metres (45 feet) wide with a central vent extending about vertically downward. During an eruption, columns of water are shot 45 to 60 metres (150 to 200 feet) into the air. Geysir managed to survive many earthquakes and volcanic eruptions that eliminated several of its competitors and brought radical changes to the entire Haukadal area. Toward the end of the last century, however, Geysir became less active and eventually fell dormant until 1935. At that time, a gap was artificially cut in the lip of the basin, forcing the water level down about three feet. Consequently, Geysir was rejuvenated and began to spout as willingly as before. The gap was later filled, and the water resumed its old, high level; in spite of this, Geysir has continued to spout and still spouts today at irregular intervals. These eruptions last for two or three minutes, after which the spring is quiet for about ten minutes.

The renowned geysers Uxahver and Ystihver, in northern Iceland, also were "improved" by slightly lowering the water table in the vents. At Larderello, Italy, fumaroles and hot springs are numerous over an area of about 250 square kilometres (about 100 square miles). Industrial development that has been in progress for almost a century has completely altered the natural surface and has given rise to artificial pools, steam wells, and so-called geysers. It is regrettable that the modern commercial exploitation in many hot-spring areas severely encroaches on natural conditions.

Theories of geyser activity. Many authorities have endeavoured to determine the special features causing geyser action, but none of the solutions set forth has been altogether convincing. The theory designed specifically to account for the activity of the Geysir is best known, although Littli Geysir, Strokkur, and many other Icelandic geysers are not reconcilable with it. The theory dates from 1846 and is based on the idea that a narrow column of water would, when rapidly heated at the bottom, form a continuously boiling spring. Slower heating from below and the presence of a sufficiently wide column to permit considerable cooling at the surface would result in a temperature distribution that is typical of a geyser before eruption. The temperature, therefore, is thought to gradually increase because of the entering of hot steam from below until boiling temperatures are attained at a depth of 12 to 15 metres (40 to 50 feet); the vapour thus produced reduces the pressure in the geyser's vent and an eruption follows (Figure 6).

Most investigators who have given special thought to the subject of mechanisms have come to the conclusion that this theory, even when limited in its application to Geysir, is unworkable. A closed water circuit is assumed for the geyser models, but in most natural geysers (including Geysir) only a negligible fraction of the erupted water is returned to the basin. The termination of the eruption must also be considered. In addition to postulating that an influx of cool water causes termination of the eruption, convectional cooling in the original theory was thought to prevent boiling from beginning in the central vent, and therefore boiling would have to begin in a side chamber. More recent theorists have stressed the fact that underground chambers serve two main purposes in geyser action: some must contain and, during eruption, contribute much water; others must act as steam chambers wherein the expansion and contractions of steam may cause the fluctuation in surface level noted in

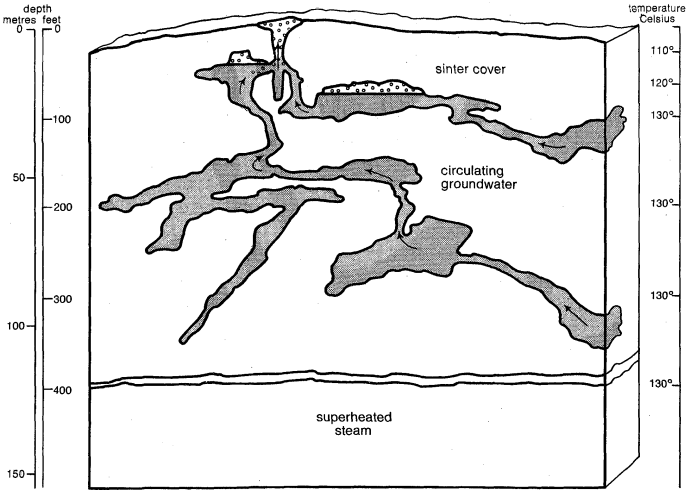

Figure 6: Cross section of geyser substructure.

geysers. Other workers contend that hot-spring waters must of necessity occlude a certain amount of gas (such as nitrogen, argon, and methane), which is carried up with the water to reach a "critical level," at which small bubbles of gas form simultaneously throughout the liquid (like the bubbles that form when a bottle of soda water is uncorked). This is shown in Figure 6, and the location of this level will determine whether geyser action or perpetual spouting ensues.

BIBLIOGRAPHY. Geysers, fumaroles, and hot springs are fed by magmatic heat and are therefore spatially connected with the active volcanic belts on the continents and on the sea floors. The world distribution of these springs with data on the salient properties and mode of occurrence has been compiled in an impressive publication by G.A. WARING, "Thermal Springs of the United States and Other Countries of the World," *Prof. Pap. U.S. Geol. Surv. 492*, rev. by R.R. BLANKENSHIP and R. BENTALL (1965). A summary report on thermal waters of the world was edited by G. KACURA, *Mineral and Thermal Waters of the World*, 2 vol. (1968), the proceedings of the 2nd Symposium of the 23rd International Geological Congress; and E.T. ALLEN and A.L. DAY published a most illuminating study in *Hot Springs of the Yellowstone National Park* (1935). A similar monograph exists on the springs of Iceland: T.F.W. BARTH, *Volcanic Geology, Hot Springs and Geysers of Iceland* (1950); and an interesting account of the Valley of Ten Thousand Smokes was provided by E.G. ZIES, "The Fumarolic Incrustations in the Valley of Ten Thousand Smokes," *Tech. Pap. Natn. Geog. Soc.*, Katmai series, vol. 1, no. 3 (1924).

(T.F.W.B.)

Ghana

Ghana is a West African republic situated on the coast of the Gulf of Guinea. It has an area of 92,100 square miles (238,539 square kilometres), and, in the early 1970s, a population of 8,500,000. Although relatively small in area and population, Ghana is among the leading countries of Africa, partly because of its considerable natural wealth, and partly because it was the first black African country south of the Sahara to achieve independence from colonial rule.

Ghana, which achieved independence on March 6, 1957, consists of the former British colony of the Gold Coast, and the part of Togoland that was formerly a United Nations Trust Territory under British administration. It is bordered on the west by the Ivory Coast, on the northwest and north by Upper Volta, on the east by Togo, and on the south by the Atlantic Ocean.

The economy is dominated by the cocoa crop, of which the country is the world's largest exporter; other important exports are diamonds, gold, manganese, bauxite, and timber. After a slow start, industrialization in the decade of the 1970s was beginning to loom as a feature in the economy. Ample electricity is available from a large hydroelectric project on the Volta River at Akosombo. The capital is Accra (see city article ACCRA). An associated physical feature may be found under VOLTA RIVER; and historical aspects may be found under WEST AFRICA, HISTORY OF.

PHYSICAL AND NATURAL FEATURES

Relief. Relief throughout Ghana is generally low, with altitudes nowhere exceeding 3,000 feet. The southwestern, northwestern, and extreme northern parts of the country consist of a dissected peneplain—a land surface worn down by erosion to a nearly flat plain, later cut by erosion into hills and valleys or into flat uplands separated by valleys; it is made of Precambrian rocks (from 570,000,000 to 4,600,000,000 years old). Most of the remainder of the country consists of Paleozoic deposits (*i.e.*, from 225,000,000 to 570,000,000 years old), which are thought to rest on older rocks. The Paleozoic sediments are composed mostly of beds of shales (laminated sediments consisting mostly of particles of clay) and sandstones in which strata of limestone occur in places. They occupy a large area, known as the Voltaian Basin, in the north central part of the country where the altitude rarely exceeds 500 feet. Along the north and south, and to some extent along the west, the uplifted edges of the basin give rise to narrow plateaus between 1,000 and 2,000 feet high, bordered by impressive scarps. The most outstanding of these are the Kwahu Scarp in the south and the Gambaga Scarp in the north. The Voltaian Basin

Surrounding the basin on all of its sides, except in the east, is the dissected Precambrian peneplain, which rises to elevations of 500 to 1,000 feet above sea level and contains several distinct ranges as high as 2,000 feet.

Along the eastern edge of the Voltaian Basin, and extending from the Togo border to the sea immediately west of Accra, is a narrow zone of folded Precambrian rocks running northeast to southwest, forming the scenically attractive Akwapim-Togo Ranges, which vary in height from 1,000 to 3,000 feet. Here are found the highest points in Ghana, including Mt. Afadjato (2,905 feet), Mt. Djebobo (2,873 feet), and Mt. Torogbani (2,862 feet), all of them situated east of the Volta River near the Togo border. These ranges are part of the Togo-Atakora Mountains, which extend northward into Togo and Dahomey.

The southeast corner of the country, between the Akwapim-Togo Ranges and the sea, consists of the gently rolling Accra Plains, which are underlain by some of the oldest Precambrian rocks known—mostly gneisses (coarse-grained rocks in which bands containing granular minerals alternate with bands containing micaceous minerals); in places they rise above the surface to form inselbergs (prominent steep-sided hills left after erosion), which dot the plains. Only in the wide, lagoon-fringed delta of the Volta, about 50 miles east of Accra, and in the extreme southwest of the country, along the Axim coast, are there extensive areas of young rocks less than 136,000,000 years old.

In the east, the predominant rocks are less than 65,000,000 years old, though there is a patch of Cretaceous sediments (from 65,000,000 to 136,000,000 years old) near the Ghana-Togo border. In the western part of the country, near the Ivory Coast frontier, west of Axim, the rocks date to the Cretaceous Period. The intervening coastal zone between eastern and western extremes contains scattered patches of Devonian sediments (from 345,000,000 to 395,000,000 years old). In combination with the older and more resistant rocks of the Precambrian peneplain, these form a low but picturesque coastline of sandy bays and rocky promontories.

The drainage system is dominated by the Volta River Basin, which includes the artificially created Lake Volta. Most of the other rivers, such as the Pra, the Ankobra, the Tano, and a number of smaller ones, flow directly south into the sea from the watershed formed by the Kwahu Plateau, which separates them from the Volta drainage system. South of Kumasi, in the south central part of the country, is Ghana's only true natural lake—Bosumtwi—lying in a deep basin without any outlet to the sea. It is believed to be of volcanic origin, although theories of a possible meteorite origin have also been ad- The rivers

vanced. Along the coast are numerous lagoons, most of them formed at the mouths of small streams.

Over much of the surface of Ghana, the rocks are weathered, and great spreads of laterite (red, leached, iron-bearing soil) and lesser spreads of bauxite and manganese are found on the flat tops of hills and mountains. Although the movements of the earth's crust that produced the basic geological structure of the country have now virtually ceased, periodic earthquakes are still experienced, especially in the immediate vicinity of Accra along the eastern foot of the Akwapim-Togo Ranges.

Climate, soils, and vegetation. Ghana's climate, like that of the rest of the Guinea coast, is mainly determined by the interplay between the tropical continental air mass, known as the harmattan, which consists of hot, dry, dust-laden air moving from the northeast across the Sahara, and the tropical maritime air mass known as the monsoon, which consists of moist and relatively cool air moving from the southwest across the southern Atlantic. The zone where these two air masses converge is characterized by seasonal line squall rainfall. The convergence zone itself oscillates north and south, following the seasonal movement of the sun overhead; it reaches its most northerly position in the central Sahara, about latitude 21° N, in August, and its most southerly position about 7° N, a few miles north of the Ghana coastline, in January. Rains occur when the dominant air mass is monsoonal (*i.e.*, characterized by rain-bearing winds), while drought prevails when the harmattan dominates.

Rainfall and temperature

In the savanna (grassy parkland) country north of the Kwahu Plateau, the year consists of two seasons—a dry season from November to March, with hot days and cool nights under clear skies, and a wet season that reaches its peak in August and September. The mean annual rainfall ranges between 45 and 50 inches, but there is a marked moisture deficit because of the long and intensely dry season that follows. In the southern forest country, where the annual mean rainfall from north to south has an approximate range of 50 to 86 inches, there are two rainy seasons—one from April to July and a lesser one from September to November—separated by two relatively dry periods that occur during the harmattan season, from December to February, and in August, which is a cool, misty month along the coast. In the Accra Plains, anomalously low annual mean rainfall figures vary between 40 inches to less than 30 inches, and the rainfall variability and the vegetation both bear close resemblance to conditions in the northern savanna zone.

In contrast to the rainfall, temperatures show much more regional uniformity. The annual mean temperature is from 78° to 84° F (26° to 29° C), and the daily range only some 10° to 15° F (6° to 8° C) along the coast, and some 13° to 30° F (7° to 17° C) in the north. Relative humidities range from nearly 100 percent in the south to 65 percent in the north, although during the harmattan season figures as low as 12 percent have been recorded in the north and around Accra. Enervating conditions produced locally by the combination of high temperatures and high humidities are considerably moderated by altitude in the higher parts and by regular land and sea breezes along the coast. In general, the hottest months are February and March, just before the rains, and the lowest temperatures occur in January or—along the coast—in August.

Although soils and biotic factors (*i.e.*, those pertaining to living organisms, including man) are important, vegetation is primarily determined by rainfall. There are three principal types of vegetation from south to north occurring in the coastal savanna, in the forest zone, and in the northern savanna zone.

The coastal savanna in the southeastern plains around Accra consists of a mixture of scrub and tall grass (mostly Guinea grass), with giant anthills, often ten to 14 feet high, forming a prominent feature of the landscape and providing an anchorage for thicket clumps that often include *Elaeophorbia* (a fleshy-leaved plant containing caustic latex) and other drought and fire-resistant species.

In the forest zone (the southern third of the country and the area along the Akwapim-Togo Ranges, where the mean annual rainfall exceeds 45 inches and is well distributed throughout the year without a pronounced dry season), the predominant vegetation is evergreen and tropical semideciduous forest. Here are tall trees of varying heights, forming a closed canopy at the top, above which tower a few forest giants, such as the silk cotton tree, the wawa tree (African whitewood, a hardwood), and the African mahogany. The evergreen forest is in the extreme southwest, where the rainfall exceeds 65 inches a year, while there is a semideciduous forest further north.

The forest zone

The dense forest zone covered an area of 30,000 square miles until farming activities and timber exploitation reduced it to about 10,000 square miles, including about 6,000 square miles of forest reserves.

The third vegetation type, the northern savanna, is found in the northern two-thirds of the country, where the low annual rainfall, between 45 and 30 inches, occurs in a single season and is followed by a period of intense drought. Here, the vegetation consists mostly of tall Guinea grass, together with a scattering of low trees, such as the shea butter tree, and various species of acacia. Along the northern border the Guinea savanna gives way to a more open type of grassland that has developed largely as a result of prolonged human interference with the natural vegetation pattern.

Types of soil

There is a close relationship between the major soil types and the broad geological, climatic, and vegetational features. Topography also plays an important local role. Throughout the country, weathering, leaching, and the formation of hard pans (hard impervious layers, composed chiefly of clay cemented by relatively insoluble materials), by capillary movement (the movement of water containing mineral salts to the surface) and evaporation, are common processes that vary in importance according to the characteristics of each locality. Leaching is more pronounced in the wet south, while the formation of hard pans and laterite is most widespread in the drier north. In general, most soils are formed in place from parent rock material, which has been subjected to prolonged denudation and consequently has limited fertility.

In the forest zone the soils are mostly lateritic, ranging in colour from reddish brown to orange brown. They are subdivided into relatively fertile and less acidic ochrosols (red, brown, and yellow-brown, relatively well-drained soils) in areas of moderate rainfall and into more highly acidic and less fertile oxysols in the extreme southwest, where the annual rainfall exceeds 65 inches. Ochrosols also occur over considerable areas within the coastal and northern savanna zones. As in the forest zone, they provide the best soils for agriculture.

The varied geology of the coastal savanna zone is reflected in an abundance of soil types, including tropical black earths, tropical gray earths, acid vleisols, and sodium vleisols. Except for the tropical black earths, known locally as Akuse clays, most of these soils are of little importance agriculturally. The Akuse clays fill a broad zone across the coastal savanna plains; although heavy and intractable, they respond well to cropping under irrigation and mechanical cultivation.

Because of their intrinsic poverty in nutrients, most of the soils are heavily dependent upon the humus supplied by the vegetation cover. There is, thus, a delicate balance between vegetation and soil fertility, which may be upset by uncontrolled burning, or overuse.

Animal life. Although it has been depleted by too much hunting and the spread of human settlement, Ghana is still comparatively rich in animal life. The large mammals include lions, leopards, hyenas, antelope, elephants, buffalo, wild hogs, chimpanzees, and many kinds of monkeys, including the black and white *Colobus* monkeys. Among the snakes are pythons, cobras, horned and puff adders, and green mambas. Crocodiles and the diminishing remnants of manatees (large water animals characterized by two flippers and a spoon-shaped tail) and otters are found in the rivers and lagoons. Hippopotamuses are found in the Volta River. There are many varieties of lizards and tortoises and giant snails.

Among the numerous birds are parrots, hornbills, kingfishers, eagles, kites, herons, cuckoos, nightjars, sunbirds, doves, pigeons, egrets, swallows, vultures, snakebirds, and plantain eaters.

Fish and other aquatic life

The adjacent ocean, the rivers, and the inland lakes are rich in fish and other forms of life. Herring in large shoals arrive seasonally in the coastal waters; other fish include mackerel, soles, skates, mullet, bonitos, flying fish, lungfish, elephant fish, sea bream, and sharks. Edible turtles, barracuda, and stingrays are fairly common, mussels and several varieties of crabs, lobsters, and prawns also are found.

Insect life is particularly abundant. There are beetles, fireflies, ants, termites, butterflies, crickets, and bugs. Among the most dangerous insects are mosquitoes, tsetse flies, and simuliids (biting flies), which are responsible for transmitting the endemic diseases of malaria and yellow fever, trypanosomiasis (sleeping sickness), and onchocerciasis (a parasitic disease), respectively.

The Mole Game Reserve in the western part of the Northern Region is 1,500 square miles in extent; other reserves are planned further south, notably on some of the islands in Lake Volta.

Traditional regions. Ghana falls naturally into three major regions, the boundaries of which are not always clearly defined.

The coastal zone. Apart from the urban centres, which are found here more frequently than in any other region, the coastal zone is traditionally a region of fishermen and small-scale food farmers. The region is occupied by a series of small kingdoms the inhabitants of which were the first to be exposed to European contact—from the 15th century onward, perhaps even earlier. From east to west, the principal ethnic groups are the Ewes, the Adangmes (Adangbes), the Gas, the Effutus, the Fantis, the Ahantas, and the Nzimas. While it is difficult to speak of any cultural cohesion embracing the whole region, the seaboard has made the region an important centre for commerce, causing population concentration exemplified by such urban centres as Accra, Cape Coast, Sekondi-Takoradi, and the new port and industrial town of Tema, a few miles east of Accra.

The forest zone. Further inland, occupying about a third of the country, is the forest region with its relatively large and prosperous traditional states and rich agricultural lands. West of the Volta these states consist mostly of Akan peoples; to the east the Ewes predominate. The forest environment and the economic activities and modes of life engendered by it, especially since the introduction of cocoa farming in 1879, have served to give the region a common stamp. Apart from the Ewes, the major ethnic groups are the Akwapims and Kwahus in the east, the Akims in the south, the Ashantis and Brongs in the centre and north, and the Wassaws and Sefwis in the west. While all of these peoples have a relatively long history of settlement and political activity to their credit, those with the most impressive record are the Ashantis, who, from the 17th to late 19th centuries, built up a large political empire centred on Kumasi, the present Ashanti capital, that included a large number of subject and satellite states spread throughout the region and in both the coastal and northern savanna zones.

The Ashantis

Practically all the timber, cocoa, and exploited mineral wealth of the country, as well as a number of minor cash crops grown for export, and a large proportion of the foodstuffs consumed in Ghana are derived from this one region. Population density is relatively high, amounting to an average of 50 to 200 persons per square mile, particularly in the cocoa-growing areas. Except for Kumasi, there are few really large urban centres.

The northern savanna zone. This region covers approximately two-thirds of the country but is economically the most backward and neglected. The largest ethnic groupings are the Dagombas, Gonjas, and Mossi (Moshis). The region has a harsh environment because of its low rainfall. The period of drought is known as the "hungry season." The southern part immediately adjoining the forest zone, forming part of the disease-ridden "middle belt" of West Africa that combines the worst features of the forest and the savanna environments, is especially unattractive for settlement. In the past it was also subject to extensive slave raiding, from both north and south. Its distance from the sea and consequent insulation from active European contact over a long period retarded the development of the northern region.

Among the advantages of the northern region, especially in the most northerly part, which is relatively free from the tsetse fly so deadly to cattle, is an extensive savanna vegetation that offers excellent prospects for livestock breeding. Its relatively light soils and the rainfall regime favour the cultivation of both yams and cereals. Although agriculture is mostly of the traditional subsistence type, irrigation and mechanized cultivation have opened up new prospects. The recently created Lake Volta extends far into the heart of the region and offers prospects for comparatively cheap communication with the south, as well as a reservoir of water for agricultural and other uses.

Population distribution is uneven, but average densities are generally low—*i.e.*, under 50 persons per square mile. In the Mamprusi area in the extreme northeast, however, where instead of compact villages the settlements consist of compound houses set amid their fields, densities of more than 200 persons to the square mile are found. Urban life is not well developed.

The landscape under human settlement. *Rural settlement.* Ghana's population is predominantly rural. In 1970 only 28 percent of the population lived in settlements of 5,000 or more, the remaining 72 percent being spread over a large number of small rural settlements, mostly with populations of under 1,000. Almost everywhere agriculture is extensive, rather than intensive, and the rural settlements form isolated nuclei surrounded by land that is either under crops or is undergoing regeneration.

The pattern of settlement

The only true examples of permanent or continuous cropping are to be found in the extreme northeast, where settlements consist of isolated compound houses, each surrounded by its own farm. Elsewhere, agriculture is based on rotational farming, a system in which land is cropped for two or three years and then abandoned for from four to seven years, in order to regenerate. When cocoa or other tree crops are grown, however, cultivation is usually permanent.

Urban settlement. Although many of the existing urban centres are expanding rapidly in size and population, they remain small by world standards. The Accra-Tema municipality, largest in the country, has a population of over 735,000, followed by Kumasi with about 350,000, and Sekondi-Takoradi with over 220,000 inhabitants.

PEOPLE AND POPULATION

Groups historically associated with the contemporary country. *Ethnic and linguistic groups.* Ethnically, the people of Ghana may be said to belong to the one broad group within the Negro family, but there is a large variety of tribal, or subethnic, units. On the basis of language, it is possible to distinguish at least 75 different tribes. Many of these, however, are very small, and only ten of them consist of more than 1 percent of the total population. The largest of these are the Akan, Mole-Dagbani, Ewe, and Ga-Adangme (Ga-Adangbe). Fortunately for Ghana, despite its tribal variety, no serious tribal divisions and animosities have asserted themselves since the country became independent in 1957, although tribal consciousness still persists in many quarters. At all levels in government and in public life, a conscious effort is made to play down tribal differences, a policy that has been helped in no small measure by the adoption of English as the country's official language.

The largest tribal groups

Religious groups. The main religions in Ghana are the indigenous religions of the various tribes, Christianity, and Islām. Although the indigenous religions are widespread and deep-rooted, they are completely lacking in any systematic body of doctrines, and are only vaguely conceptualized. Though they are based, in general, on belief in the existence of a supreme being, a number of lesser deities associated with various natural phenomena

Population density of Ghana.

are also recognized. Considerable prominence is given to dead ancestors, who are considered to be ever present, capable of influencing the course of events for the living, and capable of serving as intermediaries between the living and the divinities.

Over the years, Christianity has steadily gained ground at the expense of the indigenous religions. Christian influence is most dominant in the southern part of the country, while Islām is strongest in the extreme north and in the larger urban centres, which contain some immigrant populations from Muslim regions of West Africa. Since the 1950s a large number of spiritual churches claiming adherence to Christianity have appeared, but the main divisions of the Christian Church remain: Roman Catholics, who constitute more than 14 percent of the adult population; Methodists (10 percent); Presbyterians (just under 10 percent); Anglicans (less than 3 percent), and other smaller denominations (less than 7 percent). Islām is adhered to by about 12 percent of the adult population and 38 percent adheres to the traditional religions.

Demography. On the basis of the 1970 census, the population is generally taken to be about 8,500,000, and to be increasing at the very high rate of between 2.4 and 3 percent a year. Detailed analyses of the 1970 census are not yet available, so that the following analysis is based on 1960 figures.

With an average population density of 100 persons to the square mile, Ghana is still far from overcrowded, although there is concern for the future because of the relationship between available resources and the rapid population growth.

In 1960, when the population was about 6,700,000, there was a slight excess of males over females, due to an immigrant population of more than 800,000. Despite governmental measures to control immigration, Ghana still attracts immigrants, especially from Upper Volta, Togo, and Nigeria.

A striking characteristic is the youthfulness of the population as a whole. In 1960 about 12 percent of the entire population were 45 years old or above, and 44 percent were under 15 years old. Thanks to medical facilities and advances in medicine, life expectancy has increased in recent years; the average life expectancy is now 48 years, which in 1921 was perhaps about 28 years, and the figure is generally higher than this in the urban centres of the south. Although infant mortality rates are high, the ratio of survival among children is increasing.

Life expectancy

THE NATIONAL ECONOMY

A comparative view. Despite the economic difficulties it is now facing, Ghana is still one of the richest and most developed countries in tropical Africa. In 1968 the per capita income was $238, the fourth highest in tropical Africa. There has, however, been little substantial change in the pattern of the economy since independence was attained in 1957. Exports are still dominated by primary raw materials, both mineral and agricultural, while the bulk of imports consist of manufactured and capital goods. In recent years, however, attempts have been made to broaden the basis of agricultural exports, and local manufacturing industry for the domestic market is gradually coming into prominence. The completion of the Volta hydroelectric project in the 1960s also added a significant new factor to economic life.

Natural resources. *Mineral resources.* While Ghana possesses a wide range of minerals, only a few, namely gold, diamonds, manganese and bauxite—in that order of importance—are exploited. These are found mostly in the southern part of the country. The gold industry, with an unbroken history going back 500 years, is the oldest; the others are of more recent origin—the working of manganese dating from 1915, diamonds from 1919, and bauxite from 1942. Recently, reasonable promising reserves of iron ore and limestone have been located, and

in 1970 oil was discovered by offshore prospecting between Saltpond and Cape Coast. Although this discovery was initially classified as noncommercial, the steep world oil price increases of 1973–74 caused the Ghanaian government to reclassify it as commercial in 1974 and to undertake development. In that year there were discoveries of substantial amounts of natural gas offshore to the south and west of Cape Three Points. Although neither of these developments was expected to improve Ghana's energy situation or balance of payments substantially, they did lead to a revival of exploration activity in the mid-1970s. Salt is obtained from the sea and lagoons.

The mining industry

During the 1960s there was a general decline in the mining industry, and the possibility of further discoveries or exploitation of gold, diamonds, and manganese was thought to be unpromising. During the 1970s, however, increased world market prices for gold and manganese, new discoveries in the Prestea goldfields, and the formation of a National Manganese Corporation in 1975 to carry out a five-year plan to rehabilitate the manganese mines at Nsuta all combined to improve prospects for these metals. Bauxite reserves amount to more than 300,000,000 tons, though the output, all of which is exported, is only about 400,000 tons a year. A giant aluminum smelter, completed at Tema in 1966, relies entirely on imported alumina, although the use of bauxite found nearby, at Kibi, for conversion into alumina to feed the smelter is under development. There are also extensive supplies of building stone, gravel, and sand. High-quality sand in the Tarkwa mining area provides the basis for a small but important glass industry. Cement factories have been developed at Tema and Takoradi.

Biological resources. Biological resources, unlike mineral, are not finite. Soil and climatic conditions favour a wide range of crops. By far the most important of these is cocoa, of which Ghana is the leading world producer. Maize (corn) is gradually becoming an important cash crop and in 1975–76 was exported to Mali, Somalia, Upper Volta, and Togo. Other agricultural products that are exported are kola nuts, copra, lime juice, palm oil and kernels, rubber, and bananas.

Timber and the crops of the forest zone constitute additional important biological resources. Yams and such cereals as rice and millet are produced primarily in the northern savannah zone; cattle are also raised there. Ghana's offshore waters are rich in fish, and the creation of Lake Volta added another important source of fish for the domestic market. The various types of fish caught include cape hake, grunt, sea bream, tilapia, herring, mackerel, barracuda, and tuna. Most of the catch is sun-dried or smoked and is consumed locally. Government and private research agencies are carrying out a project designed to increase the cash income of rural fishing communities and also to modernize processing, distribution, and marketing of the catch. Game is another source of protein.

Hydroelectric resources. Apart from offshore oil, Ghana's only sources of power lie in the hydroelectric potential of its rivers, many of which have the requisite regimes and rates of flow to permit exploitation. The

The Akosombo Dam

Akosombo Dam on the Volta River has a total generating capacity of 768,000 kilowatts, which is to be augmented by the construction of an additional dam a few miles downstream at Kpong. Plans exist for the construction of another dam at Bui on the Black Volta, a short distance above the head of Lake Volta, for the generation of a further 190,000 kilowatts. Electricity from Akosombo, however, meets all of the domestic and industrial requirements, leaving a surplus for sale to Togo and Dahomey. Half the power from Akosombo is consumed by the aluminum smelter at Tema; the rest is distributed throughout southern Ghana by a grid.

Sources of national income. National income is derived primarily from agricultural and mineral output and only to a limited extent from manufacturing and services. Most of the agricultural and mineral products are for export.

Agriculture, forestry, and fishing. Apart from providing the bulk of national income, agriculture, forestry, and fishing constitute the preponderant occupations, involving about 60 percent of the population. The annual output of cocoa is around 400,000 tons, making Ghana the world's leading producer; cocoa provides about half of the country's total revenue from exports. Cocoa is of such vital importance that the world price paid for the crop directly determines Ghana's economic fortunes. Predictions that Ghana's cocoa industry would be second to that of the Ivory Coast by the mid-1980s led the government to undertake programs intended to assure its continued leadership; these included cultivation of virgin areas in Brong-Ahafo and Western regions, rehabilitation of farms withdrawn from production, and research into disease control at the Cocoa Research Institute.

Cocoa exports

Timber is also an important foreign exchange earner (9 to 17 percent of export value in the 1970s). Ghana's timber marketing is controlled by the Ghana Timber Marketing Board. From the beginning of 1973 all foreign-owned timber export firms were required to incorporate locally, so that the purchasing of timber is conducted only through the Ghana Timber Marketing Board.

The importance of the Ghanaian domestic market should not be underestimated; the value of food produced for local consumption is very considerable, as is that of fish, both marine and freshwater.

Mining and quarrying. As mentioned above, the four principal minerals extracted are gold, diamonds, manganese, and bauxite; these account for a considerable part of the country's export earnings.

Manufacturing. A policy of industrialization has resulted in the establishment of a wide range of manufacturing industries, producing food products, beverages, tobacco, textiles, clothes, footwear, timber and wood products, chemicals and pharmaceuticals, and metals, including steel and steel products. These are produced mostly for local consumption. Among the announced program directives of the five-year plan begun in 1975, however, was the maintenance of a reasonable balance on external trade, and certain major industrial projects under way in the mid-1970s were directed to the export market in either the short or long term. These included an expansion of the Aboso glass factory, to be completed by 1978; reactivation in 1976 of a large prefabricated concrete panel factory in Accra; and construction of an asphalt plant at the Tema oil refinery utilizing residual products of the plant's operations.

Management of the economy. *Private and public sectors.* The economy is a mixture of private and public enterprise. Before independence the government's role was confined mainly to the provision of such basic utilities as water, electricity, railways, roads, and postal services. Agriculture, commerce, banking, and such industry as existed were almost wholly in private hands, with foreign companies and interests controlling the greater share in all of them except agriculture.

Shortly after independence, the government set out to extend its control over the economy by setting up a large number of state-owned enterprises in both agriculture and industry. At the same time, in order to make up for the local shortage of capital and entrepreneurial skills, various measures were adopted to attract foreign investors operating either wholly on their own or in partnership with the government. These policies did not achieve the desired results because of poor planning and corrupt administration, and by the time the administration of Pres. Kwame Nkrumah (*q.v.*) was overthrown, in 1966, the crippling weight of the heavy overseas borrowing upon which the government had relied for the realization of its ambitious economic programs had succeeded not only in dissipating practically the whole of the country's overseas reserves but also in saddling the economy with external and internal debts totalling some $1,000,000,000.

One of the first concerns of governments since that time has been the rehabilitation of the economy. They have sought to deal with the adverse balance of payments, to arrest inflation, to secure a rescheduling of overseas debts, to increase agricultural productivity, and to establish industrial development on a rational basis,

as well as to save scarce foreign exchange by encouraging exports of locally manufactured goods.

Between 1966 and 1972 there was a marked contraction in governmental involvement in economic matters. The government continued to provide basic utilities, however, and remained the largest single employer of labour. After the military coup of 1972, policy makers returned to the concept of a centralized economy. The considerable debt owed to four British companies was repudiated, imports were cut, industrial projects abandoned after the fall of Nkrumah were resuscitated, and a policy of increased nationalization and state control was begun.

Taxation. A large proportion of government revenue is derived from taxation, levied in a variety of forms, including a duty on cocoa, import duty, customs and excise duties, sales tax, income tax, and a number of other taxes. Tax concessions are available to businessmen. A surcharge on many imports, including the processed and semi-processed raw material on which many local industries depend, was introduced.

Tourism. Revenue from tourism is gradually on the increase, with most of the tourists coming from the United States, United Kingdom, West Germany, Canada, Nigeria, Upper Volta, and Ivory Coast. The government has established two bodies—the Ghana Tourist Control Board and Ghana Tourist Development Company—for the regulation, financing, and development of the tourist industry. Hotels are located at Accra, Tema, Takoradi, and Kumasi, and there is a hotel at Akosombo overlooking Lake Volta. Construction of a resort complex, including a large hotel, at Ada, a coastal town about 60 miles (100 kilometres) east of Accra, began.

Trade unions. The trade-union movement played a role in the struggle for self-government, and after independence the government, no doubt recognizing the importance of the movement as a political force, sought to make it a more direct instrument of policy. All trade unions in the country were brought under the authority of the Trade Union Congress, which was virtually an integral part of the government; this development curtailed the freedom of workers to bargain with employers in general and with the government in particular. After the fall of the Nkrumah government, the monopoly of the Trade Union Congress was abolished and other unions were able to function. In 1972, however, restrictions were again placed on labour activity.

TRANSPORTATION

The principal means of transport, in order of importance, are motor vehicles, railways, and aircraft. Animals are scarcely used except in the extreme north, where horses and donkeys are sometimes employed. Ghanaians are inveterate travellers, and all available forms of transport are well patronized for social as well as business purposes.

Roads and railways. The density of roads and railways is much greater in the southern part of the country than in the north, and even in the south the cocoa-growing areas and the coastal zone tend to be favoured at the expense of other parts. It has been estimated that a combined road and rail network at least 30,000 miles in length is needed to ensure that, on the average, no place will be more than three miles from a road or railway. The country has around two-thirds of that mileage.

Rail transport

Rail transport was introduced in the early 20th century, but only a small part of the country is served by it. The rail system forms a triangle joining Sekondi-Takoradi, Kumasi, and Accra; in addition, a central line runs from Huni Valley, on the Takoradi–Kumasi line, to Kade in the centre of the triangle, and an extension joins Achiasi on this central line with Kotoku on the Accra–Kumasi line. The port of Tema is also linked to the system by a short extension running from Achimota, near Accra. The Takoradi–Kumasi line is also joined by two other branch lines, one running from Tarkwa out to the gold-mining town of Prestea and the other running from Dunkwa to the bauxite-mining town of Awaso.

Apart from the fact that its length is limited, rail transport is much less popular than road transport; railways are primarily used for the transport of freight, especially minerals and logs, although even this declined after the introduction of heavy motor transport.

The road system

Motor transport, now widespread and popular, was introduced in the towns about 1912 and spread quickly to the cocoa-producing areas. While the railways are owned by the state, motor transport is almost entirely in private hands; the state's activities are confined to municipal bus services and express coach and freight haulage services between the larger towns.

Road quality ranges from first-class paved (asphalt-surfaced) roads to third-class unsurfaced roads. First-class roads run between the large urban centres; they include the coastal Accra–Sekondi-Takoradi–Axim road; the Accra–Kumasi road, which continues northward to Tamale; and the Accra–Ho, Accra–Keta, Cape Coast–Kumasi, and Sekondi-Takoradi–Kumasi roads. The best road in Ghana is a concrete-surfaced highway, with two lanes in each direction, running from Accra to Tema. Second-class roads are narrower than first-class roads and have a base of swish (sun-dried earth) rather than quarried stone.

The creation of Lake Volta occasioned an interruption on the Kumasi–Tamale road, where the Yeji ferry, formerly only a few yards wide, became a crossing of almost seven miles. A number of other ferries across the Volta completely disappeared.

Air transport. Small airports located at Takoradi, Kumasi, and Tamale are used solely for domestic services, while the Kotoka International Airport at Accra handles both domestic and international flights. The Accra runway is long enough to accommodate large jet aircraft, and the airport has a large terminal building. Domestic services are operated by a state-owned corporation, which also operates a West African service linking the coastal states as well as an international service to the Middle East, Europe, and the United Kingdom.

While air transport is popular in Ghana, the maintenance of the national airways is costly and requires a large annual governmental subsidy.

Water transport. Sea transport, formerly important, has dwindled with the expansion of air services. Most goods entering and leaving the country are, however, carried by sea. There are two modern harbours, Takoradi (opened in 1928) and Tema (opened in 1961). Takoradi specializes in exporting timber, manganese, and bauxite, while Tema specializes in cocoa. Both ports also handle passengers. In terms of tonnage, Tema and Takoradi handle about equal amounts of cargo. Ghana has its own national shipping company, the Black Star Line, Ltd., but ships from many other countries also use Ghanaian ports; traffic is mostly with Europe, the United States, and the Far East. The Ghana Shippers' Council was established by the government to provide for mutual consultation among shippers, shipowners, railways, and ports authorities. The Ghana Railway and Ports Authority is responsible for the country's port operations under the Ministry of Transport and Communications.

Launch services on Lake Volta are being expanded; a launch service is also maintained on the lower reaches of the Volta between Ada and Amedika.

ADMINISTRATION AND SOCIAL CONDITIONS

The coup of 1972

The structure of the government. On January 13, 1972, the armed forces overthrew the government of Ghana in a bloodless coup. The constitution was suspended, the office of the presidency abolished, and the National Assembly dissolved. The military leaders then established a National Redemption Council (NRC) as the main organ of government. At its formation, the membership of the NRC was tribally balanced, with four Akan, four Ewe, two Ga, and two Northern members. A civilian National Advisory Council later was established to advise on political matters.

In October 1975, however, the NRC was superseded as the highest legislative and administrative organ by a seven-member Supreme Military Council (SMC); at the same time, the NRC was reorganized to include the members of the SMC and certain other civilian and military members. Control of both organs was military.

Government under the constitution of 1969. The constitution provided for a unicameral parliamentary form of government with a president as head of state and a prime minister as head of government. The president was elected for a term of four years (with the possibility of re-election for one further term) by an electoral college consisting of the National Assembly members and representatives of the various houses of chiefs and district councils throughout the country. The prime minister, who was appointed by the president, was either the leader of the party with the largest plurality in the National Assembly or—if no party had a clear majority—the member of the National Assembly most likely to command the support of the rest of the members.

Assisting the prime minister was a Cabinet of eight to 17 members. There was also provision for the appointment of as many as 10 non-Cabinet ministers, subject to an overall limit of 21 ministers. All ministers were appointed by the president from among members of the National Assembly on the nomination of the prime minister.

The National Assembly sat in Accra and, together with the president, made up Parliament. It consisted of 140 to 150 members elected by universal adult suffrage for terms of five years, although there was provision for an extension, in the event of an emergency, and for an earlier dissolution by the president under certain circumstances. The minimum voting age for elections, as well as for membership of Parliament, was 21. Proceedings of the National Assembly were presided over by the speaker, who was elected by the members. During the absence of the president or in the event of any temporary vacancy in that office, the speaker acted as head of state.

The president was assisted and advised in some constitutional functions by a Council of State made up of the prime minister, the speaker of the National Assembly, the leader of the opposition, the president of the National House of Chiefs, and up to as many as 12 other persons appointed by the president. There was also provision for the appointment of an ombudsman and of a National Security Council, consisting of the prime minister and a number of other persons (including certain specified Cabinet ministers).

While the National Assembly constituted the legislature, the executive branch consisted of the president, the Council of State, the National Security Council, and the Cabinet; the various courts of the land constituted the judiciary (see below).

Local government. Apart from the capital district of Accra, Ghana is divided into eight regions—Ashanti, Brong-Ahafo, Central, Eastern, Northern, Upper, Volta, and Western regions. After 1972, when the constitution was suspended, each region was administered by a regional commissioner, who was an army officer. The structure of local administration was reorganized to include 37 district councils and 270 local councils.

Under the constitution of 1969, though it was essentially unitary in character, the underlying philosophy of local government was to delegate a considerable amount of power and responsibility to regional, district, and local councils in the management of their affairs. Certain civil service departments, such as education, health, public works, social welfare, parks and gardens, and fire services, were decentralized at the regional level; the rest were controlled centrally from Accra.

Local councils were made up of elected and traditional members, the traditional members being chiefs who constituted not more than one-third of the membership. Above these in the hierarchy were the district councils. Here, again, were elected and traditional members, with traditional members forming one-third and elected members two-thirds of each council. The two councils were responsible for the administration of their areas, subject to certain limitations, and were empowered to levy rates and taxes.

Regional councils

At the top were the regional councils, their memberships composed of representatives of all the district councils, chiefs from the regional house of chiefs, and certain heads of civil service ministries and departments. The chairman of each regional council was appointed by the prime minister; council functions included coordination and regional planning.

The political process. After the military coup of 1972 the lively political life of Ghana was brought under tight control. All political parties in existence before January 13, 1972, were proscribed, and the law prohibiting a one-party state was repealed. Members of the Progress Party, which had supported the former prime minister, were imprisoned for one year, and public meetings were prohibited.

Justice. Under the constitution of 1969 the judicial system was based chiefly on the English model, but Ghanaian customary law was recognized as well as English common law. The administration of justice was handled by various courts divided into two groups: the superior courts, consisting of the Supreme Court, the Court of Appeal and the High Court; and inferior courts, consisting, in descending order, of the circuit courts, the district courts, and other courts provided by law, such as the juvenile courts. After the military government took control, the Supreme Court was abolished, and the Court of Appeal, headed by a chief justice, became the highest court in Ghana.

The adjudicating authorities in chieftaincy and purely traditional matters were the regional and national houses of chiefs. Appeals from decisions of the National House of Chiefs were made directly to the Supreme Court.

Subversion Decree

After an abortive countercoup in July 1972 the government imposed the retroactive Subversion Decree. Under the authority of a military tribunal, the death penalty could be exacted for 10 offenses including subversive political activity, robbery, theft of specified items, and damaging public property. The decree was extended to include profiteering in 1973; in that year another decree was promulgated, prohibiting the spreading of rumours.

The armed forces. The Ghana armed forces consist of the army, the navy, and the air force, as well as such ancillary services as medical, transport, engineering, and workshop corps. All of the services are organized along British lines and equipped with relatively light but modern weapons. The headquarters is in Accra, where there is a military academy for the training of officers for all three services. Instruction at the academy is provided by Ghanaian officers and personnel from the United Kingdom and Canada; the armed forces are wholly officered by Ghanaians.

The navy has bases at Takoradi and Tema, and the main base of the air force is at Takoradi. Apart from its normal training duties, the navy carries out regular patrols for fishery protection and control of smuggling. The air force, organized in 1959, is equipped with a small but effective range of planes and helicopters. Besides its purely military functions, it assists the government with various development projects involving reconnaissance and mapping surveys and helps with quick delivery of supplies in times of emergency.

Social conditions. *Educational services.* Ghana has one of the best developed educational systems in the whole of tropical Africa, but the cost is high, representing about one-fifth of the total budget.

In April 1974 the government began implementation of a new educational system at the primary and secondary levels, consisting of a pre-primary cycle for ages four to six; a basic first cycle, including six years of primary education and three years of junior secondary; and a second cycle of variable length, leading to either secondary vocational or commercial certification programs or to a senior secondary upper course leading to university studies.

The first cycle is free and compulsory; for the first three years education is to be in the predominant local language, with provision for education in at least one other Ghanaian language and English, the latter to be the language of instruction from the fourth year of the primary cycle.

Teacher training and technical education are approximately equivalent to secondary education, though they tend to attract pupils who are not aiming at university

careers. The Tarkwa School of Mines offers a three-year diploma course in mining and related subjects.

The universities

University education is provided at three institutions: the University of Ghana, at Legon, near Accra; the University of Science and Technology at Kumasi; and the University of Cape Coast. Until 1971 university education was free for all qualified Ghanaians, but in the early 1970s a scheme was introduced to enable students to meet part of the cost themselves.

The enrollment in all schools, especially in secondary schools, has soared dramatically since Ghana achieved internal self-government. In the mid-1970s, there were about 1,500,000 pupils and students, from primary to university level. Nonetheless, it is estimated that as many as 30 to 50 percent of the children of elementary school age are still not in school because of lack of facilities.

In the 1960s an attempt was made to abolish tuition fees in all government-supported primary and middle schools, the aim being to make elementary education both free and compulsory. The attempt had to be abandoned indefinitely because of financial difficulties. From September 1973 students in primary, middle, and secondary schools and in teacher training colleges paid an annual fee for their textbooks and school materials.

There is a growing number of private schools at both elementary and secondary levels.

Health and welfare services. Major health problems are communicable diseases, poor sanitation, and poor nutrition. The main emphasis of government health policy is on improved public health, and since independence many improvements have been made in nutrition and in maternal and child care. Many of the endemic diseases, such as malaria, pneumonia, and diseases of the gastroenteritis group, which took a heavy toll of life, have been brought under a considerable measure of control as a result of improved hygiene, better drugs, and education. The results are to be seen in the decline in infant mortality and the rise in the general life expectancy.

Hospitals and clinics provided by the government and by various Christian missions exist in most parts of the country. Supplementary services consist of health centres, dispensaries, and dressing stations. Considerable progress has been made in the quantity and quality of health facilities and medical personnel, but rapid population growth continues to impose great pressures on the available facilities. In addition to the large number of doctors in the public service, many private practitioners operate their own clinics and hospitals. Registered doctors and dentists are supported by a paramedical staff of nurses, midwives, and pharmacists as well as by auxiliaries.

Rural community development

Government programs of rural community development are assisted by village improvement projects undertaken with the participation of the inhabitants. Welfare and economic aspects outside urban areas are handled by the national government. In the urban areas, welfare services concentrate on casework, probation work, youth activities, and guidance through voluntary organizations.

Housing. With the rapid growth of population and the movement of large numbers of people from the rural to urban areas, housing has become an acute problem, especially in the large cities where the problem is both quantitative and qualitative. In the rural areas the problem is mainly qualitative. There is distinct overcrowding in the urban areas, where the number of persons per house averages between 21 and 23, as compared with 10 in rural areas. Most housing is provided by private individuals, and the main role of the Ministry of Works and Housing is to supplement these efforts and to meet such special needs as the provision of low-cost housing and suitable local building materials.

Police services. The police service is directed by the Ministry of Internal Affairs. The training of police officers is conducted at the Ghana Police College in Accra. Each region has a regional police committee presided over by the regional chief executive.

The police force is divided into the general police, who are literate and are qualified to perform all of the functions belonging to the police; and the escort police, who are illiterate and are chiefly employed for patrol, escort, and guard duties. An armoured car squadron, established in 1959, can deal promptly with internal disturbances or threats to security. There is also a Women's Corps, mainly concerned with matters affecting women and children. Like the police service, the prison service comes under the Ministry of Internal Affairs, but the two are separate.

Wages and cost of living. Although there is a minimum wage for workers of somewhat less than $1 (U.S.) per day, the gap in wages between the lowest paid and well-paid workers is still wide. This, coupled with rising living costs, imposes severe hardships on a large section of the working population. The government is trying to lower the cost of living not only by increasing the supply of locally produced food staples but also by controlling the prices of other essential goods.

Egalitarian tendencies

Society. Ghanaian society is without sharp class distinctions. Insofar as traditional authority is based on a system of hereditary chieftaincy, it is possible to speak of aristocratic classes within the various tribal groups, but the institution of chieftaincy is essentially democratic in operation and the authority of chiefs is broadly based.

Another important social characteristic is that land is usually owned by families, militating against the emergence of a small and powerful landed class wielding economic control over a landless class. These inherent egalitarian tendencies of the society have been further heightened by economic and social mobility, depending on education and individual enterprise.

Cultural life and institutions. *The cultural milieu.* Ghana has a rich indigenous culture marked by great regional variety. Culturally, the peoples of Ghana have many affinities with their French-speaking neighbours, but each tribal group has distinctive cultural attributes. In all parts of the country the cultural heritage is closely linked with religion and the institution of chieftaincy. Various festivals and rites are centred on chieftaincy and the family and are occasioned by such events as harvest, marriage, birth, puberty, death and funerals.

The arts. Ghana's arts include dance and music, plastic art (especially pottery and wood-carving), gold- and silverwork, and textiles, most notably the richly coloured, handwoven kente cloth of the Akans and Ewes.

Despite the country's wealth in traditional art forms, indigenous art is in keen competition with various art forms of foreign origin, especially in those areas in which the end product is intended for practical household or personal use, such as pottery, carving, gold- and silversmithing, and weaving. Consequently, only the unique and most indispensable of these forms have managed to survive without special public support or patronage. The increased national self-consciousness generated in Ghana as in other African countries by the independence movement, however, has been instrumental in fostering and popularizing many art forms. Another and equally important factor has been the growth of tourism.

Cultural institutions. Apart from small indigenous groups of craftsmen who provide for the needs of the various chiefs' stools and skins throughout the country—a stool is the traditional symbol of office for chiefs in southern Ghana, and a skin is the equivalent symbol in the north—there are few properly established cultural institutions. The most outstanding are the National Cultural Centre, based in Kumasi, and the Arts Council of Ghana, based in Accra and with branches all over the country. The National Cultural Centre is primarily concerned with the cultural heritage of Ashanti, while the Arts Council is a nationwide organization concerned both with the preservation of indigenous Ghanaian culture in all of its forms and with its development and improvement in the light of contemporary local and world trends. Dance, music, drama, painting, and sculpture all come within the purview of the council.

A third cultural institution is the Ghana Museum and Monuments Board, based in Accra. The board has two museums (an ethnological museum and a science museum) in Accra and is responsible for the care and maintenance of buildings and relics of historical importance, such as the forts and castles, and for the preservation of

important art treasures throughout the country. The forts, built by various European powers, mostly between the 14th and 18th centuries, are all, except the Kumasi fort (1897), located on the coast. The oldest fort, São Jorge da Mina, at Elmina, was built by the Portuguese in 1482.

Press and broadcasting. The press in Ghana has a history dating back only to the late 19th century. Up until the time of independence, the press was wholly in private hands, and freedom of expression on political matters was severely restricted by the harsh operation of sedition laws. Following independence, however, the government established a number of state-owned papers, the role of which was to support and explain government policies. In 1957 the government established the Ghana News Agency as a corporation for the supply of home and foreign news to the local press and radio. Under the Nkrumah government, privately owned newspapers were subjected to severe pressures from government, and most of them ceased publication. Press freedom was later restored, although the two most influential newspapers were still controlled by the government in the 1970s. Press restrictions were reinstituted by the military government in 1972.

Ghana News Agency

Radio broadcasting in Ghana dates back to pre-independence days, while television broadcasting began only in 1965. Both radio and television broadcasting are controlled by the government. There is an external radio broadcasting service aimed chiefly at other African countries, but the television service is wholly domestic and generally confined to the larger urban centres and their immediate surroundings. On the home service, commercial and educational programs are available on both radio and television. The languages used by radio and television are mainly English and six Ghanaian languages —Twi, Ewe, Ga, Nzima, Hansa, and Dagbani.

Prospects for the future. Although Ghana is a comparatively small country in size and population, it enjoys significant variety in both its natural resources and its human material. Despite the long association with Britain and the many institutional and cultural innovations that this association brought about, thanks to the British policy of encouraging indigenous institutions and to the inherent vitality of these institutions themselves, the country has succeeded in retaining a surprisingly large measure of its own culture, particularly through the institution of chieftaincy and the even more pervasive institution of the family and lineage system.

Since independence in 1957, new and stronger pressures against the traditional ways of life have been felt because of the need to modernize and to raise living standards for a rapidly growing population, the survival of which depends on how well diverse social elements can be welded together into a single nation. As the first tropical African country under British rule to achieve independence, Ghana had bright prospects at the time of the British withdrawal for developing into a model nation with a strong economy. The high hopes entertained at the outset were dashed within 10 years after independence. Between 1967 and 1972 the country stood on the verge of new economic and political developments, but the problems confronting it were immense. Economic crises and an internal struggle for power precipitated the military coup of 1972. The next year the government published its Charter of Redemption, which announced its aims as including national solidarity, economic development, self-reliance, and service to the people.

(E.A.B./Ed.)

Ghazālī, al-

Abū Ḥāmid Muḥammad ibn Muḥammad aṭ-Ṭūsī al-Ghazālī, prominent Islāmic jurist, theologian, and mystic, was one of the most powerful minds and important figures in the history of Islām, through whose efforts many Greek philosophical conceptions and methods were brought into the mainstream of Islāmic thought, while heretical aspects of philosophy were rejected. His abandonment of a brilliant career as a professor in order to lead a kind of monastic life won him many followers and critics among his contemporaries. Western scholars have been so attracted by his account of his spiritual development that they have paid him far more attention than they have other equally important Muslim thinkers.

Life

He was born at Ṭūs (near Meshed in eastern Iran) in AH 450 (AD 1058) and was educated there, then in Jorjān, and finally at Nishapur (Neyshābūr), where his teacher was al-Juwaynī, who earned the title of *imām al-ḥaramayn* (the *imām* of the two sacred cities of Mecca and Medina). After the latter's death in AH 478 (AD 1085), al-Ghazālī was invited to go to the court of Niẓām al-Mulk, the powerful vizier of the Seljuq sultans. The vizier was so impressed by his scholarship that in AH 484 (AD 1091) he appointed him chief professor in the Niẓāmīyah college in Baghdad. While lecturing to more than 300 students, he was also mastering and criticizing the Neoplatonist philosophies of al-Fārābī and Avicenna (Ibn Sīnā). He passed through a spiritual crisis that rendered him physically incapable of lecturing for a time. In November AH 488 (AD 1095) he abandoned his career and left Baghdad on the pretext of going on pilgrimage to Mecca. Making arrangements for his family, he disposed of his wealth and adopted the life of a poor Ṣūfī, or mystic. After some time in Damascus and Jerusalem, with a visit to Mecca in November AH 489 (AD 1096), al-Ghazālī settled in Ṭūs, where Ṣūfī disciples joined him in a virtually monastic communal life. In AH 499 (AD 1106) he was persuaded to return to teaching at the Neẓāmiyeh college at Nishapur. A consideration in this decision was that a "renewer" of the life of Islām was expected at the beginning of each century and his friends argued that he was the "renewer" for the century beginning in AH 500 (September, AD 1106). He continued lecturing in Nishapur at least until AH 504 (AD 1110) when he returned to Ṭūs, where he died December 18, AH 505 (AD 1111).

Works and teachings

Over 400 works are ascribed to al-Ghazālī, but he probably did not write nearly so many. Frequently the same work is found with different titles in different manuscripts; but many of the numerous manuscripts have not yet been carefully examined. Several works have also been falsely ascribed to him, and others are of doubtful authenticity. At least 50 genuine works are extant, some relatively short.

Al-Ghazālī's greatest work is *The Revival of the Religious Sciences* (*Iḥyāʾ ʿulūm ad-dīn*). In 40 "books" he explained the doctrines and practices of Islām and showed how these can be made the basis of a profound devotional life, leading to the higher stages of Ṣūfism or mysticism. The relation of mystical experience to other forms of cognition is discussed in *Mishkāt al-anwār* (*The Niche for Lights*). Al-Ghazālī's abandonment of his career and adoption of a mystical, monastic life is defended in the autobiographical work *al-Munqidh min aḍ-ḍalāl*, (*The Deliverer from Error*).

His philosophical studies began with treatises on logic and culminated in the *Tahāfut* (*The Inconsistency—or Incoherence—of the Philosophers*), in which he defended Islām against such philosophers as Avicenna who sought to demonstrate certain speculative views contrary to accepted Islāmic teaching. As preparation for this he published an objective account of *Maqāṣid al-falāsifah* (*The Aims of the Philosophers*; *i.e.*, their teachings). This book was influential in Europe and was one of the first to be translated from Arabic to Latin (12th century).

Most of his activity was in the field of jurisprudence and theology. Toward the end of his life he completed a work on general legal principles, *al-Mustaṣfā* (*Choice Part* or *Essentials*). His compendium of standard theological doctrine (translated into Spanish), *al-Iqtiṣād fī al-ʿtiqād* (*The Just Mean in Belief*), was probably written before he became a mystic, but there is nothing in the authentic writings to show that he rejected these doctrines, even though he came to hold that theology—the rational, systematic presentation of religious truths—was inferior to mystical experience. From a similar standpoint he wrote a polemical work against the militant sect of the Assassins (Ismāʿīlīs), and (if it is authentic) a criticism of Christianity, as well as a book of *Counsel for Kings* (*Naṣīḥat al-mulūk*).

BIBLIOGRAPHY. W.M. WATT, *Muslim Intellectual: A Study of al-Ghazālī* (1963), deals with his life and the development of his thought. Still of value is D.B. MACDONALD, "The Life of al-Ghazālī with Special Reference to his Religious Experience and Opinions," *Journal of the American Oriental Society*, 20:71–132 (1899). M. SMITH, *Al-Ghazālī the Mystic* (1944), is good for his mysticism, but treats some dubious works as authentic. On this point, see W.M. WATT, "The Authenticity of the Works Attributed to al-Ghazālī," *Journal of the Royal Asiatic Society*, pp. 24–45 (1952).

Ghāzān, Maḥmūd

Maḥmūd Ghāzān was the seventh and most gifted of the Il-Khans (subordinate *khāns*), the Mongol dynasty that ruled in Iran from AD 1256 to 1353 as the nominal vassals of the Great Khan (of Mongolia, later of China). Ghāzān's reign (1295–1304) was marked by the establishment of Islām as the state religion and by wars with the Mamlūk sultans of Egypt.

Mahmūd Ghāzān receiving the nobles of Khorāsān, illumination from the Mongol manuscript *Jāmiʿ at-tawārīkh*, *c.* 1307. In the University of Edinburgh Library (MS. Or.20).

Birth and early life

Ghāzān was born November 5, 1271, at Abaskun near the present-day port of Bandar-e Shāh on the southeastern shore of the Caspian Sea, his father, Arghun, the later Il-Khan (1284–91), being then only 13 years old. Ghāzān's early childhood was spent largely in the company of his grandfather, the Il-Khan Abagha (1265–82), and he was brought up in the Buddhist faith that both his father and his grandfather professed. Upon his father's accession to the throne in 1284, Ghāzān was appointed viceroy of the provinces of northeastern Persia, where he resided for the next ten years, defending the frontier against the Chagatai Mongols of Central Asia and then against his own lieutenant Nawrūz, who had risen in revolt and made common cause with the Chagatai. Ghāzān's relations with Arghun's successor, Gaykhatu (1291–95), were cool; those with Baydū, the latter's cousin, who dethroned him and usurped the throne, came to open war. After a first encounter, followed by a truce and parley, Ghāzān spent the summer of 1295 in the mountains north of present-day Tehrān, where, on the advice of Nawrūz, with whom he was now reconciled, he declared himself a convert to Islām, and his example was followed by the troops under his command. It was thus at the head of a Muslim force that he resumed the attack against Baydū, who, deserted by his supporters, was captured and executed on the very day of Ghāzān's entry into the Il-Khanid capital of Tabriz.

Ghāzān was formally enthroned on November 3, 1295, and during the first year of his reign he had to cope with a number of revolts against his authority. These were suppressed with the utmost severity, no fewer than five princes of the blood being executed for their complicity. Nawrūz himself, who had helped raise Ghāzān to the throne, was soon to pay with his life for suspected collusion with the Mamlūks. Though now the Muslim head of a Muslim state, Ghāzān took up the hereditary quarrel of his family with these champions of Islām. In 1299–1300 he invaded Syria, defeated the Egyptian army at Homs, and made a triumphal entry into Damascus; but upon his return to Persia early in 1300 the country was re-occupied by the Mamlūks. In the autumn of the same year he returned to the attack; but poor weather rendered military operations impossible, and the campaign was abandoned before contact could be made with the enemy. For a third campaign he sought an alliance with the Christian West. In a letter to Pope Boniface VIII dated April 12, 1302, he refers to a detailed plan for the invasion of Syria, which he had previously proposed to the princes of Europe and continues:

> As for now, we are making our preparations exactly in the manner [laid down in that plan]. You too should prepare your troops, send word to the rulers of the various nations and not fail to keep the rendezvous. Heaven willing, we [*i.e.*, Ghāzān] shall make the great work [*i.e.*, the war against the Mamlūks] our sole aim.

The campaign to which Ghāzān here alludes was launched in the spring of 1303 without European aid. The Mongols advanced through Syria without meeting serious resistance until they were halted and decisively defeated south of Damascus. A fourth campaign was prevented by an illness that attacked Ghāzān in the autumn of 1303; he recovered for a while but then suffered a relapse and died on May 11, 1304.

Breadth of accomplishments

Ghāzān's accomplishments were in no way restricted to his activities on the battlefield. A man of great intellectual curiosity, he was conversant with natural history, medicine, astronomy, and chemistry and was also an adept in several handicrafts. "No one surpassed him," says the Byzantine historian Pachymeres, "in making saddles, bridles, spurs, greaves and helmets; he could hammer, stitch and polish, and in such occupations employed the hours of his leisure from war." Besides his native Mongolian, he is said to have had a knowledge of the Arabic, Persian, Hindi, Kashmiri, Tibetan, Chinese, and Frankish (*i.e.*, probably French) languages.

It was at his suggestion and with his assistance that his vizier Rashīd ad-Dīn composed a celebrated history of the Mongols, afterward expanded to embrace all the peoples of Asia and Europe with which their conquests

had brought them in contact. Rashīd ad-Dīn, Ghāzān's great minister, was perhaps the real author of the fiscal reforms that go under his master's name and that were designed to protect the sedentary population from the extortions of the nomad aristocracy. These measures, coupled with the adoption of Islām, must have played their part in welding the Mongols and Persians (like the Normans and English) into a single nation, and the Il-Khans might have ended, like the Plantagenets, by becoming a truly national dynasty. In fact, Ghāzān himself, by his ruthless elimination of princely rivals, must have contributed to the extinction of the Il-Khanids, who survived his death by little more than 30 years. In appearance he was short and ill-favoured, unlike his father, Arghun, who was tall and handsome. Commenting on his bravery in the battle at Homs, the Armenian prince Haithon observes at one point in his eyewitness account of the scene:

> And the most remarkable thing of all was that within a frame so small, and ugly almost to monstrosity, there should be assembled nearly all those high qualities which nature is wont to associate with a form of symmetry and beauty. In fact among all his host of 200,000 Tartars you could scarcely find one of smaller stature or of uglier and meaner aspect than this Prince.

BIBLIOGRAPHY. J.A. BOYLE (ed.), *Cambridge History of Iran*, vol. 5, *The Saljuq and Mongol Periods* (1968)—the personal history of Ghāzān is in Boyle's chapter on the Il-Khans, and his fiscal reforms in the chapter by I.P. PETRUSHEVSKY; these are based on Oriental, chiefly Persian, sources, of which the most important is the *Jāmi' at-tawārīkh* ("Universal History") of Rashīd ad-Dīn. There is a Russian translation by A.K. ARENDS (1957) of vol. 3 of this source, which deals with the Il-Khans. BERTOLD SPULER, *Die Mongolen in Iran*, 3rd ed. (1968), also based on Persian sources, including Rashīd ad-Dīn, is the only monograph on the Il-Khans.

(J.A.Bo.)

Ghent and Bruges, History of

Ghent and Bruges (Brugge) were the two most important towns of the county of Flanders in medieval times. Both cities are located in what is now Belgium. Ghent, provincial capital of Oost-Vlaanderen (East Flanders), stands at the junction of the Leie (Lys) and Scheldt rivers; Bruges, the provincial capital of West-Vlaanderen (West Flanders), is about 15 miles directly east of the coastal city of Ostend.

Settlement and growth. Ghent and its countryside were inhabited in Roman times. Ghent became important when the abbeys of St. Bavo and St. Peter were founded there (*c.* AD 630). The urban settlement was destroyed by Viking invasions in the 9th century, particularly in 879–881. Shortly afterward Count Baldwin II built a fortification, partly conserved today in the Castle of the Counts, that attracted a civilian settlement (*portus*) near its walls. Ghent in the 11th century became a commercial and industrial centre, with a cloth industry based on locally supplied wool.

The area of Bruges was also inhabited in Roman times. The town of Bruges grew as a seaport in the 4th–8th centuries AD and was the centre of the *pagus Flandrensis*, the Frankish name for the region around Bruges; Count Baldwin II made it the seat of his government in 892, and it remained the centre of the county's administration in succeeding centuries. Situated near the sea and being fortified, the town attracted a civilian settlement, which in time developed important relations with the English across the channel.

Urban autonomy. A great political crisis broke out when Count Charles the Good was murdered in Bruges in 1127. The townspeople helped crush the conspiracy; and, thanks to the initiative of Bruges and Ghent, Thierry of Alsace became the new count in 1128. Both Ghent and Bruges acquired urban magistrates (*scabini, schepenen*) as well as urban privileges during the time of the conspiracy.

In the 13th century the counts had to accept a large degree of urban autonomy, and power became concentrated in the hands of small urban aristocracies. In Bruges, beginning in 1241, government was in the hands of the merchants of the Flemish Hanse of London; and in Ghent the "39 aldermen," belonging to about 100 families, ruled from 1228.

These urban patricians (burghers) lived in fortified houses of stone and employed a considerable proletariat. They were so jealous of their autonomy that Count Philip of Alsace built the great Castle of the Counts in Ghent (beginning *c.* 1178) to maintain his authority there. The burghers built hospitals, such as the Byloke in Ghent (1228), and other public institutions for the welfare of the people.

Growth as commercial centres. Bruges became an international commercial centre; it kept its connections with the receding sea through canals and outports, such as Damme (1180) and Sluis (late 13th century). A yearly fair, dominated by the English wool trade, was established at Bruges in 1200, and relations with England became an important factor in the period that followed. Commerce, which had been carried out overseas by merchants from Bruges, was handled, beginning in the 13th century, by foreign merchants resident in the town. Ghent established a link to the sea through the 13th-century Lieve Canal. It became mainly an industrial centre; and its luxury cloth, produced from English wool, gained a European reputation.

Dominance over Flanders. Toward the end of the 13th century the existing equilibrium in Flanders was broken. Count Guy of Dampierre attacked the power of the urban patriciate—in 1280 he suspended the 39 aldermen in Ghent—and was himself attacked by King Philip IV the Fair, of France, who wanted to bring the country under his direct rule. Various social groups in the towns also turned against their local oligarchic rulers; the latter sided with France, whereas the count sought the support of the common people. At the Battle of the Golden Spurs (1302) a Flemish army, containing contingents from Bruges and Ghent, defeated the French. Ghent, Bruges, and Ypres came to dominate the county, and their old oligarchies lost supremacy.

The Battle of the Golden Spurs

The central authority was in jeopardy, and the county nearly split into three city-states. From 1323 to 1328 Bruges supported a peasants' revolt, which was suppressed with French help. Jacob van Artevelde, captain general of Ghent from 1338 to 1345, defying the pro-French Count Louis of Nevers, made a treaty with England to keep Flanders out of the Anglo-French Hundred Years' War and to safeguard the supply of English wool. Philip van Artevelde, son of Jacob, rose against Count Louis of Male in 1379 but was beaten by a French army at Roosebeke in 1382; after a prolonged resistance Ghent made peace with the new count, Philip the Bold, duke of Burgundy, at the Peace of Tournai in 1385.

Decline of Ghent and Bruges. International commerce continued to flourish in Bruges. But the cloth industry in Ghent declined because of English and Italian competition; this led to economic hardship and social unrest. Rivalries between the craft guilds often turned into bloody street battles.

Under Burgundian rule. Under the counts of the House of Burgundy, central authority was re-established. Bruges, which accepted this more readily than did Ghent, became the artistic capital of Flanders through the patronage of the Burgundian court. In 1452 Ghent rose against Philip the Good but was beaten at the Battle of Gavere in 1453 and had to submit. After initial trouble Ghent accepted the stern rule of Charles the Bold, duke of Burgundy from 1467 to 1477, but rose, together with Bruges and other towns, in 1477 against his daughter Mary, who then revoked many centralizing measures. Both Ghent and Bruges revolted against her husband, Maximilian of Austria, particularly after Mary's death in 1482. In 1485 Bruges, which had imprisoned Maximilian, surrendered to his troops; but fresh rebellions broke out in 1487–89, 1490, and 1492.

The silting up of the Zwin estuary, the troubles under Maximilian, and the attraction of Antwerp sealed the decline of commercial Bruges in the 16th century; the town was gradually deserted by the "nations" of foreign merchants.

In 1539 Ghent rebelled against the emperor Charles V; but it was severely punished in 1540, when a new constitution was imposed. In 1566 iconoclasts destroyed many of Ghent's art treasures. From 1578 to 1584 the city was a Calvinist republic involved in a revolt against King Philip II of Spain. After it surrendered to the Spaniards under Alessandro Farnese in 1584, it lost its old vigour, partly through mass emigration of Protestant sympathizers. Bruges also fell to Farnese in 1584.

Guild houses in the old port of Ghent. The house on the left dates from about 1200; the others are late 17th century.

In modern times. Ghent recovered during the 17th century, but the wars of Louis XIV (1670s) were disastrous for the city. It revived with the development of a modern cotton industry, modelled on that of England. A university, built in 1817, and the Ghent-Terneuzen Sea Canal, built in 1825–27, both under the initiative of King William I of the Netherlands, greatly contributed to industrial and intellectual development. During the 19th century Ghent played a great role in the Flemish movement—which tried to promote the Flemish language and culture. Bruges in the 19th century was an impoverished town, but its historic buildings exerted a romantic attraction. The Bruges-Zeebrugge Sea Canal was built in 1895–1907, but industrial development was slow. In Bruges, as in Ghent, there was considerable foreign investment in industry after World War II.

(R.C.v.C.)

Ghiberti, Lorenzo

Lorenzo Ghiberti was the leading bronze sculptor in Florence in the first half of the 15th century. An early success and a recipient of valuable public commissions, Ghiberti was already a prominent artist of 40 years of age when he, Donatello, and Nanni di Banco each created a new sculptural style that formed the basis of most Italian sculpture of the Renaissance. Admiring antique art, Ghiberti aimed at making his figures lifelike but created sculptures with a personal mark of lyrical grace and the technical perfection learned in his early training as a goldsmith. Whether he was working in the earlier International Gothic style or in that of the Renaissance, Ghiberti's sense of balance and good taste was sought after and prized by both his contemporaries and the following generations.

Brogi—Alinari

Self-portrait from the "Gate of Paradise," bronze sculpture by Lorenzo Ghiberti, 1425–52. The Baptistery, Florence.

Early years and first commissions. Ghiberti was born around 1378. His mother had married Cione Ghiberti in 1370, and they lived in Pelago, near Florence; at some point she went to Florence and lived there as the common-law wife of a goldsmith named Bartolo di Michele. They were married in 1406 after Cione died, and it was in their home that Lorenzo Ghiberti grew up. It is not certain which man was Ghiberti's father, for he claimed each as his father at separate times. But throughout his early years, Lorenzo considered himself Bartolo's son, and it was Bartolo who trained the boy as a goldsmith. Lorenzo also received training as a painter; as he reported in the autobiographical part of his writings, he left Florence in 1400 with a painter to work in the town of Pesaro for its ruler, Sigismondo Malatesta.

Competition for the Florence Baptistery doors

Ghiberti returned quickly to his home city when he heard, in 1401, that a competition was being held for the commission to make a pair of bronze doors for the Baptistery of the cathedral of Florence. He and six other artists were given the task of representing the biblical scene of Abraham's sacrifice of Isaac in a bronze relief of quatrofoil shape. The entry panels of Ghiberti and of Filippo Brunelleschi are the sole survivors of the contest. In this first known youthful work, Ghiberti's art showed characteristics whose enormous appeal brought him suc-

cess: a graceful and lively composition executed with a mastery of the goldsmith's art that makes each superbly finished detail a pleasure to contemplate. In 1402 Ghiberti was chosen to make the doors by a large panel of judges; their decision brought Ghiberti, in his early 20s, the recognition and prominence that marked his entire career. The contract was signed in 1403 with Bartolo di Michele's workshop—overnight the most prestigious in Florence—and in 1407 Lorenzo legally took over the commission.

The work on the doors lasted until 1424, but Ghiberti did not devote himself to this alone. He created designs for the stained-glass windows in the cathedral; he regularly served as architectural consultant to the cathedral building supervisors, although it is unlikely that he actually collaborated with Brunelleschi on the construction of the dome as he later claimed. The Arte dei Mercanti di Calimala, the guild of the merchant bankers, gave him another commission, around 1412, to make a larger than life-size bronze statue of their patron saint, John the Baptist, for a niche on the outside of the guilds' common building, Or San Michele. The job was a bold undertaking, Ghiberti's first departure from goldsmith-scale work; it was, in fact, the first large bronze in Florence. Ghiberti successfully finished the "St. John" in 1416, adding gilding in the following year. The technical achievement and the modernity of its style brought Ghiberti commissions for two similarly large bronze figures for guild niches at Or San Michele: the "St. Matthew" in 1419 for the bankers' guild and the "St. Stephen" for the wool guild in 1425.

Niche figures at Or San Michele

These last two commissions brought Ghiberti into open competition with the newly prominent younger sculptors Donatello and Nanni di Banco, who had made stone statues for Or San Michele after Ghiberti's first figure there. The "St. John" was a frail figure enveloped by flowing draperies. It is characteristic of the style art historians call International Gothic, which swept Europe in the late 14th century and was quite new in Florence in the early 15th century. Ghiberti's "St. John" combined the soft draperies and closely observed, small-scale details in a sculpture larger than life. Donatello's "St. Mark" and "St. George" and Nanni di Banco's "St. Philip" and "Quattro Coronati" ("Four Crowned Saints") were as large as Ghiberti's figure but were designed with monumental proportions to match their scale; the boldness and strength of the weighty new classical figures constituted a challenge that Ghiberti met with success in his next sculptures, maintaining his pre-eminent position as a leading artist in Florence.

Increasing artistic success. The teens and '20s were years of flourishing expansion for Ghiberti and his firm. He had completed a great deal of the modelling and casting of the panels for the Baptistery doors by 1413, and he was in control of a smoothly functioning workshop with many assistants. In 1417 Ghiberti was asked to make two bronze reliefs for the baptismal font of the cathedral in Siena; he was so busy that he only finished them, under pressure from the Sienese authorities, ten years later. In 1419, when Pope Martin V was in Florence, Ghiberti was called on as a goldsmith to fashion a morse and mitre for the Pontiff; unfortunately these pieces, like other examples of Ghiberti's art in rare stones and precious metals, have disappeared. During these years, too, Lorenzo found a wife—Marsilia, the 16-year-old daughter of Bartolomeo di Luca, a wool carder. She soon bore him two sons: Tommaso was born in 1417 and Vittorio the next year; his sons later joined Ghiberti in his business, and Vittorio continued its operation after his father's death. Ghiberti's artistic success also had its financial rewards; a surviving tax return of 1427 lists property in Florence, land out of town, and a substantial amount of money invested in government bonds to his credit. Over the years, his real estate and monetary holdings continued to grow. In addition to being well paid, Ghiberti was a businessman who managed his affairs shrewdly. He was a well-to-do member of Florentine society and a rich man among the artists of his time.

Success of Ghiberti's workshop

Ghiberti was actively involved with and interested in other artists and their work; some (Donatello, Paolo Uccello, Michelozzo, Benozzo Gozzoli) had worked for a time in his workshop as young assistants. Ghiberti's association with the painter Fra Angelico is documented: Ghiberti designed the frame for his "Linaiuoli Altarpiece." In his commentaries, Ghiberti exaggerates only a bit when he proudly claims that "few important things were done in our city which were not devised or designed by my hand"; among his undocumented works may be noted some half-dozen floor tombs and sarcophagi, but the vast extent to which Ghiberti's providing of designs and models influenced Florentine art is hard to measure. He appears to have shared his knowledge and talent generously and freely; long before the completion of his second pair of doors (the "Gates of Paradise") in 1452, the fund of figures and models assembled in connection with this work, which the public saw only later, was open to painters of frescoes in the Chiostro Verde (green cloister) of SS. Annunziata and to the sculptor Luca della Robbia, working on a marble singing gallery for the cathedral. Naturally, the impact of the "Gates" increased after they were installed.

When he was 45 years old, Ghiberti finished the first doors. They are the effort of over 20 years of work and the major sculptural complex of the International Gothic style in Italy. They show some changes in the latest parts, however, to a more classical style that emphasizes the bodies of figures more than the elegant draperies that enfold them. Ghiberti created expressive, strong faces based on examples he knew of ancient Roman art—portrait busts and carved sarcophagi. Because of the success of the first doors, a contract was soon signed with the Calimala for a second pair, but the political and financial fortunes of the city and the guild did not permit work to get underway for about five years.

Development of humanistic theories and practices. Following the completion of the first doors, Ghiberti embarked on a decade of intense exploration of new ways of forming pictorial space and making gracefully active and lifelike figures. His works of the late 1420s show him able to make space increasingly intelligible in a series of clearly receding planes; using shallow relief, Ghiberti depicted volumes of bodies and deep architectural spaces. Examples of these are the reliefs in Siena; the Dati Tomb (the bronze plaque for the floor tomb of the Dominican general Leonardo Dati); and the two shrines in Florence, "Cassa di S. Zenobius" (a bronze casket with relief panels of stories from the saint's life) and "Shrine of SS. Protus, Hyacinth, and Nemesius" (a bronze container for the relics of three martyrs). It is likely that at this time Ghiberti encountered Leon Battista Alberti, a young Humanist scholar, who, inspired by the new art in Florence, was composing theoretical treatises on the visual arts. Their mutual belief that beauty was synonymous with the conception they shared of antique art makes it difficult to know whether or not Alberti's ideas in *De pictura* (*On Painting*) precede the three panels of the second door (Isaac, Joseph, and Solomon), which are the visual equivalent of those ideas. The beauty of antique art meant for both Alberti and Ghiberti an idealization of nature; capturing its essence meant revealing life by depicting movement, life's most salient visible characteristic. For the representation of a realistic spatial setting for these naturalistic figures, Alberti's treatise sets forth a perspective system for projecting such spaces onto the picture plane of a painting or bas relief. Ghiberti's three panels seem an embodiment of the Humanist's formulations for Renaissance pictorial art, and it is clear that any assessment of his art must account for the incorporation of the new theory as well as for the beauty and charm of these works. Ghiberti was himself so proud that he claimed to have made, in all ten panels,

Contact with Alberti and growing interest in antique art

> architectural settings in the relation with which the eye measures them, and real to such a degree that . . . one sees the figures which are near appear larger, and those that are far off smaller, as reality shows it.

Ghiberti's writings, *I Commentarii* (probably completed around 1447), shed more light on his Humanist interests.

The commentaries are composed of three books. The first, a history of art in ancient times, is Ghiberti's digest of writings of Latin authors he had read on the subject; in it he reveals his belief that the inseparability of practice and theory is responsible for the excellence of ancient art. The second book records the art of the immediate past, and Ghiberti expresses his admiration for certain Sienese painters and for a late 14th-century northern goldsmith named Gusmin who is known only through Ghiberti's pages; this book includes an autobiography, in which Ghiberti establishes his place in the history of art. The last book was apparently more theoretical, but in the surviving manuscript it is fragmentary. The commentaries demonstrate Ghiberti's confidence in his position as an important leader in the Florentine Renaissance—one interested in recapturing the art of the ancients, in studying that art as a Humanist scholar would, and one who developed a new style *all'antica* in which he freely created art works with a grace and beauty that have been found winning since their invention. Ghiberti died at Florence on December 1, 1455.

MAJOR WORKS

SCULPTURE: Competition relief for Baptistery doors, Florence (1401; Bargello, Florence); north door reliefs (1403–24; Baptistery, Florence); "St. John the Baptist" (1412–16; Or San Michele, Florence); reliefs showing St. John the Baptist before Herod and the Baptism of Christ (1417–27; Baptistery font, Siena); "St. Matthew" (1419–22; Or San Michele, Florence); "Tomb of Leonardo Dati" (1423–27; Sta. Maria Novella, Florence); "St. Stephen" (1425–28; Or San Michele, Florence); "Gates of Paradise," bronze door (1425–52; Baptistery, Florence); "Cassa di S. Zenobius" (1430s; Cathedral, Florence).

STAINED GLASS: "Assumption" (*c.* 1425; cathedral window, Florence).

BIBLIOGRAPHY. RICHARD KRAUTHEIMER, "Ghiberti and Master Gusmin," *Art Bulletin*, 29:25–35 (1947), a discussion of the literary and stylistic evidence for the connection of Ghiberti's early art with that of French goldsmiths; RICHARD KRAUTHEIMER and TRUDE KRAUTHEIMER-HESS, *Lorenzo Ghiberti* (1956, reprinted 1970 with new introduction), by far the most readable and comprehensive presentation and analysis of Ghiberti's life, art, and fame by eminent scholars (with bibliography); ULRICH MIDDELDORF, "Additions to Lorenzo Ghiberti's Work," *Burlington Magazine* 113:72–79 (1971), a study giving more examples of Ghiberti's widespread activity; JOHN POPE-HENNESSY, *An Introduction to Italian Sculpture*, 5 vol. (1955–63, reprinted 1970), a compendium of photographs, text, and scholarly notes on Ghiberti, his predecessors, and followers; FILIPPO ROSSI, "The Baptistery Doors in Florence," *Burlington Magazine* 89:334–341 (1947), details of the restoration of the doors to their present state; CHARLES SEYMOUR, *Sculpture in Italy 1400–1500* (1966), a study of Ghiberti in the general context of his century's sculptural art.

Ghiberti's writings: JULIUS VON SCHLOSSER, *Lorenzo Ghiberti's Denkwürdigkeiten (I Commentarii)*, 2 vol. (1912), the only complete printing of the text of Ghiberti's Italian, with an analysis in German; excerpts in English translation appear in ELIZABETH GILMORE HOLT (ed.), *A Documentary History of Art*, 2nd ed. (1957); and ROBERT GOLDWATER and MARCO TREVES (eds.), *Artists on Art* (1945).

(C.Lo.)

Ghirlandajo, Domenico

A leading artist in Florence during the early Renaissance, Domenico Ghirlandajo was an extremely skillful fresco painter. His specialty was large and clearly organized frescoes with a strong narrative content and usually a large number of portraits.

Domenico di Tommaso Bigordi was born in Florence in 1449, the son of a goldsmith. The nickname "Ghirlandajo" (or "Ghirlandaio") is derived from his father's skill in making garlands. Domenico probably began as an apprentice in his father's shop, but almost nothing is known about his training as a painter or the beginnings of his career. The earliest works attributed to him, dating from the early 1470s, show strong influence from the frescoes of Andrea del Castagno, who died when Ghirlandajo was about eight years old. Giorgio Vasari, the biographer of Renaissance artists, recorded in his *Lives* (1550) that Ghirlandajo was a pupil of the Florentine painter Alesso Baldovinetti, but Baldovinetti was only four or five years older than Ghirlandajo himself. He worked in fresco on large wall surfaces in preference to smaller scale paintings executed on wood panels, although he used them for the altarpieces that were the centrepieces of the fresco cycles in his major undertakings. He never experimented with oil painting, although most Florentine painters of his generation began to use it exclusively in the last quarter of the 15th century.

Early works and influences

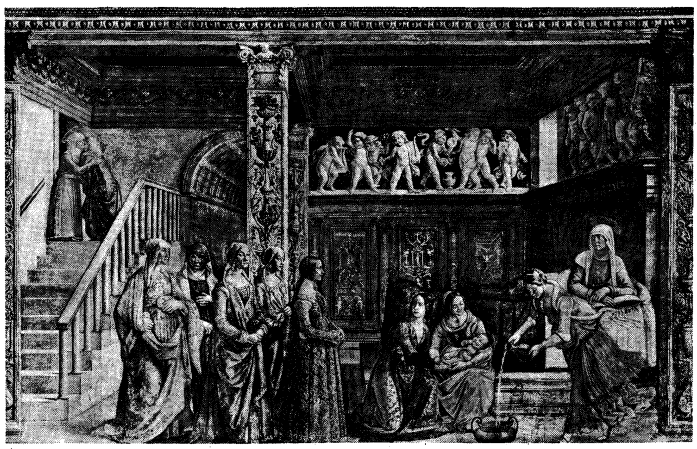
The village church of Cercina, near Florence, has a fresco of three saints, now thought to be Ghirlandajo's earliest work, but there is general agreement that some frescoes in the Church of Ognissinti in Florence, almost certainly dating from around 1472–73, show his style at its earliest developed stage. One of them represents the "Pietà" and depicts several members of the Vespucci family as mourners, thus already introducing Ghirlandajo's characteristic combination of portrait figures in contemporary dress with a specifically religious subject. Something of the passion for minute detail shown by the early Flemish painters can be found in Ghirlandajo's work at this period; his fresco "St. Jerome," also in Ognissanti and dated 1480, may even be an enlarged version in fresco of an oil painting by the Flemish painter Jan van Eyck, which had found its way to Florence. The "St. Jerome" fresco is particularly important because it is a companion piece to one of "St. Augustine" by Botticelli; the difference between the two reveals Ghirlandajo's rather pedestrian and anecdotal style.

The first major commissioned works were the frescoes the "Life of Sta. Fina," painted in 1475 in the church at San Gimignano, near Florence, which derive from Fra Filippo Lippi's slightly earlier fresco cycle in the cathedral at Prato and contain a number of portrait heads arranged, rather stiffly, in the symmetrical type of composition that was to become increasingly identified with him. Even then he was already employing assistants; in his later works he clearly could only complete large commissions in the comparatively short time allotted by the extensive use of highly trained assistants working simultaneously on different parts of the frescoes. In 1481–82 he received an important commission in the Vatican for a fresco, nominally representing the calling of the first Apostles, in the Sistine Chapel. Its style is reminiscent of the frescoes by Masaccio of about 1427, which had been the great innovating works of the early 15th century in Florence but by then must have seemed somewhat old-fashioned. The principal feature of this fresco is the group of portraits of the Florentine colony in Rome, who are represented as witnesses of the biblical event. It has been suggested that the inclusion of these Florentines in a fresco painted for the Vatican had political significance, because the Florentine government had recently accused Pope Sixtus IV of complicity in the conspiracy of the Pazzi, another powerful Tuscan banking family, to murder the leading members of the Florentine Medici family.

Ghirlandajo must have used his stay in Rome to study Roman antiquities at first hand, for many details of triumphal arches, ancient sarcophagi, and similar antique elements occur in his works throughout the rest of his career. A sketchbook filled with drawings of such antiquities (now in El Escorial, near Madrid) seems to be the work of a member of his shop.

Study of Roman antiquities

Late in his short life, Ghirlandajo and his assistants, including his brothers Davide and Benedetto, produced two major fresco cycles. The earlier, a series of frescoes and an altarpiece painted in tempera, was executed for the Sassetti Chapel in Sta. Trinità in Florence. Commissioned by Francesco Sassetti, an agent of the Medici bank, they were executed between about 1482 and 1485. They represent scenes from the life of St. Francis of Assisi, Sassetti's patron saint. Once more, the frescoes contain many details of the buildings and customs of the period—for example, the original front of the church of Sta. Trinità itself—and, in particular, there are numerous portraits of members of the Sassetti family shown together with some of the leading members of the Medici family, in what may appear to have been a closer intimacy than was actually the case. The altarpiece, dated



"The Birth of the Virgin" (with a portrait of Giovanna Tornabuoni, daughter of the patron of the series, followed by other Florentine patrician ladies in contemporary dress), one of the fresco series by Domenico Ghirlandajo, 1485–94. In Sta. Maria Novella, Florence.
Brogi—Alinari

1485, contains further evidence of Ghirlandajo's interest in classical antiquity, for it shows the "Adoration of the Shepherds" with a Roman triumphal arch in the background and a Roman sarcophagus in place of the traditional manger. This painting in tempera has several direct references to contemporary Flemish paintings, especially the enormous altarpiece painted in oil by Hugo van der Goes, which had been commissioned in Flanders by Tommaso Portinari, another agent of the Medici bank, and which arrived in Florence in the late 1470s.

Greatest fresco cycle

Ghirlandajo's last and greatest fresco cycle was painted for another Medici banker, Giovanni Tornabuoni, and represents scenes from the life of the Virgin and of St. John the Baptist. Ghirlandajo signed the contract on September 1, 1485, for these very large frescoes on the walls of the choir of Sta. Maria Novella in Florence. The altarpiece was still incomplete when he died in Florence on January 11, 1494, but his assistants, among whom was very probably the boy Michelangelo, had completed the frescoes by about 1490. Even more than in the Sassetti Chapel the narrative scenes contain a wealth of detail showing patrician interiors and contemporary dress; as a result they are one of the most important sources for current knowledge of the furnishings of a late-15th-century Florentine palace.

The frescoes in Sta. Maria Novella are overcrowded with detail, so that the compositions fail to make their full impact. Some of his smaller panel paintings, particularly the portrait of Giovanna Tornabuoni, have a simplicity that makes them far more striking than the frescoes. This portrait of Giovanna, who died in 1490, must have been used for the portrait of her in the frescoes of Sta. Maria Novella. The portrait representing an old man with a strawberry nose with his grandchild (Louvre, Paris) is perhaps Ghirlandajo's finest painting, notable for its tenderness and humanity, as well as a simplicity and directness of handling.

The vicissitudes of his reputation have been considerable. In the late 19th century, because of the high degree of realism in his work, he was ranked as a leading Florentine painter of the 15th century, but during much of the 20th century the greater imaginative power of Botticelli or Filippino Lippi made Ghirlandajo's paintings seem dull. Since the 1960s the honesty and truth of his works have brought him back into critical favour, although, significantly enough, in his lifetime Ghirlandajo never received a major commission from the Medici family, or from any other leading patrons.

MAJOR WORKS

"SS. Barbara, Jerome and Anthony Abbot" (early 1470s; Cercina, Italy); frescoes over Vespucci Altar (*c.* 1472–73; Church of Ognissanti, Florence); "Life of Sta. Fina" (1475; Chapel of Sta. Fina, Collegiata, San Gimignano); "Madonna and Child Enthroned, with SS. Michael, Raphael, Justus, and Zenobius" (*c.* 1480; Uffizi, Florence); "Last Supper" (1480; Church of Ognissanti, Florence); "St Jerome" (1480; Church of Ognissanti, Florence); "Christ Calling SS. Peter and Andrew" (1481–82; Sistine Chapel, Vatican, Rome); "Roman Heroes" (1482; Palazzo Vecchio, Sala dei Gigli, Florence); "Adoration of the Shepherds" (1485; Sta. Trinità, Sassetti Chapel, Florence); "Madonna and Saints," formerly the Sta. Maria Novella altarpiece (1485–94, unfinished; mostly in Alte Pinakothek, Munich); scenes from the lives of the Virgin and St. John the Baptist (1486–90; Choir, Sta. Maria Novella, Florence); "Adoration of the Magi" (1488; Ospedale degli Innocenti, Florence); "Giovanna Tornabuoni" (1488; Thyssen-Bornesmisza Collection, Castagnola, Switz.); "The Visitation" (1491; Louvre, Paris).

BIBLIOGRAPHY. The only modern monograph is JAN LAUTS, *Domenico Ghirlandajo* (1943). The principal source is VASARI'S *Vite* . . . (1550; 2nd ed., 1568); several English translations exist. See also the article by GIUSEPPE MARCHINI in the *Encyclopedia of World Art*, vol. 6, col. 319–325 (1962), with full bibliography; and the characterization of Ghirlandajo's art by FREDERICK HARTT in *A History of Italian Renaissance Art*, pp. 303–308 (1969).

(P.J.Mu.)

Giacometti, Alberto

Alberto Giacometti, Swiss painter and sculptor who lived mostly in Paris, was one of the outstanding artists of the 20th century. At a time when avant-garde artists aimed at rendering nonfigurative or expressive qualities rather than achieving resemblance to reality, he worked for the unattainable goal of equalling reality by rendering a portrait—whether drawing, painting, or sculpture—so that it would be perceived by the spectator with the impact it would have were it a living person. To do this, he introduced into the art of sculpture a new concept of rendering distance. Massless and weightless, his figures and heads are immediately seen from a specific frontal point of view and therefore perceived as situated in distance and space. Giacometti had such intellectual integrity—for example, living in a shabby studio in Montparnasse even after fame and fortune had reached him—that he became for his contemporaries, especially those of the postwar generation, an almost legendary figure during his lifetime.

Born on October 10, 1901, at Borgonovo in the Bergell Valley, Switzerland, Giacometti displayed precocious talent and was much encouraged by his father, Giovanni, a Postimpressionist painter, and by his godfather, Cuno Amiet, a Fauvist painter. He spent a happy childhood in the nearby village of Stampa, to which he returned regularly until his death. His brother Diego became known as a furniture designer and shared Giacometti's life as his model and aid. Another brother, Bruno, became an architect.

Giacometti left secondary school in Schiers in 1919 and then went to Geneva, where he attended art classes during the winter of 1919–20. After a time in Venice and Padova (May 1920) he went to Florence and Rome (fall 1920–summer 1921), where rich collections of Egyptian

Stay in Italy

art taught him that the impact of ancient and primitive hieratic styles—which adhere to fixed, conventional types and frontal or rigid figures—could be used as an equivalent for the force of reality.

Between 1922 and 1925, Giacometti studied at the Académie de la Grande-Chaumière in Paris. Although he owed much to his teacher, Émile-Antoine Bourdelle, his style was very different. It was related to the Cubist sculpture of Alexander Archipenko and Raymond Duchamp-Villon and to the Post-Cubist sculpture of Henri Laurens and Jacques Lipchitz. An example is "Torso" (1925). He was also inspired by African and Oceanic art, as in "The Spoon-Woman" (1926). His first important personal achievements were flat, slablike sculptures, such as "Observing Head" (1927/28), which soon made him popular among the Paris avant-garde.

Giacometti, photograph by Yousuf Karsh, 1965.

Any resemblance to reality had been abandoned in the period 1925–29, when he created mannered figures, such as "Cubist Composition" (1926) and "Three Figures Outdoors" (1929). The trend continued in the period 1930–32, in works in which emotions and erotic themes were given Surrealist sculptural form ("Suspended Ball" and "The Palace at 4 A.M."). In 1933–34 Giacometti attempted metaphorical compositions using the themes of life and death ("The Invisible Object" and "1 + 1 = 3"). At this time he was disturbed by the thought that his serious works of art had as little reference to reality as the merely decorative vases and lamps that he made to earn a living. Breaking definitely with the Surrealist group in 1935, he began to work after nature again; what had started as mere studies became a lifelong adventure and a turning point in art history: the phenomenological approach to reality—that is, the search for the given reality in what one sees when one is looking at a person.

Break with Surrealism

Around 1940, Giacometti arrived at matchstick-sized sculptures: figures and heads seen frontally as ungraspable appearances of reality far away in space. Around 1947, his massless, weightless image of reality was expressed in a skeletal style, with figures thin as beanstalks. From 1947 to 1950 he did compositions related to his work of the early 1930s—"Tall Figures"; "City Square"; "Composition with Seven Figures and a Head (The Forest)"; and "Chariot"—and became rapidly known, especially in the United States, through two exhibitions (1948 and 1950) at the Pierre Matisse Gallery in New York and an essay on his art by the French Existentialist writer Jean-Paul Sartre.

The evolution of his art continued, taking the form of a search for ways to challenge, actually to equal, reality in sculpture as well as in painting. An artwork was to become an almost magical evocation of reality in an imaginary space, as in heads of Diego and figures after his wife Annette (1952–58), executed like apparitions on gray canvases or on space-delimiting bases. Finally, the artwork was invested with the power of acting on the spectator like a double of reality in real space, as in portraits of Caroline or Elie Lotar, his models and friends in the last years (1958–65), which are heads and busts gazing intently and made only with lines of force, without contour lines or surfaces. At this point, the phenomenological approach was superseded; he felt that reality is no longer dependent on being perceived by someone; reality simply is. Like the characters of Samuel Beckett's novels and plays (Giacometti had done the set for *Waiting for Godot* in 1963), his figures represent a view of man in which space and time have their origin in the core of each being.

Figures like Beckett characters

Alberto Giacometti died on January 11, 1966, in Chur (Switzerland) of an inflammatory heart condition, without having carried out the final composition of the work he had been concerned with since the early 1930s, the metaphor of the totality of life.

MAJOR WORKS

SCULPTURE: Many of these works exist in editions of more than one cast and may therefore be seen in more than one collection. The Kunsthaus in Zürich and the Galerie Beyeler in Basel have the most comprehensive collections of Giacometti's work on loan from the Alberto Giacometti Foundation. Other important collections are in the Museum of Modern Art, New York and in the Fondation Maeght, Saint-Paul, France. "Torso" (1925); "The Couple" (1926); "The Spoon-Woman" (1926); "Cubist Composition" (1926); "Observing Head" (1927–28); "Man" (1929); "Reclining Woman Who Dreams" (1929); "Three Figures Outdoors" (1929); "Suspended Ball" (1930–31); "Disagreeable Object" (1931); "Hand Caught by a Finger" (1932); "Woman with Her Throat Cut" (1932); "The Palace at 4 A.M." (1932–33 Museum of Modern Art, New York); "No More Play" (1933); "Cubist Head" (1934–35); "Nude" (1933–34); "The Invisible Object" (1934); "1 + 1 = 3" (1934); "Woman with the Chariot I" (1942–43); "Man Pointing" (1947); "Head of a Man on a Rod" (1947); "Tall Figure I" (1947); "City Square" (1948); "Three Men Walking" (1949); "Walking Quickly Under the Rain" (1949); "Tall Figure" (1949); "Composition with Seven Figures and a Head (The Forest)" (1950); "Between Two Houses" (1950); "The Cage" (1950–51); "Four Women on a Base" (1950); "Chariot" (1950); "Dog" (1951); "Head" (1952); "Woman" (1953); "Nine Standing Figures (Venice)" (1956); "Tall Figures" (1960); "Walking Man I" (1960); "Monumental Head" (1960); "Bust of Annette" (1962); "Figure Standing" (1964); "Head of Diego" (1965); "Bust of Elie Lotar" (1965).

PAINTINGS: "Self-Portrait" (1921; Kunsthaus, Zürich); "The Artist's Mother" (1950; Museum of Modern Art, New York); "Caroline" (1961; private collection).

LITHOGRAPHS: "Paris sansfin" (1958–65).

BIBLIOGRAPHY. The most comprehensive collection of Giacometti's work is in the Alberto Giacometti-Foundation, Zürich, with fully illustrated catalog (1971). A comprehensive and systematic bibliography is in the monograph by Hohl (below). Bibliographies are also in exhibition catalogs, *Alberto Giacometti,* Museum of Modern Art, New York (1965); and Musée de l'Orangerie, Paris (1969); and in JAMES LORD, *Alberto Giacometti: Drawings* (1971). The most important autobiographical statements are the "Letters to Pierre Matisse" in the exhibition catalogs of the Pierre Matisse Gallery, New York (1948 and 1950); CARLTON LAKE, "The Wisdom of Giacometti (Interview)" in *The Atlantic Monthly,* 216:117–126 (1965); and JAMES LORD, *A Giacometti Portrait* (1965), day-by-day notes of 18 sittings with firsthand material on Giacometti's life and way of working. Many autobiographical quotations are translated into English in the monograph by Hohl. Literary articles on Giacometti include: JEAN-PAUL SARTRE, "The Search for the Absolute," in catalog *Giacometti,* Matisse Gallery, New York (1948; reprinted in *Situations III,* 1949), fundamental for the existentialist interpretation of his work; and "The Paintings of Giacometti," in catalog *Giacometti,* Maeght Gallery, Paris (1951; reprinted in *Art and Artist,* 1956); JEAN GENET, *L'Atelier d'Alberto Giacometti* (1958), fascinating personal views; JACQUES DUPIN, *Alberto Giacometti* (1962), enormously helpful, with 236 reproductions; and LUIGI CARLUCCIO, *Alberto Giacometti: le copie del passato* (1967; Eng. trans., *Giacometti: A Sketchbook of Interpretive Drawings,* 1967), which contains 144 drawings after other masters and one of the last autobiographical texts.

Some important critical studies are DAVID SYLVESTER, "Perpetuating the Transient," in catalog *Giacometti*, Arts Council, London (1955); and "The Residue of a Vision," in catalog *Giacometti*, Tate Gallery, London (1965); HILTON KRAMER, "Giacometti," *Arts Magazine*, 38:52–59 (1963), very valuable article against the existentialist interpretation of Giacometti's work; HERBERT LUST, *Alberto Giacometti: The Complete Graphics* (1971), useful for the reproductions; JAMES LORD, *Alberto Giacometti: Drawings* (1971), considerate introduction, chronology, and bibliography; and REINHOLD HOHL, *Alberto Giacometti* (1972), the most comprehensive monograph, with many quotations, a special dates and documents section, a systematic bibliography, and 196 plates.

(Re.H.)

Gibbon, Edward

Unquestionably the greatest English historian of the 18th century, Edward Gibbon combined enormous erudition with the philosophical ideals of the Enlightenment to produce the first history in English that achieved both sound scholarship and broad philosophical scope. His outstanding work, *The History of the Decline and Fall of the Roman Empire*, presents a continuous narrative from the 2nd century AD to the fall of Constantinople in 1453. A masterpiece of prose style, it has since been corrected in detail but never entirely supplanted; it continues to influence men's judgment of antiquity and the Middle Ages.

Gibbon, oil painting by Henry Walton, 1774.

Gibbon was born at Putney, Surrey, on April 27, 1737. After the reform of the calendar in 1752, his birthday fell on May 8. His grandfather, Edward, had made a considerable fortune and his father, also Edward, was able to live an easygoing life in society and Parliament. He married Judith, a daughter of James Porten (pronounced Porteen), whose family had originated in Germany. Edward, too, had independent means throughout his life. He was the eldest and the only survivor of seven children, the rest dying in infancy.

Early life. His own childhood was a series of illnesses and more than once he nearly died. Neglected by his mother, he owed his life to her sister, Catherine Porten, whom he also called "the mother of his mind," and after his mother's death in 1747 he was almost entirely in his aunt's care. He early became an omnivorous reader and could indulge his tastes the more fully since his schooling was most irregular. He attended a day school in Putney and, in 1746, Kingston grammar school, where he was to note in his *Memoirs* "at the expense of many tears and some blood, [he] purchased a knowledge of Latin syntax." In 1749 he was admitted to Westminster School. He was taken in 1750 to Bath and Winchester in search of health and after an unsuccessful attempt to return to Westminster was placed for the next two years with tutors from whom he learned little. His father took him on visits to country houses where he had the run of libraries filled with old folios. He noted his 12th year as one of great intellectual development and says in his *Memoirs* that he had early discovered his "proper food," history. By his 14th year he had already covered the main fields of his subsequent masterpiece, applying his mind as well to difficult problems of chronology. The keynote of these early years of study was self-sufficiency. Apart from his aunt's initial guidance, Gibbon followed his intellectual bent in solitary independence. This characteristic remained with him throughout his life. His great work was composed without consulting other scholars and is impressed with the seal of his unique personality.

Intellectual independence

In his *Memoirs* Gibbon remarked that with the onset of puberty his health suddenly improved and remained excellent throughout his life. Never a strong or active man, he was of diminutive stature and very slightly built and he became corpulent in later years. The improvement in his health apparently accounts for his father's sudden decision to enter him at Magdalen College, Oxford, on April 3, 1752, about three weeks before his 15th birthday. He was now privileged and independent. Any expectations of study at Oxford were soon disappointed. The authorities failed to look after him intellectually or spiritually or even to note his absences from the college. Left to himself, Gibbon turned to theology and read himself into the Roman Catholic faith. It was a purely intellectual conversion. Yet he acted on it and was received into the Roman Catholic Church by a priest in London on June 8, 1753.

Exile. His father, outraged because under the existing laws his son had disqualified himself for all public service and office, acted swiftly, and Edward was dispatched to Lausanne and lodged with a Calvinist minister, the Rev. Daniel Pavillard. Though the change was complete, and Gibbon was under strict surveillance, in great discomfort, and with the scantiest allowance, he later spoke of this period with gratitude. To Pavillard he owed kindly and competent instruction and the formation of regular habits of study. He mastered the bulk of classical Latin literature and studied mathematics and logic. He also became perfectly conversant with the language and literature of France, which exercised a permanent influence on him. These studies made him not only a man of considerable learning but a stylist for life. He began his first work, written in French, *Essai sur l'étude de la littérature* (*An Essay on the Study of Literature*). Meanwhile, the main purpose of his exile had not been neglected. Not without weighty thought, Gibbon at last abjured his new faith and was publicly readmitted to the Protestant communion at Christmas 1754. "It was here," Gibbon says somewhat ambiguously, "that I suspended my religious enquiries, acquiescing with implicit belief in the tenets and mysteries which are adopted by the general consent of Catholics and Protestants."

Further education at Lausanne

In the latter part of his exile Gibbon entered more freely into Lausanne society. He attended Voltaire's parties. He formed an enduring friendship with a young Swiss, Georges Deyverdun, and also fell in love with and rashly plighted himself to Suzanne Curchod, a pastor's daughter of great charm and intelligence. In 1758 his father called Gibbon home shortly before his 21st birthday and settled an annuity of £300 on him. On the other hand, he found that his father and his second wife were implacably opposed to his engagement, and he was compelled to break it off. ("I sighed as a lover, I obeyed as a son.") He never again thought seriously of marriage. After a natural estrangement he and Mlle Curchod became lifelong friends. She was well known as the wife of Jacques Necker, the French finance minister under Louis XVI. During the next five years Gibbon read widely and considered many possible subjects for a historical composition. He published his *Essai* first in French (1761) and later in English (1764). From 1760 until the end of 1762, his studies were seriously interrupted by his service on home defense duties with the Hampshire militia. With the rank of captain he did his duty conscientiously and later claimed that his experience of men and camps had been useful to him as a historian.

Choosing a subject. Gibbon left England on January 25, 1763, and spent some time in Paris, making the ac-

quaintance of several Philosophes, Denis Diderot and Jean Le Rond d'Alembert among others. During the autumn and winter spent in study and gaiety at Lausanne, he gained a valuable friend in John Baker Holroyd (later Lord Sheffield), who was to become his literary executor.

Visit to Rome

In 1764 Gibbon went to Rome, where he made an exhaustive study of the antiquities and, on October 15, 1764, while musing amid the ruins of the Capitol, was inspired to write of the decline and fall of the city. Some time was yet to pass before he decided on the history of the empire.

At home, the next five years were the least satisfactory in Gibbon's life. He was dependent on his father and although nearly 30 had achieved little in life. Although bent on writing a history, he had not settled on a definite subject. Impressed by the supremacy of French culture in Europe, he began in that language a history of the liberty of the Swiss but was dissuaded from continuing it. He and Deyverdun published two volumes of *Mémoires littéraires de la Grande Bretagne* (1768–69). In 1770 he sought to attract some attention by publishing *Critical Observations on the Sixth Book of the Aeneid.*

His father died intestate in 1770. After two years of tiresome business, Gibbon was established in Bentinck Street, London, and concentrated on his Roman history. At the same time he entered fully into social life. He joined the fashionable clubs and was also becoming known among men of letters. In 1775 he was elected to the Club, the brilliant circle that the painter Sir Joshua Reynolds had formed round the writer and lexicographer Dr. Samuel Johnson. Although Johnson's biographer, James Boswell, openly detested Gibbon, and it may be inferred that Johnson disliked him, Gibbon took an active part in the Club and became intimate with Reynolds and the actor David Garrick. In the previous year he had entered Parliament and was an assiduous, though silent, supporter of Lord North.

The "Decline and Fall." The first quarto volume of his history, published on February 17, 1776, immediately scored a success that was resounding, if somewhat scandalous because of the last two chapters in which he dealt with great irony with the rise of Christianity. Reactions to Gibbon's treatment of Christianity have displayed various phases. Both in his lifetime and after, he was attacked and personally ridiculed by those who feared that his skepticism would shake the existing establishment. In the 19th century he was hailed as a champion by militant agnostics. Gibbon himself was not militant. He did not cry with Voltaire, "*Écrasez l'Infâme!*" ("Crush the Infamy!") because in his England and Switzerland he saw no danger in the ecclesiastical systems. His concern was past history. One may say, however, with confidence, that he had no belief in a divine revelation and little sympathy with those who had such a belief. While he treated the supernatural with irony, his main purpose was to establish the principle that religions must be treated as phenomena of human experience. In this his successors have followed him and added to the collateral causes of Christianity's growth those that he had overlooked or could not know of, such as the various mystery religions of the empire and particularly the Mithraic cult. Although Gibbon's best known treatment of Christianity is found mainly in the 15th and 16th chapters, no less significant are later chapters in which he traced the developments of theology and ecclesiasticism in relation to the breakup of the empire.

Critical reception to his great work

Gibbon went on to prepare the next volumes. Meanwhile, he was assailed by many pamphleteers and subjected to much ridicule. His ugliness and elaborate clothes made him an easy target. For the most part he ignored his critics. The historians David Hume and William Robertson recognized him as their equal if not their superior. Only to those who had accused him of falsifying his evidence did he make a devastating reply in *A Vindication of Some Passages in the Fifteenth and Sixteenth Chapters of the Decline and Fall of the Roman Empire* (1779).

In the same year he obtained a valuable sinecure as a commissioner of trade and plantations. Shortly after that he composed *Mémoire justificatif* (1779), a masterly state paper in reply to continental criticism of the British government's policy in America. In 1781 he published the second and third volumes of his history, bringing the narrative down to the end of the empire in the West. Gibbon paused at this point to consider continuing his history. In 1782, however, Lord North's government fell, and soon Gibbon's commission was abolished. This was a serious loss of income. To economize he left England and joined Deyverdun in a house at Lausanne. There he quietly completed his history in three more volumes, writing the last lines of it on June 27, 1787. He soon returned to England with the manuscript, and these volumes were published on his 51st birthday, May 8, 1788. The completion of this great work was acclaimed on all sides.

The Decline and Fall is thus comprised of two divisions, equal in bulk but inevitably different in treatment. The first half covers a period of about 300 years to the end of the empire in the West, about AD 480. In the second half nearly 1,000 years are compressed. Yet the work is a coherent whole by virtue of its conception of the Roman Empire as a single entity throughout its long and diversified course. Gibbon imposed a further unity on his narrative by viewing it as an undeviating decline from those ideals of political and, even more, intellectual freedom that he had found in classical literature. The material decay that had inspired him in Rome was the effect and symbol of moral decadence. However well this attitude suited the history of the West, its continuance constitutes the most serious defect of the second half of Gibbon's history and involved him in obvious contradictions. He asserted, for example, that the long story of empire in the East is one of continuous decay, yet for 1,000 years Constantinople stood as a bulwark of eastern Europe. The fact is that Gibbon was not only out of sympathy with Byzantine civilization; he was less at home with Greek sources than with Latin and had no access to vast stores of material in other languages that subsequent scholars have assembled. Consequently there are serious omissions in his narrative, as well as unsatisfactory summaries.

Unity of the work

Nevertheless this second half contains much of Gibbon's best. With all its shortcomings, it marshals with masterly lucidity the successive forces that eventually overthrew Constantinople. Many of his most famous chapters occur there. These include sections on Justinian, the Trinitarian controversies, the rise of Islām, and the history of Roman law. There is, in addition, a brilliant and moving story of the last siege and capture of Constantinople and, finally, the epilogue of chapters describing medieval and Renaissance Rome, which gives some hope that the long decline is over and that mankind has some prospect of recovering intellectual freedom. The vindication of intellectual freedom is a large part of Gibbon's purpose as a historian. When toward the end of his work he remarks, "I have described the triumph of barbarism and religion," he reveals epigrammatically his view of the causes of the decay of the Greco-Roman world. They can hardly be disputed. But there is the further question of whether the changes brought about are to be regarded as ones of progress or retrogression. Writing as a mid-18th-century "philosopher," Gibbon saw the process as retrogression, and his judgment remains of perpetual interest.

Last years

Returning to Lausanne, Gibbon turned mainly to writing his memoirs. His happiness was broken first by Deyverdun's death in 1789, quickly followed by the outbreak of the French Revolution and the subsequent apprehension of an invasion of Switzerland. He had now become very fat and his health was declining. In 1793 he suddenly returned to England on hearing of Lady Sheffield's death. The journey aggravated his ailments and he died in a house in St. James's Street, London, on January 16, 1794. His remains were placed in Lord Sheffield's family vault in Fletching Church, Sussex.

Assessment. Modern knowledge of history, in Gibbon's field alone, has increased conspicuously. Economic, social, and constitutional history have grown up. The

study of coins, inscriptions, and archaeology generally has brought in a great harvest. Above all, the scientific examination of literary sources, so rigorously practiced now, was unknown to Gibbon. Yet he often exhibits a flair and an acumen that seem to anticipate these systematic studies. He had genius in large measure, as well as untiring industry and accuracy in consulting his sources. Though he was unsympathetic to Christianity, his sense of fairness and probity made him respectful of honest opinion and true devotion, even among those with whom he disagreed. These qualities, expressed with his command of historical perspective and his incomparable literary style, justify a modern historian's dictum that, "whatever else is read Gibbon must be read too," or the conclusion of the great Cambridge historian J.B. Bury:

> That Gibbon is behind date in many details and in some departments of importance, simply signifies that we and our fathers have not lived in an absolutely incompetent world. But in the main things he is still our master above and beyond "date."

BIBLIOGRAPHY

Works: The Decline and Fall, original ed., vol. 1 (1776), vol. 2–3 (1781), vol. 4–6 (1788). Numerous later editions, especially W. SMITH'S reissue of DEAN MILMAN'S ed. with GUIZOT'S notes, 8 vol. (1854 and 1872), and J.B. BURY'S ed., 7 vol. (1896–1900 and 1909–14), with valuable introduction and commentaries—abridged in 1 vol. by D.M. LOW (1960); *Miscellaneous Works*, ed. by LORD SHEFFIELD, 2 vol. (1796), 5 vol. (1814 and 1815) containing the *Memoirs*, a large selection of Gibbon's letters, and a number received by him from others; *Memoirs of My Life and Writings*, reissues of Sheffield's edition by G. BIRKBECK HILL (1900) and J.B. BURY (1907, 1923)—definitive edition by GEORGES A. BONNARD (1969); *Manuscript Drafts*, ed. by JOHN MURRAY (1896); *Letters*, ed. by R.E. PROTHERO, 2 vol. (1896); *Correspondence*, minor works and unpublished material, ed. by J.E. NORTON, 3 vol. (1956), the fullest collection of all the letters known at that date—invaluable both for its information and style.

Journals: Gibbon's Journal to January 28, 1763, ed. by D.M. LOW (1929), contains an account of Gibbon's service in the militia and contemporary social life and reading, preceded by a brief relation of his early years; *Le Journal de Gibbon à Lausanne, 1763–1764* (1945) and *Gibbon's Journey from Geneva to Rome 1764* (1961), both ed. by G.A. BONNARD.

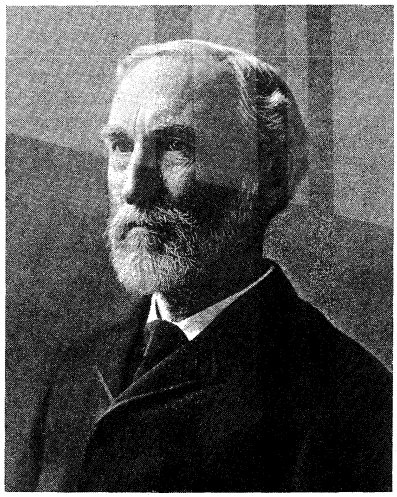
Gibbs, J. Willard

Josiah Willard Gibbs was a theoretical physicist and chemist, considered by many in the latter part of the 20th century to be the greatest scientist yet produced by the United States. His application of thermodynamic theory converted a large part of physical chemistry from an empirical into a deductive science. His work also enabled the quantities involved in many chemical industrial processes to be forecast precisely by calculation, thus greatly increasing efficiency and economy.

Early years

Gibbs was born at New Haven, Connecticut, on February 11, 1839, the fourth child and only son of Josiah Willard Gibbs, Sr., professor of sacred literature at Yale. There were college presidents among his ancestors and scientific ability in his mother's family. Facially and mentally, Gibbs resembled his mother. He was a friendly youth but withdrawn and intellectually absorbed. This circumstance and his delicate health kept him from participating much in student and social life. He was educated at the local Hopkins Grammar School and entered Yale in 1854, where he won a succession of prizes. After graduating, he pursued research in engineering. His thesis on the design of gearing was distinguished by the logical rigour with which he used geometrical methods of analysis. In 1863 Gibbs received the first doctorate of engineering to be conferred in the United States. He was appointed a tutor at Yale in the same year. He devoted some attention to engineering invention.



Gibbs.
By courtesy of Yale University

Gibbs lost his parents rather early, and he and his two older sisters inherited the family home and a modest fortune. In 1866 they went to Europe, remaining there nearly three years while Gibbs attended the lectures of European masters of mathematics and physics, whose intellectual technique he assimilated. He returned more a European than a U.S. scientist in spirit—one of the reasons why general recognition in his native country came so slowly. He applied his increasing command of theory to the improvement of James Watt's steam-engine governor. In analyzing its equilibrium, he began to develop the method by which the equilibriums of chemical processes could be calculated.

He was appointed professor of mathematical physics at Yale in 1871, before he had published his fundamental work. His first major paper was "Graphical Methods in the Thermodynamics of Fluids," published in 1873. It was followed in the same year by "A Method of Geometrical Representation of the Thermodynamic Properties of Substances by Means of Surfaces" and in 1876 by his most famous paper, "On the Equilibrium of Heterogeneous Substances." The importance of his work was immediately recognized by the Scottish physicist James Clerk Maxwell in England, who made a model of Gibbs's thermodynamic surface with his own hands and sent it to him.

He remained a bachelor, living in his surviving sister's household. In his later years he was a tall, dignified gentleman, with a healthy stride and ruddy complexion, performing his share of household chores, approachable and kind (if unintelligible) to students. He died at New Haven on April 28, 1903, at the age of 64.

Ignorance of his work

Gibbs was highly esteemed by his friends, but U.S. science was too preoccupied with practical questions to make much use of his profound theoretical work during his lifetime. He lived out his quiet life at Yale, deeply admired by a few able students but making no immediate impress on U.S. science commensurate with his genius. He never even became a member of the American Physical Society. He seems to have been unaffected by this. He was aware of the significance of what he had done and was content to let posterity appraise him.

The contemporary historian Henry Adams called Gibbs "the greatest of Americans, judged by his rank in science." His application of thermodynamics to physical processes led him to develop the science of statistical mechanics; his treatment of it was so general that it was later found to apply as well to quantum mechanics as to the classical physics from which it had been derived.

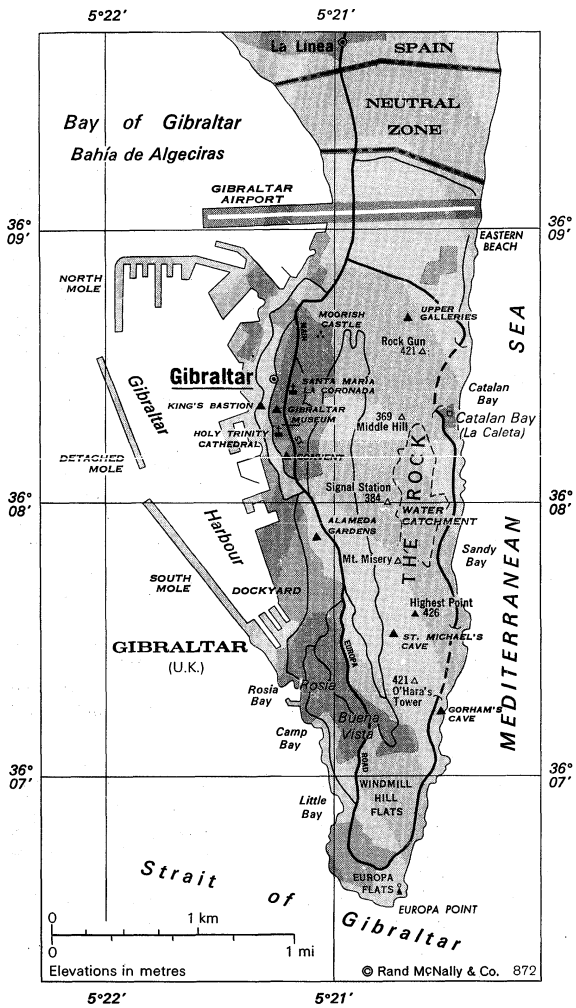
BIBLIOGRAPHY. The most considerable biography yet available is LYNDE PHELPS WHEELER, *Josiah Willard Gibbs* (1970), containing an extensive bibliography. One of the best personal accounts of Gibbs is E.B. WILSON, "Reminiscences of

Gibbs by a Student and Colleague," *Scient. Mon.*, 32:211–227 (1931). A biography for the general reader is contained in J.G. CROWTHER, *Famous American Men of Science* (1969). An appraisal of his work is F.G. DONNAN and A.E. HAAS (eds.), *A Commentary on the Scientific Writings of J. Willard Gibbs* (1936). His papers have been brought together as *The Collected Works of J. Willard Gibbs*, ed. by W.R. LONGLEY and R.G. VAN NAME, with a biographical sketch by H.A. BUMSTEAD (1928).

(J.G.Cr.)

Gibraltar

The British colony of Gibraltar occupies a narrow peninsula of Spain's southern Mediterranean coast, just northeast of the Strait of Gibraltar. Three miles long and three-quarters of a mile wide, it is connected to Spain by a low, sandy isthmus that is one mile long. Its name is derived from the Arabic Jabal Ṭāriq (Mt. Tarik), honouring Ṭāriq ibn Ziyād, who captured the peninsula in AD 711. The colony's total area is 2.25 square miles (5.8 square kilometres).



GIBRALTAR

Gibraltar was possibly one of the "Pillars of Hercules" that defined the limits of navigation for the ancient Mediterranean world. Since the 18th century, it has been a symbol of British naval strength, commonly known as "the Rock." With the opening of the Suez Canal in 1869, Gibraltar increased in strategic importance, and its position as a provisioning port was greatly enhanced. Since World War II the British military garrison and naval dockyard have continued to be an important part of Gibraltar's economy, and naval operations of the North Atlantic Treaty Organization (NATO) often use the port facilities. Attempts are being made, however, to diversify the colony's economy through its commercial port and increased tourist facilities. Gibraltar's historic heritage is reflected in the social composition and unique cultural traditions of the colony and also, less happily, in the disputes between Britain and Spain over its political status.

The natural environment. *Relief.* The peninsula consists of a limestone and shale ridge known as the Rock. It rises abruptly from the isthmus to 1,380 feet (421 metres) at Rock Gun, which is its northernmost summit. Its greatest height, 1,396 feet, is attained near its southern end. The Rock shelves down to the sea at Europa Point, which faces Ceuta (a Spanish *plaza* in Morocco), 14 miles across the strait. From the Mediterranean, Gibraltar appears as a series of sheer, inaccessible cliffs, fronting the sea, that are broken by huge sand slopes above Catalan and Sandy bays. The slope is more gradual on its western side and is occupied by tier upon tier of houses that stretch for some 300 feet above the old defensive walls. Above the houses, the steep, stony hillside is baked brown in summer and bursts into abundant vegetation after the first autumn rains. Higher up limestone cliffs almost isolate the Upper Rock, which is covered with a tangle of wild trees.

The Rock

Water supply. Gibraltar has no springs or rivers, and 34 acres of the eastern sand slopes have been sheeted over to provide a rain-catchment area. The water is stored in 13 tanks (with a total capacity of 16,000,000 gallons) that were blasted into the Rock. The rainwater is then blended with water pumped from wells on the isthmus or distilled from the sea. When these sources threaten to run short, water is imported from northern Europe. Seawater is supplied for sanitation purposes.

Soils. Most of the peninsula's soil has been formed by the disintegration of limestone. There is red sand beneath and to the south of the city, and fawn-coloured sand slopes cover over half of the eastern side of the Rock. The eastern sands are believed to have been windblown from the Sahara.

Vegetation and animal life. The Gibraltar candytuft is a flower native only to the Rock. There are more than 500 species of small flowering plants, and wild olive and pine trees grow on the Upper Rock. Mammals include rabbits, foxes, and Barbary apes. The only wild monkeys in Europe, the apes have roamed the Rock for hundreds of years and were long a symbol of British presence in Gibraltar. Although free to wander at will, they are generally to be seen on the Upper Rock. Migratory birds are common, and Gibraltar is the home of the only specimens of Barbary partridge in Europe.

The Barbary apes

The human imprint. *Settlement.* The old walled city of Gibraltar stands on the western face of the Rock. Because of the sheer face of the cliffs above 300 feet, the town has been forced to spread onto the isthmus to the north and southward toward Europa Point, and some 100 acres have been reclaimed from the sea. There is also a small village at Catalan Bay.

The people. The 1970 population total of 27,965 included 2,783 aliens and 1,003 visitors but excluded British servicemen. Only Gibraltarians—those born in Gibraltar before 1925 and their descendants—have the right to live in the colony. All others must obtain residence permits. Most Gibraltarians are of mixed Genoese, British, Spanish, Maltese, and Portuguese descent. The alien community includes Indian shopkeepers and their families and workers from Morocco.

The majority of the population belongs to the Roman Catholic Church, which established a bishopric in Gibraltar in 1910. The Anglican bishopric, created in 1842, also covers communities in southern Europe. The small Jewish community is of Sefardic descent. The birth rate averages 20 per 1,000 and the mortality rate eight per 1,000 over the course of a decade. Spanish is the language of most homes, although most Gibraltarians are bilingual in English and Spanish.

The economy. Because of lack of space, there is no agriculture. There is a small amount of light industry—tobacco, beverages, canning—but the main sources of income are tourism, provisioning of ships and military personnel, and the re-export trade. Since the 1960s, large-scale expansion of hotel and beach facilities has been funded largely by loans from the United Kingdom. The

The port

port facilities occupy most of the western shore and a portion of land reclaimed from the sea. The naval dockyard and auxiliary installations face a harbour which is formed by three moles, parts of which are now used commercially. There is also a small commercial repair yard and yacht marina. Of the re-export commodities, fuel for visiting ships is the most important, while import duties and the price of water are maintained at a low level to encourage provisioning.

Customs and income tax produce most of the colony's revenue. Aid from Britain has been received since Spain started its restrictions; before that Gibraltar balanced its own budget. Principal expenditures include medical services, education, and housing.

Transportation. Spain closed its road to Gibraltar in 1969, restricting access to the colony to sea and air service. Passenger and cargo vessels stop at the port, and a car ferry crosses daily to Tangier, Morocco. There are regular flights linking Gibraltar to London and Tangier. Over 5,000 vehicles use the 35 miles of roads and some of the 30 miles of tunnels within the Rock. A cable car ascends to the central summit of the ridge.

Administration and social conditions. *Government.* Gibraltar is a colony of the United Kingdom that is self-governing in all matters but defense. Gibraltarians of both sexes over 18 and British civilians resident for over a year are entitled to vote every four years to elect a House of Asssembly of 15 members. A government is formed from the party or coalition of parties gaining the majority of seats, with a chief minister presiding over a Council of Ministers. Instead of a city council, one minister is responsible for municipal affairs. The judicial system includes a Court of Appeal, the Supreme Court, the Court of First Instance, and the Magistrates' Court.

Defense forces

In addition to the United Kingdom forces on the Rock, the volunteer Gibraltar Regiment serves as an infantry and coast artillery unit. The police force is responsible for immigration, residential permits, ambulance service, and traffic control in addition to other police duties.

Health and welfare. A compulsory-insurance scheme for industrial workers provides benefits during unemployment and old age or after an accident. The government maintains a general hospital and one for mental illnesses. Payments are scaled to the patient's income or are abolished for members of lower income groups. The Royal Naval Hospital serves visiting warships and the garrison.

Education. Education is compulsory between the ages of five and 15. All instruction is in English and includes religious training. Fifteen primary and seven secondary schools, all tuition-free, accept Gibraltarians and the children of British service personnel. There are also private primary schools, a technical college, and a special commercial school for girls.

The media. There are two English-language daily newspapers, an English–Spanish biweekly, and a bilingual weekly. The Gibraltar Broadcasting Corporation runs television and radio broadcasts. Similar services from Spain reach many homes.

Cultural life. Art exhibitions are frequent, amateur drama thrives, and enthusiastic groups engage in cave exploration, bird watching, and archaeological research. The Gibraltar Museum houses natural-history, archaeology, and military collections, and the British Council has a periodical and record library. Football, hockey, cricket, yachting, and fishing are popular sports.

Prospects for the future. Gibraltar's future revolves around the question of its political status. Spain claims the right to sovereignty over the peninsula, the United Kingdom wishes to retain sovereignty, and Gibraltar desires the closest links with Britain. Tension has been high since the mid-1960s, when, in a series of moves, the Spanish government withdrew all Spanish workers from Gibraltar, closed the frontier, attempted to restrict air and sea traffic, and terminated telegraph and telephone services with and through Spain. In the plebiscite of 1967 Gibraltar voted by over 99 percent to remain with the United Kingdom, and by the early 1970s no solution to the problem had been reached.

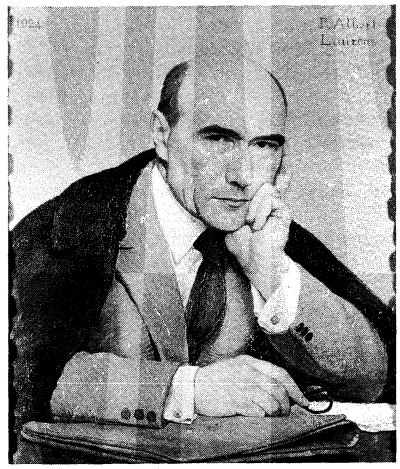
(D.M.E.)

Gide, André

For most of his life a controversial figure, André Gide, one of the most notable writers of his time, was also one of its outstanding personalities. Long regarded as a revolutionary for his open support of the claims of individual liberty of action in defiance of conventional morality, before his death he was widely recognized as first and foremost a moralist, interested rather in humanity than in individuals. It is for his integrity and nobility of thought, his purity and harmony of style, that, as a moralist in the great 17th-century French tradition, he takes his place among the masters of French literature.



Gide, oil painting by P.A. Laurens, 1924. In the National Museum of Modern Art, Paris.

Heritage and youth. Born in Paris on November 22, 1869, Gide was the only child of Paul Gide and his wife, Juliette Rondeaux. His father was of southern Huguenot peasant stock; his mother, a Norman heiress, although Protestant by upbringing, belonged to a northern Catholic family long established at Rouen. To this mixed heredity Gide was to attribute the conflict in his character between asceticism and hedonism, spirituality and sensuality.

When he was eight he was sent to the École Alsacienne in Paris, but his education was much interrupted by ill health. After his father's early death in 1880, his well-being became his mother's chief concern, and, often kept at home, he was taught by indifferent tutors and by his mother's governess. Most of his holidays were spent in Normandy: in the summer he and his mother stayed at La Roque, where she had inherited a castle dating back to the 16th century. Gide used it as a setting for two of his tales, *The Immoralist* and *Isabelle*. His closest friends were his cousins Jeanne, Valentine, and Madeleine Rondeaux, with whom he stayed in Rouen and at their country house at Cuverville, a village near the coast. A pleasant 18th-century house, it is the setting of *Strait Is the Gate*, Gide's most classically perfect work.

The turning point of Gide's life

At Rouen, when he was 13, Gide underwent the emotional experience that changed his life. One day he came upon his 15-year-old cousin Madeleine weeping as she knelt at prayer. She told him that she had discovered her mother's infidelity and knew that she must keep it secret.

Gide fell in love with her and realized that he had found the object of his lifelong devotion. The scene provides a pivot for the action of *Strait Is the Gate* and is described in his autobiography, *If It Die* . . . .

Gide returned to the École Alsacienne to prepare for his *baccalauréat* examination, and, after passing it in 1889, he decided to spend his life in writing, music, and travel. Secretly he had determined to enshrine his devotion to Madeleine in literary form and so to win her love. His first work, however, the autobiographical tale *The Notebooks of André Walter*, published anonymously at his own expense, pleased neither Madeleine nor the public. Written, like most of his later works, in the first person, it uses the confessional form in which he was to achieve his greatest successes.

Symbolist period. In the same year a school friend, the writer Pierre Louÿs, introduced him to the poet Stéphane Mallarmé's famous "Tuesday evenings," the centre of the French Symbolist movement, and for a time he was influenced by its aesthetic theories. His next work, "Narcissus" (1891), exemplifies the poetic purpose of the symbol in its story of Narcissus, who, seeking to know himself by gazing at his reflection in the River of Time, learns that truth and perfection can only be apprehended imaginatively through symbols. Two "tales" published in 1893 also belong to Gide's Symbolist period: *Urien's Voyage*, in which he first reveals a characteristic irony and satiric power; and "The Lovers' Attempt," illustrating the difference between "dispassionate love" and desire.

In 1893 Gide paid the first of many visits to North Africa, hoping to find release from dissatisfaction with the restrictions imposed by his upbringing. There, during recovery from a serious illness, he composed the paean of praise to life in all its fullness that was to form part of *Fruits of the Earth*. But after he returned to France, his relief at having shed the shackles of convention evaporated in what he calls the "stifling atmosphere" of the Paris salons. Had he been unable to satirize this in *Marshlands*—a brilliant parable of animals who, living always in dark caves, lose their sight because they never use it—he would, he claimed, have been driven to the verge of suicide.

Marshlands was completed in 1894, and in a resurgence of the mood in which he had begun *Fruits of the Earth*, Gide returned to North Africa. There he met Oscar Wilde and Lord Alfred Douglas, who encouraged him to admit the nature of his suppressed homosexual desires and to defy traditional morality. With a new freedom and serenity, he composed the greater part of *Fruits of the Earth*, a work in which he appeals to the young to escape from convention, to "act without pausing to consider whether the action is good or evil; love without troubling whether it is good or evil." But before it was finished, he was recalled to France because of his mother's illness. She died in May 1895. Grief shattered the joy he had found in Africa, and he abandoned *Fruits of the Earth* to write *Saül*, a dramatic work diametrically opposed to the former in intent.

Mayor of La Roque

In October he married his cousin Madeleine Rondeaux, who had earlier refused him. Early in 1896 he was elected mayor of the commune of La Roque—at 27 the youngest mayor in France. He took his duties seriously but managed to complete *Fruits of the Earth*. It was published in 1897 and fell completely flat, although after World War I it was to become Gide's most popular and influential work. In the postwar generation, its call to each individual to express fully whatever in him is most completely his own evoked an immediate response, and it remains the one of Gide's works most enjoyed by the young.

Great creative period. *Prometheus Misbound*, a return to the satirical style of *Urien's Voyage* and *Marshland*, is Gide's last discussion of man's search for individual values. His next tales, with which his great creative period begins—*The Immoralist*, *Strait Is the Gate*, and "The Pastoral Symphony"—reflect his attempts to achieve harmony in his marriage in their treatment of the problems of human relationships. They mark an important stage in his development: adapting treatment and style to his concern with psychological problems. In them he first achieves a mastery of classical construction and a pure, simple style.

During most of this period Gide was suffering deep anxiety and distress. Although his love for Madeleine had given his life what he called its "mystic orientation," he found himself unable, in a close, permanent relationship, to reconcile this love with his need for freedom and for experience of every kind. Floundering in doubts and scruples, he tried to find in religion a test of the ultimate values and a source of inner peace and security. But here again, certainty evaded him; although, from *Strait Is the Gate* onward, his works were widely read and many praised them highly, they were also severely criticized for immorality.

The Vatican Swindle marks the transition to the second phase of Gide's great creative period. He called it not a tale but a *sotie*, by which he meant a satirical work in which all the characters are fools or madmen. In it he explores the various ways in which all men are fools. This, the first of his works to be violently attacked for anticlericalism, lost him many Catholic friends, among them the writer Paul Claudel; paradoxically, when writing this work, Gide had come nearest to embracing Catholicism.

Literary critic

In the early 1900s he had already begun to be widely known as a literary critic, and in 1908 he was foremost among those who founded *La Nouvelle Revue Française*, the literary review that was to unite progressive French writers until World War II.

During World War I Gide worked in Paris, first for the Red Cross, then in a soldiers' convalescent home, and finally as assistant director of the Foyer Franco-Belge, giving shelter to refugees. In 1916 he returned to Cuverville, his home since his marriage, and began to write again.

The war had intensified Gide's anguish, and early in 1916 he had begun to keep a second *Journal* (published in 1926 as *Numquid et tu?*) in which he recorded his search for God. Finally, however, unable to resolve the dilemma (expressed in his statement "Catholicism is inadmissible, Protestantism is intolerable; and I feel profoundly Christian"), he resolved to achieve his own ethic, and by casting off his sense of guilt to become his true self. Now, in a desire to liquidate the past, he began his autobiography, *If It Die* . . . , an account of his life from birth to marriage that is among the great works of confessional literature. In 1918 his friendship for the young Marc Allégret caused a serious crisis in his marriage, when his wife in jealous despair destroyed her "dearest possession on earth"—his letters to her.

After the war a great change took place in Gide, and his face began to assume the serene expression of his later years. By the decision involved in beginning his autobiography and the completion in 1918 of *Corydon* (a Platonic dialogue in defense of homosexuality begun earlier), he had achieved at last an inner reconciliation. In 1923 the birth of his only child Catherine, whose mother, Elisabeth van Bysselberghe, was the feminist daughter of a lifelong friend, gave him new cause for hope. *Corydon*'s publication in 1924 was disastrous; he was violently attacked, even by his closest friends. Although he felt their betrayal keenly, it was less wounding than his own sense of self-betrayal for his long hesitation before publishing the book.

Gide called his next work, *The Coiners*, his only novel. He meant by this that in conception, range, and scope it was on a vaster scale than his tales or his *soties*. It is the most complex and intricately constructed of his works, in which, he said, he aimed to achieve in fiction what Bach achieved in music in his *Art of the Fugue*. Its structure is fugal; themes rise, are submerged, and rise again in new patterns and formations; and the numerous plots and characters are linked with a musician's skill by a "main theme"—a character who is involved in all the novel's actions. Like *The Vatican Swindle*, *The Coiners* is transitional: in it are gathered up all of Gide's favourite themes, and it looks forward to the compassionate, objective concern for humanity of his final phase. Gide's awareness of the novel's difficulties is shown by his pub-

lication of the diary he had kept while writing it, *The Logbook of the Coiners.*

Journey to Africa

In 1925 Gide set off for French Equatorial Africa. He had planned a long absence to recover from the hostility aroused by *Corydon.* When he returned he published *Travels in the Congo,* in which he criticized French colonial policy. His journey had released him from personal obsessions and had given him energy to attack the world's problems. He became the champion of social outcasts, demanding more humane conditions for criminals and equality for women; and condemning the exploitation of Africans under colonial rule and the lot of the underprivileged.

For a time it seemed to him that he had found a faith in Communism. In 1936, full of hope, he set out on a visit to the Soviet Union; his disillusionment is expressed in *Return from the U.S.S.R.* and *Afterthoughts on the U.S.S.R.*

Late works. In his *Journal* for 1938 a thick black line is ruled across the pages between the entries for April and for August as a symbol of mourning for the death of his wife. After a long estrangement they had been brought together by her fears for his safety in Africa and by her final illness. To him she was always the great—perhaps the only—love of his life. With the outbreak of World War II, Gide began to realize the value of tradition and to appreciate the past. In a series of imaginary interviews written in 1941 and 1942 for *Le Figaro,* he expressed a new concept of liberty, declaring that absolute freedom destroys both the individual and society: freedom must be linked with the discipline of tradition.

Gide's new concept of liberty

From 1942 until the end of the war Gide lived in North Africa. There he wrote "Theseus," his last great work and literary testament. In it, through the meaning he gives to the story of Theseus, he symbolizes his realization of the value of the past: Theseus returns to Ariadne only because he has clung to the thread of tradition. In Theseus' final statement of faith, Gide's own voice can be heard:

> It is without regret that I draw near to my solitary death. I have enjoyed the benefits of the earth. I am glad to think that after me, and thanks to me, men will find themselves happier, better and more free. For the good of humanity to come I have accomplished my work. I have lived.

In June 1947 Gide received the first honour of his life: the Doctor of Letters of the University of Oxford. It was followed in November by the Nobel Prize for Literature. In 1950 he published the last volume of his *Journal,* which took the record of his life up to his 80th birthday in 1949. All Gide's writings illuminate some aspect of his complex character. He is seen at his most characteristic, however, in the *Journal* he kept from 1889, a unique work of more than a million words in which he records his experiences, impressions, interests, and moral crises during a period of more than 60 years. Here the reader meets a man of rare humility and simplicity with an unusually acute psychological perception. In its depth of self-knowledge, its humanity, and its perfection of style, his *Journal* is Gide's lasting memorial. After its publication he resolved to write no more; but he recorded his random thoughts in a notebook, published after his death as *So Be It, or, The Chips Are Down.* More significant perhaps was his letter, written a month before his death, to a Japanese victim of the Nagasaki atomic bomb who had asked him what attitude a man should take on the eve of the conquest of the world by conformism and machines. Only the individual, with his hatred of falsehood, Gide answered, offered hope of salvation: "We are like unto one who, to light his way, follows a torch that he himself is carrying."

The *Journal*

Gide died on February 19, 1951, and was buried beside his wife in the country cemetery at Cuverville.

MAJOR WORKS

COLLECTIONS: *Oeuvres complètes,* 15 vol. (1932–39; index, 1954), still awaiting completion but including items unpublished elsewhere; *Romans, récits et soties, oeuvres lyriques* (1958), collected fiction, with commentary and textual notes; *Théâtre* (1947; *My Theater,* 1951); *The André Gide Reader* (1971).

VERSE AND PROSE POETRY: *Les Cahiers d'André Walter* (1891; *The Notebooks of André Walter,* 1968); *Le Traité du Narcisse* (1891; "Narcissus," in *The Return of the Prodigal,* 1953); *Les Poésies d'André Walter* (1892); *La Tentative amoureuse* (1893, "The Lovers' Attempt," in *The Return of the Prodigal,* 1953); *Le Voyage d'Urien* (1893; *Urien's Voyage,* 1964); *Les Nourritures terrestres* (1897; *Fruits of the Earth,* 1949); *El Hadj* (1899; Eng. trans. in *The Return of the Prodigal,* 1953); *Amyntas* (1906; Eng. trans., 1958); *Le Retour de l'enfant prodigue* (1907; *The Return of the Prodigal,* 1953); *Les Nouvelles Nourritures* (1935; *New Fruits of the Earth,* 1949).

STORIES, SATIRES, AND FABLES: *Paludes* (1895; *Marshlands,* 1953); *Le Prométhée mal enchaîné* (1899; *Prometheus Misbound,* 1953); *L'Immoraliste* (1902; *The Immoralist,* 1930); *La Porte étroite* (1909; *Strait Is the Gate,* 1924); *Isabelle* (1911; Eng. trans. in *Two Symphonies,* 1931); *Les Caves du Vatican* (1914; *The Vatican Swindle,* 1925; *Lafcadio's Adventures,* 1927); *La Symphonie pastorale* (1919; "The Pastoral Symphony," in *Two Symphonies,* 1931); *L'École des femmes* (1929; *The School for Wives,* 1950); *Robert* (1929; "Robert," in *The School for Wives,* 1950); *Geneviève* (1936; "Geneviève; or the Unfinished Confidence," in *The School for Wives,* 1950); *Thésée* (1946; "Theseus," in *Two Legends: Oedipus and Theseus,* 1950).

NOVEL: *Les Faux-Monnayeurs* (1926; *The Counterfeiters,* 1927; also as *The Coiners*).

DRAMA: *Philoctète* (1899; "Philoctetes," in *The Return of the Prodigal,* 1953); *Le Roi Candaule* (1901; "King Candaules," in *My Theater,* 1951); *Saül* (1903; Eng. trans. in *The Return of the Prodigal,* 1953); *Bethsabé* (1912; "Bathsheba," in *The Return of the Prodigal,* 1953); *Oedipe* (1931; "Oedipus," in *Two Legends: Oedipus and Theseus,* 1950); *Perséphone* (1934; Eng. trans. in *My Theater,* 1951); *Le Treizième arbre* (1935); *Robert, ou l'intérêt général* (1944–45); *Le Retour* (1946); *Les Caves du Vatican* (1950).

CRITICISM: *Prétextes* (1903; *Pretexts,* 1959); *Nouveaux prétextes* (1911); *Dostoïevsky* (1923; Eng. trans., 1925); *Incidences* (1924); *Le Journal des Faux-Monnayeurs* (1926; *The Logbook of the Coiners,* 1952); *Essai sur Montaigne* (1929; *Montaigne,* 1929); *Divers* (1931); *Interviews imaginaires* (1943; *Imaginary Interviews,* 1944); *Attendu que . . .* (1943); *L'Enseignement de Poussin* (1945; *Poussin,* 1947); *Poétique* (1947); *Préfaces* (1948); *Rencontres* (1948); *Éloges* (1948); *Notes sur Chopin* (1948; *Notes on Chopin,* 1949).

TRAVEL: *Voyage au Congo* (1927), and *Le Retour du Tchad* (1928; *Travels in the Congo,* 1929); *Dindiki* (1927); *Retour de l'U.R.S.S.* (1936; *Return from the U.S.S.R.,* 1937); *Retouches à mon retour de l'U.R.S.S.* (1937; *Afterthoughts on the U.S.S.R.,* 1937).

JOURNAL: *Journal, 1889–1939* (1939); *Journal, 1939–49* (1954), including most other autobiographical works; *Journals of André Gide,* 4 vol. (1947–51).

LETTERS: *Correspondence* with Francis Jammes (1948), Paul Claudel (1949), Charles du Bos (1950), Paul Valéry (1955), François Mauriac (1971).

OTHER WORKS: *Souvenirs de la Cour d'Assises* (1914; *Recollections of the Assize Court,* 1941); *Morceaux choisis* (1921); *Corydon* (1924; Eng. trans., 1950); *Si le grain ne meurt* (1926; *If It Die . . . ,* 1935); *Numquid et tu . . . ?* (1926; Eng. trans. in *Journals,* vol. 2, 1948); *Un Esprit non prévenu* (1929); *L'Affaire Redureau* (1930); *La Séquestrée de Poitiers* (1930); *Jeunesse* (1945); *Et Nunc Manet in Te* (1947, 1951; Eng. trans., 1952; U.S. title, *Madeleine*); *Feuillets d'automne* (1949; *Autumn Leaves,* 1950); *Littérature engagée* (1950); *Ainsi soit-il, ou, les jeux sont faits* (1952; *So Be It, or, The Chips Are Down,* 1959).

TRANSLATIONS: Gide's works have been translated in most western and various non-western languages, and nearly all are available in English. Specially noteworthy are the fine English translations of most of his major works by his friend Dorothy Bussy, and of his *Journals* by Justin O'Brien.

BIBLIOGRAPHY. ARNOLD NAVILLE, *Bibliographie des écrits d'André Gide depuis 1891 jusqu'en 1952* (1962), is a complete bibliography of Gide's writings. The Bibliothèque Jacques Doucet, Paris, possesses unpublished manuscripts and correspondence. Other manuscript material and letters are in the Bibliothèque Nationale, Paris. The Association des Amis d'André Gide publishes *Cahiers André Gide* (1969–).

Biography: PIERRE DE BOISDEFFRE, *Vie d'André Gide* 2 vol. (1970–71), the standard full-scale biography; JEAN DELAY, *La Jeunesse d'André Gide,* 2 vol. (1956–57; abridged Eng. trans., *The Youth of André Gide,* 1963), a sound, important psychoanalytical study, with new documentation; JEAN LAMBERT, *Gide familier* (1958), a study of Gide in his old age, by his son-in-law; CLAUDE MAHIAS, *La Vie d'André Gide* (1955), a pictorial biography; GEORGE D. PAINTER, *André*

Gide: A Critical Biography (1968), a comprehensive short study that provides a good introduction to Gide's life and work; JEAN SCHLUMBERGER, *Madeleine et André Gide* (1956), on Gide's marriage.

Criticism: GERMAINE BREE, *Gide* (1963); WALLACE FOWLIE, *André Gide: His Life and Art* (1965), an interesting account of the development of Gide's thought; ALBERT J. GUERARD, *André Gide*, 2nd ed. (1969), a critical study by a specialist on Gide; JUSTIN O'BRIEN, *Portrait of André Gide* (1963); ENID STARKIE, *André Gide* (1953), a sympathetic brief guide based on a long friendship with Gide.

(En.S.)

Giorgione

The works of Giorgione of Castelfranco mark the transition from the early Renaissance to the High Renaissance style. Despite the brevity of 34 years of life, his poetic and imaginative art left its mark in the first quarter of the 16th century upon virtually all of the Venetian painters who were his contemporaries.

Giorgione, self-portrait, oil painting. In the Herzog Anton Ulrich-Museum, Braunschweig, West Germany.

Giorgione was probably born in 1477 in Castelfranco, north of Venice. Nothing is known about his personal life except the legends reported by the biographer and Mannerist artist Giorgio Vasari in the two editions (1550 and 1568) of his *Vite de' più eccellenti pittori, scultori ed architettori italiani . . .* (*Lives of the Most Eminent Italian Painters, Sculptors and Architects . . .*). His name is given in two surviving documents of 1507 and 1508 as Zorzi da Castelfranco (in Venetian dialect); *i.e.*, Giorgio of Castelfranco. The form Giorgione (or Zorzon), which is customarily used today, first appears in the 1528 inventory of the Grimani Collection. His name means tall or big George, implying that he was a large man. Tradition holds that he was handsome and amorous. Correspondence dated October 25, 1510, between the celebrated Renaissance patroness of the arts Isabella d'Este of Mantua and her agent Taddeo Albano at Venice mentions Giorgione's death as having occurred recently, probably caused by the plague that was raging in Venice at that time. Vasari's biography is the earliest. It emphasizes the artist's humble origin, his elevated mind, and his personal charm, but this characterization undoubtedly was a product of Vasari's imagination, based upon the poetic quality of Giorgione's paintings.

That the young painter went to Venice to study about 1490 under Giovanni Bellini, the greatest Venetian master of the day, is undeniable. The technique, colour, and mood of Giorgione's pictures are clearly related to Bellini's late style.

Public commissions

Works. The commission of 1507 for a painting or paintings to be placed in the Audience Hall of the Ducal Palace at Venice was perhaps never completed, since no further notice of the work is recorded. Giorgione's principal public commission was the execution of frescoes on the exterior of the Fondaco dei Tedeschi (the German Exchange), where he painted the figures on the facade over the canal. The frescoes over the street were carried out by the young Titian, perhaps under Giorgione's direction. These works, documented in 1508, are lost, except for fragments that contain faint outlines of figures.

Aside from the works mentioned in specific documents, the notes on the art collections of Venice (*Notizie d'opere del disegno*), written between 1520 and 1543 by the Venetian patrician Marcantonio Michiel, contain references to pictures by Giorgione. This information occurs so shortly after the master's death that it is considered generally reliable. Of the 12 paintings and one drawing listed, five works have survived: "The Tempest," "The Three Philosophers," "Sleeping Venus," "Boy with an Arrow," and "Shepherd with a Flute."

"The Tempest" (*c.* 1505) is a milestone in Renaissance landscape painting with its dramatization of a storm about to break. Here is the kind of poetic interpretation of nature that the Renaissance writers Pietro Bembo and Jacopo Sannazzaro evoked. This feeling for nature is probably also intimately related to, though not directly derived from, the philosophical "naturalism" of the contemporary Venetian and Paduan Humanists grouped around the important Renaissance philosopher Pietro Pomponazzi. The meaning of the two people seated in the foreground of "The Tempest" has been the subject of numerous interpretations, none of them definitive. Michiel called them a soldier and a Gypsy. Some literary source of a romantic, Arcadian nature is generally assumed, since no Renaissance artist would include two mysterious figures devoid of meaning. The same kind of evocative literary theme involves the "Pastoral Concert" (*c.* 1510), the attribution of which is much debated, whether it is the work of Giorgione or the young Titian, or both.

The "Sleeping Venus" (*c.* 1510) was left unfinished at Giorgione's death. Michiel stated that the task of adding the landscape background fell to Titian. The picture itself validates this statement, for the landscape with buildings in the right distance is repeated in other works of Titian. Giorgione's "Sleeping Venus" inaugurates a long series of paintings of the goddess of love in Venetian art, particularly those of Titian. None, however, achieved so fully the expression of remoteness and unselfconscious beauty as this majestic and ideally conceived figure. "Judith" (*c.* 1505), though undocumented, evokes the same concept of universal beauty; she is more of a goddess than the avenger of her people.

Idealization of feminine beauty

Few religious paintings are mentioned in the early documentary sources. The panels representing the "Trial of Moses" and the "Judgment of Solomon" are generally agreed to number among the artist's first works (*c.* 1495–1500). Although the figures look slightly archaic, the beauty of the landscape setting with its soft melting distances unmistakably reveals the hand of the painter of "The Tempest." Most celebrated of his religious pictures is the "Madonna and Child with SS. Francis and Liberale" (*c.* 1504, Castelfranco). The composition of this painting forms an equilateral triangle in conformance with the search for geometric solutions characteristic of the Renaissance mind. Thoroughly in the spirit of the master are the landscape and the dreamy mood of the figures, who seem lost in a religious reverie. "The Holy Family" (*c.* 1508) and the "Adoration of the Shepherds" (*c.* 1508) are of equally fine quality. The latter is particularly noteworthy for its exquisitely adjusted colour.

"The Three Philosophers" (*c.* 1510) is one of the works Michiel saw and specifically identified as being by Giorgione. He stated, however, that it was completed by the Venetian painter Sebastiano del Piombo after the master's death. The composition and colour are so fully Giorgione's that Sebastiano could only have added a few finishing touches. In addition, the dreamy melancholy of the three men—who represent youth, maturity, and old age—embodies the spirit of the master. Though the notion of three ages of man is surely implied, little agreement prevails among critics as to whether the three magi,

three philosophers, or a literary source in ancient Roman legend is really intended.

The "Christ Carrying the Cross" (Scuola Grande di San Rocco, Venice) is widely disputed even today. Nevertheless, Vasari in 1568 specifically stated that the painter was Titian, correcting an error that he made in the edition of 1550 in attributing the picture to Giorgione. The canvas, much restored and repainted, has no more than archaeological interest. Other questioned paintings that seem to many 20th-century critics to be the works of Giorgione rather than Titian are "The Adulteress Brought Before Christ" (*c.* 1500), the "Madonna and Child with SS. Roch and Anthony of Padua" (*c.* 1505), and the "Madonna and Child in a Landscape" (*c.* 1504).

Significance as a portraitist

Influence and significance. In portraiture Giorgione made a most profound and far-reaching impression. Venetian painters such as Titian, Palma Vecchio, and Lorenzo Lotto so closely imitated him in the early 16th century that it is at times virtually impossible to distinguish between them. Nevertheless, the portrait of a "Youth" (*c.* 1504) is universally considered to be by Giorgione. The indescribably subtle expression of serenity and the immobile features, added to the chiselled effect of the silhouette and modelling, combine to make the "Youth" an unforgettable expression of Renaissance man. The same sort of exquisite refinement and sensibility characterizes the disputed portrait supposedly of the poet "Antonio Broccardo" (*c.* 1506). Accepted by all critics is the portrait of the so-called "Laura," on the back of which is an inscription giving the date as June 1, 1506, and Zorzi of Castelfranco as the painter. "La Vecchia" ("The Old Woman") bears an inscription *"col tempo"* ("with time") that clearly indicates an allegorical significance of the devastating effects of the passage of time. Despite the singularity of subject in Giorgione's career, the compositional formula and the mention of the picture in the 1569 inventory of Gabriele Vendramin's collection reinforce the attribution.

Giorgione's "Self Portrait as David" (*c.* 1510), recorded in an engraving of 1650 by the well-known German engraver Wenzel Hollar, can safely be considered a much damaged original that has been drastically cut down in size. The artist gave his own portrait more dramatic force by the frown upon his face and by turning the body inward at an angle to the parapet. Titian adopted the same arrangement in his portrait of a gentleman in blue (*c.* 1512, National Gallery, London), where the initials "TV" (Tiziano Vecellio) establish him as the painter rather than Giorgione, as was formerly believed. Despite considerable recent research, the short-lived master from Castelfranco still remains one of the most enigmatic of Renaissance painters. Yet the quality and charm of his paintings have made him as highly esteemed today as he was in his own time—a Venetian master of poetic mood created through idealized form, colour, and light.

MAJOR WORKS

"Judgment of Solomon" and "Trial of Moses" (*c.* 1495–1500; Uffizi, Florence); "The Adulteress Brought Before Christ" (cut down at the right; *c.* 1500; Museum and Art Gallery, Glasgow, Scotland); "Madonna and Child in a Landscape" (*c.* 1504; Hermitage, Leningrad); "Madonna and Child with SS. Francis and Liberale" (*c.* 1504; Cathedral, Castelfranco, Italy); "Portrait of a Youth" (*c.* 1504; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Boy with an Arrow" (*c.* 1505; Kunsthistorisches Museum Vienna); "Fugger Youth" (*c.* 1505; Alte Pinakothek, Munich); "Judith" (*c.* 1505; Hermitage, Leningrad); "Madonna and Child with SS. Giotto

Giotto di Bondone was a 14th-century Italian painter who for more than six centuries has been revered as the first of the great Italian masters. Certainly, he achieved great personal fame in his own lifetime; in the *Divine Comedy*, Dante says of his relation to his reputed teacher, the Florentine artist Cimabue, that "Cimabue thought to hold the field in painting, but now Giotto has the cry, so that the fame of Cimabue is obscured." The mere fact that he was mentioned in Dante, whether or not in a particularly flattering context, was sufficient to establish and maintain this fame in 14th- and 15th-century Italy, and legends soon began to crystallize around his name. When, in 1550, the artist and biographer Giorgio Vasari published *Le vite de' più eccellenti pittori, scultori ed architettori italiani . . .* (*Lives of the Most Eminent Italian Painters, Sculptors and Architects* . . .), he naturally began his history of Italian art with Giotto as the man who, even more than Cimabue, broke away from the Middle Ages and ushered in the "good modern manner."

Anderson—Alinari

"The Lamentation," fresco by Giotto, *c.* 1305–06. In the Arena Chapel, Padua, Italy.

Giotto was born at Vespignano near Florence. Very little is known of his life. Much of his biography and artistic development must be deduced from the evidence of surviving works (a large portion of which cannot be attributed to him with certainty) and stories that originate for the most part from the late 14th century on. The date of Giotto's birth can be taken as either 1266/67 or 1276, and the ten years' difference is of fundamental impor-

Birth date controversy

tance in assessing his early development and is crucial to the problem of the attribution of the frescoes in the church of S. Francesco, in Assisi, which, if indeed by Giotto, are his great early works. It is known that Giotto died on January 8, 1337 (1336, old style); this was recorded at the time in the Villani chronicle. In about 1373, a rhymed version of the Villani chronicle was produced by Antonio Pucci, town crier of Florence and amateur poet, in which it is stated that Giotto was 70 when he died. This fact would imply that he was born in 1266/67, and it is clear that there was 14th-century authority for the statement (possibly Giotto's original tombstone, now lost). Vasari, however, gives 1276 as the year of Giotto's birth, and it may be that he was copying one of the two known versions of the *Libro di Antonio Billi*, a 16th-century collection of notes on Florentine artists. In the *Codex Petrei* version, a statement that Giotto was born in 1276 at Vespignano, the son of a peasant, occurs at the very end of the "Life" and may have been added much later, even, conceivably, from Vasari. In any case, whether Vasari or "Antonio Billi" first made the statement, it cannot have the same authority as that attached to Antonio Pucci, who was about 27 when Giotto died. Certainty of the date of Giotto's birth, if settled by new documents, could help to solve the problem of his work at Assisi, as well as the question of the origins of his style.

Pupil of Cimabue

Giotto has always been assumed to have been the pupil of Cimabue; two independent traditions, each differing on the particular circumstances, assert this, and it is probably correct. Furthermore, Cimabue's style was, in certain respects, so similar to Giotto's in intention that a connection seems inescapable. Cimabue was the most outstanding painter in Italy at the end of the 13th century; he tried, as no artist had before, to break through, with the power of reality and imaginative force, the stylized forms of medieval art. He did not fully succeed, but it seems almost certain that Giotto began his remarkable development with him, inspired by his strength of drawing and his ability to incorporate dramatic tension into his works. On the other hand, whatever Giotto may have learned from Cimabue, it is clear that, even more than the sculptor Nicola Pisano about 30 years earlier, he succeeded in an astonishing innovation that originated in his own genius—a true revival of classical ideals and an expression in art of the new humanity that St. Francis had in the early 13th century brought to religion.

In Giotto's works human beings are the exclusive subject matter, and they act with dedicated passion their parts in the great Christian drama of sacrifice and redemption. By comparison, all his predecessors and most of his immediate successors painted a puppet show with lifeless manikins tricked out in the rags of the splendid, hieratic, and impersonal art of Byzantium, which was to be entirely superseded by the urgent emotionalism of the Franciscan approach to Christianity.

The Assisi problem. The central problem in Giotto studies, the attribution of the Assisi frescoes, may be summed up as the question whether Giotto ever painted at Assisi and, if so, what? There can be no reasonable doubt that he did work at Assisi, for a long literary tradition goes back to the *Compilatio chronologica* of Riccobaldo Ferrarese, who wrote in or before 1319, when Giotto was alive and famous. Later writers down to Vasari expanded this and made it clear that Giotto's works were in the great double church of S. Francesco. By Vasari's time, several frescoes in both upper and lower churches were attributed to Giotto, the most important being the cycle of 28 scenes from the life of St. Francis of Assisi in the nave of the Upper Church and the "Franciscan Virtues" and some other frescoes in the Lower Church.

Revolutionary expression

The majority of these scenes, mostly narrative, are revolutionary in their expression of reality and humanity. In these frescoes, the emphasis is on the dramatic moment of each situation, and, with details of dress and background at a minimum, the inner reality of human emotion is intensified through crucial gestures and glances. In the 19th century, however, it was observed that all these frescoes, though similar in style, could not be by the same hand, and the new trend toward skepticism of Vasari's statements led to the position that rejected all the Assisi frescoes and dated the St. Francis cycle to a period after Giotto's death. This extreme view has been generally abandoned, and, indeed, a dated picture of 1307 can be shown to derive from the St. Francis cycle. Nevertheless, many scholars prefer to accept the idea of an otherwise totally unknown Master of the St. Francis legend, on the grounds that the style of the cycle is irreconcilable with that of the later Arena Chapel frescoes in Padua, which are universally accepted as Giotto's. This involves the idea that the works referred to (in Giotto's lifetime) by Riccobaldo cannot be identified with anything now extant and must have perished centuries ago, so that the early-15th-century sculptor Lorenzo Ghiberti, Vasari, and others mistakenly transferred the existing St. Francis cycle to Giotto. Five hundred years of tradition are thus written off.

Still more difficult, if Giotto did not paint the St. Francis frescoes, major works of art, then they must be attributed to a painter who cannot be shown to have created anything else, whose name has disappeared without trace, although he was of the first rank, and, odder still, was formed by the combined influences of Cimabue, the Florentine sculptor Arnolfo di Cambio, and the Roman painter Pietro Cavallini—influences which coalesce at Assisi and may be taken as the influences that formed Giotto himself.

Influences of Cimabue, Cavallini, and Arnolfo

Arising out of the fusion of Roman and Florentine influences in the Assisi frescoes, there was later a tendency to see the hand of Giotto, as a very young man, in the works of the Isaac Master, the painter of two scenes of "Isaac and Esau" and "Jacob and Isaac" in the nave above the St. Francis cycle. If this theory is accepted, it is easy to understand that Giotto, as a young man, made such a success of this commission that he was entrusted with the most important one, the official painted biography of St. Francis based on the new official biography written around 1266 by St. Bonaventura. In fact, the whole of today's mental picture of St. Francis stems largely from these frescoes. Clearly, a man born in 1276 was less likely to have received such a commission than one ten years older, if, as was always thought, the commission was given in 1296 or soon after by Fra Giovanni di Muro, general of the Franciscans. The works in the Lower Church are generally regarded as productions of Giotto's followers (there are, indeed, resemblances to his works at Padua), and there is real disagreement only over the "Legend of St. Francis." The main strength of the non-Giotto school lies in the admittedly sharp stylistic contrasts between the St. Francis cycle and the frescoes in the Arena Chapel at Padua, especially if the Assisi frescoes were painted 1296–*c.* 1300 and those of the Arena *c.* 1303–05; for the interval between the two cycles is too small to allow for major stylistic developments. This argument becomes less compelling when the validity of the dates proposed and the Roman period *c.* 1300 are taken into account. As already mentioned, the Assisi frescoes may have been painted before 1296 and not necessarily afterward, and the Arena frescoes are datable with certainty only in or before 1309, although probably painted *c.* 1305–06; clearly, a greater time lag between the two cycles can help to explain stylistic differences, as can the experiences that Giotto underwent in what was probably his second Roman period.

Roman period. Three principal works are attributed to Giotto in Rome. They are the great mosaic of "Christ Walking on the Water" (the "Navicella"), over the entrance to St. Peter's; the altarpiece painted for Cardinal Stefaneschi, (Vatican Museum); and the fresco fragment of "Boniface VIII Proclaiming the Jubilee," in S. Giovanni in Laterano (St. John Lateran). Giotto is also known to have painted some frescoes in the choir of old St. Peter's, but these are lost.

Attribution and criticism of the Roman works

These Roman works also pose problems in attribution and criticism. The attribution of the "Navicella" is certain; it is known that Cardinal Stefaneschi commissioned Giotto to do it. The mosaic, however, was almost entirely

remade in the 17th century except for two fragmentary heads of angels, so that old copies must be used for all stylistic deductions. The fresco fragment in S. Giovanni in Laterano was cleaned in the 20th century and was tentatively reattributed to Giotto on the basis of its likeness to the Assisi frescoes, but the original attribution can be traced only as far back as the 17th century. The "Stefaneschi Altarpiece," with its portrait of the Cardinal himself, must be one of the works commissioned by him. The fact that he commissioned Giotto to do the "Navicella" might suggest that this work is by Giotto as well, but the altarpiece is so poor in quality that it cannot be by Giotto's own hand. It may be observed that several works bearing Giotto's signature, notably the "St. Francis of Assisi" (Louvre, Paris) and the altarpieces in Bologna and Florence (Sta. Croce), are generally regarded as school pieces bearing his trademark, whereas the "Ognissanti Madonna," unsigned and virtually undocumented, is so superlative in quality that it is accepted as entirely by his hand.

During this period Giotto may also have done the "Crucifix" in Sta. Maria Novella and the "Madonna" in S. Giorgio e Massimiliano dello Spirito Santo (both in Florence). These works may be possibly identifiable with works mentioned in very early sources, and if so they throw light on Giotto's early style (before 1300). It is also possible that, about 1305, Giotto went to Avignon, in France, but the evidence for this is slender.

Paduan period. There is thus no very generally agreed picture of Giotto's early development. It is some relief, therefore, to turn to the fresco cycle in the chapel in Padua known as the Arena or Scrovegni Chapel. Its name derives from the fact that it was built on the site of a Roman amphitheatre by Enrico Scrovegni, the son of a notorious usurer mentioned by Dante. The founder is shown offering a model of the church in the huge "Last Judgment," which covers the whole west wall. The rest of the small, bare church is covered with frescoes in three tiers representing scenes from the lives of Joachim and Anna, the life of the Virgin, the Annunciation (on the chancel arch), and the life and Passion of Christ, concluding with Pentecost. Below these three narrative bands is a fourth containing monochrome personifications of the Virtues and Vices. The chapel was apparently founded in 1303 and consecrated on March 25, 1305. It is known that the frescoes were completed in or before 1309, and they are generally dated *c.* 1305–06, but even with several assistants it must have taken at least two years to complete so large a cycle.

Narrative skill

The frescoes are in relatively good condition, and all that has been said of Giotto's power to render the bare essentials of a setting with a few impressive and simple figures telling the story as dramatically and yet as economically as possible is usually based on the narrative power that is the fundamental characteristic of these frescoes. These dominating figures, simple and severe, similar to those in the Assisi cycle but placed in settings of more formal abstraction and rendered with more grandeur, are the quintessence of his style, and anatomy and perspective were used—or even invented—by him as adjuncts to his narrative gifts. He never attained to the skill that so often, in fact, misled the men of the 15th and 16th centuries. In the Padua frescoes the details are always significant, whereas it is a characteristic of the Assisi cycle that there occurs from time to time a delighted dwelling on details that are not absolutely essential to the story.

Sta. Croce frescoes. Documents show that Giotto was in Florence in 1311–14 and 1320; and it was probably during these years, before going to Naples (*c.* 1329), that he painted frescoes in four chapels in Sta. Croce belonging to the Giugni, Tosinghi-Spinelli, Bardi, and Peruzzi families. The Giugni Chapel frescoes are lost as are all the Tosinghi-Spinelli ones, except for an "Assumption" over the entrance, not universally accepted as by Giotto. The Bardi and Peruzzi chapels contained cycles of St. Francis, St. John the Baptist, and St. John the Evangelist, but the frescoes were whitewashed and were not recovered until the mid-19th century, when they were damaged in the process of removing the whitewash and then heavily restored. Much the same happened to a portrait of Dante in the Bargello, also in Florence, for which there is a traditional attribution to Giotto. Writers tended to take more or less account of these additions and restorations according to the view they held of the Assisi problem, but a prolonged cleaning and re-restoration of both chapels in the mid-20th century has demonstrated that the Bardi Chapel has few but splendid figures remaining, painted in true fresco, whereas the Peruzzi Chapel figures are now largely ghosts, since they were painted in a different technique. The older view, that the two cycles were contemporary, is no longer necessarily valid, and there is no evidence for the date of either cycle, except that both are probably later than the Arena Chapel frescoes.

Naples and the last Florentine period. In January, 1330, King Robert of Naples promoted Giotto to the rank of "familiar" (member of the royal household), which implies that he had been in Naples for some while, possibly since 1329, and he remained there until 1332–33. All the works he executed there have been lost, but traces of his style may be distinguished in the local school. On April 12, 1334, he was appointed *capomastro*, or surveyor, of the Duomo in Florence and architect to the city. This was a tribute to his great fame as a painter and not on account of any special architectural knowledge. On July 19 of the same year he began the campanile, or bell tower, of the Duomo. It was later altered but is known, in part at least, from a drawing in Siena. He may have designed some of the reliefs carved by Andrea Pisano on the campanile; certainly the bronze doors of the baptistery by Andrea show clear traces of Giotto's frescoes in Sta. Croce. Indeed the whole course of painting in Tuscany was dominated by his pupils and followers—by Taddeo Gaddi, Bernardo Daddi, Maso di Banco, Andrea Orcagna, and Pietro and Ambrogio Lorenzetti in Siena—but none of these really understood all of his innovations, and it was not until the Renaissance, with Masaccio and Michelangelo, that his true successors arose.

Architect to the city of Florence

MAJOR WORKS

The only works universally accepted as Giotto's are the fresco cycle in Padua, firmly datable in the first decade of the 14th century, and the two chapels in Sta. Croce, Florence, which used to be dated around 1320, but since their cleaning in the 1950s and 1960s are now placed anywhere in the second or third decade. The only panel painting universally accepted as Giotto's own work is "The Madonna in Glory" ("Ognissanti Madonna"; Uffizi, Florence), usually dated *c.* 1305–10.

The most controversial attribution is the fresco cycle at Assisi, but other important works in this category are the "Crucifix" in Sta. Maria Novella, Florence (*c.* 1295–1300); the "Dormition of the Virgin" (Staatliche Museen Preussischer Kulturbesitz, Berlin); and the polyptych now in the Museo dell'Opera, Sta. Croce, Florence.

Works that are certainly from Giotto's shop, not necessarily painted by his own hand, include panels in Bologna Pinacoteca Nazionale and the Vatican, and others in Boston (Isabella Stewart Gardner Museum) and the galleries of London, Munich, New York, and Washington. A fragment of the original mosaic from St. Peter's is now in the church at Boville Ernica, near Rome, and another is in the Vatican Museum.

BIBLIOGRAPHY. There is a full bibliography, from the 14th century to 1937, in ROBERTO SALVINI, *Giotto bibliografia* (1938). The earliest important biography is by GIORGIO VASARI in his *Vite*, published in Florence in 1550 and 1568: the 1550 edition has not been translated, but there are many English versions of the 1568 one. Full-scale monographs are ROBERTO SALVINI, *Tutta la pittura di Giotto*, 2nd ed. (1962; Eng. trans., *All the Paintings of Giotto*, 1963); and CESARE GNUDI, *Giotto* (1958; Eng. trans., 1959); and special studies include P. MURRAY, "On the Date of Giotto's Birth," in *Giotto e il suo tempo* (1971); ALASTAIR SMART, *The Assisi Problem and the Art of Giotto* (1971); LEONETTO TINTORI and MILLARD MEISS, *The Painting of the Life of St. Francis in Assisi* (1962); JAMES STUBBLEBINE (comp.), *Giotto: The Arena Chapel Frescoes* (1969); and LEONETTO TINTORI and EVE BORSOOK, *Giotto: The Peruzzi Chapel* (1965).

(P.J.Mu.)

Glaciation, Landforms Produced by

The form and distribution of landscape features on the earth's surface are the imprints of the geological processes that produced them. Those parts of the earth's land surface that were covered by glacier ice during the geologic past contain a variety of landforms testifying to the former presence of glaciers. These are, quite properly, called glacial landforms, but even regions beyond the former glacier boundary—either in the cold-dominated zones of polar latitudes or in latitudes in which more temperate climates prevail today—contain landforms that are wholly or partly the result of climatic conditions not existing today. These features also are attributable to glaciation and will be discussed and described in this article.

Landforms produced by glaciation are of two general types, erosional and depositional. Erosional landforms are those produced by the direct down-wearing action of the ice as it moved across the preglacial land surface. Depositional landforms are those formed directly by ice, either at the bottom of the glacier or at the margin, or by glacial meltwaters flowing in ice channels, subglacial tunnels, or along and beyond the glacier front.

Extent of Pleistocene glaciation

The extent of glaciation during the Pleistocene Epoch (2,500,000 to 10,000 years ago) has been determined principally from the geographic distribution of glacial landforms and deposits of glacial origin. Glacial landforms produced by past glaciations are found on all continents. Ice sheets or continental glaciers covered all of Canada and much of the United States as far south as the Ohio and Missouri rivers. Existing glaciers in Alaska and the Rocky Mountains were greatly enlarged. Many mountain valleys that contain no glaciers today were occupied by glaciers during the Pleistocene. These valley or alpine glaciers were confined to former river valleys, in contrast to the ice sheets that engulfed whole landscapes of continental proportions. Approximately one-third of the earth's total land area was covered by glaciers during the maximum ice advance.

In Europe the Scandinavian countries, England, northern Germany, and the Baltic areas were glaciated. The glaciers of the Alps were greatly enlarged and many modern river valleys, such as the Inn Valley in Austria, were filled with huge glaciers—literally rivers of ice.

In the Soviet Union both the European sector (west of the Ural Mountains) and much of Siberia were glaciated. The Arctic islands such as Novaya Zemlya and Franz Josef Land were nearly completely ice covered.

High mountain ranges throughout the world—the Himalayas, the Andes, and the volcanic peaks of Ruwenzori, Mt. Kenya, and Kilimanjaro in Equatorial Africa, for example—were more extensively glaciated during the Pleistocene than they are today. The southern Andes (Patagonia) was the scene of greatly expanded glaciers, and the Southern Alps in New Zealand were glaciated over an area that was perhaps 50 times larger than the area covered by existing mountain glaciers in that country. In the Pacific, Mauna Kea on the island of Hawaii supported glaciers on its summit, where there are no glaciers today.

Glacial landforms and geological history

The geological record shows that at least three times in the last third of geological history extensive glaciation occurred in many parts of the world where no glaciers exist today. The earliest widespread glaciation occurred during Precambrian time (prior to 570,000,000 years ago). The evidence for this lies mainly in glacially derived sedimentary materials called tillites and in glacial markings, such as grooves and scratches, on the older rocks on which the tillites occur. The Gowganda Glacial Tillite of central Canada indicates the presence of an ice sheet that covered several thousand square miles during Middle Precambrian time. Tillites in North America, Scandinavia, Greenland, India, China, Africa, and Australia testify to the possibility that the greatest glaciation the earth has ever experienced took place during the final phases of the Precambrian.

Tillites in South America, South Africa, Australia, India, and Antarctica seem to record the subsequent depositional activity of several large glaciers during the Permian Period (225,000,000 to 280,000,000 years ago). The Dwyka Tillite of South Africa lies on an older rock surface that bears the grooves and other markings of this inferred Permian glacial action. The widespread occurrence of tillites equivalent in age to the Dwyka and the direction of ice movement deduced from scratches and grooves have been used to support the hypothesis of continental drift (*q.v.*). Accordingly, the origin of the Dwyka and related tillites has been related to a single ice sheet of continental dimensions that existed when the continents of the Southern Hemisphere and India, and possibly China, were part of a single large landmass. It should be noted, however, that some authorities believe that the tillites reflect 30 or more separate ice masses, scattered throughout the Southern Hemisphere during the Permian and the preceding Carboniferous Period. In either case glacially derived landforms and deposits are of considerable value in reconstructing the gross geography of the earth at various times in its history.

The last of the great glaciations occurred during the Pleistocene Epoch (2,500,000 to 10,000 years ago). The maximum extent of the Pleistocene glaciers is much easier to establish than that of older glaciations because the Pleistocene glacial landforms and related deposits generally are not covered by extensive blankets of younger sediments. In some cases, the oldest Pleistocene deposits are overlain by younger glacial materials or have been severely dissected by postglacial streams.

The greatest success in the use of glacial landforms as a means of reconstructing the detailed history of a particular Pleistocene glacial event has been in the establishment of a glacier border during its retreat from a position of maximum advance. Studies of modern glaciers, both those confined to valleys (valley glaciers) and those covering broad expanses of the landscape (continental glaciers), reveal the development of ridges and hummocky topography at the ice border, where glacial sediments (till) and related glacial meltwater deposits are dumped along the ice front. When a glacier retreats from a position it has occupied for some time, perhaps several hundred years, the belt of ridged and hummocky terrain marking the former glacier margin is left behind. This feature is called an end moraine; a single end moraine may be traced for several hundred miles and plotted on a map to show the position of the glacier margin at the time the end moraine was formed. Parallel end moraines thus reveal successive positions of the retreating ice front during the general shrinking of a continental glacier in the waning phases of the Pleistocene. Tree stumps may become incorporated in a moraine and can be dated by geochemical methods. If it is assumed that the trees were killed by glacier overriding, then the absolute age of the dead trees is also the age of the moraine materials containing them.

Importance of glacial landforms and deposits to man

The landscapes produced by continental glaciers extend from the high latitudes to the more temperate middle latitudes, especially in Europe and North America. Glacial drift (ice-transported debris) provided an excellent source material for the development of fertile soils during postglacial time. Wherever the presence of such soils has coincided with favourable climatic conditions, as in the Upper Mississippi Valley or northern Europe, agricultural enterprises of extremely high productivity have emerged. Many farming and dairying industries are thus related to the distribution of glacially derived soils.

Glacial terrains of Pleistocene age generally are associated with abundant surface and subsurface water, the single most important natural resource for the sustenance of large populations and industrial centres. Modern rivers the origins of which are related to glaciation provide hydroelectric power in North America, in the fjord (drowned valley) regions of Scandinavia, and elsewhere in the world. The tens of thousands of lakes in Canada, the Great Lakes of the United States, and the lakes in Scandinavian countries are mostly of glacial origin, and are invaluable for recreation and other uses.

Groundwater supplies in the glaciated areas are contained in aquifers consisting of glacial sands and gravels.

Many municipalities and a multitude of industries derive their primary water supplies from relatively shallow groundwater reservoirs in the glacial landscape.

Earth materials of glacial origin are also of significant economic value. Sand and gravel, widely available in glaciated areas, are used for aggregate in the manufacture of concrete and for road material on secondary roads. Clays deposited in ancient glacial lakes are exploited for bricks, drain tile, and various clay products.

Glaciated landscapes thus provide man with a great variety of natural resources ranging from agricultural lands, water, and constructional materials to scenic lakes and picturesque expanses of wooded hills and valleys.

The direct and indirect effects of glaciation in terms of glacial landforms, features, and deposits are dealt with in this article. For further information on the geological time intervals that coincided with major glaciations, see PRECAMBRIAN TIME; PERMIAN PERIOD; and PLEISTOCENE EPOCH. The modern distribution of ice is covered in the articles ICE SHEETS AND GLACIERS; ICEBERGS AND PACK ICE; and ICE IN RIVERS AND LAKES; and certain glacially derived features or deposits are described in COASTAL FEATURES; CONTINENTAL SHELF AND SLOPE; WATERFALLS; PERMAFROST; VARVED DEPOSITS; and CONGLOMERATES AND BRECCIAS. See also CLIMATIC CHANGE for the evidence of climatic fluctuation through time; HYDROLOGIC CYCLE for a discussion of the importance of ice in the earth's water balance; and LANDFORM EVOLUTION for treatment of the general cause-and-effect relations that govern the configuration of landforms.

This article is divided into the following sections:

I. The processes of glaciation

As a glacier moves over the land surface it modifies the terrain by removing material (glacial erosion) or by depositing debris carried within the ice mass or on the glacier surface (glacial deposition). Each of these major glacial processes produces distinctive landforms that remain long after the glacier has disappeared. In addition to direct glacial erosion and deposition, closely related geological events occur in nonglaciated regions as a direct consequence of the glacial ice, or the climatic conditions that caused the glaciers to grow and expand. These events include the depression of the earth's crust resulting from the superimposed weight of glacier ice, the creation of lakes at the edge of the glacier during its retreat, the distribution of wind-transported sand dunes and silt blankets, emerged and submerged shorelines resulting from sea-level fluctuations in response to waxing and waning of the ice sheets, and the development of characteristic features produced by frost action in cold-dominated regions that were not covered by glacier ice.

GLACIAL EROSION

Glaciers are made up of interlocked grains of ice crystals. Laboratory experiments on single ice crystals and on samples of glacier ice show that ice deforms plastically when stress is applied. In nature the stress is gravity, the basic cause of ice movement. Two kinds of glacier movement have been identified: internal deformation of the ice by slippage or shear along certain planes in the individual ice crystals, and sliding of the base of the glacier on its bed. The velocity of the glacier thus consists of two components, an internal one resulting from deformation or creep of the glacier, and a basal one resulting from the sliding of the glacier on its bed.

The basal ice in many glaciers is at or near the pressure-melting point of ice, so that freezing and thawing occur at various times at the plane of contact between the glacier and the rock or soil beneath it. This permits loose debris such as silt, sand, cobbles, and larger rock fragments to be incorporated as part of the moving glacier mass. These basal, non-ice constituents of the glacier are abrasive tools that scratch, polish, or groove the rock or frozen ground over which the glacier moves.

Glacial quarrying

The melting and refreezing of basal ice is a process that is capable of removing very large blocks of bedrock and incorporating them in the moving glacier mass. Many rocks of the earth's crust characteristically contain intersecting fractures or cracks, called joints, which define incipient angular blocks that can be incorporated into the base of a glacier through the melting-freezing process. Large-scale excavation of many blocks (the individual dimensions of which may range from a few feet to more than ten feet) is another form of glacial erosion known as glacial quarrying, or plucking.

The exact mechanism of glacial quarrying is not known because conditions at the base of a glacier cannot be directly observed. Tunnels, driven into glaciers along the ice-rock basal contact, have yielded very little information about quarrying. Generally, the excavation of rock by glacial quarrying seems to be restricted to rocks that are well-jointed. Massive, unjointed rocks, such as quartzite and others with few joints, are smoothed and polished by overriding glaciers. Glacially quarried surfaces, on the other hand, are rough and jagged because blocks were lifted out by the poorly understood quarrying process.

A good deal of controversy exists about the efficacy of glacial erosion. Some geologists admit that glaciers are capable of abrading rock surfaces but deny that glaciers produce any major landforms comparable to the large canyons cut by rivers. It is suggested instead that such features were produced by preglacial erosion and that glacial modification of them was insufficient to obliterate their preglacial forms.

The real question is not whether glaciers are capable of eroding the land surface but, rather, the magnitude of glacier erosion (see the later section of this article, *Landforms produced by glacial erosion*).

GLACIAL TRANSPORT

Material incorporated in a glacier by abrasion or plucking is transported by glacier flow until it is deposited directly by the ice, or until the glacier melts and leaves its load as a mantle over the landscape. Valley glaciers receive material from the valley walls confining them. Individual boulders and rock fragments, loosened by frost action from cliffs above the glacier surface, fall onto the glacier and are carried in conveyor-belt fashion as the ice stream flows down-valley. In some instances large landslides and debris flows may descend to the surface of a valley glacier, which then transports the rock and soil debris in a down-glacier direction.

Ablation and accumulation of glaciers

A glacier consists of two parts, the zone of accumulation and the zone of ablation. The former occurs in the upper reaches of the glacier where more snow falls each winter than is melted in the following summer. The latter is found at lower elevations on a glacier where, in addition to melting of the annual snowfall during the summer months, part of the glacier ice is destroyed by melting. If a glacier ends in a lake or the ocean, large masses of glacier ice become detached from the glacier terminus to become icebergs. Ablation thus is any process that removes ice from the glacier mass.

Rock debris that falls on a glacier in the zone of accumulation becomes buried by the snowfall of successive winters. A boulder that comes to rest on the glacier surface in the zone of accumulation has two components of movement as it is carried by the glacier. One component is down-valley, parallel to the general surface of the glacier. The other component is vertically downward as the boulder becomes covered by successive snow layers. Snow in the accumulation zone is transformed to glacier ice by a process of recrystallization as it is buried deeper and deeper each year. Debris falling on the glacier surface as airborne dust or boulders from a rockfall ultimately becomes imbedded in the glacier ice.

The flow lines of a glacier in the zone of accumulation are thus inclined downward toward the base of the glacier, whereas in the ablation zone, the flow lines have an upward component toward the glacier surface. Because of this pattern of flow, debris falling on the uppermost reaches of a glacier will be carried to the base of the glacier and then move upward until it reappears at the surface of the ice in the ablation zone.

The boundary between the ablation zone and the accumulation zone is called the snowline. It is best observed in late summer at the end of the ablation season. At that time the accumulation zone still has a residual layer of snow from the previous winter, whereas the ablation zone is strewn with debris released from the melting glacier ice.

If the amount of annual accumulation exceeds annual ablation over a period of years, then mass is added to the glacier. The glacier responds in two ways: it thickens, and it expands over a larger area. Valley glaciers expand in a down-valley direction and ice sheets expand by spreading outward in all directions. In both cases the glacier is said to be advancing.

If, on the other hand, ablation exceeds accumulation over a period of time, the glacier responds by thinning and by reducing its total area. The terminus of a valley glacier retreats in an up-valley direction while the edge of an ice sheet withdraws along the entire margin. During advance and retreat, the glacier continues to transport material in the direction of glacier flow.

From the foregoing it can be deduced that a vigorously advancing glacier may transport debris lying at its terminus by a "snowplow" action, thereby pushing material forward as the snout or margin advances. The snout is also the site of transportation of debris along thrust planes within the glacier itself. Thrust planes in some glaciers are exposed in crevasses near the glacier terminus or on the ablation surface, where the edges of the thrust planes occur as a series of parallel or subparallel bands emphasized by a concentration of dirt and stones that have been carried to the glacier surface by thrusting.

GLACIAL DEPOSITION

Material transported by glacier ice eventually comes to rest on the land surface. Glaciers that terminate in the ocean (tidewater glaciers), such as those discharging from Greenland, Alaska, or Antarctica, deposit material on the sea floor. If the terminus of a tidewater glacier is grounded on the sea floor, deposition is concentrated around the edges of the grounded portion as debris frozen in the glacier is released by melting. If the terminus is afloat, sediment released from the underside of the glacier will fall to the sea floor as melting progresses. These glacio-marine sediments are distinguished from other marine deposits by their heterogeneous detrital content.

Fluvioglacial processes at the ice margin

During the height of the ablation season, the terminus of a glacier on land is a chaotic mixture of melting ice, running water, and mounds of rock and soil debris recently released from the ice by ablation. These conditions change hourly; in late afternoon the discharge of glacial meltwater reaches a maximum, and large volumes of water can be seen flowing on the glacier surface in ice channels or debouching from tunnels in the ice. The flow of meltwater slackens after sunset, and by the early morning hours of the following day, the volume of meltwater being discharged from the glacier may be only a small fraction of the maximum flow of the preceding day.

These conditions give rise to a great variety of glacially derived sediments ranging from ablation debris blanketed over stagnant ice masses to sands and gravels deposited by glacial meltwaters a few miles down-valley from the glacier terminus. The extremely variable conditions of transportation in space and time give rise to extremely varied deposition of sediments. Ablation boulders and unsorted rock rubble may slump onto a deposit of well-sorted gravels, or boulders may fall from the ice front into a quiet meltwater pool where fine sand and silt are accumulating on the bottom.

If a glacier margin retreats year after year, these chaotic ice-marginal deposits will persist over a wide expanse of recently deglaciated terrain. Pauses in the retreat may result in a concentration of the ice-marginal deposits in the terminal zone. If the ice front advances, it may override the older debris-covered areas or push some of it into ridges and mounds that remain for centuries after the glacier has retreated or disappeared entirely.

Meltwater issuing from the ice front in rivulets on the ice, or torrential discharges from ice tunnels, generally converges to form a single channel or series of channels that divide and recombine in an anastomosing (braided) pattern. These braided rivers are choked with glacially derived sediment called outwash or glaciofluvial sediments.

Bedrock channel near the head of Søndre Strømfjord, West Greenland, carved by silt-laden glacial meltwaters. The rock surface was smoothed by glacial erosion.

If a glaciofluvial river empties into a lake, the coarser fraction of the suspended load is deposited at the river mouth while the silt and clay, called rock flour, are deposited on the lake floor. Glacial meltwaters heavily charged with rock flour are distinctively grayish-white in colour and are referred to as *Gletschermilch* in the Alpine regions of Europe.

GLACIAL LOADING AND UNLOADING

The Earth's crust tends toward a condition of balance or isostatic equilibrium. If the crust is considered to be a series of large blocks extending to a constant depth, approximately 20 to 50 kilometres (12 to 30 miles), each of the blocks will stand at a different elevation above sea level because of its difference in density. This condition of crustal balance is constantly changing because material from the higher-standing blocks (the continents) is being eroded and transported to the lower blocks (the ocean basins).

If glacier ice accumulates to some appreciable thickness over a large part of the earth, the crust will be depressed about 300 metres (1,000 feet) for every 900 metres (3,000 feet) of ice. Crustal downwarping increases in magnitude from the marginal areas of a large ice sheet toward the zone of greatest thickness. Where the ice is thin, the crustal downwarping is zero, and where the ice is thickest, the depression of the crust is greatest.

Deformation of the crust because of glacial loading is not a permanent condition. After an ice sheet has melted away, the crust restores itself to a new condition of isostatic balance by rising in response to the glacial unloading.

Postglacial uplift in progress today

Crustal downwarping from glacial loading, and crustal uplift from glacial unloading are operative on the earth today. The crust beneath Greenland and the Antarctic ice sheets is downwarped several thousand feet because of the load of glacier ice on each. In contrast, crustal upwarping is going on in Scandinavia, North America, and the British Isles as a result of the disappearance of the ice sheets from those areas somewhat less than 10,000 years ago. The rate of uplift is determined by the change in the elevation of tide gauges with respect to mean sea level during historical time. The Scandinavian Peninsula, for example, is currently rising at differential rates: north of the Gulf of Bothnia the rate is about 88 centimetres (35 inches) per century, near Stockholm it is around 40 centimetres (16 inches) per century, and at Copenhagen it is zero. These rates are undoubtedly less than they were in the earlier stages of deglaciation, but it appears from other evidence that the land around the Baltic Sea may rise another 600 feet in the centre of the area of uplift before isostatic equilibrium is regained. The maximum uplift in Fennoscandia at that time will have been as great as 760 metres (2,500 feet). If it is assumed that the postglacial rebound equals the total amount of downwarping, and that the ratio of downwarping to ice thickness is about one to three, then the maximum ice thickness for the Fennoscandian region was about 2,300 metres (7,500 feet). This is comparable to the measured ice thickness of the Greenland Ice Sheet, which covers about the same area today as did the Scandinavian Ice Sheet during the Pleistocene.

The depression of the earth's crust by glacier ice produces some side effects in the nearby nonglaciated areas. Coastal regions are submerged, causing invasion of the land by the sea. River mouths are inundated by seawater and river gradients are reduced, giving rise to deposition of river sediments.

The postglacial rise of a previously glaciated land area is recognized in coastal regions such as Scandinavia, the eastern United States, and the Great Lakes region of southern Canada (Figure 1). The evidence comes from differentially uplifted or warped strandlines, which marked the shorelines of water bodies marginal to the retreating Pleistocene ice sheets. These strandlines, represented by beach ridge deposits, were horizontal when formed, but because of glacial rebound since deglaciation these linear features now rise toward the direction of greatest ice thickness. Accurate dating of successively younger strandlines provides the basis for determining postglacial rates of uplift. Crustal recovery patterns are depicted in maps showing isobases, lines connecting points of equal uplift in a given region, as around the Great Lakes or the Gulf of Bothnia and the Baltic Sea. The limit of uplift is defined by the zero isobase (no uplift) or "hinge line." In the Great Lakes region the hinge line has an east-west trend roughly from Milwaukee through Cleveland to New York City. South of that line, all strandlines of the ancestral Great Lakes are horizontal, a fact that implies no uplift. Northward from the zero isobase of the Great Lakes region, uplift is still in progress, but the rate appears to be declining. It has been shown that the maximum uplift north of the Great Lakes occurred at Golfe de Richmond at about latitude 56° N on the east coast of Hudson Bay. There, at least 300 metres (1,000 feet) of uplift has occurred since the load of the ice sheet was reduced by thinning at the end of Pleistocene time. Assuming that complete uplift represents one-third of the ice thickness, the uplift at Golfe de Richmond reflects only about 900 metres (3,000 feet) of ice. This value is too small in relation to maximum Pleistocene ice thickness for the Greenland and Antarctic ice sheets, at comparable distances from their margins. It must therefore be assumed that uplift in the Hudson Bay region is still in progress, and that as much as 600 metres (2,000 feet) of additional uplift can be expected to occur.

PERIGLACIAL PROCESSES

As originally used, the term periglacial was an adjective used to describe the climatic conditions prevailing in a nonglacial zone marginal to a large ice sheet. As used today, the term is synonymous with "cold-dominated" and is applicable to a rigorous climate in which the freeze-thaw process predominates. Generally speaking, the periglacial environment is characterized by perennially frozen ground (permafrost), low precipitation, strong winds, and vegetation ranging from the boreal forests (central Alaska), through taiga (northern Canada) and tundra (Arctic Alaska and Siberia), to vegetation-free areas (northern coast of Greenland and glacier-free areas of Antarctica).

The periglacial environment was undoubtedly more widespread during the Pleistocene than now, and many effects of this environment are preserved in various landforms that resulted from periglacial processes that are no longer active. The landforms resulting from these processes will be discussed later in this article. Whereas such features are not, in the strictest sense, landforms produced by glaciation, they are closely related to glacial climates and are commonly superimposed on terrains that originated through glaciation. Moreover, the presence of underground ice, and its thawing and refreezing are basic requirements for many of the landforms associated with the periglacial environment.

II. Landforms produced by glacial erosion

Glacial movement consists of two parts, internal flow or plastic deformation, and slippage of the basal ice along the ground surface over which it moves. Along the margins of valley glaciers, where glacier ice is in contact with the rock surface, some of the effects of a glacier moving over a bedrock surface can be assessed.

Erosion by glacier ice has been deduced from the study of areas formerly covered by glaciers, and from direct observations along the walls of glaciated valleys where the contact between ice and bedrock can be seen. The landforms resulting from the erosive action of glaciers range in size from very small forms of microrelief to large-scale phenomena with dimensions in hundreds or thousands of metres. These landforms are the product of glacial abrasion, glacial quarrying or plucking, or a combination of these two processes.

MICRORELIEF AND SMALL-SCALE FEATURES

Rock polish, striations, grooves, and friction cracks. Pure ice at its pressure-melting point has little abrasive ability on hard rock, yet many granite outcrops are highly polished as the result of the passage of glacier ice. Other rocks such as massive limestones and basaltic lavas exhibit small scratches and other markings that were made by glaciers. These features are caused by debris-laden ice during its passage over rock outcrops.

Determination of ice-movement directions

Striations are scratches on a rock surface, and when the orientations of a sufficient number of them are plotted on a map, they provide a means of determining the former direction of ice movement over a relatively large area. The mapping of glacial striae in Finland, New England, and parts of the Canadian Shield are examples of how this technique has been used to deduce the general flow pattern of Pleistocene ice sheets. Many glaciated rock surfaces contain striae that diverge in orientation. Although it is possible that crossing striae on a single rock outcrop represent two distinct periods of glaciation, it is more likely that they reflect local variations in the flow direction of the basal ice during a single glacial advance. Because striae may diverge as much as 90 degrees from the direction of regional ice movement, a few scattered observations of striae orientations are not reliable indicators of regional flow direction. Only when hundreds of striae directions are plotted on a map covering thousands of square kilometres will regional flow patterns emerge.

Glacially formed grooves in bedrock are less common than striae. Some grooves appear to be the result of a single angular rock fragment carried by glacier ice over a relatively soft and fine-grained rock surface such as limestone. The glacial grooves of Kelleys Island in western Lake Erie occur in limestone bedrock, and range from less than 0.3 metre (one foot) to more than one metre (three feet) deep and are three metres (ten feet) or more in length. The origin of these and other glacial grooves is in dispute because it is not known whether subglacial meltwater or a slurry of mud moving beneath the ice could have produced all or part of them. The presence of true striae and glacial polish along the walls of such grooves is a clear indication of the passage of ice along their axes, but it does not prove that the entire groove was caused by glacier abrasion. Some geologists have argued that fast-flowing subglacial meltwater or slurries of mud and other glacial-fluvial sediments scoured these grooves while the ice was present. Others suggest that grooves are nonglacial features the gross shapes of which were only slightly modified by the passage of glacier ice.

Some of the largest grooves associated with glaciated terrain are those in the Mackenzie Valley in the Northwest Territories of Canada. There the bedrock is furrowed with grooves, some of which are as much as 30 metres (100 feet) deep and more than 1.5 kilometres (one mile) long. The grooves occur with parallel alignment and are indifferent to the regional "grain" of the bedrock or surface drainage lines. It is believed, however, that the axes of the grooves coincide with the true direction of ice movement.

Crescentic and lunate fractures and chatter marks

Friction cracks are small-scale markings on rock surfaces formerly overridden by glacier ice. They appear to be the result of frictional contact between a glacier-carried boulder and a bedrock surface. Commonly, these features are curved linear cracks in plan view with either the convex or concave side oriented toward the direction of ice movement. In cross section, a friction crack consists of two intersecting rock crevices that are inclined at different angles with respect to the rock surface. The more steeply inclined crack always faces away from the direction of ice movement, regardless of the surface manifestation of the marking. This generalization has been verified by the orientation of striae on the same rock surface. Friction cracks have been given a number of names such as crescentic gouges, crescentic fractures, or lunate fractures, depending on specific characteristics of each. These cracks were formerly called chatter marks in reference to the kind of markings achieved on a hard surface by forcing another hard material across it.

Roche moutonnée in southern Sweden. Ice moved from left to right.

Roches moutonnées. A roche moutonnée is a bedrock knob or protuberance that has been shaped by glacier overriding. These bedrock hills range in size from a few metres to several kilometres in the longest horizontal dimension, and about three metres to 30 (98 feet) or more metres high.

Roches moutonnées are a characteristic landform of a glaciated bedrock surface. They result from erosion by valley glaciers as well as by ice sheets. Commonly they are elongate in plan view with the long axis parallel to ice movement, but this is not by any means a universal relationship. More diagnostic than the plan view is the vertical profile parallel to the direction of ice movement. The side facing the oncoming ice (stoss side) is gently inclined, smoothed with glacial polish, and contains the usual marks of glacial abrasion. The side away from the moving ice (lee side), on the other hand, is steeply inclined, jagged, and rough, with little sign of abrasive action. The smooth stoss side is formed by glacier abrasion, and the jagged lee side is commonly regarded as the product of glacier plucking. This stoss-and-lee profile is the hallmark of a roche moutonnée, large or small, and is, along with glacial polish, one of the unique products of glacier erosion in bedrock.

GLACIATED VALLEYS AND ASSOCIATED FEATURES

Some of the most scenic landscapes in the world are valleys formerly occupied by glaciers. These valleys occur in most mountainous regions and bear witness to the climatic regime of the Pleistocene. A glaciated valley has a unique geometric form that sets it apart from a valley that was cut solely by running water. Its gross shape, as well as specific features on its walls and floor, reflects the sculpturing effect of a valley glacier (Figure 2).

A valley glacier comes into existence in mountainous regions in which temperature and snowfall are conducive to the annual net accumulation of snow. A succession of years in which more snow accumulates at high elevations than is lost by ablation eventually produces glacier ice that flows under the influence of gravity down the valleys carved by preglacial rivers. Gradually, the regime of running water is replaced by flowing ice as the glaciers grow in size and expand in a down-valley direction. These "rivers of ice" modify the former river valley by ice erosion and produce profound changes in both the longitudinal and cross-sectional valley profiles.

Cirques, arêtes, horns, and cols. The upper reaches of a glaciated valley are very steep and commonly begin in

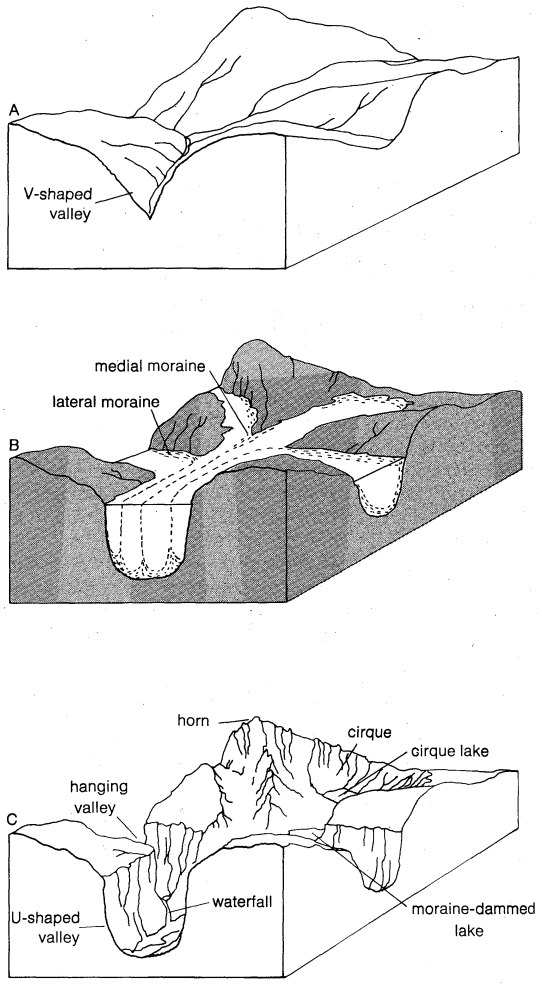

Figure 2: *Changes produced by valley glaciation.* (A) Unglaciated topography, characterized by V-shaped valleys and rounded to rolling hills. (B) Area occupied by valley glaciers that produce deep erosion and down-valley transport of debris (moraines). (C) Area after glacier retreat: main valleys have become U-shaped; tributary, more shallow valleys now hang above main valleys, causing waterfalls; and upland terrain has become more rugged as a result of both frost action and glaciation.

The process of cirque formation

a cirque, a rock-bound, amphitheatre-like feature that characterizes almost all headward reaches of glaciated valleys. The floor of a well-developed cirque contains a bedrock depression in which water may collect to form a lake. A cirque is universally regarded as a product of glacial erosion, but the actual mechanics of the process are uncertain. Studies on cirques that are still occupied by small glaciers indicate that frost action in the headwall region may be the most important process in the development of the cirque walls. The loosening of bedrock by this mechanism was originally thought to occur in the bergschrund, the opening between the glacier and the cirque wall. Temperature fluctuations in the bergschrund, above and below the freezing point, were supposed to have caused extensive frost shattering of the cirque wall. Blocks loosened from the rock wall of the bergschrund would fall to the bottom of the bergschrund and become incorporated into the glacier, which would transport them to the snout of the glacier over a period of years. This hypothesis is not supported by actual temperature measurements in the bergschrund itself. Such measurements in bergschrunds of Switzerland, Greenland, and Norway show that no appreciable freeze-thaw temperature fluctuations occur in bergschrunds to depths of almost 30 metres (98 feet). Only in very wide bergschrunds does the temperature fluctuate above and below the freezing point in response to diurnal or seasonal changes in air temperature. Water from melting snow or ice that enters these bergschrunds from above freezes to the rock face in the upper part of the bergschrund and acts as a protective covering for any further frost shattering. Some frost shattering occurs in the cirque walls above the bergschrund (*i.e.*, above the glacier surface), where rapid temperature fluctuations across the freezing point are commonplace. Frost-rived blocks produced there would tumble into the bergschrund or become lodged on the glacier surface; in either case they would be transported away from the cirque wall.

Frost shattering thus may be the dominant process in cirque-wall enlargement and retreat. Some frost-rived blocks undoubtedly are derived from the rock wall of the bergschrund, but the conditions for intense frost action are more favourable on the cirque walls above the glacier than in the bergschrund.

The excavation of the cirque floor is a more difficult problem to solve because glacier abrasion appears to be the chief means whereby the cirque floor is lowered. Glacial polish and striations on cirque floors confirm that abrasion did operate at one time during the development of the cirque basin. The possibility of periglacial conditions in the high mountains prior to the growth of glaciers, however, should not be overlooked. Intense frost action associated with such a climatic regime could have produced considerable frost rubble that would have been easily removable by glacial transportation at a later date. This explanation is incomplete, however, because of the difficulty in accounting for the rock sill on most cirque basins if glacial action is considered to be responsible only for removing preglacial frost rubble. This problem needs more study.

Studies of modern cirque glaciers (less than 300 metres [1,000 feet] long and about 50 metres [150 feet] thick), in which horizontal tunnels have been excavated, reveal a sliding action of the basal ice over the bedrock floors. This sliding action has an upward component in the lower reaches of the glacier where the bedrock deepening apparently is taking place. Although it should not be assumed that cirque glaciers move only by a sliding on their beds, there is sufficient motion of this type to account for considerable bedrock scour by glacial abrasion. Thus, in addition to removing any frost rubble or other regolith that formed prior to the onset of glacierization, a cirque glacier further deepens the bedrock by abrasion.

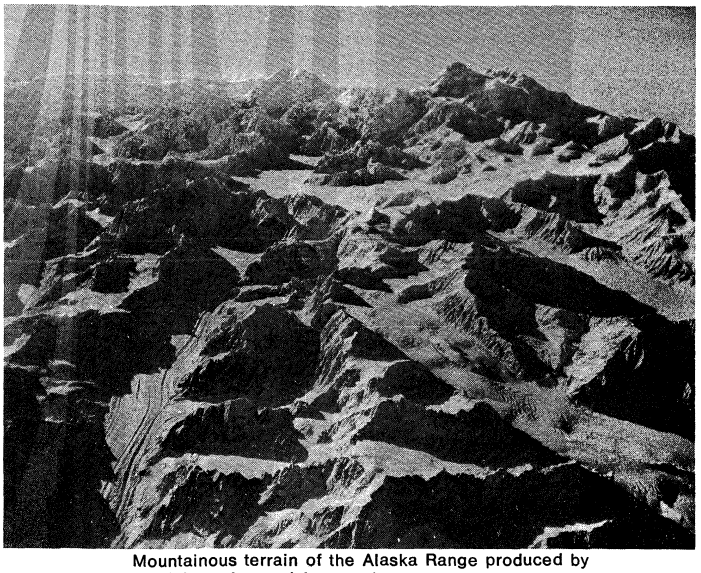
Headward extension of cirques and the formation of serrate divides

When a number of cirques on the flanks of a mountain range enlarge by headward extension, the sidewalls and the headwalls of adjacent cirques intersect. The headward erosion of cirques may continue after the glaciers contained in them have disappeared. Postglacial cirque enlargement is accomplished by continued frost action on the walls; the accumulation of frost rubble at the base of cirque cliffs bears witness to the continuation of the frost-shattering process even when no glaciers are present.

The headward extension of cirques, either during or after glaciation, produces the jagged ridges of glaciated mountains. These serrate divides can be observed in the Alps, Himalayas, Andes, and Alaska Range, and a number of other high mountains of the world. A single sharp crested ridge between the sidewalls of two cirques is called an arête. Two cirques that intersect on a major divide produce a low point on the divide called a col. Three cirques, each migrating headward toward a central point on a ridge produce a horn. The Matterhorn, near Zermatt in the Swiss Alps, is a classic example and the best known horn in the world.

Longitudinal profiles. Unlike valleys that are cut by streams, glacially sculptured valleys are characterized by a very irregular longitudinal profile consisting of alternating steps and rock basins. The true bedrock profile of a glacial valley may be masked or modified by various depositional features, but evidence from many sources indicates the geometry of the bedrock profile along the axis of a glacial valley.

The first inference drawn from the irregularity of longitudinal profile is that the efficacy of glacial erosion was not everywhere uniform, or that the bedrock forming the valley floor was not uniform in its susceptibility to glacial erosion. The question is whether a rock basin was



Mountainous terrain of the Alaska Range produced by glacial erosion and frost action.

produced where the glacier had an intrinsically greater capacity to erode, or where rocks were more susceptible to glacial erosion than those in which no basins occur.

There is reason to believe that both explanations account for the alternating rock steps and rock basins that characterize the longitudinal profile of a glacial valley. The analysis of flow characteristics in existing valley glaciers reveals two general types of flow, extending flow and compressional flow. Both may occur in different reaches of the glacier stream. Extending flow occurs in the steeper reaches and compressional flow is restricted to the flatter reaches. Extending flow is characterized by shear planes in the ice that curve downward and approach the bedrock floor tangentially. In compressive flow, the shear planes curve tangentially upward from the base of the ice toward the glacier surface in a downvalley direction. Compressive flow is conducive to the removal of bedrock material, whereas extending flow tends to force rock debris along the bedrock floor. Thus the glacier would tend to be a more efficient agent of bedrock erosion in areas in which compressive flow was dominant.

A glacier flowing in a valley inherits the longitudinal profile produced by the preglacial stream. This profile has a number of irregularities that are accentuated by glacial erosion. Small declivities in the original preglacial profile become enlarged through compressive flow as previously described, until rock basins are formed.

Differential rock resistance and weathered zones

Another factor to consider in explaining the sequence of rock basins and intervening steps and sills is the differential resistance of bedrock types that occurs along the valley. Even if the bedrock is of uniform composition, such as a granite, differences in the spacing of joints are reflected in the depth of preglacial weathering. Closely spaced joints permit deeper penetration of downward percolating surface water, which weakens and loosens mineral grains by chemical decomposition, and also enhance the efficacy of frost action prior to glaciation. Preglacial deep weathering along a valley thus guides the future course of glacial erosion. The more deeply weathered zones are the places at which rock basins are excavated by glacial ice, and the less deeply weathered zones become the intervening rock sills or "glacial steps."

The basin-and-step profile of a glacial valley is therefore controlled by at least three factors, the minor irregularities in the original stream-valley profile, differential preglacial weathering, and the action of extending or compressive flow of the glacier ice.

Valley cross sections. Stream-cut valleys normally have a V-shaped cross section, whereas glaciated valleys are U-shaped in cross section. The direct erosive action of a river is confined to the apex of the valley in which it flows. The stream of flowing water occupies only a relatively small segment of the valley. A stream of ice, on the other hand, may be in direct contact with more than half the cross-sectional perimeter of the valley, thereby putting flowing ice in direct contact with valley walls that were never directly in contact with the preglacial stream. Glacial erosion on the valley walls will, over a period of time, transform the V-shape into a U-shape.

V-shaped stream valleys are characterized by spurs that develop between adjacent entering tributaries or merely as a consequence of the curving course of the river as it incises its channel deeper. These spurs are truncated by glacier flow because an ice stream tends to straighten the inherited course of the preglacial stream valley. Vigorous ice erosion takes place not only on the valley floor but on the valley sidewalls as well.

Valley glaciers commonly occur as systems in which a master ice stream is fed by a number of tributary glaciers. The main ice stream and its tributaries form an ice-drainage pattern that is generally inherited from a former stream-drainage pattern. Under normal conditions of stream erosion, tributaries join the trunk stream at the same level. This "law of accordant junctions" was formulated long ago by geologists who recognized the regularity of the juncture of a tributary and channel it joined. Because the main glacier normally carries a much larger volume of ice than any of the tributary glaciers, it will have proportionally greater erosive power and will cut the trunk valley deeper than the inflowing tributary glaciers. After the glacier episode of erosion is terminated, and the glaciers are replaced by streams, the junction of tributary valleys with the main valley will no longer be at accordant elevations. The tributary valleys are left "hanging" above the floor of the trunk valley. Streams that occupy the hanging valleys plunge over steep cliffs where they debouch into the overdeepened main valley. Spectacular waterfalls in many formerly glaciated regions originated in this way.

Fjords. The mountainous coastal regions of the world that lie poleward of 45° north or south latitude contain steepwalled, long, and deep embayments known as fjords. Fjords abound on the Pacific coasts of southern Alaska and British Columbia, and the Baffin Bay coast of Baffin Island; in Greenland, Iceland, and Norway; in the Southern Hemisphere, the Chilean coast of Patagonia, South Island of New Zealand, and the coastal regions of Antarctica contain fjords. Many of those in Antarctica are still filled or partially filled with glacier ice.

Longitudinal profile of fjords

The longitudinal profile of a typical fjord reveals a very steep landward segment, the headwall, that descends rapidly to below sea level. From the inner headwall to the seaward entrance of the fjord, the longitudinal profile is similar to the profile of a glaciated valley because it contains deep rock basins separated by rock sills or thresholds. From the mouth of the fjord seaward, the profile rises to a rock platform or strandflat that is relatively shallow compared with the water depths over the inner rock basins. The great Sognafjorden of southern Norway, for example, is 204 kilometres (127 miles) long and reaches a maximum water depth of 1,300 metres (4,300 feet) behind the strandflat, which is only about 200 metres (650 feet) below sea level.

Fjords are generally considered to be glacially modified river valleys. The longitudinal profile of a fjord, however, is a feature that cannot be accounted for by river erosion because of the deeply submerged rock basins and intervening rock thresholds. The rock basins are too deep to be explained by stream erosion during periods of lower sea level because there is no independent evidence of sea level lowering of this magnitude. Moreover, rivers are incapable of excavating long and deep rock basins along their courses. Therefore, it is concluded by many geologists that glacier ice, not river water, was responsible for the creation of fjord profiles.

This explanation is challenged by a few geologists because the occurrence and distribution of many fjord systems appear to be related to major structural trends in the bedrock of the fjord regions. Intersecting fracture zones, for example, can account for the rectilinear pat-

tern of fjord distribution in many coastal regions. A few geologists have argued the extreme viewpoint that because the fjord axes coincide with linear joints, fractures, or faults in the bedrock, fjords are therefore of tectonic origin, *i.e.*, they represent primary downfaulted blocks produced by tensional stresses in the earth's crust. Although some rectilinear fjord systems do, in fact, reflect an intersecting system of faults or other linear tectonic features, there are many fjord patterns that bear no apparent relationship to such crustal lineaments. Furthermore, the fact that some fjord systems are aligned with structural elements of the crust does not necessarily prove a tectonic origin of the fjord troughs. A more likely explanation is that fault zones, closely spaced joints, and soft tilted rock layers in juxtaposition with hard layers would have been normal zones of weakness that were more vulnerable to the forces of rock weathering than the more massive intervening rock masses. Differential weathering and stream erosion during the millions of years prior to Pleistocene glaciation would have resulted in an etching of the landscape into a pattern controlled by the linear zones of more easily weathered and eroded materials. These preglacial valleys would then have been the natural troughs for the channelling action of valley glaciers during the Pleistocene.

Other critics of the glacier-erosion hypothesis for the origin of fjords argue against the efficacy of valley glaciers to erode such deep basins below sea level. They suggest that these rock basins were formed by valley glaciers in the early Pleistocene when the coastline stood relatively higher above sea level, and before the ice reached a thickness sufficient to cause depression of the crust. The rock basins in the fjords, according to this view, are submerged at such great depths because postglacial crustal uplift is not yet complete, and also because the level of the oceans is higher now than it was during the glacial maximum. Both explanations are true in essence, but neither separately nor in combination can they account for the maximum known depth of the submerged rock basins in fjords. Assuming that sea level is now about 90 metres (300 feet) higher than it was during the glacial maximum, and assuming further that the total amount of crustal depression in the fjord region of Norway was about 605 metres (1,980 feet), of which perhaps 450 metres (1,500 feet) have been recovered by late Pleistocene and postglacial uplift, it can be deduced that only about 240 metres (790 feet) of the present water depth of Sognafjorden is due to these factors (90 metres [295 feet] of sea-level rise plus 150 metres [492 feet] of glacial rebound still to occur). Using the same values for sea-level changes and the amount of total crustal subsidence due to the weight of ice, the deepest part of Sognafjorden would have been about 1,700 metres (5,600 feet) below the Pleistocene sea level. In order for a glacier to rest on the floor of the ocean in this depth of water it would have to have been about 1800 metres (5,900 feet) thick.

Fjord formation and ice thickness

The reasonableness of this analysis is sustained by geophysical study of the Skelton Glacier near McMurdo Sound in Antarctica at its confluence with the Ross Ice Shelf. The Skelton Glacier is in the process of eroding a deep fjord and the longitudinal profile of the fjord shows the typical basin and threshold configuration of other fjord profiles. The greatest known thickness of ice along the 62-kilometre (39-mile) length of the Skelton Glacier occurs at a point about 50 kilometres (30 miles) back of the floating snout. There the glacier ice is about 1,450 metres (4,760 feet) thick and is in contact with the sea floor, which at that point is over 1,240 metres (4,070 feet) below sea level. Because it is known that the glaciers in Antarctica were thicker at some time in the geologically recent past, the Skelton Glacier could have attained a thickness equal to or greater than the postulated thickness of the glacier that occupied Sognafjorden during the Pleistocene.

GLACIALLY ERODED ROCK BASINS IN NONMOUNTAINOUS REGIONS

The bedrock basins in fjords and other glaciated valleys tend to be elongated in the direction of glacier flow. This relationship has led geologists to assume that elongate bedrock basins in other regions of the glaciated part of the world were aligned parallel to the flow lines of the glacier. A detailed reconstruction of flow lines based on striae, grooves, and other glacier markings on bedrock in areas where rockbound lakes exist by the thousands shows that the orientation of the elongate basins bears no consistent relationship to the direction of glacier movement.

Bedrock lakes of glacial origin occur in very great numbers in areas of relatively low relief such as the Canadian Shield of North America, the nonmountainous parts of Sweden and Finland around the Gulf of Bothnia, and some parts of Scotland and Northern Ireland. These lake basins occur in many different shapes and sizes, both in the configurations of their shorelines and in their bottom topography. The depths of many of these lakes exceed 100 metres. Seneca Lake, one of the Finger Lakes of New York, for example, has a maximum depth of 192 metres (633 feet).

Prior to the growth of the continental ice sheets in North America, Europe, and northern Asia, the land surface was exposed to other agents of denudation. Exposed rock masses were weathered by chemical breakdown and physical disruption, and the comminuted rock fragments were carried by surface runoff to river channels that transported the sediment to the ocean basins. The length of time during which the forces of weathering and erosion were at work on the land area that was later covered by Pleistocene ice sheets varied from place to place. The geological record in all of the ice-covered areas of North America suggests that the period of downwearing of the earth's surface prior to the Pleistocene was about 60,000,000 years or longer. This was ample time for a well-developed stream-erosional landscape to be produced. The preglacial landscape was therefore one of valleys and divides with few, if any, lakes. The spread of glaciers over this kind of topography continued the wearing away of the land surface by exploiting the areas of deeply weathered bedrock. Most rockbound lakes within the Pleistocene glacier border, therefore, were probably formed by glacial excavation. As with the origin of fjords, however, not all geologists agree that glacial erosion has the efficacy to produce rock basins the size of the Great Lakes.

The Great Lakes of North America

The five Great Lakes of Superior, Michigan, Huron, Erie, and Ontario constitute the largest inland system of freshwater in the world. Their combined area is about 246,000 square kilometres (95,000 square miles), and all but Lake Erie have a maximum depth well below sea level. Geologically, the lake basins lie in bedrock although the shorelines are developed mainly in glacial drift. An exception is Lake Superior, the shoreline of which is almost entirely rockbound.

Since the late 19th century, geologists have proposed four processes to explain the origin of these lake basins: (1) stream erosion during the Tertiary Period (from 2,500,000 to 65,000,000 years ago); (2) glacial erosion during the Pleistocene Epoch; (3) damming by glacial deposits; and (4) large-scale crustal movements (tectonism). Over the years, some geologists have taken extreme views on one or more of these hypotheses. Some have argued that the excavation of such large basins by glacier ice is not possible, whereas others have held that glacier erosion has been the only agent in the creation of the basins.

The final answer is yet to be found, but any hypothesis must take into consideration the following facts: first, that glacier ice invaded all the Great Lakes is not questioned by any scientist familiar with the Pleistocene history of east central North America; second, the Great Lakes did not exist prior to the Pleistocene; and, third, because the long axes of the lakes are more or less parallel to the major structural trends of the bedrock in which they lie, the present sites of the basins were occupied in pre-Pleistocene times by a system of stream valleys that were adjusted to the regional structural elements of the bedrock trends.

Geophysical studies and bottom drilling by shipboard techniques in the 1960s in Lake Superior showed that glacial sediments many metres thick lie on the bedrock

floor of the lake. Glacial deposition rather than glacial erosion must have been operative at that time in the history of the basin. One geologist has even suggested that the Lake Superior Basin may have been an ancient rift valley, similar to those in Africa, which was later modified by the passage of glacier ice.

Still unanswered is the basic question of how much glacier erosion added to the size and depth of the basin. It cannot be proved beyond a reasonable doubt that Lake Superior or any of the other Great Lakes was excavated wholly by glacial erosion.

III. Landforms produced by glacial deposition

Materials that are picked up by eroding glaciers are transported by the moving ice and deposited at the base of the glacier or along its margin. Meltwater streams debouching from glacier margins carry sediment beyond the ice front and deposit it in a variety of forms (Figure 3). Ice-marginal lakes and even the oceans receive sedi-

Characteristics of glacial sediments

ments from melting icebergs as well as from glacial meltwater streams. All of these sediments, regardless of whether they are deposited directly by glacier ice, or whether they accumulated in meltwater river channels or ice-marginal lakes or seas, are collectively known as drift. This term is based on the mistaken assumption by geologists of the 19th century that the loose and unconsolidated surficial deposits of England and northern Europe, now known to be of glacial origin, were deposited in the universal seas of the Deluge related in the Biblical story of Noah. The term drift was used because the heterogeneous nature of some of the surficial materials—especially those that contained huge boulders—was explained as having been released from drifting icebergs that supposedly infested the higher latitudes of the worldwide oceans during the biblical Flood. This explanation is now known to be false, but the term has remained in usage to the present day.

Drift is classified into two major categories, nonstratified and stratified. The former implies the lack of any transporting agent capable of sorting a heterogeneous mixture of sediment into layers of gravel, sand, silt, or clay. The term stratified designates drift that was originally carried by glacier ice, but was subsequently deposited in layers of sorted sediments either along stream channels, in lake basins, or in parts of the ocean. Both nonstratified and stratified glacially derived sediments occur in geometric forms that are characteristic of a landscape produced by glacial-depositional processes. These processes are constructional in that landforms produced by them are "built-up" by an accumulation of materials, whereas glacial erosion is a destruction process and the landforms produced are destructional in origin.

NONSTRATIFIED DRIFT AND ASSOCIATED LANDFORMS

The main feature of nonstratified drift is the heterogeneity of its texture. A mixture of detrital particles ranging in size from clay, less than four microns (.004 millimetre) in diameter, to boulders, larger than 256 millimetres (ten inches) in diameter, characterizes many nonstratified drift deposits. The term till refers to the sedimentary materials of a nonstratified glacial deposit, and the term moraine is used with reference to its topographic expression. In Germany, Scandinavia, and some other parts of Europe, till and moraine are used synonymously, but in North America and the Soviet Union, till refers to the sedimentary material, and moraine refers to the surface morphology of a mass of till.

Glacial till. Widespread deposits of till occur where glaciers once covered the land. Tills laid down by Pleistocene glaciers are generally compact, clay-rich deposits that can be loosened with a pick and shovel, or excavated by earth-moving equipment. Tills deposited during older glaciations are indurated into hard rock. These ancient glacial sediments are called tillites and their distribution in space and time on the earth's surface provides a means for reconstructing the climatic conditions during past geologic time.

Unsorted deposits of nonglacial origin

Not all unsorted, heterogeneous sediments can be ascribed to glacial origins. The debris that accumulates as the result of a rock avalanche, a mudflow, or the poorly sorted sediments associated with flash floods or other fluvial activity are commonly mistaken for tills, or ancient tillites. Moreover, the absence of large boulders does not preclude an otherwise "layerless" sediment from being a nonstratified glacial deposit. Geologists who have a special interest in the study of tillites use the term diamictite to describe any nonstratified rock that has the characteristics of a till but the origin of which may not have had any association with glaciation.

Two kinds of till are generally recognized, lodgment till and ablation till. Lodgment till is the material released from the base of a moving glacier by pressure melting, whereas ablation till is a residual mass of debris released from the upper portions of the glacier ice in the ablation zone. Lodgment till is compact and dense and can occur in blanket thicknesses as great as 100 or more metres. Ablation till is loose, less compact than lodgment till, and generally much thinner than the lodgment till on which it lies.

Both lodgment and ablation tills contain rock fragments that differ in lithology from the local, underlying bedrock. All pebbles, cobbles, stones, and larger rock fragments contained in till are called clasts. Most clasts are derived from local bedrock sources, but some have been transported as far as 800 kilometres (500 miles) or more by glacial movement. A large clast that differs from the underlying bedrock is called a glacial erratic. An erratic whose place of origin can be identified can be used to indicate the general direction of ice movement. So-called indicator erratics normally consist of rock types that contain an unusual assemblage of minerals or possess other characteristics that make the geographic location of bedrock origin unassailable.

Some erratics are so large that they are mistaken for bedrock outcrops. The longest dimension of some of the largest ones exceeds 30 metres (100 feet), and they stand

above the general level of the glaciated landscape as conspicuous features.

Moraines. Many different types of moraines are recognized, each of which has some genetic implication in terms of its specific mode of glacial origin. The two main types of moraines are ground moraine and end moraine. Ground moraine is a blanket of till of varying thickness laid down beneath a moving glacier. Its chief morphologic characteristic is an undulating or gently rolling surface, commonly referred to as swell-and-swale topography. Surface drainage on ground moraine deposited by the most recent ice advances of Pleistocene glaciers in North America, Europe, and the Soviet Union is poorly integrated with many undrained swampy depressions and shallow lakes. The maximum relief of ground moraine is about six to eight metres (20 to 26 feet).

If the ground moraine is thicker than the maximum relief of the underlying bedrock surface, its topographic expression is generally independent of the topography on which it lies. Preglacial stream valleys may be buried to such an extent that their existence is not recognizable, except where occupied by chains of lakes formed from the melting of blocks of stagnant glacier ice.

Older ground moraine, deposited by earlier advances of Pleistocene continental glaciers, retains few of the original constructional features because of the action of surface runoff. The swamps and lakes have either been filled with muck, peat, and sediments washed in by streams, or drained by the downcutting of the outlet. The network of surface streams and tributaries is well integrated in the older ground moraine areas. These stream systems also erode the land surface, thereby destroying the original topographic expression of the ground moraine.

End moraines and their implications

End moraines are formed along the margins of a glacier and consist of belts of hummocky terrain that persist long after the glacier has retreated or disappeared. A glacier acts as a conveyor belt in which sediment is carried to the glacier margin where it is dumped. The formation of an end moraine requires an actively moving glacier with an adequate supply of sediment. Because of the meltwater discharge from a glacier margin, it is not uncommon for end moraines to contain considerable quantities of stratified drift, the topographic forms of which are described in the next section of this article.

The presence of an end moraine carries with it the implication that the ice margin was more or less stationary while the end moraine was constructed. A large end moraine implies a long period during which the glacier margin remained in one place, and a poorly developed end moraine of low relief implies a short period of ice-margin stability.

During general phases of retreat of glaciers, a number of successively younger, more or less parallel end moraines are built. Though these "recessional moraines" could represent a pause in the general shrinkage of the ice sheet or valley glacier, it is more likely that they reflect a series of readvances of the glacier of short duration. Composite end moraines are formed when a glacier retreats from a position marked by an end moraine, and then readvances at a later date to build another end moraine against the former one, or to completely override the older feature and deposit a new load of till on top.

End moraines plotted on a map of suitable scale provide the means of reconstructing the position of the glacier border as it existed when the moraines were built. The mapping of contemporaneous end moraines in areas formerly covered by the last advance of the Pleistocene ice sheets reveals that the glacier margin was lobate in form. In the Great Lakes region, several lobes were deployed along the axes of the modern Great Lakes. This relationship is clearly indicated by the festoon of end moraines around Lake Michigan, Lake Huron, and Lake Erie.

The area in which two lobes were in juxtaposition is now marked by adjacent end moraines built by each lobe. Such a moraine is called an interlobate moraine. One of the best known examples is the Kettle Moraine of Wisconsin, which was produced by the Michigan lobe and the adjoining Green Bay lobe.

A valley glacier builds an end moraine at its snout or terminus, and a lateral moraine along the glacier sides in contact with the valley walls. Two lateral moraines joining at the confluence of two valley glaciers combine to form a medial moraine. End moraines and lateral moraines are commonly preserved in formerly glaciated valleys. These old lateral moraines and their end moraine equivalents provide the basis for reconstructing the history of glacial advances and retreats in the Alps, the Rocky Mountains, and other mountainous regions of the world that contain shrunken remnants of extensive glaciers or have no modern glaciers at all.

Drumlins. A drumlin, ideally, is an elongate streamlined hill with a long axis that is parallel to the direction of ice movement. Commonly, drumlins occur in swarms or fields that give a definite "grain" to the topography. Individual drumlins are from less than a kilometre to several kilometres long, 300 to 600 metres (1,000 to 2,000 feet) wide, and five to more than 30 metres (ten to 100 feet) high. A single drumlin field may contain several thousand drumlins.

Drumlins are thought to be "ice-molded" forms and range in composition from 100 percent till to 100 percent bedrock. The latter are generally considered to be erosional in origin and are called rock drumlins. The till drumlins on ground moraine are shaped by the overriding ice in a manner not clearly understood. These are usually regarded as depositional or constructional in origin. Some drumlins contain bedrock cores with a till veneer.

STRATIFIED DRIFT AND ASSOCIATED LANDFORMS

Most glaciers, with the notable exception of the Antarctic Ice Sheet, lose most of their masses by melting in the ablation area. During the summer melt season, the glacier surface is characterized by meltwater channels in the ice. The water released by melting eventually reaches the glacier front through surface runoff, or discharge through subglacial tunnels. As the ice melts, the sedimentary load entrapped in the ice is released and redistributed by the meltwater streams in various ways. The general term, outwash, is applied to the sand and gravel fraction of glacially derived, water-laid sediments.

The role of meltwater

By courtesy of James Zumberge, University of Arizona, Tucson

Glaciofluvial sediments in southern Norway. Boulders are from an overlying till not pictured.

In valley glaciers the meltwater flows from the glacier snout down the nonglaciated part of the valley, carrying with it a heavy load of outwash, which is deposited along the many channels of the river. If the volume of debris released by the melting glacier is more than the river channel can transport, the outwash is spread over a large segment of the valley floor in a number of anastomosing channels through the outwash materials. These channels join, separate, and shift their positions as the volume of

water released from the melting glacier changes from time to time. The term braided stream is applied to a river with the aforementioned characteristics. Sediment deposited by a glacially-fed braided stream, called a valley train deposit, consists of stratified sands and gravels.

During the retreat of a continental glacier, several adjacent braided streams originating from the ice margin may deposit glacial outwash over an extensive area beyond the ice front. These flat plains of stratified materials are called outwash plains. Stagnant masses of glacier ice that become detached and isolated from the main glacier during the course of ablation and retreat may be buried or partially buried in outwash. Later, the melting of these ice blocks causes the outwash over and around them to collapse and slump into the resulting depression. The depressions are called ice-block pits and may persist for thousands of years after they are formed. An outwash plain pockmarked with ice-block pits is called a pitted outwash plain. Thousands of lakes in the glaciated regions of the world originated as ice-block pits.

Ice-contact deposits. Outwash that accumulates in contact with glacier ice is an ice-contact deposit. Some of these deposits occur as distinct morphological features, whereas others are so small or so intermingled with till that they have no recognizable surface expression.

Glacier margin conditions

The conditions around the margin of a glacier during the height of the ablation season are chaotic. Running water, mud slurries, slumping mounds of debris, stagnant blocks of ice, and quiet pools of water coexist within a very small area along the ice margin. Conditions are constantly changing, not only from week to week and day to day but from midday to midnight, as the volume of meltwater waxes and wanes with the diurnal changes in temperature, variability of incoming and outgoing solar radiation resulting from changes in cloud cover, and the precipitation of rain or snow. Glaciofluvial sediments that accumulate in the ice-marginal zone reflect the local environment of deposition. Fine silt and clay settle into pools, poorly sorted sand and gravel are almost ubiquitous, and ablation till and large boulders are widespread. Layers of glaciofluvial sediments that abut against an ice wall will be disturbed or destroyed when the adjoining ice wall melts.

Disjointed and distorted layering of glaciofluvial sediments is thus the chief depositional characteristic of ice-contact deposits. Ice-contact deposits are also identified by the abrupt vertical change in grain size of the different layers, a condition that reflects the rapid change in the depositional conditions.

The ablation zone of a valley glacier extends upvalley some distance from the glacier terminus. Meltwater streams issue not only from the toe of the glacier but also from along the sides of the glacier. These ice-marginal streams flow in a channel defined by the valley wall on one side and the sloping glacier surface on the other. Sand and gravel that accumulate in such an ice-marginal channel form a bench of outwash parallel to the valley wall. Retreat of the glacier results in the slumping of that part of the sand-and-gravel bench that was formerly supported by the ice. The geomorphic feature thus produced is a kame terrace, and if it contains ice-block pits, it is a pitted kame terrace. The collapsed side of a kame terrace has a characteristic slope equal to the angle of repose of the material of which it is composed, generally about 30°. This slope is called an ice-contact slope.

Kames and eskers. A kame is a mound or hill composed of ice-contact glaciofluvial sediment. A kame forms either as a mass of outwash that accumulates in a zone surrounded by stagnant ice, or as a cone of outwash banked against an ice slope or wall. Individual kames may be very irregular in shape, depending on the configuration of the ice walls that contained them. Kames occur in clusters or groups that stand above the general ground level. They are commonly associated with end moraines and are not easily distinguished from individual knobs or hillocks of till with which they occur. Ice-block pits may occur in close association with kames. A landscape dominated by many kames and ice-block depressions is called kame-and-kettle topography.

The ice-tunnel hypothesis

An esker is a long ridge composed of sand and gravel. Some eskers are only 100 metres (330 feet) in length, whereas others attain lengths of 150 kilometres (90 miles) or more. In plan view, an esker follows a sinuous course not unlike a stream channel; this fact has led to the generally accepted hypothesis that eskers are outwash-filled ice tunnels that formed in stagnant or nearly stagnant ice of the ablation zone. Eskers may attain a height of 100 metres, but most are seven to 15 metres (23 to 49 feet) high. They tend to occupy the lower ground of a glaciated landscape but do cross divides from one swale or valley to the next. The glacial meltwater flowing in an ice tunnel is analogous to water flowing through a pipe under pressure rather than water flowing in an open channel. Some of the longer eskers have tributaries, indicating that an extensive system of subglacial tunnels was present when they were formed.

The chief material in an esker is glacial outwash, mostly well-washed sand and gravel. Cross-bedding is visible where eskers have been breached by a road cut or where they have been exposed through exploitation of their gravel content. Some eskers are capped by a thin layer of ablation till, which is usually patchy and discontinuous. Others contain numerous boulders that presumably are residuals from the previous ice cover. The esker flanks are ice-contact slopes, a fact that accounts for their general steepness.

GLACIOLACUSTRINE SEDIMENTS AND ASSOCIATED LANDFORMS

Meltwater that accumulates along a glacier border is called a proglacial lake, one in which part of the shoreline is formed by glacier ice. When the glacier retreats, the proglacial lake may shrink in size or its waters may be drained completely. In either case, the area formerly submerged can be identified because features of the former lake basin are preserved. Among these are the shorelines composed of beach sands and gravels that fringed the old lake basins. These ridges may occur in a series of parallel ridges at different elevations, each of which reflects a different level of the proglacial lake during the deglacial history of the glacier that formed part of its shoreline. Old beach ridges parallel to the coastlines of the Great Lakes mark the shorelines of the precursors of these water bodies. These ancient beaches became natural trails for Indians, and even today, secondary roads and major highways follow their crests as a legacy of early transportation routes established by 19th-century settlers.

The floors of the former proglacial lake basins are now flat lake plains. In some places these plains have been trenched by streams so that the nature and composition of the old lake sediments can be observed directly. These glaciolacustrine deposits are layered and well-sorted, and reflect the different depths of water in which they were deposited. In the nearshore zone, sandy material predominates, and in the deeper parts of the old basins, silts and clays are the dominant grain sizes. Clasts of pebbles and even boulders are commonly found embedded in the beds of clay and silt. The most plausible explanation for their presence in fine-grained lake sediments is that they were rafted in by ice, either icebergs or drifting slabs of lake ice that were detached from the shore during the spring breakup.

Other glacial lacustrine features include deltas built by streams flowing directly off the ice or by the normal accumulation of detrital sediment deposited by other streams emptying into the lake. The back or proximal side of a delta built by the discharge from a superglacial channel or a subglacial tunnel may have an ice-contact slope similar in steepness to the ice-contact slopes on kames and eskers. The surface of the delta, however, tends to be flat, and the lakeward or distal edge of the delta is characterized by a gentle slope that merges with the lake plain.

IV. Landforms produced by periglacial processes

The periglacial environment is generally confined to areas of high latitudes or high altitudes in which the

freeze-thaw process, sometimes called frost action, is dominant. Most workers agree that most of the periglacial zone is coincident with the areas of the earth underlain by permafrost. More than three-fourths of Alaska, half of Canada, and most of Siberia are underlain by permafrost, and hence are characterized by periglacial conditions. Smaller periglacial areas exist in high mountainous regions where permafrost may be absent but where strong freeze-thaw action prevails nonetheless.

PERMAFROST

Characteristics and occurrence of permafrost

Permafrost (also known as perennially frozen ground) is a surficial layer or zone of naturally occurring material the temperature of which has been at or below 0° C (32° F) continuously for more than two years. Water may be present either in the frozen state or in a supercooled condition (*i.e.*, in liquid form at temperatures below freezing), or the permafrost may be dry. Most permafrost contains ice in one form or another, the most common occurrences being in the form of pore ice, segregated pure ice lenses, or ice wedges. Pore ice is ice that fills the pores and interstices of rock or soil, just as water occupies the pores of natural materials in nonpermafrost areas. Ice segregations are seams or irregular-shaped pure ice masses that form by the drawing of water into the permafrost layer from below, thereby increasing the total bulk moisture content of the permafrost zone. Ice wedges are ice masses that occur as wedge-shaped sheets with a vertical or inclined attitude. Their thickness ranges from less than 30 centimetres (about one foot) to more than three metres (ten feet) and they possess an internal foliation that is more or less parallel to the boundaries of the ice wedges. Ice wedges form in only the most vigorous periglacial climates, those in which the mean annual air temperature is −7° to −8° C (19° to 18° F) or colder.

The permafrost zone is divided into two broad geographical units, the continuous zone and the discontinuous zone. In the Northern Hemisphere the southern boundary of the discontinuous zone is roughly parallel to the 0° C (32° F) mean annual surface temperature isotherm. From this boundary northward, the permafrost layer increases in thickness and continuity until, at the boundary between the discontinuous and continuous zone, permafrost exists everywhere except beneath lakes and rivers that do not freeze to the bottom in winter.

The permafrost layer is bounded on the top by the permafrost table that is defined by the depth of summer thaw. The base of the permafrost is determined by the mean annual temperature of the region, seasonal snow cover, thermal conductivity of rock and soil, vegetational cover, and past climatic conditions. The base of the permafrost in northern Siberia is 1,500 metres (5,000 feet) below the surface, 600 metres (2,000 feet) in northern Alaska, and it becomes progressively shallower toward the southern boundary.

The layer between the permafrost table and the ground surface is called the active layer, and it is here that frost action is most vigorous. The active layer is less than 30 centimetres thick in the northern areas of continuous permafrost, and more than three metres thick near the southern boundary of permafrost.

In nonpermafrost regions, especially at high elevations, frost action results in the creation of rock rubble —accumulations of coarse, angular boulders and smaller particles that are loosened from a cliff or rock escarpment by the freeze-thaw process. Water that accumulates in cracks or joints in an exposed bedrock surface, exerts a strong wedging action during the freezing process. This frost-wedging process is responsible for the origin of many distinct landforms associated with the mountainous regions of the world, regardless of the presence or absence of permafrost.

TALUS, ROCK GLACIERS, AND BLOCKFIELDS

Debris formed by frost wedging along a steep rock wall, such as might exist in a glacially carved valley, accumulates at the base of the cliff as talus. If the cliff face is a uniformly straight rock wall without indentations or notches, the talus forms a uniform apron at the cliff base. The inclination of a talus apron or talus slope is determined by the angle of repose of the constituent talus fragments. The largest and most angular blocks produce talus aprons with the highest slope angles. These exceed 35° (measured from the horizontal) in some cases, but slope angles of about 30° are more common.

Along rocky cliffs that contain notches or indentations in the form of rock chutes, the talus blocks accumulate as talus cones. Several adjacent talus cones may coalesce to produce a compound talus apron, which unlike the simple talus apron, has an undulating surface because the talus originates primarily from the chutes instead of uniformly along the entire cliff face.

Physical properties and flow of rock glaciers

A talus cone that contains interstitial ice as a cementing agent will flow and become a rock glacier. Some rock glaciers are thought to be relicts of true valley glaciers in which the superglacial debris has become so concentrated because of thinning of the glaciers that no glacier ice is visible at the surface. Rock glaciers that originate in cirques may have originated in this way, but others appear to bear no relationship to previous valley glaciers. In plan view, a rock glacier is a tongue or lobe of angular rock debris that shows signs of movement similar to a true glacier. Surface ridges parallel to the edges of the rock glacier, and terminal hummocks and ridges, not unlike end moraines, are manifestations of glacier-like movement. Surface movement studies on rock glaciers indicate velocities of about one metre or less per year. These are less than velocities of true glaciers because of the higher proportion of rock debris in the rock glaciers.

Rock glaciers range in width to more than 300 metres (1,000 feet) in length to one kilometre, and in thickness to 30 metres (100 feet) or more. Excavations in several rock glaciers have revealed the presence of interstitial ice within three metres (ten feet) of the surface. Rock glaciers are active (moving) or inactive (not moving). The latter are clearly distinguishable by the presence of lichens and other vegetation on the surface and marginal slopes.

Frost rubble that accumulates on a level or gently undulating surface forms a blockfield, also known as a felsenmeer. The blocks are derived from frost heaving of the underlying bedrock. The size and shape of an individual block is determined by the spacing and orientation of joints in the bedrock. Most of the detritus in a blockfield is very angular, a criterion that distinguishes blockfields from ablation till. Blockfields are actively being produced today under the periglacial environment of high mountains or polar regions, but others are relicts of a past periglacial climate and are covered with lichens, moss, turf, or higher vegetational forms.

PATTERNED GROUND

Ice-wedge polygons. Areas underlain by permafrost exhibit a characteristic microrelief pattern consisting of a network of intersecting ridges or troughs that outline polygonal ground areas from about three metres (ten feet) to more than 30 metres (100 feet) in diameter. Polygonal ground is conspicuous in the tundra areas of Alaska, Siberia, northern Canada, and other polar areas.

Formation of polygons

The ridges or troughs that outline the polygons are caused by the presence of ice wedges, which underlie them. Ice wedges are formed when the ground contracts during the cold winter months of the extreme periglacial zones. Thermal contraction produces a polygonal network of cracks that fill with water from melting snow in the spring. Because the subsurface temperature is below freezing, the water in the cracks freezes to form an ice vein. Summer warming causes the ice vein to expand slightly against the enclosing sediments on either side of the vein. The following winter, contraction occurs again and the entire cycle is repeated. Over a period of several hundred years, the original ice vein becomes an ice wedge and the displaced sediments are thrust upward to form the ridges that enclose the polygons.

Ice-wedge polygons are low-centre polygons if they are outlined by a ridge, and high-centre polygons if they are outlined by a trough. The ridges surrounding the low-

centre polygons are indicative of actively growing ice wedges. The troughs surrounding the high-centre polygons indicate that the material upturned by ice-wedge expansion is being removed by surface erosion.

Relict ice-wedge polygons are those formed during the Pleistocene when periglacial conditions were much more widespread than today. These fossil polygonal networks are best seen in freshly plowed fields because native vegetation or field crops tend to obscure the outlines of polygons.

Stone nets, stripes, thermokarst, and pingos. Repeated frost action also produces sorting in coarse clastic materials. The sorting process is complex and results in stone nets, circles, or polygons on flat surfaces, and stone garlands and stone stripes on hillsides.

Stone nets contain coarse cobbles and boulders on their borders and finer material near the centre. The diameter of stone polygons ranges from a few centimetres to about six metres (20 feet). They do not necessarily require permafrost conditions for growth.

Thermokarst is the general name applied to an area in which the thawing of permafrost has created a variety of features including lakes, mounds, and a hummocky surface similar to limestone terrains. Lakes are formed by the sinking of the ground surface when ice-rich permafrost is melted. The melting of ice wedges leaves the centre of the polygon elevated as a mound or hummock.

Pingos are ice-cored elliptical or circular hills of frozen sediments ranging in height from three metres to more than 60 metres (200 feet) and from less than 30 metres (100 feet) to nearly 400 metres (1,300 feet) in diameter. They occur in permafrost regions and are very conspicuous because they tend to occur singly or in clusters of two or three that rise abruptly above the general level of the tundra.

Pingos form when free groundwater becomes trapped by permafrost that is advancing into an area in which it did not previously exist, such as beneath a lake that has become filled with sediments. The freezing of the groundwater causes the overlying sediments, also frozen, to heave upward. The updoming of the surface materials causes them to crack and exposes the ice core to melting. As melting progresses, a summit depression or small crater forms. If the periglacial climate is replaced by more temperate conditions, the crater is enlarged, and the pingo itself decays to a circular peat-filled basin surrounded by a low ridge or rampart.

EOLIAN DEPOSITS

Deposits produced by wind action require a source from which sand and silt can be deflated. These sources are generally of three types. The first includes extensive stretches of desert regions in which weathered bedrock or regolith, or alluvial deposits are exposed to attack by wind. The second is composed mainly of outwash areas and till plains associated with continental glaciation. The third is found along coastal regions in which waves provide a renewed supply of beach sand for redistribution by the wind.

Sand dunes and loess deposits

Eolian deposits associated with glaciation are of two types: sand dunes and loess (*q.v.*). Sand dunes occur in a variety of geometric shapes and patterns that depend on wind direction and velocity, supply of sand, and amount of vegetational cover. Many of the sand dunes formed during the Pleistocene were derived from outwash areas. Most of them are stabilized today because of the encroachment of vegetation.

Loess is a windblown silt that occurs as a "blanket" deposit over large areas of the Mississippi Valley and northern High Plains of central North America, in parts of Europe, and over large areas of the eastern Soviet Union. Loess deposits in these areas were derived from outwash areas during the Pleistocene, especially the floodplains of the major rivers that carried large volumes of glacial meltwaters heavily charged with silt and other clastics.

A loess terrain is characterized by a "billowy" topography that may reflect the hills and valleys on which it was deposited. The silty texture of loess, its high water holding capacity, and its rich content of minerals make it one of the best materials for the formation of fertile soils. The crop yields of corn, wheat, and other grains grown on loess soils testify to the enormous value of loess as a natural resource.

Loess deposits have an internal structure and cohesiveness that accounts for the vertical bluffs along river channels eroded into a loess-covered terrain. These escarpments reveal the generally nonstratified structure of loess and provide excellent exposure for the study of these remarkable windblown materials associated with Pleistocene glaciation.

V. Modern landforms and former glaciation

The Ice Age ended about 10,000 years ago, but more than half the earth's land surface retains landforms that are a direct or indirect result of the climatic conditions associated with this last major epoch of geological history. These include such features as modern lakes and the strandlines of their expanded ancestral basins, coastal features related to former sea levels, the modern courses of major rivers that came into existence as a result of the ice advances, and relict landscapes that bear the imprints of erosional or depositional processes connected with the climate of the Pleistocene.

MODERN LAKES AND PLEISTOCENE FORERUNNERS

Two regions will serve to illustrate the relationships of modern lakes and their Pleistocene forerunners. The Great Lakes and their ancestral water bodies had a long and complex history directly related to the general retreat of the glacier lobes of late Pleistocene time. On the other hand, the lakes of the western United States, especially those in Utah and Nevada, were never directly influenced by glacier ice but their histories reveal a close relationship to the glacial and interglacial climates of the Pleistocene.

The lowlands now occupied by the Great Lakes were filled with lobate tongues of glacier ice during the beginning of the final deglaciation of the Pleistocene. Water bodies that formed along the lobate ice margins increased in area as the lobes continued their irregular but persistent retreat. The elevation of the water surface of any one of these ice-marginal or proglacial lakes remained constant for a period of time to allow wave action to build beach ridges around the part of the lakeshore that was not ice-bordered. A lake level would rise, however, if the ice-lobe advanced temporarily, thus reducing the area of the lake basin. Or, the lake level would fall if the ice lobe retreated and uncovered more glacier-free terrain over which the lake waters could spread. During some episodes of retreat, much lower outlets became ice-free so that the lake level dropped markedly when the waters abandoned the old higher outlet for the new lower one.

The shorelines of the modern Great Lakes are roughly parallel to the older strandlines, the study of which has provided the details of the complex history of the ancestral Great Lakes.

Lake Bonneville and Great Salt Lake

The ancient beach ridges that occur in western Utah define one or more ancestral water bodies that existed during the Pleistocene. The largest of all these former lakes was Lake Bonneville the shrunken remnants of which are Great Salt Lake, Lake Provo, and Lake Sevier. It is generally agreed that the many fluctuations of the water level in Lake Bonneville and other contemporary lakes in the Basin and Range Province of the western United States were caused by increases or decreases in water volumes that coincided with the major advances and retreats of the Pleistocene ice sheet. Higher levels existed during glacial periods, and low levels, such as those today, are indicative of interglacial times. The implication is that the same climatic changes that caused ice caps to grow and expand also caused wetter conditions to prevail over the watersheds encompassing these basins. The wetter conditions that caused higher lake levels are called pluvial, and the greatly expanded water bodies in the Bonneville basin are termed pluvial lakes.

But not all the changes in level of Lake Bonneville are attributable to climatic changes from pluvial to nonplu-

vial climates. Detailed studies indicate quite clearly that downcutting of the outlet was a nonclimatic cause of at least one lowering of the water level. Another change in lake level was caused by a lava flow that diverted a stream into the basin, causing an increased volume of water and a subsequent rise in lake level. Whatever the climatic or nonclimatic causes of the ancient Bonneville shore features, they remain today as a link with geologic events of the Pleistocene.

COASTAL FEATURES AND SEA-LEVEL CHANGE

During the Pleistocene Epoch, sea level fell during the buildup of the continental ice sheets, and rose during their retreat. The maximum lowering during the Pleistocene was about 120 metres (400 feet) below the present ocean surface, and the maximum rise was about 90 metres (300 feet) above modern mean sea level. During the Wisconsin or last glaciation, sea level was about 90 metres below present sea level, and during the last interglacial (Sangamon), sea level was about 18 metres (60 feet) higher than at present. During the last 20,000 years, sea level has gradually risen to its present position.

The effects of these glacial-eustatic changes in sea level are preserved along the coastal regions of the world. Higher sea levels are recorded in raised beaches, wave-cut coastal terraces, and elevated coral reefs. The evidence for lower sea levels is found in submerged ridges that appear to be former beach ridges along Pleistocene coastlines that existed during periods of maximum glaciation.

Other effects of a lower sea level are the terraces along major river valleys such as the Mississippi and Rhine. These and other rivers eroded their channels deeper during the low sea levels of the glacial advances, and filled them with alluvium during the high sea levels of interglacial times. The repetition of the cut-and-fill cycle, coupled with a general absolute elevation of the coastal land surface, is the simplest explanation for these terraces.

The persistent rise in sea level during the last 200 centuries accounts for many of the estuaries and long coastal indentations that characterize many present-day coastal regions of the world. These long and relatively narrow bays and inlets are the drowned mouths of river valleys. A coastline dominated by drowned river valleys is called a ria coast. A ria differs from a fjord in that the latter was deepened by glacial erosion whereas the former was never occupied by glacier ice.

DRAINAGE PATTERNS AND ICE DISRUPTION

When the Pleistocene ice sheets began their first expansion over the North American, European, and Asian continents, the existing drainage lines were disrupted if not destroyed completely. The present system of river channels in the areas overrun by the continental glaciers thus differs from the preglacial system. In some cases, major changes enlarged the areas of some drainage basins at the expense of others. In other cases, the segments of some river channels were dislocated by the advancing ice and forced to flow in new channels parallel to the ice margin. In still other instances, the preglacial system of river channels was obliterated through filling by drift. In the glaciated regions of the world in which detailed borings and geophysical exploration have been accomplished, the preglacial topography reveals the configuration of the old drainage patterns. Some are drift-filled bedrock valleys that date from pre-Pleistocene time; others were formed during interglacial times.

One of the most thoroughly studied examples of major drainage changes brought about by the advance of the Pleistocene ice sheets occurs on the upper reaches of the Missouri River and its tributaries. Before the onset of glaciation, the preglacial Missouri system flowed northeastward toward the Hudson Bay lowland. Invasion of this area by ice from the northeast blocked the system and created a new glacier-margin channel that flowed southeastward and eventually became part of the modern Missouri River.

Elsewhere in the world it has been shown that segments of the Thames River in England and the Rhine and other rivers in northern Germany, plus several smaller stream systems in Scandinavia, Poland, and the Soviet Union, occupy channels that resulted from diversions caused by invading ice.

CLIMATIC IMPLICATIONS

Most of the landforms of the earth are not the products of a single geologic event or a constant climatic regime. Although there can be no doubt about the glacial origins of such landforms as drumlins, eskers, moraines, and the like, other landforms beyond the glacier borders may bear more subtle imprints of Pleistocene climatic conditions. These climatic conditions included not only the colder periods associated with the glacial stages but also the warmer periods of the interglacials. Paleontological evidence indicates that at least one of the interglacials was characterized by a climate warmer than today, a fact that is frequently overlooked in deciphering the origin of landforms beyond the borders of Pleistocene glaciation.

Warmer climates are more conducive to rock weathering than colder climates. Wetter climates produce more runoff but also more vegetation than drier conditions. Aridity enhances eolian activity and increases surface runoff rates, because of scarce vegetational cover and torrential thunderstorms that are commonplace in many arid or semi-arid regions of the world.

Scientists have access to evidence other than landforms, such as fossil plants and animals, from which climatic conditions can be inferred. If such means are absent, however, landforms may be the only means for deducing the nature and extent of past climatic changes. The relationships between landforms and climate can be understood only if the contemporary geomorphic processes are understood. In the quarter century following World War II, great impetus was given to the quantitative study of geomorphic processes. These include fluvial mechanics, glacier dynamics, eolian processes, weathering rates, and the many intricate and complex processes that are unique to periglacial conditions. Insofar as these studies have illuminated the geomorphic results of those processes, they are useful also in aiding the students of Quaternary history in reconstructing the succession of climatic fluctuations that have dominated the last 2,500,000 years of Earth history.

BIBLIOGRAPHY. R.J.E. BROWN, *Permafrost in Canada* (1970), includes a brief general discussion of permafrost conditions in Canada and a lengthy discourse on the relationship of permafrost to engineering and construction problems in the north (well written with a minimum of technical jargon); J.L. DAVIES, *Landforms of Cold Climates* (1969), a college-level treatment of geomorphic processes and landforms associated with glacial and periglacial environments, with most examples drawn from southeastern Australia (including Tasmania) and New Zealand; C. EMBLETON and C.A.M. KING, *Glacial and Periglacial Geomorphology* (1968), a scholarly, comprehensive treatment of the origin of glacial and periglacial landforms, written for the student with some previous knowledge of geomorphology or physical geography, and including many references to original works, organized on a chapter-by-chapter basis; R.W. FAIRBRIDGE (ed.), *The Encyclopedia of Geomorphology* (1968), a many-authored, international, one-volume encyclopaedia of geomorphic terms, processes, and studies, with precise definitions and relevant source literature; R.F. FLINT, *Glacial and Quaternary Geology* (1971), encyclopaedic and world coverage of all aspects of Pleistocene glaciation, Quaternary climatic changes, the fossil record, and geomorphic history of nonglaciated regions, including a bibliography of more than 1,300 entries covering the relevant literature of the world; K. RANKAMA (ed.), *The Quaternary*, vol. 1 (1965), comprehensive, authoritative summaries of the Quaternary history of Denmark, Norway, Sweden, and Finland, with excellent photographs, many diagrams, extensive bibliography, and a good index; and vol. 2 (1967), a companion volume with the same format, but covering the Quaternary of the British Isles, France, Germany, and The Netherlands.

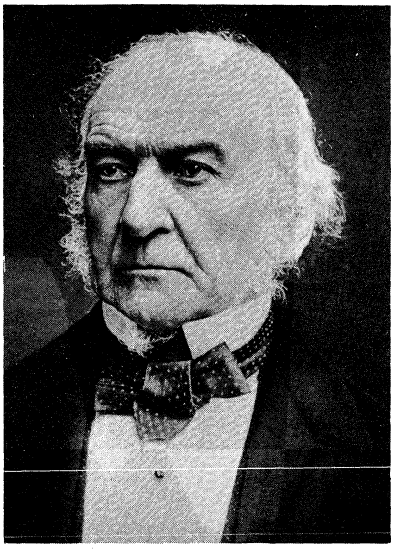
(J.H.Z.)

Gladstone, William Ewart

William Ewart Gladstone was beyond doubt the greatest British statesman of the 19th century. As leader of the Liberal Party and four times prime minister he, along

with his great opponent and rival Benjamin Disraeli, dominated British politics throughout the later Victorian age. His humanitarianism and his high-minded notions of political morality make him an outstanding figure in the history of European Liberalism. Gladstone was born in Liverpool on December 29, 1809, of purely Scottish descent. His mother, formerly Anne Robertson of Dingwall, was of a good Highland family; and his father, John, was descended from the Gledstanes of Lanarkshire. John Gladstone made himself a merchant prince by trading with the East and West Indies and became a leading citizen of the great slaving port of Liverpool. He was a member of Parliament from 1818–27 and died worth about £600,000. William Ewart Gladstone, named after a friend of his father's, and the fifth of six children, was sent to Eton, where he did not particularly distinguish himself. He first displayed his considerable powers of intellect at Christ Church, Oxford, where in 1831 he secured first classes in classics and mathematics.

Culver Pictures



Gladstone.

Though his father dissuaded him from his original intention of taking orders in the Church of England, he devoted his life, as he saw it, to serving the principles of the gospel in politics. As a disciple of the conservative philosopher Edmund Burke, he mistrusted parliamentary reform; his speech against it in May 1831 at the Oxford Union, of which he had been president, made a strong impression. One of his Christ Church friends, the son of the Duke of Newcastle, persuaded the Duke to support Gladstone as candidate for Parliament for Newark in the general election of December 1832; and the "Grand Old Man" of Liberalism thus began a parliamentary career of more than 60 years as a Tory member for what was little better than a pocket borough.

Election to Parliament

His abilities were noticed early; his maiden speech on June 3, 1833, defending the treatment of slaves on a plantation his father owned in Demerara, British Guiana, made a decided mark. He held minor office in Sir Robert Peel's short government of 1834–35, first at the treasury, then as undersecretary for the colonies. His first book, *The State in Its Relations with the Church*, was published in 1838; in it he argued narrow Anglican doctrines he soon outgrew.

After two other women had refused him, in July 1839 he married Catherine, the daughter of Sir Stephen Glynne of Hawarden, near Chester. A woman of lively wit, complete discretion, and exceptional charm, she was utterly devoted to her husband, to whom she bore eight children. This marriage gave him a secure base of personal happiness for the rest of his life. It also established him in the aristocratic governing class of the time; his wife's mother had been Pitt's first cousin.

The influence of Peel. Macaulay, in reviewing Gladstone's first book, had referred to him as the rising hope of stern and unbending Tories. His early parliamentary performances were indeed strongly Tory; but time after time actual contact with the effects of Tory policy was to force him to take a more liberal view. His conversion from the conservatism in which he had been brought up to the liberalism that gave him lasting fame took place in prolonged stages, over a generation. He took his first steps in a liberal direction during Peel's second ministry (1841–46). Peel rightly judged that the son of so successful a merchant would be useful at the board of trade. Gladstone, made vice president of the board under the ineffective Lord Ripon, complained privately that he was "set to govern packages"; yet the wisdom of Peel's choice was soon apparent. The vice president's powers of application astonished even his hardworking colleagues.

Under Peel's supervision he embarked on a major simplification of the tariff; while mastering the complexities of this subject, Gladstone became indeed a more thoroughgoing free trader than Peel himself. The Prime Minister felt that Gladstone was outstanding among all the promising young men in the government, and in May 1843 invited him into the Cabinet as president of the board of trade. The Railway Act of 1844 set up minimum requirements for railroad companies and provided for eventual state purchase of railway lines. Among other useful tasks, Gladstone much improved working conditions for London dock workers. Early in 1845, when the Cabinet proposed to increase a state grant to the Irish Roman Catholic college at Maynooth, Gladstone resigned—not because he did not approve of the increase but because it went against views he had published seven years before. At the end of the year he rejoined the Cabinet as secretary of state for the colonies, and so gave up his seat. For six months, till Peel's government fell in June 1846, he was in office, but not in Parliament —a position of doubtful constitutional propriety. While he was at the Colonial Office, he was led nearer to liberalism by being forced to consider the claims of English-speaking colonists to govern themselves.

Resignation over Maynooth

Private preoccupations. The Glynne family estates were deeply involved in the financial panic of 1847. For several years Gladstone was concerned with extricating them, devoting his customary energy to the intricacies of industrial investment and land tenure. In the course of these operations, he became the largest landlord in the county of Flint. At about the same time he began a habit of charitable work, which was open to a great deal of misinterpretation; he often tried, in the streets of London, to persuade prostitutes to enter a "rescue" home that he and his wife maintained or in some other way to take up a different way of life. He spent much time and money on these efforts till well past his 80th birthday.

Several of Gladstone's closest Oxford friends were among the many Anglicans who converted to Roman Catholicism under the impact of the Oxford Movement. Gladstone, though he had been brought up by an evangelical mother, had moved to a High Anglican position when in Italy, just after leaving Oxford; and once he had reached it he retained it. It pained him deeply when his younger sister became a Roman Catholic. Neither affection nor argumentative skill could ever persuade him to become a Catholic himself, but the suspicion that he was one dogged him and was used against him from time to time by his adversaries, of whom he had many in the University of Oxford, for which he was elected MP in August 1847. He scandalized many of his new constituents at once by voting for the admission of Jews to Parliament and many more by his tolerant opposition to Lord John Russell's Ecclesiastical Titles Act of 1851.

Gladstone made his first weighty speech on foreign affairs in June 1850, opposing foreign secretary Lord Palmerston's high-handed jingoism in the celebrated Don Pacifico debate over the rights of British nationals abroad. That autumn he visited Naples, where he was so appalled by the conditions that he found in the prisons that when he returned to London next February he could talk of little else. In July 1851 he published two trenchant letters to Lord Aberdeen that described what he

had seen and appealed to all Conservatives to set an iniquity right. The results were far from what he had desired. For the time, the Neapolitan prisoners were treated even worse than before, and most conservatives, all over Europe, were deaf to his appeal. But Palmerston circulated the letters to all the British missions on the Continent, and they delighted every liberal who heard of them.

Financial policy. For nine years after Peel's death in 1850, Gladstone's political position was seldom comfortable. As one of the most eminent of the dwindling band of distinguished Peelites, he was mistrusted by the leaders of both the main parties and distrusted some of them—particularly Palmerston and Disraeli—in his turn. He refused to join Lord Derby's government in 1852. At the end of that year, by a brilliant attack on Disraeli's budget, he brought the government down and took a long stride forward in public estimation as a result. He then joined Aberdeen's coalition as chancellor of the exchequer. His first budget speech, on April 18, 1853, adumbrated his great qualities of leadership. In a bold and comprehensive plan he made further large reductions in duties, proposed the eventual elimination of the income tax, and, with considerable political courage, carried a scheme (which every other Cabinet member had at first opposed) for the extension of the legacy duty to real property.

First budget speech

His budget provided the backbone of the coalition's success in 1853, a year in which he spent much time devising a scheme for a competitive civil service system. He was also busy preparing the Oxford University Bill that was passed in the following year; this local preoccupation kept him from taking any detailed interest in the events which led up to the Crimean War. He defended the war as necessary for the defense of the public law of Europe; but its outbreak disrupted his financial plans. Determined to pay for it as far as possible by taxation, he doubled the income tax in 1854. When Aberdeen fell in January 1855, Gladstone agreed to join Palmerston's Cabinet; but he resigned three weeks later, with two other Peelites, rather than embarrass his party by accepting a committee of inquiry into the conduct of the Crimean War. He was, as a result, unpopular in the country; and he made himself more unpopular still by speeches in Parliament in the summer of 1855, in which he held that the war was no longer justified, as its proper objects had already been attained. Meanwhile, still haunted by the horrors of Naples, he helped finance a quixotic project to send a steamer to rescue some Neapolitan prisoners confined on a Mediterranean island. The good or harm that might have resulted were both averted when the vessel sank on the way.

Gladstone always kept up his reading in classical studies, as well as in theology and Italian poetry; and he used his leisure while out of office to prepare a long book, *Studies on Homer and the Homeric Age* (3 vol., 1858), which suggested that ancient Greek life had been designed by providence to show men how they should behave to each other. He helped to defeat Palmerston in the Commons by a speech on China, in March 1857, and later that year opposed, on religious grounds, a bill putting divorce within the reach of the poor with such persistency that he was accused long afterward of having invented parliamentary obstruction himself. He twice refused to join Derby's government in 1858, in spite of a generous letter from Disraeli, but accepted an offer to visit the Ionian Islands Protectorate as lord high commissioner in the winter of 1858–59.

Joins Palmerston's Cabinet

In June 1859 Gladstone cast a silent and unavailing vote for Derby's Conservative government on a confidence motion and caused surprise by joining Palmerston's Whig Cabinet as chancellor of the exchequer a week later. His sole, but overwhelming, reason for joining a statesman he neither liked nor trusted was the critical state of the Italian question. The triumvirate of Palmerston, Russell, and Gladstone did indeed help, over the next 18 months, to secure the unification of almost all Italy, but on other matters the cabinet was much divided.

Gladstone was constantly at issue with his Prime Minister over defense spending. By prolonged efforts, he managed to get the service estimates down by 1866 to a lower figure than that for 1859. He took little other part in the government's foreign policy, except for a reference to the seceding Southern American states as "a nation" in October 1862. The national economy responded well to his policies at the exchequer, which included the further abolition of import duties by the celebrated budget of 1860. That year he supported an Anglo-French trade treaty, which shortly doubled the value of Anglo-French trade, and proposed to abolish the duties on paper, which to Palmerston's ill-concealed delight the House of Lords declined to do. Next year Gladstone repeated the proposal, and included it with all the other budget arrangements in a single finance bill that the Lords dared not amend, a procedure that has been followed ever since. Another particularly useful step was the creation of the post office savings bank. These measures brought him into increased contact and increased popularity with the leaders of working class opinion; journeys round the main centres of industry did the same.

In the general election of July 1865, Gladstone was defeated at Oxford but secured a seat in south Lancashire. When Palmerston died in October and Russell became prime minister, Gladstone took over the leadership of the House of Commons, while remaining at the exchequer. He was not well suited for the new post; he was too busy to ingratiate himself to backbenchers, and while Whigs distrusted him as a former Conservative, Conservatives distrusted him as a renegade, and radicals as a churchman.

By now quite convinced of the need for a further reform of Parliament, he introduced a bill for the moderate extension of the franchise in March 1866. Violently attacked by Whig dissidents led by Robert Lowe, it foundered in committee in June, and the whole government resigned. Next year Disraeli introduced a stronger Reform Bill that gave a vote to most householders in boroughs. Disraeli became prime minister early in 1868. Two months later, Gladstone carried against him in the Commons three resolutions calling for the disestablishment of the Protestant church in Ireland, and that autumn, in *A Chapter of Autobiography*, he explained the reasons that had led him so far from the conclusions of his first book. Russell had by now resigned from active politics, and it was to Gladstone that the Liberal whips looked for instructions during the general election at the end of the year. Though Gladstone lost his Lancashire seat, he was returned for Greenwich; and the Liberal Party won handsomely in the country as a whole. His abilities had made his its indispensable leader, and when Disraeli resigned, Queen Victoria called on him to form a government.

First administration. Gladstone's first Cabinet (1868–74) was perhaps the most capable of the century. Its Prime Minister tried to supervise the work of each department, devoting his main efforts to Irish and foreign policy. The Irish church was successfully disestablished in 1869, and a first attempt to grapple with oppressive landlordism in Ireland was made unsuccessfully in 1870; abroad, an attempt to promote disarmament in 1868 failed when Bismarck refused to consider it. The Franco-German War took the government completely by surprise, and the Cabinet would not allow Gladstone to propose to Prussia the neutralization of Alsace and Lorraine. The principal achievements of 1871 and 1872—a London declaration by the great powers that they would not in future abrogate treaties without the consent of all the signatories, and the settlement by arbitration of the "Alabama" claim of the United States—look well in retrospect but were thought pusillanimous at the time. The most useful reforms at home were administrative, except for the Education Act of 1870 and the Ballot Act of 1872; these measures supplemented the work of parliamentary reform but antagonized opposite wings of the Liberal Party. When an Irish University Bill failed by three votes to pass the Commons, in March 1873, Gladstone resigned but was forced back into office by Dis-

raeli's refusal to form a government. In August he had to reshuffle his Cabinet and again took on the chancellorship of the exchequer himself. Fascinated by another plan to abolish income tax altogether, he dissolved Parliament suddenly in January 1874, but his party was heavily defeated and his government resigned. Gladstone gave up the party leadership (though he remained MP for Greenwich) and retired to Hawarden to write pamphlets attacking papal infallibility and articles on Homer.

Retirement

Bulgarian atrocities. The indifference of Disraeli's government to the brutality of Turkish reprisals against risings in the Balkans, in 1875–76, brought Gladstone back to active politics. For years he had held that the only just solution to Balkan problems was self-government. He joined, rather late, an agitation begun by Liddon, E.A. Freeman, and W.T. Stead against the government's Eastern policy. In September 1876, he published a famous pamphlet on "Bulgarian Horrors and the Question of the East," which demanded that the Turkish irregulars should remove themselves, "one and all, bag and baggage," from the peninsula. London society and the London mob were both against him; the Queen, under the blandishments of Disraeli, strongly disapproved; the Whiggish elements in his own party were lukewarm or indifferent at first; and only some radicals, with whom he had little in common, really supported him. Yet in the end he triumphed. He gave up his Greenwich seat and stood for the Scottish county of Midlothian. In two tremendous outbursts of oratory, in November 1879 and March 1880, Gladstone secured his own return to Parliament, but he also did much more: he overthrew a government. The general election of March and April 1880 had more, and on the whole more ardent, contests than any before, and it was this one man's eloquence that decided the result and secured a large Liberal majority. The feat is unique. Gladstone was able, by his manifest sincerity and skill of argument, to convince a majority of the electorate that recent Conservative policy had been morally wrong, and the Conservative government had to resign.

Midlothian campaign

Second administration. In his second administration (1880–85), Gladstone foolishly combined again for two and a half years the duties of prime minister and chancellor of the exchequer. Party lines had not yet set firm, and his large apparent majority in the Commons was unruly. It was not until 1884 that he could introduce the measure for which most Liberals had been pressing—a third Reform Act that nearly doubled the electorate by giving votes to householders in country districts. This measure was passed only after a stiff quarrel with the House of Lords. Gladstone had hoped to settle the Eastern question quickly and then retire. As it was, he and Granville, the foreign secretary, did manage by a brusque naval threat to compel Turkey to cede Thessaly to Greece; yet Granville would not let him go on to give up Cyprus, as the government had already been weakened by other questions and had vital work still before it. There were still graver troubles in Ireland, in the throes of agricultural catastrophe. The exceedingly complicated Irish Land Act of 1881, largely Gladstone's own work, did in the long run promote the prosperity of the Irish peasant; but violent crime continued, culminating in the murder of Gladstone's close friend and nephew-in-law Lord Frederick Cavendish by Irish Nationalists. No alternatives to strong police powers were left in Ireland, and measures to restrict the freedom of Irish members to obstruct the work of the Commons had to be taken. Gladstone hated both, but had to sanction them.

A third imperial imbroglio arose in 1882 when a series of unavoidable decisions compelled the Cabinet to authorize the occupation of Egypt. Gladstone's settlement of the Egyptian debt question (1885) was honourable to his belief in the concert of Europe but had the unintended effect of tying British foreign policy to German. The worst mistakes he ever made were to allow Gen. C.G. Gordon ("Chinese Gordon"), whom he never met, to go to Khartoum in Sudan and then fail to rescue him; Gordon was killed in January 1885, and his death cost Gladstone much in popularity. Firm handling of a dispute with Russia over the border of Afghanistan did something to restore his prestige; but when the government was defeated on the budget in June 1885, he was glad to resign. He refused a gracefully worded offer of an earldom from the Queen.

Failure to rescue Gordon

Irish Home Rule. Though he had only spent three weeks in Ireland in his life (in 1877), Gladstone had imagination enough to appreciate the full force of Irish nationalism. As his close colleagues knew, he had for years looked favourably on the case for Irish Home Rule, that is, for a subordinate parliament in Dublin. In the autumn of 1885 he believed the time for it was ripe; but as a combination of Irish with Conservative votes had defeated him in June, he waited silently to see what an Irish–Conservative combination would produce. The general election of November–December 1885 returned a Parliament in which the Liberal members exactly equaled the total of Conservatives plus Irish. At this moment, Gladstone's youngest son revealed his father's conversion to Home Rule, and most Conservatives therefore turned against it. Lord Salisbury's government was defeated when Parliament met, and Gladstone formed his third Cabinet in February 1886. His Home Rule Bill was rejected in Parliament in June, by a large secession of Whigs, and in the country at a general election in July, and Gladstone resigned office.

He had kept his Midlothian seat, unopposed, and carried with him into the new Parliament a personal following 190 strong, supported by the National Liberal Federation, the most powerful political machine in the country. He devoted the next six years to an effort to convince the British electorate that to grant Home Rule to the Irish nation would be an act of justice and wisdom. This policy was abhorrent to the English upper classes, and for the first time a marked class division between the leading parties opened. At the jubilee of 1887, Gladstone was cheered from the pavements but hissed from the balconies. The act was symbolic of the position he had reached as the great popular hero of the age. His reputation stood higher with Scotsmen, Irishmen, and Welshmen than with Englishmen, except for the English Nonconformists, to whom his tendency to regard and describe great political questions as moral ones made a strong appeal. Portraits of him were far commoner in poor men's cottages than those of any other political leader. He spoke at many great meetings and cooperated with the Irish leader Charles Stewart Parnell. But in 1890, when he was 80, momentary excitement led him into a dangerous quarrel with Parnell about the political consequences of the O'Shea divorce. (Gladstone had not believed the rumours about Parnell's liaison, holding that Parnell would never "imperil the future of Ireland for an adulterous intrigue.") He never sought to correct the stories Parnell spread about him in Ireland. He sanctioned an extensive program of Liberal reforms drawn up at Newcastle in 1891, because it was headed by Home Rule, and on this platform the Liberals won in the general election of 1892 a majority of 40—if the Irish voted with them.

Quarrel with Parnell

Gladstone, an "old, wild, and incomprehensible man of 82½," as the Queen called him in a letter at the time, formed his fourth Cabinet in August 1892. Its members were held together only by awe of him. He piloted another Home Rule Bill through 85 sittings of the Commons in 1893; the Lords rejected it by the largest majority ever recorded there, 419–41, but the full discussion in the Commons brought Ireland eventual benefit. The Cabinet rejected Gladstone's proposal to dissolve.

He could not agree with his colleagues that a large increase in naval expenditure was necessary and finally resigned—ostensibly because sight and hearing were failing—on March 3, 1894. He was much mortified by the coolness of his last official interview with the Queen he had served loyally all her reign; by now she frankly detested him and had to struggle to conceal the fact in his presence. He retired to Hawarden and busied himself with a critical edition of the works of Bishop Joseph Butler (2 vol., 1896). Humanitarian to the end, in his last great speech, at Liverpool in September 1896, he de-

nounced Turkish atrocities in Armenia. After a painful illness, he died of cancer of the palate at Hawarden, on May 19, 1898. He was buried in Westminster Abbey.

Character. His truly extraordinary vigour far exceeded that of other men and was coupled with no less extraordinary powers of self-control and an iron devotion to duty. Training and natural ability led him to qualify statements and subdivide arguments; his thoughts indeed were often complicated, but his character was fundamentally simple. Thus, it was a simple sense of duty that took him into politics, a career in which he never felt really at home and for which he was in some ways unfitted, not least by his tendency to believe that other men's motives were invariably as disinterested as his own and by his excessive anxiety to maintain the consistency of his own conduct. Political courage and personal magnanimity he had in abundance, and he was the most efficient administrator of his age. His gift for concentration was remarkable; this helped people who did not know him well to think him hard or even hypocritical. But no one who knew him intimately doubted his entire sincerity or failed to be captivated by his delightful manners, his warmth, and his range of mind. His combative instinct, quickness of understanding, retentive memory, and inexhaustible fund of phrase made him a fearsome adversary in debate. Purely as an orator, he had two or three equals in his own day; as a statesman, only Peel came near him. A few British prime ministers —Walpole, Chatham, Pitt, Churchill—have been leaders as great; none has been more inspiring. Lord Acton, indeed, assessing for Gladstone's daughter, in 1879, her father's standing among the world's statesmen of the past two centuries, concluded that "in the three elements of greatness combined—the man, the power, and the result—character, genius, and success—none reached his level."

BIBLIOGRAPHY. Among nearly 40 lives, the best is still JOHN MORLEY, *The Life of William Ewart Gladstone*, 3 vol. (1903), although it emphasizes Gladstone's liberalism too much and his dependence on God too little. Many family points suppressed by Morley are in SIR PHILIP MAGNUS, *Gladstone* (1954); and in S.G. CHECKLAND, *The Gladstones, 1764–1851* (1971), the best modern studies. His political and literary papers, in 760 volumes in the British Museum, await full research; he has left his mark also in thousands of Public Record Office files. Of his published letters, AGATHA RAMM (ed.), *The Political Correspondence of Mr. Gladstone and Lord Granville, 1868–76*, 2 vol. (1952), and . . . *1876–86*, 2 vol. (1962), are important and revealing; as is D.C. LATHBURY, *Correspondence on Church and Religion of William Ewart Gladstone*, 2 vol. (1910). PHILIP GUEDALLA (ed.), *Gladstone and Palmerston* (1928) and *The Queen and Mr. Gladstone*, 2 vol. (1933), provide plenty of colour. Of Gladstone's own writings, the *Autobiographica*, vol. 1 (1972), though written in old age, is rewarding. His *Chapter of Autobiography* (1868) and *Midlothian Speeches . . . 1885* (1886, reprinted 1971) repay study. He collected many of his learned articles in *Gleanings of Past Years, 1843–78*, 7 vol. (1879), and *Later Gleanings* (1897). There is a bibliography of his work in A.T. BASSETT, *Gladstone's Speeches* (1916). M.R.D. FOOT (ed.), *The Gladstone Diaries*, 2 vol. (1968), so far only covers 1825–39.

(M.R.D.F.)

Glass, History of

From very early times glass has been used for various kinds of vessels, and in all countries where the industry has been developed glass has been produced in a great variety of forms and kinds of decoration, much of it of great beauty. The aesthetic or artistic aspect of glass is the subject of this article. For the composition and properties of glass and the manufacture of various glass products such as glass containers, window glass, plate glass, optical glass, and glass fibres, see GLASS PRODUCTS AND PRODUCTION.

ANTIQUITY

Early glass. It is not certain in which of the civilizations of the ancient Near East glass was first made. The earliest wholly glass objects from Egypt are beads dating from some time after *c.* 2500 BC. A green glass rod found at Eshnunna in Babylonia may go back earlier, possibly to 2600 BC. A small piece of blue glass found at Eridu dates from before 2200 BC. The manufacture of glass vessels, which may have begun slightly earlier in Mesopotamia, was carried to a high point of excellence in Egypt during the 18th dynasty (*c.* 1490 onwards). These vessels

Egyptian technique

are distinguished by a peculiar technique: the shape required was first formed of clay (probably mixed with dung) fixed to a metal rod. On this core the body of the vessel was built up, usually of opaque blue glass, on which, in turn, were coiled threads of glass of contrasting colour. The threads were pulled alternately up and down by a comb-like instrument to form feather, zigzag, or arcade patterns. The threads—usually yellow, white, or green in colour, and sometimes sealing-wax red—were rolled in (marvered) flush with the surface of the vessel. Finally, if desired, handles—often of translucent glass and sometimes of patterned "canes"—were added. The vessels were nearly always small, mainly for unguents and the like. Occasionally glass was decorated on the lapidary's wheel. Glass is known to have been made on the palace site of Tell el-Amarna, the residence of Akhenaton (reigned *c.* 1379–1362 BC), and the number of fragments found in and near the palace of Amenhotep III (reigned *c.* 1417–1379 BC) at Thebes suggests that it was made there also. This palace activity seems then to have died down and after the 21st dynasty (1085–945 BC) to have ceased altogether.

In Mesopotamia the Nineveh tablets of the reign of Ashurbanipal (668–*c.* 626 BC) and the remains of glass in various forms excavated at Nimrūd (ancient Calah, Assyria) indicate that glassmaking was carried on there during the 8th to the 6th centuries BC. It is probable that certain vessels of palish-green or deep blue glass, cut from a solid mass as if from stone, are Mesopotamian and date from as early as the 8th century BC (as a dish from controlled excavations in Phrygia proves). A vase of this type, contrasting completely with the core-wound glass of Egypt, bears the cartouche (panel enclosing the name) of the Assyrian king Sargon II (reigned 721–705 BC), and it is probable that glass treated in this way was manufactured over a long period in Mesopotamia.

Glass was made in Greece in Mycenaean times (*c.* 1400–1200 BC) usually in the form of small molded architectural details. A few pieces suggest, however, that perhaps some vessel glass also was made by the Egyptian technique, though not in Egyptian forms. Other Aegean-area glass of this period may have been imported from Egypt.

In general, glass of the earlier half of the 1st millennium BC is scarce and displays little homogeneity. From the 6th century BC, however, glass begins to appear in great quantities once again, particularly on the Greek-inhabited islands of the Aegean, in Greece itself, in Italy and Sicily, and even farther west. This contrasts with the meagre contemporary finds on Egyptian soil. The later glasses in the old Egyptian core-wound technique were probably made in Syria or some part of the Greek world. Such vessels were still small but differ in shape from the earlier Egyptian dynastic work. They were usually decorated

with light-coloured threads on a dark, usually blue, ground (familiar from the Egyptian 18th dynasty), but a notable variation was displayed in pieces decorated with dark purple threads on a white ground. In the Hellenistic period (roughly from the 4th century BC) the shapes of glass degenerated. The technique of decoration, however, remained the same; new colour combinations were used, and indeed these combinations continued into the era of blown glass.

Dominance of Alexandria in glass-making

The Roman Empire. In Egypt during the Ptolemaic period (330–305 BC) Alexandria came to the fore in glass-making. By about the 1st century BC, which saw the beginnings of glass as known today, it had become pre-eminent in certain glass techniques. Alexandria inherited and perfected the manipulation of coloured glass rods to make composite canes, which, when cut across, revealed a design (mosaic glass). Slices from such canes could be arranged side by side to produce repetitive patterns. When, as often happens, the cane slices show starry or flowerlike designs, the resultant glass is called millefiori ("thousand flowers"). An Alexandrian technical speciality more important for the future, however, was molding,

glass being pressed into, or powdered glass melted in, a mold. A combination of this process with the millefiori technique produced bowls with variegated designs in infinite variety. Sometimes glass of various colours was irregularly compounded to give the effect of a natural veined stone; occasionally enclosures of gold leaf in the glass simulated the glitter of natural pyrites (aventurine glass). Bowls were often finished around the rim with a cordon made of a clear glass thread twisted with one of opaque white. Sometimes such cable threads were themselves coiled round and round from a centre to make a bowl of lacy appearance, with the opaque white glass threads apparently set in a clear colourless matrix.

All these pieces might be finished with a fire polish by returning them to the furnace, but many mold-pressed glasses were, in fact, given a rotary polish, either by means of a spinning wheel fed with abrasives or by a process similar to lathe turning, in which the object spins and the tool is stationary. Similar equipment probably produced the numerous pieces that give every appearance of having been cut from a solid block of glass or at least from a thick, mold-pressed blank. Such pieces (usually flat dishes or two-handled cups) follow the contemporary forms of pottery and metalwork. Wheel engraving appears to have become an Alexandrian specialty around the 1st century BC and probably continued so throughout the two succeeding centuries. Alexandrian wheel engravers produced not only massive cut shapes, but also intaglio (incised) and relief surface decoration, the latter by laboriously grinding back the surface of the glass to form a background for the design. Simple motifs such as lotus buds or lotus flowers were produced in this way and occasionally more elaborate figural compositions were also done. Other specialties attributed to Alexandria were enamel painting (pigments mixed with a glassy flux were fused to the surface of the glass vessel by a separate firing) and an extraordinary technique of sandwiching a gold leaf etched with a design between two layers of clear glass.

Introduction of blown glass

The most important innovation in the whole history of glass manufacture was blowing. Perhaps by a stroke of pure inventive genius it was perceived that glass on the end of a hollow metal tube could be blown into a mold as easily as it had theretofore been pressed in. The next stage was to use molds for forms, such as flasks, that could not be made by pressing. Finally, it was realized that the glass bulb on the end of the blowpipe could be shaped freehand to any form desired, and handles, feet, and decorative elements could be added at will. This liberating discovery, probably made during the 1st century BC, gave rise to the astonishing growth of the glass industry in Roman imperial times. In addition to the luxury vessels of types already described, which were produced with an elaboration of skill that astonishes and often baffles the modern technician, commercial containers in great variety were mass-produced in common greenish glass on a scale that was not matched until the 19th century.

The discovery of glass blowing may well be credited to the Syrian glassworkers, since the first mold-blown glasses bear the signatures of Syrian masters and since the readily ductile Syrian soda glass was especially apt for this purpose. Syrian glassworkers, however, seem to have migrated wherever demand promised a ready market, and some masters of mold blowing appear to have moved to Italy early in the 1st century AD; in the course of that century Italy became an important glass-producing area. Glass engraving especially seems to have flourished there and particularly one form of the art—grinding through an opaque white layer to a darker ground (cameo glass). The most famous example of this exacting technique is the Portland vase, in the British Museum, London. The capacity of the Italian glass craftsman to surpass all earlier masters in work of the most complex character is seen in the so-called cage cups (*diatreta*), on which the design—usually a mesh of circles that touch one another, with or without a convivial inscription—is so undercut that it stands completely free of the body of the vessel, except for an occasional supporting strut. These cups were made perhaps at Aquileia and date from the 3rd and 4th centuries.

Cameo glass engraving technique

Parallel to the pottery industry, glassmaking spread from Italy to northern Gaul, in particular to the valleys of the Rhône and the Rhine. In Britain the industry was probably not of great importance. The Rhineland, how-

ever, became one of the great glassmaking areas of the Roman world (partly, it is thought, because of successive migrations of Near Eastern workers) and, although Rhenish glass is always recognizably Roman, several types of decorated glass were specialities of the district. Glasses decorated in serpentine patterns by threads trailed on and then pressed flat and notched are perhaps the most important and typical (*Schlangenfadengläser*). A considerable school of glass engraving also seems to have flourished, probably around Cologne. Although some engraving shows an impoverished linear style eked out by lines scratched with a hard stone point, some is executed by means of wheels sufficiently thick to permit rounded cuts corresponding to the modelling of the human figure, and simulating it when the piece is seen against the light. Both types of decoration flourished in the 3rd and 4th centuries.

In Egypt in the later centuries of the Roman epoch glass was in frequent use for tableware, but artistic standards were not high. Plain dishes, cups, bowls, and lamps are characteristic; the glass of such tablewares ranges from an almost colourless "metal" (basic glass) of good quality to a greenish brownish substance full of bubbles and impurities. Decoration in this late period is mainly restricted to a few rough-cut lines, an occasional group of coloured glass blobs on the lamps, or a zigzag trail of glass thread running between the lip and the shoulder of a vase. In Syria during the same period, however, this trailing technique, which was particularly suitable to the ductile Syrian material, was carried to extreme lengths—threads circling the body or neck of a vessel, a profusion of zigzags, and fantastically worked handles.

Syrian use of trailing technique

MIDDLE AGES

With the breakdown of the Roman Empire, glassmaking fared differently in different parts of the world. In the East, urban life continued relatively undisturbed, and glassmaking evolved in an unbroken progress into Islāmic times. In the northern provinces, however, glassmaking became an affair of small, often isolated, glasshouses working in the forests that supplied them with fuel. Relatively simple shapes were made of an impure greenish or yellowish material, and decoration was restricted to simple trails of thread. Considerable virtuosity, however, was displayed from *c.* 500 onward in the manufacture of elaborate and fantastic *Rüsselbecher* ("claw beakers") on which two superimposed rows of hollow, trunklike protrusions curve down to rejoin the wall of the vessel above a small button foot.

In the East, Syria appears to have continued its predilection for trailed and applied ornamentation. In Egypt the art of glass suffered a catastrophic decline; only small rough vessels of impure green or blue material were manufactured.

Byzantium. In Byzantium itself the position of glassmaking is obscure. A distinction was made between *vitrarii* ("glassmakers") and *diatretarii* ("glass cutters") in edicts of Constantine the Great, Theodosius, and Justinian—suggesting that cutting played an important part in Byzantine glass decoration. This is borne out by the fact that cut glass made up the greater part of the glass that was brought back from the sack of Constantinople by the crusaders and placed in the treasury of St. Mark's in Venice. Apart from a few pieces of obviously Roman glass, presumably kept as heirlooms in Byzantium, these glasses are decorated either with tessellated (mosaic) patterns of overlapping round or oval facets or with round bosses in relief. These same two forms of cutting are observable in glass of the 5th century excavated at Kish in Mesopotamia; it is a fair assumption that Byzantine taste in glass, as in some of the other arts, was strongly influenced by the East. It is probable, however, that some enamelled and gilt glass also was made in the Byzantine provinces (*e.g.*, in Corinth), if not in Byzantium itself.

Glass from the sack of Constantinople

Islām. In the 7th century the whole Near East was overrun by the Arabs, and a number of rival dynasties were established in different parts of the conquered territory. An Islāmic civilization developed comparable to the preceding area of Greco-Roman culture, and a distinctively Islāmic glass style evolved. Although often it is not possible to say where a particular glass was made, different parts of the Islāmic world seem to have shown predilections for one or another type of glassmaking. In Syria, pieces more or less heavily decorated with trailed threads or applied blobs and pieces blown in molds, patterned with ribs or other allover designs, were still made. In Mesopotamia, glassmaking and, in particular, engraving flourished, especially during the ʿAbbāsid dynasty (750–1258), and attracted many of the best artists in the Islāmic world. Not only were the earlier modes of facet and boss cutting continued, but (perhaps deriving from them) two splendid new styles were created, one of linear intaglio, the other of relief cutting (outlines were left in relief by cutting back the ground and were then enlivened by crosshatching). Bowls, bottles, and ewers of remarkable sumptuousness were decorated with forms of running animals and plant scrolls. The quantity of engraved glass of these types found in Persia suggests that such work was done there also.

In Egypt there was both innovation and, after the post-Roman period, a notable revival of earlier techniques. Among the innovations was the stamping of glass by means of tongs, one jaw of which was patterned. The technique also is found in other lands. One extension of it, by which a bottle's upper and lower halves, made separately in contrasting colours, were decorated by the tongs and then joined together, was probably a Syrian innovation. More important was the Egyptian invention of lustre painting. In its simplest form it consisted of painting with a pigment containing silver that when fired in a smoky atmosphere (*i.e.*, without oxygen) produced on the glass a thin, metallic film that varied in colour from pale yellow to brown. Intact bowls and a bottle decorated by this technique exist, but whole classes of much more elaborate lustre-painted glass are represented only by fragments. A very wide variety of sumptuous polychrome effects are represented, although many were probably not produced by lustre properly so-called. The technical processes by which these effects were achieved are not yet understood.

Egyptian tong stamping and lustre painting

Egyptian Islāmic revivals in glass included millefiori effects, mainly in plaques for wall decoration, and white fern and feather patterns produced on dark glass vessels by combed and imbedded glass threads. Glass cutting was

also practiced in Egypt, mainly for the production of deeply incised small perfume bottles of square section, the bases of which were often cut into four tapering feet ("molar tooth" bottles). It seems probable that Egypt also perfected the techniques of gilding, decisive for the next phase in Islāmic glassmaking. In gilding, gold leaf is applied to an object that is then fired to fix the glass.

Syrian enamelled and gilt glass

Glassworkers migrating from Egypt to Syria after the fall of the Egyptian Fāṭimid dynasty in 1171 may have laid the foundation of the Syrian art of enamelled and gilt glass. Although earlier phases of this art are incompletely understood, the first group of enamelled and gilt glasses seems to be one in which thick enamels are used (particularly white and turquoise blue), often in series of beadlike drops; this group is tentatively associated with the town of Raqqah in Syria. A similar doubt surrounds the origins of two broad families into which Syrian glass of the 13th century is divided. One, characterized by the use of thick, jewellike enamels, is connected with the town of Aleppo; the other, notable for its exquisitely painted small-scale figural decoration, is attributed to Damascus.

Both cities were famous for their glass at this time, but it is uncertain what each produced. Wherever made, these two types of glass represent one of the highlights in the history of the art, whether one considers the rich green, red, yellow, white, and turquoise-blue enamels of the "Aleppo" group or the masterly red outline drawing of the "Damascus" group.

Toward 1300, Chinese influence, infiltrating by way of the Mongols and Tatars, makes itself felt in the decoration of these glasses, as is apparent in the series of great mosque lamps that then began to be inscribed with the names of rulers and great officers of state in Egypt. From a peak of excellence at the beginning of the 14th century a decline set in, greatly precipitated by the Mongol conqueror Timur's sacking of the chief Syrian cities at the end of the century.

Damascus fell finally in 1400, and it is recorded that the glassworkers of that city were carried into captivity in Samarkand. Nevertheless, some enamelled glass of inferior quality continued to be made in the 15th century, perhaps in Egypt. By the end of that century, however, there is evidence that mosque lamps were being made in Venice for the oriental market and the great Near Eastern tradition of enamelled and gilt glass was clearly moribund.

MID-15TH TO MID-19TH CENTURY

Venice and the façon de Venise. A glass industry was already established near Venice in the 7th century, and vessel glass was made there by the last quarter of the 10th century. In 1291 the glass furnaces were removed to the neighbouring island of Murano to remove the risk of fire from the city. Although Venice had constant contact with the East, there is no evidence that it was indebted to that source for its skill in glassmaking. Venetian enamelled glasses appear in the second half of the 15th century, and, although their technique is essentially similar to that of the Syrian glassmakers, it is likely that they are of independent development. Little is known of the vessels made before this period, but it is evident from representations in pictures that they were mainly footed flasks and low beakers. The Venetians attributed the introduction of enamelling to a member of the glassmaking family of Barovier. The earliest pieces known, commencing with a goblet dated to 1465, certainly show no signs of outside influence. These, like most Venetian glass of the period, were inspired by the artistic ideals of the Italian Renaissance. The decorations represent triumphs, allegories of love, grotesques (fanciful combinations of human and animal forms), and so forth, with borders of dots of enamel laid on a ground of gold etched in scale pattern. Many of these pieces were of richly coloured glass, blue, green, or purple.

Goblet, green glass enamelled and gilt, Venetian c. 1500. in the British Museum. Height 22.2 cm.

The Venetians were keenly aware of Roman achievements in glassmaking as in the other arts; they reproduced mosaic, millefiori, and aventurine glass, and glass resembling natural layered stones (*calcedonio*, sometimes miscalled *Schmelzglas*), and they even copied a Roman form of bowl that had vertical, external ribs. All these types of glass were Venetian specialities, and they were probably developed as a part of the extensive local bead industry.

Clear, colourless *cristallo* glass

The greatest achievement of Venice, however, and that upon which its great export trade came to be based, was the manufacture of clear, colourless glass, which was apparently exclusive to Italy during the Middle Ages. From its resemblance to natural crystal, this material was called *cristallo*, although in fact it often has a not unpleasing brownish or grayish cast. Made with soda, it was very ductile and cooled quickly. It therefore de-

manded of the workmen great speed and dexterity, and this, in turn, affected the nature of the glasses made. In the first half of the 16th century the Venetian glassblowers produced glasses of an austere simplicity. As the century proceeded (and more markedly still in the 17th century), however, there was a tendency to produce elaborate and fantastic forms. Enamelling on glass went out of fashion in Venice (except on pieces for export) in the first half of the 16th century. Its place was taken to some extent by the use of opaque white glass threads for decorative purposes (latticinio). This form of decoration became progressively more complex; opaque threads were embedded in a matrix of clear glass and then twisted into cables, which were themselves used to build up the wall of a vessel. The height of complexity was reached when a bulb of glass decorated with cables or threads running obliquely in one direction was blown inside a second bulb with threads twisted in the other direction. The composite globe thus formed was then worked into the desired form. This resulted in a vessel completely covered with a lacy white pattern (*vetro di trina*). Other methods of decoration at this time were mold blowing and dipping a vessel while hot into water or rolling it on a bed of glass fragments to produce a crackled surface (ice glass). *Cristallo* was also found suitable for engraving with a diamond point, a technique which produced spidery opaque lines that were especially suitable for delicate designs. The technique seems to have come into use about 1530.

Spread of Venetian glass-making

The glassworkers of the island of Murano were forbidden to leave Venice or to teach their secrets to outsiders, under dire penalties both to themselves and their families. Such was the demand for Venetian glass in the rest of Europe, however, and such was the desire of kings and nobles to control and reap the profits of its manufacture, that many Venetian workmen in the course of the 16th century were tempted to abscond to other countries, where they helped to set up glassworks. Furthermore, at Altare, near Genoa, existed a second great centre of glassmaking. Its glass was so like the Venetian in style and material that it is nowadays impossible to distinguish between the two. The glassworkers at Altare, moreover, were governed by no such laws as the Venetians; rather, they made it their policy to supply their men and teach their methods wherever there was demand for them. Thus, the fugitive Venetians and the willing Altarists spread the Italian art of glass to the rest of Europe, and glasshouses were established in France, Spain, Portugal, Austria, and Germany, while in the North, Antwerp seems to have been a secondary source of diffusion.

Italian glassworkers ranged as far north as England, Denmark, and Sweden. Their labour was necessarily diluted by that of native workmen to whom they were often required to teach their methods. Variations in locally available raw materials modified the quality of the glass, and local taste influenced the form and ornamentation of the objects they produced. Nevertheless, in the late 16th and the 17th centuries an international style in glass developed, wholly Italian in origin and inspiration (*façon de Venise*).

Although there was everywhere a family likeness among glasses of the *façon de Venise*, certain countries developed types peculiar to themselves that are worthy of mention. Thus in Spain not only were fantastic and even bizarre shapes evolved in green glass, but in Barcelona a characteristic kind of enamelled decoration was developed, the peculiarities of which include a light-leaf-green colour and a constantly recurring lily-of-the-valley motif (late 15th–16th century). Elsewhere, at Hall, in the Tirol, a characteristic decoration with the diamond point, often supplemented by cold painting (*i.e.*, unfired oil—or other paint applied to a finished object), was favoured in alternating broad and narrow upright panels containing symmetrical scrollwork or coats of arms and other devices. Almost equally stiff and formal diamond-point work is to be seen on glasses probably made at the London glasshouse of Jacopo Verzelini (examples dated between 1577 and 1590). A more promising development of diamond-point engraving occurred in the Netherlands. There too the work of the 16th century was relatively formal and stiff, linear and clear, with simple hatching only. In the succeeding century, however, diamond-point engraving became initially more supple and pleasing, only to degenerate eventually into overelaboration.

Diamond-point engraving in the Netherlands

Diamond-point engraving was practiced there widely by talented amateurs in the 17th century, among them Humanists such as Maria Tesselschade Roemers Visscher, her even more famous sister Anna Roemers Visscher, and Anna Maria van Schurman. The latter two decorated their glasses with flowers and insects drawn with a gossamer touch, often accompanied by epigrams in Latin or Greek capitals scratched with severe precision or in the free scrolled style of the Italianate writing

masters of the time. A similar calligraphy was practiced later in the century by the amateur Willem Jacobsz van Heemskerk, with notably beautiful results.

Engraving in the first half of the 17th century gradually abandoned linear clarity in favour of crosshatched chiaroscuro (shading) effects, the highlights formed by sometimes completely opaque spots. Many artists worked in this manner; two are worthy of special mention. One was an accomplished engraver signing "C.J.M.," whose earliest dated glass is of 1644; the other was Willem Mooleyser, of Rotterdam, who worked in the last two decades of the 17th century with a scribbled freedom and vigour that raised his work above the average. By the end of the century this type of diamond-point work was superseded in popularity by wheel engraving.

Germany. In Germany toward the end of the 17th century a reaction to Venetian glass styles seems to have set in. In that country there had been a continuous survival, probably from late Roman times, of a local type of green glass, a product of forest glasshouses made with potash obtained by burning forest vegetation and called therefore Waldglas ("forest glass"). From this material, often of great beauty of colour, were made shapes peculiar to Germany, notably a cylindrical beer glass studded with projecting bosses, or prunts (*Krautstrunk*, or "cabbage stalk"), and a wineglass (*Römer*) with cup-shaped or ovoid bowl set on a similarly prunted hollow

The Waldglas tradition

stem. This became the classic German shape of wineglass, which survived into the 18th century and, with modifications, to the present day. Apart from these indigenous forms, German glass in Venetian-type *cristallo* developed local characteristics of its own in the latter part of the 17th century.

In Nürnberg, for instance, the tall-stemmed Italianate goblet underwent a transformation into a severe glass with stem composed of no more than a baluster-shaped element and a bulb, joined together by a number of disk-shaped elements, or mereses, and attached to foot and bowl by the same means. Such goblets display some of the most accomplished glass engraving that was ever practiced.

The leader and founder of the Nürnberg school of engravers was Georg Schwanhardt, a pupil of Caspar Lehmann. Lehmann had been gem cutter to the emperor Rudolf II in Prague and there had taken the decisive step of transferring the art of engraving from precious stones to glass. His first dated work is a beaker of 1605; in 1609 he obtained an exclusive privilege for engraving glass. Although he is the first great personality in glass engraving, he was not the first to practice the art in the German area. On Lehmann's death in 1622 Schwanhardt inherited his patent and moved to his own native city, Nürnberg, where a whole school of glass engraving grew up around him and his family. Schwanhardt's work is characterized by delicate, tiny landscapes, often accompanied by bold formal scrollwork. His son Heinrich excelled in minute landscapes but also engraved inscriptions of fine calligraphic quality. Other notable Nürnberg engravers of the late 17th century were Paulus Eder; Hermann Schwinger, a master calligrapher; and H.W. Schmidt and G.F. Killinger, both notable for the delicacy with which they rendered landscapes. Somewhat similar work was done at Frankfurt am Main by members of the Hess family.

In Bohemia, after Lehmann's death, little engraving of high quality was done. Just before 1700, however, with the perfection of a massive, crystal-clear, potash-lime glass that allowed cuts of considerable depth, the engravers of the Bohemian–Silesian area came into prominence. The harnessing of the mountain streams in the Riesengebirge for water power enabled engravers (those of the Hirschberger Valley in particular) to practice relief engraving, which demands immense energy for grinding down the background of the design. Massive covered goblets were decorated with powerful acanthus scrolls in the contemporary baroque taste. Relief engraving (*Hochschnitt*) was only occasionally used by itself in the Bohemian–Silesian area in the 18th century; more often it was employed in conjunction with intaglio (*Tiefschnitt*). By the turn of the 18th century the engravers of this area —anonymous workmen regarded as artisans rather than as artists—had acquired great technical skill; this enabled them to adapt to glass all the changing fashions of the 18th century in the decorative arts. Glass engraving, often of fine quality, was also practiced in many parts of Germany—notably Thuringia, Saxony, and Brunswick—but the most significant work of the late 17th and early 18th centuries was that done in Brandenburg. There, the glassworks at Potsdam (moved to Zechlin in 1736) produced massive goblets and beakers that were engraved—usually to order for the court—in Berlin, where a water-powered engraving shop had been installed in 1687. Both relief and intaglio engraving were practiced, the latter being favoured. This workshop, indeed, produced perhaps the greatest of the German intaglio engravers, Gottfried Spiller, whose deep cutting on the thick Potsdam glass has seldom, if ever, been surpassed. A notable, if lesser, engraver from the same shop was Heinrich Jäger; and later, in the 1730s and 1740s, work of high quality was done by Elias Rosbach.

Bohemian relief and intaglio engraving

Another workshop of great significance was established toward the end of the 17th century at Kassel, in Hesse. There perhaps the greatest of all the relief engravers, Franz Gondelach, handled glass with a truly sculptural feeling.

In the second half of the 18th century, engraved glass declined in favour, although the technical skill required for its production never died out in the Bohemian–Silesian area. It experienced a great revival in the second quarter of the 19th century, when the taste of the newly prosperous bourgeoisie favoured elaborate decoration. The engraving of this period is often skillful in the extreme, although marred by excessive naturalism. Striking innovations of the period were the use of a casing (normally ruby red, blue or opaque white) through which the design was cut down to the colourless glass. A yellow coating (the silver stain of the stained-glass artist) was often used in the same way. Notable engravers of this epoch were Dominik Bimann, August Böhm, A.H. Pfeiffer, and members of the Pelikan and Simm families.

Second in importance only to engraving as a method of decorating glass in Germany was enamelling. Germany had proved a profitable market for enamelled Venetian glass during the 16th century, and, in the latter part of that century, glass enamelling began to be practiced in the Germanic lands themselves, most notably in Bohemia. This enamelling, in bright opaque colours, was much fa-

German enamelled glass

voured throughout the 17th century, chiefly on the cylindrical drinking glasses, often of great size, known as *Humpen*. The glass they were made of was frequently impure and of a greenish or yellowish cast, while the painting itself was the simplified repetitive work of artisans rather than of original artists. Nevertheless, the gaiety of colour of these glasses and a certain naïveté in their painting give them an authentic unsophisticated charm. The most favoured types of decoration include a representation of the imperial double-headed eagle (*Reichsadlerhumpen*); representations of the emperor with his seven electors, either seated or mounted on horseback (*Kurfürstenhumpen*); subjects from the Old and New Testaments; and allegorical themes such as the Eight Virtues and the Ages of Man. These were painted between borders of multicoloured or white dots or intersecting ellipses, often on a gold ground. This general

style continued into the 18th century; but in the course of that century the levels of artistic and technical competence sank and the tumblers and spirit bottles, which were the main types produced, can be regarded only as objects of peasant art.

The *Schwarzlotmalerei* technique

A far more sophisticated type of enamel painting was carried on during the third quarter of the 17th century at Nürnberg. There, painting in black or sepia (*Schwarzlotmalerei*)—a technique borrowed from the stained-glass artist—was used to decorate the small cylindrical beakers (often resting on three hollow ball feet), which were a locally favoured shape. Other colours, notably red used in touches with the black, were occasionally employed. The greatest and most original artist of this school was Johann Schaper, who painted delicate architectural and landscape compositions in which a fine point was used to etch in details. The best of Schaper's followers were J.L. Faber, Hermann Bencherlt, Johann Keyll, and Abraham Helmhack, but none of them equalled him in artistic competence. Comparable work appears to have been done,

although on a more restricted scale, in the Rhineland, notably by Johann Anton Carli of Andernach. At the beginning of the 18th century *Schwarzlot* painting, often with touches of gold, was practiced in Bohemia and Silesia and reflected the changing fashions in the decorative arts. Daniel Preissler and his son Ignaz are known to have done this work.

In the first half of the 19th century the decorators of vessel glass once again borrowed from the stained-glass artist. Samuel Mohn, his son Gottlob Samuel Mohn, and Anton Kothgasser painted the beakers typical of this "Biedermeier" period in transparent enamels and yellow stain.

The *Zwischengoldgläser* technique

A technique peculiar to Bohemia in the 18th century was that of the "gold sandwich glasses" (*Zwischengoldgläser*). These were beakers or less often goblets made of two layers of glass, exactly fitting one over the other, between which was sandwiched a gold leaf previously etched with a steel point to the desired design. The earliest work in this technique was anonymous, but late in the century J.J. Mildner employed it with notable success, making gift tumblers decorated with medallions of etched gold or silver leaf (often backed with red pigment) and sometimes also engraved on the wheel or with the diamond point.

England. Glass was certainly made in England during the later Middle Ages, but most of it was used for church windows (see STAINED GLASS). The vessel glass of the peri-

od has not been much studied and is only imperfectly understood. Only by the second half of the 16th century does the picture become clearer. Two lines of development may be traced in this period. One is the glass of German waldglas type, made in the woods that supplied the furnaces with fuel and a source of potash. These glasses were made by workers whose traditions were those of Lorraine and northern France. Much of their production was of window glass, but they also made vessels in a modest variety of shapes and modes of decoration. Chief among them was a tumbler-like drinking glass with a low, double foot-rim produced by pushing in the bottom of the bulb from which the glass was made; this might be decorated either by mold-blown diaper (overall repeat) patterns, by swirled ribbing imparted by mold blowing and subsequent twisting, or by a zone of trailed threading below the rim. Applied notched ribbons or small circular motifs also were used. Small bottles of mold-blown hexagonal section or of flattened ovate form with diagonal ribbing also were made. The second line of development was that of the international Venetian style brought by immigrant Italians; this, however, in time acquired an English idiom. The work was done mainly in London.

17th-century English glass

In the 17th century these two traditions were welded into one, spurred by the proclamation of 1615 that forbade the use of wood in glass furnaces, as well as in certain other industries, in an effort to prevent the deforestation of the country. Thereafter, with coal as the sole means of fusing glass, glassworks tended to be located where coal deposits (and the frequently concomitant fire clays for making glass pots) were abundant. Since such areas for the most part were those that have been continuously occupied by industry (*e.g.*, the Stourbridge area and Tyneside), exploration of the early glass factory sites has seldom been practicable. Little, therefore, is known of provincial glassmaking in England in the 17th century, but it is clear that Venetian influences gradually replaced the earlier Waldglas tradition, which had depended on supplies of wood. Some idea of the new style may be gained from the fragments of glasses often excavated in London and other cities. It is frequently difficult to distinguish between an English glass and an imported European one, although a certain coarseness may be taken as symptomatic of English make.

During the first half of the 17th century, glassmaking was among the English industries for which monopoly rights were granted by the crown; the greatest of a series of monopoly holders was Sir Robert Mansell, who effectively controlled the industry from 1623 until his death in 1656. After the Restoration, although some monopolies were granted for certain categories of glasswares, an increasingly important role in the English industry was played by the Worshipful Company of Glass Sellers (reincorporated in 1664), which was able to keep closely in touch with the needs of the English market. Its members seem to have laid stress on simplicity of shape and durability of material, as appears from the correspondence of one of them, John Greene, with his suppliers in Venice. Dissatisfied with the quality of glass supplied to them and no doubt also anxious to make England independent of foreign sources of both finished glass and raw materials, they commissioned George Ravenscroft to make experiments with native materials in the hope of evolving a more solid glass than the Venetian and one that more closely resembled rock crystal.

Discovery of lead glass

Ravenscroft was completely successful; his crucial discovery was the value of adding lead oxide. His "glass of lead," evolved about 1675, was perfected toward the end of the century and set a standard for the rest of Europe. It was solid and heavy and more durable than the Venetian-type glass, which it progressively displaced. It was also characterized by brilliance and dark shadow paradoxically combined. It was slower to work than the Venetian glass and gradually the Venetian idioms were dropped from English glassmaking in favour of a genuine native style. This style is best exhibited in the drinking glasses that, by the end of the 17th century and the beginning of the 18th, constituted the chief glory of the English industry. These often massive baluster-stem glasses were composed of a usually funnel-shaped bowl and a stem compiled of any of a large variety of pear-shaped and bulbous knops (ornamental knobs). In their simplicity and the harmony of their proportions they rank among the classics of the Queen Anne style.

Toward the middle of the 18th century, taste in the arts generally inclined to lighter forms, and in glass this tendency was given additional impetus by an excise (1745–46) levied on glass by weight. Drinking glasses became slighter, the bowls smaller, and the stems taller and more slender. The loss in architectonic values was often offset by extraneous decoration. At first this tended to be concentrated in the stem. Bubbles of air had sometimes previously been enclosed in a knop forming part of the stem of a wineglass, and these bubbles were now drawn out and twisted so that they formed a cable of air ribbons inside a cylindrical stem. Stems of this type were popular about the middle of the century. Just before 1750 a stem decorated with threads of opaque white glass instead of air twists came into favour. These stems were made by much the same techniques as the Venetian latticinio glass. They remained in fashion until about the time of the second Glass Excise Act in 1777, which imposed a tax on the opaque white "enamel" glass, previously exempt.

These forms of ornament had been restricted to the stems of glasses, but other methods of decoration were simultaneously evolved to embellish the whole glass.

Development of engraving and enamelling in England

First of these was engraving, which had been sporadically practiced in England as early as the end of the 17th century. This work and the inscriptions, coats of arms, and arabesque borders in German style that were engraved during the first 20 years or so of the 18th century were undoubtedly the work of immigrant (probably German) artisans. By 1735, however, at least one English engraver was capable of executing such commissions and from about this time engraving on glass began to take on a more English character. An artless use of floral motifs, chinoiseries (Chinese themes), and scenes from country life is typical of the engraving of the third quarter of the 18th century, as were the frequent representations on glasses of Jacobite themes—portraits of the Old and Young Pretenders (James III and Charles Edward), the rose with buds, the honeysuckle, and the other flowers used in the symbology of the Stuart cause, together with the mottoes of such "loyal" societies as the Cycle Club.

Engraving never reached great heights in England, but English glasses were in demand by engravers in Europe, particularly in the Netherlands, where the work of at least one notable artist—Jacob Sang, of Amsterdam—was almost exclusively done on imported English drinking glasses. English lead glass also seems to have been

particularly favoured by the Dutch diamond-point engravers, whose work in this period was executed almost exclusively in stipple (*i.e.*, dotted engraving). The chief masters of this delicate art, in which the design seems no more than a bloom on the surface of the glass, were Frans Greenwood of Dordrecht, the originator of the style, and David Wolff of The Hague, whose work, if uninspired, is of high technical accomplishment.

Enamelling, the second decorative technique of foreign inspiration, began to be used on English glass in the mid-18th century. It embellished opaque white glass in imitation of china—a type of work usually associated with the name of Michael Edkins, a Bristol artist, but in fact done in many parts of the country. Perhaps the most original work in this medium was done on clear glass by members of the Beilby family of Newcastle upon Tyne during the 1760s and 1770s. Their rendering in usually blue-toned white enamel of ruins, trophies of arms, and rural pastimes, often framed in scrollwork of the utmost delicacy, is one of the best things in English Rococo glass. Gilding was also used at this time to decorate glasses, usually with simple designs of vines and grapes.

These ornamental techniques, however, were of ephemeral growth in England. Far more significant than any of them, because more firmly rooted in the very nature of English glass, was the art of cutting. Although literary references to cut glass occur before 1720, the earliest known pieces can hardly be dated much before 1725. On them the cutting is mainly confined to brims and feet, which are scalloped or notched; or, on wineglasses, to the thicker parts of the glass, such as the stem, which might be fluted or cut in an allover pattern of flat diamonds. Throughout the period from about 1745 to 1770, shallow cutting was the norm. Diamonds, hexagons, flutes, and scale pattern were combined with segmental lunate cuts (produced by holding the glass at an angle to the cutting wheel) and with triangular and diamond motifs in very low relief. All of these elements could be combined to produce designs of great complexity and richness. This period marked the golden age of English cutting.

Importance of cutting as a decorative technique

About 1770 a plainer style, employing mainly flutes, responded to the rising Neoclassical fashion in the other arts. The flutes were sometimes combined with diamonds in relief. When further taxes were imposed on glass in 1777 and 1781 and when in 1780 trade between England and Ireland was freed, it was this relief-diamond style that was taken up in Ireland by the glasshouses founded there. The Irish glassworkers could afford to be more lavish with their material and on this thicker glass increasingly deeply cut diamonds and other relief motifs could be produced. About the turn of the century the diamonds began to be reduced in size and to be incorporated into a diaper pattern covering whole areas, often alternating with fields of larger truncated diamonds, the surfaces of which were themselves diversified with cut crosshatching. Such designs were often combined with deeply cut horizontal grooves. These styles, which were subsequently followed in England as well as in Ireland, finally led to a complete breaking up of the face of the glass into points and ridges, with increased prismatic effect but with a disastrous loss of surface quality, which is one of the peculiar beauties of glass. The prismatic brilliance was enhanced by the progressively greater purity and whiteness of the glass made during the second quarter of the 19th century. The temptation to cut ever more deeply and with greater complexity finally seduced the glassmakers into producing the "prickly monstrosities" of the Great Exhibition of 1851.

Throughout the 18th century there had been great admiration in Europe for English lead "crystal," and in the second half of it some of the European glasshouses were using lead oxide and had contrived to produce a comparable material. English cut glass was admired and exported, and the styles of cutting of the late 18th and early 19th centuries were much imitated abroad.

(R.J.Ch.)

United States. Glassmaking was apparently the first industry to be transplanted from Europe in the wake of the Spanish conquerors. As early as 1535 glass was being made at Puebla in Mexico, and in 1592 a glasshouse was located in the territory of the Río de la Plata in the town of Córdoba del Tucumán, Argentina. Broken glass, undoubtedly of European origin, was remelted at Córdoba and fashioned into various objects including thick, semi-transparent flat glass.

The London Company of Virginia set up a glasshouse in Jamestown in 1608 for the manufacture of "glasses" and beads. A "tryal of glasse" was sent off to England before the winter of 1609, the "starving time" during which 440 of the colony's 500 inhabitants died. In 1621 the company tried again and, although the second attempt was more carefully planned, it too failed. Excavation of the site has revealed that glass was melted in considerable quantities though no evidence of glass bead manufacture has been found.

South Jersey-type glass. For more than a century after Jamestown, there was little American glass. The earliest successful glasshouse was begun in 1739 by Caspar Wistar in Salem County, New Jersey. The fact that his works produced only humble utilitarian vessels and windowpanes saved him from extermination by the "lords of trade." Wistar died in 1752, after which the factory was operated by his son Richard. It was offered for sale in 1780. Although few, if any, objects exist that can be assigned to the Wistar Glass Works with certainty, it is important as the cradle of the American glass known today as South Jersey type. That glass is the work of individual glassblowers using ordinary bottle or window glass to make objects of their own design. Applied glass and, occasionally, pattern molding were the only feasible means of decoration, and the resultant loopings and threadings are typical of European traditions. One decorative device, the lily pad, is of particular importance, as no European prototype is known. A hot mass of glass applied to the base of the bowl is pulled up around the sides in a series of projections in which the bowl appears to rest.

Wistar's glasshouse

The second great name in early American glass is Henry William Stiegel. In 1763, 13 years after his arrival in America and after several years in the iron business, he built his first glasshouse in Lancaster County, Pennsylvania. Like Caspar Wistar, Stiegel at first was concerned with the manufacture of bottles and windowpanes. With the founding of his second house at Manheim, Pennsyl-

Stiegel glass

vania, in 1765, however, he ventured into the table-glass business. No longer beneath the notice of the "lords of trade," he reported to them in 1767 that the glass he made was both inconsiderable in quantity and ordinary in quality.

This report is in sharp contrast to the many advertisements in which he favourably compares his wares with English imports. Encouraged by the patriotic adoption of the non-importation agreement, Stiegel built a third glasshouse, the American Flint Glass Works, also located at Manheim and completed in 1769. Adverse economic conditions, caused by both the approaching war and the colonial preference for imported tablewares, brought final failure in 1774.

Few pieces can be attributed with confidence to the Stiegel factories, and, like that of Wistar, his name survives as the founder of a tradition. Stiegel-type glass is characterized by the use of clear and artificially coloured glasses; by extrinsic decoration such as engraving, enamelling, and pattern molding; and, in general, by two distinct styles, one employing English and the other German techniques and decorative devices. Certain mold-blown patterns, such as the diamond daisy and daisy in hexagon, are believed to have been originated at the Stiegel houses, no European prototypes having been identified.

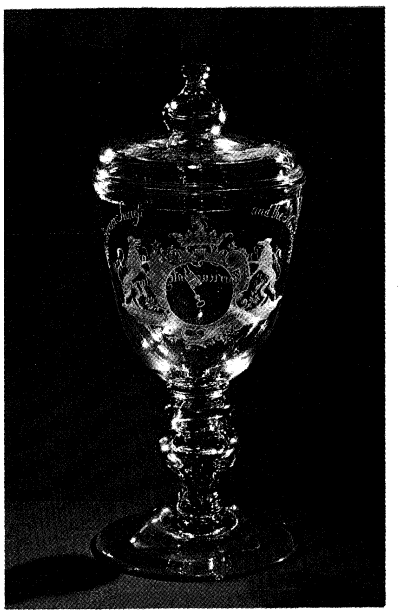
Post-Revolutionary glassworks. Before the turn of the century, several other glassworks were founded, but few survived the Revolution. These houses were devoted largely to the manufacture of bottles and window glasses and, with the notable exception of the New Bremen Glassmanufactory, most of the offhand (*i.e.*, shaped by hand) pieces that can be tentatively assigned to them are of the South Jersey tradition. Three of these enterprises are of particular importance. First, the New Bremen (Maryland) Glassmanufactory, founded by John Frederick Amelung and Company, is of special interest as many of its presentation pieces are both signed and dated as well as being among the finest produced in the United States before 1800. Originally from Bremen, Germany, Amelung was persuaded to go to America for the express purpose of founding what he believed to be a much-needed industry. By 1785 his works offered green and white hollow ware for sale; by 1795 the glassworks themselves were offered for sale. One of the most famous pieces in the history of American glass is the Bremen pokal (the German word for goblet), blown and engraved in 1788 and sent back to Amelung's financiers in Bremen (now in the Metropolitan Museum of Art, New York City), probably the only return they ever received on their investment.

The second factory of importance, later known as the



Bremen pokal, presentation piece engraved at the Amelung works near Frederick, Maryland; inscribed "Old Bremen Success and the New Progress and New Bremen Glassmanufactory—1788—North America, State of Maryland." In the Metropolitan Museum of Art, New York. Height with cover 28.6 cm.

Olive Glass Works, Gloucester County, New Jersey, was completed in 1781 by former employees of the Wistar Glass Works, the Stanger brothers. In addition to the many fine South Jersey pieces attributed to this house, it is of interest because of its long history, eventually becoming part of the Owens Bottle Company, a forerunner of the Libbey-Owens-Ford Glass Company.

The Pitkin glassworks

The third notable venture begun before 1800 is the well-known works associated with the name Pitkin. Erected at East Hartford, Connecticut, near the Connecticut River in 1783, it was intended for the manufacture of window glass, but in 1788 it was converted to the manufacture of bottles and flasks. The factory thrived until 1830 and is best known for the half-post (*i.e.*, dipped twice up to the neck) ribbed flasks in natural browns, ambers, and greens. Today the word Pitkin denotes a type of flask and not a specific glassworks.

After the War of 1812. The few houses that survived the 1790s and the depression after the War of 1812 had multiplied to more than 90 by 1830. For convenience, the glassworks are divided into three geographical groups: New England, the Middle Atlantic, and the Midwest. Until that time, they had produced little more than simple imitations of European glasses, at best interesting and often very handsome combinations of various decorative devices and traditions. The big change occurred between 1830 and 1840 with the production of fine lead glass, the use of the full-size incised mold, and, finally, the pressing machine.

Bakewell's fine glass

The glasshouse known as Bakewell's was synonymous with the finest achievements of the revived industry. Originally established in 1808 in Pittsburgh, the first city to use coal for fuel in glassmaking, the company survived under several different firms until 1882. Glass cutting, introduced to Pittsburgh by William Peter Eichbaum, glass cutter to Louis XVI, was an important part of Bakewell's operation. In addition to being the first American company to supply the White House, serving President James Monroe in 1817, Bakewell's produced such specialties as lead-glass tumblers with "sulphides" (cameo insertions of white fireproof material in an envelope of glass) in the bases portraying the Marquis de Lafayette, Andrew Jackson, New York governor George Clinton, Benjamin Franklin, and George Washington.

The company also held the first patent on mechanical pressing, granted in 1825 for a device to make knobs.

Fine lead glass in the New England area was first successfully made in the South Boston works of the Boston Crown Glass Company. Thomas Cains was making flint glass there in 1813. He left the firm in 1824 to found the Phoenix Glass Works in South Boston, which survived until 1870. One particular device usually associated with the Boston manufactories of this period is the guilloche, or chain, employed in the decoration of a large variety of tableware.

The New England Glass Company, founded in 1818 in Cambridge, Massachusetts, maintained the same high standards as Bakewell's, even to the point of making glass for President Monroe. This factory held the second patent on a device for mechanical pressing, granted in 1826, and produced quantities of pressed glass of all types before it was moved to Toledo, Ohio, in 1888. The New England Glass Company was also famous for its very fine free-blown and engraved glass. In addition, vessels were made there in the so-called blown three-mold technique, in which decorative designs adapted from cut-glass patterns of the period were impressed in the glass by blowing in molds hinged in two, three, or more sections. More than 400 different molds have been determined and grouped according to pattern under three primary headings: geometric, arch, and baroque. By 1830 this type of production was being replaced by the much more efficient pressing machine.

The three-mold technique

Deming Jarves, one of the founders of the New England Glass Company, founded the Boston and Sandwich Glass Company in 1825. Because of his *Reminiscences of Glassmaking*, extensive advertisements, and thorough excavations of the factory site in Sandwich, Massachusetts, more is known about this particular factory than any other of the period. Consequently, "Sandwich" has become a generic term for pressed glass even though many other factories used identical machinery and, in some cases, identical molds. Jarves's first patent on a pressing device, the fifth to be granted, was received in 1828 after the Boston mold maker Hiram Dillaway entered his employ. Jarves founded the Mount Washington Glass Works in 1837 in New Bedford, Massachusetts, and the Cape Cod Glass Works in 1857.

Among the outstanding makers of fine lead glass in the middle Atlantic states were the Brooklyn Flint Glass Works of John L. Gilliland and Company and the Dorflinger Glass Works. Gilliland, a partner in the Bloomingdale Flint Glass Works, sold out in 1823 and founded his own works in Brooklyn, New York. In 1864 two members of the Houghton family acquired controlling interest, and in 1868 the works was moved by barge to Corning, New York, to form part of the now famous Corning Glass Works.

Historical flasks. Perhaps the most fascinating aspect of American glass is a series of pictorially molded bottles known as historical flasks, produced between 1815 and 1870. Three hundred ninety-eight different examples have been divided into the following groups: (1) Masonic; (2) emblems and designs related to economic life; (3) portraits of national heroes and designs associated with them and their deeds; and (4) portraits of presidential candidates, emblems and slogans of political campaigns. In the second group are a number of interesting designs encouraging the United States system of better internal transportation and high protective tariffs. Among the 16 celebrities portrayed in the third and fourth groups are Jenny Lind, the Swedish singer; Lajos Kossuth, the Hungarian patriot; Marquis de Lafayette, the French hero of the American Revolution; and the notorious Thomas W. Dyott, a patent-medicine vendor and bottle manufacturer. These containers were used also as propaganda during political campaigns. William Henry Harrison is pictured in this connection with other impedimenta relative to the "Log Cabin and Hard Cider" campaign of 1840.

The first 25 years of pressed glass, 1825 to 1850, are referred to by collectors as the "lacy period." A milestone within this brief span occurred in 1830 with the development of the cap ring, a device that ensured uniform thickness at the edge of each piece regardless of the amount of glass forced into the mold. Before this date most impressed designs were inspired by Anglo-Irish cut glass, often coupled with popular American devices such as a sheaf of wheat. Between 1830 and 1840 the objects were thinner and more lavishly decorated, often including elaborate motifs based on the classic and Gothic revivals. Because of the unpleasant surface left by the mold and in an effort to imitate the brilliance of cut glass, unstippled areas were filled in with overall lacelike patterns; hence the term "lacy." About 1840 economic conditions forced glassmakers to revert to cheaper molds and simpler geometric forms and to abandon the stippled patterns.

The "lacy period" of pressed glass

"Portrait of Kossuth" flask, Bridgeton, New Jersey, 1840–55. In the Corning Museum of Glass, New York. Height 17.5 cm.

During this period the mechanical press became firmly established, and by mid-century glassmaking had become one of the United States' new mass-production industries.

(T.S.Bu.)

MID-19TH TO 20TH CENTURY

The modern history of glass can be said to begin in the middle of the 19th century with the great exhibitions and with the new self-consciousness in the decorative arts that they expressed. Glassware was being publicly discussed in art journals and collected in museums, and this new spirit of awareness led to a greatly increased exchange of ideas among the leading glass centres and to the borrowing of ideas from the past.

In some degree the established glass-producing centres were still concerned in the modern period with the styles of glassware for which they had achieved an earlier reputation. The English glasshouses continued their production of deeply cut crystal; engraved glass and to a lesser extent coloured and painted glass were given the greatest attention in central Europe; the Venetian glasshouses at Murano were the leading exponents of furnace-manipulated glass. But alongside these traditional methods of using and decorating glassware can be discerned the development of a renewed interest in the beauty of the material itself. Expressed in various ways, in the use of thick masses and in internal figuring and patterning, this interest has been the keynote of the most significant modern contributions to the art of glass.

Pressed glassware, which had been first made with great promise in the first half of the 19th century, was being widely made in the middle of the century, and later, as a cheap imitation of cut crystal. The decorative possibilities of the process continued, however, to be exploited in a variety of popular wares; and in the 20th century a series of new simple forms of pressed glassware appeared that had been expressly designed in relation to the characteristics of its manufacture.

Great Britain. The Great Exhibition of 1851 was the culmination of a period of intense activity in the British

glasshouses. The excise duty on glass had been removed in 1845, and the British glassmakers were determined not only to excel in their traditional deeply cut crystal but also to rival the Bohemians and the French in coloured, layered, and enamel-painted wares. Probably the most enterprising of the English glassmakers of the period was Benjamin Richardson, of Wordsley near Stourbridge; surviving pieces of this period from the Richardson firm include some admirable painted and engraved pieces as well as crystal wares deeply cut in elaborate patterns.

Probably in reaction against the banality of pressed-glass imitations of cutting, the most sophisticated work in crystal during the later 1850s through the 1870s was decorated by engraving, often carried out by immigrant Bohemian craftsmen.

The Venetian style of furnace-manipulated glass was also exerting a strong influence. It can be seen, for instance, in the development of the elaborate Victorian centrepieces in the 1860s and 1870s. In some degree the Venetian style was also an influence, alongside that of the Far East, in the fashioning of the fancy wares that were made in Great Britain—as it was in the United States and elsewhere—during the 1880s and 1890s. These wares were often given specific trade names and were mostly made in the English Midlands by firms such as Thomas Webb & Sons of Stourbridge and John Walsh Walsh of Birmingham.

A striking form of mid-Victorian virtuosity was the cameo glass produced by Stourbridge glassworkers. This work, inspired by the Portland vase, required a lengthy process of etching and carving, normally through an opaque-white-glass layer to leave a white carved design in relief on a dark-coloured glass body. The first important pieces, such as the "Pegasus vase" (Smithsonian Institution, Washington, D.C.), were produced in the 1870s by John Northwood, and in the later part of the century the most distinguished cameo work was carried out by George Woodall.

The "Pegasus vase," carved in cameo relief by John Northwood of Stourbridge, England. In the Smithsonian Institution, Washington, D.C. Height 54.6 cm.

The influence of the Arts and Crafts Movement was toward the use of plastic forms and furnace decoration, which the English art critic John Ruskin had advocated in *The Stones of Venice*. In 1859 Philip Webb designed for William Morris some simply formed tableware that was made at the London glassworks of James Powell & Sons. From about 1880 this glassworks was under the control of Harry J. Powell who, working until World War I, developed a simple, dignified style of handmade blown glass, which was subsequently continued in designs by Barnaby Powell, James Hogan, and others.

Influence of the Arts and Crafts Movement

During the 1930s and after World War II other firms produced work in which a restrained and distinctively modern approach was made to the cutting of faultless crystal glass. Notable designs were produced by Keith Murray for Stevens & Williams shortly before World War II and by David Queensberry (12th marquess of Queensberry) for Webb Corbett in the 1960s. Among the more distinguished glass engraving may be mentioned the diamond-point fantasies of Laurence Whistler and the work of John Hutton, made by a movable wheel held in the hand, such as his great screen in the new Coventry Cathedral. The appearance of new factories in the 1960s, concerned primarily with form and colour, widened the scope of British glass design; and at this time the glass-teaching schools were especially significant as centres for original work by individual artists.

United States. By the middle of the 19th century, American pressed glass was already a disturbing influence on the design of the finer wares. Its decoration was by that time mostly designed in imitation of cut glass, and the process of fire polishing was being used to give a surface almost as smooth as that of blown glass. During the succeeding decades pressed-glass designs became increasingly complicated. This tendency was accentuated in the soda-lime glass that William Leighton began to use for pressed work at Wheeling, West Virginia, in the 1860s, and that was later widely used in the western glasshouses for the cheapest coloured wares.

Importance of pressed glass

In general the finer wares of the early part of the period were similar to those of the Biedermeier and later styles of Europe. The New England Glass Company at Cambridge, Massachusetts, was employing many European craftsmen and was producing a wide variety of richly decorated layered and engraved wares. At the Boston and Sandwich Glass Company layered glass was extensively used for large kerosene lamps. The effect of the competition of pressed glass on cut-crystal work can be seen in the appearance of fine-line cuttings, and, during the period up to the Philadelphia Centennial Exposition of 1876, the most significant crystal work was decorated by engraving. Louis Vaupel and Henry S. Fillebrown were two notable engravers employed by the New England Glass Company from 1856 and 1860, respectively.

At the time of the Centennial Exposition, cut-crystal work began to revive, and by 1880 a considerable boom in its production had developed—a boom that was to continue throughout the 1880s and 1890s. New industrial methods contributed to the production of crystal glass of flawless quality and to its deep cutting with mathematical accuracy in elaborate designs. Among many others, a noteworthy producer of this type of glass in the 1890s and later was the Libbey Glass Company, the successor to the New England Glass Company. Later, in the early years of the 20th century, intaglio cutting in crystal became popular, and work in this expensive process was carried out in a number of cut-glass factories such as the T.G. Hawkes Glass Company at Corning, New York.

As in Great Britain and elsewhere, a great amount of glass was made in fancy forms and colours in the 1880s and 1890s. Although undisciplined and often tasteless, such glass nevertheless preserves perhaps more than any other the flavour of the period. These wares, often bearing specific names such as Pomona, Burmese, and Peachblow, were made by such firms as the New England Glass Company, the Mount Washington Glass Company at New Bedford, and the Hobbs, Brockunier Company at Wheeling, West Virginia.

Although belonging essentially to the category of the

fancy glasses, the Favrile glass of Louis Comfort Tiffany represented an altogether higher level of achievement both in its shapes and in the colouring and figuring of the glass. It was first shown to the public in 1893, and in pieces that were produced a few years later Tiffany achieved an outstanding expression in glassware of the Art Nouveau style. Much of his work was in a heavily lustred glass that was considerably admired abroad, especially in central Europe where it created a new fashion.

Tiffany's Favrile glass

From the period of World War I onward, new forms of pressed glassware appeared in simple, satisfying designs appropriate to their purpose and the process of manufacture, such as the Pyrex ovenware shapes of the Corning Glass Works. The Steuben Glass Company of Corning was known for fancy glasses designed by Frederick Carder, until in 1933 the company was given a change of direction by Arthur Amory Houghton, Jr., who, with the help of John Monteith Gates and the sculptor and designer Sidney Waugh, aimed to produce glass with engraved decoration that would rank as fine art. Other noteworthy modern American work included simple designs in blown glass by the Blenko Glass Company of Milton, West Virginia, and enamel patterned bowls by the independent artist Maurice Heaton. The appearance in the United States of studio blown glass, produced by individual artists, was a development of international significance. It was initiated in the 1960s notably by Harvey Littleton and Dominick Labino and included work such as that produced personally by Joel P. Myers at the Blenko Glass Company.

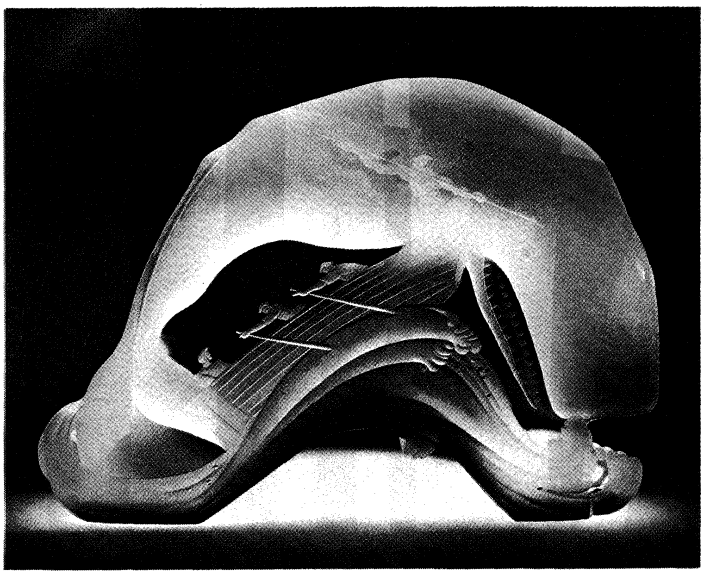
Czechoslovakia, Austria, and Germany. In the middle of the 19th century the glasshouses of central Europe were producing a great variety of the layered and coloured wares that had become particularly associated with Bohemia in the preceding Biedermeier period. They were also producing a great amount of cut crystal glass in the deeply cut English style, and indeed work of this nature continued with little change throughout the modern period.

Revival of engraving

A revival of the indigenous art of engraving was initiated by Ludwig Lobmeyr, who from 1864 was in control of the Viennese firm of J. and L. Lobmeyr. His first opportunity came at the Paris International Exhibition of 1867, and his reputation was firmly established at the Vienna International Exhibition of 1873. He commissioned designs for his glasses from the leading Viennese architects and painters of the time, and his work was carried out by the finest craftsmen in Bohemia and Austria.



"Moby Dick," Steuben crystal sculpture designed by Donald Pollard and Sidney Waugh, first piece made in 1959. Length 28.6 cm.

The Art Nouveau style, which went under the name of Jugendstil in central Europe, made a deep impression on central European glassware. The work made around the turn of the century abounds in slender shapes and flowing organic motifs. Glasses designed by Karl Köpping in Berlin, with long, waving stems and tulip-like bowls, were perhaps the extreme instance of Art Nouveau style applied to glassware. In 1897 an exhibition of glass by Tiffany was shown at several of the museums in the area. Not only the forms of the Tiffany glasses but also their figured and heavily lustred material attracted great interest. Several factories started making a similar heavily lustred glass, including the firm of J. Lötz' Witwe of Klášterský Mlýn (Klostermühle), which won a *grand*

prix at the Paris Exhibition of 1900 with this type of glassware.

From around 1900 onward a movement toward a modern purist approach to glass was largely fostered by the work of designers connected with the Vienna Kunstgewerbeschule (School of Industrial Art). Men such as Kolo Moser and Josef Hoffmann, who were also closely associated with the Vienna Werkstätte (Workshop), were designing glasses in simple rational forms. Much initiative in this movement was shown by the firms of E. Bakalowits Söhne of Vienna and J. Lötz' Witwe. The Czech architect Jan Kotěra was influential in the modern design of glass, and in the early years of World War I the Czech Artěl organization of artists and architects was concerned with the design of glass in a forward-looking Cubist manner.

Post-World War I glass

After World War I the outstanding figure in Czech glass art was Josef Drahoňovský, who was professor at the Prague School of Industrial Art. He was essentially a sculptor, and most of his glass designs were for sumptuously engraved glass of a monumental quality. His colleague in Prague, Jaroslav Horejc, designed for engraved work of a broadly similar character, some of it for the Lobmeyr firm of Vienna. The decades after World War II saw considerable activity in glass design. Notable artists in the 1960s were Stanislav Libenský, René Roubíček, Pavel Hlava, and Václav Cígler.

In Austria after World War I the Lobmeyr firm under the control of Stefan Rath produced many engraved and relief-carved pieces designed by artists such as Ena Rottenberg, Lotte Fink, and Vally Wieselthier. Lobmeyr also produced some of the best designs of Michael Powolny, who had his own workshop and had designed for the firm of J. Lötz' Witwe.

In Germany the outstanding engraver and glass carver of the period after World War I was Wilhelm von Eiff, who was professor at the Stuttgart Kunstgewerbeschule, while Bruno Mauder of the glass-teaching school at Zwiesel in Bavaria was a strong influence for the use of natural and appropriate glass forms. Some fine tablewares were produced, especially after mid-century, by designers such as Wilhelm Wagenfeld, Richard Süssmuth and Heinrich Löffelhardt. An interesting development was that of the Rosenthal firm, which used the Finnish designer Tapio Wirkkala and the Dane Bjørn Wiinblad to effect in each case matching glass and porcelain suites of the firm's own manufacture.

France. In France, as in central Europe and in England, the production of fine glassware in the middle of the 19th century was mainly divided between cut crystal and coloured wares. The "opalines," the semi-opaque white and coloured wares, often with elaborately painted and gilt decoration, were especially popular; and it was during these years that the French paperweights, containing coloured patterns, became internationally known and admired. The larger factories, particularly Baccarat and Saint-Louis, continued to participate in the international fashions of the rest of the century and beyond. But in France inventive genius manifested itself mainly in the work of individual artists and thereby a new spirit was introduced into the modern conception of glass.

In the late 1860s and 1870s three individual artists were experimenting in glasswork, and all of them were represented in the International Exhibition of 1878 in Paris. The first was Joseph Brocard, who was studying the enamelling of glass and whose main ambition was to reproduce medieval Syrian glass. The second was Eugène Rousseau, a commissioning dealer in ceramics who had turned to glasswork at the end of the 1860s and was at the height of his achievement in the years *c.* 1880. Typically his glasses were thick walled and translucid, often with interior crackling and shot with random streaks of colour. In 1885 he associated with E. Léveillé, who continued to work in a similar style after Rousseau's death in 1891. The third of the individual artists at the

Gallé glass

1878 exhibition and the best known of them was Émile Gallé of Nancy, who had been experimenting in glasswork since about 1867. His earliest work was in clear glass, lightly tinted and decorated with enamel and engraving. But he soon developed the use of deeply coloured, almost opaque glasses in heavy masses, often layered in several thicknesses and carved or etched to form plant motifs. His work reflected the prevailing interest in Japanese art and with its frequently asymmetrical form contributed largely to the Art Nouveau of the end of the century. In this period much of Gallé's manner was reflected in the glassware produced on a more commercial basis by the firm of Daum Frères of Nancy.

A number of French artists successfully explored the use of *pâte de verre* (powdered glass fired in a mold). The pioneer in its use was Henri Cros, who was working near the end of the 19th century. It was later the medium for important work by Albert Dammouse and François Décorchemont.

Among the later leaders of French glass art was René Lalique, who around the 1920s was producing his most typical work, which is characterized by relief decoration produced by blowing into molds or by pressing. He was a leading advocate of the use of glass in architecture and much of his work was in the form of lighting equipment and in details of interior decoration. The work of his contemporary, Maurice Marinot, was more in the tradition of Rousseau, with heavy, thick-walled vessels in strong forms often with boldly cut-away abstract decoration; and Henri Navarre in the 1930s was producing work of a similar monumental nature.

The most significant work of Jean Luce and Marcel Goupy, designers of glass and ceramics, was in the production of elegant tablewares. For a long period André Thuret made glasses in thick plastic forms; and Jean Sala worked in bubbled glass. The firm of Daum was distinguished, after World War II, by its thick clear glass vessels manipulated into flowing shapes to designs by Michel Daum.

The Scandinavian countries. Up to the time of World War I the Swedish glass industry produced little original work. The sudden development of modern Swedish glass in the 1920s was attributable mainly to the initiative of the Swedish Arts and Crafts Society that resulted in the employment of the painters Simon Gate and Edward Hald by Orrefors glassworks and Edvin Ollers by Kosta glassworks, both in the glass-producing area of Småland in southern Sweden. The first results were exhibited in Stockholm in 1917 and consisted of handblown, undecorated tablewares, together with the luxury "Graal" glass with internal stained decoration, which had been rapidly developed under Gate's inspiration at Orrefors. It was, however, engraved glasswork, chiefly that designed by Gate and Hald at Orrefors, on which the reputation of Swedish glass was established in the 1920s and particularly at the Paris International Exhibition of Decorative Arts in 1925.

Development of modern Swedish glass

In the 1930s came a change of direction. The Swedish factories began to take less interest in engraving and followed the initiative of the French artists in making thick tinted and figured glasses. In this mode they found their greatest success—attributed largely to their having achieved a system of intimate association between the artists and the glassmaker craftsmen.

At Orrefors additional artists were added to the establishment from 1929 onward, including Vicke Lindstrand, Sven Palmqvist, Nils Landberg, Edvin Öhrström, John Selbing, and Ingeborg Lundin. Each of them worked in an individual style, and in addition to decorative pieces many of them designed tablewares for the subsidiary Sandvik factory. At Kosta important work was produced by Elis Bergh and later by Lindstrand. Gerda Strömberg designed for both Eda glassworks and for Strömbergshyttan. In the 1960s many new methods of forming and decorating glass were explored by young designers; and an element of the current Pop art was discernible, such as in the work of Gunnar Cyrén at Orrefors.

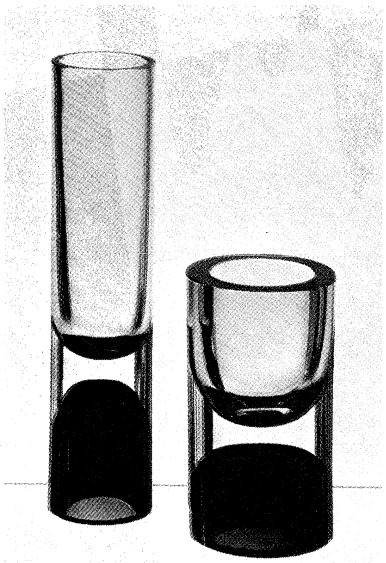
In Denmark the Holmegaard glassworks and in Norway the Hadeland glassworks both followed in some respects the example of Swedish glass. At Holmegaard the movement began in the late 1920s with the appointment as art director of Jacob E. Bang, whose designs included an amount of striking engraved work, and was continued in

the clean forms of his successor, Per Lütken. At Hadeland some distinctive glass was designed by a number of artists including Sverre Pettersen, Willy Johansson, and Arne Jon Jutrem.

Modern Finnish design

In Finland original modern work of great significance has been carried out. Following the example of the Swedish factories, the artist Henry Ericsson was appointed designer at the Riihimäki glassworks in the late 1920s, and Göran Hongell was employed in a similar capacity at the Karhula glassworks in the 1930s. At this time the well-known Finnish artists Arttu Brummer and Alvar Aalto were also concerned in glass design. Shortly after World War I the influential designer Gunnel Nyman

By courtesy of Die Neue Sammlung, Munich



Double-cased glass vases designed by Timo Sarpaneva, Iittala glassworks, Finland, 1957. In Die Neue Sammlung, Munich. Height (left) 30 cm., (right) 17.5 cm.

was producing glasses freely blown in thick masses to form asymmetrical shapes. Other important designers were Tapio Wirkkala and Timo Sarpaneva working for the Iittala glassworks, Kaj Franck for the Nnutajärvi glassworks (trading as Wärtsilä-Notsjö), and Helena Tynell and Nanny Still for Riihimäki. In the 1960s Timo Sarpaneva struck a new note with his sculptures formed from the charred inner surface of wooden molds, while Oiva Toikka designed for Wärtsilä-Notsjö objects of a markedly Pop art nature.

Belgium and The Netherlands. In Belgium the Val-Saint-Lambert factory was an important producer of heavily cut crystal throughout the period. It is also associated with layered work and was particularly prominent with original work of this nature around 1900. Later Charles Graffart designed for it wares made in a variety of techniques, some of them with engraved decoration.

The Dutch glassworks at Leerdam played an important part in the modern movement and followed a line of development distinct from that of the Scandinavian factories. In 1915 the decision was made to invite designs from artists, and by the early 1920s excellent simple tablewares were being made to designs by the architects K.P.C. de Bazel and H.P. Berlage and by the decorative artist C. de Lorm. From the early 1920s onward individually designed pieces called Unica were made; some of the earlier examples were by Chris Lebeau, but most were produced by Andries D. Copier. Later decorative work included designs by Floris Meydam and Willem Heesen.

Variations of traditional Venetian glass

Italy. By the middle of the 19th century, Italian glassmaking had partly revived. In the 1860s the Museo Vetrario was founded at Murano (Venice), and Antonio Salviati began to produce the glasses that attracted much attention at the Paris Exhibition of 1867. These were variations of the traditional Venetian style with elaborate furnace decoration, and the production of glasses of this nature continued at Murano throughout the remainder of the 19th century and beyond.

The 1920s saw the development of a more conscious spirit of artistry in Italian glasswork. Paolo Venini was concerned in producing simple elegant glasses designed by the decorative artist Vittorio Zecchin, and G. Balsamo Stella and his Swedish wife Anna were producing engraved work. In later years, both before and after World War II, much research was done in new methods of colouring and figuring glass; the results were seen in the glasses designed by Ercole Barovier for the firm of Barovier & Toso and in those designed by Giulio Radi for the firm Arte Vetraria Muranese.

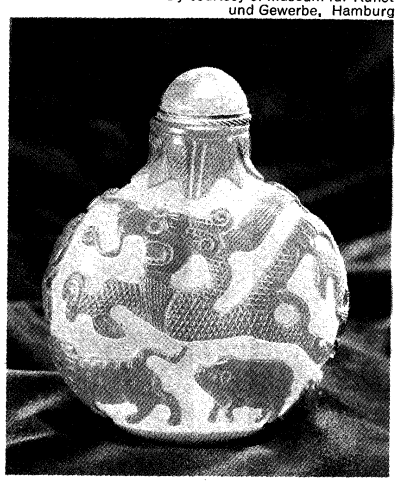
From the Venini firm, presided over by Paolo Venini until his death in 1959, came many interesting innovations, such as the colourful glasses designed by Carlo Scarpa and by Fulvio Bianconi and an interesting series by the Finn Tapio Wirkkala. For the firm of Vistosi some striking modern glasses were designed by artists such as Peter Pelzel and Alessandro Pianon. Some of the work, such as a series of vases designed by Flavio Poli for Seguso Vetri d'Arte, showed some influence from the thick-glass techniques of the north, but the modern Italian glass mostly retained a distinctly Venetian, volatile character. An experiment of interest was the production of a series of glass sculptures from sketches and models commissioned by the dealer Egidio Constantini from internationally prominent painters and other artists.

(Hu.Wa.)

CHINESE GLASS

Glass has never been truly at home in China. Records suggest that it was brought there from the West as early as the 3rd century, but finds of small glass objects of typical Chinese shapes dating from as early as the Han dynasty (206 BC–AD 220) suggest that, even if the material was brought from the West, it could be worked on the spot to conform to Chinese usage. It was no doubt regarded as a cheap substitute for jade. The Chinese themselves do not claim to have made glass before the 5th century, and even then it is doubtful if they knew more than how to make beads and other similar small objects. The vessels of glass occasionally found in burials of the T'ang (618–907) and later dynasties, although perhaps locally made, are more likely imports. Of the extant glass vessels typically Chinese in form, none can be shown to be of a date earlier than the reign of the K'ang-hsi emperor (1662–1722), and there is every likelihood that glassmaking was in fact introduced in this period when, through the Jesuits, China became vividly aware of Western culture. To this period probably belongs a series of bowls and vases of which the blown character is manifest. They are often of a deteriorated material that appears to suffer from the same defects as European glass of the same

By courtesy of Museum fur Kunst und Gewerbe, Hamburg



Snuff bottle, opaque whitish glass with red cut overlay, Chinese, 18th century. In the Museum für Kunst und Gewerbe, Hamburg. Height 10.5 cm.

epoch. During the reigns of the Yung-cheng (1723–35) and Ch'ien-lung (1736–96) emperors, the emphasis on blown forms is subordinated to the desire to make glass a surrogate for natural stones. Although the colours used are often not such as are found in nature, the glass is handled as though it were jade, the foot in particular being fashioned as though cut from stone. This lapidary treatment is further emphasized in the cased glass bottles cut on the wheel in such a way that the design stands in one or more colours on a ground of a contrasting tone.

(R.J.Ch.)

BIBLIOGRAPHY. There is ample literature on the history of glass. The following selection of titles includes basic reference works and handbooks as well as some specialized studies many of which contain bibliographical references. In addition, the *Journal of Glass Studies*, issued annually by The Corning Museum of Glass, includes extensive bibliographies.

The basic sources for medieval glassmanufacture are HERACLIUS, *Von den Farben und Künsten der Römer*, ed. by ALBERT ILG (1873); and THEOPHILUS PRESBYTER, *Schedula diversarum artium*, ed. by ALBERT ILG (1874; Eng. trans., *On Divers Arts: The Treatise of Theophilus*, 1963). GEORG AGRICOLA, *De re metallica* (1556; Eng. trans., 1912, reprinted 1950); and particularly ANTONIO NERI, *L'arte vetraria* (1612; Eng. trans. by CHRISTOPHER MERRET, *The Art of Glass . . .*, 1662), describe in detail glassmaking in the 16th and 17th centuries. See also JOHANN KUNCKEL, *Ars vetraria experimentalis*, 2 pt. (1679). Other technological studies are APSLEY PELLATT, *Curiosities of Glass Making* (1849); and ALFRED LUCAS, *Ancient Egyptian Materials and Industries*, 4th ed. rev. (1962).

EDWARD DILLON, *Glass* (1907); ROBERT SCHMIDT, *Das Glas*, 2nd ed. (1922); and W.B. HONEY, *Glass: A Handbook . . . Victoria and Albert Museum* (1946), are among the best and most comprehensive general surveys of the history of glass. *Masterpieces of Glass* (1968), a catalog of some of the holdings in the British Museum, is the most recent scholarly publication on the subject in general, accompanied by a large bibliography. CHARLES G. JANNEAU, *Modern Glass* (1931), is a review of world glass at the beginning of the 1930s. For a general study of the international development of art glass, see ADA BUCH POLAK, *Modern Glass* (1962). GEOFFREY W. BEARD, *Modern Glass* (1968), provides a brief account of modern glasswork from various countries.

Comprehensive illustrative material on glass of the ancient world is found in GUSTAVUS A. EISEN and FAHIM KOUCHAKJI, *Glass*, 2 vol. (1927); the most scholarly survey is that of THE CORNING MUSEUM, *Glass from the Ancient World: The Ray Winfield Smith Collection* (1957). Roman glass in particular was treated exhaustively by ANTON KISA in *Das Glas im Altertume*, 3 vol. (1908). Basic treatises on pre-Roman glass include H.C. BECK, "Glass Before 1500 B.C.," in *Ancient Egypt and the East*, pt. 1, pp. 7–21 (June 1934); POUL FOSSING, *Glass Vessels Before Glass-Blowing* (1940); and BIRGIT NOLTE, *Die Glasgefässe im alten Ägypten* (1968). In addition to KISA (*op. cit.*), general books on Roman glass, such as MORIN-JEAN, *La Verrerie en Gaule sous l'Empire romain* (1913); CLASINA ISINGS, *Roman Glass from Dated Finds* (1957); and DONALD B. HARDEN, *Roman Glass from Karanis Found by the University of Michigan Archaeological Expedition in Egypt 1924–29* (1936), are important for the understanding of this period. The latter has become the standard reference work for describing and cataloging ancient glass in general. Western glass of the 5th–8th centuries is treated in detail by D.B. HARDEN, "Glass Vessels in Britain and Ireland, A.D. 400–1000," in *Dark Age Britain* (1956). The standard handbooks on Islāmic and Western medieval glass are still CARL J. LAMM, *Mittelalterliche Gläser und Steinschnittarbeiten aus dem Nahen Osten*, 2 vol. (1929–30); and FRANZ RADEMACHER, *Die deutschen Gläser des Mittelalters* (1933). Byzantine glass is described in JOSEPH PHILIPPE, *Le Monde byzantin dans l'histoire de la verrerie, V^e–XVI^e siècle* (1970). The basic handbooks on French and Belgian glass are JAMES BARRELET, *La Verrerie en France de l'époque gallo-romaine à nos jours* (1953); and RAYMOND CHAMBON, *L'Histoire de la verrerie en Belgique du II^e siècle à nos jours* (1955), the latter including ample bibliographic references on literary sources. WILLIAM A. THORPE, *A History of English and Irish Glass*, 2 vol. (1929), is still the standard reference work on English glass while HUGH WAKEFIELD covers *Nineteenth Century British Glass* (1961). German, Bohemian, and Austrian glass is treated exhaustively in ROBERT SCHMIDT, *Die Gläser der Sammler Mühsam*, 2 vol. (1914–27). For polychrome painting on vessels, see AXEL VON SALDERN, *German Enameled Glass* (1965). The handbooks on glass from *c.* 1800 to *c.* 1900 are GUSTAV PAZAUREK, *Gläser der Empire und Biedermeierzeit* (1923) and *Moderne Gläser* (1901). ASTONE GASPARETTO, *Il vetro di Murano dalle origini ad oggi* (1958), is the basic reference work on Venetian glass. The best surveys on Spanish glass are JOSEP GUDIOL Y RICART, *Los vidrios catalanes* (1941); and ALICE WILSON FROTHINGHAM, *Spanish Glass* (1964). For Scandinavian material, ADA BUCH POLAK, *Gammelt Norsk Glass* (1953); and HERIBERT SEITZ, *Äldre Svenska Glas . . .* (1936), should be consulted—both contain an English summary. Glass in the United States has been dealt with in great detail by GEORGE S. and HELEN MCKEARIN in *American Glass* (1948) and *Two Hundred Years of American Blown Glass*, rev. ed. (1966). LURA W. WATKINS, *American Glass and Glassmaking* (1950, reprinted 1970), presents a useful outline of 19th- and 20th-century American glass. RAY and LEE GROVER, *Art Glass Nouveau* (1967), is valuable for its colour illustrations of 19th- and 20th-century fancy glasses in American collections.

On Chinese glass, see W.C. WHITE, *Tombs of Old Lo-Yang* (1934); FRIEDRICH HIRTH, *China and the Roman Orient*, pp. 228–234 (1885); W.B. HONEY, "Early Chinese Glass," *Burlington Magazine*, 71:211–223 (1937); and H.C. BECK, "Far Eastern Glass: Some Western Origins," *Bulletin of the Museum of Far Eastern Antiquities*, 10:1–64 (1938).

Glass Products and Production

The common article of commercial manufacture known as glass is normally a transparent, hard, brittle substance formed from certain liquids that have the property of cooling below their freezing point without crystallizing, thus becoming liquids of increasingly high viscosity (stiffness) until eventually they are so stiff that by all ordinary definitions these liquids have the properties of a solid.

Of all the many substances that can form glass, the most widely used is silica (SiO_2), usually in combination with lime (calcium oxide, CaO) and soda (sodium oxide, Na_2O) in varying proportions, to make the soda-lime glass used in enormous quantities for windows, lamp bulbs, bottles, and low-cost tableware. Though glass could be made from silica alone, it would have an impractically high softening temperature, making it difficult to work. Nevertheless, it is the basic chemical nature of silica that determines both the structure of ordinary glass and the way in which it changes from a free-flowing liquid at high temperature to a virtually rigid condition as it cools.

The silica molecule

The silica molecule can be visualized as a single atom of silicon, to the four bonds of which oxygen atoms are attached. The bond angles are fixed at 108° to each other, in three dimensions, at the centre. The oxygen atoms thus occupy the four points of a tetrahedron surrounding the silicon. Each oxygen atom plays a role in two such tetrahedra, but the bonds that unite it with its silicon partners do not lie in a fixed plane or at a precise angle. There is thus an almost infinite range of possibilities in the relative dispositions of the many tetrahedra that comprise even a minute speck of silica.

The silicon–oxygen bond is very powerful; considerable heat energy must be supplied if such material is to flow freely, because the fluid condition arises from the continued breaking, remaking, and rebreaking of this bond. Though heating and cooling crystalline silica can result in resumption of the crystalline form (and in materials that are not glass formers will do so), if cooling proceeds rapidly enough, the temperature at which transformation could occur is passed too quickly for the necessary rearrangement of atoms to take place; thereafter, the material is too stiff. The continuous random changes in the disordered structure are brought to a halt, and the structure remains as it was in its last fluid moment; in effect, a liquid whose molecules are immobilized.

Such a random liquid-type structure is a good deal less compact than one in which a state of maximum order prevails. It is full of cavities and holes that are of very considerable importance in practical glassmaking. If a metallic oxide is incorporated into the glass, many of these spaces will be occupied by metal ions, each of which will employ one of the bonds of an oxygen atom, so removing one of the props of the firm three-dimensional silica network. This, and the fact that the oxygen-ion bond is nondirectional, results in a much lower vis-

cosity in the two materials at a given temperature. Ordinary glass contains about 15 percent soda to render it workable at moderate temperatures. Lime is also necessary to prevent water solubility.

This article has been divided as follows:

THE GENERAL PROPERTIES OF GLASSES

Chemical properties. Although glass is used for many purposes for which other materials are less suitable because of their chemical instability, there is nothing about the glassy state as such that ensures its stability. Water glass, for example, composed of silica and soda alone, is useful only as a temporary glaze because it dissolves readily in water.

Though pure silica is insoluble in water, it has poor resistance to attack by alkaline solutions. Thus, the familiar soda-lime glass contains the agent of its eventual destruction. After soda-lime glass has been in use for a time, moisture in the atmosphere begins to leach sodium ions from the surface; these form sodium hydroxide, an alkaline substance that, in turn, attacks the silica in the glass. Though this etching process causes no significant contamination of most substances likely to be stored in the glass and produces no readily apparent effect, the submicroscopic fissures it creates ultimately have a profound effect on the mechanical strength of the article. Carbon dioxide can also cause deterioration in glass surfaces when moisture is present.

Natural etching of glass

In spite of such deterioration, ordinary glass generally has a long, useful life. Furthermore, the number of substances that will form glass is sufficiently great that special glasses can be formulated that will resist attack by specific substances at normal or elevated temperatures. Boric and aluminum oxides, for example, can be mixed with silica to produce a glass highly resistant to attack by hot alkaline solutions; and glass containing large amounts of alumina and alkaline-earth oxides is resistant to hot sodium vapour that would destroy common soda-lime glass.

In some applications, all of the desired characteristics cannot be combined in a single glass. In such cases, ways can often be found of modifying the surface of the glass itself by some form of chemical treatment that gives the glass surface chemical properties not shared by the substance as a whole. When this is not practicable, a coating of one kind of glass may be applied to the surface of another kind, and the resulting material is, in effect, two-ply glass.

Physical properties. Although everyday experience would seem to suggest that glass is an exceptionally rigid material, its behaviour at room temperature is actually that of an elastic solid. It can be bent or otherwise deformed and, so long as its breaking strain is not exceeded, will return to its original undistorted shape when the strain is removed. Indeed, many of its present-day applications would be impossible unless glass were possessed of some degree of flexibility.

Though everyday experience also suggests that glass is brittle and of low strength, it is actually quite strong and will not fail as a result of simple compressional loading. Glass breakage, even when it results from impact, commences as tensile failure (*i.e.*, the glass is pulled apart, as described below).

When free from surface flaws, glass also possesses immense tensile strength. Generally arising as a result of chemical activity, surface flaws can be so slight as to defy detection, even with optical aid. However, their weakening effect can be measured by comparing the tensile strength of glass that has been in use awhile with the strength of glass in an undamaged state; *i.e.*, with its fire-finished surface unmarred by contact with other substances. Nearest to perfect glass are fine, newly produced glass fibres, which have been found to support loads of up to 500 tons per square inch (about 70,000 kilograms per square centimetre), a tensile strength about five times as great as that of the best practically available steel and about double the theoretical maximum for steel.

The way in which surface defects reduce tensile strength is demonstrated when a diamond cutter is employed to produce a controlled fracture in a sheet of glass. Once the sheet has been lightly scored, pressure applied on the scored side, over a suitable support, will cause separation. The relative rigidity of glass itself provides the lever that concentrates the available force on the very few interatomic bonds at the base of a tiny crack (microcrack). The ultramicroscopic structures fail under an assault by what is, relatively, truly colossal stress, which may amount to a tensile load of thousands of tons per square inch or centimetre. Effective leverage increases as the crack becomes deeper. The liquid structure of the glass presents no crystal boundaries or discontinuities that might arrest the progress of the crack, and it rapidly travels through the glass.

That glass is subject to fatigue fracture can be demonstrated by subjecting it to prolonged static loading. It will eventually fail under stresses far lower than those that a precisely similar sheet of glass can initially withstand. It is believed that such fatigue fractures are assisted by chemical assault. Once a microcrack exists with an orientation that allows it to be opened by the effect of the applied load, silicon ions in the exposed base of the crack can be dissolved out. Though deepening of the crack by such means will initially be very slow, purely mechanical forces will take over in time and the crack will spread very rapidly, eventually proceeding through the medium faster than the speed of sound.

Chemical action and cracking

The belief that chemical action does indeed assist in the initial deepening of a crack is supported by the fact that water, as has been seen, readily removes sodium ions from the glass. This property has long been exploited by glassworkers, who commonly wet the cracks made by a cutter before breaking sheets of glass.

Spontaneous fracture of badly annealed glass, in which internal strains are frozen in, can be seen from the preceding paragraphs to be inevitable when the surface has accumulated defects of the kind that are the natural consequence of normal use. Careful annealing to remove such strains is an important part of glassmaking technique. No less important are the methods by which glass surfaces are made more resistant to minor damage or protected against it.

Molten glass acts like a liquid in contrast to ductile metals, which quickly develop weak spots causing them

to narrow (neck) and eventually break when drawn by straightforward methods. Glass does not neck when drawn; tubing and rod can be stretched steadily, and almost indefinitely, as long as the viscosity of the material is carefully controlled.

Thermal properties. Glass expands when heated, shrinks when cooled, and is a poor conductor of heat. Though the surface of a slab of glass can lose heat very quickly by radiation into the atmosphere or through contact with any efficient heat-conducting medium, the interior loses heat by a slow process of conduction. In consequence, abrupt changes of temperature in rigid glass result in temperature differences between the interior and surface (thermal shock), creating stress that often leads to breakage. When glass is suddenly cooled, for example, the expanded interior puts the surface in a state of tensile stress. Careful annealing of ordinary glass eliminates the freezing in of strains that might aggravate stress resulting from mild thermal shock. Some kinds of glass expand and contract considerably as a result of temperature changes. Even well-annealed objects made from these are likely to fail as a result of thermally induced tensile stress acting on minor surface damage. Common soda-lime glass, with its high coefficient of thermal expansion, is unsuitable for any applications in which thermal shock may be encountered. Borosilicate glass (Pyrex type) is far more resistant to tensile stress; while both the so-called Vycor glass, containing 96 percent silica, and pure silica glass are virtually immune to thermal shock.

Thermal shock

The reaction of a glass to changes in temperature is very important in optics, in which use a dimensional change amounting to a single wavelength of light can very seriously affect performance. For critical applications, Pyrex and Vycor types are increasingly used.

Because no real stresses exist in molten glass, sudden extreme chilling of its surface has a contrary effect to that described above. Such chilling immediately creates a very tough outer skin that has a far higher viscosity than the interior. As the glass cools to room temperature and temperature differences diminish between interior and surface, the interior is denied the dimensional shrinkage normal to its temperature condition. In consequence, the interior is left under severe and permanent tensile stress; it exerts a powerful compressional force on the surface. Glass in this condition is very resistant to impact and more resistant than untreated glass to thermal shock.

Electrical properties. Although most glass contains metallic ions (charged atoms or molecules) capable of carrying a current, the high viscosity of glass impedes their movements and electrical activity. Thus, glass is an efficient electrical insulator, though this quality varies with viscosity, which is a function of temperature. Indeed, if glass is first heated sufficiently by normal methods, it can be treated as a conductor and melted electrically.

Though the use of glass as an insulating material in electrical equipment might seem to be ruled out by its conductivity at high temperatures, special varieties have been developed that retain desirable insulating properties at several hundred degrees Fahrenheit. Furthermore, the conductivity of small components can be greatly reduced by prolonged annealing, which ensures maximum compactness of the glass and considerably decreases movement of ions.

Optical properties. Unlike those in most solid substances, electrons in glass molecules are confined to particular energy levels, and hence they cannot absorb and re-emit light energy in the form of photons (units of light energy) by skipping from one energy level to another and back again. Light energy, in consequence, travels through glass instead of being reflected, so that glass is transparent. Furthermore, the molecular units in glass are so small in comparison to light waves of ordinary frequency that their absorption effect is negligible. Light waves in some frequencies, such as the infrared or ultraviolet, can cause glass molecules to vibrate, however, making the glass opaque to light of these frequencies. Furthermore, glass to which certain metallic oxides have been added will absorb wavelengths of certain colours, thus appearing tinted to the eye.

Because of its amorphous liquid structure, glass is transparent in a manner associated with ordinary liquids rather than with transparent crystals. Light is not polarized (constrained to vibrate in a single plane) in passing through glass, nor is it much reflected, as it is in such materials as mica, which has been strained at internal optical boundaries. This optical neutrality can, however, be destroyed locally in glass as a result of internal structural strains such as arise from inadequate annealing.

Light rays are deviated on passing from one transparent medium to another of different density unless the boundary between the two is at a right angle to the direction in which the rays are travelling. The extent to which light is bent, or refracted, on passing into a medium such as glass depends on the angle at which the light meets the surface (angle of incidence) and on the relative densities of the glass and the other medium involved, usually air. Refraction can be expressed as a constant, the index of refraction, derived mathematically from the ratio of the sines of the angles of incidence and refraction. The constant has a different value for different wavelengths and for different types of glass.

Refraction of light

On emerging from glass into air, a light ray will be similarly deviated, but in the opposite sense. That is to say, if the faces of the glass sheet are flat and parallel, the final path will be parallel to the original path of the ray, but if the faces are not parallel (as in a lens or triangular prism), the ray will emerge in an entirely new direction.

Since the index of refraction is different for different wavelengths of light, a prism can be used to separate the constituent wavelengths of "white" light. A lens can be considered as a series of infinitely small prisms the face angles of which are such as to deviate parallel rays of light toward a single point. Though no single lens can do this for all colours, a combination of lenses of different types of glass can do so for several different wavelengths, thus producing a focussed image free from any noticeable false spread of colour.

If the angle at which light rays inside glass arrive on the second surface is large enough, the deviation on emergence will give the light rays a direction parallel and close to the surface on emergence. This critical angle cannot be exceeded without the ray being reflected on the glass–air boundary. Called internal reflection, this phenomenon is widely exploited in making prismatic binoculars, single-lens reflex cameras, and range finders. It also has important new applications in light piping and fibre optics, which are described below.

HISTORY OF GLASS PRODUCTION

From ancient times to the 19th century. The oldest specimens of manufactured glass, beads from Mesopotamia and ancient Egypt, date from about 2500 BC. These beads and very much later specimens are of particular interest because their dates of origin reveal how long a period of time elapsed before glassmakers became aware of the many ways in which hot plastic glass could be manipulated.

Mesopotamian glass

Small glass vessels, nearly 4,000 years old and of presumed Mesopotamian origin, were neither blown nor molded but painstakingly sculpted from solid blocks. Only after a thousand years or more of experience did glass vessels begin to appear in Egypt; these were produced not by exploiting the ductile nature of hot glass but by an extension of the already established method of glazing pottery. Molten glass was poured over a shaped sand core in successive layers until the vessel was sufficiently sturdy. The surface was decorated with molten drops of coloured glass poured over the outer layer and pressed into it before the vessel had cooled. This method was employed for more than a thousand years until the introduction of a simple tool that revolutionized glassworking.

The blowing iron. Probably dating from about 200 BC, the blowing iron is believed to have been used first in

Babylon and adopted with enthusiasm by the Romans. Along with the blowing iron (an iron tube about 5 feet, or 1.5 metres, long with a mouthpiece at one end and a knob for holding the soft glass at the other), the craftsman employed a marver, or polished block of iron, and a pontil, a solid iron rod. A blob of soft glass on the knob end of the blowing iron was first rolled into a suitable shape on the marver. Next, it could be blown either into a constraining mold or freely in air. The pontil was employed to roll, squeeze, twirl, or pinch a similar blob of glass into shapes of almost any desired complexity and to weld them to the globe of hot glass on the blowing iron, making, for example, the stem and foot of a goblet. The still soft globe could be cut from the blowing iron with shears; the completed vessel, when cooled, was made to part company with the pontil by means of a sharp rap on the iron (cracking off).

Millefiori glass

Another development in glass manipulation adopted by the Romans led to what became known eventually as millefiori glass. Threads of coloured glass, made by stretching when hot, were laid in carefully arranged bundles so that they could be fused together to make a "cane," which could in turn be cut into slices, all with exactly the same surface pattern. The pattern units were then laid side by side on a suitable sand core and heated until they fused together to form a continuous self-supporting shell.

Both the Romans and the Egyptians showed astonishing skill in the way they used metallic oxides as colorizers. Very small differences in oxide content can drastically affect the final colour of a glass; yet colours and tints were reproduced time and again with remarkable consistency. Copper was used to make green and ruby-red glass; iron produced black, brown, and green; antimony, yellow; manganese was employed to make purple and amethyst glass. An opaque white glass, made by using tin, was important in glass cameo work, of which the famous Portland vase, made in 1st-century Rome, is an outstanding example. To make this vase, a layer of white glass was superimposed on a darker material and afterward sculpted, pierced, and cut away to leave the white figures in relief against the darker background.

Roman attempts to make flat glass by pouring slabs about one-half inch (12 millimetres) thick were unrewarding. Proper transparency cannot be achieved by such means without grinding and polishing the cast material; the lack of transparency and the difficulty encountered in making any but small panes by this method led to the introduction of stained-glass windows, first used in the Eastern Roman Empire in the early 12th century.

The Middle Ages. Glassmaking skills in Europe declined after AD 200; for about a thousand years, standards remained far below those of the Romans. The range of articles, as well as the quality of the material, was poor; the glass was of inferior colour and marred by streaks and bubbles. The stained-glass windows that began to appear in the new Gothic churches in Europe in the 12th century reached their full splendour in the 13th and 14th centuries. Many of the colours were produced by the method of fusing stains to the surface of the glass. Clear, colourless glass proved extremely difficult to achieve, however.

Glassmaking in Venice

The real revival of glassmaking skills in Europe came by way of Venice through contact with the Eastern Roman Empire (Byzantium). The Venetians made discoveries and innovations of their own, learning, for example, to eliminate all accidental colorizers from a glass melt by adding countercolorizers. The natural result was a gray glass the overall transparency of which was even less than that of the otherwise slightly tinted glass. So long as the amounts of the original colorizer and of its antidote were small and the thickness of the finished article was slight, however, the loss of transparency was less noticeable than the unwanted colour would have been.

The Venetians eventually redeveloped all the skills of the Romans. Their products and their secrets were so much sought that the glassworks, said to be a mile long, was moved in its entirety to the island of Murano in 1291 to protect its secrets and to make emigration of its workers more difficult. By the 16th century, however, most of the secrets and all of the manual skills of Venice had spread. Glass of improving quality was being produced over most of Europe in ever-growing amounts.

Although ingredients varied from place to place, most glass produced in the past, as today, was soda-lime glass. Satisfactory for most purposes because it is very stable chemically and of reasonable hardness, soda-lime glass is also easily made, and its moderate softening temperature makes it very workable, and it can be readily resoftened a number of times if necessary to complete an article. Above all, the materials needed for its manufacture were plentiful; sand and limestone exist almost all over Europe, and the soda ash was readily obtainable from the hardwood forests that also provided fuel for the furnaces. Desirable but scarcer materials included potash, produced by burning seaweed and favoured by the Venetians above soda ash, and calcined and crushed river pebbles (selected for their whiteness), which most Italian glassmakers preferred to common sand.

Glass furnace

The 15th-century German authority Georgius Agricola recommended a glass furnace nine to ten yards (eight to nine metres) wide and five times as long, large enough to keep 100 or more craftsmen busy. Agricola's specifications would have made glassworks in the mid-16th century very large compared to other industrial operations at the time. It was a standard practice to roast all the ingredients of a glass batch in order to remove as much moisture as possible before use. Mixing was carried out in a separate furnace; and after being stirred and heated for 24 hours, the ingredients were ready to be shovelled into fireclay pots for melting.

The furnace was roofed over and fitted with flues; its floor, called a siege floor, stood somewhat above ground level. The fuel chamber, which lay underneath this siege floor, had a series of holes along its length. These allowed the fuel to be ignited at many points and provided adequate access of air. The hot gases from the burning fuel entered the melting chamber through a series of vents confined to about three-quarters of the length of the siege floor. This arrangement provided the melting chamber with a relatively cool zone into which pots of molten and refined glass could be pushed to achieve working viscosity as they became needed by the workers.

Window glass. Glassblowing was indispensable to nearly all glassmaking operations until the 20th century. Not only tableware and bottles but flat glass, too, depended on the use of the blowing iron. Until well into the 19th century, the only method of making window glass was, first, to blow a large globe of glass; this was cut from the blowing iron after welding the pontil to a point diametrically opposite. The open side of the glass balloon, 20 inches (50 centimetres) or so in diameter, was then flattened on the marver; then, with the pontil being continuously rotated, the glass was reheated until it became very soft. Immediately after it was removed from the heat, the rate of spin of the pontil was increased; suddenly, the centrifugal stress on the soft glass caused it to flow rapidly outward from the centre and to take the form of a large disk, which was kept spinning until the glass was rigid.

Such glass of course was not truly flat. The disk was very uneven, being thickest near the centre and marked by concentric circular waves; at the very middle was the fractured nub, or crown, marking the point of former attachment to the pontil. Disks more than about five feet (1.5 metres) in diameter were hardly practical. The manufacturing process and the need for great economy in cutting the material, rather than aesthetic taste, account for the sector-shaped fanlights and small window panes in English Georgian houses of the 18th and early 19th century. Polished cast-plate glass, first produced in France toward the end of the 17th century, was little used, even by the wealthy, because of its prohibitive cost.

Flint glass

First made in the 17th century, using a large proportion of calcined flints with potash substituted for soda ash, flint glass was initially a failure. It spontaneously developed a maze of fine cracks that made it useless. The addition of lead oxide, however, eliminated this defect

and produced a fine lustrous glass, soft enough to be cut and engraved easily and of greater refractive power than the common crown glass. It was also more dispersive of light, but not to the same degree. Telescope makers took advantage of these properties: they placed a flint-glass lens and a crown-glass lens one behind the other to eliminate the worst of the coloured haze surrounding telescopic images of bright objects.

Development of the modern industry. During most of the 18th century, glass, apart from a few small windows, was a rarity in the homes of ordinary citizens. Containers and tableware were commonly made of pewter or earthenware. By the end of the 19th century, however, glass was a common material, pouring from the furnaces in a seemingly endless flood to be etched, scratched, engraved, and plated; rolled, ground, and polished; blown, cast, and molded into every conceivable form and for almost every conceivable purpose.

The first important mechanical manufacturing innovation was the hand-operated split mold, patented in 1821, which was made of two hollow blocks of iron. This device made it possible to blow the whole bottle, instead of the body only, in the mold. Sixty years later, semi-automatic bottle-making machines were coming into use.

The production of flat glass by breaking and spinning a blown globe gave way to the glass cylinder, blown by using compressed air, which could be slit lengthwise, reheated, and allowed to flatten on an iron table under its own weight. Although the natural fire finish was destroyed on one surface, the final product, still far from being truly flat, was flatter than crown glass. Output increased dramatically, so that the glassmaker and the engineer were able to astonish the world by midcentury with the Crystal Palace in London, made from 300,000 sheets of cylinder-blown glass resting on a lightweight iron framework.

Fundamental to the great increase in output was the introduction of the regenerative furnace, originally developed for the metallurgical industry, in which hot gases were recycled. This furnace provided far more usable heat from a given amount of fuel than had been possible before, and enormously speeded up the melting process. Of even greater importance was conversion of the old siege floor into a vast tank in which the materials were melted directly. Fed in at one end, the batch melted and flowed steadily toward the far end, at which it was taken up by the working teams, or later by machines, that converted it into finished glass products.

The greatly increased flow of glass from the new furnaces found steadily improving machines waiting to receive it, and the increasing amounts of mechanical power available began to make plate-glass polishing, though still costly, a practical business proposition that soon started to change the appearance of the main thoroughfares in large European and American cities.

Optical glass

Glass of optically reliable quality was a rarity at the beginning of the 19th century, except perhaps in France, where a means was found of producing truly homogeneous flint. Optical glass, formulated for the lens and instrument designer, however, did not exist. Its development called for the application of an altogether more scientific and less empirical approach to the problems of the effects of ingredients on the properties of glass. This progress came with the remarkable collaboration of the German scientists Carl Zeiss, Ernst Abbe, and Otto Schott in Jena, with the result that many new elements came into use in glassmaking; the effect on the quality of microscopes was immediate.

The new scientific approach to glassmaking was paralleled by a more scientific attitude toward the properties and possibilities of glass, so that new methods of using and handling glass continue to multiply, as do the applications of glass. If the beginning of the modern industry is dated from the beginning of the 20th century, then the number of important innovations and changes in glassmaking technique during its short history can be seen to outnumber very easily all those of the preceding 4,500 years. So numerous are they that a list would be tediously long and a description impossible. For example, there are at least four major changes in the methods used to produce flat glass; twin grinders that can produce about 400 square yards per hour of polished plate glass; machines that provide 2,000 or more lamp-bulb glasses per minute, and others that produce astronomical lengths of glass filament. There are also many newer glass types: heat-resistant, low-expansion glass; thermally toughened and laminated glasses; photosensitive and photochromic glass; foam glass, glass filters, glass fabrics; glass that is transparent to ultraviolet and to infrared rays; and glass that provides protection against X-rays and gamma radiation. Some of these processes and new glass types are described more fully in the later text.

PRODUCTION OF CONVENTIONAL FORMS OF GLASS

Raw materials. The greater part of glass produced today consists of variations of the silica–lime–soda mixture. Enormous quantities are used for flat glass of all kinds and for containers, including light bulbs. Optical glass, even in technologically advanced countries, accounts for only about 4 percent of the total value of the output; in terms of tonnage, it is very much less.

Modern continuous methods of production involve a high degree of organization. One of the first requirements is a continuous supply of raw materials, consistent in quality, that lend themselves to standardized cleaning treatment. Thus, the glass manufacturer first looks for conveniently situated sources of adequate size that he can own or control. An idea of the standards required of the ingredients at firing time is given by the fact that the iron oxide content of even common domestic ware is unlikely to be more than about one part in 2,000. For higher quality materials, this figure is frequently cut to one part in 10,000 and sometimes very much less.

Soda is normally provided in the form of sodium carbonate (soda ash), and lime as calcium carbonate. Magnesia is added to the batch when dolomitic lime is used. For more specialized glasses, boric acid and borax are employed to provide boron oxide; zinc is directly oxidized to provide zinc oxide; litharge (red lead) is ordinarily used to provide the lead oxide for crystal ware and for dense flint optical glass, in which it may amount to 50 percent by weight of the total batch. Many minor ingredients are used as colorizers, decolorizers, and to assist in refining the glass, or to give it special working properties or special characteristics when finished. Oxides of copper, chromium, cobalt, iron, and nickel are used as colorizers, as are colloidal gold and copper. Antimony and arsenic are useful refining agents: phosphates and fluorides are employed in opal glass. Table 1 lists the principal ingredients of important types of glass.

Use of cullet

One particularly important ingredient of glass has not been mentioned because it does not, or should not, affect the balance of the constituents of the final product. Cullet, or broken waste glass of the same type as that being manufactured, almost always forms from 50 to 75 percent of the batch. Cullet acts as a solvent. Because any glass becomes fluid at a lower temperature than any of its constituents and because glassmaking depends on the intersolution of its ingredients rather than melting, the entire process is enormously speeded up by the quick provision of an adequate amount of fluid glass.

Uniformity of sand-grain size is also important in melting. Sand grains of different sizes tend to separate as a result of the vibrations suffered during transit and handling. During the melting process, their behaviour would be unpredictable and the time allowed for homogeneous intersolution of the glass ingredients would sometimes be inadequate. Streaks of glass of differing viscosity would result. This, in turn, would cause undesirable optical effects and possibly provide a mechanically weak final product.

Furnaces. The regenerative furnaces used in large-scale glass production are invariably tank furnaces, normally designed for continuous production throughout the whole useful life of their refractory (heat-proof) linings. These linings eventually corrode to a point at which they become deeply scored, and pieces are likely to break

Table 1: Chemical Contents of Various Kinds of Glass

	composition (percentage)
Soda-lime silica	silica (SiO_2), 70; soda (Na_2O), 15; lime (CaO), 10; magnesia (MgO), 2.5; alumina (Al_2O_3), 2.5
Borosilicate	silica (SiO_2), 60–80; boric oxide (B_2O_3), 10–15; alumina (Al_2O_3), 1–4
High silica (shrunken glass)	silica (SiO_2), 96; boric oxide (B_2O_3), 3–4
Aluminosilicate	silica (SiO_2), 5–60; alumina (Al_2O_3), 20–40; lime (CaO), 5–50; boric oxide (B_2O_3), 0–10
Light barium crown	silica (SiO_2), 45–50; boric oxide (B_2O_3), 3–5; soda (Na_2O), 1; potassium (K_2O), 7; barium oxide (BaO), 20–30; zinc oxide, (ZnO), 10–15
Dense barium crown	silica (SiO_2), 30–40; boric oxide (B_2O_3), 10–15; zinc oxide (ZnO), 0–10; alumina (Al_2O_3), 0–10
Extra dense flint	silica (SiO_2), 20–40; potassium oxide (K_2O), 0–10; lead oxide (PbO), 50–80
Soft solder glass	silica (SiO_2), 5; boric oxide (B_2O_3), 15; lead oxide (PbO), 64; zinc oxide (ZnO), 16
Antiradiation	silica (SiO_2), 20; lead oxide (PbO), 80
Infrared (semi-conducting)	arsenic (As), 44; tellurium (Te), 24; iodine (I), 32
Photosensitive	silica (SiO_2), 72; soda (Na_2O), 17; lime (CaO), 11; gold (Au), 0.02; selenium (Se), 0.04
Photochromic	silica (SiO_2), 60; soda (Na_2O), 10; boric oxide (B_2O_3), 20; alumina (Al_2O_3), 10; iodine (I), 0.9; silver (Ag), 0.6; chlorine (Cl), 0.3

off. A furnace lining may last up to several years; its life depends not only on the material used in making it but also on the type of glass being made, for some glasses are much more corrosive than others.

A tank furnace may be nearly 30 feet (nine metres) wide and five times as long, with a capacity of more than 1,000 metric tons. The frit (glass ingredients), well dried and thoroughly mixed, is mechanically conveyed to overhead hoppers located at the end of the furnace, through which it is allowed to trickle down across the whole width of the furnace for introduction into the melt by mechanical pushers. The rate of feed is controlled automatically by the withdrawal of glass at the far end of the furnace, so that the level in the tank remains constant.

The furnace may be oil or gas fired; large fuel reserves are necessary in order to ensure continuity of firing. Electric furnaces, employing resistance heating, although used for special glasses produced in relatively small quantities, are too costly to operate for production of common glass. Electric boosters in regenerative furnaces, however, are used; these not only help to increase output but also provide a means of quickly and accurately controlling the heat distribution along the tank.

Heat distribution

Heat distribution is most important if a continuous supply of properly refined glass is to be delivered to the forehearth (point of extraction) at the required viscosity. During the early stages of the melting process, the newly introduced batch is converted into a stiff, doughlike mass in which the ingredients participate in the chemical reactions that will eventually yield glass. Even when odd lumps of broken glass (cullet) cannot be seen, as they can for a foot or two within the tank, the mass looks uncompromisingly gritty and full of bubbles. Steady addition of new material forces the batch further into the tank, where the temperature is maintained at about 1,500°–1,600° C (2,700°–2,900° F). At this temperature common glass is as fluid as water; bubbles formed by trapped air and gases liberated from chemical agents escape. The further end of the tank, toward which the material continuously flows, is much cooler (less than 1,000° C, or 1,800° F), so that working viscosity is assured at the delivery point.

Production processes. *Flat glass.* All previous methods of obtaining flat glass by flattening blown globes and cylinders and by drawing cylinders are now obsolete. Even the Colburn process for direct continuous production of flat sheet has been superseded. This was a horizontal process, which, though continuous, marred the fire-finished surface of the material. The principal methods used today are vertical drawing of flat sheet and roller casting, flat casting, and floating on molten metal.

Vertical drawing of flat sheet is basically an extension of the principle applied by the hand craftsman who relies on the ductility of very hot glass to draw a bar attached to his pontil into a long, thin rod of uniform cross section. Glass is delivered from the furnace by way of a throat, or bridge, which holds back any overly viscous patches and controls the flow into an adaptation of the forehearth called a drawing trough, or drawing kiln.

Drawing operations commence by dropping a long bait, made of openwork iron, into the hot molten glass passing through the drawing slot of a form, or drawing boat, in the trough. The glass quickly welds to the metal, which is then slowly raised, with glass running from it much as treacle (molasses) runs from a knife blade. Like treacle on a knife blade, too, it would quickly run in toward the middle and form a narrow stream, but for the fact that the edges of the rising sheet are cooled immediately as it rises from the drawing boat, by passing them between, but not touching, a pair of water-cooled steel boxes. The edges are then gripped by cooled, electrically-powered knurled rollers, which drive the hot, growing sheet upward to the cutting loft. The iron bait is discarded; its only role is to start the process by raising the glass until it can be gripped at the edges, after which the rising sheet will be self-sustaining so long as the gripping rollers continue to turn. The thickness of the sheet can be closely controlled by the speed at which it is drawn off from the trough.

The sheet is forced to rise through an annealing lehr (oven) in which close temperature control ensures that it is free from strains when it reaches the cutting loft about 30 feet (nine metres) above the furnace.

In the cutting loft, the glass sheet comes at last under some degree of direct human control. As it rises through the floor it is seized by large suction pads, suspended from overhead gear, and worked hydraulically by a human operator. As the top of the sheet reaches a predetermined height, it automatically triggers a mechanically operated cutter, which sweeps across the glass at an angle that allows for the continued rise of the glass during the cutting operation. A slight movement of the levers attached to the suction pads separates the standard sized sheet, which is then placed on an easel. There, the edges, marred by the gripping rollers when still soft, are cut away. These and the scraps that gradually accumulate as the result of accidental breakage are shovelled into a chute to be returned to the melt as cullet.

Rolled glass

At one time plate glass was produced by pouring it onto large tables with raised edges. Heavy rollers were then employed to squeeze the glass to an even thickness determined by the depth of the table edges. The modern equivalent of this process involves passing hot glass as a continuous ribbon between a pair of rollers so spaced as to control the thickness of the sheet. Though the glass is still hot and plastic when it issues from the forming rollers and passes over other rollers, it has attained a reasonable flatness by the time it reaches the annealing lehr. Though general surface quality suffers through contact with the metal, the final product, while lacking in transparency, is completely adequate for a number of uses. It is often given a texture, usually on one side but occasionally on both, by specially patterned rollers, so that it emerges finally as single- or double-reeded glass, so-called hammered glass, arctic glass, or Georgian glass; all these effects are intended to reduce further, rather than enhance, transparency. The process is also used to make wired glass by resoftening two sheets so that they can be united by rolling pressure over an intervening wire mesh.

The huge quantities of plate glass for the building industry are produced, like the bulk of other modern glass, by regenerative tank furnaces of the continuous type. Modern furnaces can easily deliver continuous ribbons up to eight or nine feet (2.4 or 2.7 metres) wide; these can be processed by twin grinders so that they eventually emerge, ground and polished on both faces, as high-

quality plate glass produced at up to about 1,000 feet (300 metres) per hour.

The degree of flatness and parallelism achieved by these machines is of a high standard, which can be improved on only by optical methods of grinding and polishing. Indeed, so good is it that selected small pieces of up to several square inches can often be brought up to a high optical standard without further grinding by polishing according to traditional handworking methods.

Flame-finished surfaces have already been seen to be impossible to preserve when plastic glass comes into contact with solid materials. The finish can only be restored by reheating, or replaced by grinding with abrasives and then polishing with agents such as rouge or cerium oxide.

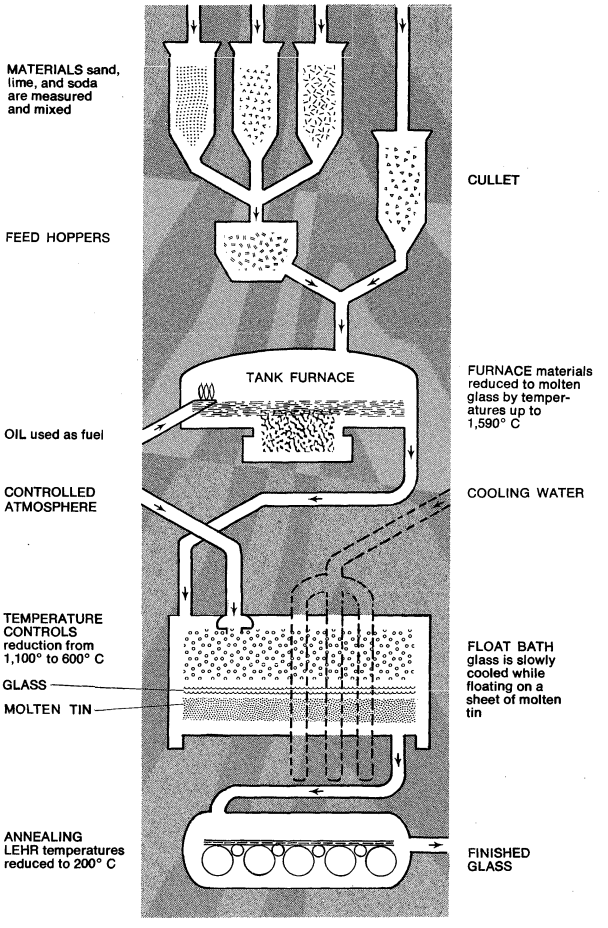
Sheet glass of admirable flatness for many common purposes, unmarred by glass-to-metal contact, is produced by the continuous vertical draw processes described above. Its virtues are most apparent, however, in thicknesses of about $\frac{1}{16}$–$\frac{1}{8}$ inch (1.6–3.2 millimetres). For thicknesses not much greater than these, plate glass was, until the late 1960s, always necessary for purposes in which quality was important. Grinding and polishing costs are disproportionately high relative to weight cost in such material. Yet, there is a great demand for glass of good optical quality in these very gauges in which polishing costs are relatively so high. Glass of the required thickness and quality is now being produced in ever-growing quantities without expensive mechanical reworking by means of the float-glass process evolved in Great Britain.

Float glass

In the float-glass process illustrated in the Figure, the frit is melted in an oil-fired continuous tank furnace and, as in making plate glass, emerges as a continuous band. In the new process, it issues through a slot onto the surface of a pool of molten tin contained in a closed chamber, in which the atmosphere is carefully controlled to avoid oxidation of the metal, which would disastrously affect the transparency. Inside the chamber, the glass is heated from above to a temperature that renders it fluid, so that it takes up the form of a plane-parallel film of the required thickness on its bath of molten tin. Once past the high-temperature zone, the glass flows on through the chamber, still supported by the tin, until it is quite hard; then it passes into the annealing lehr. The end result is a glass that retains the fire polish of crown glass and vertically drawn sheet and that also has a degree of flatness and parallelism rivalling glass produced by the more costly grinding and polishing process. In the early 1970s, four float-glass tanks in Britain annually produced a 10,000-mile-long ribbon of the material, 11 feet wide.

Bottles and containers. The continuous regenerative tank furnaces used for the production of flat glass serve equally well with minor modifications to supply glass for the high-speed production methods of the container industry. Container-production methods consist of molding and of extensions of the ages-old glassblowing process, frequently in combination. By their nature, these are intermittent rather than continuous processes. They could, however, be given a virtual continuity if all the necessary stages in the production of a glass container could be passed through at sufficient speed. There is, however, a limit to the extent at which glass can be hurried through the complex operations necessary to make it into a bottle. The answer to the problem is the multi-station machine, which can be likened to a carousel, at every arm of which a bottle is at some stage of production. The machine revolves not continuously but in a series of stops and starts, as each arm receives its gobbet of hot glass, which has to be shaped and then removed to leave its place vacant at the end of the circuit so that a new measure of hot glass can be processed.

Glass molds are generally fabricated of fine gray cast iron worked to a polished finish. The term iron mold as used by glass makers refers to a type of mold, made in one piece, for forming shallow, easily removable items. Other molds, even though made of iron, are called press molds and paste molds.



Basic steps in the float-glass process.
Drawing by D. Meighan

Blow molding

Blow molding demands that the glass be provided in precisely measured amounts of the right consistency when introduced into the blowing mold. Furthermore, unless the container is to be very small, it must be of the right shape if correct distribution of the glass thickness is to be possible. This requirement calls for a preliminary molding operation to make the partially hollowed blank, or parison. At this stage the rim, or collar, of the bottle attains its final form in a removable part of the mold called the neck ring. The glass is introduced into the parison mold either by suction or, downward, by gravity, and it is hollowed either by a puff of compressed air, which also ensures proper overall contact with the mold interior, or by pressure of a suitably shaped die. The parison is then transferred by means of the neck ring to the blow mold in which it is finally shaped.

Press molding is little different in its essentials from the making of a parison by pressing, except that the pressing can be permitted to lose a good deal more heat during processing because it is the end product. Solid molds of low cost can be used instead of expensive opening molds, because they rarely need to be of great dimensional precision. A measured amount of glass is dropped into the mold and pressed to shape by a cooled plunger so that it fills the controlled space between the two units. Ashtrays, dishes, and ovenware are typical items so produced. Quality products are finally polished by high-temperature gas flames on the inside and around their rims while still in the mold.

As in other glass-shaping processes, molding involves careful temperature control. If the glass is too fluid when it is blown, a proper distribution thickness will be impossible; it may even be torn by sticking to the iron. If it is too cool, it will not flow as it should; the surface of the completed item will be of poor quality and any fine detail, such as a trademark or lettering, is apt to be poorly reproduced. Good container processing, espe-

cially in large sizes and complex forms, frequently requires that much ingenuity be exercised in distribution of the mold's own mass as part of the means of localized temperature control.

For practical reasons, many items have to be blown into molds despite the fact that their finish must be such as cannot be obtained when glass-to-metal contact is involved. Ordinary table glasses of tumbler shape are an example. The so-called paste mold is an iron mold lined with material, such as soap or beeswax, to which wood flour or sawdust can be made to adhere. Once the flour or sawdust has been converted into an absorbent carbon coating, it can be dampened before the glass is blown into it. The glass is kept rotating while being blown; the steam pressure generated by the heat prevents the glass coming into contact with the mold much as air pressure keeps a hovercraft from contact with the ground. Carboys and similar large containers can be blown into paste molds by skilled workers; at the other extreme are small electric bulbs, which are blown into paste molds at rates of many hundreds per minute.

Until 1821 only the body of a container could be blown into a mold; shape and general finish remained poor for many decades afterward. Even today most mold-blown articles need some finishing before they can be considered complete. Molds and neck rings must be made so they can open and release the product, and however well-fitting they may be, a seam mark is made on the glass. Nearly all modern closures require that a perfectly even and smooth finish be given to the rim so that a perfect seal can result. This finish is assured by a short application to the rim of a very hot flame, which causes the surface to flow and obliterate mold marks.

Finishing operations

Articles made on the blowing iron need more extended finishing treatment, as do paste-molded items such as table glasses. Waste material is removed by lightly scoring the surface at the appropriate position. The object is then rotated while being quickly heated by gas jets. This action cracks off the material above the scribed line. A well-directed needle of flame, sometimes preceded by a brief grinding of the edge to square it off, quickly melts the surface around the rim and rids it of the sharp corners that would soon cause it to become chipped if they were allowed to remain.

Light bulbs and tubing. Lamp bulbs can well be regarded as a specialized variety of bottle. Their extreme thinness, however, calls both for special handling methods and for special techniques to manufacture them economically and in large quantities. A machine can produce light-bulb glasses at rates of up to 33 per second. It is supplied with a continuous ribbon of hot glass, travelling between rollers that preform it with a series of regularly spaced depressions. These glass forms are blown by puffs of compressed air to their final shape and size inside paste molds, which rise around them as the ribbon passes along the conveyor.

Tubing, once produced by a combination of blowing and stretching, is almost all mechanically made today. A hollow mandrel (metal bar), through which air is forced at low pressure, takes the place of the blowing iron. Molten glass is allowed to flow over the downward-pointing mandrel at a rate that maintains an evenly thick coating during the whole process of drawing off. Air is passed through the mandrel so that as the glass is drawn off a tube is formed. A steady pull is maintained by the grip of a pair of moving asbestos-faced belts placed at such a distance from the mandrel that the glass is quite firm and nearly cold by the time it reaches them. Large-diameter tubing and cylinders, which cannot be dealt with in this fashion, are produced by a very similar process. They are drawn off vertically upward over a mandrel consisting of a refractory ring that is positioned on the surface of the molten glass, through which air is passed.

Glass fibres. Once a novelty, glass fibre is now produced in enormous quantities for its thermal and electrical insulating properties and to provide reinforcement of lightweight synthetic resins (plastics) to form boat hulls and car bodies. Filaments as fine as a few thousandths of a millimetre in diameter can be produced. The continuous-filament process is used when the fibres are intended for the making of glass yarn. Molten glass is fed through bushings (removable metal linings) that terminate in very accurately sized spinarets, or forming tips. About 400 such tips may be required to supply the very fine filaments to be united as a single strand of yarn.

The fine streams of glass issuing from the forming dies are drawn off at speeds measured in miles per minute. As they are drawn together, they are thinly coated with an adhesive, which ensures their cohesion as they pass on to the high-speed winders as a united strand. Previously, glass fibres were formed from remelted, uniformly sized glass marbles, but the simplified direct-melt method described is now commonplace and is used to produce many million miles of even quality filaments.

Glass wool

The production of glass wool demands very different treatment. Here, the problem is not to produce an orderly assembly of fibres but a mass of randomly distributed filaments. The system most generally used is the crown process. A steady stream of molten glass from the forehearth is made to fall into a rapidly spinning dish that has hundreds of minute holes in its wall. Fine streams of glass are flung out much as water is forced through the vents of the rotating drum of a spin dryer by centrifugal force. As they issue from the dish, they first meet a blast of air from an air ring that controls their direction downward toward a continuous fine spray of a binding agent. They are then subjected to a further air-jet treatment, the turbulence of which tumbles them into a state of maximum disorder as they fall onto a moving conveyor, on which they form a continuous mat.

Toughened and laminated glass. The rapidity with which cracks travel through glass when it fails under tensile stress was described above. In many applications, such as doors or automobile windshields, failures of this kind would have disastrous results; and neither wired glass nor very thick plate glass can be used. Fortunately, there are two ways—toughening and lamination—of ensuring that glass will not shatter into a mass of lethal fragments on fracture.

It has been known for centuries that a large blob of molten glass dropped into cold water will congeal into a rigid lump that can survive repeated blows with a heavy hammer. It was also known that such blobs (called Prince Rupert's drops after their 17th-century popularizer) immediately collapsed into a heap of granules when the tail of the drop was fractured by applying sufficient pressure with a vise or pliers. This condition can be simply explained.

The sudden chilling of the exterior of the drop renders it rigid before the interior has undergone the configurational shrinkage appropriate to its falling temperature. The forces acting to attain greater density place the surface under powerful compressive stress. This compression must be overcome before the surface can be subjected to any tensile stress whatever. It is easiest to do so at the tail end of the drop, at which little material and only relatively minor stress is involved; fracture there immediately releases a considerable amount of stored energy that sends shock waves through the interior, already overstressed in tension, so that it cracks in all directions, causing fragmentation of the entire drop.

Heat toughening of plate glass is carried out by heating the material to just below its softening temperature and suddenly chilling it with jets of air or cold gas. This process produces a condition that allows it to be bent farther, and to be hit about five times harder, than ordinary glass of the same thickness before failure results. An ordinary amount of bending merely goes part way to relieving the compressive stress. When it does break, the sheet disintegrates into small, relatively harmless cubelike fragments that can be seen to have concave edges, resulting from the sudden, long-delayed shrinkage of the interior. All necessary cutting and drilling operations must be carried out before the glass is tempered.

Though toughened glass is widely used in Great Britain for car windshields, it is not acceptable in the United States and some other countries. In certain situations its

very toughness can be a disadvantage; it is, for example, very much more rigid than the skulls of the car's occupants. For this reason, laminated glass, made to yield without disastrous results, is often considered to be a more suitable material for windshields.

Laminated glass

Laminated glass suffered a period of eclipse after its introduction because it was originally formed as a sandwich of two sheets of glass bonded to a celluloid interlayer. The celluloid quickly yellowed in some climates, first around the edges, but eventually over a wide zone. Today a very tough interlayer of polyvinyl butyral, which does not suffer from optical aging defects, is used. With flat glass, laminating is a very straightforward process, but modern curved windshields have necessarily complicated matters because the two layers of glass must be perfectly matched. This matching is achieved by placing paired sheets on a suitably shaped frame in an electrically-heated furnace in which they are caused to soften and take on their required contours. Next, the thoroughly dried plastic is introduced between the two glass layers in an air-conditioned room the temperature of which does not exceed 60° F (16° C) and which has a maximum relative humidity of 30 percent. Preliminary adhesion is obtained by means of mild electrical heating, and pressure supplied by rubber rollers. The assembly is then placed in an autoclave (closed vessel) in which the air pressure is raised to 50 pounds per square inch (3.5 kilograms per square centimetre) and the temperature to slightly above normal boiling point.

The vinyl layer in ordinary laminated glass, though very thin, is quite tough. Severe impacts will crack the glass but will not damage the interlayer; adhesion is such that splinters cannot fly. The process can also be extended to produce laminates that can resist almost any kind of attack; thicker layers of vinyl or glass (or more layers) can be used to make the material proof against deliberate assault by any means up to small-arms fire. Laminated glass also has the virtue of being a far more effective absorber of sound than unlaminated glass of equal thickness. A pistol shot, even at close range, will not penetrate ¾-inch- (19-millimetre-) thick laminated glass. Glass of this type is often termed bulletproof.

Glass in electricity and electronics. The uses of glass in electricity and electronics are too numerous to list; some common application problems, however, deserve mention. The lamp globes and tubes described above contain components largely constructed of glass, usually of a type very different from that of the outer shell. The high temperature frequently met in electrical use and the differing thermal expansions of the components involve the use of special glasses at junction points.

In sodium-vapour lamps, an envelope made of ordinary glass would be useless since the intensely active vapour would quickly destroy it. Chemically resistant glass containing large amounts of alkaline-earth oxides and alumina is not only costly to produce but also falls an easy victim to ordinary atmospheric attack. In consequence, sodium-vapour lamps have an envelope of cheap weather-resistant glass with a thin interior layer of the sodium-resistant material.

Glass in insulation

The great dielectric (electrically nonconducting) strength of glass makes it a valuable insulator; a great deal of glass yarn is used in the electrical industries for insulation purposes. High-voltage power lines are usually suspended from toughened glass insulators made up of as many subunits as circumstances demand. Their great mechanical strength withstands the considerable stresses imposed by the heavy cables as they swing in strong winds; failure, when it occurs, takes place not in the glass but in the high-tensile steel units that link the glass components together. Many specially formulated glasses are used in electronics for such common components as insulators, capacitors, and resistors and for many sophisticated devices employed in radar, television, and computer circuitry.

Miniature electronic components are often far too small for their glass parts to be molded by conventional means. In order to overcome this difficulty, thin glass rods are heated until they are sufficiently plastic to be shaped between precision dies. Sintering processes, which heat a substance to coherence without melting, are also used; finely powdered glass mixed with a removable binder is pressed to shape in dies, and then fired. Larger items can be fabricated by mixing the powdered glass with water and shaping it in a plaster mold; it emerges firm but still damp. After being thoroughly dried, it will retain its shape when fired at high temperature.

Heat-resistant glass. When ordinary glass fails as a result of thermal shock, it usually does so on abrupt cooling, because the surface is subjected to tensile stress by the still thermally expanded interior, which cools far more slowly than on the surface. Generally speaking, thick-walled articles fail more often from thermal shock than very thin ones. Microscope slides and cover slips, and even thin table glasses, can survive considerable thermal shock because there is in them so little interior material to apply a stress to the surface. Toughened glass, too, is fairly resistant. In many glass products, such as industrial chemically-resistant piping, high-temperature lamps, laboratory glassware, industrial thermometers, and ovenware, toughening after shaping is impracticable. These objects in consequence are fabricated from low-expansion glass, the smaller dimensional changes of which reduce thermally induced surface tensile stresses.

Borosilicate glass expands only about one-third as much as common glass for equal changes of temperature; it also has good chemical resistance and is an excellent electrical insulator. Like ordinary glass, it can be used to produce fibres and fabrics; because of their high melting point, these give excellent protection against fire, as well as being good heat insulators.

The low thermal expansion of Pyrex-type glass gives it a particular value in reflection optics because it reduces the changes of optical figure that arise in concave and convex surfaces as a result of their cross sections being different at different temperatures. The first, and most spectacular, use of low-expansion glass for this purpose was the creation of the 200-inch diameter mirror for the large reflecting telescope erected on Mt. Palomar in California. Reflecting telescopes of diameters as small as eight inches (20 centimetres) are being made today from Pyrex or other low-expansion material as a matter of course. Although its thermal expansion exceeds that of Pyrex, aluminosilicate glass may be employed in high temperature applications that also require specially high resistance to alkalies.

Shrunken glass

Shrunken glass in its finished form has less thermal expansion than any glass except pure silica. With its very high melting point, it can be used wherever extreme resistance to thermal shock is necessary. Articles are preformed from special borosilicate glass to a size larger than required; the nonsilicate ingredients are then leached out, leaving the material porous. It is then cleansed and heated until the pores vanish and the article assumes its desired dimensions. It is virtually immune to thermal shock and can be used in applications that involve working temperatures of well over 1,000° C (1,800° F).

Tableware. Among all the methods of glass production used at the present time, those employed in the making of fine tableware remain closest to traditional glass-making techniques. Advantage is taken, however, of the improvement in furnaces and greater knowledge of glass chemistry. The range of colours from metallic oxides in the melt is greater than at any time in the past.

Offhand blowing is still an important process; tools are roughly identical with those of the past. Lead crystal is generally gathered, at temperatures around 1,000° C (1,800° F), from the middle of a fireclay ring, which ensures freedom from any scum or material of anomalous viscosity. The size of the glass gob needed is a matter of judgment, not measurement. The soft glass is then carefully shaped (marvered) on a charred wood block to ensure that it is suitably preformed before blowing, which cannot safely commence until the outer skin is viscous enough to resist expansion sufficiently so that glass flow remains controllable and proper distribution of the material can be assured. Stem and foot are added separately when the globe is firm, but still very hot.

Glassware stems

Stems can be plain or very complex. A hot gob of glass can be squeezed so that a number of evenly separated vertical grooves are formed in it. If these are then folded in they form tubes that remain when the gob is stretched; when the hot stem is twisted, they, too, are twisted, forming a helix of hollow tubes within the stem. In much the same way, the growing stem can be flattened to a square cross section and afterwards twisted. Coloured or opaque white-glass canes can be incorporated and twisted to form helices of almost any desired complexity.

Decoration of glass. Engraving processes of fine ware can be carried out on abrasive wheels if the article is substantial; water is used as a coolant and to wash away sludge. The cuts can be of various sections: flat, V-shaped, or curved (concave or convex). The cuts can be buffed to a polish afterward, on felt wheels, fed with very fine abrasive and water, or smoothed with acid.

Fine cuts on thin material and the very complex relief working on sculptured surfaces is carried out by holding the glass against the edges of rotating copper wheels fed with abrasive in an oil medium. Several dozen different sizes of wheels may be used to complete an engraving.

Diamond point stipple engraving is used occasionally; in this technique, minute specks are fractured from the surface. Considerable freedom of treatment is possible by the drypoint-etching technique, consisting of covering the article with an acid-resistant film, scratching through this coating, and then placing the glassware in hydrofluoric acid.

Masking enables broad areas to be etched by acid vapour or by air blasting with fine abrasives. In commercial glassware, considerable use is made of silk-screen printing methods to apply enamels of various colours to the glass; these are afterward rendered permanent by heat. Organic metals, similarly applied, can be used to create a thin metal film by firing the glass.

Diffusion methods

Diffusion methods can also be used, although their primary employment is in the marking of laboratory ware. A copper-silver stain is first applied by screen printing. When the article is fired, the silver and copper ions enter the glass structure to a depth determined by time and temperature control. The printing, being an integral part of the glass substance, is as permanent as the article itself.

Vacuum flasks and jars. The low thermal conductivity of glass does not prevent the contents of jars and bottles from responding as a result of heat transfer by radiation to changes in ambient temperature. Vacuum flasks, often made of low-expansion borosilicate glass, make direct conduction and radiation of heat through the walls of the container impossible. The flask consists of two spaced containers, fused together around their rims. Small pads between the components prevent flexural variations of the space between them, both during manufacture and use. After being united, the air-separated surfaces are silver plated and washed out. After being dried and heated the flasks are attached to a vacuum pump that exhausts the air from between the walls and the space is then sealed off.

The silvered surfaces are necessary to prevent losses by radiation across the vacuum space. Heat is simply reflected back into the contents and, conversely, to the air surrounding the flask. The only route of heat transfer available is by conduction along the very thin walls of the inner component. This process is so slow that fluids inserted at boiling temperature will still be hot 24 hours later; ice can remain unmelted after two days or more.

PRODUCTION OF SPECIAL GLASS PRODUCTS

Foam glass. A strange but nevertheless useful form of glass that has been called synthetic lava is made in molds from a mixture of ground glass and carbon. When heated, the mixture expands to many times its original volume and sets as a very light, rigid material. Because it is nothing but a mass of thin-walled bubbles, the foam glass can be sawed quite easily; and because the bubbles thus broken and exposed do not communicate with other bubbles, its extreme buoyancy is unaffected. Besides being useful as a buoyant medium, it is employed as insulation, an application in which its rigidity and immunity to insect and atmospheric attack make it superior to natural substances such as cork.

Glass bricks. Entire walls of steel-framed buildings have sometimes been constructed of hollow glass blocks laid with mortar bonding in the same way as ordinary household bricks. Glass bricks are made from molded halves fused together; the partial vacuum created by contraction of the residual trapped air on cooling after sealing makes them highly efficient sound insulators.

Fused spaced window-panes

A similar process is used to unite spaced panes in standard sizes as ready-made double glazing units. The complete and permanent nature of the seal ensures that moisture cannot condense inside the enclosure, makes satisfactory fitting independent of local weather conditions, and greatly simplifies installation problems.

Sulfated glass. The destructive effect of alkaline attack on ordinary glass was described above. Although resistant glasses can be fabricated, their cost or working characteristics can make them impractical in large-scale bottle making. Sulfating is not a glassmaking operation but a form of treatment that consists of changing the constitution of the glass at the surface. The bottles are filled with acid gases, sulfur dioxide and sulfur trioxide. By a process of replacement by diffusion, most of the sodium ions from the surface are removed, with a consequent raising of chemical resistance by factors of up to 100.

Photosensitive glass. By 1943 it had been well established that glass can be rendered photosensitive to ultraviolet light. It was found that the colour of certain types of clear ruby glass could be deepened by exposure to ultraviolet radiation before being subjected to the reheating process that made them acquire colour. The next step was the making of glass in which no colouring would occur during the reheating process without the preliminary ultraviolet irradiation; any desired pattern could be introduced deep inside the glass itself by interposing a suitably designed ultraviolet–opaque mask between the glass and the irradiating source.

Modern photosensitive glasses contain optical sensitizers, such as univalent cerium ions. Radiation readily removes an electron from these ions; when the glass is heated sufficiently, these can be captured by any gold ions that have been included in the glass, so that gold atoms form and remain in coalescence when the glass is cooled. Unlike the silver halides used in ordinary photographic processes, an image formed by these means is completely grainless because the opaque units are well beyond the threshold of resolution in visible wavelengths.

Photochromic glass. Unlike photosensitive glass, photochromic glass does not depend on heat treatment but on the action of ultraviolet or visible radiation in order to darken it; and unlike ordinary photosensitive materials the process of darkening is completely reversible. The action is due to the inclusion of silver chlorides, bromides, iodides, or their mixture in the glass material; these, in processing, form microscopic crystals thinly dispersed throughout the material. The darkening effect is similar to the action that occurs in ordinary photographic processes but is reversible principally, it is thought, because of the very different sizes of the crystals in the two different materials. A typical single crystal in a photographic emulsion is, by volume, many million times as great as the crystal units in photochromic glass and encourages the neutral silver alone to form stable particles. Additionally, in the impermeable glass material, the neutral chlorine atoms do not diffuse from the zones of reaction as in photo emulsions; the silver and chlorine are not removed by other reactions.

Opal glass. An ultraviolet-sensitive glass containing lithium silicate, which can be converted by heat into an opal glass, has special applications because it then becomes far more readily soluble in hydrofluoric acid. The use of a suitable mask makes it possible to irradiate the glass so that an opal print of almost any desired degree of complexity can be reproduced by heat treatment. This print can then be etched right through the glass with acid. The high resolution obtained makes it possible by this

means to "drill" accurately dimensioned, and accurately positioned, holes with distribution densities as high as 320,000 per square inch (50,000 per square centimetre).

Chemically toughened glass. The thermal-toughening process cannot be applied to very thin sections; where these need much more than ordinary flexural strength, chemically toughened glass is used. One method employed involves an ion-exchange process that produces a change in the chemical composition of the surface layer. If a glass that is rich in lithium ions is immersed in molten sodium chloride, many of the lithium ions escape and are replaced on a one-to-one basis by far larger sodium ions. This substitution results in considerable compressive stress being applied to the surface when the glass cools. Flexural strength of up to 98,000 pounds per square inch (6,900 kilograms per square centimetre) can be achieved by this treatment, much more than is possible by thermal toughening. Chemically toughened glass can actually be used to make springs.

Titanized glass. In common with many other forms of glass, bottles do not lend themselves to thermal toughening; maximum strength must be obtained by designing their shapes to withstand the impacts that inevitably result from mechanical handling. They can also be protected to some extent by suitable chemical treatment. The titanizing process, developed in Great Britain, consists of spraying bottles with a titanium compound before annealing, while the bottles are still red hot. Part of the compound volatilizes, leaving a very thin surface layer of titanium oxide, which is soluble in glass. The resulting increase in the working life of returnable bottles, which have to withstand being transported and passing through cleaning and filling plants, is due to the reduction of friction and resistance to the formation of tiny cracks in the treated glass.

Optical fibres. The phenomenon of total internal reflection described at the beginning of this article allows light to be piped around bends through the interior of a glass rod. As long as the ratio of the rod diameter and radius of curvature of the bend is not such as to allow internally reflected rays to arrive at another point of the interior surface at less than the critical angle, only absorption losses will occur.

Glass fibres are essentially very thin rods. It follows that a quarter-inch- (six-millimetre-) diameter bundle of fibres can convey light around a much sharper curve than a single rod of the same diameter. If the individual fibres are sufficiently fine and coherently arranged, the opposite ends of the bundle can be ground and polished. If one end is placed in contact with, or very close to, an object, the image of that object will appear at the distant face. Flexiscopes made from bundles of optical fibres for the investigation of otherwise inaccessible sites are used in medicine and industry. Very small bundles are called optical catheters.

The diameter of individual fibres must be extremely small for good resolution; very fine fibres are hard to handle. The task is simplified by first drawing together a bundle of coarser fibres, embedded for protection in a sheath of matrix glass. This group is then drawn together, like millefiori glass (described above) and can be stretched until it is of sufficiently small diameter, normally a few microns. The multiple fibres can be wound on a drum and afterward used to make up coherent bundles of fibrescopes.

Bundling optical fibres

Short bundles of fibres can be carefully stacked and fused together as a mass. The resulting slab or sheet has very different properties from those of ordinary glass. When its surfaces are ground and polished, light falling on a point at one surface will be transmitted without deviation to a corresponding point on the distant surface. Used as a faceplate on a cathode-ray tube it acts as an imaging screen that, because it directs the light as a bundle of parallel units, overcomes the difficulties normally arising because of light scatter when photographing the display.

Electrically conducting glass. Aircraft windshields, especially supersonic windshields, must withstand environmental conditions very different from those in automobiles. Air friction can raise the surface temperature of the glass to about 310° F (150° C) at low-level high-speed flight; and the ambient temperature may be as low as −200° F (−130° C) at some altitudes.

Laminated toughened glass with interlayers of vinyl up to one-quarter inch (six millimetres) thick is used; in military aircraft, four toughened glass sheets and three interlayers of plastic bonded together give a large degree of protection against bullets and flak splinters. A plating of gold, thin enough to be transparent, makes it possible to pass an electric current through the assembly to warm the glass and prevent ice formation. Very thin wires, less than $\frac{1}{1000}$ inch (0.03 millimetre) thick, can also be embedded for this purpose.

Optical windows. When photographing objects in supersonic wind tunnels, vacuum chambers, or any site into which the investigator or his instruments cannot easily be introduced, the camera is aimed through a special window fitted with glass the surfaces of which are exactly parallel, thus permitting undistorted photography. Even large optical windows are unlikely to deviate from true flatness by more than one-half wavelength of sodium light. For use in applications for which protection against X- and gamma radiation is required, very thick windows of extremely dense flint glass containing up to 80 percent of lead oxide are employed.

Pure silica glass. Ordinary glass is useless for ultraviolet transmission; large aluminized optical mirrors are necessary for ultraviolet spectroscopy in astronomy. Silica itself, however, is transparent to ultraviolet, although its great viscosity even at very high temperatures makes it unsuitable for molding, by ordinary means, of optical lens blanks.

The contemporary method of making 99.5 percent silica glass (fused quartz) satisfies most applications. Even

higher purity, however, can be obtained by first making disks of silicon tetra-chloride. Electrochemical methods (hydrolysis) are then employed at high temperatures, to cause the hydrochloric acid to be driven off in the form of a vapour and to leave a disk of virtually elemental glass. This is transparent to ultraviolet and near infrared light as well as to the entire visible spectrum.

Purity is such that the glass composition must be described as 100 percent silica because the impurities amount to no more than one or two parts per 100,000,000.

PRODUCTION STATISTICS

Table 2 shows the international trade in five glass categories for selected countries in 1969.

BIBLIOGRAPHY. T.K. DERRY and T.I. WILLIAMS, *A Short History of Technology from the Earliest Times to A.D. 1900* (1960), provides a useful summary of the development of glass technology. C.J. PHILLIPS, *Glass: The Miracle Maker* (1941), is intended to be of interest and use to such users of glass as architects and engineers. J. HOME DICKSON (ed.), *Glass: A Handbook for Students and Technicians* (1951); and F.J.T. MALONEY, *Glass in the Modern World* (1967), are both useful introductions to the subject for non-specialist readers with some scientific or technical knowledge, and the latter is probably the most up-to-date work of this type currently available in English. F. GIFFIN, *Glass* (1963), is suitable for non-scientific readers. Among more highly technical studies, G.O. JONES, *Glass* (1956) and G.W. MOREY, *The Properties of Glass* (1956), both contain a great deal of useful data; L. HOLLAND, *Properties of Glass Surfaces* (1964), is an exhaustive theoretical study of a narrower and more specialized field. B.E. MOODY, *Packaging in Glass* (1963), deals with the production of bottles and jars of most kinds as well as with their design and with the associated problems of filling and mechanical handling.

(Fr.J.M.)

Glassy State

Glass is a state of matter best defined by the process that produces it: when a substance in the liquid state is cooled to a rigid condition without any crystallization having taken place, the substance is said to be in the glassy state. As a liquid cools, the vibration of its atoms due to heat decreases and their spatial arrangement becomes less open. A steady contraction in the volume of the liquid results. At the freezing point, a liquid that crystallizes releases heat (called heat of fusion; the energy required to keep atoms in a liquid state is greater than the energy required to keep the same atoms in a crystalline state) with a sharp reduction in total volume as the atoms are rearranged into the crystal state. On further cooling, the crystal contracts much less rapidly because no more changes take place in the configuration of the atoms, even though the atomic, thermal, or heat, vibrations still continue. If the liquid can be cooled below its freezing point without crystallization, the supercooled liquid will be in internal thermodynamic equilibrium, in contrast to the condition of a crystallizing liquid at the freezing point. This means that the available free energy of the supercooled liquid is less than the available free energy in any other structure into which the atoms could rearrange themselves and, therefore, the supercooled structure will not by itself change. It needs energy to do so and it can remain in a precariously stable, or what is called a metastable, state until the energy is supplied. If complete nuclei form, or if crystals are dropped into the supercooled liquid, freezing will begin at those points with consequent release of heat of fusion. The system will no longer be in internal equilibrium and crystallization will spread through it.

GENERAL PROPERTIES OF GLASS

Volume and temperature relationship. Figure 1 shows typical volume changes plotted against temperature changes, and the resulting graphs give a general description of glassy state. A liquid at A is cooled to the freezing point at B. The volume shrinks as indicated from A to B and then contracts drastically from B to C without change in temperature (heat must be constantly removed from the system), as the liquid turns into a crystal. Further cooling results in moderate contraction as shown by CD. But if the liquid does not freeze at B, shrinkage continues smoothly through B on into the supercooled state to E. On further rapid removal of heat, the rate of contraction begins to change and from F to G it approximates that of the crystal. In the range E to F the atomic adjustments necessary for configurational contraction occur slowly enough to be measurable, and a glass transition temperature, T_f, is defined for a particular experiment by extending LF to cut the extended line BE.

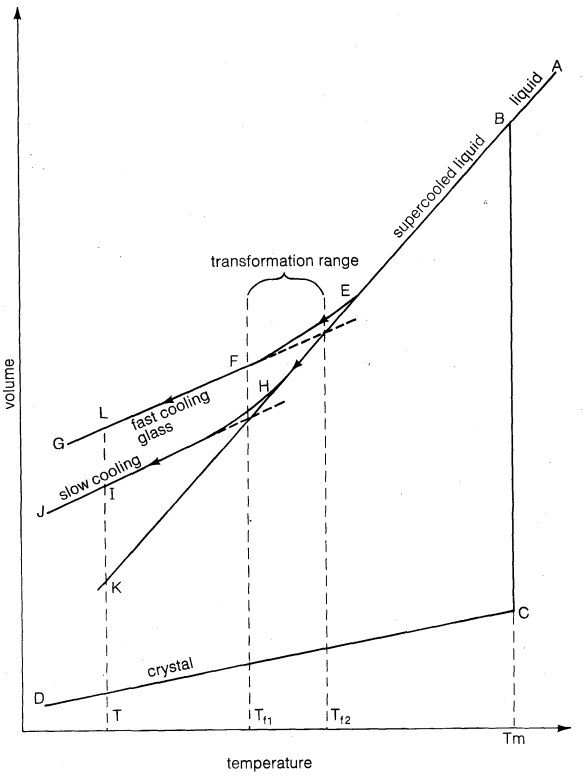

Figure 1: Volume–temperature plots for glasses, liquids, and crystals (see text).

It is more correct, however, to speak of a transformation range of temperature between the values T_{f2} and T_{f1}, which are defined by the attainable cooling rate limits. Below the transformation range the material is a glass and is in a thermodynamically unstable state. If it is cooled quickly enough to be following the line FG, and if the cooling is then stopped and the temperature held constant at T, say, the glass will slowly contract from L to K. The glass is then said to have been stabilized. The slower the rate of cooling, the further the line EK is followed, and BEHIJ is the curve obtained for a glass-forming liquid subject to a slower cooling rate than that experienced by the liquid represented by BEFG. Ordinarily, eventual departure from the equilibrium line will always occur because of the rapidly increasing times necessary for atomic rearrangement. Thus a particular glass composition has a "configurational temperature," or "fictive temperature" (T_{f1}, T_{f2}), which corresponds to the structural configuration frozen in at that temperature and persisting at lower temperatures.

Stabilized glass condition

Viscosity and temperature relationship. The variation of viscosity with temperatures indicates the ease of atomic rearrangements within the glass and is an essential property of glass that is utilized in industrial processes.

Molten glass may have a viscosity of about 10^3 poises (a poise is the unit of coefficient of viscosity and expresses the force required to maintain a unit difference in velocity between two parallel planes separated by one centimetre of fluid; one poise = one dyne-second per square centimetre) somewhat stiffer than honey on a cold day, and if cooled it gets much stiffer. At the temperatures at which molten glass can be shaped into useful articles its vis-

cosity lies between 10^4 and 10^8 poises, well below the 10^{13} poises characteristic of glass in the transformation range. At this viscosity, the time required for the stress of distortion to be relaxed at constant strain is about one minute and the time scale for atomic rearrangements is similar. In the transformation range the physical properties are time-dependent, and below the transformation range the configuration is fixed, essentially, and the glass has the general properties of an elastic solid.

The effect of composition on glass properties. The wide range of the properties of glasses depends on their composition, and special effects result from the presence of various modifying agents in certain basic glass-forming materials (see below, *The structure of glass*).

Silica glass formers

One of the most important glass-formers is silica (SiO_2). Pure crystalline silica melts at 1,710° C. In pure form, silica glass exhibits such properties as low thermal expansion, high softening temperatures, and excellent chemical and electrical resistance. In pure form, it is relatively transparent over a wide range of wavelengths to visible and ultraviolet light, and to ultrasonic waves.

The high viscosity and melting temperature of silica glass are affected by the presence or absence of other materials. For example, if certain materials called fluxes are added, the most important being soda (Na_2O), both the viscosity and melting temperature can be reduced. If too much Na_2O is added, the resulting glass is readily attacked by water, but if stabilizing oxides, such as lime (CaO) and magnesia (MgO), are present in suitable amounts, the glass becomes more durable. Most commercial glass has a soda–lime–silica composition and is produced in vast quantities for plate and sheet glass, for containers, and for lamp bulbs.

In soda–lime–silica glasses, if lime is replaced by lead oxide (PbO), and potash (K_2O) is used as a partial replacement for soda, lead–alkali–silicate glasses result that have lower softening points than lime glasses. The refractive indices, dispersive powers, and electrical resistance of these glasses are generally much greater than those of soda–lime–silica glasses.

Boric oxide (B_2O_3), itself a glass former, acts as a flux when present in silica and forms borosilicate glass and the substitution of small percentages of alkali and alumina increase the chemical stability. It also exhibits low thermal expansion, high dielectric strength, and high softening temperature.

Aluminosilicate glasses find applications similar to those of borosilicates, but the former can stand higher operating temperatures; glasses with relatively high alumina contents and no boric oxide are exceptionally resistant to alkalies.

Nonsilica glass formers

The above glasses all have silica as the glass former. With other glass formers, glasses have special properties. For example, if boric oxide (the basis of Lindemann glass) is present, X rays are transmitted and rare-earth glasses will exhibit low dispersion and a high refractive index. Phosphate glasses (used as optical glasses) based on phosphorus pentoxide (P_2O_5), are highly resistant to hydrofluoric acid, and act as efficient heat absorbers when iron oxide is added. The Table gives the compositions and physical properties of some typical commercial glasses of the types described.

THE STRUCTURE OF GLASS

Absence of long-range order. A glass is essentially a substance that has a frozen-in, liquid type of structure characteristic of that substance at a higher temperature than the actual temperature of its glassy state. Figure 2 shows, in two dimensions, the ways in which the atoms of an imaginary two-dimensional oxide (G_2O_3) would be arranged as a crystal (A) and as a glass (B). This imaginary oxide is the two-dimensional analogue of the three-dimensional tetrahedral silicon dioxide (SiO_2) in which each silicon atom is bonded to four oxygen atoms. In the crystal the structural unit is repeated regularly throughout the material and the crystal, therefore, shows long-range order. The structure of glass shows no such order. Although in both cases the number of bonds per atom is the same, in the amorphous structure of glass the bond angles are slightly distorted, and there is no long-range regularity.

X-ray evidence of structure. The broad X-ray-diffraction patterns for a glass are similar to those obtained for a liquid and they are in contrast to the crystal patterns that show sharp lines. The results are expressed in the form of radial distribution curves, two of which are shown in Figure 3. These graphs are plots of radial density; that is, they give the probability of finding a second atom at a given distance from the reference atom. For silica glass, a peak occurs at about 1.6 angstroms, which coincides with the average silicon-oxygen (Si–O) distance in crystalline silica and silicates. The area under this peak

Characteristics of Various Types of Glass

	fused silica	soda–lime–silica	borosilicate	alumino-silicate	lead
Approximate composition*	SiO_2 99.9% H_2O 0.1%	SiO_2 73% Al_2O_3 1% Na_2O 17% MgO 4% CaO 5%	SiO_2 81% Al_2O_3 2% B_2O_3 13% Na_2O 4%	SiO_2 62% Al_2O_3 17% B_2O_3 5% Na_2O 1% MgO 7% CaO 8%	SiO_2 56% Al_2O_3 2% Na_2O 4% K_2O 9% PbO 29%
Coefficient of thermal expansion (linear expansion per °C × 10^7)	5.5	93	33	42	89

Density (g/cm³)	2.20	2.47	2.23	2.52	3.05

*These compositions are typical of the various glass types. †Temperature at which internal stresses are reduced significantly over a few hours. ‡Temperature at which internal stresses are reduced significantly over a few minutes. §Temperature at which glass will rapidly deform under its own weight. ‖The strain point and softening point roughly define the annealing range.

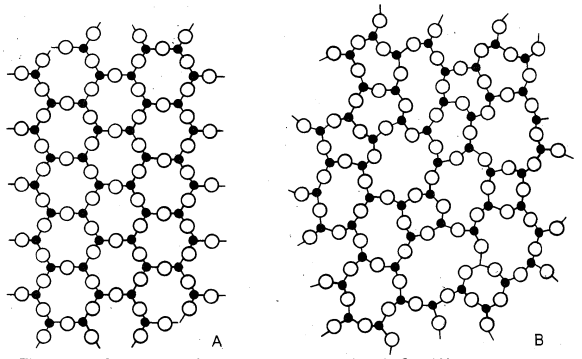

Figure 2: Structure of an imaginary oxide, G_2O_3, (A) as a crystal and (B) as a glass.

in the radial distribution curve shows that the number of oxygen atoms about each silicon atom is 4.3, which, within experimental error, is 4, and 4 is the coordination number of silicon by oxygen in crystalline silica and silicates. Other peaks and humps in the curve are thought to correspond to various characteristic interatomic distances in the silica. In the sodium–silica glass, for example, a new peak appears that probably represents the sodium–oxygen (Na–O) distance, giving an average of six oxygens near each sodium atom. Figure 3 also demonstrates an important property of glasses, namely, that they possess short-range order but no long-range order. The sharpness of the peaks is a measure of the amount of disorder present, and the peaks broaden to give a fairly smooth curve after a few interatomic distances confirming the lack of long-range order.

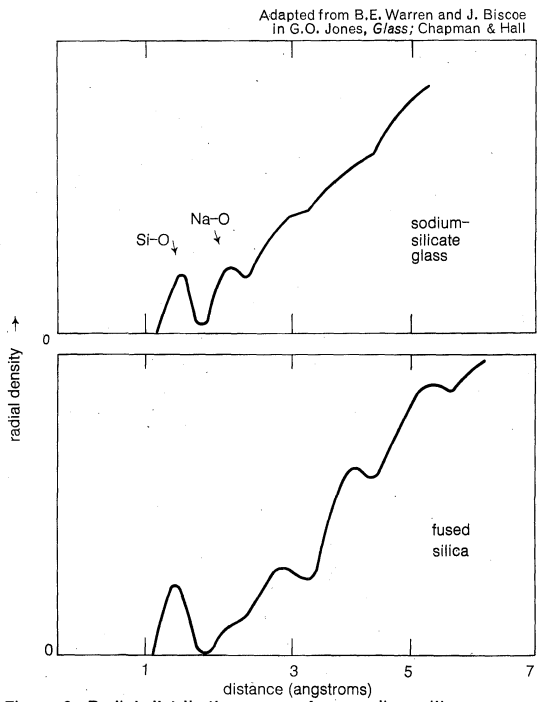

Figure 3: Radial distribution curves for a sodium–silica glass and for pure fused silica (see text).

Functions of network modifiers and glass formers. Network modifiers, in the form of large metallic cations (positively charged atoms), weaken the structure. Although it occupies a space in the open structure, the modifier removes one of the strong directional oxygen–silicon bonds from the basic network and replaces it with a weaker nondirectional bond, thereby lowering the viscosity of the glass. Alkali and alkaline-earth ions act as network modifiers.

Examples of elements other than silicon whose oxides, sulfides, selenides, and tellurides form strong directional bonds and act as glass formers are boron, phosphorus, germanium, vanadium, and arsenic. Network modifiers, with their low bond strengths and property of lowering the viscosity, include sodium oxide and calcium oxide. There is also a class of substances whose oxides are known as intermediates, including titanium, aluminum, thorium, and beryllium. Alone, intermediates will not form glasses but do so in combination with glass formers. They can enter the network if a suitable modifier oxide is available; if not, they act, themselves, as modifiers.

Spectroscopy of glasses. X-ray-diffraction studies of glasses give fairly reliable information about the number of oxygen atoms surrounding the small, highly charged, glass-forming cations, but far less about the positions of the modifying alkali ions. Spectroscopic techniques yield further useful information about the glass structure.

In spectroscopy, differences between allowed energies or quantum states of the system are measured, and these results are compared with theoretically calculated quantum states of a particular arrangement of atoms.

In the infrared region of the spectrum, the allowed energies, or quantum states, are associated with the vibrational motion of atoms but little theoretical progress toward understanding can be made because, in solids and liquids, the vibrations of all the atoms together must be considered. Spectral absorption peaks can, however, often be matched with observed peaks for crystals of known structure. Correspondence is taken to indicate the presence of particular groups of atoms, or "complexes."

In the ultraviolet region, the quantum states are those associated with the movement of an electron from a negative oxygen ion to a positive ion, or cation, but a large contribution is made by energy of vibrational modes (called phonons), which interact with the electronic energies to give intense broad absorption bands.

In the visible region, absorption bands arise from transition metal and rare-earth ions in solution in the glass. In this case the quantum states are only slightly modified by the nearest neighbours.

Deductions from ligand field theory

These nearest neighbours, which surround the central glass-forming ion, are known as ligands. Their modifications of the quantum states, and the symmetry of their arrangement around the central ion can be deduced from ligand field theory. This theory enables the relative energies of the absorption peaks to be derived and also allows the absorption intensities to be classified in groups according to the symmetry of arrangement of the nearest neighbours. It has been of great use in recent years in the study of coloured glasses.

Solution and colloidal colours in glass. Normally, in the visible region, only ions that give rise to colour need be considered when studying the transmission properties of glass because the characteristic absorptions due to vibration of the silicon–oxygen bond lie outside this region. The most common colouring ions are those of the transition metals cobalt (Co), chromium (Cr), copper (Cu), manganese (Mn), and iron (Fe). The colours are affected by three major factors, namely, the nature and concentration of the colouring ion, the composition of the base glass, and the oxidation state of the colouring ion.

Small quantities of the colouring ion, about one-tenth of a percent, are sufficient to colour glass. For this reason, the yellow-green colour caused by iron is a serious problem in the glass industry. This is alleviated by the choice of pure sands and by the addition of decolorizers. Ferrous iron absorbs energy in the near infrared, and its broad absorption band spreads into the visible spectrum causing a blue colour. The decolorizer contains an oxidizing agent, which converts iron cations with 2 charges (Fe^{2+}) to cations with 3 charges (Fe^{3+}), and also a little selenium and cobalt. Addition of the latter elements, together with the ferric iron, Fe^{3+}, give a residual absorption that is essentially neutral. The manganese dioxide, MnO_2, which was formerly used, oxidized the iron and gave a complementary purple colour, but was less stable.

Colour in glass can also be caused by colloidal precipitation of very small metallic crystals, such as those of copper or gold, to produce a "ruby" colour. The particles develop when a glass of suitable composition, previously

melted under certain reducing conditions, is heat treated. The particle size is critical, between 10 and 1,000 angstroms, and selective absorption then gives the glass its red colour.

Nucleation and crystallization in glass-forming liquids. It was noted above that a supercooled glass-forming liquid is in a metastable state (a stability that is maintained only by a slight margin over an unstable state) and that if crystals or crystal nuclei are introduced and freezing can begin, the crystallization will spread throughout the liquid.

Two aspects of the crystallization process must be considered separately, namely, the rates of formation of nuclei and their growth. So many nuclei are present in normal freezing processes that the crystallization process depends essentially upon the growth rate, and as this is negative above the freezing point, and very large and positive just below it, the liquid freezes at, or very near, the expected freezing point. For liquids (typically the highly viscous glass formers) that can be greatly supercooled, however, the crystallization rate also depends critically on the rate of formation of nuclei. Nuclei can be introduced from outside (heterogenous nucleation) or can appear spontaneously within the supercooled liquid (homogeneous nucleation). Homogeneous nucleation occurs because of thermal fluctuations within the liquid; consideration of the contribution of the surface energy of the embryonic nuclei to their total free energy shows that, at any given temperature, there is a critical size below which the nuclei are unstable and redissolve, and above which they can grow.

Homogeneous nucleation

When nucleation and crystal growth occurs in glasses, it is known as devitrification. It is most marked in glasses in which the rates of nucleation and crystal growth nearly coincide when plotted as functions of temperature. Closeness of these curves results in nucleation and crystal growth over a wide temperature range. More stable glasses have a high viscosity at the freezing point, and crystal growth, which proceeds by diffusion process at the surface of the crystal, is slowed down. Heterogeneous nucleation, however, can still occur, especially at glass surfaces, when impurity particles are present.

Studies of nucleation and crystallization in glasses have been made in recent years. One result of these efforts was the discovery of a glass containing a small amount of dissolved metal, such as gold or silver, which, after exposure to ultraviolet radiation and subsequent heat treatment, develops a colour caused by the growth of small metal particles in the glass. If this photosensitive glass is heat treated further, the particles act as nuclei, and opalescent regions of the glass devitrification products are formed wherever the glass was exposed to the ultraviolet radiation. Much less resistant to chemical attack than the parent glass, these regions are dissolved away while the parent glass remains. By the commercial use of this process, pieces and patterns of desired shapes can be obtained—for instance, fluid amplification elements.

Glass ceramics

A glass has been produced that can be changed almost completely into crystalline material—the glass ceramic. In application, an article of suitable glass composition fabricated by the usual method is subjected to appropriate heat treatment to convert it into a ceramic. Such materials are extremely inert chemically and can be designed to have either zero or a very small expansion coefficient.

SPECIFIC PROPERTIES OF GLASS

Mechanical properties. Glass rods with untouched surfaces have a tensile strength of 500,000 pounds per square inch. By considering the energy changes involved in the surfaces formed by fracture the theoretical strength of glass is estimated to be about 1,000,000 pounds per square inch. Glass articles normally show strengths that are much lower, about 30,000 lb/in^2; and this difference is due to submicroscopic surface flaws that, produced by the slightest contact with another body, act as stress magnifiers. Glass in ordinary use, therefore, is far less strong than it would be in a flawless state. Although the flaws have the same stress-reducing effect as dislocations in crystals, the exact identity of the flaws remains uncertain. Their presence, however, and number can be revealed by treating the glass with some modifying agent; for example, by immersing glass in molten lithium nitrate, the sodium in the surface is exchanged for lithium. The foreign layer that is produced is in tension when the glass cools and minute cracks develop at the flaws.

At temperatures below the transformation range, glass behaves as a solid and stresses will be present if the temperature varies within a glass object; a piece of hot glass cooled suddenly will contract more on the outside than on the inside; the further contraction of the outer layers is thus prevented and they are put into tension; the higher the thermal expansion coefficient of a glass is (the more it expands for each degree rise), the greater this tension will be. Some glasses expand very little. Thus, fused silica has excellent resistance to heat shock, while borosilicate glass can undergo repeated reheating below the transformation range without cracking. It makes excellent ovenware.

In the transformation range the glass behaves instantaneously as a solid, an immediate elastic strain being produced when an external force is applied, but this strain increases if the force is not removed. If the force is continually reduced to keep the strain constant, the internal stress gradually disappears. The rate of this change depends on the viscosity of the glass. When the coefficient of viscosity, η, equals 10^{13} poise, the stress is halved in about one minute. If a temperature gradient (a variation of temperature) exists in a piece of glass in the transformation range, the resulting stresses die away and the glass then has a temperature gradient but is stress free. On cooling to room temperature the hotter interior has to contract more than the outer layers and is, therefore, in tension while the outer layers are in compression. These stresses remain until the glass is reheated to the transformation or annealing range. The principle is applied in annealing, which is a process of minimizing the permanent stresses in glass by heating until they disappear and then cooling slowly so that only very small temperature gradients, and ultimately, therefore, only very small stresses, appear. Unless a glass article is properly annealed it might break spontaneously after cooling. Large volumes of stress-free uncracked glass are rare and difficult to achieve. Annealing for exacting uses, such as in some optical applications, moreover, involves more than the removal of thermal stresses; the atomic structure of the glass will vary within the piece unless all parts of it have had exactly the same thermal history through the transformation range.

Annealing

Chemical properties. Common glasses are chemically inert but reactions with many substances do occur slowly. In contact with aqueous media the reaction begins with an exchange of hydronium ions, H_3O^+, for sodium ions, Na^+. (Hydronium ions exist in equilibrium with hydroxyl ions, OH^-, in water.) Immediately, a surface layer starts to build up in which the sodium ions in the glass have been replaced by hydronium ions. For the reaction to continue, sodium ions must diffuse through this surface layer. While the silica itself dissolves slowly, eventually the rate of diffusion of sodium ions and the rate of removal of silica may be such that the surface layer, although moving into the glass, will remain at a constant thickness.

With commercial glasses these conditions are hardly attainable. The complexity of the process makes it very difficult to design accelerated test procedures. Components such as alumina may be added to increase the chemical durability of the glass. The action of alumina is to provide sites that hold sodium ions on the surface, thus producing a more uniform layer of sodium ions and lowering their rate of diffusion. The occupancy of atomic sites on the glass surface determines the behaviour of glass when it is used as an electrode in determining hydrogen ion (H^+) concentrations. When measuring hydrogen ion concentrations, it is important that the surface sites on the electrode be occupied by protons. Normally,

The effect of pH

with glass electrodes, as the hydrogen ion concentration decreases, and the pH value rises (pH is a logarithmic expression of hydrogen ion concentration) to a sufficiently high pH value, the electrode emf (electromotive force or voltage) is no longer proportional to the hydrogen ion concentration; this produces an "alkali error" because the sites have become occupied by sodium ions instead of by protons. If a glass contains a high proportion of alumina, the change point in the measurement can occur at quite low pH values so that over a large range of pH the electrode can be used to determine sodium ion concentrations. There is a close correlation between the electrode behaviour and variation of durability with the pH of the attacking solution.

Optical properties. Optical glass must be homogeneous. Inhomogeneities are of two general types, chemical and physical. Chemical inhomogeneities include gas bubbles and blisters, unmelted batch materials, and devitrification products, while physical inhomogeneity can result from the presence of strain in the glass caused by faulty annealing. Chemical and physical inhomogeneities may result in glass that differs in composition, and therefore in refractive index (the measure of the change in direction of light as it passes from one medium into another) from place to place in the glass.

Batch materials for optical glass manufacture must be of exceptionally high purity in order to give a highly transparent glass free from colour. In order to ensure chemical homogeneity the molten glass is stirred to promote thorough mixing. Physical inhomogeneity is minimized by extremely slow annealing (see above *Mechanical properties*).

The optical characteristics of any glass can be completely described by giving two values n and ν, n being the refractive index and ν the reciprocal of the dispersive power, a property related to the angular separation of two rays of light of different colours, passing through glass, and called the constringence. Thus any glass can be represented by a single point on an n-ν plot, as shown in Figure 4.

The tiny dark-shaded area (Figure 4) represents the entire range of optical glasses available in 1880. All earlier optical glasses were either soda–lime–silica crown glasses or potash–lead–silica flints, with a very limited range of optical properties and a dispersive power that increased with the refractive index. By controlled scientific experiments it was possible to add to these two glass types a range of optical glasses such as borosilicate crowns, barium crowns, barium flints, and borate and phosphate glasses. From these, pairs of crown and flint glasses could be used in the manufacture of lenses that gave images free of colour fringes. The new glasses also had a greater diversity in both refractive index and dispersive power and much more versatile optical systems became possible. The unshaded area of Figure 4 shows how far the range had been extended by 1934.

The remaining shaded area in Figure 4 has been filled in by glasses developed since 1934, owing largely to the introduction of rare-earth and fluoride types. New glasses of high dispersion combined with low refractive index, and of high refractive index combined with low dispersion, were especially sought. It was shown that optical glasses could be made by replacing silica with boric oxide, with additions of rare earths such as lanthana and thoria, and other oxides such as titania, and tantalum and tungsten oxides. These gave optical glasses with very high refractive indices but low dispersions.

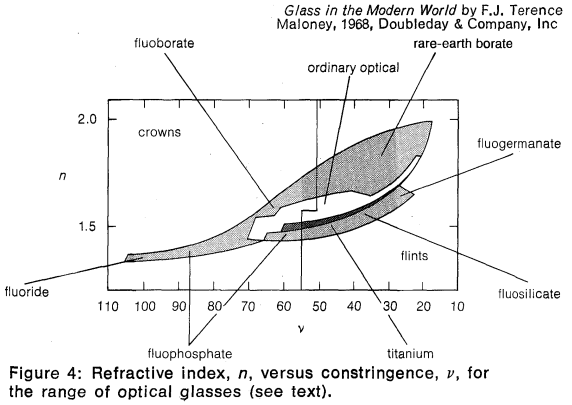

Figure 4: Refractive index, n, versus constringence, ν, for the range of optical glasses (see text).

The range of available dispersions and refractive indices was further extended by the use of fluosilicate flints, or "super flints"—glasses with dispersions greater than conventional flint glasses of the same refractive index. Figure 4 demonstrates the importance of glasses such as the fluoborates, phosphates and germanates, and even types of all-fluoride glasses. These glasses, with their very low dispersions and refractive indices, have an extended range of radiation transmission in both the infrared and ultraviolet.

Thus modern optical designers have available to them a very wide range of glasses with independently varying dispersions and refractive indices. This enables them to design versatile optical systems actually requiring fewer glasses with slightly differing compositions than previously; digital computers now aid in the work.

Electrical properties. All glasses containing alkali ions are electrolytic conductors and show great changes in resistivity with temperature. At room temperature, in addition to volume conductivity through the whole body of the glass, there is a conductivity restricted to the surface, caused by a layer of adsorbed moisture that decreases the surface resistivity. In a very humid atmosphere the surface conductivity of high-alkali glasses can be many times the volume conductivity. The effect is reduced by silicone surface treatment and disappears when the glass is tested in a vacuum.

In volume conductivity nearly all the current is carried by monovalent alkali cations. For this reason, the resistivity is determined mainly by the amount of alkali present and, to a lesser degree, by the network structure and thermal history of the glass. At room temperatures the volume resistivity can be as low as 10^6 ohm centimetres for certain high-alkali glasses; for glasses in which trace alkali conductivity is blocked by the addition of divalent ions, it can be as high as 10^{20} ohm centimetres.

Semiconductors

In recent years a new class of semiconducting glasses has been discovered that shows a decrease in resistivity with increasing temperature, but no polarization. Conduction occurs by electrons or holes (fictitious electron vacancies for which the electrical charge is positive) or both, and such glasses can have a resistivity as low as 10^4 ohm centimetres at room temperature. Typical glasses of this type contain arsenic, selenium, tellurium, and germanium. Glasses that contain large amounts of transition metal ions (for example, vanadium oxide) also conduct by the passage of electrons and show the same low resistivities.

Amorphous semiconducting materials, in particular some chalcogenide glasses, have been used in electronic switches, and a new technology is beginning to develop. An advantage claimed for amorphous switching devices, over conventional crystalline semiconductor switch types, is that they are basically less susceptible, or more insensitive to, the degrading caused by neutron or X-ray irradiation in "hot" environments or to the radiation of outer space.

BIBLIOGRAPHY. Modern general works include: F.J.T. MALONEY, *Glass in the Modern World: A Study in Materials Development* (1967), an excellent, comprehensive book for the general reader describing the history, technology, and properties of glass; and J.R. HUTCHINS and R.V. HARRINGTON, "Glass" in the *Encyclopaedia of Chemical Technology*, 2nd ed., vol. 10, pp. 533–604 (1966), a review article with an extensive bibliography, covering all aspects of modern glass science and manufacture. The following references contain a great deal of useful information: G.O. JONES, *Glass* (1956), a clear, short introduction to the physics of the glassy state; G.W. MOREY, *The Properties of Glass*, 2nd ed. (1954), a collection and discussion of the measurements of the physical properties of glasses and of their dependence on chemical composition; and F.V. TOOLEY (ed.), *Handbook of Glass Manufacture,*

2 vol. (1953), a reference book on all aspects of glass technology. There are no detailed modern texts on the glassy state but recent advances may be found in the following journals: *Physics and Chemistry of Glasses;* and *Glass Technology* (bi-monthly), *Journal of the American Ceramic Society* (monthly), both containing extensive abstracts; and the *Journal of Non-Crystalline Solids* (bi-monthly).

(R.W.D.)

Gluck, Christoph

A leading composer of the 18th century, Gluck reversed the Italian opera tradition in which music took precedence over the drama and thus decisively influenced the development of musical drama in France, Italy, Austria, Sweden, and England. He was born on July 2, 1714, at Erasbach, near Berching, in the Upper Palatinate. His paternal forebears, mostly foresters, were of the border territory between the Upper Palatinate and Bohemia; nothing is known of his ancestors on his mother's side. His father, Alexander Gluck, had moved to Erasbach as a ranger in 1711–12; the family then moved to Reichstadt near Böhmisch-Leipa in Bohemia. Between 1722 and 1727 they lived near Böhmisch-Kamnitz and after this, until 1736, in Eisenberg (near Komotau), where Alexander Gluck held the post of master forester to Prince Philipp Hyazinth von Lobkowitz.

Gluck, painting by Joseph Siffred Duplessis, 1775. In the Kunsthistorisches Museum, Vienna.

Early life

Christoph Willibald, whose father probably intended for him to continue in the family employment of forestry, at an early age showed a strong inclination toward music. In order to escape from disagreements with his father, the young Gluck finally left home and, supporting himself by his music, made his way to Prague, where he played in several churches, began university studies (1731), and continued his musical studies. He went to Vienna in the winter of 1735–36. There he was discovered by a Lombard nobleman who took him to Milan, where Gluck, apart from fulfilling his duties in the Melzi family chapel, spent four years studying composition with Italian organist and composer Giovanni Battista Sammartini, from whom he learned the new Italian style of instrumental music. Probably six trio sonatas, consisting of two movements with a minuet as conclusion, printed in London in 1746 were the fruits of his studies with Sammartini in Milan. Besides the six "London" sonatas, Gluck probably composed further trio sonatas under Sammartini.

On December 26, 1741, in the Teatro Ducal in Milan, Gluck had his first great dramatic success with his first opera, *Artaserse*, to a libretto by P. Metastasio. Until 1745 there then followed an annual succession of operas for this theatre: *Demofoonte* (1742), *Arsace* (in collaboration with G.B. Lampugnani; 1743), *Sofonisba* (1744), and *Ippolito* (1745). In addition Gluck wrote *Cleonice* (*Demetrio*) (1742) and *La finta schiava*, a *pasticcio* (1744), for Venice; *Il Tigrane* (1743) for Crema; and *Poro* (1744) for Turin. In these early works, of which mostly only fragments have survived, Gluck largely followed the existing operatic fashion that was Italian—melodic but never grand, charming without intensity. Occasional intensely passionate outbursts and the beginning of characterization, however, foreshadow the great dramatic composer he was to become. In 1745 Gluck, by then well known as an operatic composer, was invited to England at the instigation of Lord Middlesex, director of Italian opera at the Haymarket Theatre, London, in order to challenge Handel's solid hold on London music goers. The plan at first failed when, because of the political chaos caused by the Stuart rising, all theatres in London were closed before Gluck arrived in England. When the situation became calmer, theatrical activities recommenced with a performance of Gluck's opera *La caduta de' giganti* on January 17, 1746; the liberetto, by A.F. Vanneschi, glorified the hero of the day, the Duke of Cumberland, after his victory at Culloden over the forces of Prince Charles Edward, the Stuart claimant to the British throne. This work, as well as Gluck's second London opera, *Artamene*, produced on March 14, 1746, consisted largely of music from his own earlier works, lack of time having forced him to this device. Neither opera met with success. On March 25, shortly after the production of *Artamene*, Handel and Gluck together gave a concert in the Haymarket Theatre consisting of works by Gluck and an organ concerto by Handel, played by the composer. Gluck had won Handel's interest despite the latter's later much-quoted criticism of Gluck's lack of contrapuntal ability (Handel said that Gluck "knows no more counterpoint than my cook"). Gluck himself, according to the Irish singer Michael Kelly, tried to emulate Handel, whom he described as the "divine master of our art."

London: competition with Handel

After he left England (possibly in 1746) Gluck came into contact with two travelling opera companies, one of which, on June 29, 1747, performed his opera-serenade *Le nozze d'Ercole e d'Ebe* at Pillnitz Castle, near Dresden, on the occasion of the double wedding between the electoral families of Bavaria and Saxony. By early 1748 at the latest, Gluck was back in Vienna, at work on Pietro Metastasio's *Semiramide riconosciuta*, with which, on May 14, 1748, the Burgtheater was inaugurated. It proved a brilliant success for the composer. At that time Gluck met his future wife, Marianne Pergin, the 16-year-old daughter of a rich merchant, and in the same year as conductor of the P. and A. Mingotti Travelling Opera company, he travelled via Hamburg to Copenhagen, where he composed the opera-serenade *La contesa dei Numi* in celebration of the birth of the heir to the Danish throne. During the following two winters Gluck was in Prague, where he wrote *Ezio* (1750) and *Issipile* (1751–52). On September 15, 1750, he married Marianne Pergin in the Church of St. Ulrich in Vienna. Their marriage, a harmonious one, was childless. Later Gluck adopted his niece, Marianne. Before the young couple set up a permanent home in Vienna in the winter of 1752–53, Gluck took his wife to Naples for the summer of 1752, where he composed music for Metastasio's drama *La clemenza di Tito* after having rejected the text of *Arsace*, which he had already once set to music.

In Vienna, Gluck soon found a patron in the imperial field marshal Prince Joseph Friedrich von Sachsen-Hildburghausen, who engaged him first as *Konzertmeister* of his orchestra and later as *Kapellmeister*. Gluck gave successful performances of his symphonies and arias at weekly concerts in the prince's palace and made a particular impression with his opera-serenade *Le Cinesi*, which was performed on September 24, 1754, in the presence of the Emperor and Empress at a magnificent celebration at Schlosshof Castle. This success may well have contributed to the decision of the director of the court theatre to entrust the provision of the "theatrical and academic music" for the imperial court to Gluck. On May 5,

1755, Gluck's opera-serenade *La danza* was performed at the imperial Castle of Laxenburg, near Vienna and on December 8 of the same year followed *L'innocenza giustificata*. The following year (1756) Vienna saw *Il rè pastore*, while the first performance of the opera *Antigono* was given during a visit to Rome. In Rome Gluck was created Knight of the Golden Spur, and after his return to Vienna he set to work to provide music for a number of French *vaudeville* comedies imported from Paris. *Tircis et Doristée* (1756) may have been a first attempt at this genre. In these Parisian comedies the dialogue was spoken or sung in the manner of street songs, so-called *timbres*. After 1758 Gluck proceeded more independently and composed for such works as *La fausse esclave*, *L'ile de Merlin* (1758), *La Cythère assiégée* (1759), *Le diable à quatre*, *L'arbre enchanté* (1759), *L'ivrogne corrigé* (1760), and *Le cadi dupé* (1761), which contained, in addition to the overture, a steadily increasing number of new songs in place of the stock *vaudeville* tunes. In *La rencontre imprévue*, first performed in Vienna on January 7, 1764, no *vaudeville* elements remain at all, with the result that the work is a perfect example of *opéra comique*. Gluck gave the scores of *Le cadi dupé* and *La rencontre imprévue* particular charm by using "oriental" instrumental effects. In many of the arias, tuneful melody and programmatic writing foreshadow later developments in Gluck's operatic style: in, for example, the first examples of complex scene development in *L'ile de Merlin* and *L'ivrogne corrigé*.

French *vaudeville* comedies

In February 1761 Raniero Calzabigi, a friend of the adventurer Giovanni Giacomo Casanova, visited Vienna. His libretto for *Orfeo ed Euridice*, partly based on the theories and practices of such literary men as D. Diderot, F.M. von Grimm, Rousseau, and Voltaire, was enthusiastically greeted by Gluck's friends, who immediately brought the two together. On October 17, 1761, the first performance of their first work of collaboration, the dramatic ballet *Le festin de pierre* (Don Juan) was presented. Gluck later composed the music for the dance dramas *Semiramide* and *Iphigenie* (both 1765) to a scenario by Calzabigi and *L'orfano della China* (1774). The choreography for these works was created by the Viennese ballet master G. Angiolini. Together with Calzabigi, Gluck also wrote the three Italian "reform operas," *Orfeo ed Euridice* (1762), *Alceste* (1767), and *Paride ed Elena* (1770).

Gluck himself, in the foreword to *Alceste*, described his and Calzabigi's aims with the words "simplicity, truth and naturalness," demands that primarily affected the libretto. In place of involved plots in the older manner, there was to be a simple, true, and natural action in the tradition of the classical drama; in place of courtly conventions, there was to be a purely human element. The chorus, again on the classical pattern, was to have equal importance with the main characters of the action and participated directly in the dramatic events. The function of the music was, in Gluck's own words (foreword to *Alceste*), "to serve poetry by means of expression and by following the situations of the story, without interrupting the action or stifling it with a useless superfluity of ornaments." The *recitativo secco* ("unaccompanied recitative") was banished (except in *Alceste*); the *recitativo accompagnato*, arioso, aria, chorus, and pantomime were welded together with declamatory style and expressive orchestral writing to form scenes and groups of scenes as parts of a great work of architecture. As Gluck himself confessed, the impulse toward opera reform came from Calzabigi, but it must also be recognized that Calzabigi proceeded largely from the ideas put forward after 1750 by the Parisian poetic and literary circles mentioned above, while important new musical features (*e.g.*, the complex scene development) were the contributions of Gluck's own genius.

Aims of the reforms

Besides the three Italian "reform operas," which were not written as the result of a particular request, there appeared a series of commissioned works, partly after librettos by Metastasio: *Il trionfo di Clelia* (Bologna, 1763), the second version of *Ezio* of 1750 (Vienna, 1763) and, after a short visit to Paris in the spring of 1764, *Il Parnasso confuso*, *Telemacco o sia L'isola di Circe*, and the dance drama *Semiramide*, all written for the second marriage of the Holy Roman emperor Joseph II in 1765. The opera-serenade *La corona*, written in the same year, was not performed owing to court mourning for the death of the emperor Francis I. In Florence on February 22, 1767, Gluck gave performances of his festival opera *Il prologo*, together with T. Traetta's *Ifigenia in Tauride; La Vestale*, the revised version of *L'innocenza giustificata* of 1755, followed in Vienna in 1768; and in Parma in 1769, he presented *Le feste d'Apollo*.

On August 1, 1772, the Paris Opéra was encouraged to stage Gluck's newly completed opera, *Iphigénie en Aulide* (the text, after Racine's tragedy, was by François-Louis Leblanc, bailli Du Roullet); and as Gluck had undertaken to form from the genial Italian style to the more serious opera cultivated by French composers as well as to provide six more similar operas, he went to Paris in the autumn of 1773. The performances of *Iphigénie* on April 19, 1774, and of the French version of *Orfeo* in the summer of the same year met with tremendous success. In Vienna, Gluck was appointed official court composer, but he soon took leave to return to Paris, where the new version of *L'arbre enchanté* in 1775 brought him little success, and the completely rewritten *Cythère assiégée* proved a failure. The French version of *Alceste*, which was produced during his third visit to Paris on April 23, 1776, also met with disapproval. Deeply distressed by this, and the death of his niece, Marianne, Gluck left Paris in May 1776 and returned to Vienna.

In Paris Gluck left both friends and enemies, who began to form two opposing parties: his adherents, the Gluckists, under the leadership of the French writers and music critics L'abbé François Arnaud and Jean-Baptiste-Antoine Suard; his opponents, called Piccinnists after the Italian composer N. Piccinni, who had been prevailed upon to come to Paris in the summer of 1776 to write opera in opposition to Gluck's style. The struggle, which reached its full fury in 1777, never drew either Gluck or Piccinni into active participation in the dispute. Gluck, in Vienna, had completed *Armide* but had destroyed his sketches for *Roland* on hearing that Piccinni was setting the same text for Paris. At the end of May 1777, Gluck returned to Paris.

The opera "war"

At the first performance of *Armide* on September 23, 1777, the war of the theatres reached a climax, but soon after the performance of Piccinni's *Roland* on January 27, 1778, the struggle abated again. Gluck retired to Vienna and his last visit to Paris began at the end of 1778, where he arrived with his two latest completed dramatic works, *Iphigénie en Tauride* and *Écho et Narcisse*. The performance of *Iphigénie* on May 18, 1779, brought him his greatest success in Paris, but *Écho* (which was first performed on September 24, 1779) met with little appreciation. Gluck, who had suffered a stroke during the rehearsals of *Écho*, left Paris for the last time at the beginning of October 1779.

Gluck's great French "reform operas" are more strongly governed by the principle of contrast than are the Italian works; the declamatory style of the vocal line is more marked than in the Viennese operas, and the power and orchestral colour are more intense. The works are constructed in shorter sections, which frequently follow each other without a break, and the spacious conception of the scenes is partly sacrificed in order to achieve a greater degree of dramatic and psychological flexibility.

Gluck spent the last eight years of his life in Vienna and in Perchtholdsdorf nearby, in the care of his wife, continuing to work tirelessly. His attention turned again to F.G. Klopstock's *Hermannsschlacht*, which had occupied him as early as 1770; he revised *Écho et Narcisse* and, together with a Viennese poet, J.B. von Alxinger, produced a German version of *Iphigénie en Tauride*, first performed in Vienna on October 23, 1781, on the occasion of the visit by the Russian grand duke Pavel Petrovich, later Emperor Paul I. At this time the paths of the aging Gluck again crossed those of Mozart, as had already occurred once in Paris; they met on several occa-

sions, but no close personal relationship developed between them. In 1781 Gluck suffered a second stroke, which partly paralyzed him, and his physical powers began to decline. Only a few years before his death he published his *Klopstocks Oden und Lieder* (seven numbers), which must have been written *c.* 1770.

On November 15, 1787, Gluck had a further stroke, from which he died. Two days later he was buried in the central cemetery in Vienna amid general mourning. The requiem mass included a performance of Gluck's own *De profundis*, conducted by A. Salieri.

MAJOR WORKS

OPERAS: *Artaserse* (1741); *Sofonisba* (or *Siface*) and *Ipermestra* (both 1744); *Le nozze d'Ercole e d'Ebe* (1747); *Semiramide riconosciuta* (1748); *Ezio* (1750, second version 1763); *La clemenze di Tito* (1752); *Orfeo ed Euridice* (1762); *Alceste* (1767); *Paride ed Elena* (1770); *Iphigénie en Aulide* (1774); *Orphée et Eurydice* (French version of *Orfeo ed Euridice*, 1774); *Alceste* (French version, 1776); *Armide* (1777); *Écho et Narcisse* (1779); *Iphigénie en Tauride* (1779); *Iphigene auf Tauris* (German version, 1781).

COMIC OPERAS (OPERAS COMIQUES): *L'ile de Merlin* (1758); *L'arbre enchanté* (1759, second version 1775); *La Cythère assiégée* (1759, second version 1775); *Le cadi dupé* (1761); *La rencontre imprévue* or *Die Pilgrime von Mekka* (1764).

DRAMATIC BALLETS AND PANTOMIMES: *Don Juan ou le festin de pierre* (1761); *Semiramide* (1765); *Iphigenie* (1765); *Achille* (1770?).

ODES: *Klopstocks Oden und Lieder* (seven odes for voice and piano with texts by Klopstock, composed *c.* 1770).

CHURCH MUSIC: *De profundis* (after 1785?).

INSTRUMENTAL MUSIC: Six trio sonatas; about 15 sinfonies (overtures).

(G.Cr.)

Gnosticism

Gnosticism is a syncretistic theosophical and philosophical religious movement especially important in the 2nd century AD that contributed to the development of Christianity by forcing the early church (in its reaction to Gnosticism) to develop a scriptural canon, a creedal theology, and an episcopal organization. Its emphasis on *gnōsis* (esoteric knowledge) was in sharp contrast to orthodox Christianity's emphasis on *pistis* (faith).

NATURE AND SIGNIFICANCE

Gnosis and Gnosticism

The term Gnosticism is derived from the Greek word *gnōstikos*, one who knows; what he knows is *gnōsis*, or knowledge of an esoteric nature. The context in which *gnōsis* is used determines whether or not it is different from *sophia*, wisdom, or *epistēmē*, generally knowledge acquired by learning or empirical observation. The gnosis claimed by the Gnostic may therefore be different from other kinds of knowledge and viewed as derived not from ordinary sources but from special divine revelation. Gnosticism is a modern term ordinarily used to describe the theological or theosophical systems prominent in the 2nd century of the Christian Era and attacked by leading early Christian theologians.

In essence, the Gnostic sects believed that there is a divine spark in man that has come from the divine realm above and has fallen into the world of fate, birth, and death; it can be awakened by its divine counterpart because of a revelation and can then be reintegrated into the spiritual world. This kind of view, which has obvious antecedents in Hellenistic philosophy and Jewish-Christian religion, came to full expression only after the rise of Christianity. On the other hand, ideas that seem to point toward it already were present in pre-Christian times and in non-Christian circles. The basic question is whether there were pre-Gnostic ideas expressed in Jewish apocalyptic thought (views about God's intervention in history accompanied by cataclysmic events) or even among the Pharisees (Jewish sect, *fl.* 1st century BC–1st century AD), as well as by some early Christians and perhaps by religious thinkers in Egypt or Mesopotamia, or whether there were proto-Gnostic ideas, involving the essence of Gnosticism, already present in Iran or India or even early Greece (Platonism, Orphism, Pythagoreanism). An attempt to clarify scholarly terminology in regard to this question was made at the Colloquio di Messina (Colloquium of Messina) on the origins of Gnosticism in 1966, and a distinction was drawn between Gnosticism, as defined above, and gnosis, which has the more general meaning of "knowledge of the divine mysteries reserved for an élite." Obviously, modern theological concerns are involved, especially as regards the influence of gnosis on early Christianity and the extent to which Christianity itself was, or became, Gnostic.

Ideally, the definition of Gnosticism should follow, not precede, the investigation of the sources available for its study. Unfortunately, the sources are difficult to obtain and to assess. In modern times a whole library of Gnostic documents, Coptic translations from Greek originals, was discovered near Chenoboskion (Naj' Ḥammādī) in Egypt; but the publication of them has been impeded chiefly by political problems related to the establishment of the State of Israel and the difficulties between Israel and the United Arab Republic. All of the documents have been read, but relatively few have been published. There are 53 documents (48 of them different) bound in 13 leather volumes; of this total about 25 have appeared in print. In addition, three Gnostic documents in Coptic in a Berlin collection (two of them also at Chenoboskion) were published in 1955. Other Gnostic documents that have been published are considerably later in date. In ancient times the Christian opponents of Gnosticism had access to documents but often paraphrased or distorted (or both) their meaning, so that considerable caution is needed in dealing with the accounts provided by such anti-Gnostic writers as Irenaeus (*c.* 185), Hippolytus (*c.* 230), and Epiphanius (*c.* 375). They were convinced that their opponents were immoral heretics, and they were trying to present Gnostic views in the worst possible light. In spite of these difficulties, it is possible to reconstruct the Gnostic systems, even in con-

Coptic library near Naj' Ḥammādī

siderable detail, and it is possible to determine their general characteristics.

HISTORY

Iranian and Hellenistic influences

Roots. Iranian dualism, perhaps mediated through heterodox (sectarian) Judaism or Hellenistic thought, may well have provided one of the essential preconditions for the rise of Gnosticism. As early as the 2nd century, the anti-Christian writer Celsus compared the teaching of the Ophite Gnostics about heavens and gates with the mysteries of Mithra. More important is the thoroughgoing dualism of Iranian thought, with its conflict between the good god Ormazd and the evil god Ahriman and the astrological setting later provided. There is also a primordial man who seems also to be the saviour. Clearly, there are remarkable similarities between Gnosticism and the kind of Iranian religious thought known in the Roman world. One should not try, however, to ascribe a single source or impetus to the whole complex movement called Gnosticism. There are analogies with Egyptian and Mesopotamian thought as well as with Iranian.

Gnosticism arose and flourished in the Greco-Roman world during a period when philosophers, especially Pythagoreans and Platonists, were seeking to transcend diversity and contradiction and to find a religious foundation for their thought. Middle Platonists attempted to reconcile Plato with Aristotle and to interpret both as teachers of ancient Greco-Oriental wisdom, liberally employing the allegorical (symbolical) method in their quest. They laid emphasis on the absolute transcendence of the One, or the Good, and sometimes separated it from the creative Mind, identified with Plato's Demiurge (creator). It could be held that knowledge of the One was given only through intuition of revealed truth and that this knowledge was so valuable that it had to be kept secret. Emphasis on transcendence, revelation, and secrecy occurred among Gnostics and philosophers alike. In addition, the very idea of a philosophical or theological system is itself Greek. It should be noted, however, that the Hermetic writings (astrological, occult, and medical documents attributed to Hermes Trismegistos) of the 2nd century and later, often used as witnesses for a "Greek" Gnosticism or gnosis, are essentially expressions of Middle Platonic commonplaces. Some of them expressed pessimism about the world, but this was not uniquely a Gnostic idea—even though the Neoplatonist Plotinus attacked the Gnostic doctrines as anticosmic and, indeed, blasphemous.

Jewish and Christian influences

Similar dualistic tendencies were present in heterodox Judaism, partly among Hellenized Jews like Philo of Alexandria and in more rigorously dualistic form among adherents of apocalyptic thought. Among apocalyptists, alienation from political, social, and religious structures led to belief not only in two ages (the present, evil; the future, good) but also in two "powers" and in knowledge of the future through secret revelation. Themes from Jewish apocalyptic angelology are to be found in several Christian Gnostic systems, and there were at least a few Jewish Gnostics. Generally, however, Gnostics were much more anti-Judaic than Judaic, and it is not possible to find in Jewish circles the idea of an imperfect, subordinate, or evil demiurge (creator).

The Gnostic idea that a redeemer figure provided saving gnosis to the elite is sometimes regarded as pre-Christian, but no evidence is as yet available to support this view. Simon Magus, whom 2nd-century Christians viewed as the founder of Gnosticism, was apparently regarded as "the great Power" of God (Acts 8:10), and the earliest account of Simonian doctrine, about 150, describes him as the supreme god. An expansion of this view by Irenaeus, bishop of Lyon, however, clearly reflects Christian doctrine. Simon appeared to the Jews as Son, to the Samaritans as Father, to others as the Holy Spirit. It seems likely that the idea of a redeemer figure was derived from Christian sources or at least was given impetus by the concurrent Christian proclamation. The constant use of New Testament books among 2nd-century Gnostics at least shows that they regarded them as media of revelation if rightly understood.

Origins and early history. The first Gnostic teachers about whom anything is known were Simon and his so-called disciple Menander, who held that he was sent down himself as the saviour. Both men probably lived within the 1st century, and both were described as teaching the existence of a subordinate female creative principle, superior to world-creating angels, and as encouraging the use of magic. A little later, Saturninus of Antioch drastically reinterpreted the story of Jesus in relation to world- and woman-denying asceticism. There is neither female principle nor magic in his thought. These two types of early Gnosticism, the one leading to "permissive" behaviour, the other to extreme asceticism, set the stage for later developments. During the first third of the 2nd century, Basilides presented a more philosophical system at Alexandria, possibly with some Indian sources, in which the illusory nature of "the nonexistent god" and his nonexistent cosmos was stressed. At the same time, Basilides drew close to Christian texts and provided interpretations of the Old Testament and the Gospels. He was succeeded by his son Isidore, who emphasized ethical problems and allegorical exegesis.

Basilides, Valentinus, and other Gnostic teachers

The most prominent figure of the time, however, was a certain Valentinus, who claimed that his revelation had come when the Logos appeared to him as an infant. Fragments of letters, sermons, and a psalm show that Valentinus expressed mythological ideas in semiphilosophical dress. His later disciples moved in diverse directions. The greatest of them, Ptolemaeus, apparently taught at Rome and created a systematic philosophical theology, ostensibly based on biblical texts. Another, Marcus, was active in Asia Minor or Gaul, or both, and developed the master's teaching in the direction of ritual practices and numerology. In the East, Theodotus laid emphasis on theology, exegesis (interpretive studies), and cultic rites. A disciple of Ptolemaeus, Heracleon, became the first systematic exegete of the Gospel According to John, interpreting it as a Valentinian book. The ideas of the Valentinians aroused the opposition of the early Church Fathers, and by the early 3rd century their influence was vanishing. They were succeeded by other schools, largely anonymous, in which permutations and combinations of Gnostic doctrines were provided.

Within the 2nd century also, anonymous or, rather, pseudonymous, Gnostic doctrines flourished. There were Gnostic gospels and epistles and revelations, the most important of which seems to have been the *Apocryphon* (secret book) *of John*. Irenaeus knew something like it; three copies have turned up at Chenoboskion.

It is a question whether or not Marcion, an important Bible critic and heretic of the mid-2nd century, should be called a Gnostic. The basic difference between him and the others, however, lies only in his rejection of secrecy and secret revelation; otherwise he shared the major tenets of ascetic Gnosticism. In his view there was a supreme, good Father god, unknown but by revelation and superior to the merely just demiurge. The revelation of the demiurge is contained in the Old Testament; the revelation of the Father was given by Jesus, the "saving spirit" who came down from the highest heaven in the 15th year of Tiberius. The teaching of Jesus was corrupted by his disciples, who were trying to present it to Jews. A new revelation was then given to Paul, who alone understood Jesus' gospel and taught it to Luke. Later on, however, both the Gospel and Paul's letters were interpolated. Only Marcion was able to restore their primitive form and content. He also wrote *Antitheses*, a book contrasting the Old Testament with his *Gospel* and *Apostle*. Apparently he was able to remain within the Roman Church between 137 and 144, then being excommunicated. His initial success, or at least toleration, shows how impressive Gnostic teaching could seem in Christian circles before the rise of systematic theology.

Decline. By the early 3rd century the great days of Gnosticism were over. At Alexandria theologians such as Clement and Origen created philosophical theologies

that made Gnosticism seem naïve; Origen converted Valentinians to Christianity. At Antioch, according to Tertullian, one true Valentinian teacher remained. At Rome Hippolytus wrote against Gnostics but relied on archaic sources. The earlier Gnostic doctrines did not survive the publicity that church writers gave them, and the Gnostics' lack of orthodoxy and organization caused their sects to fall apart. Christian writers of the later 3rd century paid hardly any attention to Gnosticism, and when Eusebius wrote his *Ecclesiastical History*, beginning about 303, he knew almost nothing about it. Only a few conventicles survived, at Rome and elsewhere. Epiphanius wrote against heresies toward the end of the 4th century and investigated many old Gnostic ideas; Gnostic women had once invited him to join their group, but his primary targets were not Gnostics but unorthodox Christians like Origen.

Manichaeism and the Mandaeans

The new threat to Christian orthodoxy was presented by Mani (a 3rd-century Iranian prophet who was executed for his teachings) and by his numerous followers, the Manichees. After the year 297, when an imperial rescript denounced this semi-Gnostic group, Christian leaders attacked it on scriptural and philosophical grounds. Eusebius said that Mani made use of "the countless, long-extinct, godless heresies." His words illustrate the general tendency to use Gnosticism as a stick for beating more modern ideas. Among the 65 decrees against heretics cited in the Theodosian Code (439), only two even mention Gnostic groups. Gnosticism was not a significant option in the 4th and 5th centuries.

Thus, Gnostic survivals after the 3rd century exist as gnosis, in the Gnostic sense of esoteric knowledge, but not in Gnosticism as a movement. To be sure, Gnostic documents survived and were imitated in Egypt and Syria. The existence of the "library in a jar" at Chenoboskion does not prove that a Gnostic sect flourished there in the 4th and 5th centuries, much less that it would have had any influence in major centres.

Survivals. Among the Mandaeans, a small sect still existing in Iraq, Gnostic books are still preserved, dating from the 7th or 8th century but using earlier materials. Their mythology is not altogether consistent and seems to reflect the gradual appropriation of Gnostic themes by a group whose centre lay in the cult, especially baptism. The question of Mandaean origins, hotly debated during the early 20th century, is still not solved.

Medieval Christian heretical groups sometimes made use of supposedly primitive apocryphal (noncanonical) books, and it has often been claimed that they represent survivals from early Gnosticism. Generally speaking, such is not the case. In so far as they were influenced by earlier movements, they were acquainted with Manichaeism, not with its forerunners. In more modern times there have been self-consciously Gnostic groups, especially in Europe; the basic source of their ideas seems to lie not in early Gnosticism but in a kind of Faustian Romanticism. The tendency to classify opponents, whether religious, political, or social, as "Gnostics" may have some polemical value, as it seems to have been the case in ancient times, but it is historically invalid. The attempt, for example, to trace aspects of the 20th-century German philosopher Martin Heidegger's thought to Gnostic sources was unsatisfactory since an existentialist description of Gnosticism, influenced by Heidegger, was being used.

A more complex approach to Gnosticism is found among certain Roman Catholic authors who view various decisions of the early church as necessary at the time because of the threat of Gnosticism, but therefore historically conditioned and not binding now. They follow the line taken (*e.g.*, by the American Protestant scholar A.C. McGiffert in 1902), arguing that what underlies the Apostles' Creed is an early formulation directed exclusively against Marcion and therefore not fully relevant afterward.

MYTHOLOGY

Cosmology. The essence of Gnostic knowledge was concerned with man and his place in the universe, a universe understood as vastly larger than the world of sense perception and superior to it. The universe was viewed as consisting of concentric spheres, of which the earth was the centre. These spheres were marked by the circular orbits of the planets, each governed by a deity hostile to spiritual men. Beyond them was the sphere of the fixed stars, equivalent to the Valentinians' *plērōma*, or totality. It was made up of 30 "aeons," or primary spiritual powers, each corresponding to the 30 days of the month. Valentinus' disciple Marcus found astrological significance in the subdivisions of the 30: the highest 8 above were reflected in fire and heat, water and wetness, earth and cold, air and dryness; the next 10 in the 7 heavens, the sphere about them, the sun, and the moon; the last 12 in the zodiac and in the "zones" of the earth. Gnostics knew about the spiritual "doubles" of all these, confirming their calculations by numerology, or religious symbolism: ". . . the Apostles were substituted for the twelve signs of the Zodiac, for, as birth is directed by them, so is rebirth by the Apostles" (Theodotus). The primary function of Gnostic revelation was to free spiritual men from astral determinism: "Until baptism . . . Fate is real, but after it the astrologers are no longer right." Thus the Gnostic knew the whole story of his origin in the *plērōma*, and this liberated him from the power of planets and stars. Some sects even provided diagrams to show what the spiritual world was like. After death, the Gnostic passed upward through the "barrier of evil" to the supreme power of which he knew he was a part.

The astral *plērōma*

Creation of the world. If the supreme unknown power above is perfect and good, why does the universe, experienced as imperfect or evil, exist? Various explanations were given. The most widespread view seems to have been that the spiritual world came into existence out of unions ("syzygies") between pairs of aeons. The 30th (sometimes the 12th) aeon, named Sophia ("wisdom") produced, or her desire produced, an imperfect and inferior demiurge, sometimes called Ialdabaoth (perhaps a parody of Yahweh, the name of the Jewish God). This evil creator made the world or the angels who (sometimes with him) in turn made the world. He is almost always described as the God of the Old Testament, passages from which were cited to show that he was jealous (of the supreme power) but claimed to be the only God. The six or seven (sometimes 12) angels he created bear names like Michael, (S)Uriel, Raphael, and Gabriel (archangels in Jewish and Christian thought) or divine names from the Old Testament (Iao, Sabaoth, Adonai, and other such names). The flourishing angelology of the 2nd century later provided further names. Some systems do not state what the world was made of; the Valentinians held that it came from the ignorance, grief, fear, and consternation of Sophia or her (individuated) desire. This doctrine is clearly mythological, not philosophical. Like the Neoplatonic philosopher Plotinus, the Christian theologian Irenaeus criticized the Gnostic doctrine as anticosmic and blasphemous. In the Gnostic view, the universe was imperfect and hostile to man and could not have been made by the supreme being above.

Role of Sophia

Man. Gnostics were not concerned primarily with the universe as such, however, but with the nature of man, who for them is essentially a spirit dwelling in a body. For some, man's spirit is held prisoner in the body; for others, the situation is more complicated. Saturninus held that the creator angels tried to copy an image of the power above but were too weak to make the copy live. Man's life is due to the pity of the power, which sent down the spark of life (*cf.* Gen. 2:7). Others held that the spark or spirit was given by Sophia or even, by accident, through Ialdabaoth. In any case, it was the spirit alone that constituted true humanity; it alone was capable of salvation. Another way of explaining the human situation was by saying that man was made of matter "in our image" (Gen. 1:26), and possessed soul "after our likeness" and, in addition, the "spirit of life" (2:7); his "coat of skin" (3:21) was his flesh. It is obvious that whereas in Judaism and Christianity man's condition was

explained by Adam's fall, for the Gnostic it was not the first man who fell but his distant ancestor Sophia.

Classes of men

In Valentinian thought there were three classes of men: spiritual; psychic (animate or possessing soul: ordinary Christians); and material, or fleshly. Spiritual men (Gnostics) were, it was believed, perfect and would be "by nature saved"; psychic men possessed free will and could go upward or, in decay, downward; material men could not be saved, since they were "by nature sons of the devil." Obviously Pauline language was important for making such a distinction (*cf.* I Thess. 5:23; I Cor. 2:6–3:3), though Paul's differentiations were moral, not ontological (concerning grades or levels of being). According to the Valentinian Gnostic Ptolemaeus, the three classes also were to be found in sayings of Jesus, but obviously his claim was the result of allegorical exegesis.

Some Gnostics were concerned with the origin of various parts of the body and control over the parts by creator angels, by the signs of the zodiac, or by 360 or 365 angels related to the days of the solar year. Such doctrines are astrological in origin.

Redemption. The spirit of man was believed to dwell in an alien body in an alien world. How was he, like the Prodigal Son of Luke 15, to "come to himself" and go to his true father? The answer the Gnostics offered was that man needed salvation through knowledge. The Simonians held that Simon, the supreme deity himself, came down through the spheres and rescued his "first thought," apparently related to human spirits generally. He had earlier been present among men as Son, indeed as Jesus, but suffering would have been irrelevant and he was not crucified. (Basilidians even held that Simon of Cyrene was crucified in Jesus' place.) Generally, however, the Gnostics claimed that Jesus was a man into whom the spiritual Christ came from above; Christ was produced in the spiritual world. Because the Christ came from above he could reveal the mysteries of spiritual cosmology (order of the world) and cosmogony (origin of the world). He

Role of Christ

was responsible for Jesus' miracles and as spirit departed from Jesus at the crucifixion (*cf.* Luke 23:46). Others held that Christ was a psychic being like his father the creator and spoke of him through the Hebrew prophets; what descended upon him was the spiritual Saviour. (The Gnostic Menander held that he himself was the saviour.) According to Basilides, Jesus became the Saviour when illuminated by light from above; he was subject to astral influences but ascended in order to lead other spiritual beings upward. Obviously, the revelation of knowledge was what mattered. The cross existed as a symbol of the dividing line between the spiritual world and what lies below. Even when Jesus was described as crucified, his crucifixion was simply the occasion for his ascension and not, as in Christian thought, a sacrifice. Christ, as in the Gospel According to John, is the revealer. In the *Gospel of Truth* Jesus was "nailed to a cross" but as teacher. His mission was to speak "in a mystery privately to his disciples and apostles" (Carpocratians).

In some measure Jews and Christians held similar views. The death of the Qumrān Teacher of Righteousness in the Jewish sect revealed in the Dead Sea Scrolls was not redemptive, and Christian apologists could compare Jesus' death with that of the good teacher Socrates. Generally, however, Christians believed that Jesus' death, not just his teaching, had redemptive significance.

Eschatology. Though mystical experience was possible during life, the true ascent of the spirit took place after death when it imitated the saviour or Christ and moved upward through the spheres governed by the planetary angels. (Menander taught that his disciples would not die, but time proved him wrong.) The spirit had learned formulas to proclaim that he traced his origin to the preexistent one and was returning to his own. Valentinians held that "the spirituals will put off their souls and will become intelligent spirits . . . given as brides to the angels about the Savior." In the system of Saturninus the same point is made very simply: "after death the spark of life returns to what is of the same nature as itself, and the other elements of man's composition are dissolved into what they were made from." There is thus a cosmic tendency for the spirit to rise (as Basilides says), and it is simply reinforced by what the Saviour taught.

Fate of the material world

But what would happen to the universe after the withdrawal of the spiritual elements in it? Ptolemaeus held that "then the fire hidden in the universe will shine forth and ignite and become effective in consuming all matter along with itself and finally will become non-existent." (This resembles the Stoic doctrine of cosmic conflagration.) On the other hand, Basilides taught that the world would remain but God would bring ignorance upon it, so that souls remaining below will not desire anything contrary to their nature and thus experience torment. "Everything that remains in its place is imperishable; it is perishable only if it wants to pass beyond its natural limits."

WORSHIP, PRACTICES, AND INSTITUTIONS

Sacred writings. The Gnostic sects of the 2nd century generally made use of Hebrew and Christian religious writings, employing the allegorical method to extricate Gnostic meanings from them. Some could find three classes of men in various parables of Jesus. Apocryphal gospels, letters, acts, and apocalypses were often employed. The Neoplatonist philosopher Porphyry attacked Gnostics for composing fraudulent apocalypses ascribed to Zoroaster, Zostrianus, and Allogenes; a "discussion by Zostrianus" and a book called *Allogenes* are among the books found at Chenoboskion. The *Apocryphon of John*, supposedly based on a revelation received by John the son of Zebedee, reinterprets the first few chapters of Genesis and says the truth is "not as Moses said."

Prominent among the Gnostic books is the *Gospel of Thomas*, first known in modern times from Greek fragments found at Oxyrhynchus in Egypt and extant in a Coptic version from Chenoboskion. This gospel consists of nothing but sayings of Jesus, derived partly from the synoptic gospels or traditions and partly from the Gnostics' own traditions. Another "gospel" is the *Gospel of Philip*, an esoteric collection of Valentinian doctrines. The *Gospel of Mary* (Magdalene) contains postresurrection teachings of the Saviour (Jesus) to the disciples, especially to Mary (whom he loved more than the others). Andrew and Peter doubt, but Levi persuades the others that she received the true Gnostic doctrine.

The Chenoboskion collection includes apocalypses ascribed to Adam, James, Peter, and Paul, and other apocalypses are known because of mention by church writers.

In addition, Gnostics generally believed that by allegorization they could interpret all religious literature in relation to their systems. They claimed to know the true meaning of the mystery religions and of Greek and oriental mythology; they could explain the hidden significance of Homer, Hesiod, and other poets. Anyone who knew the story of "Elohim and Eden" in the Gnostic *Baruch* could understand the labours of Hercules and the stories about Zeus and Leda and Danaë. Hermetic writings were included in the Chenoboskion collection.

Teachers. The picture the Church Fathers give of Gnostic teachers in succession is wrong. Menander was not the disciple of Simon; Basilides and Saturninus were not their followers. There were real "successions" among the Gnostics, however. Basilides claimed that he had been

Basis of Gnostic teachers' authority

taught by a certain Glaukias, who (like the evangelist Mark) had been an "interpreter" of the Apostle Peter. In turn, his principal pupil was his own son Isidore. Similarly, Valentinus said that he had learned from Theodas, a companion (like Luke) of the Apostle Paul. The names of five of his chief disciples are known, but early in the 3rd century Tertullian could claim that only one teacher still preserved Valentinus' authentic doctrine. At an earlier date, Ptolemaeus was writing to Roman Christians and claiming that Valentinians too had "received the apostolic tradition by succession." Other Gnostics had ideals of secret traditions derived from apostles, but in general the links in the tradition, like the later teachers, remained anonymous. A certain Justin, who wrote a book entitled *Baruch*, provides one of the few exceptions.

Organization. Most Gnostic groups seem to have been organized as schools, in which the authoritative teaching was transmitted, interpreted, and kept secret. There must have been regular meetings of some sort, for Gnostics were in danger of arrest during times when Christians were persecuted. Among some groups there were regular meetings for sacramental and prophetic worship. In the late 4th century such meetings were forbidden and Gnostic books were burned. Gnostics seem to have gone underground, although an early 4th-century inscription refers to "the synagogue of the Marcionites of the Lord and Savior Jesus Chrestos" (the Greek word *chrēstos* means "good"), and as early as the 2nd century there were Marcionite bishops and presbyters.

Rites. Gnostics disagreed among themselves as to the importance of rites. Many rejected conventional worship, including prayer, fasting, and almsgiving, not to mention Baptism and Eucharist. Some insisted that "true redemption" was given the "inner spiritual man" through gnosis, while others held that a rite called "redemption," often involving "Hebrew names" and unguents, was important and necessary. Among the liturgically minded there were Eucharists with bread and wine and Baptisms with water and chrism, just as among Christians of the time. The followers of Basilides celebrated the day of Christ's Baptism, presumably because then the spiritual Christ descended upon the human Jesus, and the day of his death, because then Christ left him. It is hard to tell whether or not there was actually a rite called "spiritual marriage," for the language of the *Gospel of Philip* is ambiguous; certainly Irenaeus believed they practiced this rite. "Redemption" and other rites seem intended primarily to aid the divine spark in its ascent, following the death of the body, to the divine realms above. Formulas were provided for use in passing through the various planetary spheres.

In addition, some groups had rites involving "prophecy." The leader in worship, according to one account, would inform his hearer that grace from above had descended upon her and would command her to open her mouth and prophesy. If she replied, "I have never prophesied and do not know how to prophesy," he would say, "Open your mouth and say anything, and you will prophesy." The notion of Epiphanius and other church writers that some Gnostics participated in sex orgies as religious rites seems somewhat exaggerated but cannot be disproved. There is not much evidence for it in the early days of Gnosticism.

Libertinism and asceticism

Ethics. Gnostic ethics ran the gamut from compulsive promiscuity to extreme asceticism. What the Gnostic normally rejected was conventional law or wisdom, especially as expressed in the Old Testament. This kind of law, they held, had been imposed on men by the world-creating angels, who desired to enslave them. The Carpocratians and the Cainites (two Gnostic sects) insisted that it was necessary to experience "everything" in order to be freed from the control of these angels. Even the Valentinians argued that ordinary Christians, who were "from the world" as Gnostics were not, could not love a woman and possess her, while Gnostics, "in the world" but not "from" it, had to do so. Church writers accused many Gnostics of employing love magic. On the other hand, there were Gnostics who claimed that marriage and generation originated with Satan (as in Gen. 2–3, taken literally); some also abstained from eating meat.

Basilides explicitly taught that suffering took place only in consequence of sin, actual or potential, and quoted Job (14:4) to prove that "no one is pure . . . from defilement." His son Isidore claimed that sin was always voluntary and (like Epicureans) argued that sin could involve what was natural but not necessary. Epiphanes followed radical Platonic lines and insisted that equality and sharing were intended by God; men should not treat wealth or women as private possessions.

GNOSTICISM AND CHRISTIANITY

It is difficult to disentangle the relations between early Christianity and Gnosticism. The chronology is rather obscure, and it is hard to differentiate causes from effects. Two main views have been held: (1) that Gnosticism arose before Christianity and influenced such Christians as Paul and John even though they argued against it and (2) that Gnosticism was a form of Jewish heterodoxy or Christian heresy or both, probably not known to the New Testament writers but flourishing from the early 2nd century onward. Conceivably a third view could be supported: that the beginnings of the Gnostic and the Christian movement were virtually simultaneous and that the story is therefore one of cross-fertilization. It would appear that neither the Church Fathers nor the Chenoboskion documents provide evidence for a final decision. The fact that the major Gnostic teachers claimed to have been taught by disciples of Jesus proves no more than that 2nd-century Gnosticism owes much to Christianity. It does not indicate what underlay the doctrinal struggles reflected in I Corinthians, Colossians–Ephesians, John, and I John.

Contributions of Gnosticism to Christianity

One thing is clear, however. In developing its organizational and doctrinal structures the church owed much to the Gnostics. The structures were not Gnostic in origin, but without the Gnostic crisis they would have taken longer to evolve. The formulation of creedal symbols, the canonization of the New Testament Scriptures, and the emphasis on episcopal authority were made necessary by the Gnostics' claims. Moreover, in some measure the Gnostics were the first theologians. They made it necessary for Irenaeus to develop what systematic thought he had and prepared the way for treatises like Origen's *On First Principles.* Origen owed much to church tradition and philosophical teaching, and much also to his Gnostic forerunners, some of whom raised the kinds of questions he tried to answer.

The Gnostics influenced Christianity positively as well as negatively. They kept alive the great issues of freedom, redemption, and grace, which, after the times of Paul and John, were not adequately discussed by 2nd-century Christian writers. The Gnostic solutions did not prove tenable in the Christian framework, but at least the Gnostics kept such issues alive. At a later date the theology of Augustine owed a good deal to the experience he had had as a Manichee.

INTERPRETATIONS OF THE ROLE OF GNOSTICISM

Patristic. For the Church Fathers Gnosticism was a perverse heresy; particular Gnostic sects, they supposed, often originated when unstable Christians sought church office and failed to obtain it. Sometimes they explained the consequent heresy as derived from Jewish sectarianism; sometimes they ascribed it to the influence of one Greek philosophical school or another. Irenaeus suggested that the Gnostic simply loved novelty: "they pretend to find something new every day and to produce what no one ever thought of." On the other hand, most of the fathers believed in the genetic development of Gnosticism: Simon founded it, and one could trace its history through disciples who came after him. Unfortunately this explanation is quite wrong. There was no uniform original doctrine that spread like the branches of a tree. Instead, the various systems reflect a common Gnostic attitude but, along with it, remarkable diversities in doctrine. What must underlie the diversity is a variety of approaches to the world, to human nature, and to ideas of knowledge. Again, when the Church Fathers related Gnosticism to philosophy they were apparently trying to bring it under the judgment of a common criterion. All they could say of the Gnostic myths is that they were myths. They had to engage in rational argument in order to show that the myths were irrational.

Modern. Modern man, more aware of the role of myth than were the Church Fathers, has found it possible to understand aspects, at least, of the Gnostic world views. The leading interpretations have been made in psychological and in existential terms. The principal student of Gnostic ideas among psychologists has been C.G. Jung, who was long interested in Basilides and Carpocrates and with Karl Kerényi wrote "essays on a science

Psychological and existential interpretations

of mythology." In his theory of "archetypes," primordial images at work in the human psyche and presented as symbolic representations, Jung was fairly close to the Gnostic depiction of aeons and their unions and separations. Speaking of the "body schema as archetype of the first man" in Gnostic thought, his pupil Erich Neumann wrote that ". . . early man lived in the middle of . . . psychophysical space in which outside and inside, world and man, powers and things, are bound together in an indissoluble unity." According to "modern consciousness," Gnostic myths are "projections, i.e. . . an outside experience of archetypal images." Of Sophia, Neumann wrote: "In the patriarchal development of the Judaeo-Christian West . . . the goddess, as a feminine figure of wisdom, was disenthroned and repressed. She survived only secretly, for the most part on heretical and revolutionary by-paths." One may add that among the Valentinians there is a double Sophia, in some measure reflecting the "elementary characters" of the primordial goddess that Neumann calls positive and negative.

Relying to some extent on the thought of Martin Heidegger, Hans Jonas started from the relatively late Mandaean literature and described "Gnostic imagery and symbolic language" in terms reminiscent of Existentialism. He spoke of alienation and estrangement, of "fall, sinking, capture," of "forlornness, dread, homesickness," and "numbness, sleep, intoxication." Such terms are indubitably present in Gnostic thought, and Jonas rightly endeavoured to show what bound Gnosticism together, laying less emphasis on its origins and on diversities within it. He was concerned with morphology, not genetics. And there are indubitable similarities between "Gnosticism and modern nihilism," to which Jonas has drawn attention.

CONCLUSION

The basic question, as Jonas pointed out, is "what is Gnosticism?" But it must be answered in modern times by asking "what was Gnosticism?" The subject under discussion, whether or not alive today, is a phenomenon of the past, and therefore the problems of origins, sources, and possible development need to be considered, as well as the problem of definition. With Jung, Jonas, and others, one finds the goal in an understanding of what gnosis and Gnosticism were as differentiated from their sources and even their influences. It is not enough to call Gnosticism "the acute Hellenizing of Christianity" (Adolf von Harnack) or to trace its ingredients to Greek or Oriental ideas without explaining how and why men found it meaningful. It arose in an age of syncretism, but it was not merely syncretistic. It was not precisely Greek, Jewish, or Christian, though elements of all existed in it. To a greater degree it was an anti-Greek, anti-Jewish, anti-Christian movement; in the 2nd century, and in Manichaean form still later, it captured at least for a time the imaginations of such theologians as Basilides, Valentinus, and Augustine.

Gobi (Desert)

One of the great desert and semidesert regions of the globe, the Gobi (from Mongolian *gobi*, meaning "waterless place") stretches across the vastness of Inner Asia over huge stretches of both the Mongolian and Chinese People's republics. Contrary to the perhaps romantic image long associated with what—at least to the European mind—was a remote and unexplored region, much of the Gobi is not sandy desert but bare rock. One may drive over this surface by car for long distances in any direction; northward, say, toward the mountains of the Altai and Hangayn ranges or eastward toward the city of T'ien-shan or southward toward the Pei Shan-mo. To the west, 1,000 miles from the Gobi's eastern limits, lies the Sinkiang region, a great basin enclosed by the Plateau of Tibet to the south and the Tien Shan ranges to the north. The desert as a whole occupies a vast arc of land 1,000 miles long and 300 to 600 miles wide. The region first became known to Europeans through the remarkable 13th-century descriptions of Marco Polo. Modern geographical study of the Gobi has mainly been undertaken by Russian scholars, though a series of works has appeared in Mongolian and Chinese since the 1960s. For the purposes of the present article, the Gobi is defined as lying between the Altai Mountains and Hangayn Nuruu (Hangayn Mountains) in the north; the eastern Tien Shan in the west; and the A-erh-chin Shan-mo, Pei Shan-mo, and Yin-shan Shan-mo in the south. For related information on physical geography, see TAKLA MAKAN DESERT, which covers a western region sometimes included in the Gobi; TIEN SHAN (MOUNTAINS); ALTAI MOUNTAINS; for information on human geography, see SINKIANG UIGHUR; KANSU; INNER MONGOLIA; and MONGOLIA.

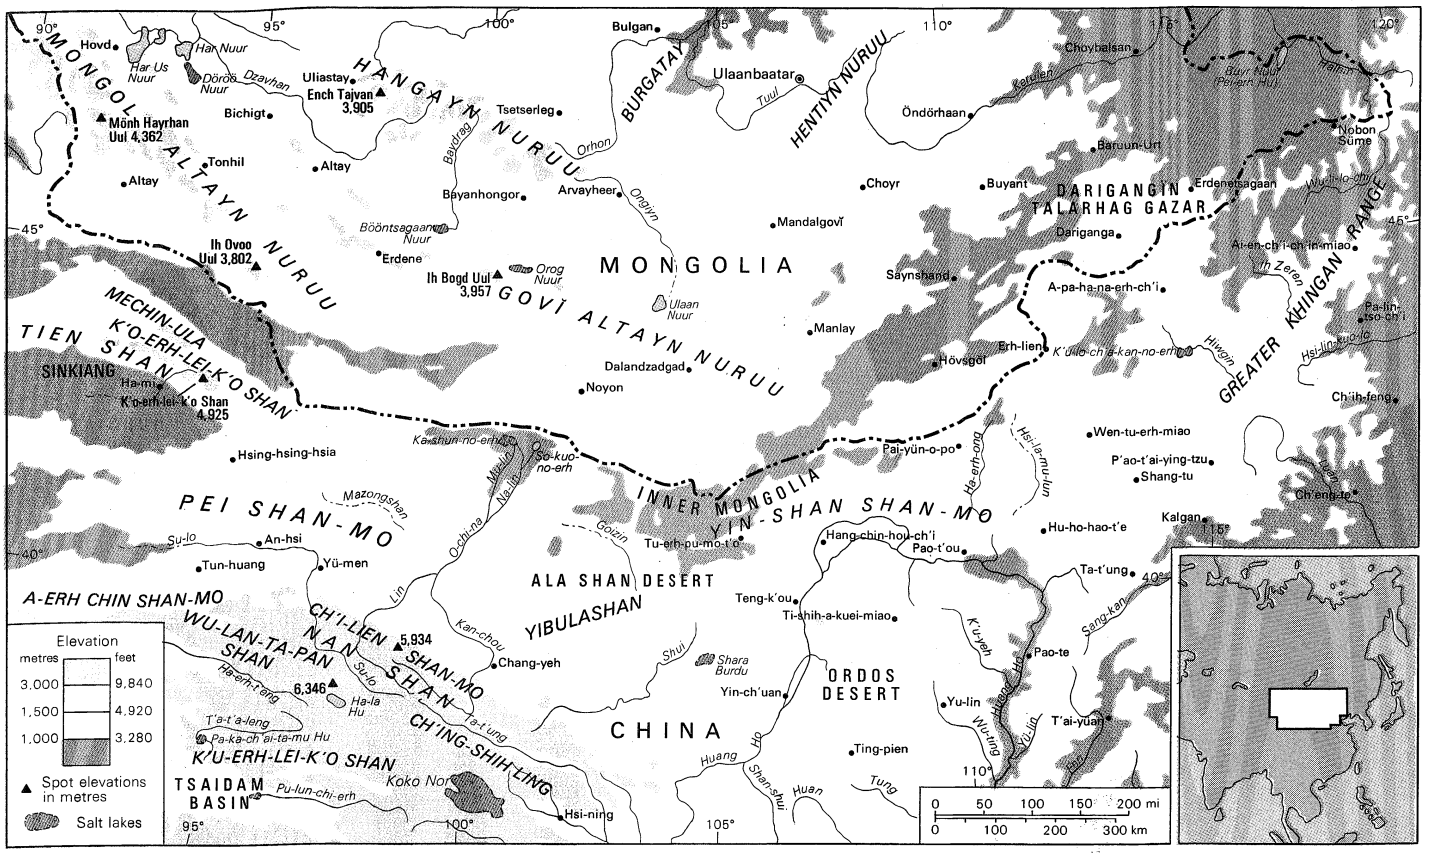
Regional subdivisions

Physical features. The Gobi may be subdivided into the Ka-shun, Dzungarian, and Trans-Altai Gobi (south of the Mongolian Altai Mountains) in the west and the Eastern, or Mongolian, Gobi in the centre and east.

The Ka-shun is bounded by the spurs of the Tien Shan to the west and the Pei Shan-mo in the south and rises as high as 5,000 feet. It is gently corrugated, with a complex labyrinth of wide hollows separated by flat hills and rocky crests sometimes rising more than 300 feet above the plain. The desert is stony and waterless, though salt marshes lie in the secluded depressions. The soil is grayish brown and contains gypsum. Vegetation is very rare, though richer in the riverbeds, where there are individual shrubs of tamarisk, zaysansky haloxylon and nitre bush (both saltworts), and annual halophytes (plants growing naturally in soils containing certain salts).

The Trans-Altai Gobi is situated between the eastern spurs of the Mongol Altayn Nuruu (Mongolian Altai), the Govĭ Altayn Nuruu (Gobi Altai) in the north and east, and Pei Shan-mo in the south. The plain is elevated, sharp, and rugged. Alongside the plains and the isolated group of low, rounded hills is a fairly extensive mountain area, extending over six miles out into the plain. The mountains are very barren and broken up by dry ravines. The western section of the Trans-Altai Gobi is basically a plain, too, but interspersed with small raised areas and furrowed by dry riverbeds and, again, with extensive salt marshes. In the central portion this fragmentation increases, and mesas (flat-topped, steep-sided hills) appear along with dry gullies ending in flat depressions, occupied by *takyr* (clayey tracts). The Trans-Altai Gobi is quite parched, with annual precipitation of less than four inches, though there is always water underground. There are virtually no wells and springs, however, and vegetation is very sparse and almost useless for livestock.

The Dzungarian Gobi is situated north of the Ka-shun Gobi, between the eastern spurs of the Mongol Altayn



The Gobi

Nuruu and the eastern extremity of the eastern Tien Shan (the K'o-erh-lei-k'o Shan). It is like the Trans-Altai Gobi, and its edges are fractured by ravines, alternating with residual hills and low mountain ridges.

The Eastern Gobi is of similar character, with altitudes varying from 2,300 to 5,000 feet, but enjoys rather more precipitation—up to eight inches a year—though with virtually no rivers. The underground waters are relatively abundant and only partly mineralized. They are also near the surface, feeding small lakes and springs. The vegetation, however, is sparse: herb wormwood in coarse, grayish-brown soil. In the moister depressions there are the usual salt marshes and grassy swamps. In the northern and eastern outlying regions, where more precipitation occurs, the landscape of the desert gradually mellows, sometimes even becoming steppes.

Geologic character and fossils. The Gobi's various chalky plains are chiefly Paleocene to Recent (up to 65,000,000 years old), though some of the low, isolated hills are older. The terrain contains small masses of shifting sands. In the central Gobi, Mesozoic remains of dinosaurs (65,000,000 to 225,000,000 years old) and Paleogenic and Neogenic fossils of mammals have been found. The desert also contains Paleolithic and Neolithic sites occupied by ancient man.

Fossils

Climate. The climate is acutely continental and dry, ranging from January's −40° F (−40° C) to 113° F (45° C) in July. Winter is severe; spring is dry and cold; and summer is warm. The annual total precipitation varies from 2.7 inches in the west to more than eight inches in the northeast (the maximum falls in summer), and in the eastern regions the impact is quite monsoonal. North and northwestern winds prevail over the Gobi.

Drainage. Aridity in the Gobi depends on the relative chalkiness of the soil and has been aggravated by the strong mountain structure to the west. The lakes have correspondingly shrunk, leaving a series of terraces considerably farther from and higher than the present shorelines. Indeed, Wu-lan Hu (east of the Pei Chan-mo), Orog Nuur, and Bööntsagaan Nuur (in the easternmost Mongolian Altai) are but shadows of their former selves.

The drainage of the desert is largely underground; surface rivers have very little constant flow. Mountain streams are confined to the Gobi's fringes and even then quickly dry up, as they disappear into the loose soil or the salty, enclosed depressions. Many rivers flow only in summer. On the other hand, subterranean water is widespread and of sufficient quality to allow cattle raising.

Soil types and plants. The soil is chiefly grayish-brown and brown carbonaceous (rich in carbon), gypseous (containing gypsum), coarse gravel, often combined with sandy salt marshes and *takyr*. Vegetation is sparse and rare. On the plateau, and on the plains beneath the mountains, small bushlike vegetation occurs: echinochloa (a type of succulent grass found in warm regions), yellowwood bean caper, winterfat (a shrub covered with densely matted hairs), Dzungarian reaumur, nitre bush, and bushlike halophytic vegetation. In the salt marshes, too, halophilous groups prevail: potash bush, Siberian nitre bush, tamarisk, and annual halophytes; in the sands grow zaysansky haloxylon, the sandy wormwood, and sparse perennial and annual herbs such as the Gobi kumarchik and timuriya. In semidesert tracts vegetation is richer, belonging to the herbaceous-wormwood groups: Gobi feather grass; the annual Gobi kumarchik (*Agriophylum gobicum*); the perennials timuriya (*Timouria villosa*) and snakeweed (*Cleistogenes* sp.); and cold wormwood. There are herb meadows with rhizome Mongolian onions and herb salt marshes with sparse beds of bushlike *Caragana*. In the Gobi Altai and other high mountains, desert-grass steppes completely cover the lower slopes, and, on the upper parts, mountain versions of the feather-grass steppes appear.

Areas with fairly rich vegetation

Animal life. Animal life is varied, with such large mammals as the wild camel, the ass kulan (*Equus asinus ferus*), the Przhevalsk wild horses (named after a town in the Kirgiz region of the Soviet Union), the dzheiran gazelle, and the dzeren (an antelope). Rodents include marmots and gophers, and there are reptiles.

The population density is small—fewer than three persons per square mile—mostly Mongols with Chinese in Inner Mongolia. The Chinese have increased greatly in

recent years. The main occupation of the inhabitants is nomadic cattle raising, though, in regions where the Chinese are concentrated, agriculture is predominant. The living quarters of the Mongol nomads are felt yurts (types of tent), while the Chinese farmers live in *fanzy*, clay homes built from crude brick.

Farming and land use. The province of the Gobi and its semidesert sections is mainly a livestock region, sheep and goats comprising 57 percent of the total herds. Next come the large-horned cattle, accounting for 25 percent. Horses only make up about 4 percent of the total and, together with the large-horned cattle, are concentrated in the lusher semidesert of the southeastern region. About 15 percent of the livestock still consists of two-humped camels, still used for transportation in some areas. Pasturage for cattle is available all year round because of underground waters. Livestock raising is nomadic, and herds move ten times a year, migrating as much as 120 miles between extreme points.

Natural resources

Useful mineral deposits are scant, but there are pockets of petroleum around the city of Saynshand (about 250 miles southeast of Ulaanbaatar), and, in the Mongolias as a whole, salt and light metal ores are mined. Agriculture is developed only along the river valleys.

Transportation. The Gobi is intersected by railroads in the east and west. There are several highways: from the town of An-hsi to the town of Ha-mi across Pei Shan-mo and the Ka-shun Gobi, from the town of Kalgan (northwest of Peking) to Ulaanbaatar, and from Ulaanbaatar to Dalandzadgad (some 300 miles south-southwest of Ulaanbaatar). In addition, various ancient caravan tracks crisscross the Gobi in all directions.

Future prospects for the development of the Gobi area rest upon industrial development of the mineral wealth and on cattle and sheep breeding. In the early 1970s, the rate of economic development in those Gobi areas in the Mongolian Peoples Republic was faster than that for the desert portions of the Inner Mongolia regions of China.

BIBLIOGRAPHY. Additional information on the Gobi Desert may be found in MILDRED CABLE, *The Gobi Desert* (1942); SVEN A. HEDIN, *Åter till Asien* (1928; Eng. trans., *Across the Gobi Desert*, 1931, reprinted 1968); and ALONZO W. POND, *Climate and Weather in the Central Gobi of Mongolia* (1954).

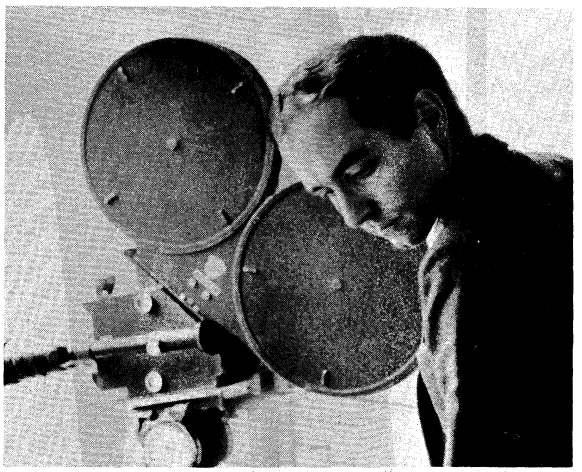
(M.P.Pe.)

Godard, Jean-Luc

Of all the former critics of the journal *Cahiers du Cinéma* who, in the late 1950s, became the major French film makers of the "New Wave" (*e.g.*, François Truffaut, Alain Resnais), none has had a more prolific or more controversial career than Jean-Luc Godard. No less boldly radical in his political views than in his aesthetic convictions, he has written and directed highly personal films, such as *Breathless*, that are fascinating in expressing so forcefully his readiness to sacrifice both his art and his way of life to a tortuous conscience. Although Godard's films have provoked a wide range of critical responses, it is indisputable that they have exercised an immense influence on film making throughout the world.

Though he was born in Paris, on December 3, 1930, Godard spent his formative years on the Swiss side of Lake Geneva, where his father directed a clinic. His higher education comprised study for a degree in ethnology at the University of Paris, interminable student cafe conversations, and a labouring job on a dam, which inspired his first short film, *Opération Béton* (1954). His ethnological interests link with the influence on his work of Jean Rouch, an anthropologist who became the first practitioner and theoretician of the documentary-like film style *cinéma vérité* ("cinema truth"). Film makers of this school employ lightweight television equipment in order to observe their subject with the utmost informality and so completely without preconceived bias that the theme and motifs of the film emerge only while shooting, or even later, at the editing stage. Godard (often writing under the pseudonym of Hans Lucas) also evinced a then unfashionable devotion to such studio-bound German expressionist film makers as Fritz Lang.

Improvisatory techniques



Godard.
By courtesy of The Museum of Modern Art Film Stills Archive, New York

Godard's first feature film, *Breathless*, which was produced by Truffaut, his colleague on *Cahiers*, won the Prix Jean Vigo in 1960. It inaugurated a long series of features, all celebrated for the often drastic nonchalance of Godard's improvisatory film-making procedures. *Breathless* was shot without a script; Godard sketched the dialogue overnight and revised it between and during rehearsals. In subsequent films he even resorted to speaking the characters' replies to the actors from behind the camera during takes. Thus, he used improvisatory techniques sometimes to observe reality, sometimes to impose his own vision, and often to interrelate the two so as to create a strangely abstract effect.

His 1963 film *Contempt*, based on a story by the Italian novelist Alberto Moravia, marked his only venture into orthodox and comparatively expensive film making. Afterward, he maintained an almost unique position as an absolute, independent creator, using extraordinarily cheap alfresco production methods and enjoying repeated success on the international "art cinema" circuit.

Breathless recounts the misadventures of a petty crook (played by Jean-Paul Belmondo, often Godard's alter ego on screen) who admires Humphrey Bogart and is betrayed to the police by an American girl. Being uncertain whether or not she loves him, she informs on him simply to see if she can. For some years, Godard's work showed an increasingly desperate obsession with themes of fickleness (both male and female), indignity, caprice, and the impossibility of distinguishing a meaningful reality from the imposture perpetrated by others, by one's own mind, by ideology, and by art. Godard used the face of the actress who was then his wife, Anna Karina, as a sphinxlike icon representing this existential duplicity in several films, notably *The Little Soldier* (1960), an ironically flip tragedy, banned for many years, about torture and countertorture. *My Life to Live* (1962), a study of a young Parisian prostitute, used, with ironical solipsism, pastiches of documentary form and clinical jargon. And on the strength of *Pierrot le fou* (1965), he was asked to direct what was to be an immensely successful U.S. film, *Bonnie and Clyde* (he refused it because of his suspicion of the Hollywood system).

Early themes of fickleness

Godard offered his visual and verbal images as delusive counterfeits for a life whose meaning has become irretrievably lost, or, perhaps was always intrinsically absurd. These images are endowed with additional depth by his extensive culture. Increasingly, his films came to include shots of books brandished or read from and suggestive street signs or posters and dialogue that is delivered as if the performers were alienated from their roles, merely reading texts. Historically impossible or subtly fantastic settings are juxtaposed, and his films compel disrupting awareness of the medium itself. Thus, in two of his films, Belmondo, as the hero, addresses the audience directly, through the camera, while driving. His allusions to other films in themselves constitute an

intricate maze. The heroine of *The Little Soldier*, for instance, is surnamed "Dreyer" after Carl Dreyer, the director whom Godard admires; an extract from one of Dreyer's films is watched by the heroine of *My Life to Live*. *Alphaville* (1965) features scenes from *Metropolis* (1926), whose director, Fritz Lang, plays a film director in *Contempt*. In these ways, Godard's films become intellectual essays: in them, the acted, experienced fictions of earlier motion pictures are transformed into the illustrative ideological cinema of the late 1960s. In 1966 two features—*Made in U.S.A.*, devoted to America, and *Two or Three Things I Know About Her*, devoted to Paris—marked a nadir of Godard's generalized despair, which by then was aimed at society as well as at interpersonal relationships. An increasing interest in left-wing thought was implicit in *La Chinoise* (1967; its title is slang for Parisian Maoists) and was confirmed by Godard's active participation in the Paris student riots of 1968 and other demonstrations.

Revolutionary militancy

By then married to the actress Anne Wiazemsky, he moved from fiction and aesthetic preoccupation to the Marxism of Herbert Marcuse, "Che" Guevara, Frantz Fanon, and others. *Le Gai Savoir* (1968) is a flatly illustrated text spoken by two students named Émile Rousseau and Patricia Lumumba. His subsequent texts have exhibited a complete indifference to their appeal to the public and have been intended as intellectual agitprop (*i.e.*, agitation–propaganda): in Godard's own words, they are "not a show, a struggle." With this ideological twist Godard disconcerted those who had admired him, whether their particular enthusiasm was for the dexterity of his film form, for his reputation as a second creator of the intellectual cinema (as adumbrated by the Soviet director Sergey Eisenstein a generation earlier), for his skill in posing complex cultural riddles, or for his cool but sad recording of Western man's crises of identity. His evolution has posed a problem, also, for his detractors, whether they criticized him for solipsism, for nihilism, or for his suspiciously complacent celebration of the ignominies of bourgeois man under the shadow of revolution. Even the minority that declared his earlier films to be honourable failures, or exercises in intellectual tedium, have had to agree that, of all directors, he remains the most recklessly volatile, and his development the most fascinatingly unpredictable.

MAJOR WORKS

À bout de souffle (1960; *Breathless*); *Le Petit Soldat* (1960; *The Little Soldier*); *Une Femme est une femme* (1961; *A Woman is a Woman*); *Vivre sa vie* (1962; *My Life to Live*); *Les Carabiniers* (1963; *The Soldiers*); *Le Mépris* (1963; *Contempt*); *Bande à part* (1964; U.S. title, *Band of Outsiders;* British title, *The Outsiders*); *Une Femme mariée* (1964; U.S. title, *The Married Woman;* British title, *A Married Woman*); *Alphaville* (1965); *Pierrot le fou* (1965; *Crazy Pete*); *Masculin-féminin* (1965); *Made in U.S.A.* (1966); *Deux ou trois choses que je sais d'elle* (1966); *La Chinoise* (1967); *Loin de Viêt-nam* (1967; *Far from Vietnam,* episode); *Week-end* (1967); *Le Gai Savoir* (1968); *One plus One* (1968; alternate title, *Sympathy for the Devil*); *British Sounds* (1969); *Le Vent d'est* (1969); *Pravda* (1970).

BIBLIOGRAPHY. The English bibliography is dominated by two collections of essays: *The Films of Jean-Luc Godard*, 2nd ed. by IAN CAMERON (1970); and *Jean-Luc Godard: A Critical Anthology*, ed. by TOBY MUSSMAN (1968). Other English material includes RICHARD ROUD *Jean-Luc Godard*, 2nd ed. (1970); and the following scripts: *Le Petit Soldat, The Married Woman, Alphaville, Pierrot le fou, Masculin-féminin*, and *Made in U.S.A.*

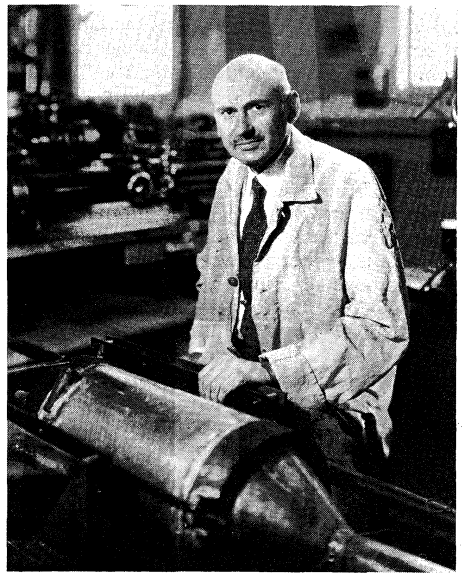
(R.Du.)

Goddard, Robert Hutchings

Robert Hutchings Goddard, a retiring New England professor who dreamed of interplanetary travel at the turn of the 20th century and became America's earliest inventor of rocket engines, is generally acknowledged to be the father of modern rocketry. Among the more than 200 rocket patents issued to Goddard from 1914 to the mid-1940s are methods of propulsion in airless space anticipated by the physicist as a young man. In 1919, the publication of his classical treatise, *A Method of Reaching Extreme Altitudes* (*Smithsonian Miscellaneous Collections*, vol. 71, no. 2) quietly ushered in the age of space flight and man's travel to other planets.

Born October 5, 1882, in Worcester, Massachusetts, Goddard was the only child of a bookkeeper, salesman,

By courtesy of Esther C. Goddard



Goddard in his workshop, 1935.

and machine-shop owner of modest means. The boy had a genteel upbringing and in early youth felt the excitement of the post-Civil War Industrial Revolution when Worcester factories were producing machinery and goods for the burgeoning country. From childhood on he displayed great curiosity about physical phenomena and a bent toward inventiveness. He read in physics and mechanics, and dreamed of great inventions.

In 1898, young Goddard's imagination was fired by the H. G. Wells space-fiction novel, *War of the Worlds*, then serialized in the *Boston Post*. Shortly thereafter, as he recounted, he actually dreamed of constructing a workable space-flight machine. On October 19, 1899, a day that became his "Anniversary Day," he climbed a cherry tree in his backyard and ". . . imagined how wonderful it would be to make some device which had even the *possibility* of ascending to Mars . . . when I descended the tree . . . ," he wrote in his diary, "existence at last seemed very purposive."

Goddard's fascination with space flight and the means of attaining it continued into his college years at the Worcester Polytechnic Institute. In an assigned theme, "Travelling in 1950," he was also intrigued with the notion of "the fastest possible travel for living bodies on the earth's surface" and projected a plan for travel inside a steel vacuum tube in which cars were suspended and driven by the attraction and repulsion of electromagnets. Patents on a vacuum-tube system of transport were later granted the inventor, with thrust—acceleration and deceleration—the chief principle.

In 1908 Goddard began a long association with Clark University, Worcester, where he earned his doctorate, taught physics, and carried out rocket experiments. In his small laboratory there, he was the first to prove that thrust and consequent propulsion can take place in a vacuum, needing no air to push against. He was the first to explore mathematically the ratios of energy and thrust per weight of various fuels, including liquid oxygen and liquid hydrogen. He was also the first to develop a rocket motor using liquid fuels (liquid oxygen and gasoline), as used in the German V-2 rocket weapon 15 years later. In a small structure adjoining his laboratory, a liquid-propelled rocket in a static test in 1925 "operated satisfactorily and lifted its own weight," he wrote. On March 16, 1926, the world's first flight of a liquid-propelled rocket engine took place on his Aunt Effie's farm in Auburn, Massachusetts, achieving a brief lift-off.

World's first rocket flight

In achieving lift-off of his small but sophisticated rocket engine, Goddard carried his experiments further than did the Russian and German space pioneers of the day. As is frequently the case with scientific theory and invention, developments proceeded in various parts of the world. While Goddard was engaged in building models of a space-bound vehicle, he was unaware that an obscure schoolteacher in a remote village of Russia was equally fascinated by the potential for space flight. In 1903 Konstantin E. Tsiolkovsky wrote "Investigations of Space by Means of Rockets," which many years later was hailed by the Soviet Union as the forerunner of space flight. The other member of the pioneer space trio—Hermann Oberth of Germany—published his space-flight treatise, *Die Rakete zu den Planetenräumen*, in 1923, four years after the appearance of Goddard's early monograph.

Goddard's early tests and others were modestly financed over a period of several years by the Smithsonian Institution, whose secretary, Charles G. Abbot, had responded to Goddard's appeal for financial support. In 1929, following an aborted and noisy flight test that brought unwanted press notice to the publicity-shy inventor, Charles A. Lindbergh was instrumental in procuring greater financial assistance for Goddard's experiments. From 1930 to the mid-1940s, the Guggenheim Fund for the Promotion of Aeronautics financed the work on a scale that made possible a small shop and crew and experimental flights in the open spaces of the American southwest, at Roswell, New Mexico. There, Goddard spent most of his remaining days in the unending trial-and-error reach for high altitudes.

Experiments at Roswell

In the course of his experiments there he became the first to shoot a liquid-fuel rocket faster than the speed of sound (1935). He obtained the first patents of a steering apparatus for the rocket machine, and of the use of "step rockets" to gain great altitudes. He also developed the first pumps suitable for rocket fuels, self-cooling rocket motors, and other components of an engine designed to carry man to outer space. Furthermore, his experiments and calculations took place at a time when any news of his work drew from the press and the public high amusement that "Moony" Goddard could take seriously the possibility of travel beyond Earth. His small rockets, early prototypes of the modern Moon thrusters, achieved altitudes of up to one mile above the prairie.

During World War II, Goddard offered his work to the military, but lack of interest in rocket development led to his closing down the Roswell establishment and participating in the war effort through a small Navy contract for work at Annapolis, Maryland, on the development of a jet-thrust booster for seaplane takeoff. Lindbergh and the industrialist and philanthropist Harry F. Guggenheim remained staunch advocates of the Worcester inventor and the feasibility of space exploration.

Goddard died of throat cancer August 10, 1945, at the threshold of the age of jet and rocket. Years later, his work was acknowledged by the United States government when a $1,000,000 settlement was made for the use of his patents. Honours paid posthumously included a Goddard Memorial Library at Clark University.

Goebbels, Joseph

Paul Joseph Goebbels, the leading propagandist of the Nazi Party and minister of propaganda of Adolf Hitler's Third Reich, mastered, to the point of near perfection, every contemporary device for leading and misleading the public. It was largely due to his extraordinarily persuasive propaganda that the German people followed Hitler into the abyss, long after they knew where he was leading them.

Early years

Goebbels was born on October 29, 1897, the third of five children of a factory clerk in Rheydt, in the Rhineland. The parents, eager to see their talented son rise in the world, not only provided him with a high school education but also helped support him during the five years of his undergraduate studies. In World War I he was exempted from active wartime duty and all other military service because of his clubfoot, which later enabled his enemies to draw a parallel with the cloven hoof and limp of the Devil. This defect, presumably not congenital but rather the result of a childhood disease, played a disastrous role in his life by engendering strong desires for compensation.

Goebbels, c. 1935.
Interfoto-Friedrich Rauch, Munich

After graduating from Heidelberg University in 1921, with a doctorate in German philology, Goebbels engaged in—largely unremunerative—literary, dramatic, and journalistic efforts. Although not yet involved in politics, Goebbels, in common with most of his contemporaries, was imbued with a nationalistic fervour made more intense by the frustrating outcome of the war. During his university days, a friend also introduced him to socialistic and communistic ideas. Antibourgeois from his youth, Goebbels remained so in spite of all his later upper class affectations. On the other hand, he was initially not anti-Semitic. The high school teachers he valued most were Jews, and he was, during that time, engaged to a half-Jewish girl. At that point his options, if he chose to enter politics, were still wide open. An accident determined the party he was to join.

Rise in the party

In the autumn of 1924 he made friends with a group of National Socialists. A gifted speaker, he was soon made the district administrator of the Nationalsozialistische Deutsche Arbeiterpartei (National Socialist German Workers' Party [NSDAP]) in Elberfeld and editor of a biweekly National Socialist magazine. In November 1926 Hitler appointed him district leader in Berlin. The NSDAP, or Nazi Party, had been founded and developed in Bavaria, and, up to that time, there had been practically no party organization in Berlin, the country's capital. Goebbels owed his new appointment to the prudent choice he made in a conflict between Gregor Strasser, representing the "left-wing," anti-capitalist faction of the NSDAP, and the "right-wing" party leader, Hitler. In this conflict, Goebbels, against his own inner convictions, took Hitler's side.

Personally courageous and never shirking danger, Goebbels proceeded to build Nazi strength in Berlin until Hitler's accession to power at the end of January 1933. In 1928 Hitler gave the successful orator, well-versed propagandist, and brilliant journalist (he was editor of *Der Angriff* ["The Assault"] and later, from 1940 to 1945, *Das Reich*) the additional post of propaganda director for the NSDAP for all of Germany. With great diligence Goebbels began to create the Führer myth around the person of Hitler and to institute the ritual of party celebrations and demonstrations that played a decisive role in converting the masses to Nazism. In addition, he

spread propaganda by continuing his rigorous schedule of speechmaking.

Control of propaganda

After the "seizure of power," Goebbels was also able to take control of the national propaganda machinery. A "National Ministry for Public Enlightenment and Propaganda" was created for him, and in addition he became president of the newly formed "Chamber of Culture" for the *Reich*. In these positions he controlled, in addition to actual propaganda, the press, the radio, films, publication, the theatre, music, and the visual arts. In the case of foreign propaganda, the press, publications, and the theatre, he engaged in occasionally bitter jurisdictional struggles with other functionaries; he controlled music and art without too much interest. He did not, however, succeed in extending his power into other areas, such as the high schools.

His cultural policies were relatively liberal, but he often had to capitulate to the demands of nationalist extremists. Even his propaganda messages were limited by the rational argument that ceaseless agitation only dulls the receptive powers of the listener. As far as Goebbels was concerned, efficiency always took precedence over dogmatism, expediency over principles.

Goebbels' influence decreased in the years 1937 and 1938, when he came within a hair's breadth of giving up his career and family because of a deep love affair with a Czechoslovakian film star. (Since 1931 he had been married to a woman of good family who eventually bore him six children.) His position underwent little change with the outbreak of World War II (which he did not welcome): in times of victory, the propagandist's services are not much in demand. Goebbels' hour came with the turn in fortunes of the war after the defeats in Stalingrad and Africa, when he was to prove himself a master of the clever propaganda of holding out in the face of defeat.

Contrary to common belief, Goebbels did not at that time falsify the facts of the situation. On the contrary, the main thrust of his propaganda—which he carried on personally and without respite in the press and over the radio—was to continually raise hopes by citing historical parallels and making other comparisons, by conjuring up allegedly immutable laws of history, or even, as a last resort, by referring to some secret miracle weapons. Here, too, he demonstrated personal courage by appearing constantly before the public long after the other prominent Nazis had retreated to their bunkers and fortifications. His public appearances in these years did much to improve an image that had until then been overwhelmingly negative. Goebbels' work was especially effective in intensifying the efforts of the home front: he became the protagonist of total war. After several false starts, the attempted assassination of Hitler on July 20, 1944, brought him within view of his goal. On July 25 he was "invested by the Reich with full powers to implement total war"—but it was too late.

On May 1, 1945, the only one of the original Nazi leaders to remain with Hitler in the besieged bunker in Berlin, Goebbels, together with his wife, took his own life and those of his six children. This was the last and, if not the bloodiest, at least the most macabre production of this talented stage manager. The day before, he had been named chancellor of the *Reich* in Hitler's will. For one day, on a few square metres, he thus became the last successor to Otto von Bismarck.

Goethe, Johann Wolfgang von

A German writer, universally acknowledged to be one of the giants of world literature, Goethe was perhaps the last European to attempt the many-sidedness of the great Renaissance personalities: critic, journalist, painter, theatre manager, statesman, educationalist, natural philosopher. The bulk and diversity of his output is in itself phenomenal: his writings on science alone fill about 14 volumes. In the lyric vein he displayed a unique variety of theme and style; in fiction he ranged from fairy tales, which have proved a quarry for psychoanalysts, through the poetic concentration of his shorter novels and *Novellen* to the "open," symbolic form of *Wilhelm Meister;* in the theatre, from historical, political, or psychological plays in prose through blank-verse drama to his *Faust*, one of the masterpieces of modern literature. He achieved in his 82 years a wisdom often termed Olympian, even inhuman; yet almost to the end he retained a willingness to let himself be shaken to his foundations by love or sorrow. He disciplined himself to a routine that might armour him against chaos; yet he never lost the power of producing magical short lyrics in which the mystery of living, loving, and thinking was distilled into sheer transparency.

Goethe, oil painting by Joseph Karl Stieler, 1828. In the Bayerische Staatsgemäldesammlungen, Munich.

And at the last there was granted him a gift, uncanny even to himself, of tapping at will the springs of creativity in order to complete the work he had carried with him for 60 years. When, a few months before his death, he sealed his *Faust*, he bequeathed it with ironic resignation to the critics of posterity to discover its imperfections. Its final couplet, "Das Ewig-Weibliche/Zieht uns hinan" ("Eternal Womanhead/Leads us on high"), epitomizes his own feeling about the central polarity of human existence: woman was to him at once man's energizer and his civilizer, source of creative life and focus of the highest endeavours of both mind and spirit.

There was in Goethe a natural, if not always painless, swing between poles of existence often thought to be mutually exclusive and an innate commitment to change and process. And in the last letter he was to write, he rounded off what has sometimes been called his greatest work, his life, by setting the seal of his approval on a mode of growth that sees the art of living as the intensification of inborn talents through a judicious surrender to the natural rhythm of opposing tendencies.

Early life and influences. Born on August 28, 1749, in Frankfurt am Main, Goethe came of middle class stock, the *Bürgertum* that he never ceased to praise as a breeding ground of the finest culture. His father, Johann Kaspar Goethe, was of north German extraction. A retired lawyer, he was able to lead a life of cultured leisure, travelled in Italy, and amassed a well-stocked library and picture gallery in his handsomely furnished house. His mother, Katharine Elisabeth Textor, daughter of a *Bürgermeister* of Frankfurt, opened up to her son valued connections with the patriciate of the free city. Thus even in his heredity Goethe unites those opposing tendencies that have always prevailed in German lands: the intellectual and moral rigour of the north and the easygoing artistic sensuousness of the south. Of eight children, only Wolfgang, the firstborn, and a sister, Cornelia, survived.

In his autobiography, *Dichtung und Wahrheit* ("Poetry and Truth"), Goethe left an unforgettable picture of a happy childhood. Here are set out with acute psychological insight the emotional complexities of his bond with Cornelia, which found expression in numerous portrayals of the brother-sister relationship in his works; his passionate attachment to a barmaid, Gretchen, which foreshadowed the rejection pattern of many of his loves; the broadening of outlook that came with French occupation during the Seven Years' War; the coronation of Joseph II in the Frankfurt *Römer*, with its indelible impressions of medieval pageantry; the fervent religiosity of Pietistic circles, which led him to declaim F.G. Klopstock's *Messias* as a kind of Lenten exercise, to write a prose epic on Joseph and a poem on Christ's descent into hell. The French army had brought its own troupe of actors, and their performances intensified a passion for the stage first kindled in him by his grandmother's gift of a puppet theatre, and inspired a lifelong devotion to Racine. A love of things English was fostered by friendship with a young clothier from Leeds (Goethe's paternal grandfather was a fashionable tailor) with whom Cornelia, seeing herself as the heroine of a Richardsonian novel, fell hopelessly in love. Wolfgang's reaction was the inception of a novel in letters, a kind of linguistic exercise in which four brothers correspond in different languages.

Study at Leipzig

In October 1765 Goethe was sent to study law at his father's old University of Leipzig, though he himself would have preferred to read classics in the newly founded university at Göttingen, where English influence prevailed. In Leipzig, or "little Paris" as he calls it in *Faust*, by contrast, a world of elegance and fashion made the young provincial feel like a fish out of water. The Frenchifying influence of the critic J.C. Gottsched still dominated the theatre and provided a repertory of the best plays of contemporary Europe. But C.F. Gellert, poet and author of fables and hymns, now in the heyday of his fame, presented the new sensibility of Edward Young, Laurence Sterne, and Samuel Richardson. Goethe praised Gellert's lectures as "the foundation of German moral culture" and learned from them invaluable lessons in epistolary style and in social conduct. Gellert's literary influence was reinforced by the robust elegance and ironic sagacity of the novels, tales, and epics of C.M. Wieland. Wieland's work was brought to Goethe's notice by A.F. Oeser, friend and teacher of the archaeologist and art historian J.J. Winckelmann, who profoundly influenced European fashions in art. From Oeser, Goethe learned a love of Greek art and two things that stood him in good stead all his life: to use his eyes and to master the craft of whatever he undertook. A visit to Dresden, "the Florence of the north," as the poet and critic J.G. Herder called it, opened his eyes to the splendours of Rococo architecture as well as classical statuary. Nor was music neglected in his education; a new 18th-century concert society, under the direction of the musician and composer J.A. Hiller, provided splendid performances, which became world famous as the *Gewandhaus* concerts.

Early works in the Rococo fashion

The literary harvest of Goethe's Leipzig period manifested itself in a songbook written in the prevailing Rococo mode—songs praising love and wine in the manner of the Greek poet Anacreon. Appropriately titled *Das Leipziger Liederbuch* (*The Leipzig Song Book*), it was ostensibly inspired by the daughter of the wine merchant at whose tavern he took his midday meal. But neither his 1766–67 poems *Das Buch Annette* (as he called her in Rococo fashion) nor the *Neue Lieder* of 1769 made any pretense of real passion. Yet it was in connection with these literary trifles that he subsequently made the famous and much abused statement that all his works were "fragments of a great confession." The same note is struck in two plays written in alexandrine verse (a twelve-syllable iambic line borrowed from the French), *Die Laune des Verliebten* ("The Mood of the Beloved") and a more sombre farce, *Die Mitschuldigen* ("The Accomplices"), which foreshadows the psychological preoccupations of later works. From then on, Rococo was one element in Goethe's repertoire to be drawn on as occasion demanded. It was to reappear in the setting of *Torquato Tasso* and *Die Wahlverwandtschaften* ("Kindred by Choice"); he was to pay tribute to its charm in *Anakreons Grab* ("Anacreon's Grave"; 1806) and amalgamate it with Eastern influence in enchanting poems of the *West-östlicher Divan* ("The West-East Divan").

Works of the storm and stress period. Goethe's stay in Leipzig was cut short by severe illness, and by the autumn of 1768 he was back home. A long convalescence fostered introspection and religious mysticism. He played with alchemy, astrology, and occult philosophy, all of which left their mark on *Faust*. On his recovery it was decided that he should pursue legal studies in Strassburg as a first stage on the way to Paris and the Grand Tour (never actually completed). His stay there proved a turning point for his whole life and work. In this German capital of a French province, he experienced a reaction against the cosmopolitan atmosphere of Leipzig and under the impact of the great cathedral proclaimed his conversion to the Gothic German ideal. More decisive still was the influence of J.G. Herder, who spent the winter of 1770–71 there undergoing treatment for his eyes. From him Goethe learned the role played by touch, the haptic sense, in the growth of the mind; a new view of the artist as a creator fashioning forms expressive of feeling; a new theory of poetry as the original and most vital language of man; the virtues of a new style, that of the *Volkslied* (folk song) and the poetry of "primitive" peoples as enshrined in the Bible, the epics of Homer, and the poems attributed (probably falsely) to Ossian, a 3rd-century Celtic poet. It is this new sense of felt immediacy, and of the plasticity of his linguistic medium, that informs the lyrics Goethe wrote to one of his early loves, Friederike Brion, the pastor's daughter of Sesenheim. They mark the beginning of a new epoch in the German lyric. Such poems as "Mailied" and "Willkommen und Abschied" are still the most popular, though not the greatest, of his *Lieder*. The latter, especially in its revised form of 1790, touchingly expresses the guilt he felt that this time he himself had the role of deserter and rejecter, and the whole idyl as recounted in *Dichtung und Wahrheit* reveals that cross-fertilization of life and literature that he increasingly saw as a potent factor in human development.

Influence of J.G. Herder

If, as Herder maintained, energy was one of the marks of poetry, it was clearly in the passions acted out on the stage that it could find its most vital expression. And where more vital than in the colossal figures of the "Gothic Shakespeare"? In writing the *Geschichte Gottfriedens von Berlichingen mit der eisernen Hand dramatisiert* ("The History of Gottfried von Berlichingen Dramatized with the Iron Hand"; 1771), Goethe was deliberately vying with Shakespeare. For the real Götz, who died two years before Shakespeare was born, was near enough in time to represent that bustling spacious 16th century, the animal vitality of which contrasted so forcibly with the straitlaced affectations of Goethe's own day. With the publication in 1773 of *Götz von Berlichingen*, a radically tautened version of that "History," the Shakespeare cult was launched and the Sturm und Drang provided with its first major work of genius. The manifesto of the movement, heralded by Goethe's enthusiastic *Rede zum Schakespears Tag* ("Conversation from Shakespeare's Day"), had appeared after Goethe's return to Frankfurt in August 1771. "Von deutscher Art und Kunst" ("Concerning German Nature and Art"), as it was called, contained a defense of German nationality by the historian J.M. Möser, two essays by Herder championing Ossian and Shakespeare, and a rhapsody on Gothic architecture by Goethe.

The success of *Götz von Berlichingen*

Though ostensibly in practice as a lawyer, the young poet now found himself caught up in a whirl of literary and social duties—helping to edit the *Frankfurter Gelehrte Anzeigen* ("Frankfurt Scholarly Reviews"), for instance—and it was to break loose from this that he left for Wetzlar, seat of the supreme court of the Empire. But again literature won the day over law, and an impassioned yet self-ironic ode in free verse, "Wandrers Sturmlied," is testimony both to a recently inspired admiration for Pindar, the greatest lyric poet of ancient

Greece, and to a hesitant certainty that he himself might be destined for greatness. And in Wetzlar he experienced a new passion, this time for a girl safely out of reach from the start, Charlotte Buff. Her betrothed, Johann Christian Kestner, showed great understanding until, as it seemed to him, he found the affair exposed to public gaze in *Die Leiden des jungen Werthers* (*The Sorrows of Young Werther;* 1774).

But much besides the Wetzlar experience had gone into the making of this novel: Herder's scathing comments on his young pupil's lack of formal- and self-mastery; the recent indictment by G.E. Lessing of the Neoplatonic doctrine of artistic creation in *Emilia Galotti;* a passing attraction to Maximiliane, the daughter of the German novelist Sophie von La Roche, who probably endowed his heroine with her black eyes. And it was only when Kestner reported the suicide of a Wetzlar acquaintance who had killed himself out of hopeless love that all this was precipitated into a plot. If *Werther* took the world by storm it was because, in Thomas Carlyle's words, it gave expression to "the nameless unrest and longing discontent which was then agitating every bosom." But this first novel is no sentimental tearjerker. Nor is disappointed love its real theme. It is rather what the 18th century called Enthusiasm: the fatal effects of a predilection for absolutes, whether in love, art, society, or the realm of thought. The mind that conceived its symmetry, wove its intricate linguistic patterns, and handled the subtle differentiation of hero and narrator was moved by a formal as well as a personal passion. Even the title has been trivialized in translation: *Sorrows* (instead of "Sufferings") obscures the allusion to the Passion of Christ and individualizes what Goethe himself thought of as a "general confession," in a tradition going back to St. Augustine.

Lyrical and dramatic hymns

Besides *Werther* and *Götz*, the period 1771–75 saw the appearance of a number of magnificent hymns—lyrical or dramatic, according to whether the influence of Pindar or Shakespeare prevailed—"Cäsar," "Mahomets Gesang," "Der Ewige Jude," "Prometheus," "Sokrates," "Satyros," "Der Wandrer"; the inception of *Egmont* and *Faust* (this so-called *Urfaust*, or "original" version of *Faust* was discovered by a lucky chance in 1887); the completion of *Clavigo*, a play of more "regular" form on a theme of the French playwright Beaumarchais, and of *Stella* (1775), with its conciliatory ending of a *mariage à trois*, subsequently conventionalized into tragedy. Two operettas, *Erwin und Elmire* and *Claudine von Villa Bella*, reflect a return to the elegance of Rococo inspired by Goethe's betrothal to Lili Schönemann, daughter of a rich banker, who moved in fashionable circles that were soon to prove unbearably restrictive to the young Stürmer und Dränger. From the conflicts of this love he took refuge, as so often, in nature; and in a poem written on the lake of Zurich, "Auf dem See," created the first of those many short lyrics in which language of radiant simplicity is made the vehicle of inexhaustible significance. With his departure for Weimar in November 1775, the engagement was allowed to lapse.

The mature years at Weimar. Going to Weimar was the major turning point of Goethe's life. He went on a visit to the reigning duke, Charles Augustus. It remained his home—despite Napoleon's invitation to Paris—until his death there on March 22, 1832. From now on, mastery of life became his chief concern; and *Wilhelm Meisters Lehrjahre* (*Wilhelm Meister's Apprenticeship;* 1824), the title he eventually gave his next novel (1795–96), suggests the long apprenticeship such mastery involves. He served his own in the innumerable and ever increasing official duties the young duke heaped on his willing shoulders until, as indispensable minister of the little state, he was inspecting mines, superintending irrigation schemes, and even organizing the issue of uniforms to its tiny army.

Friendship with Charlotte von Stein

He served his apprenticeship, too, in his passionate devotion to the wife of a court official, Charlotte von Stein. For the first time he found himself in love with a woman who could also meet him on the intellectual plane. From the 1,500 or so letters he wrote her we can see her become the guiding principle of his life, teaching him the graces of society, dominating the details of his daily existence, engaging his imagination and desire, yet insisting on a relation governed by decorum and conventional virtue. She would be his sister and nothing more, and the sublimation she increasingly enforced on him, though irksome, could inspire the almost psychoanalytical probings of "Warum gabst du uns die tiefen Blicke?", the tortures of Orest and their assuagement by Iphigenie, the delicate one-act play, *Die Geschwister* ("Brother and Sister"; 1776), and such well-loved lyrics as "An den Mond," "Der Becher," "Jägers Abendlied," "Seefahrt," and the two exquisite "Wandrers Nachtlieder."

In these and other poems of this period—"Grenzen der Menschheit," "Gesang der Geister über den Wassern," "Das Göttliche," "Harzreise im Winter," "Ilmenau"—nature has ceased to be a mere reflection of man's moods and has become something existing in its own right, a setting for an idea or a force indifferent, even hostile to him. This new "objectivity" is in tune with Goethe's growing scientific preoccupations. Yet such is his versatility that he could, when he chose, revert to the temper of "Der König in Thule" (written in 1774) and compose ballads such as "Erlkönig" or "Der Fischer," in which nature bears the projection of unconscious forces; while a number of *Singspiele* or musical plays betoken his readiness and ability to provide light entertainment for the court. *Der Triumph der Empfindsamkeit* ("The Triumph of Sensibility") even satirizes the sensibility his own *Werther* had helped to foster.

But neither the cares of state nor those of a frustrating love affair were conducive to the peace and leisure required to complete works of such magnitude as *Egmont*, *Faust*, *Tasso*, and *Iphigenie* (a prose version of this last was sufficiently advanced to be put on before the court in 1779 with Goethe himself in the role of Orestes). And in September 1786, in dramatic secrecy and with the haste of one pursued, he set out on his long-postponed Italian journey. This flight was at once a death and a rebirth. And it was in these terms that he wrote of it in his letters. He sought the renewal of himself, both as man and artist, and so deliberately cut himself off from his emotional, literary, and cultural past, scorning the "Gothic follies" he had once acclaimed, rejecting Juliet's tomb in Verona in favour of the Greek steles in the museum, finding delight in Palladio's churches rather than in San Marco or the doge's palace, devoting barely three hours to Florence, and ignoring completely the medieval glories of Assisi for the sake of its temple of Minerva, feverishly bent on arriving in Rome, "capital of the ancient world," but seeing even that as a prelude to Magna Graecia, to the temples of Paestum, and the revelation of classical grandeur in Sicily, "key to the whole," a prelude to the world of Homer, which he recaptured in a glorious dramatic fragment, *Nausikaa* (1787). And just as he sought and found the *Urmensch*, or archetypal man, in the forms of Greek antiquity, so in these landscapes there came to his mind the extension of this idea to plants as well. In his literary work these pursuits led to the creation of beings who are individual manifestations but of a clearly discernible type; to themes that are universal and timeless but treated in a highly differentiated way; to the measured cadences of verse that are yet vibrant with personal passion.

Italian influence

This new conception of form is apparent in the revision of the four plays he had taken with him to Italy. *Faust, Ein Fragment*, published in 1790, is quite clearly, by its excisions as well as its additions, a step in the direction of the stupendous cultural symbol the play would eventually become rather than any attempt to weld into dramatic unity the sharply individualized episodes of the original version, the *Urfaust*. *Egmont*, though not actually cast into verse, is raised to the level of poetic drama not by virtue of its frequent iambic rhythms but by a thickening of the verbal texture, so that when music finally takes over it seems the inevitable culmination of a gradual convergence and sudden contraction of themes rather than the "*salto mortale* (*i.e.*, somersault) into the world of opera" Schiller was to dub it. By such means,

the personal and the political aspects of the problem become completely interfused—Egmont and his beloved Klärchen, the most lovable characters Goethe ever created, are embodiments of an inner freedom that is a heightened form of the easygoing independence of the Netherlands people—and what had started as a dramatic portrayal of a daemonic individual is transformed into a tragedy of the very idea of freedom, of its fate in a world ruled not just by calculation or intrigue but by unpredictable conjunctures of persons and events.

Torquato Tasso

In *Torquato Tasso* such linguistic density is carried to lengths possible only in verse. Goethe spoke of having expended a positively "unlawful care" on it. But this is not inappropriate to a play about a poet, an artist whose medium is the ordinary vehicle of communication between men. The tragic conflict here arises from misunderstandings about the various modes of language, and the temperamental clashes are presented as concomitants of this rather than as the prime focus of interest (though there is enough psychology to justify the description by the French writer Mme de Staël of Goethe as "*le Racine de l'Allemagne*"). The slightness of the outward action in *Torquato Tasso* has been much criticized, but it can be justified in a study of the "poetical character" per se—a creature for whom "any little vexation grows in five minutes into a theme for Sophocles." By placing him in a society that, far from being indifferent or hostile, cherishes him and values his work, Goethe has thrown into sharpest relief the incurable "discrepancy" between poet and world, and this rift is not healed by Tasso's discovery that even the extremes of anguish can be transmuted into imperishable verse.

Iphigenie

But it was perhaps *Iphigenie auf Tauris* (1787) that benefited most from his encounter with classical antiquity. And yet Schiller was right in calling it "astonishingly modern and un-Greek." Like *Tasso*, it too treats of the problems of communication: of the unforeseeable power of words once they are released into the world; of the double face of language, which conceals as much as it reveals; of truth, whose opposite is not just an outright lie but the withholding of self. But it treats, too, of man's power to free himself from his myths by recognizing them as projections of his own unconscious, of his power to break the chain of events that seems to determine his present (symbolized in the monotonously regular crime sequence of the race of Tantalus) by a reorientation of outlook. The conciliatory ending, which Euripides contrived by the sudden appearance of the goddess Athena, here comes with the apparent suddenness of new insight: the words of the oracle are susceptible to a different interpretation. In its synthesis of Greek and Christian values, its elevation of the physical to the spiritual through the identification of Iphigenie with the divine sister, Diana, this play represents the highest achievement of 18th-century humanism.

Römische Elegien

The chief lyrical product of the Italian journey was the *Römische Elegien* (the "Roman Elegies"; written 1788–89). In their plastic beauty and unabashed sensuality, their blending of erotic tenderness with an enhanced sense of our cultural heritage, these pagan, highly civilized poems are unique in any modern language. Had they been written in the metre of Byron's *Don Juan*, Goethe acknowledged, they might easily have been offensive; but the classical distichs (couplets) lend them that veil of aesthetic distance that reveals even as it shrouds. The true begetter of these elegies was not some passing Roman amour but Christiane Vulpius, daughter of a humble official, whom Goethe had taken into heart and home soon after his return from Italy in April 1788. Christiane bore him several children; but it was not until 1806, when life and property were threatened by the French invasion, that the nonconformist eventually conformed and in grateful recognition of its indissoluble bonds regularized their union in the eyes of society.

His first Italian journey finally brought home to Goethe that, for all his interest and talent, he was not destined to be a painter. Despite diligent practice with his artist friends in Rome, he was never able to master this medium to the point at which it became expressive of his deepest feeling, and with rare exceptions his numerous drawings have no more than the charm of a sensitive amateur. But his abiding preoccupation with the visual arts left an indelible mark on his literary as well as his scientific work and gave added precision to his many critical and aesthetic essays. And it was on this first visit to Italy, too, that he finally reached the decision that he must shed his administrative duties and devote himself henceforth to his true vocation of literature and science.

Political writings during the French Revolution

A return visit to Italy in 1790 brought nothing but disappointment, and a restlessness aggravated by the revolutionary events in the outer world. The *Venetian Epigrams* of 1790 reflect something of this discontent. In 1792 Goethe accompanied his duke on the disastrous campaign into France, was present at the battle of Valmy, and wrote up his experiences in two still very readable war books, *Campagne in Frankreich 1792* and *Belagerung von Mainz*. His liberal-conservative attitudes found expression in *Reineke Fuchs* ("Reynard the Fox"), a recasting of the Low German satire, the *Unterhaltungen deutscher Ausgewanderten*, and three plays. *Der Gross-Cophta*, *Die Aufgeregten* and *Der Bürgergeneral*, which, though artistically unsuccessful, are of interest in being among the few examples of political literature produced by German poets. But it was only as the French Revolution receded that he was able to transmute its overwhelming actuality into timeless poetry. It still forms the background of his Homeric treatment of the refugee problem, *Hermann und Dorothea* (1797). It fills the whole canvas of *Die Natürliche Tochter* ("The Natural Daughter"; 1804). Planned as a trilogy but never completed, this was Goethe's final reckoning with the greatest event of his time. Beneath the coolness of its formal perfection there stirs a profound concern with revolutionary phenomena, with the role of death and destruction in the perpetuation of social and cultural, no less than of natural, forms of life.

Schiller and the classical ideal. The human and spiritual isolation in which Goethe found himself on his return from Italy was unexpectedly relieved by the development of a friendship with Schiller. His acceptance of a formal invitation to contribute to a new journal, *Die Horen* (1795–97), called forth Schiller's now-famous letter of Aug. 23, 1794, in which, with marvelous insight, he summed up Goethe's whole existence. Here, it seemed to him, was the very embodiment of the naïve poet—but consciously naïve, moving from feeling to reflection and then transforming reflection back into feeling, concepts of the mind back into percepts of the senses. It was this conscious assent to a mode of thinking different from Schiller's own more abstractive reflection that made possible their immensely fruitful partnership, and the four volumes of their daily correspondence offer not only an invaluable commentary on the ideals and achievements of the greatest period of German literature but astonishing insight into the processes of artistic creation. Some of the works Goethe produced during the next few years are embodiments of their classical ideal. *Hermann und Dorothea*, one of the best loved, is his attempt to "produce a Greece from within." In it he claimed to have "separated the purely human from the dross." The characters are types—except for the hero and heroine, they have no proper names, and even theirs are symbolic—and like those of the *Odyssey* they vindicate peace and home and the domestic virtues. Yet, as always in Goethe's works, these are shown as never secure for long, as constantly in need of being fostered by man's efforts to be human and humane. In the Helena act of *Faust, Part II*, in which the meeting and mating of Faust and Helen of Troy marks the synthesis of paganism and Christianity, of Greece and Germany, he captured the Greek spirit so successfully that competent critics hold that if translated into Attic Greek it might well pass for a lost fragment of the Athenian stage.

A never completed epic, *Achilleis*, is his last attempt to "be a Greek after his own fashion." Other works of this period are in tune with Schiller's growing conviction that the only future for literature in a world that increasingly clamoured for the naturalistic and the tendentious lay in

a hermetic closing of the poetic world by a frank introduction of symbolic devices. *Wilhelm Meisters Theatralische Sendung* ("Wilhelm Meister's Theatrical Mission"; a manuscript of this version turned up in 1910) is now widened to a vocation for life, a theme dear to the heart of Schiller, who had himself just completed a treatise *On the Aesthetic Education of Man* (1795) and wholly in tune with their joint conviction that art, though not the handmaid of either truth or morality, has nevertheless its own peculiar part to play in making better men and better citizens. Fictional realism is now blended with abstraction; characterization, however psychologically acute, subordinated to an overall poetic significance; and the presence in a novel of contemporary society of such mysteriously compelling figures as the Harper and Mignon seems to justify Goethe's claim that his novel is "thoroughly symbolic."

Schiller's influence on *Faust*

It was Schiller, too, who turned his thoughts to the continuation of *Faust* and discerned the difficulties involved in reconciling this "barbarous composition" with their classical ideal, in blending the evident seriousness of its "idea" with that element of "play" that was the prerequisite of the art of the future. By his insistence on such problems, he inspired the fictional framework of *Faust's* "Prelude on the Stage" no less than the philosophical framework of the "Prologue in Heaven." If in spite of such indications, the world insisted on reading *Faust, Part I* (1808) as a love story, which stamped its author as a Romantic; it was because at this stage the almost unbearable pathos of the Gretchen tragedy had not yet found its place in the wider tragedy of Western man.

Goethe and Schiller blamed the failure of the journals in which they strove to propagate their ideals of art and literature (Goethe's *Propyläen*, 1798–1800, was a quasi-successor to Schiller's *Horen*) on the indifference of an uncultivated public and vented their disappointment in *Xenien*, about 400 mordant distichs in the manner of Martial. A more positive reply to their detractors was a wonderful harvest of ballads. Goethe's own—"Der Schatzgräber," "Die Braut von Korinth," "Die Zauberlehrling"—differ from his earlier ones in that man rather than nature now holds sway. The "white" magic of reflection is consciously, even ironically, introduced. And in the ballad, with its blend of lyric, epic, and dramatic elements, Goethe now discerned the *Urei*, or archetypal form, of poetry by analogy with the *Urpflanze* he had discovered in the vegetable world.

Goethe's relation to the Romantics. With Schiller's death in 1805, Goethe felt he had lost "the half of his existence" and he wrote a magnificent tribute to his great friend in *Epilog zu Schillers Glocke*. His intellectual loneliness was eased in some measure by his relations to the new school of Romantics then flourishing in Jena. For they had much in common. Friedrich von Schlegel had begun his career with a book extolling Greek culture and gone on to praise the Orient as the summit of Romantic thought and poetry. His brother Wilhelm's absorption in form and metre was after Goethe's own heart, and he could not be indifferent to their enthusiastic praise of *Wilhelm Meister* or to Novalis' description of him as "the viceregent of poetry upon earth." In Bettina Brentano, daughter of his old love, Maximiliane von La Roche, he found an ardent response to both his genius and his humanity, and her *Briefwechsel Goethes mit einem Kinde* (1835) remains one of the most readable books in German literature, whatever doubts maybe cast on its reliability. Though Goethe decried the Romantics as "forced talents," amateurishly oblivious of the virtues of form, though he deplored their catholicizing tendencies, their uncritical addiction to all things medieval, their attempts to blur the literary genres and confuse the boundaries between art and life, he yet remained open to many of their enthusiasms, even letting himself be moved to a renewed interest in Gothic architecture. And in *Die Wahlverwandtschaften* ("Elective Affinities"; 1809) he drew heavily for his thematic material upon their preoccupation with "the night-side of nature," with the animal, magnetic affinities that attract human beings to each other, as elements are in the chemical world.

Die Wahlverwandtschaften

But this novel offers no support at all for a superstitious surrender to forces natural or supernatural, for a subhuman abdication of moral responsibility. Catastrophe follows inexorably upon the arbitrary interpretation of signs and portents; the heroine enters upon a path of renunciation that brings her near sainthood; marriage may be presented with ruthless realism as "a synthesis of impossibilities," but it remains nevertheless "the beginning and end of all civilization." The Romantics were here taught a lesson of social behaviour—and of artistic form. The narrative is conducted with a serene impartiality, and all the classical values of plasticity, restraint, and symmetry are brought to bear on a subject that is sensational to the point of improbability.

By their translations—Romanticism *is* translation, Clemens Brentano declared—the Romantics were opening up the literary treasures of the world, and *Weltliteratur* was to become one of Goethe's most treasured concepts. Its aim was, as he put it, to advance civilization by encouraging mutual understanding and respect—whether through translation or criticism (his own attempts to interpret Serbian poetry to the Germans is an excellent example of this latter) or through the blending of different literary traditions. Two great ballads, "Der Gott und die Bajadere" and "Paria," and two exquisite cycles, the late and lesser known *Chinesisch-Deutsche Jahres- und Tageszeiten* ("Chinese-German Hours and Seasons"; 1830) and the *West-östlicher Divan* ("Divan of West and East"; 1819), are his own outstanding attempts to marry East with West. This latter is a book of love in all its aspects—tender, playful, sensuous, ironic, wise, and wanton—all of it irradiated by that quality of *Geist*—of intellect, spirit, wit—which he discerned as "the predominant passion" of Persian poetry. His living muse this time, Marianne, the young wife of his friend von Willemer, was perhaps the most completely satisfying of all his loves, so attuned to him in spirit that she could even take a hand in the creation of some of these poems.

The last decade. But the world vision of the aging poet did not only find expression in a silent communing with the past. In his last years, Goethe found himself a world figure, and little Weimar became a Mecca that drew a constant stream of pilgrims from both the Old World and the New. Reports of his stiffness and reserve in the face of almost daily invasions are far outweighed by the testimony of those to whom he showed warmth, understanding, an insatiable curiosity about what was going on in the outside world, and an abiding openness to the present and the future. This is nowhere more apparent than in *Wilhelm Meisters Wanderjahre* (1821–29; "*Wilhelm Meister's Travels*"), with its commitment to social and technological progress (what he would most like to see before he died, Goethe once said, was the completion of the Panama and Suez canals), to a type of education better adapted to modern specialization than the old humanistic studies, to a world no longer centred wholly in Europe—a major "complication" of his plot is a resettlement plan for emigrants in the land of the future ("Amerika, du hast es besser!" ["America, you are better!"]). *Wilhelm Meister* points the truth that mastery of life is not conferred at the end of the "apprentice years" and henceforth an inalienable possession, but a ceaseless wandering in which the goal turns out to be the way, and the way the goal.

Wilhelm Meister

At first sight the subtitle, *Die Entsagenden* ("Renunciation"), seems curiously at odds with such purposeful unrest. But renunciation for Goethe implies no passive resignation to the status quo. It is a growing acceptance of the limits imposed by life itself, limits arising from the nature of space and time and from the conflict of interests and potentialities. The apparent formlessness of the novel reflects the duality of its title. It meanders, its narrative interspersed with tales, anecdotes, episodes and maxims, having but the loosest connection with the plot but a formal, if often subterranean, connection with the poetic significance. These interpolations, like the increasingly symbolic characters, display the whole spectrum of human modes of renunciation. The "whole man" is here represented not by any single individual but by a constel-

lation of many, and the informing principle is the spatial one of configuration rather than the temporal one of succession.

Faust

Faust, too, is often decried as formless, though the climate of criticism is now more propitious to the discovery of its "law." The array of lyric, epic, dramatic, operatic, and balletic elements, of almost every known metre, from doggerel through terza rima (an Italian form of iambic verse consisting of stanzas of three lines) to six-foot trimeter (a line of verse consisting of three measures) of styles ranging from Greek tragedy through medieval mystery, baroque allegory, Renaissance masque, commedia dell'arte, and the "temerities of the English stage," to something akin to the modern revue, all suggest a deliberate attempt to make these various forms a vehicle of cultural comment rather than any failure to create a coherent form of his own. And the content with which Goethe invests his forms bears this out. He draws on an immense variety of cultural material—theological, mythological, philosophical, political, economic, scientific, aesthetic, musical, literary—for the more realistic Part I no less than for the more symbolic Part II (first published posthumously in 1832): if Faust's wooing of Helena in the "Classic-Romantic Phantasmagoria" (as the first publication of the scene in 1827 called it) is accomplished by teaching her the unfamiliar delights of rhymed verse, his seduction of Gretchen is firmly set in the long tradition of erotic mysticism going back to the Song of Solomon. The Faust myth is here made the medium of a profoundly serious but highly ironic commentary on our cultural heritage, presented not as historical pageant—Faust's "progress" from his 18th–16th-century beginnings back through the Middle Ages and classical antiquity to the origins of life, and beyond that to the "Mothers," timeless source of all forms of being, annuls the historical time sequence—but as a drama of the diverse potentialities that coexist in Western civilization.

This Faust, unlike his creator, is the very type of Western man, with two souls warring within his breast and a restlessly inquiring spirit. To the 19th century his ceaseless striving seemed a good thing in itself. To a generation shocked into doubts about progress and the value of action, the disastrous consequences of his attempts to experience "the weal and woe of all mankind" (the *libido sciendi* of Marlowe's Faustus is here but briefly indulged and as swiftly transcended) loom larger than the quotable "message" of any of the speeches, and his ultimate "salvation" becomes correspondingly suspect. Yet the love that bears his mortal remains to "higher spheres" does not mitigate the ironic defeat of his highest mortal endeavour. If the seal of approval is set on a spirit that has eluded Mephisto's every effort to lull him into sloth, the evil into which it led him is not condoned. It needs the combined intercession of human wisdom and human suffering, human innocence and human experience, before compassionate verdict is passed on the erring and straying of this soul "in ferment." Indeed, none of Goethe's conciliatory endings, except that of *Iphigenie*, really removes the sting of tragedy. Critics have tended to excuse or deplore them by reference to his own *konziliante Natur* (his "conciliatory nature"). But at least as relevant is his preoccupation with the form of Greek trilogies and tetralogies and his unorthodox interpretation of Aristotle's catharsis as an effect only likely to be produced in the spectator if there is a corresponding element of "reconciliation" in the structure of the play itself. The apotheosis of the hero, whether Faust's, Egmont's or Ottilie's in the *Wahlverwandtschaften*, is always set in a context reminiscent of a theophany and of the ritual origins of tragedy.

Interest in music

Nor can his interest in the cathartic effect of music be ignored. Unlike the German Romantic poet Novalis, for whom music was "the key to the universe," Goethe was profoundly aware of its dual nature and as suspicious as Plato of its orgiastic power. As in every art he looked for the taming of the Dionysiac by the Apolline, nowhere more movingly symbolized than by the taming of the lion through the piping of the little child in his *Novelle* of 1828, a theme he had already discussed with Schiller as far back as 1797. And increasingly he turned to music for assuagement of his own suffering. His *Trilogie der Leidenschaft* ("Trilogy of Passion"; 1823–27) is at once the lyrical precipitate of an old man's anguished love for a girl of 18 and a tribute to the cathartic effect of this "heavenly art," which restores to life even as it soothes. His *Zauberflöte, Zweiter Teil* is a tribute to his favourite Mozart's *Magic Flute:* Mozart would, he thought, have been the ideal composer for *Faust*. And one of the comforts of his later years was an intimate friendship with the composer K.F. Zelter, whose most brilliant pupil, the young Mendelssohn, afforded him hours of musical delight and deepened his musical understanding—though he never succeeded in reconciling him to the daemonic aspects of Beethoven's music.

Scientific work

By common consent, *Faust* is one of the supreme, if as yet unclassified, achievements of literature. But there were moments when Goethe rated his scientific work higher than all his poetry. His predilection for his *Farbenlehre* ("Theory of Colour"; 1805–10) has something of the love of a parent for a problem child, and nothing is easier than for the physicist to pick holes in his systematic attempt to prove Newton wrong, or for the psychologist to find the cause of his stubbornness in his sense of mathematical inadequacy or in his neurotic attachment to the doctrine that light is one and indivisible and never to be explained by any theory of particles. On the other hand, the usefulness of the Psycho-Physiological Section, together with his study, *Entoptische Farben* ("On Entoptic Images"), is generally acknowledged, while the Historical Section is something of a pioneer work in the writing of the history of science. His work in botany and biology is less controversial. His *Metamorphose der Pflanzen* ("Attempt to Explain the Metamorphosis of Plants"; 1790) is a model of presentation, and the drawings in it are a botanist's delight. His main thesis, that all the parts of the plant are modifications of a type-leaf, has met with a measure of acceptance, though his categorical neglect of the root is regarded as an unscientific exclusion of a possible area of relevance. His hypothesis of a type-plant, by contrast, commands no interest among orthodox botanists today. His discovery in 1784, arrived at independently even if he was not the first to make it, of a recognizable os intermaxillare (the premaxilla of modern anatomists) in the human species was yet another result of his sustained quest for unity and continuity in nature and caused Darwin to hail him as a forerunner.

But what makes for the continuing interest of Goethe's science is not his discoveries: he could not always claim priority for them at the time, nor was he in the least interested to do so. It is his insight into his methods of arriving at them. Few have been as aware of the mental processes involved in the study of natural phenomena; few have been more alive to the hazards that beset the scientist, at every level, from sheer observation to the construction of a theory; and few have been more conscious of the unwitting theorizing involved in even the simplest act of perception. And no one has argued more convincingly that the only way of coping with this inescapable involvement of the observer in the phenomena to be observed is to let "knowledge of self" develop with "knowledge of world."

Such scrupulous awareness of his own mental operations was, of course, of paramount importance in morphology, the science Goethe founded and named. Morphology, as he understood it, was the systematic study of formation and transformation—whether of rocks, clouds, colours, plants, animals, or the cultural phenomena of human society—as these present themselves to sentient experience. He did not propose it as a substitute for the quantitative sciences, which break down forms as we know them and by converting them into mathematical terms ensure a measure of prediction and control. He was not, contrary to common belief, opposed to analysis —one of his favourite maxims was that analysis and synthesis must alternate as naturally as breathing in and breathing out—and his only objection to physics was its increasing tendency to claim monopoly of understanding.

What he was aiming at was rather a humanizing supplement, an understanding of nature in all its qualitative manifestations; and one of his most impassioned pleas is for a concert of all the sciences, a cooperation of all types of method and mind.

This impulse, to find a scientific as well as an aesthetic corrective to the inevitably esoteric tendencies of specialization, is nowhere more apparent than in his two elegies on plant and animal metamorphosis in which he tries to present to imagination and feeling what has been understood by the mind. They eventually took their place in a cycle of philosophical poems entitled *Gott und Welt* ("God and World"). Though no orthodox believer, Goethe was by no means the pure pagan the 19th century liked to imagine. Spinoza's pantheism certainly struck a sympathetic chord, for the deist idea of a God who, having created the world, then left it to revolve, was repugnant to him. But he was and remained a grateful heir of the Christian tradition—*bibelfest*, rooted in the Bible—as his language constantly proclaims. And it was from this centre that he extended sympathetic understanding to all other religions, seeking their common ground without destroying their individual excellences, seeing them as different manifestations of an *Ur*, or archetypal, religion and thus giving expression, in this field as elsewhere, to the essentially morphological temper of his mind. "Pan-entheism" has been proposed as a more exact term for his belief in a divinity at once immanent and transcendent, and he rebuked those who tried to confine him to one mode of thought by saying that as poet he was polytheist, as scientist pantheist, and that when, as a moral being, he had need of a personal God, "that too had been taken care of." This was one of the meanings he attached to the biblical text: "In my father's house are many mansions."

Religious views

Appraisal. A day will come, Carlyle predicted in a letter to Ralph Waldo Emerson, when "you will find that this sunny-looking courtly Goethe held veiled in him a Prophetic sorrow deep as Dante's." And since World War II there have been many attempts to replace the image of the serene optimist by that of the tortured skeptic. The one is as inadequate as the other—as inadequate as T.S. Eliot's conclusion that he was sage rather than poet—though this is perhaps inevitable when a writer is such a master of his own medium that even his prose proves resistant to translation. Even his Werther knew that the realities of existence are rarely to be grasped by Either-Or. And the reality of Goethe himself certainly eludes any such attempt. If he was a skeptic, and he often was, he was a hopeful skeptic. He looked deep into the abyss, but he deliberately emphasized life and light. He lived life to the full at every level, but never to the detriment of the civilized virtues. He remained closely in touch with the richness of his unconscious mind, but he shed on it the light of reflection without destroying the spontaneity of its processes. He was, as befits a son of the Enlightenment, wholly committed to the adventure of science; but he stood in awe and reverence before the mystery of the universe. Goethe nowhere formulated a system of thought. He was as impatient of the sterilities of logic chopping as of the inflations of metaphysics, though he acknowledged his indebtedness to many philosophers, including Kant. But here again he was not to be confined. Truth for him lay not in compromise but in the embracing of opposites. And this is expressed in the form of his *Maximen* ("Maxims"), which, together with his *Gespräche* ("Conversations"), contain the sum of his wisdom. As with proverbs, one can always find among them a twin that expresses the complementary opposite. And they have something of the banality of proverbs too. But it is, as André Gide observed, "*une banalité supérieure*." What makes it "superior" is that the thought has been felt and lived and that the formulation betrays this. And for all his specialized talents, there was a kind of "superior banality" about Goethe's life. If he himself felt it was "symbolic" and worth presenting as such in a series of autobiographical writings, it was not from arrogance but from a realization that he was an extraordinarily ordinary man in whom ordinary men might see themselves reflected. Not an ascetic, a mystic, a saint, or a recluse, not a Don Juan or a poet's poet but one who to the best of his ability had tried to achieve the highest form of *l'homme moyen sensuel*—which is perhaps what Napoleon sensed when after their meeting in Erfurt he uttered his famous "*Voilà un homme!*"

MAJOR WORKS

VERSE: *Das Buch Annette* (1767); *Neue Lieder*, so-called *Leipziger Liederbuch* (1770); *Römische Elegien* (1793); *Venezianische Epigramme* (1795); *Xenien*, written with Schiller (1796); *Balladenjahr* (1797); *Epilog zu Schillers Glocke* (1805); *West-östlicher Divan* (1819); *Trilogie der Leidenschaft* (1823–27).

DRAMATIC WORKS: *Die Laune des Verliebten* (1767, printed 1806); *Die Mitschuldigen* (1768, printed 1787); *Götz von Berlichingen* (1773); *Götter, Helden und Wieland* (1774); *Clavigo* (1774); *Erwin und Elmire* (1775), operetta; *Stella* (1776); *Claudine von Villa Bella* (1776), operetta; *Die Geschwister* (1776); *Der Triumph der Empfindsamkeit* (1777–78); *Iphigenie auf Tauris* (1779; final version, 1787); *Egmont* (1788); *Torquato Tasso* (1790); *Faust, Ein Fragment* (1790); *Der Gross-Cophta* (1792); *Der Bürgergeneral* (1793); *Die Natürliche Tochter* (1804); *Faust I* (1808); *Pandoras Wiederkunft* (1808); *Des Epimenides Erwachen* (1815); *Faust II* (1832).

NOVELS AND EPICS: *Die Leiden des jungen Werthers* (1774); *Reineke Fuchs* (1794), satire; *Unterhaltungen deutscher Ausgewanderten* (1795); *Wilhelm Meisters Lehrjahre* (1795–96); *Hermann und Dorothea* (1797); *Achilleis* (1808), epic fragment; *Die Wahlverwandtschaften* (1809); *Wilhelm Meisters Wanderjahre* (1821–29); *Novelle* (1826).

AUTOBIOGRAPHY: *Aus meinem Leben, Dichtung und Wahrheit* (1811–22); *Italienische Reise* (1816–17); *Campagne in Frankreich, 1792* (1822); *Die Belagerung von Mainz 1793* (1822).

SCIENCE: *Versuch die Metamorphose der Pflanzen zu erklären* (1790); *Beiträge zur Optik* (1791–92); *Zur Farbenlehre* (1810); *Zur Naturwissenschaft überhaupt, besonders zur Morphologie* (1817–23), journal.

CRITICISM: *Von deutscher Baukunst* (1773); *Die Propyläen* (1798–1800), journal ed. by Goethe; *Winkelmann und sein Jahrhundert* (1805); *Über Kunst und Altertum*, 6 vol. (1816–32), periodical.

TRANSLATIONS: There is still no uniform edition in English though the chief works have been frequently translated and many of them are to be found in Bohn's Standard Library, 14 vol. (1846–90). For details see Lina and Eugen Oswald, and Alexander Dickson, *Goethe in England (and America)* in *Publications of the English Goethe Society*, 2 vol. (1909, 1951). Translations include: *Wilhelm Meister's Theatrical Mission* by G.A. Page (1913); *Wilhelm Meister* by Thomas Carlyle (1824; Everyman ed., 1912, reissued 1965). *Faust I and II* by A.G. Latham (1902-06; Everyman ed., 1908); other translations of *Faust* by Bayard Taylor (1870-71; World's Classics, 1932); Philip Wayne (Penguin ed., 1949); Louis MacNeice (1951); Bertram Jessup (1958); John Shawcross (1959); Alice Raphael (1963); Walter Kaufmann (1963); and C.E. Passage (1965). *Egmont* by Michael Hamburger in *The Classic Theatre*, vol. 2 ed. by E. Bentley (1959); by Willard R. Trask (1960); *Götz von Berlichingen*, by C.E. Passage (1965); *Iphigenia in Tauris*, by C.E. Passage (1963); *Italian Journey, 1786–1788*, by W.H. Auden and Elizabeth Mayer (1962); *Torquato Tasso*, by C.E. Passage (1966); *Kindred by Choice* (*Die Wahlverwandtschaften*) by H.M. Waidson (1961); by Elizabeth Mayer and Louise Bogan (1963); *Werther* by William Rose (1929); *Werther* by B.Q. Morgan (1957); *Die Leiden des jungen Werther*, Dual-Language book, ed. by H. Steinhauer (1962); *Werther: The New Melusina. Novelle* by Victor Lange (1949); *Novelle* by C.P. Middleton (1959); *The West-Eastern Divan* by Edward Dowden (1914). *The Briefwechsel* with Schiller and a collection of early and miscellaneous letters are in Bohn (see above); that with Carlyle, ed. by C.E. Norton (1887). *Letters from Goethe*, selected and trans. by M. von Herzfeld and C.M. Sym (1957). *Conversations With Eckermann* by John Oxenford, 2 vol. (1850; vol. 6 of Bohn); by R.O. Moon (1951).

BIBLIOGRAPHY

Works, drawings, diaries, correspondence, and conversations: Goethes Werke (*Vollständige Ausgabe letzter Hand*), 40 vol. (1827–30), and its continuation, *Nachgelassene Werke*, 20 vol. (1832–42)—both also in a *Taschenausgabe*. The standard critical edition was published in Weimar at first under the auspices of the grand duchess Sophie (hence known as the *Weimarer Ausgabe* or *Sophienausgabe*), 133 vol., including the scientific works, diaries, and letters (1887–1919); a new critical edition by the Deutschen Akademie der Wissen-

schaften zu Berlin is in progress (1952–). Of modern editions the most noteworthy are: the *Jubiläums-Ausgabe*, ed. by EDUARD VON DER HELLEN, 40 vol., plus an invaluable *Registerband*, with introductions and notes (1902–12); the *Gedenkausgabe*, ed. by ERNST BEUTLER, 24 vol., including selections from the scientific works, correspondence, and conversations, with useful indexes (1948–54) plus *Ergänzungsband I: Briefe aus dem Elternhaus* (1960); and the *Hamburger Ausgabe*, ed. by ERICH TRUNZ, 14 vol., the most up-to-date in its introductions and bibliographical surveys (1948–60). There are innumerable collections of selected works, such as *Goethes Amtliche Schriften*, ed. by WILLY FLACH (1950, in progress). Goethe's drawings and sketches are being published in the *Corpus der Goethezeichnungen*, ed. by GERHARD FEMMEL, 6 vol. to date (1958–70); see also LUDWIG MUNZ, *Goethes Zeichnungen und Radierungen* (1949); *Goethes Gespräche*, ed by F.W. VON BIEDERMANN (1st ed., 10 vol., 1889–96; 2nd ed., 5 vol., 1909–11); and JOHANN P. ECKERMANN, *Gespräche mit Goethe . . . 1823–32*, 3 vol. (1836–48, many times reprinted). The only complete collection of Goethe's letters is in the *Weimarer Ausgabe;* see also the letters to Goethe, ed. by RUDOLF C. GOLDSCHMIDT-JENTNER, *Eine Weltschreibt an Goethe* (1937). His correspondence with particular individuals, German and foreign, is conveniently listed in the *Hamburger Ausgabe*, vol. 14; see also D.F.S. SCOTT (ed.), *Some English Correspondents of Goethe* (Matthew ["Monk"] Lewis, T. Holcroft, Sir Walter Scott, P.P. Gillies, Sir John Bowring, Lord Leveson-Gower, Sarah Austin, etc.; 1949).

Bibliography: Only the researcher will consult the vast compilation in KARL GOEDEKE, *Grundriss . . .*, 4 pt. (1910–13 and later editions), superseded by HANS PYRITZ, *Goethe-Bibliographie*, new ed., 2 vol. (1965–68). Vol. 14 of the *Hamburger-Ausgabe* (1960), is adequate for most purposes. The *Goethe-Handbuch*, ed. by ALFRED ZASTRAU (1955, in progress), provides alphabetical references to all topics relating to Goethe. HEINZ KINDERMANN, *Das Goethebild des XX. Jahrhunderts* (1952), is in effect a lively catalogue raisonné of European and American critical literature during the 20th century.

Goethe societies: Wiener Goethe-verein, 1878; Weimarer Goethe Gesellschaft, 1885; English Goethe Society, 1886, with sister societies in the Commonwealth of Nations from 1949; Goethe Society of Maryland and the District of Columbia, 1932, Japanese Goethe Gesellschaft, 1932. All issue publications.

Biography and criticism: The best introduction in English is still GEORGE H. LEWES, *The Life and Works of Goethe*, 2 vol. (1855; 18th ed., 1903; new ed., *The Life of Goethe*, 1965). Others available in English are by ALBERT BIELSCHOWSKY, 3 vol. (1905–08, reprinted 1969); BENEDETTO CROCE (1923, reprinted 1970); and GEORGE M. BRANDES, 2 vol. (1925). See also EMIL LUDWIG, *Goethe, Geschichte eines Menschen*, 2 vol. (1926; Eng. trans., *Goethe: the History of a Man, 1749–1832*, 2 vol., 1928); HENRY W. NEVINSON, *Goethe: Man and Poet* (1931); JOHN G. ROBERTSON, *The Life and Work of Goethe, 1749–1832*, 2nd ed. (1932); LUDWIG LEWISOHN (ed.), *Goethe: The Story of a Man*, 2 vol. (1949); ALBERT SCHWEITZER, *Goethe* (1949); and KARL VIETOR, *Goethe, The Poet* (1949, reprinted 1970). Criticism in English includes BARKER FAIRLEY, *Goethe, as Revealed in His Poetry* (1932) and *A Study of Goethe* (1947); THOMAS MANN, *Three Essays* (Eng. trans. 1932); WILLIAM ROSE (ed.), *Essays on Goethe* (1949); A.R. HOHLFELD, *Fifty Years with Goethe, 1901–1951: Collected Studies* (1953); ELIZABETH M. WILKINSON and LEONARD A. WILLOUGHBY, *Goethe: Poet and Thinker* (1962); RONALD PEACOCK, *Goethe's Major Plays* (1959).

On Faust: Urfaust and Faust, ed. by LEONARD A. WILLOUGHBY (1943); *Faust I and II*, ed. by R.-M.S. HEFFNER, HELMUT REHDER, and W.F. TWADDELL (1954–55); HERMANN G. FIEDLER, *Textual Studies of Goethe's Faust* (1946). Further interpretations of Faust in English are by F.M. STAWELL and G.L. DICKINSON (1928); RONALD D. MILLER (1939); D.J. ENRIGHT (1949); BARKER FAIRLEY (1953); ALEXANDER GILLIES (1957); and STUART ATKINS (1958); see also ELIZA M. BUTLER, *The Fortunes of Faust* (1952); and ADOLF I. FRANTZ, *Half a Hundred Thralls to Faust* (1949).

Science, philosophy, and aesthetics: SIR CHARLES SHERRINGTON, *Goethe on Nature and on Science*, 2nd ed. (1949), unsympathetic; as corrective, AGNES ARBER, *Goethe's Botany*, including trans. of *Die Metamorphose der Pflanzen* (1946), and *The Natural Philosophy of Plant Form* (1950); RENE MICHEA, *Les Travaux scientifiques de Goethe* (1943); RONALD D. GRAY, *Goethe, the Alchemist* (1952); ERICH HELLER, *The Disinherited Mind*, 3rd ed. (1971); OTTO HARNACK, *Goethe in der Epoche seiner Vollendung, 1805–1832*, 3rd ed. (1905); GEORG SIMMEL, *Goethe* (1913); LANCELOT L. WHYTE, *The Next Development in Man* (1944); CARL J. OBENAUER, *Goethe in seinem Verhältnis zur Religion* (1921); PETER DEMETZ, *Goethes "Die Aufgeregten": Zur Frage der politischen Dichtung in Deutschland* (1952); KARL VIETOR, *Goethe: Dichtung, Wissenschaft, Weltbild* (1949; Eng. trans. of pt. 2–3, *Goethe the Thinker*, 1950); HANS M. WOLFF, *Goethes Weg zur Humanität* (1951); FRITZ-JOACHIM VON RINTELEN, *Der Rang des Geistes: Goethes Weltverständnis* (1955); PAUL STOCKLEIN, *Wege zum späten Goethe: Dichtung, Gedanke, Zeichnung*, 2nd ed. (1960); MATTHIJS JOLLES, *Goethes Kunstanschauung* (1957); HERMANN J. WEIGAND (ed. and trans.), *Goethe: Wisdom and Experience* (1949), selections in English; GUNTHER MULLER, *Maximen und Reflexionen* (1943); THOMAS MANN, *The Permanent Goethe* (1948); WOLFGANG LEPPMANN, *The German Image of Goethe* (1961).

Weltliteratur: JEAN M. CARRE, *Goethe en Angleterre* (1920); WILLIAM ROSE, *From Goethe to Byron: The Development of "Weltschmerz" in German Literature* (1924); JOHN G. ROBERTSON, *Goethe and Byron* (1925); STUART ATKINS, *The Testament of "Werther" in Poetry and Drama* (1949); ELIZA M. BUTLER, *Byron and Goethe: Analysis of a Passion* (1956); FREDERICK NORMAN, *Henry Crabb Robinson and Goethe*, 2 vol. (1930–31); JAMES B. ORRICK, *Matthew Arnold and Goethe* (1928); FRITZ STRICH, *Goethe und die Weltliteratur* (1946; Eng. trans., *Goethe and World Literature*, 1949); HUMPHRY TREVELYAN, *Goethe and the Greeks* (1941; a corrective to ELIZA M. BUTLER, *The Tyranny of Greece Over Germany*, 1935); JAMES BOYD, *Goethe's Knowledge of English Literature* (1932); BERTRAM BARNES, *Goethe's Knowledge of French Literature* (1937); HORST OPPEL, *Das Shakespeare-Bild Goethes* (1949); ARNOLD FEDERMANN, *Der junge Goethe und England* (1949).

Gogh, Vincent van

Largely on the basis of the works of the last three years of his life, which ended in suicide in 1890, when he was only 37, Vincent van Gogh is generally held to have been the greatest Dutch painter after Rembrandt. Everything in van Gogh's pictures seems to be pulsating with life. His work exerted a powerful influence on the development of much modern painting, in particular on the works of Soutine and the German Expressionists. Yet of the more than 800 oil paintings and 700 drawings which constitute his life's work, he sold only one in his lifetime. Always desperately poor, he was sustained by his faith

in the urgency of what he had to communicate and by the generosity of a younger brother, Theo, who believed in him implicitly. The letters that he wrote to Theo from 1872 onward, and to other friends, give such a vivid account of his aims and beliefs, his hopes and disappointments, his fluctuating physical and mental state, that they form a unique and touching biographical record which is also a great human document.

Vincent Willem van Gogh was born on March 30, 1853, the eldest of six children of a Protestant pastor, at Zundert, a small village in the Brabant region of southern Netherlands. His early years in his father's parsonage were happy, and he loved wandering in the countryside. At 16 he was apprenticed to the Hague branch of the art dealers Goupil and Co., of which his uncle was a partner.

Van Gogh's working life can be roughly divided into two periods. The first, from 1873 to 1885, during which he wrestled with temperamental difficulties and sought his true means of self-expression, was a period of repeated apprenticeships, failures, and changes of direction. The second, from 1886 to 1890, was a period of dedication, rapid development, and fulfillment, until it was interrupted by a series of mental crises from 1889 onward.

He worked for the art-dealing firm Goupil in London from 1873 to May of 1875 and in Paris from May 1875 to April 1876.

Daily contact with works of art aroused van Gogh's artistic sensibility, and he soon formed a taste for Rembrandt, Hals, and other Dutch masters, although his preference was for two contemporary French painters, Millet and Corot, whose influence was to last throughout his life. Van Gogh disliked art dealing. Moreover, his approach to life darkened when his love was rejected by a London girl in 1874. His burning desire for human affection thwarted, he became and remained increasingly solitary. He became a language teacher and lay preacher in England and, in 1877, worked for a bookseller in Dordrecht. Impelled by a longing to give himself to his fellowmen, he envisaged entering the ministry and took up theology but abandoned this project for short-term training as an evangelist in Brussels in 1878. A conflict with authority ensued when he disputed an orthodox doctrinal approach. Failing to get an appointment after three months, he left to do missionary work among the impoverished population of the Borinage, a coal-mining region in southwest Belgium. There, in the winter of 1879–80, he experienced the first great spiritual crisis of his life. He was sharing the life of the poor completely but in an impassioned moment gave away all his worldly goods and was thereupon dismissed for a too literal interpretation of Christian teaching.

Penniless and with his faith destroyed, he sank into despair, cut himself off from everyone, and began seriously to draw, thereby discovering in 1880 his true vocation. Van Gogh decided that his mission from then on would be to bring consolation to humanity through art, and this realization of his creative powers restored his self-confidence.

Discovery of his vocation

His artistic career was extremely short, lasting only the ten years from 1880 to 1890. During the first four years of this period, while acquiring technical proficiency, he confined himself almost entirely to drawings and watercolours. First, he went to study drawing at the Brussels Academy; in 1881 he moved to his father's parsonage at Etten, The Netherlands, and began to work from nature.

Van Gogh worked hard and methodically but soon perceived the difficulty of self-training and sought the guidance of more experienced artists. Late in 1881 he settled at The Hague to work with a Dutch landscape painter, Anton Mauve. He made visits to museums and had meetings with other painters. Van Gogh thus extended his technical knowledge and experimented in the summer of 1882 with oil paint. In 1883 the urge to be "alone with nature" and the peasants took him to Drenthe, a desolate part of northern Netherlands frequented by Mauve and other Dutch artists, where he spent three months before returning home, which was now at Nuenen, another village in the Brabant. He remained at Nuenen during most of 1884 and 1885, and during these years his art grew bolder and more assured. He painted three types of subject—still life, landscape, and figure—all interrelated by their reference to the peasants' daily life, to the hardships they endured and the countryside they cultivated. Émile Zola's *Germinal* (1885), a novel about the coal-mining region of France, greatly impressed van Gogh, and sociological criticism is implicit in many of his pictures—*e.g.*, "Weavers" and "The Potato Eaters." Eventually he felt too isolated in Nuenen.

His understanding of the possibilities of painting was evolving rapidly; from studying Hals he saw that academic finish destroys the freshness of a visual impression; Veronese and Delacroix taught him that colour expresses something by itself. This led to enthusiasm for Rubens and a sudden departure for Antwerp, where the greatest number of Rubens' works can be seen. The revelation of Rubens' simple means, of his direct notation, and of his ability to express a mood by a combination of colours proved decisive. Simultaneously, van Gogh discovered Japanese prints and Impressionist painting. His refusal to follow academic principles led to rows at the Antwerp academy, where he was enrolled, and after three months he left precipitately in 1886 to join his brother Theo in Paris. There, still concerned with improving his drawing, van Gogh met Toulouse-Lautrec, Paul Gauguin, and others who were to play historic roles in modern art. They opened his eyes to the latest developments in French painting. At the same time, Theo showed him Impressionist paintings at Goupil's and introduced him to Camille Pissarro, Georges Seurat, and other artists of the group.

Influence of the Impressionists and Post-impressionists

By this time van Gogh was ready for such revelations, and the changes that his painting underwent in Paris between the spring of 1886 and February 1888 led to the creation of his personal idiom and style of brushwork. His palette at last became colourful, his vision less traditional, and his tonalities lighter, as may be seen in his first paintings of Montmartre. Finally, van Gogh's Post-impressionist style crystallized by the beginning of 1888 in masterpieces such as "Portrait of Père Tanguy" and "Self-Portrait in Front of an Easel," as well as in some landscapes of the Parisian suburbs.

After two years, van Gogh was tired of city life, physically exhausted, and longing "to look at nature under a brighter sky." His passion was now for "the Japanese way of feeling and drawing" and for "a full effect of colour." He left Paris in February 1888 for Arles.

In his pictures of the following 12 months—his first great period—he strove to respect natural appearances and yet to convey by emphatic contours and heightened effects of colour the reality of his own feelings about the subject. Van Gogh's pictorial conception was partly Expressionist and partly Symbolist. His procedure was not calculated, however, but spontaneous and instinctive, for he worked with great speed and intensity, determined to capture an effect or a mood while it possessed him. His Arles subjects include blossoming fruit trees, views of the town and surroundings, self-portraits, portraits of Roulin the postman and his family and other friends, interiors and exteriors of the house, a series of sunflowers, and a "starry night."

Van Gogh knew that his approach to painting was individualistic, but he was also deeply aware that some tasks are beyond the power of isolated individuals to accomplish. In Paris he had hoped to form a separate Impressionist group with Gauguin, Toulouse-Lautrec, and others whom he supposed to have similar aims. He rented and decorated "a yellow house" in Arles with the intention of persuading them to join him and found a working community of "Impressionists of the South." Gauguin arrived in October 1888, and for two months they worked together; but while each influenced the other to some extent, their relations rapidly deteriorated because they had opposing ideas and were temperamentally incompatible.

Mental breakdown

On Christmas Eve 1888, van Gogh broke under the strain and cut off part of his left ear. Gauguin left, and van Gogh was taken to a hospital; he returned to the

"Bedroom at Arles," oil painting by van Gogh, 1888 or 1889. In The Art Institute of Chicago.

"yellow house" a fortnight later and resumed painting: "Self-Portrait with Pipe and Bandaged Ear," still lifes, "La Berceuse." Several weeks later, he again showed symptoms of mental disturbance severe enough to cause him to be sent back to the hospital. At the end of April 1889, fearful of losing his renewed capacity for work, which he regarded as a guarantee of his sanity, he asked to be temporarily shut up in the asylum at Saint-Rémy-de-Provence in order to be under medical supervision.

Vincent stayed there for 12 months, haunted by recurrent attacks, alternating between moods of calm and despair, and working intermittently: "Garden of the Asylum," "Cypresses," "Olive Trees," "Les Alpilles," portraits of doctors, and interpretations of paintings by Rembrandt, Delacroix, and Millet. The keynote of this phase (1889–90) is fear of losing touch with reality and a certain sadness. Confined for long periods to his cell or the asylum garden, having no choice of subjects, and realizing that his inspiration depended on direct observation, van Gogh fought against having to work from memory. At Saint-Rémy he muted the violent colours of the previous summer and tried to make his painting calmer. As he repressed his excitement, however, he involved himself more imaginatively in the drama of the elements, developing a style based on dynamic forms and a vigorous use of line (line often equated with colour). The best of his Saint-Rémy pictures are thus bolder and more visionary than those of Arles.

Van Gogh himself brought this period to an end. Oppressed by homesickness—he painted souvenirs of Holland—and loneliness, he longed to see Theo and the north once more and arrived in Paris in May 1890. Four days later he went to stay with a homeopathic doctor-artist, Dr. Paul-Ferdinand Gachet, a friend of Pissarro and Paul Cézanne, at Auvers-sur-Oise. Back in a village community such as he had not known since Nuenen, four years earlier, van Gogh worked at first enthusiastically; and his choice of subjects such as fields of corn, the river valley, peasants' cottages, the church, and the town hall reflects his spiritual relief. A modification of his style follows: in the northern light he adopted pale, fresh tonalities; the brushwork is broader and more expressive; the vision of nature more lyrical. But this phase was short; it ended in quarrels with Gachet and feelings of guilt at his inescapable dependence on Theo (now married and with a son) and his inability to succeed. In despair of ever overcoming his loneliness or of being cured, he shot himself and died two days later, on July 29, 1890. Coincidentally, Theo died six months later (January 25, 1891) of chronic nephritis.

The name of van Gogh was virtually unknown when he took his life. He had exhibited a few canvases at the Salon des Indépendants in Paris between 1888 and 1890 and in Brussels in 1890; both salons showed small commemorative groups of his work in 1891. One-man shows of his work did not occur until 1892; only one article about him appeared during his lifetime. His fame, made largely by other painters, dates from the early years of the 20th century and his reputation has never ceased to grow.

MAJOR WORKS

"In the Field" (1883; Rijksmuseum Vincent van Gogh, Amsterdam); "The Loom" (1884; Rijksmuseum Kröller-Müller, Otterlo, The Netherlands); "Autumn Landscape with Four Trees" (1885; Rijksmuseum Kröller-Müller, Otterlo); "Peasant Woman in a Red Bonnet" (1885; Rijksmuseum Vincent van Gogh, Amsterdam); "The Potato Eaters" (1885; Rijksmuseum Vincent van Gogh, Amsterdam); "Skull with a Cigarette" (1886; Rijksmuseum Vincent van Gogh, Amsterdam); "Boots" (1887; Museum of Art, Baltimore); "View of Arles with Irises" (1888; Rijksmuseum Vincent van Gogh, Amsterdam); "La Mousmé" (1888; Chester Dale Collection, National Gallery of Art, Washington, D.C.); "The Postman Roulin" (1888; Museum of Fine Arts, Boston); "The Chair and the Pipe," popularly known as "Van Gogh's Chair" (1888–89; Tate Gallery, London); "Self-Portrait in Front of an Easel" (1888; Rijksmuseum Vincent van Gogh, Amsterdam); "The Night Café" (1888; Yale University Art Gallery); "Self-Portrait with Pipe and Bandaged Ear" (1889; Leigh B. Block Collection, Chicago); "Green Corn" (1889; Národní Galerie, Prague); "Pietà" (1889; Rijksmuseum Vincent van Gogh, Amsterdam); "L'Arlésienne" (1890; Museu de Arte, São Paulo, Brazil); "Hospital Corridor at Saint-Rémy" (1889; Museum of Modern Art, New York); "The Starry Night" (1889; Museum of Modern Art, New York); "Old Man in Sorrow," also known as "On the Threshold of Eternity" (1890; Rijksmuseum Kröller-Müller, Otterlo); "Mademoiselle Gachet at the Piano" (1890; Kunstmuseum, Basel, Switzerland); "Stairway at Auvers" (1890; City Art Museum, St. Louis, Missouri); "The Church at Auvers" (1890; Louvre, Paris); "Self-Portrait" (1890; Louvre, Paris).

BIBLIOGRAPHY. There is no thorough, detached biography of van Gogh. The best recent contributions are JEAN LEYMARIE, *Van Gogh* (1951), a sound and intelligent study; also the same author's *Qui était Van Gogh?* (1968; Eng. trans., *Who Was Van Gogh?*, 1968); CARL A.J. NORDENFALK, *The Life and Work of Vincent van Gogh* (1953), an elementary work; HENRI PERRUCHOT, *La Vie de van Gogh* (1955), a journalistic account; and MARC E. TRALBAUT, *Vincent van Gogh* (1969), well documented but erratic and melodramatic. The basic reference books are *The Complete Letters of Vin-*

cent van Gogh, 3 vol. (1958)—the translation, transcription, and chronology are erratic and can be corrected against the original texts published in *Verzamelde brieven van Vincent van Gogh*, 4 vol. (1952–54), and acceptable revised datings argued by J. HULSKER in articles in the review *Maatstaaf* (1958–61), summarized in English in numbers of the review *Museumjournaal* (1959–61); and J. BAERT DE LA FAILLE, *L'Oeuvre de Vincent van Gogh*, 4 vol. (1928; Eng. trans., *The Works of Vincent Van Gogh: His Paintings and Drawings*, 3rd ed. rev., 1970), a catalogue raisonné critically revised (though inadequately) by Dutch art historians. The following scholarly studies of specific aspects of van Gogh's work are also specially recommendable: ANNA SZYMANSKA, *Unbekannte Jugendzeichnungen Vincent van Goghs . . . 1870–1880*, 2nd ed. (1968); W. VANBESELAERE, *De Hollandsche periode (1880–85) in het werk van Vincent Van Gogh* (1937); MARK W. ROSKILL, *Van Gogh, Gauguin and the Impressionist Circle* (1970; with a complementary *Catalogue Raisonné of Key Works*, 1971); KURT BADT, *Die Farbenlehre Van Goghs* (1961); DOUGLAS COOPER, *Drawings and Watercolours by Van Gogh* (1955); and NICHOLAS WADLEY, *The Drawings of Van Gogh* (1969).

Gogol, Nikolay

The great tradition of the Russian novel—through which Russia assumed a place among the major literary peoples of the world—was established largely by Nikolay Gogol, whose stories, plays, and novels of Russian life—noted for their satiric humour and their mixture of realistic and fantastic elements—revealed the proclivity of Russian fiction for a medium of expression that was more Realist than Romantic.

Gogol, oil painting by F.A. Moller, 1840. In the State Tretyakov Gallery, Moscow.

Youth and early fame. Nikolay Vasilyevich Gogol was born on March 31 (March 19, old style), 1809, at Sorochintsy near Poltava. The Ukrainian countryside, with its colourful peasantry, its Cossack traditions, and rich folklore, constituted the background of his boyhood. A member of the petty Ukrainian gentry, Gogol was sent at the age of 12 to the high school at Nezhin. There he distinguished himself by his biting tongue, his contributions of prose and poetry to a magazine, and his portrayal of comic old men and women in school theatricals. In 1828 he went to St. Petersburg, hoping to enter the civil service, but soon discovered that without money and connections he would have to fight hard for a living. He even tried to become an actor, but his audition was unsuccessful. In this predicament he remembered a mediocre sentimental–idyllic poem he had written in the high school. Anxious to achieve fame as a poet, he published it at his own expense, but its failure was so disastrous that he burned all the copies and thought of emigrating to the United States. Though he actually took a boat to Lübeck, he soon ran out of money in Germany and returned to St. Petersburg to look again for a job. What he obtained was such an ill-paid government post that after three months he exchanged it for another, which he also left about a year later.

In the meantime he wrote occasionally for periodicals, finding an escape in childhood memories of the Ukraine. He committed to paper what he remembered of the sunny landscapes, peasants, and boisterous village lads and also related tales about devils, witches, and other demonic or fantastic agents that enliven Ukrainian folklore. Romantic stories of the past were thus intermingled with realistic incidents of the present, in which Gogol's sense of fun and at times his feeling of evil came into their own. Such was the origin of his eight narratives, published in two volumes in 1831–32 under the title *Evenings on a Farm near Dikanka* (*Vechera na khutore bliz Dikanki*). Written in a lively and at times colloquial prose, they contributed something fresh and new to Russian literature. In addition to the author's whimsical inflection, they abounded in genuine folk flavour, including many Ukrainian words and phrases, all of which captivated the Russian literary world.

Use of colloquial language and folklore

Mature career. The young author became famous overnight. Among his first admirers were the poets Aleksandr Pushkin and Vasily Zhukovsky, both of whom he had met before. This esteem was soon shared by the writer Sergey Aksakov and the critic Vissarion Belinsky, among others. Having given up his second government post, Gogol was now teaching history in a boarding school for girls. In 1834 he was appointed assistant professor of medieval history at St. Petersburg University, but he felt inadequately equipped for the position and left it after a year. Meanwhile, he prepared energetically for the publication of his next two books, *Mirgorod* and *Arabesques* (*Arabeski*), which appeared in 1835. The four stories comprising *Mirgorod* were a continuation of the *Evenings*, but they revealed a strong gap between Gogol's romantic escapism and his otherwise pessimistic attitude toward life. Such a splendid narrative of the Cossack past as "Taras Bulba" certainly provided an escape from the present. "Story of the Quarrel between Ivan Ivanovich and Ivan Nikiforovich" ("Povest o tom, kak possorilsya Ivan Ivanovich s Ivanom Nikiforovichem") was, for all its humour, full of bitterness about the meanness and vulgarity of existence. Even the idyllic motif of Gogol's "Old-World Landowners" ("Starosvetskiye pomeshchiki") is undermined with satire, for the mutual affection of the aged couple is marred by gluttony, their ceaseless eating for eating's sake.

Aggressive realism of a romantic who can neither adapt himself to the world nor escape from it, and is therefore all the more anxious to expose its vulgarity and evil, predominates in Gogol's Petersburg stories printed (together with some essays) in the second work, *Arabesques*. In one of these stories, "Diary of a Madman" ("Zapiski sumasshedshego"), the hero is an utterly frustrated office drudge who finds compensation in megalomania and ends in a lunatic asylum. In another, "Nevsky Prospect," a tragic romantic dreamer is contrasted to an adventurous vulgarian, while in the revised finale of "The Portrait" ("Portret") the author stresses his conviction that evil is ineradicable in this world. In 1836 Gogol published in Pushkin's *Sovremennik* ("The Contemporary") one of his gayest satirical stories, "The Coach" ("Kolyaska"). In the same periodical also appeared his amusingly caustic surrealist tale, "The Nose" ("Nos"). Gogol's association with Pushkin was of great value because he always trusted his friend's taste and criticism; moreover, he received from Pushkin the themes for his two principal works, *The Government Inspector* (*Revizor*), sometimes translated *The Inspector General*, and *Dead Souls* (*Myortvye dushi*), which were important not only to Russian literature but also to Gogol's further destiny.

Publication of the Petersburg stories

A great comedy, *The Government Inspector* mercilessly lampoons the corrupt bureaucracy under Nicholas I. Having mistaken a well-dressed windbag for the dreaded incognito inspector, the officials of a provincial town bribe and banquet him in order to turn his attention away from the crying evils of their administration. But during the triumph, after the bogus inspector's departure, the arrival of the real inspector is announced—to the horror of those concerned. It was only by a special order of the tsar that the first performance of this comedy of indictment and "laughter through tears" took place on April 19, 1836. Yet the hue and cry raised by the reactionary press and officialdom was such that Gogol left

Russia for Rome, where he remained, with some interruptions, until 1842. The atmosphere he found in Italy appealed to his taste and to his somewhat patriarchal—not to say primitive—religious propensity. The religious painter Aleksandr Ivanov, who worked in Rome, became his close friend. He also met a number of travelling Russian aristocrats and often saw the émigrée Princess Zinaida Volkonsky, a convert to Roman Catholicism, in whose circle religious themes were much discussed. It was in Rome, too, that Gogol wrote most of his masterpiece, *Dead Souls.*

Composition of *Dead Souls*

This novel, or "epic," as the author labelled it, reflects feudal Russia, with its serfdom and bureaucratic iniquities. Chichikov, the hero of the novel, is a polished swindler who, after several reverses of fortune, wants to get rich quick. His bright but criminal idea is to buy from various landowners a number of the recently deceased serfs (or "souls," as they were called in Russia) whose deaths have not yet been registered by the official census and are therefore regarded as still being alive. The landowners are only too happy to rid themselves of the fictitious property on which they continue to pay taxes until the next census. Chichikov intends to pawn the "souls" in a bank, and, with the money thus raised, settle down in a distant region as a respectable gentleman. The provincial townsmen of his first stop are charmed by his polite manners; he approaches several owners in the district who are all willing to sell the "souls" in question, knowing full well the fraudulent nature of the deal. The sad conditions of Russia, in which serfs used to be bought and sold like cattle, are evident throughout the grotesquely humorous transactions. The landowners, one more queer and repellent than the last, have become nicknames known to every Russian reader. When the secret of Chichikov's errands begins to leak out, he hurriedly leaves the town.

Dead Souls appeared in 1842, the same year in which the first edition of Gogol's collected works was published. The edition included, among his other writings, a sprightly comedy titled the *Marriage* (*Zhenitba*) and the story "The Overcoat" ("Shinel"). The latter concerns a humble scribe who, with untold sacrifices, has acquired a smart overcoat; when robbed of it he dies of a broken heart. The tragedy of this insignificant man was worked out with so many significant trifles that, years later, Dostoyevsky was to exclaim that all Russian Realists had come "from under Gogol's greatcoat." The apex of Gogol's fame was, however, *Dead Souls.* The democratic intellectuals of Belinsky's brand saw in this novel a work permeated with the spirit of their own liberal aspirations. Its author was all the more popular because after Pushkin's tragic death he was now looked upon as the head of Russian literature. Gogol, however, began to see his leading role in a perspective of his own. Having witnessed the beneficent results of the laughter caused by his indictments, he was sure that God had given him a great literary talent in order to make him not only castigate abuses through laughter but also to reveal to Russia the righteous way of living in an evil world. He therefore decided to continue *Dead Souls* as a kind of *Divine Comedy* in prose; the already published part would represent the *Inferno* of Russian life, and the second and third parts (with Chichikov's moral regeneration) would be its *Purgatorio* and *Paradiso.*

Creative decline. Unfortunately, having embarked upon such a soul-saving task, Gogol noticed that his former creative capacity was deserting him. He worked on the second part of his novel for over ten years, but with meagre results. In drafts of four chapters and a fragment of the fifth found among his papers, the negative and grotesque characters are drawn with some intensity, whereas the virtuous types he was so anxious to exalt are stilted and devoid of life. This lack of zest was interpreted by Gogol as a sign that, for some reason, God no longer wanted him to be the voice exhorting his countrymen to a more worthy existence. In spite of this he decided to prove that at least as teacher and preacher—if not as artist—he was still able to set forth what was needed for Russia's moral and worldly improvement. This he did in his ill-starred *Selected Passages from Correspondence with My Friends* (*Vybrannye mesta iz perepiski s druzyami*, 1847), a collection of 32 discourses eulogizing not only the conservative official church but also the very powers that he had so mercilessly condemned only a few years before. It is no wonder that the book was fiercely attacked by his one-time admirers, most of all by Belinsky, who in an indignant letter called him "a preacher of the knout, a defender of obscurantism and of darkest oppression." Crushed by it all, Gogol saw in it a further proof that, sinful as he was, he had lost God's favour forever. He increased his prayers and his ascetic practices; in 1848 he even made a pilgrimage to Palestine, but in vain. Despite a few bright moments he began to wander from place to place like a doomed soul. Finally he settled in Moscow where he came under the influence of a fanatical priest, Father Matvey Konstantinovsky, who seems to have practiced on Gogol a kind of spiritual sadism. Ordered by him, Gogol burned the presumably completed manuscript of the second volume of *Dead Souls* on February 24 (February 11, O.S.), 1852. Ten days later, on March 4 (February 21, O.S.), he died, on the verge of semi-madness.

Political conservatism and religious fanaticism

Influence and reputation. Whatever the vagaries of Gogol's mind and life, his part in Russian literature was enormous. Above all, it was from the nature of such works as *The Government Inspector*, *Dead Souls*, and "The Overcoat" that Belinsky derived the tenets of the "natural school" (as distinct from the "rhetorical," or Romantic, school) that was responsible for the trend of subsequent Russian fiction. Gogol was among the first authors to have revealed Russia to herself. Yet in contrast to the simple classical–realistic prose of Pushkin, adopted by Leo Tolstoy, Ivan Goncharov, and Ivan Turgenev, Gogol's ornate and agitated prose was assumed by Fyodor Dostoyevsky and, later, by the Symbolist poet and novelist Andrey Bely whose style has, in turn, influenced several post-revolutionary writers of the Soviet Union. Gogol's realism of indictment found many followers, among them the great satirist Saltykov-Shchedrin. He was also a champion of the little man as a literary hero. His vexation of spirit, too, was continued (but on a higher level) by both Tolstoy and Dostoyevsky as was his effort to transcend "mere literature."

MAJOR WORKS

NOVEL: *Myortvye dushi* (1842; *Dead Souls*, trans. by Constance Garnett in *The Works of Nikolay Gogol*, 1922–23; by G. Reavey, 1948; and David Magarshack, 1961).

STORIES: *Vechera na khutore bliz Dikanki*, vol. 1 (1831), vol. 2 (1832), including "Sorochinskaya yarmarka," trans. by Rosa Portnova as "Sorochinsky Fair" in *Tales from Gogol* (1945); "Vecher nakanune Ivana Kupala," trans. by Constance Garnett as "St. John's Eve" in *The Works of Nikolay Gogol;* "Mayskaya noch; ili, utoplennitsa," trans. by C. Field as "A May Night" (1915); "Propavshaya gramota," trans. by Constance Garnett as "The Lost Letter" in *The Works of Nikolay Gogol;* "Noch pered Rozhdestvom," trans. by Rosa Portnova as "Christmas Eve" in *Tales from Gogol;* and "Zakoldovannoye mesto," trans. by Constance Garnett as "The Bewitched Spot" in *The Works of Nikolay Gogol; Arabeski* (1835), including "Portret," "Nevsky prospekt," trans. by Rosa Portnova as "The Nevsky Prospect" in *Tales from Gogol*, and "Zapiski sumasshedshego," trans. by C. Field as "Memoirs of a Madman" (1915): the first two were trans. by David Magarshack as "The Portrait" and "Nevsky Avenue" in *Tales of Good and Evil* (1949): the last two were translated separately by B. Scott as "Diary of a Madman" and "Nevski Prospect" (1945); *Mirgorod* (1835), including "Starosvetskiye pomeshchiki," trans. by Constance Garnett as "Old-World Landowners" in *The Works of Nikolay Gogol;* and "Povest o tom, kak possorilsya Ivan Ivanovich s Ivanom Nikiforovichem," trans. by Rosa Portnova as "How the Two Ivans Quarrelled" in *Tales from Gogol;* "Viy," trans. by C. Field (1915); and "Taras Bulba," trans. by David Magarshack in *Tales of Good and Evil;* "*Nos*" (1836; "The Nose," trans. by C. Field, 1915); "Kolyaska" (1836; trans. by Rosa Portnova as "The Coach" in *Tales from Gogol*); "Shinel" (1842; trans. by C. Field as "The Mantle," 1915; and as "The Overcoat," trans. by David Magarshack in *Tales of Good and Evil*).

PLAYS: *Zhenitba* (1842; *Marriage*, trans. by B. Costello, 1969); *Revizor*, trans. by David Magarshack as *The Government Inspector*, and by E.O. Marsh and J. Brooks, 1968).

OTHER WORKS: *Vybrannye mesta iz perepiski s druzyami* (1847; trans. by Constance Garnett as *Selected Passages from Correspondence with My Friends* in *The Works of Nikolay Gogol*, 1922).

BIBLIOGRAPHY. One of the best of the numerous Russian editions of Gogol's works is that by Н.С. ТИХОНРАВОВ, 7 vol. (1889). *Собрание сочинений*, 7 vol. (1950, 1966–67), is also a good Soviet edition. In English, see *The Works of Nikolay Gogol*, 6 vol., trans. by CONSTANCE GARNETT (1922–23). Selections include *Tales from Gogol*, trans. by ROSA PORTNOVA (1945); and *Tales of Good and Evil*, trans. by DAVID MAGARSHACK (1949). Владимир Иванович Шенрок, *Материалы для биографии Гоголя*, 4 vol. (1892–97), is indispensable for thorough investigation of Gogol's life and work. Виссарион Григорьевич Белинский, *В.Г. Белинский о Гоголе; статьи, рецензии, письма* (1949); and Николай Гаврилович Чернышевский, *Очерки Гоголевского периода русской литературы* (1953), are Soviet re-editions of the important early, for the most part, socio-political essays. Нестор Александрович Котляревский, *Николай Васильевичь Гоголь 1829–1842* (1903), is an excellent early biography. A popular, more recent biography is В.В. Ермилов, *Гоголь (Николай Васильевич)* (1952). In English, see PAUL DEBRECZENY, *N. Gogol and His Contemporary Critics* (1966), a survey; V.V. NABOKOV, *Nikolai Gogol* (1944), an astute and rather subjective monograph; J. LAVRIN, *Gogol* (1951, reprinted 1968), mainly a psychological approach; DAVID MAGARSHACK, *Gogol: A Life* (1957, reprinted 1969), based on contemporary evidence; and VICTOR ERLICH, *Gogol* (1969), an excellent, recent study.

(Ja.La.)

Goiás

An inland state (*estado*) of Brazil, Goiás, the site of the federal district (*distrito federal*) and capital, Brasília, is part of the rapidly developing frontier of the country. It is bounded by the states of Maranhão on the north, Mato Grosso and Pará on the west, Minas Gerais and Mato Grosso on the south, and Maranhão, Bahia, and Minas Gerais on the east. Its area is 247,913 square miles (642,092 square kilometres). Its population early in the 1970s was about 3,000,000. The state capital, since 1937, has been Goiânia.

History. The first European exploration of this interior part of Brazil was carried on by expeditions from São Paulo in the 17th century. Gold was discovered in the stream gravels of a tributary of the Rio Araguaia by the explorer Bartolomé Bueno de Silva in 1682. The settlement he founded there, called Santa Anna, became the colonial town of Goiás, the former state capital. In 1744 the large inland area, much of it still unexplored by Europeans, was made a captaincy general, and in 1822 it became a province of the empire of Brazil. It became a state in 1889. The Brazilian constitution of 1891 specified that the nation's capital should be moved to the Planalto Central (Central Plateau), and in 1956 Goiás was selected as the site for the federal district and capital city, Brasília. The seat of the federal government was officially moved to Brasília in 1960.

Physical geography. Goiás lies wholly within the Brazilian Highlands. In the south it occupies the larger part of the Planalto Central, the vast level surface of which stands between 2,500 and 3,000 feet above sea level. A few rounded ridges stand higher than this, the highest being the Chapada dos Veadeiros (5,505 feet [1,678 metres]). The Planalto Central forms the divide between three of Brazil's largest river systems: to the south Goiás is drained through the Rio Paranaíba, a tributary of the Paraná River; to the east it is drained by tributaries of the São Francisco River; and the greater part of the state is drained northward through the Rio Araguaia and the Rio Tocantins and their tributaries. None of these rivers is navigable except for short distances. The southern part of the state is covered with a woodland savanna known in Brazil as *campo cerrado*. To the north, where the Rio Araguaia and Rio Tocantins have eroded deep valleys, the land is covered with tropical rain forest, or *selva*.

Climate

The climate of the plateau, usually described as moderate, is subtropical. The deeper valley regions are tropical. Average monthly temperatures vary from 78.1° F (25.6° C) in the warmest month to 72° F (22° C) in the coldest month. The year is divided into a rainy season (October–March) and a dry season (April–September). Average annual rainfall is about 67 inches (1,700 millimetres).

Population. The Grande Região Centro-Oeste (Great Central East Region), consisting of Goiás, Mato Grosso, and the federal district, is the fastest growing region of Brazil. The population of Goiás was 1,214,921 in 1950; 1,954,862 in 1960; and 2,997,570 in 1970. Outside the federal district the greater part of Goiás is still very thinly populated. Only a few isolated settlements are scattered throughout the northern two-thirds of the area. The chief concentration of settlement is in the southeast, across the border from Minas Gerais. Population density in the state is 11.9 persons per square mile (4.6 per square kilometre).

The population has been predominantly rural (57.7 percent), the influx of immigrants after 1950 consisting of approximately equal numbers of rural and urban dwellers. Thus, the state has experienced rural and urban expansion at the same time. Areas adjacent to the federal district have grown the most rapidly.

Historically, the inhabitants have been predominantly of mixed European–Indian ancestry. The new settlers have come from all parts of Brazil, including many from nearby areas, and thus represent varying degrees of European, Indian, and Negro origins so that the ethnic composition of the population is becoming more typical of the nation as a whole.

Administration and social conditions. The state government moved from Goiás to Goiânia in 1937 and was officially inaugurated there in 1942. Although Goiás has been a state since 1889, it remained undeveloped in both population and resources so that, like most of the other states of Brazil, it has been unable to carry out the functions of modern government, having to rely on support at the federal level.

The standard of living is low, especially in the rural areas. Deaths from malaria have been reduced, but health services are limited, and life expectancy is still low. More primary and secondary schools have been built and attendance has increased, but growth has not kept up with the increase in population. Higher education is offered at the Universidade Católica de Goiás (founded 1959) and the Universidade Federal de Goiás (1961), both at Goiânia, and the Universidade de Brasília.

Economy. Goiás is a modern frontier area reflecting a spirit of growth and progress. Agriculture and livestock raising continue to be the most important economic activities, serving the growing urban markets. The principal crops are rice, corn (maize), beans, manioc (cassava), and coffee. Livestock raising is expanding, with cattle predominant on the open *campos* and pigs in the settled farming regions. Mineral resources include gold and diamonds (mining, carried on since the 16th century, continues although the output has never been large); tin and titanium ores (of which Goiás is Brazil's leading producer); and rock crystal (quartz crystal), chromium, and mica.

Principal crops

Goods and services for the growing pioneer society have been expanding with the growth of population since 1950. Anápolis, for example, reached by rail from Rio de Janeiro and São Paulo, has become a rapidly growing frontier town, serving the new zone of pioneer settlement in the northwest, the Mato Grosso de Goiás. Farm settlements along the valleys in the southeast have also required goods and services. The construction of Brasília and the formal transfer of the capital there reinforced Goiás' economic growth and assured its continuance.

Transportation. Until Anápolis was connected by rail with São Paulo in 1913, transport to and from the coast was by mule train. A network of feeder roads has been constructed in southern Goiás and a highway extended to Brasília. Direct access to the interior is by air.

Cultural life. Outside of Goiânia, the seat of two young universities, the state has had few cultural institutions. The establishment of the national capital within its boundaries has resulted in the development of major cultural centres there.

(P.E.J.)

Gold Products and Production

Gold possesses several outstanding qualities that have made it exceptionally valuable throughout history. It is attractive in colour and brightness, durable to the point of virtual indestructibility, highly malleable, and usually found in nature in a comparatively pure form. Examples of elaborate gold workmanship survive from ancient Egyptian, Minoan, Assyrian, and Etruscan artists, many in nearly perfect condition. The development of a more complex economic system gave gold a new major function as high-denomination currency and later as backing for paper-currency systems, a function it has retained in many countries to the present. So precious was gold in the Middle Ages that the foundation of chemistry derived largely from the vain experiments of medieval alchemists seeking to convert other metals into gold.

Gold is widely dispersed throughout the Earth's crust. Naturally occurring metallic, or native, gold usually contains variable amounts of silver, copper, platinum, palladium, or certain other elements mixed with it. Gold exists in association with most copper and lead deposits, and although the quantity of gold present is often extremely small, it is readily recovered as a by-product in the refining of those base metals.

Large masses of rock rich enough to be called ores are unusual. Those that do exist are usually quartz lodes or veins. Ores may also be found in deposits which were brought to their sites from veins, such as in river gravels and gold-bearing quartz conglomerate beds (called blankets or reefs) of the Witwatersrand system in the Transvaal and Orange Free State in South Africa. The mineral most commonly associated with gold, other than quartz, is pyrite, FeS_2, or "fool's gold," the yellow disulfide of iron.

The gold mined during great gold strikes in California, Colorado, and Alaska was removed by the placer method (see below *Placer mining*) from alluvial deposits in which metallic gold occurred in the form of gold dust, larger grains, irregularly shaped masses, or occasional nuggets dispersed through the sand or caught in rock crevices.

For the most part, the gold found in rock is invisible to the naked eye, although it does sometimes occur as grains or flakes large enough to be seen, and more rarely as specimen rock. Crystals an inch or more across have been found in alluvial deposits in California. Boulders of pure gold were found in the early days of the Australian gold rush of 1851. Compounds formed with the element tellurium, known as gold tellurides, are found principally in Western Australia and Colorado: the principal ores are calaverite, a bronze-yellow telluride that contains 40 percent gold, and sylvanite, steel gray in colour and containing up to 28 percent gold combined with some silver.

Gold is also found in seawater. Though the total amount in the oceans is estimated at billions of tons, the concentration of it is less than six parts per 1,000,000,000,000 parts of seawater, making it not economically feasible to mine the sea.

Alluvial deposits of native gold found in or along streams were the principal sources of the metal for the ancient civilizations of the Middle East. The washing of gold ores is depicted on Egyptian monuments of the 1st dynasty (*c.* 3100–*c.* 2890 BC). The famous legend of the Golden Fleece was based on an expedition (about 1200 BC) to seize gold that was washed out of the river sands with the aid of sheepskins in the region later known as Armenia. Rich deposits were known in Lydia and the lands of the Aegean, and in Persia (now Iran), India, China, and other lands.

During the Middle Ages the chief sources of gold in Europe were the mines of Saxony and Austria; Spain also produced some gold.

The era of gold production that followed the discovery of the Americas was in all probability the greatest the world had witnessed to that time. The exploitation of mines by slave labour and the looting of palaces, temples, and graves in Central and South America resulted in an influx of gold that literally unbalanced the economic structure of Europe and disturbed its political structure. From the discovery of America by Columbus in 1492 until 1600, more than 8,000,000 ounces (225,000 kilograms) of gold, or 35 percent of world production, came from South America. South American mines—especially in Colombia—continued into the 17th and 18th centuries to account for 61 and 80 percent, respectively, of world production; 48,000,000 ounces (1,350,000 kilograms) were mined in the 18th century.

Gold in Central and South America

Miners panning for gold in the Klondike, Yukon Territory, 1897.
The Bettman Archive

Russia became the leading producer in 1823, and for 14 years contributed the bulk of the world supply.

During the second great era of expanding production (1850–75) more gold was produced in the world than in all the years since 1492, chiefly because of discoveries in California and Australia. A third marked increase in world gold recovery (1890–1915) stemmed from discoveries in Alaska, Yukon Territory, and South Africa. Beginning in the 1920s, gold production was increased by the development of gold fields in Canada. A major factor in the increase of the world supply of gold was the introduction in 1890 of the cyanide process for recovery of gold from low-grade ores and ores containing minute, particle-size gold.

Throughout the years gold production rose until the average yearly production reached almost 52,000,000 ounces (1,500,000 kilograms) in 1970, which was greater than the totals for either 1493–1600 or 1600–1700.

MINING

Gold is recovered by placer mining of alluvial deposits, and by lode or vein mining. It is also recovered as a by-product of base-metal mining. Placer mining, the oldest method, entails exploiting the high density (or heaviness) of gold to separate it from the much lighter siliceous material with which it is found. The alluvial deposits mined by placer methods are the gold-bearing sands and gravel that have been deposited by rapidly moving streams and rivers at places where they widen or for some other reason lose speed. As the current slows, the sediment being carried downstream settles to the bottom.

Placer mining. Although the basic principles of placer mining have not altered since early times, the methods have improved considerably, chiefly in mechanical procedures. In the great American gold strikes in California, Colorado, and Alaska, placer mines were almost exclusively the source of gold, and the panning method was the technique utilized by the individual miners. The miner used a pan or a batea (a pan or basin with radial corrugations) in which he placed a few handfuls of dirt and a large amount of water. Swirling the pan washed the siliceous material over the side and left the denser material in the centre of the pan. After many washings,

Panning

only gold and the other heavy minerals were left. At this point, if the gold particles were large enough, it was comparatively easy to separate them from other materials. If not, further concentration was needed.

The cradle or rocker was an improvement over the pan and the batea. The cradle, named for a child's cradle, which it resembled, could process larger quantities of ore. Gravel was shovelled onto a perforated iron plate, and water was poured on. The finer material dropped onto the apron, which distributed it across riffles, pieces of wood or iron perpendicularly fixed to the bottom and sides of the cradle. The entire apparatus was rocked, and as the material moved through the rocker, the gold was caught by the riffles. When enough gold was accumulated, the riffles were cleaned.

Although the cradle or rocker is largely obsolete, its riffles remain in use in sluice boxes and corduroy tables. The name riffle is applied to any strip, bar, or groove placed at right angles to the flowing stream to provide a protective spot where the gold can settle. The corduroy table consists of wide, sloping plates with shallow sides that hold a coarse corduroy cloth. Periodically, the corduroy is removed and washed by hand in boxes partly filled with water to recover the gold-rich concentrates.

Hydraulic mining. In California, thick beds of gravel on the hillsides were worked by hydraulic mining. Powerful jets of water at pressures of hundreds of pounds per square inch were passed through giant swivel-mounted nozzles to break down the gravel banks and wash the material through lines of sluices. Although great volumes of water and many miles of pipes and flumes were required, the cost of treatment was only a few cents per cubic yard, which made it possible to work even poor ground at a profit. The millions of tons of tailings (discarded residue) that were washed into the Yuba and Feather rivers, however, had such an adverse effect on farming downstream that an injunction was obtained against hydraulic miners in 1880, and the work thereafter was strictly limited.

Dredging. In the early 1900s, dredging became the most important type of placer mining and has become probably the single most prevalent technique. The dredge generally used the world over is similar to that employed to deepen harbours and rivers. Invented in New Zealand, the gold-mining dredge achieved its greatest popularity on the rivers there and in California. Dredging is the major technique used today in the U.S.S.R.

Paddock dredging, a later development in the western United States, makes it possible to work placer deposits even if they are not in or near a riverbed. The paddock dredge floats in a pond that is continuously extended by the digging equipment at one end of the dredge while simultaneously being filled in by the waste or tailings at the other end. In this way, the dredge moves across country taking its pond or reservoir with it. By piling more gravel around the reservoir and increasing the water level, the dredge can be made to work its way uphill. In 1910 there were 72 operating dredges in California. After World War II, however, only a few remained in operation.

Lode mining. Many of the methods used in the underground mining and exploration of gold lode or vein deposits are similar to the shaft- and pit-mining methods used for other metals. Tremendous tonnages of gold ore are treated throughout the world since most gold-mine ores contain an extremely low percentage of gold. For example, in one area three tons of ore are processed for every ounce of gold obtained. Ordinarily, a vertical shaft is sunk to allow the miner to get to the lode. Horizontal working levels then follow the vein. In the Homestake mine in South Dakota (the largest in the U.S.), the working depth lies 6,800 feet (2 kilometres) below the surface, and since 1877, some 200 horizontal miles (320 kilometres) have been worked.

RECOVERY AND REFINING

Gold particles wetted by mercury adhere to each other and to copper plates that have been coated with mercury, a process called amalgamation. It forms the basis for a technique for recovering gold from ore. For many centuries this was the method used in treating massive ores. The percentage of gold recovered varied with the type of ores, and considerable gold was lost.

Amalgamation

Cyanide process. The cyanide process, introduced in South Africa in 1890, effected a vast improvement over amalgamation and other earlier methods, and has been extensively used ever since. In this process, the gold in finely ground ore is dissolved by treating it with a very dilute solution of sodium cyanide or, the less expensive calcium cyanide plus lime and oxygen from air. The mixture is held for some hours in large tanks equipped with agitators. The chemical reaction yields a water solution of gold cyanide and sodium cyanoaurite. This solution of gold is treated to remove oxygen, then clarified and mixed with zinc dust to precipitate the gold and the other metals, such as silver and copper, that were dissolved by the cyanide. The precipitate is then treated with dilute sulfuric acid to dissolve residual zinc plus most of the copper. The residue is washed, dried, and melted with fluxes (materials used to promote fusion of the gold and silver and to dissolve the remaining copper). The operation may be repeated to flux off more base metal. The remaining gold and silver alloy, called doré, is then cast into moulds for assay.

The cyanide process may constitute the whole recovery process or may follow amalgamation. At some mines in the United States amalgamation is used to recover about 60 percent of the gold, after which cyanidation achieves an overall recovery of 95 to 96 percent. The cyanide process has been used to treat the tailings from early operations and fortunes have been made in reworking old dumps. The process is employed almost exclusively in recovering gold from the South African mines, the world's largest source in the 1970s.

Some South African mines reach depths of at least two miles. In contrast, open-pit mining has opened in a new region, northeastern Nevada. The Carlin mine there is the second-largest U.S. producer. Deposits there are sedimentary and originally contained some organic material, which prevented satisfactory cyanide extractions. Weathering, however, destroys the organic material and makes the use of cyanide effective. An electrolytic method has been devised for oxidizing the deeper unoxidized deposits and destroying the troublesome organic material so that they ultimately can be worked with the cyanide process.

The dominant position of South Africa in world production of gold (see Table) is a tribute to the ability of modern mining methods to cope with the tremendous rock pressures and high temperatures encountered at great depths.

In addition to the gold from placers and hard rock mines, considerable gold is recovered from copper and copper nickel ores in the course of electrolytic refining, a process in which a metal is refined by being deposited electrolytically much as in electroplating.

Recovery from scrap. Considerable amounts of gold are recovered from scrap. The composition of scrap varies widely and dictates the process to be used. The scrap is largely produced in the manufacture of gold jewelry and electrical contacts, and as electroplating residues. Melting the scrap under oxidizing conditions will volatilize some of the zinc and remove some of the iron in the slag. The metal may then be formed into pellets and if the gold content is about 20 percent it can be treated with nitric acid to remove the base metals. If the pellets are low in lead, treatment with hot sulfuric acid may suffice. Retreatment will be required, however, to yield gold of acceptable purity if the sulfuric acid process is used. These methods are appropriate for scrap that is free of platinum metals. Lower-grade scrap may be melted and cast into anodes that are electrolyzed in a sulfate solution. The gold will remain in the anode mud and can be recovered by first converting it to gold chloride and then precipitating the gold by adding ferrous sulfate.

Wohlwill process

Refining. In the Wohlwill process, doré gold from the usual mining and smelting operations is electrolyzed in a chloride solution using direct plus alternating currents. The gold in the doré anode dissolves and is deposited on the cathode as very pure gold. The silver is converted into chloride of which some clings to the anode and must be removed from time to time. This material also contains considerable gold and must be reworked. Any platinum or palladium in the anode will dissolve and is recovered by treating the electrolyte. This extensively used process yields gold at least 99.95 percent pure.

Because the Wohlwill process is rather slow, and for other reasons, it has largely been replaced by the Miller process in which chlorine is bubbled through the molten doré, converting the base metals into chlorides, some of which volatilize. The silver also is converted to silver chloride, which is molten and can be poured off and recovered. After this treatment, the remaining gold usually has a purity of 99.5 percent or above.

ASSAYING

Fire assay. Assaying, a process for determining the content of gold in ores, scrap, and refinery products demands great skill in collecting a proper sample as well as in carrying out all the subsequent steps. A sample of an ore, for example, must be finely ground, then mixed with a flux consisting of soda, borax, silica (if needed), lead oxide (litharge), and flour to reduce the lead oxide to metallic lead during fusion by heat. The reduced lead picks up the precious metals and settles to the bottom. After solidification the lead button is placed in a cupel (small porous cup) made of bone ash and heated in a special furnace provided with a strongly oxidizing atmosphere. The lead oxidizes and the resulting litharge soaks into the cupel.

When the oxidation is complete the appearance of the remaining metallic bead changes and the cupel is removed from the furnace and allowed to cool slowly. The bead, which consists of gold and silver, is removed, cleaned, hammered, and rolled into a thin strip, which is treated with nitric acid to remove the silver, an operation called parting. For proper parting, the silver content of the bead should be about three times that of the gold.

The gold strip, which should remain intact, is washed, heated, and weighed as gold. If platinum metals are present, they will enter the bead and alter its appearance.

Examining arc spectrum

An examination of the arc spectrum of the bead will give both some clue to its content of platinum metals and guidance in selecting a method for further detailed analysis. If osmium is present initially, it may be lost during oxidation in the cupel and the wet analysis must begin with the lead button. Fire assay is excellent for laboratories that are set up to carry it out on a routine basis, but for occasional use in general laboratories it is quite unsuitable.

Assay of low-grade ores. A method has been devised for the accurate assay of low-grade gold ores. In it, the ore is ground fine enough to pass through a screen woven of 100 wires per inch, heated at 550° C to destroy organic matter, dissolved in a mixture of nitric and hydrochloric acids, then dried to a paste. Slightly diluted hydrochloric acid is then added, followed with a measured amount of 4-methyl-2-pentanone, that extracts the gold chloride. After this product is shaken and allowed to separate, small amounts of the ketone, which carry the gold, are fed into an ethyne air burner and the amount of gold determined by atomic absorption measurements.

Gold compounds. Since gold is not attacked by any single acid and does not react with oxygen, sulfur, or the dry halogens (chlorine, bromine, fluorine), it remains bright after outdoor exposure. It is attacked by wet halogens and particularly by a 3:1 mixture of hydrochloric and nitric acids called aqua regia. It is also attacked when it becomes the positive electrode of an electrolytic cell in a hydrochloric acid solution. This fact is the basis for an electrolytic refining process.

The gold chlorine compounds $AuCl_3$, AuCl, and $HAuCl_4$ are involved in the electrolytic refining of gold. When gold is dissolved in aqua regia, $HAuCl_4$ is produced, and gold can be precipitated, after evaporation and resolution, by adding sulfur dioxide, formic acid, or other reductants. If palladium is present in the chloride solution, however, great care is necessary to insure complete precipitation of the gold to avoid the production of the explosive fulminating gold during the later recovery of palladium.

Potassium cyanoaurate $K[Au(CN)_2]$ is the basis for most gold plating baths (the solution employed when gold is electroplated) and is best made by passing current from a gold anode in a potassium cyanide solution to a cathode within a porous pot filled with a potassium hydroxide solution.

Gold forms a host of other inorganic compounds, most of them of little practical importance. Likewise, a large number of organic gold compounds exist. Only two will be mentioned here. The first forms the base of the "liquid bright gold" and is made by reacting gold chloride with a sulfurized terpene. The resulting compound is dissolved in certain organic solvents, mixed with fluxing materials and a trace of rhodium, and then applied to glass or ceramics. After drying and firing, a bright film of gold will remain, well bonded to the glass.

Organic gold compounds

The second, disodium aurothiomalate, is used in the treatment of rheumatoid arthritis. The compound is administered in small intramuscular injections over a period of 24 weeks. Careful supervision of the patient is required because the amount of gold needed for a useful result is close to the point where undesirable side effects result.

USES OF GOLD

Jewelry remains the largest single use for gold in all parts of the world. Monetary use is rare, but industrial applications are increasing, especially in electronics and related industries. In some countries, considerable amounts are used in dentistry.

Most gold used in jewelry is alloyed with silver, copper, and a little zinc to produce various shades of yellow gold, or with nickel, copper, and zinc to produce white gold. Most of this gold is of 14-karat quality, the karat representing a measure of purity in a scale of 1 to 24; thus 14-karat gold contains 14/24 or 58.35 percent gold. Considerable amount of jewelry is gold clad—that is, coated over with a thin cover of gold and is called "gold filled" or "rolled gold plate." Varying international designations describe the weight of gold cladding in accordance with government or industry regulations.

Electronics. In the electrical and electronics industries, gold is applied as a finish to electrical connectors, and as a thin coating over palladium in telephone relay con-

tacts. It is also used in the manufacture of transistors and microelectronic assemblies, and to protect etched circuit boards during storage. Large quantities of less expensive jewelry are finished with an electrodeposit of nearly pure gold.

Dental use. Dental applications include wrought and cast gold alloys with a gold content of 60 percent or more along with silver, copper, and sometimes platinum; the rest of the alloy consists of palladium. Some of these dental alloys can be hardened by heat treatment; all possess good strength and a high resistance to corrosion. Gold solders also are used in some industrial fields in which strength plus corrosion resistance are required.

Other uses. Small amounts of gold are used in decorating china and glassware and to provide heat-reflecting surfaces for window glass. Extremely thin coatings on glass with a metal cost of about five cents per square foot will reflect most of the sun's heat rays, but will transmit a reasonable amount of visible light. Some gold goes into heat-reflecting shields in aircraft, and small quantities find applications in the medical and chemical fields. Gold leaf is used for decorative purposes.

World use of gold. Gold is used in so many ways and circulates through so many channels that it is difficult to determine amounts and end uses. The mode of use differs sharply in the various countries.

The total of fabricated gold (excluding the U.S.S.R.) about equals the amount of gold mined (about 85 percent in 1968). The total amount of gold released, including newly mined gold and that from banking and other international operations, is about 61,600,000 ounces (1,700,000 kilograms), however. The difference between mine production and gold released amounted to nearly 20,000,000 ounces (600,000 kilograms) in 1968 and comprised net hoarding and speculative buying, as well as errors in estimating consumption in the various countries.

In 1968, the United States consumed about 16 percent of the world's fabricated gold, Europe 41 percent, and India and Pakistan about 14 percent, almost entirely in jewelry. The United States was the largest user for electronics and dentistry.

BIBLIOGRAPHY. Illustrations of the ancient artistic uses of gold and the history of the principal sources are well treated by C.H.V. SUTHERLAND in *Gold: Its Beauty, Power and Allure*, 2nd rev. ed. (1969). The discovery and development of the South African sources is detailed by ERIC ROSENTHAL in *Gold, Gold, Gold* (1970). A new U.S. source is described in *Gold Resources in the Oxidized Ores and Carbonaceous Sediments —Northeastern Nevada*, Bureau of Mines Heavy Metals Program Progress Report (March 1968). The properties of the alloys of gold and their major applications are covered by E.M. WISE in "Gold and its Compounds," *Encyclopedia of Chemical Technology*, 2nd ed., vol. 10 (1966), and in *Gold: Recovery, Properties, and Applications*, ed. by WISE (1964). For information on the uses of gold in the U.S., see *Trends in the Usage of Gold*, Report of the National Materials Advisory Board, Pub. NMAB 254 (1969). An estimate of the mode of consumption of gold throughout the world has been made by D.O. LLOYD-JACOB and P.D. FELLS in *Gold* (1969). A tabulation of the important physical properties of pure gold is given in J. PENTON, *Properties of High Purity Noble Metals* (1965). The chemistry of gold and silver is presented by J.W. LAIST, "Copper, Silver and Gold," in *Comprehensive Inorganic Chemistry*, vol. 2 (1954). Analytical methods are summarized in E.E. BUGBEE, *Textbook of Fire Assaying*, 3rd ed. (1940), and in F.E. BEAMISH, *The Analytical Chemistry of the Noble Metals* (1966).

(E.M.W.)

Goldsmith, Oliver

When Oliver Goldsmith died unexpectedly in April 1774 at the approximate age of 43, he had achieved eminence among the writers of his time as an essayist, a poet, and a dramatist. He was one "who left scarcely any kind of writing untouched and who touched nothing that he did not adorn"—such was the judgment expressed by his friend Dr. Johnson in the Latin epitaph on the monument placed in the Poets' Corner of Westminster Abbey by Goldsmith's friends. It is a judgment that over the years has remained undisputed. His contemporaries were as one in their high regard for Goldsmith the writer, but they were of different minds concerning the man himself. He was, they all agreed, one of the oddest personalities of his time. Born in Ireland of established Anglo-Irish stock, he kept his brogue and his provincial manners in the midst of the sophisticated Londoners among whom he moved. His bearing was undistinguished, and he was unattractive physically—ugly, some called him—with ill-proportioned features and a pock-marked face. He was a poor manager of his own affairs and an inveterate gambler, wildly extravagant when in funds, generous sometimes beyond his means to people in distress. The graceful fluency with words that he commanded as a writer deserted him totally when he was in society—his conversational mishaps were memorable things. Instances were cited of his incredible vanity, of his constant desire to be conspicuous in company, of his envy of others' achievements. "Poor Doctor Goldsmith!" wrote Johnson's friend Mrs. Thrale (afterward Mrs. Piozzi), who had no high regard for him: "Lord bless us what an anomalous Character was his. . . ." According to the writer Horace Walpole he was "an inspired idiot." Johnson's biographer, James Boswell, described him as an *étourdi*—a giddy scatterbrain. Yet there were those who held him in deep affection, remembering him for his great personal charm. The painter Sir Joshua Reynolds, one of Goldsmith's closest friends, observed that a genius such as he "could not be a fool or such a weak man as many people thought him." In the end what most impressed Goldsmith's contemporaries was the paradox he presented to the world: on the one hand the assured and polished literary artist, on the other the person notorious for his ineptitudes in and out of society. Again it was Johnson who summed up the common sentiment. "No man," he declared, "was more foolish when he had not a pen in his hand, or more wise when he had."

Life and works. Goldsmith was the son of an Anglo-Irish clergyman, the Rev. Charles Goldsmith, curate in

charge of Kilkenny West, County Westmeath. At about the time of his birth—November 10, 1730, is the date now generally accepted, though the precise records are lacking—the family moved into a substantial house at nearby Lissoy, where Oliver spent his childhood. Much has been recorded concerning his youth, his unhappy years as an undergraduate at Trinity College, Dublin, where he received the B.A. degree in February 1749, and his many misadventures before he left Ireland in the autumn of 1752 to study in the medical school at Edinburgh. His father was now dead, but several of his relations had undertaken to support him in his pursuit of a medical degree. Later on, in London, he came to be known as Dr. Goldsmith—Doctor being the courtesy title for one who held the Bachelor of Medicine—but he took no degree while at Edinburgh nor, so far as anyone

knows, during the two-year period when, despite his meagre funds, which were eventually exhausted, he somehow managed to make his way through Europe. The first period of his life ended with his arrival in London, bedraggled and penniless, early in 1756.

Rise from obscurity

Goldsmith's rise from total obscurity was a matter of only a few years. An usher (assistant schoolmaster) in a boys' school, then a literary hack writing book reviews for magazines, he became an author in his own right with the publication, in April 1759, of his first book, *An Enquiry into the Present State of Polite Learning in Europe*. He scored his first triumph with an amusing series of essays appearing during 1760–61 in a newspaper, *The Public Ledger*, and originally known as the *Chinese Letters* and later, in collected form, as *The Citizen of the World*. By now he was well on the way to recognition. He had been introduced to Johnson, foremost among the men of letters; he was already on friendly terms with Joshua Reynolds, not yet knighted but firmly established as London's most fashionable portrait painter; and on Christmas Day 1762 he and the young Boswell met for the first time. With the publication of his poem *The Traveller* (December 1764), Goldsmith came fully into his own. He was one of the nine original members of the famous Club founded at this time, and his presence there, his conversational encounters with Johnson and others, his foolishness and his wit have been preserved for all time in Boswell's *Life of Samuel Johnson*. Meanwhile, he was extending his reputation as an author in the fictional field with *The Vicar of Wakefield* (1766); in poetry, with *The Deserted Village* (1770); in comedy for the theatre, with his first play, *The Good Natur'd Man* (first performed 1768), and his dramatic triumph, *She Stoops to Conquer* (1773).

His income as a professional writer was now considerable, but his extravagances kept him in debt and to maintain himself he accepted all sorts of commissions from the publishers for books of a strictly popular nature—biographies, histories, and the work he was finishing at the time of his death, *An History of the Earth, and Animated Nature*. He lived for some time in handsomely furnished rooms at No. 2, Brick Court, in the Temple; and it was here that he died after a short illness on April 4, 1774. He was buried privately in the Temple burying ground; and at the last moment the coffin was opened so that a lock of his hair might be obtained in compliance with the belated request of Mary Horneck, one of the two sisters, still in their youth and well-known in London society for their charm and beauty, to whom Goldsmith had been a devoted friend. He left behind him several works of a minor character, together with a masterly but unfinished set of verses, *Retaliation*, in which he took off some of his famous friends and acquaintances—the statesman and writer Edmund Burke, for one, and the actor David Garrick and Reynolds—in a way that was at once witty, penetrating, and good-natured.

Early death

Reputation. Goldsmith's world—the world of Georgian London during the 1750s and 1760s—was one in which men of achievement rapidly became well-known personalities, to be commented upon then and thereafter in newspapers, magazines, letters, diaries, memoirs, and in biographies by those who held them in high regard, by those who did not, and by the merely curious. About Goldsmith, too much has been told and not enough—too much that is trivial, too little that bears on the essential qualities of his genius. It is, for instance, obvious enough that Goldsmith commanded nothing like Johnson's ordered and encyclopaedic knowledge; but it is not true, as his contemporaries liked to believe, that he was intellectually shallow, a writer whose charm and ease of manner compensated for a lack of ideas. Read today, he seems to be one who had a keener insight into the forces shaping later 18th-century civilization both in England and abroad than did some of his eminent friends. He hated the sentimentalism that had taken root in literature. He looked with apprehension on the increasingly materialistic temper of England. He found nothing to glorify in the military exploits in foreign lands that were laying the foundations of a British Empire. An admirer of the French writers Montesquieu and Voltaire and taking from them something of a sociological approach that was more French than English, he was an observer of European culture, commenting on national differences in manners and taste and seeking for common norms. His writings that most clearly embody these ideas in one fashion or another are the *Enquiry into the Present State of Polite Learning* and the two long poems *The Traveller* and *The Deserted Village*. Goldsmith best deserves to be remembered not only as a poet but as the writer whose comic sense found memorable expression in *The Citizen of the World*, *The Vicar of Wakefield*, and, dramatically, in *She Stoops to Conquer*. Here again he was often mistakenly described as one who worked more or less without a plan, achieving his happiest effects on the spur of the moment. But planning there was—a great deal of it in the calculated action of *She Stoops to Conquer* and more than was generally perceived in *The Vicar of Wakefield*, with its sly and skillfully controlled ambiguities. Goldsmith saw people, human situations, and indeed the human predicament from the comic point of view; he was a realist, something of a satirist, but in his final judgments unfailingly charitable.

Goldsmith's comic sense

MAJOR WORKS

An Enquiry into the Present State of Polite Learning in Europe (1759); *The Bee* (1759), a collection of essays originally published in the periodical of the same name; *The Citizen of the World; or, Letters from a Chinese Philosopher, Residing in London, to his Friends in the East*, 2 vol. (1762); *The Life of Richard Nash, of Bath, Esq.* (1762); *An History of England in a Series of Letters from a Nobleman to His Son*, 2 vol. (1764); *The Traveller, or a Prospect of Society* (1764), verse; *The Vicar of Wakefield: A Tale*, 2 vol. (1766); *The Good Natur'd Man: A Comedy* (1768); *The Deserted Village* (1770), verse; *She Stoops to Conquer: or, The Mistakes of a Night. A Comedy* (1773); *Retaliation. A Poem* (1774); *An History of the Earth, and Animated Nature*, 8 vol. (1774).

BIBLIOGRAPHY. The Goldsmith bibliography in *The New Cambridge Bibliography of English Literature*, vol. 2 (1971), covers both Goldsmith's writings and Goldsmith criticism through 1969. RICARDO QUINTANA, *Oliver Goldsmith: A Georgian Study* (1967), contains bibliographical notes in the appendix. There is a bibliography of Goldsmith first editions in I.A. WILLIAMS, *Seven XVIIIth Century Bibliographies* (1924). Still of interest is TEMPLE SCOTT, *Oliver Goldsmith Bibliographically and Biographically Considered* (1928), based on the material in the W.M. Elkins collection now in the Free Library of Philadelphia. On the accessibility of Goldsmith manuscripts, see K.C. BALDERSTON, *A Census of the Manuscripts of Oliver Goldsmith* (1926).

Major collected editions, editions of separate works, and selections: *The Collected Works of Oliver Goldsmith*, ed. by ARTHUR FRIEDMAN, 5 vol. (1966), supersedes all other collected editions; those by PETER CUNNINGHAM, 4 vol. (1854), and J.W.M. GIBBS, 5 vol. (1884–86), though now outdated, still possess a limited usefulness. *The Collected Letters of Oliver Goldsmith*, ed. by K.C. BALDERSTON (1928), is standard. All of the poetry, together with full notes and extensive commentary, is given in *The Poems of Thomas Gray, William Collins, and Oliver Goldsmith*, ed. by R.H. LONSDALE (1969). *The Complete Poetical Works of Oliver Goldsmith*, ed. by A. DOBSON (1906), is still valuable for its commentary and notes, as is the edition of the plays by A. DOBSON and G.P. BAKER, *The Good Natur'd Man and She Stoops to Conquer* (1905). Of the many editions of *The Vicar of Wakefield* those by OSWALD DOUGHTY (1928) and F.W. HILLES (1951) are outstanding by reason of their critical introductions. Selections are numerous; those of more recent date include *Goldsmith: Selected Works*, by RICHARD GARNETT (1950); *Oliver Goldsmith: The Vicar of Wakefield, and Other Writings*, by F.W. HILLES (1955); *A Goldsmith Selection*, by A.N. JEFFARES (1963); *Selected Poems of Samuel Johnson and Oliver Goldsmith*, by ALAN RUDRUM and PETER DIXON (1965).

Biography and criticism: The authoritative biography is R.M. WARDLE, *Oliver Goldsmith* (1957). Significant older biographical works are SIR JAMES PRIOR, *The Life*, 2 vol. (1837), and JOHN FORSTER, *The Life and Times of Oliver Goldsmith*, 2nd ed., 2 vol. (1854). Of the many treatments of Goldsmith by contemporaries of his, the more important are these: that by BOSWELL in his *Life of Samuel Johnson*, 2 vol. (1791); the prose portrait by SIR JOSHUA REYNOLDS in *Portraits*, ed. by F.W. HILLES (1952); and MRS. THRALE's remarks in her *Anecdotes of Johnson* (1786) and in her diary, *Thrali-*

ana, ed. by K.C. BALDERSTON, 2nd ed. (1951). Recent critical studies include C.M. KIRK, *Oliver Goldsmith* (1967); RICARDO QUINTANA, *Oliver Goldsmith: A Georgian Study* (1967); and R.H. HOPKINS, *The True Genius of Oliver Goldsmith* (1969). More specialized is KARL EICHENBERGER, *Oliver Goldsmith: Das Komische in den Werken seiner Reifeperiode* (1954). A.N. JEFFARES, *Oliver Goldsmith* (1959), is brief but informative. Studies of individual writings include J.H. PITMAN, *Goldsmith's Animated Nature: A Study of Goldsmith* (1924); H.J. SMITH, *Goldsmith's The Citizen of the World: A Study* (1926); and MACDONALD EMSLIE, *Goldsmith: The Vicar of Wakefield* (1963); and SVEN BACKMAN, *This Singular Tale: A Study of the Vicar of Wakefield and Its Literary Background* (1971).

(R.Q.)

Golf

Golf is a cross-country game played by striking a small ball with various clubs from a series of teeing grounds into a like series of holes on a course. The player who holes his ball in the fewest strokes is the winner. The game developed originally in Scotland and has spread from obscure antiquity to worldwide popularity. Played in the beginning on seaside links with their crisp turf and natural hazards and afterward on downs, moorland, and parkland courses of various lengths and individual characteristics, it combines with its open air and exercise an intrinsic fascination. Its devotees—men, women, and children—now number millions around the world. A few examples of the numbers of players include, in the United States, 10,000,000; Australia, about 2,000,000; the British Isles, approximately 600,000; Japan and Canada, 50,000 each. The 10,000th course in the United States was opened in 1970.

This article is divided into the following sections:

I. History

ORIGINS AND EARLY HISTORY

Controversy over origin of the game

The game's origin has long been a subject of controversy. Broadly, the issue has been whether its natal source is Scotland or Holland. Its antiquity in Scotland is beyond question, though the problem of tracing its unknown roots was summed up by the noted Scots essayist Andrew Lang who contended that its exhaustive history would necessitate a thorough study of all Scots Acts of Parliament, Kirk Session records, and many other sources; and it was essential that it be undertaken by a young man as he would be aged at the end of the task. The Scottish claim has at any rate documentary proof of its long lineage; for instance, in the oft-quoted statute of the Parliament of King James II of 1457 that decreed that both "Fute-ball and Golfe be utterly cryed downe" because they interfered with the practice of archery, which was necessary for the defense of the realm. Two other decrees to the same effect were also enacted, the third in 1491 in the reign of James IV, which indicted them as "unproffitable sportis." One obvious implication of these laws is that golf had become a popular obsession in Scotland even before the middle of the 15th century.

Continental games. Comparisons between ancient continental games and Scottish golf make an interesting study, with the balance of evidence in favour of Scotland. In the time of the Roman domination in Europe, a popular game was *paganica* (from *paganus*, "country man" or "rustic"), a cross-country pastime played with a bent stick and with, it seems, a ball of leather stuffed with feathers, as were early golf balls in Scotland; but it can be disregarded merely as what Scots golf historian Sir Guy Campbell called a link between legend and history. Other old-time games prevalent in the Netherlands have a more striking similarity to golf. Of these, the Dutch game of *kolven* or *kolf* has appealed to the imagination of some as being a source of golf partly because of the name *kolf* for a club and the fact that the clubs seen in early Dutch pictures suggest something like golf. Notwithstanding such evidence, there are obvious and vital differences between that game and golf. *Kolven* is not a cross-country game but is played in a walled court, and its objective is not holing out but the striking of posts either first or in the fewer strokes. According to delightfully scenic 17th-century Dutch paintings, *kolven* was also played on ice, but, in their inclusion of posts and the crowded state of the ice, which would be incompatible with the conditions needed for golf, the illustrations by no means suffice to clinch the Dutch-origin argument; also, the game had been played in Scotland for about two centuries before the pictures were painted.

The games of *kolven* and *chole*

Of the continental games, the venerable game of *chole* (*choulla* or *choulle*) had some resemblance to golf. More Belgian (Flemish) than Dutch, it was a cross-country pastime in which each side, whether one player or several, used one ball and played to a prearranged target—a church door, for example—at a considerable distance from the starting point. At the outset each player (or side) bid the number of strokes it would employ to reach the goal—subject to the proviso that after each three-stroke turn the opposing player (or side) had the right to hit the ball into any available hazard, the more difficult the better. Such interference with the play of an opponent is, of course, utterly alien to golf. Still, certain features of the game noticeable in old pictures—the types of club used (though only one to each player) and the teeing up of the ball—have suggested that golf may have been an offshoot of *chole*.

Scotland. Passing from conjecture to chronicle, Scotland's King James IV, who had embargoed the game in 1491, later became the first player of whom there is authentic record. The Lord High Treasurer's accounts early in the 16th century include payments for the King's equipment—"golf clubbis and ballis." The royal line of the Stuarts gave the game its first woman golfer, too, in the person of Mary, queen of Scots, who was charged with playing in the fields beside Seton only a few days after the murder of her husband, Darnley.

James VI was noted for his zest in playing and promoting the game. When he succeeded to the English throne as James I, he took his courtiers and his clubs south with him. He had in the meantime (1603) appointed William Mayne, a burgess bower (the bow maker also made golf clubs) of Edinburgh, to be the royal club maker for life, and some years later he enacted a protective ban on behalf of Scottish trade that projects an element of confusion into the debate on the origin of golf: he forbade the purchase of balls from Holland (on which Scots were spending "no small quantitie" of gold and silver) and assigned a monopoly of ball making in Scotland to James Melvill for 21 years. The inference of the words "no small quantitie" spent on the Dutch imports confirms

Dutchmen playing *kolven* on the ice. Detail from "Riverscape in Winter," oil painting by Aert van der Neer (b.c. 1603). In the Rijksmuseum, Amsterdam.
By courtesy of the Rijksmuseum, Amsterdam

the popularity of the game with the Scots, but, as some historians have pointed out, not necessarily that the game they were used for in the Netherlands was golf.

DEVELOPMENT OF GOLFERS' ASSOCIATIONS

Early British societies. There is a tradition that James I introduced golf to Blackheath in 1608, which has been given, erroneously according to some authorities, as the foundation year of the historic Royal Blackheath Golf Club. But, though no doubt King James and his courtiers played their golf somewhere in the vicinity, it is doubtful whether any organized societies then existed, and research has set its date nearly two centuries later. In the *Chronicles of Blackheath Golfers*, W.E. Hughes, editor of the *Chronicles*, ascribes the club's foundation to 1787.

The Honourable Company. The oldest club with documentary proof of its origin is the Company of Gentlemen Golfers, now the Honourable Company of Edinburgh Golfers, whose modern home is at Muirfield in East Lothian. Its genesis was a move by a group of players to hold a competition or tournament. In 1744 "several Gentlemen of Honour skillful in the ancient and healthfull exercise of Golf" petitioned the Edinburgh city council to provide a Silver Club for annual competition on the links of Leith, which the magistrates agreed to do. The winner was to be named "Captain of the Golf"; *i.e.*, captain of the Company of Gentlemen Golfers. Intended to be open to all comers, the continued absence of outside challengers resulted in the contest being limited to members only after 1764.

The Silver Club was first played for in 1745, and the first winner, thus the first captain of the company, was an Edinburgh surgeon, John Rattray, who also won in the following year and again in 1751. The earliest known rules of golf are the 13 recorded in the first minute book of the company under Rattray's captaincy. The code, therefore, cannot be more recent than 1751 and more likely was entered in the minute book when the competition for the Silver Club was instituted in 1745.

Earliest rules of golf

The Royal and Ancient Golf Club. The Society of St. Andrews, now the Royal and Ancient Golf Club of St. Andrews, Scotland, was formed in 1754 by a group of 22 golfers who played there. The rules that the society adopted were almost identical with the Edinburgh Gentlemen Golfers' rules. These two clubs played major roles in the development of the game in Scotland. Eventually, the Royal and Ancient Golf Club (R. and A.) became, by common consent, the oracle on rules. In 1919 it accepted the management of the British Open and Amateur championships. The R. and A. thus became the governing body for men's golf in the British Isles and throughout most of the Commonwealth.

Other cradles of history. The Royal Musselburgh Golf Club, a few miles from Edinburgh, derives from the presentation to local golfers in 1774 of a cup for competition, and the trophy is still played for. In the early days, as on other courses, money matches were the chief media of rivalry, and bitter feelings often were aroused among spectators. In 1925 the club moved from the old links to the enclosed Prestongrange Estate nearby.

At the ancient Bruntsfield Links in Edinburgh, within 50 yards of one of the capital's busiest traffic arteries, players from small schoolboys to keen octogenarians can be seen at the "gowff" where it held sway five centuries ago. Formerly a conventional course with holes needing full-length shots, time and circumstances have forced it into short-hole compass. The members of the Royal Burgess Golfing Society were staunch conservators of the citizens' right to play there and for many years successfully resisted the intrusion of proposed quarries, new pathways, the beating of carpets, the training of horses, and the drilling of troops. Conditions did, however, eventually compel the members to leave; and in 1877 they migrated to Musselburgh, as did also the Bruntsfield Links Society and other clubs. With the encroachment of the city, the Leith golfers also had to desert their links. The city corporation, however, purchased the Braid Hills, where the game has since 1890 been extremely popular. The "Golfers' Tavern" on the edge of the links was refreshing golfers in 1717 and is still doing so. Musselburgh in time became congested. The Honourable Company moved down the coast in 1892 to Muirfield, and the Burgess Society and the Bruntsfield Society became close neighbours on the outskirts of Edinburgh.

Early clubs in England

With the birth of the Royal North Devon Club in 1864, the game took a firm foothold in England. It was the first course on seaside links outside Scotland. The Royal Liverpool Club was established in 1869 on a rabbit warren at Hoylake. In its infancy players simply cut holes with their penknives and stuck feathers in them for the guidance of those who were coming behind. The rabbits were the greenkeepers. By 1870 the club was fairly founded, and members played matches against Blackheath, Royal North Devon Club at Westward Ho!, and others. Their influence widened interest in the game. The Royal Liverpool Club hosted Great Britain's first Amateur Championship in 1885 and the first English Amateur Championship in 1925; the first Scotland–England amateur match was organized in 1902; and it was at Hoylake in 1921 that an unofficial contest between Brit-

ish and U.S. players, a curtain raiser to the Amateur Championship, was the genesis of the Walker Cup series.

The United States and Canada. The ancient Dutch game of *het kolven* apparently was played in the New World in the 17th and 18th centuries. The record of a court in Dutch-settled Fort Orange (now Albany, New York) reveals that the sheriff there filed a complaint against three men who had been playing the game on the ice on a Sunday in 1657, and in 1659 the magistrates of Fort Orange issued an ordinance to "forbid all persons to play 'het kolven' in the streets." While these documents are sometimes cited as evidence of the earliest playing of golf in the United States, the game does not seem to have been the linksland pastime handed down by the Scots. There seems little doubt, however, that the following advertisement, which appeared in James Rivington's *Gazette* in New York on April 21, 1779, referred to golf: "To the GOLF PLAYERS: The Season for this pleasant and healthy Exercise now advancing, Gentlemen may be furnished with excellent CLUBS and the veritable Caledonian BALLS, by enquiring at the Printer's."

Early records of golf in America

The next evidence appears in the Carolinas. The *South Carolina and Georgia Almanac* of 1793 published, under the heading "Societies Established in Charleston," the following item: "Golf Club Formed 1786. Dr. Purcell —President. Edward Penman—Vice President. James Gardner—Treasurer and Secretary." The *Charleston City Gazette and Daily Advertiser* of September 18, 1788, reported: "There is lately erected that pleasing and genteel amusement, the KOLF BAAN. Any person wishing to treat for the same at private sale will please apply to Mr. David Denoon in Charleston, or to the subscriber on the spot." Later notices dated 1791 and 1794 referred to the South Carolina Golf Club, which celebrated an anniversary with a dinner on Harleston's Green in the latter year. Although these fragments constitute the earliest clear evidence of golf clubs in the United States, the clubs appear to have been primarily social organizations that did not survive the War of 1812.

Early clubs and courses. The first permanent golf club in the Western Hemisphere was the Royal Montreal Golf Club, established in 1873. The members played on Fletcher's Fields in the city's central area until urban growth compelled a move of some miles to Dixie, a name derived from a group of Southern refugees who arrived there after the U.S. Civil War. The Royal Quebec Golf Club was founded in 1874; the Toronto and Niagara, Ontario, clubs in 1876; and the Brantford, Ontario, club in 1879. In the meantime, golf was played experimentally at many places in the United States without taking permanent root until, in 1885, it was played in Foxburg, Pennsylvania. The Oakhurst Golf Club in West Virginia, which later became the Greenbrier Club, is said to have been formed in 1884; and the Dorset Field Club in Dorset, Vermont, claims to have been organized and to have laid out its course in 1886, although in both instances written records are lacking. The Foxburg Golf Club has provided strong support for the claim that it was organized in 1887 and is the oldest golf club in the United States with a permanent existence. Foxburg also claims the oldest U.S. golf course. The course and club came into existence through the interest and generosity of Joseph Mickle Fox of Philadelphia, a summer resident of Foxburg who is believed to have been introduced to golf and to have acquired his first (left-handed) clubs and balls while in Scotland in 1884. The next oldest course may be that of the Middlesborough (Kentucky) club, which apparently was founded in 1889 by English immigrants. The course is still in existence, but there is a question as to whether play has been continuous on it.

Golf as an organized game. But golf as an organized game in the United States usually is dated from the founding of the St. Andrews Golf Club at Yonkers on the Hudson in 1888. As its name implies, its progenitors were Scots, John Reid and Robert Lockhart, both natives of Dunfermline in Fifeshire. Lockhart, a merchant in Yonkers, after a visit to his hometown, imported some golf clubs and balls and on February 22, 1888, tried them out with his friends Reid and John B. Upham on an improvised three-hole layout. At a meeting that fall, five men formed the club. Reid, who was its first president, has been dubbed "the father of American golf." Their original course was later extended to six holes on a cow pasture, and its hazards were numerous apple trees. In consequence, these pioneers have been known as the "Apple Tree Gang." Each player used six clubs, three woods and three irons, and a gutta-percha ball, and the group was the subject of the earliest known photograph of golf in America. The club moved several times but has been at Hastings-on-Hudson since 1897.

Other early courses included Newport, Rhode Island (1890); Shinnecock Hills on Long Island (1891), laid out by the Scottish professional Willie Dunn of the Royal Montreal Club; and the Chicago Golf Club (1892) at Wheaton. The Tuxedo Golf Club, New York, founded 1889, met the Shinnecock men in 1894 in what has been assumed to be the first interclub match in the United States. The Newport club staged an invitation tournament for amateurs in September 1894, and in October the St. Andrews Club promoted a similar competition. These were announced as championships, but that was questioned because the events were each promoted by a single club and on an invitational basis. It was from the controversy roused by these promotions that the United States Golf Association (USGA) was instituted in 1894. Its aims were to organize the U.S. Amateur and Open championships and to formulate a set of rules for the game. The founding fathers, two from each club, were from St. Andrews, Shinnecock Hills, Chicago, the Country Club at Brookline, and Newport. The following year saw the inaugural U.S. national championships—the Amateur, the Women's Amateur, and the Open.

First championships and the founding of the USGA

Other countries. Before organized clubs had been established in North America, the global extension of the game had already set in as colonies of British settlers, merchants, and civil servants carried their devotion to golf with them.

India can claim to have had the oldest club outside of Great Britain—the Royal Calcutta Golf Club founded in 1829, and the Royal Bombay Golf Club came some dozen years later. The Royal Calcutta initiated an amateur championship for India, and the two clubs paved the way for many in the Far East. The Royal Bangkok Golf Club (1890) was housed to begin with in an ancient temple. Golfers made their debut in China when the Shanghai Golf Club came into being in 1896, until which time the game was apparently unknown outside of Hong Kong. The Japanese were a few years later in their adoption of the game when a course was constructed at Kōbe. The Tokyo Golf Club was founded in 1914. With the boom in the popularity of the game in that country after World War II, addicts can now be numbered in the thousands.

The first club in Australia, the Royal Adelaide Golf Club, was formed in 1870, and it is believed that the game was planted in Melbourne in 1847 but went into abeyance for nearly half a century, the gold rush having taken priority over golf for the settlers.

New Zealand origins have been dated from the formation of the Christchurch Golf Club in 1873. South Africa's first golf shot was, according to some research, hit at the Maritzburg Golf Club, the first in Natal, in 1884; though the Royal Cape Golf Club (1885) has been rated as the country's senior club.

DEVELOPMENT OF EQUIPMENT

Golf balls. How the ball is hit and directed is the essence of the game. The result can be fun or frustration, delight or despair. The changing story of the ball's manufacture falls broadly into well-defined phases after it emerged from the unknown primitive, beginning with the "feathery," which was used for centuries until it was superseded by gutta-percha.

The feather-ball era. Some time in the past balls were made from wood, but in the early years of the 17th century the era of feather balls opened and was no doubt hailed for its advance on anything that was used previously. These balls consisted of boiled feathers that were

Manufacture of the feather ball

compressed through a hole left in pieces of stitched leather that composed the cover. For stuffing in the feathers a wooden tool was first used, after which the stuffing iron had to complete the job. When the leather case was crammed beyond increase, the hole was stitched up, the ball hammered and made as round as possible, and then painted white. The whole process was so slow that the maker did well to finish four in a day, so that they cost as much as five shillings each. Although the "feathery" could be hit a surprisingly long way, it became sodden and disabled in wet weather and was destroyed by hacks from iron clubs, so that the balls were short-lived as well as expensive.

The gutta-percha era. Gutta-percha is the evaporated milky juice or latex of various South American and South Pacific islands trees. It is soft and impressible at the temperature of boiling water, but becomes hard, non-brittle, and retains its shape when cooled. It is not affected by water except at boiling temperature. The emergence of the gutta-percha ball about 1848 brought a revolutionary change in the game. There have been differing views as to where and by whom it was invented. A substantial account narrates the arrival for R.A. Paterson, a professor in the University of St. Andrews, of a marble statue of the Hindu god Viṣṇu (Vishnu), which was packed in gutta-percha. A son of the consignee began experimenting with the gutta wrapping and made it into a rough ball, and, though his first trials with it were discouraging, he persisted with the experiment and sought the cooperation of his brother near Edinburgh, who was quick to size up its potential and improved it into a marketable product. But when it was displayed in London nobody wanted it. The professionals had divided views: St. Andrews' Allan Robertson, a leading manufacturer of "featheries," would have nothing to do with it; but "Old Tom" Morris, who was then his assistant, wisely foresaw the possibilities of the "gutty," and on this issue the two actually parted company in 1852, Morris going into business on his own. The ball was heartily welcomed by the golf community, not least for its economy—cost, one shilling each—and its coming immediately swelled the golfing ranks.

The first examples were smooth and ducked suddenly and went to the ground after a short flight, until they had been hacked and marked in the course of play. Consequently, the ball makers learned to nick them and then to mold them with raised or indented surface patterns so they would fly properly. The "feathery" was dead and gone.

Invention of the rubber ball

The rubber ball. The beginning of the 20th century introduced a new ball and a new era. It was ushered in with the American patent of the rubber ball, the invention of Coburn Haskell, a golfer of Cleveland, and Bertram G. Work of the B.F. Goodrich Company. It had a tension-wound rubber thread around a solid rubber core. Its resilience was a joyous advent after the "gutty," which was a hard, irresponsive ball that required skill and strength to get it into the air after the tee shots. The rubber ball was more congenial to hit and gave the striker great pleasure and a sense of power. Its impetus created a tidal wave in the game's popularity. Men who were getting on in years found it easier to play, and hosts of women and children were drawn into the fold. A number of varieties of ball appeared in the wake of the Haskell, such as the Kempshall, the Zodiac, the Spalding, the Dunlop, and the Silver King. The makers' main objective was to cater to the golfer's desire to hit the ball farther. Length was the lure, but the trade race in this connection was upsetting the design of courses, and championship and other tees had to be sited farther back. The development set the game's legislators a nagging problem, and shortly after World War I the Royal and Ancient Club enacted what is called "the 1-62 formula"—that the ball should have a maximum weight of 1.62 ounces (45.93 grams) and a minimum diameter of 1.62 inches (4.11 centimetres). The USGA tried for two years a ball 1.55 ounces (43.94 grams) in weight and 1.68 inches (4.27 centimetres) in diameter, but in 1932 it reverted to a weight of 1.62 ounces while retaining a diameter of 1.68 inches. The figures on both sides of the Atlantic remain as stated and are the sole exception to a uniform code. Various attempts were made to produce satisfactory solid rubber or artificial-rubber balls over the years, and in the early 1970s solid balls had been improved enough to challenge tension-wound balls in popularity.

Golf clubs. *Early clubs.* Reference has already been made to the royal warrant to make clubs granted to Mayne in 1603, but no product of that time exists, and the oldest clubs known were discovered in a house in Hull along with a newspaper carrying a date in 1741. All of the clubs were made of wood, and antiquarian theory is that they were used in the time of the Stuart kings.

Introduction of iron heads

In the Royal and Ancient Club's museum there are specimens of ancient clubs including two woods and an especially notable putting cleek—*i.e.*, a putter having an iron head on a wooden shaft—made in the second half of the 18th century by Simon Cossar of Leith, club maker to the Company of Gentlemen Golfers. During that period, when Robertson saw that his craft would not be injured by the gutta-percha ball, he realized the value of iron clubs for approaching and made a cleek for steadier putting. Other developments included "Young Tom" Morris' idea for the cup-faced niblick for playing the shorter approaches. He could not have better proved the value of iron heads for clubs than by his victory in the series of matches against Arthur Molesworth, the leading Westward Ho! amateur. In a famous round played in wintry conditions at St. Andrews, a circle was cleared in the snow on the greens, and, whereas Molesworth's pitches invariably ran too far, Morris' pitches with the iron-headed niblick were hit right up to the pin and stopped with backspin.

The club makers of outstanding repute in the early years of the 19th century were Hugh Philp at St. Andrews and the McEwan brothers of Musselburgh, notably Douglas, whose clubs were described as models of symmetry and shape. They were artists at a time when clubs were passing from "rude and clumsy bludgeons" to a new and handsome look. The older, thorn-tree cuts were a thing of the past, and apple and afterward beech, which was a superior driving wood, were used and made the clubs more stylish. Philp, who was the master craftsman, specialized in making wooden putters with a long head of pear-shaped design, and he is reputed to have made no more than 100. A genuine Philp is now a prized collector's piece.

The clubs of a well-equipped player

In his illustrated *Golfing* (1887), the famous encyclopaedia publisher Robert Chambers lists the clubs the well-equipped player used: play club, for driving; long spoon, for a hanging or rough lie; short spoon, for the vital shot within about 100 yards (90 metres) of the green; brassie, brass soled to protect the clubhead; sand iron, for bunkers or other hazards and lofting balls over stymies; cleek, for long shots (note: originally referring to any iron-headed club, cleek had become a Scots name for a no. 1 or driving iron); niblick, or track iron, was small with a heavy iron head for getting the ball out of cart ruts or tough whins.

The hickory shafts of the woods—the play club (modern driver), the spoons, and the brassie—were spliced to heads of apple or beech faced with horn.

Modern clubs. Golf was being overtaken by the Industrial Revolution when the rubber ball came into the game at the beginning of the 20th century. These two factors wrought major changes in the clubs and the production methods, as craftsmanship moved out of the individual professional's shop and into the factory.

NEW MANUFACTURING METHODS

The harder rubber ball brought about the use of persimmon and, later, laminated club heads. Hard insets appeared in the faces. Increased demand led to the adaptation of shoe-last machine tools for the fashioning of wooden club heads. Sockets were bored in the club heads, and shafts were inserted rather than spliced. Drop-forging completely replaced hand forging in the

fashioning of iron clubs, and faces were deepened to accommodate the livelier ball and were machine lined to increase the spin on the ball in flight. Stainless steel replaced carbon steels. Seamless steel shafts took the place of hickory. Composition materials were developed as an alternative to leather in grips, and the grip foundations were molded in so many ways that they were regulated in 1947. Inventive minds created novel clubs, not only centre-shafted and aluminum putters and the sand wedge but also types that were such radical departures from the traditional form and make that they could not be approved by the USGA or the R. and A.

Rules related to club manufacture

In promulgating its revised code of rules in September 1908, the R. and A. appended the notation that it would not sanction any substantial departure from the traditional and accepted form and make of golf clubs. This principle has been invoked many times in an effort to preserve the original form of the game. When Jock Hutchison won the British Open in 1921 with deeply slotted faces on his pitching clubs, the R. and A. immediately banned such faces, and the USGA concurred with a regulation governing markings that became effective in 1924. After Horton Smith, a prominent tournament professional in the 1930s, had effectively used a sand wedge with a concave face designed by E.M. MacClain of Houston, Texas, the principle of concavity was banned in 1931. The U.S. golfer Gene Sarazen, however, developed a straight-faced sand wedge and used it so well in winning the British and USGA opens in 1932 that he completed the revolution of bunker play. Experiments with steel shafts went through several phases. In 1924 the Union Hardware Company of Torrington, Connecticut, drew a seamless shaft of high-carbon steel that could be heat-treated and tempered. Approved by the R. and A. in 1929, it substantially replaced hickory in the early 1930s. Later, shafts of fibre glass and of aluminum were introduced.

Improvement of the shaft was accompanied by the general introduction of numbered, rather than named, clubs and by the merchandising of matched sets rather than individual clubs; clubs had become more numerous and more finely graduated than the names that traditionally had been applied to them, and shafts could be manufactured to specifications for flexibility and point of flex. Whereas formerly a golfer seeking new clubs went through a rack of mashies until he found one that "felt right" and then tried to find other clubs of similar feel, he later bought a whole set manufactured to impart the same feel. The merchandising opportunities inherent in the numbered and matched sets were carried to an extreme, and in 1938 the USGA limited the number of clubs a player might use in a round to 14. The R. and A. concurred in a similar edict the next year.

PLAYERS AND CHAMPIONSHIPS

Whatever uncertainties may remain about the origins of golf, there is no doubt that its development as an organized sport was distinctly British, and Britain produced the first great players of the game. As the early golfing associations, or clubs, became established in Scotland and then England, there emerged a group of professionals who made golf balls, fashioned and repaired clubs, laid out and maintained courses, and gave lessons. Many of them were outstanding golfers and would take on all comers in the popular stakes (money) matches of their day. St. Andrews' Robertson, for example, is regarded as the greatest golfer of his time, and, according to legend, he was never beaten in a stakes match played on even terms (that is, without giving his opponent a handicap). The British professionals and their amateur counterparts represented the best golf in the world from the second half of the 19th century, when the sport began to gain some world prominence, up to about the 1920s, when U.S. players began to excel. With the tremendous increases in financial rewards to be gained in golf after about 1950, especially on the U.S. professional tour, and with the great mobility provided by jet-airplane transportation, golfers from other countries (Australia, New Zealand, South Africa, Japan, Argentina, for example) began to appear in the top tournaments.

The premier championships. The most prestigious championships are the Open and Amateur championships of the British Isles and the U.S. Open, Amateur, Professional Golfers Association (PGA), and Masters.

Great Britain. The Open Championship of the British Isles, which the British like to call The Open to emphasize the tradition and priority of the event begun in 1860, was the concept of the Prestwick Club in Scotland, whose minutes recorded a proposal that all clubs should contribute to raise a fund for a trophy for professional competition. Their hope, however, was badly disappointed, and the offer of support was so meagre that Prestwick decided to go it alone and spent 30 guineas on the ornamental challenge belt to be awarded to the champion. That first Open Championship was won by Willie Park, who repeated in 1863 and 1866. "Old Tom" Morris won in 1861, 1862, 1864, and 1867, and Andrew Strath won in 1865. After Morris' last victory his son "Young Tom" Morris retired the belt, which became his property by virtue of his three successive wins (1868, 1869, and 1870). In the absence of a prize, there was no championship in 1871; but the next year a cup, which has been in competition ever since, was put up, and "Young Tom" won it, for his fourth successive victory. Jamie Anderson, St. Andrews, and Bob Ferguson, Musselburgh, were the idols of their towns in the late 1870s and early 1880s, each winning the Open three times in consecutive years.

The Open Championship

In the late 1880s the championship consisted of four rounds of the nine-hole Musselburgh course in a single day, and to end it before dark bribes were given to competitors who obviously had no chance to induce them to leave the course. Even so, scores had to be checked by candlelight. Willie Park, Jr., who coined the aphorism that "the man who can putt is a match for anyone," was champion in 1887 and 1889.

At the end of the 19th century, England was producing great players. John Henry Taylor and Harry Vardon, together with James Braid, a Scotsman, between them won the Open Championship 16 times between 1894 and 1914. Vardon, the greatest player that the world had seen up to that time, won the title six times. These three supreme golfers were known as "the great triumvirate" and were primarily responsible for the formation of the Professional Golfers Association in 1901. This body is responsible for professional tournaments in Great Britain and for the biennial Ryder Cup match (for professionals) when it is played there.

The early 1900s, however, did not see a complete British monopoly of the Open. In 1907 the title was won by Arnaud Massy of France, the first player from outside Great Britain to achieve this distinction.

The British Amateur and Women's championships

The British Amateur Championship was started in 1885 after the Royal Liverpool Golf Club at Hoylake had proposed a tournament "open to all amateur golfers." The winner was Alan F. MacFie, a Scottish member. The tournament attracted nearly all the best amateurs of the time, but it was not immediately recognized as the championship. The following year the Royal Liverpool suggested to the R. and A. that the tournament be established as the amateur championship, and 24 clubs joined together to purchase a trophy and manage the event. Among British players who won the amateur championship at least two times before the series was interrupted by World War I were H.G. Hutchinson (1886 and 1887), John Ball (1888, 1890, 1892, 1894, 1899, 1907, 1910, and 1912), J.E. Laidlay (1889 and 1891), and H.H. Hilton (1900, 1901, 1911, and 1913). Ball also won the Open in 1890, the first English golfer to do so. Hilton won the Open in 1892 and again in 1897.

Outstanding British amateurs between World Wars I and II were Cyril Tolley, who was Amateur champion in 1920 and 1929 and a regular Walker Cup choice; Roger Wethered, who tied for the 1921 Open and was Amateur champion in 1923; and Scots Hector Thomson, Jack McLean, and A.T. Kyle. Gifted players after World War II included the Irish golfer Joe Carr, who won the title in

1953, 1958, and 1960, and Michael Bonallack, who won in 1961, 1965, 1968, 1969, and 1970.

The tendency for a talented amateur to turn professional is less marked in Great Britain and Ireland than it is in the United States, but a handful of young players did so in the late 1960s, and the tendency increases. As in the United States, the decision is commonly prompted by the amount of tournament prize money on offer and hardly ever by the desire to serve as a club professional. In both countries the professional tends to settle down to a club appointment when his touring days are over. The better he performs on the circuit or in national championships, the more lucrative the eventual appointment.

The Ladies Golf Union was formed rather late, in 1893. The first British Ladies Amateur Championship was held that year on the old St. Anne's course in England and won by Lady Margaret Scott, as were the next two championships. One of the first outstanding woman golfers was Dorothy Campbell, who won the Ladies Amateur Championship in 1909 and 1911 and was runner-up in 1908. She won the U.S. Women's Amateur Championship in 1909, 1910, and 1924 and the Canadian championship in 1910, 1911, and 1912. In all, she won more than 750 prizes in golf.

Of the many women who played championship golf between the wars, Joyce Wethered, sister of Roger Wethered, was outstanding. She won the British Ladies Amateur title in 1922, 1924, 1925, and 1929. Later Lady Heathcoat-Amory, she still played occasionally, delighting spectators with a style and ability that Bobby Jones considered supreme among women golfers. Her great rival was four times British Ladies Amateur champion Cecil Leitch, who had something like Braid's "Divine Fury" in her swing. Enid Wilson and Frances Stephens were among the many fine players who succeeded them.

The United States championships

United States. The first official U.S. Open, Amateur, and Women's Amateur championships were held in 1895; the respective winners were Horace Rawlins, Charles B. Macdonald, and Mrs. Brown. An unofficial open, at match play, in 1894 was won by Willie Dunn.

Walter J. Travis was the first great U.S. golfer. He was born in Australia, but his golf was wholly learned in the United States. Of striking appearance, with jet-black beard and impeccable garb, he was unpopular with fellow golfers because of his austere, taciturn demeanour. But he proved his ability as a golfer by winning the U.S. Amateur in 1900, 1901, and 1903, by reaching the semifinals in five other years, and by winning the qualifying medal in 1900, 1901, 1902, 1906, 1907, and 1908. He won the British Amateur title the only year he entered this event—1904.

Jerome D. Travers learned his golf at Nassau Country Club, Long Island, under the tutelage of Alex Smith, a famous Scots professional who went to the U.S. in 1898. Travers was a player with indomitable courage, an ability to outgame an opponent at match play, and nerve that rarely failed him in a crisis. He won the U.S. Amateur Championship in 1907, 1908, 1912, and 1913 and was finalist in 1914; he won the U.S. Open title in 1915; and he won a long list of sectional championships.

Among the women golfers, after Mrs. Brown won the first amateur championship in 1895, Beatrix Hoyt won the next three in a row. Other early multiple winners were Genevieve Hecker (1901 and 1902) and the outstanding Margaret Curtis (1907, 1911, and 1912).

Ascendancy of U.S. players. After World War I the influence of the many Scottish golfers who had emigrated to the United States became evident. U.S. golfers (principally Walter Hagen and Robert T. [Bobby] Jones, Jr., who achieved the unparalleled performance of winning the Open and Amateur championships of Great Britain and the U.S. in the same year, 1930) monopolized the British Open Championship until Henry Cotton won in 1934, a feat he repeated in 1937 and 1948. Cotton had determined to break the U.S. monopoly and did so after long practice and severe self-denial.

By the early 1930s U.S. dominance of the international scene was growing. Since 1933 the only victories by British teams in the biennial matches against the United States have been in 1938 and 1971, when the amateurs won the Walker Cup (the match was tied in 1965); in 1952 and 1956, when the women won the Curtis Cup, which they retained in 1958 with a tie; and in 1957, when the professionals won the Ryder Cup.

Early amateur golf champions

Francis D. Ouimet became a national hero in 1913 when, unknown as a golfer except around Boston, he tied Vardon and Ted Ray, two of the best British professionals, at 304 strokes for 72 holes in the U.S. Open, held at Brookline, and defeated them in a play-off. The following year Ouimet won the U.S. Amateur, and he repeated 17 years later, in 1931. He was runner-up in 1920 and a semifinalist in 1923, 1924, 1926, and 1927. He was a member of the United States team against Great Britain for the Walker Cup from the first of these international matches in 1922 to 1949, serving as captain in 1932, 1934, 1936, 1938, 1947, and 1949.

Charles ("Chick") Evans, Jr., first showed promise as a golfer around Chicago in the period 1906–10. He was runner-up in the U.S. Amateur of 1912 and the U.S. Open of 1914, winning the Western Amateur title in both those years and also in 1909 and in 1915, 1920, 1921, 1922, and 1923. In 1916 he became the first golfer to win the U.S. Amateur and Open in the same year; his score of 286 in the Open was unbeaten for 20 years, until Tony Manero scored 282 in the 1936 Open. In 1944, at the age of 54, he won the Chicago city championship, for the fourth time. Evans competed in 50 USGA Amateur championships and won 57 individual matches through 1962.

Bobby Jones was regarded as the greatest amateur golfer of modern times. His career was brilliant from his debut in national competition in the U.S. Amateur of 1916 until his unparalleled performance in 1930 of winning all four of the world's most difficult titles—the British Amateur, the British Open, the U.S. Amateur, and the U.S. Open. This feat became known as Jones's "grand slam." During his golfing career Jones won the British Open three times, the British Amateur once, the U.S. Open four times, and the U.S. Amateur five times. He played for the U.S. against Britain in the Walker Cup team matches in 1922, 1924, 1926, 1928, and 1930.

W. Lawson Little, Jr., in 1934 won both the United States and British amateur titles and the following year repeated his victories in both events. Little turned professional in 1936 and won the Canadian Open that year and the U.S. Open in 1940.

Jack Nicklaus, a very long hitter, won the U.S. Amateur twice, in 1959 and 1961, by the time he had reached the age of 21; but he turned professional later that same year and compiled an even more impressive record by winning the PGA Championship and the British Open twice each, the U.S. Open three times, and the Masters four times.

Arnold Palmer, also a golfer of exceptional strength, first won the U.S. Amateur in 1954 and after turning professional compiled another great modern record in winning the U.S. Open once, the British Open twice, and the Masters four times.

The popular appeal of the U.S. Amateur Championship has been seriously weakened by these departures to the professional ranks, and it has become exceptional for an amateur champion to resist the lure of tournament money. It is equally unlikely that he will have made his name without having had the experience of playing collegiate and intercollegiate golf, in which standards of instruction and play are generally high.

Professional golfers have contributed richly to the history of the game in the United States, and, while it was well into the 20th century before there was a native-born champion among them, the overall record of the professionals was remarkable—Walter Hagen and Gene Sarazen were particularly outstanding.

Walter Hagen and Gene Sarazen

Hagen first appeared on the national scene in the 1913 U.S. Open at Brookline, where he gave an excellent account of himself, considering his competitive inexperience, and tied for fourth against an expert field. The following year at Chicago he won the event. His golf was unorthodox; he had no desire to copy the smoother

swings of his fellow professionals, and he was entirely self-taught. He scorned to practice by the hour. He dressed immaculately and lived luxuriously, and to him, more than to any other golfer, goes the credit for breaking down the social barriers between amateurs and professionals. Between 1914 and 1936 Hagen won the U.S. Open twice, the British Open four times (a feat matched after World War I only by A.D. ("Bobby") Locke of South Africa and Peter Thomson of Australia), the PGA Championship five times (including four in a row—1924, 1925, 1926, 1927), the Canadian, French, and Belgian opens once each, and at least 45 other events. In all, he participated in not less than 200 open tournaments and was rarely out of the money. In addition, he played in about 1,500 exhibition matches in the U.S. and other countries, many of them for high fees or stakes. He is said to have earned around $1,000,000 during the 22 years he was rated as a topflight golfer.

Sarazen, a man of small stature, reached golfing fame in 1922 by winning the U.S. Open at Chicago and proved he was a golfer of more than passing ability by adding the professional title that same year at Oakmont, Pennsylvania, and the following year at Pelham, New York. No further titles of importance came his way for ten years, but during this period he was a constant competitive threat. In 1932 he reappeared as a champion, winning the British Open with a brilliant 283 and the U.S. Open with an equally brilliant 286, which tied the then low-scoring record established in 1916 by "Chick" Evans. In 1933 he won the PGA title for the third time and in 1934 came within one stroke of winning the British Open. In 1940 he tied Lawson Little for the U.S. Open Championship with a score of 287, but lost the play-off with 73 to Little's 70. He was a persistent opponent to slow play, which has blemished numerous championships, particularly after World War II. (The practice, unhappily, spread to club golf as well.)

In the late 1930s the so-called pro circuit, underwritten by civic and club organizations throughout the country, began putting up major prize money for the experts. Robert E. Harlow developed this circuit and was the first tournament manager of the PGA. Fred Corcoran succeeded him in 1936. That year, aggregate prize monies totalled $100,000; when Corcoran left the field, in 1947, they totalled $650,000. In the 1970s the PGA circuit offered in excess of $7,000,000 in prizes annually.

Other leading professionals

Other names in U.S. professional golf history include the English-born James Barnes, who won the professional title in 1916 and 1919, the U.S. Open in 1921, and the British Open in 1925; Leo Diegel, who won the PGA title in 1928 and 1929; Denny Shute, who won in 1936 and 1937; and Ralph Guldahl, who won the U.S. Open title in 1937 and 1938. After 1940 Byron Nelson, Ben Hogan, and Sam Snead, a gifted natural athlete, shared the major portion of prize monies. Following World War II Nelson, an extraordinarily accurate iron player, retired from serious tournament participation. After winning the U.S. Open and the PGA title in 1948, Hogan, following his recovery from serious injuries suffered in an automobile accident, returned to the golfing circuit in 1950 and won the U.S. Open in that year and in 1951 and 1953, the year he also won the British Open—to duplicate the feats of only two other Americans at that time, Bobby Jones and Gene Sarazen, each of whom won both opens in one year, as did Lee Trevino in 1971. Hogan also scored a record 14-under-par 274 to win the Masters.

The Masters tournament, an open, invitational event played each spring at Augusta, Georgia, was originated in 1934. Hogan's record fell to 25-year-old Jack Nicklaus (1963 winner) in 1965 when he scored a 17-under-par 271, including one round of 64, tieing the record set by Lloyd Mangrum in 1940. Nicklaus won by 9 strokes over Palmer and Gary Player of South Africa (winner in 1961); Jones called it "the greatest performance in golfing history."

The years succeeding World War II saw many other outstanding players approach and often attain these high standards. Cary Middlecoff, a very deliberate player who had turned professional shortly before, won the U.S. Open in 1949 and again in 1956. Julius Boros, who captured the title in 1952, regained it 11 years later. Bill Casper, an immensely consistent golfer, was U.S. Open champion in 1959 and 1966. In 1964 Tony Lema, who had come up through the caddie ranks, at his first attempt on the British Open took the title after giving himself almost no time to practice. Lema was the first eminent golfer of Portuguese ancestry and a formidable contender on the professional tour.

During this era the professional talent in particular became more and more a product of the Southern and Western states and less characteristic of the Eastern Seaboard, as it had been in Hagen's and Sarazen's day. This was especially true of San Diego, where the encouragement offered to juniors later brought onto the national scene not only Casper but also Gene Littler, Phil Rodgers, and—in ladies' golf—Mickey Wright. Littler was U.S. Open champion in 1961 and won numerous tournaments with a swing of great elegance. Rodgers, a capable tournament player, tied for third in the British Open of 1962 and a year later tied for first (he was defeated by Bob Charles of New Zealand in the play-off). Miss Wright's record will be referred to later.

The year 1971 saw an extraordinary accomplishment by Lee Trevino. Partly of Mexican birth, he had developed his game in the U.S. Army, principally in the Far East, and came to prominence as U.S. Open champion in 1968. Three years afterward he recaptured the Open title, won the Canadian Open, and then triumphed in the British Open, all within the record period of a month.

As the pace quickened and increasing numbers of promising players set their minds on a tournament career, the amateurs found themselves outclassed in national opens. There was now no Bobby Jones or Chick Evans to draw more spectators than were following the professionals. Once they had turned professional, the leading amateurs, for the most part, were quite successful, but no national title holder emerged from the amateur ranks after Doug Sanders won the Canadian Open in 1956. Subsequently, he too turned professional.

On the British circuit no player had a longer or more remunerative career than Dai Rees, though he continually failed to win the British Open, just as Sam Snead never won the U.S. title. In many ways their careers—at the beginning of the 1970s almost 40 years in duration—ran in parallel. Both began to play golf in economically depressed areas, Snead in Virginia, Rees in South Wales; both were Ryder Cup selections over a long period (and were honoured with captaincies); and both won numerous events abroad as well as in their own countries.

It was not until 1970 that a British professional made the first serious dent into American supremacy. Tony Jacklin, after playing successfully on the American circuit, became U.S. Open champion by a seven-shot margin. This was the first time a Briton had won America's most important championship since Ted Ray had done so half a century before.

In women's golf, Alexa Stirling of Atlanta, Georgia, won her first U.S. Women's Amateur while quite young in 1916 and repeated in 1919 and 1920. She was runner-up in 1921, 1923, and in 1925, as Alexa Fraser. She also won the Canadian championship in 1920 and 1934.

Outstanding women golfers

Another great U.S. woman golfer, Glenna Collett Vare, won her first Women's Amateur title in 1922 and repeated on five occasions—1925, 1928, 1929, 1930, and 1935. She made four attempts at the British championship but was turned back—on two occasions in the final round. Mrs. Vare's extended hold on women's golf was broken when Virginia van Wie of Chicago replaced her as champion during the three seasons of 1932, 1933, and 1934. Miss van Wie forfeited her title without contest in 1935, when Mrs. Vare regained the title by defeating Patty Berg. Betty Jameson won the title twice in a row, in 1939 and 1940. And in 1960 Mrs. Vare won the U.S. women's Senior championship.

The greatest names in women's golf after World War II included Mrs. Mildred ("Babe") Didrikson Zaharias, Patty Berg, Louise Suggs, Betsy Rawls, and Mickey Wright, all of whom played professionally. Mrs. Zahari-

as, an Olympic winner in track and field in 1932, picked up a golf club that year at the invitation of the sports writer Grantland Rice and from that time played the game with astounding success. She regained her amateur status long enough to win the British Ladies Amateur title in 1947—the first American to do so. Thereafter she turned professional again and embarked on a series of successful golf tours. The women follow a professional circuit similar to that of their male counterparts. From 1946, when the women started their own open championship, Mrs. Zaharias continued to be the leading woman player until her death in 1956.

Outstanding amateurs of the 1950s and 1960s included JoAnne Gunderson Carner, five times winner of the U.S. Women's Amateur championship, and Anne Quast Decker Welts, the winner three times. Among the professionals, Mickey Wright and Betsy Rawls each won the U.S. Women's Open four times during those years; Donna Caponi won the Open both in 1969 and 1970.

The international scene. *International matches and tournaments.* The first organized series of regular international matches were between Great Britain and the United States. The amateur team match between the two countries for the Walker Cup was inaugurated in 1922 and the professional team match (Ryder Cup) in 1927. The women's amateur team match (Curtis Cup) began in 1932. Although the competition in all of these contests has often been close, the U.S. players have managed to win the cups, with rare exceptions.

More truly international matches appeared on the scene in the 1950s. The World Cup (formerly the Canada Cup), played for by two-man teams of professionals, was first offered in 1953, when it was won by Argentina. Only seven nations took part in that first contest; there were 25 in the second; and when Canada, the original host nation won for the first time in 1968, there were 40 teams of two players. More than 50 countries are represented on the World Amateur Golf Council, which was organized by officials of the USGA and the R. and A. in 1958. Its first tournament for the Eisenhower Trophy, held that year, was won by the Australian team. In women's golf, the World Women's Amateur Team Championship for the Espirito Santo Trophy was instituted in 1964. The first winner was France.

International circuits. The coming of speed and sophistication in jet transport stimulated competition. Ocean hopping has become routine, enabling outstanding players from South America, Australia, New Zealand, and South Africa to compete in the premier championships in Great Britain and the United States and on the rich U.S. PGA tour. The first successful invader from the Southern Hemisphere was Bobby Locke of South Africa, a magnificent putter, who won the British Open in 1949, 1950, 1952, and 1957. Peter Thomson of Australia won it five times, the first in 1954 and the last in 1965. In the 1960s Kel Nagle (Australia), left-hander Bob Charles (New Zealand), and Roberto de Vicenzo (Argentina) each won the Open once. But South African Gary Player made perhaps the biggest mark on the international scene, winning the British Open in 1959 and 1968, the U.S. Open in 1965, the U.S. PGA in 1962, and the Masters in 1961. He also did well on the PGA tour through the 1960s and into the 1970s and was the leading official money winner in 1961.

Players from the Southern Hemisphere

With more overseas players entering, and sometimes winning, tournaments in the United States and Great Britain, more U.S. and British players, especially British professionals during the winter months, began to take part in various circuit itineraries in other parts of the world—in Australia, New Zealand, South Africa, and the Far East. The Far Eastern circuit takes in promotions in the Philippines, Singapore, Malaysia, Thailand, Hong Kong, Taiwan, Tokyo, and India. The Asian players have been especially noted for their short-game precision. In Japan the game has become an endemic fever, and it was a sign of the times when Japan won the World Cup in 1957. (For records of the premier championships and international events see also SPORTING RECORD in the *Ready Reference and Index*.)

Finance. Professionals with expertise and crowd-pulling attributes have become a new affluent society thanks to the co-sponsorship, by the PGA and local promoters, of lucrative weekly tournaments with television rights to negotiate. The modern professional also has many sources of peripheral income. The great Harry Vardon received £50 with his medal for winning his record sixth British Open in 1914. By 1971 the winner's prize was £5,500; and in 1972 for the first time all professionals in the championship proper received prize money, including a minimum of £125 for those completing the 72 holes. The emoluments in America far overshadow the escalation of those in Britain. Men who get to the top in America reach the $200,000 bracket, fly their own private planes, and have their lucrative, outside business interests expertly managed for them.

The emoluments of professional golf

The traditional Open Championship in Great Britain has an attached bonus of munificent value. It is one of the four events the winners of which compete in the 36-hole World Series of Golf in the United States, with its first prize of $50,000. The other events that count for this award are the U.S. Open, the Masters, and the U.S. PGA Championship. The U.S. professional match-play championship—revived in 1971—had a total prize payout of $200,000. The largess regularly brings in recruits. There were 250 applicants in 1970 for the 18 qualifying schools held by the PGA to determine approved tournament players. More than $7,000,000 was disbursed in tournament prize money in 1970, but rigid qualifying systems, even after the aspirant has become an approved tournament player, make the circuit life an arduous and frequently disappointing one. To give the less successful professionals some encouragement, events known as satellite tournaments, played concurrently with the main promotion but offering less prize money, now appear on the tournament calendar.

The U.S. PGA is fortunate in their lavish sponsorships. In Great Britain finance is not so easy, and the Royal and Ancient Club, being without any commercial sponsorship, has to rely for meeting its expenses for the Open Championship and international and other commitments, such as the Walker Cup and Eisenhower Trophy tournaments, largely on the Open Championship gate money. The costs are high, with the new standards of spectator accommodation and other amenities, and more than one championship has left a deficit. Promotional costs climbed by five times in about a dozen years up to 1970. Happily, the club has come out on the profit side at other times and has reserves to call upon. The championship proceeds are kept entirely separate from the club's domestic funds and have never been used to subsidize these.

Senior golf. One of the most significant developments in golf in the 20th century occurred in senior golf after 1905, when Horace L. Hotchkiss arranged the first seniors' tournament, for players aged 55 and older, at the Apawamis Club, Rye, New York. Hotchkiss, who was more than 60 at the time, attempted to prove that golf was not exclusively a young man's game. The tournament was such a success that within ten years the number of contestants had passed the 300 mark. The United States Seniors Golf Association was organized on January 17, 1917, in New York with a membership of 400, which within six months increased to 500 and subsequently to 1,000. While the United States seniors' tournament is the leading event of its kind, many membership and invitation events of the same type developed—the American Seniors' Golf Association, the Western Seniors' Golf Association, the North and South Senior Tournament, and others. There are at least 50 senior golfing organizations in the United States alone. Members of the United States Senior Women's Golf Association play annually. In 1918 the Governor General of Canada presented a trophy to be played for annually by the United States Seniors Golf Association and the newly formed Canadian Seniors' Golf Association. Another match was initiated with the Senior Golfers' Society of Great Britain. The annual World Senior Amateur Championship was first held in 1960; the biennial World Amateur Team Championship was established in 1967.

II. The modern game

COURSES AND FORMS OF PLAY

The game consists in playing the ball from a teeing ground into a hole by successive strokes in accordance with the rules. The stipulated round consists of 18 holes, and most golf courses have 18. Standard 18-hole courses measure from 6,500 to 7,000 yards (5,900 to 6,400 metres); individual holes, from 100 to 600 yards (90 to 550 metres). Some courses, however, have only nine holes, and these are played twice in a stipulated round. The clubs are designed for the various positions in which the ball may come to rest and for the various distances to the hole. The objective is to hole the ball in the fewest strokes.

The number of holes on a course

When the game entered the 19th century, there was no agreement on the number of holes on a course; localities differed widely in the matter. When the popularity of Leith, with its five holes, waned and St. Andrews became the hub, the round of 18 holes became the established order. Originally the St. Andrews holes filed straight out alongside the shore and were simply played in reverse for the return journey—11 holes each way. In 1764 the round was modified to 18 holes. The infinite variety of courses gives golf an intrinsic charm. Gleneagles in Scotland and the Augusta National in Georgia are cited as representing only two of the many outstanding examples of environmental beauty of courses around the world.

Course architecture has been greatly modernized. Planning at the beginning of the 20th century was on simple, even primitive, lines. The bunker, or sand trap, that by constructional canons stretched an ugly line across the fairway to trap topped balls was fashionable. The strategic, as against the frankly penal, type of hazard was developed, and bunkers and other hazards that can be artificially created have been a key role in the design of interesting and challenging holes on the best courses. The modern green, even on flat ground, is usually banked, and teeing grounds have been lengthened and—in a few instances—given a crescent shape, in order to vary the distance or the angle to the hole.

Match and medal play. There are two distinct forms of play: match play and stroke (medal) play. In match play the player and his opponent are playing together and competing only against each other, while in stroke play each competitor is competing against every other player in the tournament. In match play the game is played by holes, and each hole is won by the player who holes his ball in the fewer strokes. If both players score the same number of strokes, the hole is halved. When a player has won one more hole than his opponents, he is said to be 1 up. The match is won by the player who is leading by a number of holes greater than the number of holes remaining to be played, as, for example, 3 up and 2 to play. In stroke play the competitor who holes the stipulated round or rounds in the fewest total strokes is the winner. Amateur championships once were all at match play and open championships and most professional events at stroke play, over 72 holes. Some amateur events have been changed to stroke play (the U.S. Amateur event was at stroke play from 1965 to 1973), as has the U.S. PGA Championship. An additional PGA championship, in a modified form of match play, was initiated in 1971; players won or lost on their 18-hole scores, instead of hole by hole.

Scoring match and medal play

Stroke play requires a greater degree of consistency in a player, for one hole where he lapses into a high figure can ruin his total and cost him victory. The same high score on a hole in match play means only the loss of that hole. In both match and stroke play, players can compete as individuals or as partners. When two players compete as partners, each playing his own ball, the better ball on each hole is their score for that hole; this is a four-ball or best ball match. Two players may compete as partners with two others, each pair playing alternate strokes on a single ball; this is a match foursome.

Handicaps. Players of varying abilities compete against each other by using handicaps. A handicap is the number of strokes a player receives to adjust his score to a common level. The better the player, the smaller his handicap, and the best players have handicaps of zero (scratch players). A scratch player whose average score is 70 can have an even match with a player whose average score is 80 by giving him a handicap of 10 strokes. Handicap golf is limited to amateur competitions, and championship tournaments are played without handicaps.

Par golf. An expert golfer plays most of the holes on the course in 4 strokes, a drive of 225 to 250 yards (200 to 225 metres), a shot to the green, and 2 putts. Every course, however, contains a few short holes on which the expert might be expected to drive onto the putting green and a few long holes on which the expert might require a drive and 2 more strokes to reach the putting green. On the former, he would be expected to make 3 and on the latter 5, since 2 putts on each green is the standard.

Every course has a par, which is defined as the score an expert (*i.e.*, a scratch player) would be expected to make, and many courses also have a bogey, which is defined as the score that a moderately good golfer would be expected to make. Both par and bogey are defined as errorless play without flukes and under ordinary weather conditions, allowing 2 strokes on the putting green. Par is essentially a U.S. term that came into use in the early 1900s as a base for computing handicaps under the system devised by L. Calkins of Plainfield, New Jersey. Bogey is essentially a British term that came into use in England in 1891 and was derived from a mythical Colonel Bogey, who was described as uniformly steady but never overbrilliant. Colloquially in the United States, "bogey" is used to indicate a score 1 stroke above par.

The British Standard Scratch Score

The basic Standard Scratch Score (sss) used in Great Britain for a normal course of 6,300 yards (5,800 metres) is 70, but a stroke is added or deducted for each 200 yards (180 metres) by which the total length of the course varies from that figure. An addition may be made to the sss to allow for courses with exceptional difficulties other than length. Handicaps are based on the sss.

EQUIPMENT

Golf balls. Regulation golf balls have a maximum weight of 1.62 ounces (45.93 grams). The minimum size of the United States ball is 1.68 inches (4.27 centimetres) in diameter; that of the British ball 1.62 inches (4.11 centimetres) in diameter. The velocity of the U.S. ball may not be greater than 250 feet (75 metres) per second when measured under prescribed conditions on an apparatus maintained by the USGA, but there is no velocity specification for the British ball.

Golf clubs. In the average good player's set there are either three or four wood clubs and nine or ten irons (no more than 14 clubs may be carried during a round). No two clubs in a set are the same. There are differences in length and suppleness of shaft, weight, size and shape of head, the angle at which the shaft ends and the head begins (the lie), and the angle of the face of the club from the vertical (the loft).

The various clubs are known both by number and by name. The names have come down from the early days of golf; the numbers are a U.S. innovation dating from the early 1920s, when matched sets came into use (see above *New manufacturing methods*). The most widely used clubs are identified below.

Wood clubs

Number 1 (driver), used from the tee for maximum distance; has a large head and a deep, almost vertical, face. The face has an angle of loft of about 10°.

Number 2 (brassie), so called because the sole of the club originally was covered with a brass plate. Used mostly for long shots from good fairway lies, the club has a slightly smaller and shallower face than a driver but with more loft.

Number 3 (spoon), shorter shaft and shallower face than driver or brassie, but face has considerably more loft. The club is used to play the ball from lies too poor for a brassie and also for strokes when the use of a driver or brassie would send the ball beyond the green.

Number 4 (baffy), smaller head, shallower face, and more loft than a spoon. It will hit a ball about as far as a number 1 iron.

Number 5, a great favourite with players who have an

aversion to iron clubs, it replaces the number 3 or 4 iron. It has a small and compact head.

Irons

Number 1 (driving iron or cleek), a long shaft and an angle of loft of about 20°. Used for tee shots and full shots from lies too "heavy" for a wood. A difficult club to use, it produces a long, low shot.

Number 2 (midiron), slightly more loft, for shots of shorter distance than number 1 iron.

Number 3 (mid-mashie), more loft; for shorter distances than number 2.

Number 4 (mashie iron), more loft; for shorter distances than number 3.

Number 5 (mashie), more loft; for shorter distances than number 4. The ball pitches high and stops quickly after hitting the ground. This club is also used for pitch-and-run shots to the green; the ball travels part of the way through the air, then rolls the rest of the way.

Number 6 (spade mashie), more loft; for shorter distances than number 5 and also for playing the ball from high grass or difficult lies, when getting out is more important than distance.

Number 7 (mashie niblick), resembles the spade mashie but has still more loft and head weight; puts considerable backspin on the ball.

Number 8 (pitching niblick), still more loft; for shorter distances than number 7.

Number 9 (niblick), face has a loft of about 47°, and the head is heavy, to carry it through long, tough grass or heavy sand. A ball, properly hit, rises almost vertically and upon hitting the ground may jump backward as a result of the backspin this club imparts.

Number 10 (wedge), face has a loft of more than 50°, but the club has a broad flange on the sole. There are two types—the sand wedge to use in bunkers and the pitching wedge for pitch shots.

The putter, a club with a short, stiff shaft and a straight, or nearly straight, face, for rolling the ball on the green. There are many styles of putters.

THE RULES OF GOLF

The rule-making bodies for golf are the R. and A. and the USGA. They attempt to perpetuate the uniformity in rules by exchanging views on interpretations and on recommendations for revision. The rules govern play all over the world. While the basic principle of the rules is simple, the code itself has become complex over the years.

The first rules

The present code makes an amazing contrast with the first documentary rules in history, 13 in number, that were framed by the Honourable Company. The first of them ordained that the ball had to be teed within a club length of the previous hole and the tee had to be on the ground. Tee and green were one. The ball struck from the tee was not to be changed, and the player could (Rule 5) take his ball out of water or "watery filth" to play it and allow his opponent a stroke. The St. Andrews golfers, in founding the Royal and Ancient Club, adopted an almost carbon copy of the Leith rules. There were periodical adjustments and abortive efforts at reform before the rules committee of the R. and A. was formed in 1897 to become the final authority.

The rules committee has co-opted representatives from the Commonwealth, the European Golf Federation, the United States, and the British Unions Advisory Committee. Britain and America have had separate codes at various times, but a uniform code went into effect in 1967. The sole exception to the arrangement is in the specifications for the ball (see above).

Local rules. Rule 27 of the current code permits clubs to make local rules to cope with abnormal conditions on their courses, but any penalty imposed by the code must not be waived by a local rule. There have been many curious instances of local rules—the Duke of Windsor, for example, used a concession at Jinja on an African tour to lift his ball from a hippopotamus' footprint.

The World Cup competition has its own regulations, which, in effect, come into the category of local rules; and, because the U.S. PGA tournaments are played under varying conditions and in different climates, their rules, too, are not identical with those of the USGA and the R. and A.

Definition of amateur. The rules of golf define an amateur golfer as "one who plays the game solely as a non-remunerative and non-profit-making sport." But the elasticity of this definition perturbs the game's legislators for what it does not define. The whole question of status in its various aspects engages the attention jointly of the R. and A. and the USGA.

Under a recent change, an amateur remains so until and unless he takes specific action toward becoming a professional, even though he might have indicated his intention of becoming a professional in the future. The expense of becoming a top-class amateur is formidable if not impossible unless a player is financially well situated, and the difficulty may drive him into one of two channels—a profitable post obtained through his golf reputation or some form of sponsorship, which is prohibited.

The official veto against an amateur accepting golf merchandise without paying the market price for it has been enforced in the case of nationally known players who received unsolicited golf balls from a firm that aimed at publicity through the gift. The players were temporarily suspended. The USGA committee on status warned commercial interests against offering prizes to amateur golfers as a disservice to both the game itself and the players. It is illegal to accept a prize or prizes in any one competition of a retail value of £50, or $200 in the United States. Prizes of symbolic value such as metal trophies are permissible.

Applications by amateurs for reinstatement are decided on their merits, but a player who has been in the professional ranks for five years is ineligible for it. In the United States over 100 players had their amateur status restored in 1970.

PLAY OF THE GAME

Driving, playing the fairway, and hazards

The starting place for each hole to be played is the teeing ground. The front is indicated by two markers, and the teeing ground is the rectangular space two club lengths in depth directly behind the line indicated by the markers. The player tees his ball anywhere within this space, usually setting it up on a small wooden or plastic peg, and strikes it toward the hole. The stroke from the teeing ground is called the drive. For this, the player usually employs a number 1 wood club, or driver, although to avoid a hazard or to attempt to place his ball in a favourable position for his second shot (for example, on a long hole with a sharp bend, or dogleg) he may prefer one of the other woods, or an iron. On short, par-three holes most players use an iron.

The preferred line to the hole is generally a clear, mowed route called the fairway. The fairway was historically bordered by unmowed vegetation—heather, grasses, weeds, bushes—called rough. Today, however, most courses in the United States are not characterized by deep and tangled rough and when inland make effective use of trees. At strategic places along the preferred line to the hole and guarding the putting green are obstacles called bunkers, depressions in the ground filled with sand (sand traps). Some holes require the player to skirt or cross streams or ponds. Both bunkers and bodies of water are termed "hazards." If a player's drive lands on the fairway, on a long hole he will normally use a number 2 or higher wood or one of the lower numbered irons to attempt to reach the green. If his ball has landed in the rough, he usually will have to use an iron to hit it out—and consider himself fortunate if he happens to get good direction and distance as well. A ball in the water, unless it is very shallow, usually is unplayable, and the player must take a penalty; if the ball is in the loose sand of a bunker, he will try to blast it out, usually with a number 10 iron, or wedge, although if the bunker is at a distance from the green and the ball lies well perched on the sand he may be able to use a longer iron.

Approaching and putting

When the player has come within close range of the green, two methods of play are open to him. He may pitch the ball all the way and depend on backspin to stop his ball near the pin, or he may play a chip shot, in which the ball flies part way through the air, as to the edge of the close-clipped surface of the green, and then rolls the remaining distance.

The hole itself measures 4¼ inches (10.8 centimetres)

in diameter, is at least 4 inches (10 centimetres) deep, and is set in an area of turf especially prepared and maintained and closely mowed for putting. When the player putts he uses a straight-faced club and rolls the ball across the putting green toward and eventually into the hole. The player must hit the ball along a line that allows for very little margin of error and with enough force to roll the ball to the hole but not too far beyond in case he misses it. And, since most greens are not level but have numerous pitches and minor slopes, great care must be taken to select the proper line, which may be quite far to one side or the other of the hole. There are many styles of putters and many styles of putting: the style in which the ball is straddled in the "croquet" stance was banned under R. and A. and USGA rules in 1968.

VARIANTS

Par-three golf. Par-three golf courses, on which each hole measures 100 yards (90 metres) more or less and plays at par three, were developed as a result of the shortage of available open land in congested urban areas. A classic example is Edinburgh's Bruntsfield Links (see above *History*), now a short course. Whereas a regulation 18-hole course may stretch to over 7,000 yards, about four miles (6½ kilometres), an 18-hole par-three, or short-hole, course can be laid out in about 1,800 yards (1.6 kilometres), and a nine-hole short course in less than 1,000 yards (0.9 kilometres). Short courses have appealed to golfers in areas where public courses are overcrowded and private clubs have waiting lists or high membership fees, and they have proved popular among inexperienced players. Their limited area is an important consideration when urban land has greatly increased in value, and they would seem to have a prosperous future. Some par-three courses are flood-lighted for night play.

Driving ranges. Driving ranges were developed as commercial establishments at which golfers and aspiring golfers could, for a small fee, practice their swings and hitting the ball for distance or accuracy or both. They, too, have appealed to golfers in areas in which courses are overcrowded or hard to reach. Driving ranges have proved to be especially popular in Japan, where crowded conditions prevail. By the early 1970s there were over 2,000 of them in that country, with some 300 in the immediate vicinity of Tokyo.

Putting games. Practice putting greens have long been a feature of most courses for the use of even the most expert players in refining the difficult and delicate skills of rolling the ball over slanting surfaces into the hole. With the great growth of interest in golf, more putting greens have been established for recreational purposes.

In the 1930s a putting game known as miniature golf produced a brief craze in the United States. In this game a putter was used to hit a golf ball across a smooth surface (usually crushed cottonseed hulls) and through, over, or around various baffles, or hazards—abrupt dips or rises, sharp turns, curved sections of tin pipe, and so on—and into a series of holes, nine or 18, laid out as a replica of a golf course. Briefly extremely popular, the game survived as a minor attraction in some amusement parks. Other putting games have been invented, and numerous practice putting devices have been marketed, primarily for indoor practice by the individual golfer.

NEW TRENDS

In the last third of the 20th century the game appeared to be moving still further from its Scottish infancy. If the golfer's object was unchanged and his method of playing the conventional one, a number of minor revolutions were taking place in other departments of the game.

Course maintenance

Because the earliest golf courses were links, the natural qualities of seaside turf made greenkeeping much less of a science than it is now. Courses that have been laid out over less helpful terrain—such as desert country—may look artificial in comparison, but they demand a sophisticated knowledge of maintenance, likely to be acquired through university courses in agronomy and augmented by the results of turf-institute research. The modern course superintendent needs to be an expert in the complexities of tractors and machinery, fertilizers, insecticides, weedkillers, and irrigation systems.

Caddies, golf carts, and buggies

As for the traditional caddie (the word derives from the French *cadet*), he is a dying breed in the English-speaking countries, mainly because work of this kind no longer appeals to boys seeking pocket money or to restless, unskilled men. The few remaining caddies who really understand their duties are likely to be nomadic and highly individual, if not downright eccentric, in character. Their employers are normally the amateur champions and the touring professionals, and in the PGA events a caddie can receive a handsome bonus when his man wins.

Partly because of the shortage of caddies, the two-wheel bag carrier—called a golf cart or, in Britain, a trolley—has been widely used since World War II. More recently, the electrically driven golf car or buggy (a two-seater) has proved a blessing, if an expensive one, to players with limited time or who may be physically unable to walk long distances. It is also a useful vehicle to tournament supervisors in the field.

Men's apparel has changed considerably. No one plays in a jacket any longer, and plus fours, or knickers, are all but obsolete. Women still play in skirts, but slacks or shorts are widely accepted.

From the 1960s onward there was a marked increase in the number of courses designed for vacation or retirement living. In some parts of the world—notably the Caribbean islands and the Mediterranean countries—this gave golf a new internationalism. In such states as Florida, Arizona, and California, the golf course was often the best inducement, except for the climate itself, that a land developer could offer his clients.

Official rules of the game are published both by the R. and A. and the USGA.

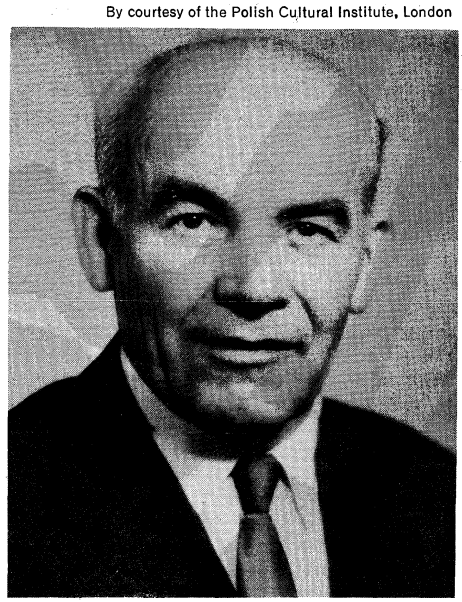
(F.Mo.)

Gomułka, Władysław

Władysław Gomułka stands as the central figure in Polish politics in the mid-20th century. Frail in appearance and

colourless in personality, with a modest, almost severe life style, Gomułka has had an uneventful private life. His only passion has been politics, but his public career has been full of dramatic turns. Emerging as the Communist leader of Poland at the end of World War II, he was later denounced and imprisoned by Premier Joseph Stalin of the U.S.S.R. Restored to power amid popular acclaim in 1956, for the next 14 years, until his ouster in late 1970, he attempted to steer a middle course between the liberals and neo-Stalinists. In victory as well as defeat he has left a deep personal imprint on Poland's recent history.

By courtesy of the Polish Cultural Institute, London



Gomułka.

Gomułka was born Feb. 6, 1905, in Białobrzegi, near Krosno in southern Poland. Before his birth his parents had emigrated to the United States but had returned disillusioned. His father, Jan, was a Socialist and worked in the oil fields. Gomułka completed primary school in 1917 and afterward was trained as a locksmith. From 1922 to 1926 he worked in an oil refinery. At the age of 16 he joined the youth Socialist movement. In 1926 he entered the clandestine Communist Party of Poland and in the same year was first arrested for revolutionary activity.

Professional revolutionary

At this time Gomułka became a professional trade union organizer, and in 1930 he was elected a national secretary of the Chemical Workers' Union. Thereafter he organized workers' strikes throughout the country. During the textile strike at Łódź in 1932, he was seriously wounded in the leg by the police and was left with a permanent limp. He was arrested and sentenced to four years' imprisonment but was released for reasons of health in 1934. In 1934–35 Gomułka studied at the International Lenin School in Moscow. After his return to Poland he continued revolutionary activity in Silesia, and in 1936 he was re-arrested and sentenced to seven years' imprisonment. When the Polish Communist Party was dissolved on Stalin's orders in 1938 and most of its leaders were exterminated in the Soviet Union, Gomułka stayed in prison in Poland. At the outbreak of World War II he was released. After participating in the defense of Warsaw, he moved to the Soviet-occupied eastern part of the country, where he worked as a minor official in a paper mill in Lwów.

Wartime leader

With the outbreak of war between Germany and the Soviet Union in 1941, Gomułka resumed his political activities. At first he returned to his native region of Krosno and organized the Communist underground there. In July 1942 he moved to Warsaw, where he became district secretary and a member of the Central Committee of the newly founded Polish Workers' Party (PPR). There he organized some daring attacks by the underground on the Nazi occupiers. In November 1943, after the arrest of his predecessor, Gomułka became secretary general of the Polish Workers' Party. He is credited with writing the Party's ideological manifesto and helping to establish the Home National Council in cooperation with some other leftist groups. When the Soviet troops entered Poland in July 1944, Gomułka moved to Lublin, where the Communist-dominated provisional government had been set up. In January 1945 he was appointed deputy premier, and in June he also assumed the portfolio of the Recovered Territories, with responsibility for the administration of all the lands taken over by Poland from Germany. In December 1945, at the First Congress of the Polish Workers' Party in Warsaw, Gomułka was elected a member of the Politburo and secretary general of the Central Committee.

Gomułka was ruthless in eliminating all opposition to the Communist rule. He personally led the struggle to crush the Polish Peasant Party (PSL), and he was a strong advocate of the merger, on Communist terms, of the Polish Socialist Party (PPS) and the Polish Workers' Party. At the same time, however, he came out against forcible collectivization of agriculture and spoke favourably of the socialist tradition. In opposing the formation of the Cominform in September 1947, he was even critical of the Soviet line. This led to his political eclipse.

Persecution by Stalin

On Stalin's orders, Gomułka was accused of "nationalist deviation," and in September 1948 he was replaced as secretary general of the Polish Workers' Party by Bolesław Bierut. After the Communist and Socialist parties merged into the Polish United Worker's Party (PZPR) in December 1948, Gomułka was also dropped from the Politburo. In January 1949 he was relieved of his government posts, and in November of the same year he was stripped of his membership in the Communist Party. Finally, in July 1951 he was arrested. Throughout his persecution—even when imprisoned, his life clearly in peril—Gomułka acted in a dignified and courageous manner and refused to admit his guilt.

Toward the end of 1954, after Stalin's death, Gomułka was released, and in 1956, after Premier Nikita Khrushchev had launched the de-Stalinization campaign in February and Bierut had died in March, he was politically rehabilitated. In April the new party secretary, Edward Ochab, reiterated the charges of "nationalist deviation" against Gomułka but admitted he should not have been arrested. After the Poznań workers rioted against the Communist government in June, Gomułka's political fortunes started to rise once again. His persecution by Stalin had turned Gomułka into a popular figure among the Poles, and they now demanded that he be restored to power.

Restoration to power

In the tense atmosphere prevailing in the country, the Communist leaders acceded to the popular wishes. In August 1956 Gomułka was re-admitted to the party and in October was re-elected to the Politburo and to the position of first secretary of the Central Committee. Soon he was also elected a member of Poland's collective presidency, the Council of State. His return to power was a moment of great personal triumph for Gomułka. Hoping that he would undertake substantial reforms, the people gave him their almost universal support.

The reforms adopted by Gomułka were half-hearted. The most oppressive Stalinist features were eliminated: the rule of terror was curbed, the persecution of the Catholic Church was ended, and the collectivization of agriculture was abandoned. Several objectionable features of the older system were, however, preserved: intellectual freedom remained restricted, and no major economic reform was carried out. His retrogressive course led to disillusionment with Gomułka among the Poles, but in the late 1950s many people still believed his policies resulted from pressure from Moscow.

In 1961, after Khrushchev launched his second de-Stalinization campaign, Gomułka failed to exploit this opportunity to undertake further reforms and the situation in Poland remained stagnant. From then on, Gomułka's popular support declined rapidly. The ferment among the people steadily gathered strength until it

Waning of popularity

culminated in March 1968 in the open defiance of the Gomułka regime by the intellectuals and in students' riots in Warsaw and several other Polish cities.

Gomułka survived the crisis and at the Fifth Party Congress in November 1968 was re-elected first secretary, but his political influence was clearly on the wane. He was discredited among a large segment of the people and was challenged by powerful rivals within the party leadership. Gomułka tried to stave off defeat by belatedly adopting some new policies. In 1969 he changed Poland's policy vis-à-vis West Germany, leading to the signing early in December 1970 of a Polish–West German treaty normalizing relations between the two countries and sanctioning the Polish western boundary. At the same time, he launched substantial economic reforms, but by now the Polish economy was so run down that drastic measures were needed. The announcement of increased food prices on the eve of the Christmas holiday led to workers' riots in the coastal cities of Gdańsk, Gdynia, and Szczecin. As in 1956, the new ferment in the country resulted in a change in the top party leadership. On Dec. 20, 1970, Gomułka was ousted as first secretary and was replaced in that post by Edward Gierek.

Göring, Hermann

Nominated by Adolf Hitler in 1939 to be his eventual successor, Hermann Göring throughout all of his service to the Nazi Party ranked high among its leadership. At the International Military Tribunal in Nürnberg in 1945–46, he was universally recognized as the principal defendant and spokesman for the Nazi regime. Before Hitler attained the German chancellorship in 1933, Göring had been a prime mover in achieving support for the party among the German industrialists; and, as president of the Reichstag (the lower house of the German parliament) from August 1932, he had served the party's interests. Once the Nazi regime was established, he successfully developed the Nazi police state in its initial form in Prussia, created Germany's new air force (the Luftwaffe), supervised Germany's war economy and rearmament, and played a leading part in promoting Germany's expansion into Austria and eastern Europe.

Göring was born in Bavaria on January 12, 1893, the second son by the second wife of Heinrich Ernst Göring, at the time German consul general in Haiti. The family was reunited in Germany on the father's retirement in 1896. Göring, as a child, was brought up near Nürnberg, in the small castle of Veldenstein, whose owner was Hermann, Ritter von Epenstein, a Jew who was, until 1913, the lover of Göring's mother and the godfather of her children. Trained for an army career, Göring received his commission in 1912 and served with distinction during World War I, joining the embryonic air force. In 1918 he became commander of the celebrated squadron in which the great German aviator Manfred, Freiherr von Richthofen, served. Göring so deeply resented the treatment given army officers by the civilian population during the troubled period after Germany's capitulation that he left the country. After a period as a commercial pilot in Denmark and Sweden, he met the Swedish Baroness Carin von Rosen, who divorced her husband and married Göring in Munich on February 3, 1922.

Göring had met Hitler the previous year and had joined the small National Socialist German Workers' (Nazi) Party late in 1922. As a former officer, he had been given command of Hitler's Storm Troopers (the SA, Sturmabteilung). Göring took part in the abortive Munich *Putsch* of November 1923 in which Hitler tried to seize power prematurely. During the *Putsch*, Göring was badly wounded in the groin. His arrest was ordered, but he escaped with his wife into Austria. Given morphine to deaden the pain from his wounds, he became so severely addicted that he twice underwent treatment in 1925–26 at Långbro mental hospital in Sweden.

Göring, as commander of the Sturmabteilung, 1933.
Heinrich Hoffmann, Munich

Göring's drug addiction

He returned to Germany in 1927, where his contacts in German industry proved useful, and he was taken back into the party leadership. He occupied one of the 12 Reichstag seats that the Nazi Party won in the 1928 election. Thereafter, Göring became the acknowledged party leader in the lower house, and, when the Nazis won 230 seats in the election of July 1932, he was elected president of the Reichstag.

Göring's sole concern in the Reichstag was to stultify the democratic system, which the Reichstag ostensibly represented up to March 1933. He had the ear of 84-year-old president Paul von Hindenburg and used his position to outmanoeuvre the successive chancellors, particularly Kurt von Schleicher and Franz von Papen, until Hindenburg was finally forced to invite Hitler to become chancellor on January 30, 1933. The battle for dictatorial power, however, was still not won; between January 30 and March 23, when an enabling bill giving Hitler his dictatorial powers was passed, Göring was tirelessly active. He used his new position as minister of the interior in Prussia, Germany's largest and most influential state, to Nazify the Prussian police and establish the Gestapo, or secret political police. He also established concentration camps for the "corrective treatment" of difficult opponents. The Reichstag fire of February 27, 1933, which the Nazis most probably instigated, made it possible for Göring to accuse the Communists of intending a coup d'état. The wholesale arrest of Communist and even some Social Democrat deputies succeeded in removing any effective opposition to the passage of the enabling bill the following month.

Göring's position as Hitler's most loyal supporter remained unassailable for the rest of the decade. He collected offices of state almost at will. He was *Reich* commissioner for aviation and head of the newly developed Luftwaffe, which was disguised as a civilian enterprise until March 1935. In 1933 he became master of the German hunt and of the German forests. In June 1934 he took a leading part in the party's purge of the SA leader Ernst Röhm but in the same year ceded his position as security chief to Heinrich Himmler, thus ridding himself of responsibility for the Gestapo and the concentration

camps. In 1937 he displaced Hjalmar Schacht, after 1934 Hitler's minister for economic affairs. Later, in 1936, without consulting Schacht, Hitler made Göring commissioner for his Four-Year Plan for the war economy. He was also constantly employed as Hitler's roving ambassador.

Popularity among the Nazi leaders

Göring was the most popular of the Nazi leaders, not only with the German people but also with the ambassadors and diplomats of foreign powers. He used his impregnable position to enrich himself. The more ruthless aspect of his nature showed in the recorded telephone conversation by means of which he blackmailed the surrender of Austria before the *Anschluss* (political union) with Germany in 1938. It was Göring who led the economic despoliation of the Jews in Germany and in the various territories that fell under Hitler's power.

Göring's first wife had died in 1931, and on April 10, 1935, he married the actress Emmy Sonnemann. Göring was devoted in turn to each of his wives. His hunting interests enabled him to obtain a vast forest estate in the Schorfheide, north of Berlin, where from 1933 he developed a great baronial establishment on a scale commensurate with his ambitions. This he called Carinhall in honour of his first wife. It was at Carinhall that he kept the greater part of his enormous art collection. On June 2, 1938, Emmy bore him a daughter, his only child, Edda.

Although Göring was probably sincere in his desire to avert or postpone war—as his abortive negotiations in 1939 with the Swedish industrialist Birger Dahlerus indicate—it was his Luftwaffe that conducted the blitzkrieg that smashed Polish resistance and softened up country after country as Hitler's campaigns developed. But Göring's self-indulgent nature was too weak to sustain the rigours of war or oppose Hitler's blind prejudice in favour of the production of bombers rather than fighter planes. The Luftwaffe's capacity for defense declined as Hitler's battlefronts extended from northern Europe to the Mediterranean and North Africa, and Göring lost face when the Luftwaffe failed to win the Battle of Britain or prevent the Allied bombing of Germany. On the plea of ill health, Göring retired as much as Hitler would let him into private life, enjoying the luxuries of Carinhall, where he continued to amass his art collection (further enriched with spoils from the Jewish collections in the occupied countries) and receive many gifts from those who sought his favour. His colossal girth was more the result of glandular defect than of gluttony, but his excessive resort to paracodeine tablets (a mild derivative from morphine) poisoned his system and made recurrent treatment for drug addiction necessary. His addiction helped to make him alternately elated or depressed; he was egocentric and bombastic, delighting in flamboyant clothes and uniforms, decorations, and exhibitionist jewelry.

Decline of the Luftwaffe

In spite of Göring's faults, Hitler felt he could not afford to discard a man so closely identified with the regime. In 1939 he had declared him his successor and in 1940 had given him the special rank of *Reichsmarschall des Grossdeutschen Reiches*. The other Nazi leaders both resented his favoured position and despised his self-indulgence, but Hitler did not displace him until the last days of the war, when, in accordance with the decrees of 1939, Göring attempted to assume the Führer's powers, believing him to be encircled and helpless in Berlin. Nevertheless, Göring expected to be treated as a plenipotentiary when, after Hitler's suicide, he surrendered himself to the Americans.

Cured finally of his drug addiction during his period of captivity awaiting trial as a war criminal, he defended himself ably before the International Military Tribunal at Nürnberg. He saw himself as the star defendant, a historical figure; he denied any complicity in the more hideous activities of the regime, which he claimed to be the secret work of Himmler. When after his condemnation his plea to be shot and not hanged was refused, he took poison and died in his cell at Nürnberg on October 15, 1946, the night his execution was ordered. Only in 1967 was it revealed that he had left a note explaining that the poison capsule had been secreted all the while in a container of pomade.

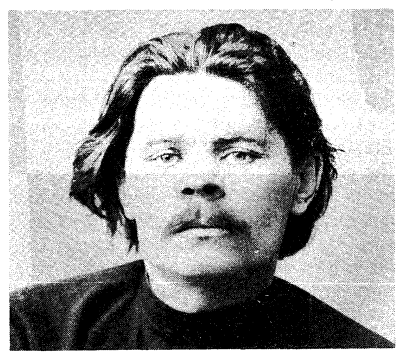
BIBLIOGRAPHY. The fullest life of Göring to date is R. MANVELL and H. FRAENKEL, *Hermann Göring* (1962), with a full bibliography. First-hand accounts of Göring appear in many books, notably in ADOLF GALLAND, *Die Ersten und die Letzten* (1953; Eng. trans., *The First and the Last*, 1955); G.M. GILBERT, *Nuremberg Diary* (1947); NEVILE M. HENDERSON, *Failure of a Mission* (1940); ERNST HANFSTAENGL, *Hitler: The Missing Years* (1957); FRANZ VON PAPEN, *Der Wahrheit eine Gasse* (1952; Eng. trans., *Memoirs*, 1952); HJALMAR SCHACHT, *Abrechnung mit Hitler* (1948; Eng. trans., *Account Settled*, 1949), and *76 Jahre meines Lebens* (1953; Eng. trans., *My First Seventy-Six Years*, 1955); ALBERT SPEER, *Inside the Third Reich* (1970); and in the sentimental recollections of Göring's sister-in-law, FANNY VON WILAMOWITZ-MOELLENDORFF, *Carin Göring* (1934). Göring's own full statements appear in the official record of the International Military Tribunal, Nürnberg (1947–49).

(R.M./H.Fra.)

Gorky, Maksim

Maksim Gorky is the pen name of the Russian author Aleksey Maksimovich Peshkov, whose plays, novels, and memoirs of working class life brought him an international reputation. He was the only Soviet writer whose work embraced the prerevolutionary and postrevolutionary period so exhaustively, and though he by no means stands with Chekhov, Tolstoy, and others in the front rank of Russian writers, he remains one of the most important literary figures of his age.

H. Roger-Viollet



Gorky.

LIFE

He was born on March 28 (March 16, old style), 1868, at Nizhny Novgorod, since renamed Gorky in his honour; and his earliest years were spent in Astrakhan, where his father, a former upholsterer, became a shipping agent. When the boy was five his father died; Gorky returned to Nizhny Novgorod to live with his maternal grandparents, who brought him up after his mother remarried. The grandfather was a dyer whose business deteriorated and who treated Gorky harshly. It was from his grandmother that he received most of what little kindness he experienced as a child. The bitterness of these early experiences later led him to choose the word *gorky* ("bitter") as his pseudonym. Technically of lower middle class origin, he lived in such poverty as a child and young man that he is often considered the greatest "proletarian" in Russian literature. This circumstance, coinciding with the rise of working class movements all over the world, helped to give Gorky an immense literary reputation, which his works do not wholly merit.

He knew the Russian working class background intimately, for his grandfather afforded him only a few months of formal schooling, sending him out into the world to earn his living at the age of eight. His jobs included, among many others, work as assistant in a shoemaker's shop, as errand boy for an icon painter, and as dishwasher on a Volga steamer, where the cook introduced him to reading—soon to become his main passion in life. Frequently beaten by his employers, nearly always hungry and ill clothed, he came to know the seamy

side of Russian life as few other Russian authors before or since. His late adolescence and early manhood were spent in Kazan, where he worked as a baker, docker, and night watchman. It was here that he made his first contact with Russian revolutionary ideas, meeting representatives of the Populist movement, whose tendency to idealize the Russian peasant he came to reject. During this period, oppressed by the misery of his surroundings, he attempted suicide by shooting himself. Leaving Kazan at the age of 21, he became a tramp, doing odd jobs of all kinds during extensive wanderings through south Russia.

First stories

It was in Tbilisi (Tiflis) that Gorky began to publish stories in the provincial press, of which the first was "Makar Chudra" (1892), followed by a series of similar wild Romantic legends and allegories, which have now only a documentary interest. But with the publication of the story "Chelkash" (1895; first Eng. trans., 1902) in a leading St. Petersburg journal, a success story began as spectacular as any other in the history of Russian literature. "Chelkash" itself remains one of his outstanding works and is the story of a colourful harbour thief in which elements of Romanticism and realism are mingled. It began Gorky's celebrated "tramp period," during which he described the social dregs of Russia. He expressed sympathy and self-identification with the strength and determination of the individual hobo or criminal, thus tapping a new vein in Russian literature, for such characters had previously been described more from the outside. Also to the tramp period belong "Malva" (1897), "Byvshye lyudi" (1897; *Creatures That Once Were Men*), and "Dvadtsat shest i odna" (1899; Eng. trans., "Twenty-Six Men and a Girl," 1902). The last, describing the sweated labour conditions in a bakery, is often regarded as his best short story. So great was the success of these works that Gorky's reputation quickly soared, and he began to be spoken of almost as an equal of Tolstoy and Chekhov.

Plays and novels

With the turn of the century Gorky embarked on a series of plays and novels, all less excellent as works of art than his best earlier stories. The first novel, *Foma Gordeyev* (1899), continues to illustrate his admiration for strength of body and will in the person of the masterful barge owner and rising capitalist Ignat Gordeyev, who is contrasted with his relatively feeble and intellectual son Foma, a "seeker after the meaning of life," as are many of Gorky's other characters. From this point, the rise of Russian capitalism became one of Gorky's main fictional interests. Other novels of the period are *Troye* (1900; *Three of Them*, 1905), *Ispoved* (1908; *A Confession*, 1910), *Gorodok Okurov* (1909; "Okurov City"), and *Zhizn Matveya Kozhemyakina* (1910; "The Life of Matvey Kozhemyakin"). These are all to some extent failures because of Gorky's inability to sustain a powerful narrative such as he was well able to begin, and also because of a tendency to overload his work with irrelevant discussions about the meaning of life. *Mat* (1906; Eng. trans., *Mother*, 1911) is probably the least successful of the novels, yet has considerable interest as Gorky's only long work devoted to the Russian revolutionary movement. It was made into a notable silent film by Vsevolod Pudovkin in 1926 and dramatized by Bertolt Brecht in *Die Mutter*, 1930–31. Simultaneously, Gorky was producing a series of plays—*Na dne* (1902; Eng. trans., *The Lower Depths*, 1906), *Vassa Zheleznova* (1910), *Dachniki* (1905; "Summer Residents"), *Vragi* (1906; "The Enemies"), and others. The most famous of these is *The Lower Depths*, which still enjoys great success abroad and in the U.S.S.R., putting on the stage the kind of flophouse character that Gorky had already described so extensively in narrative fiction.

Between 1899 and 1906 Gorky was living mainly in St. Petersburg (Leningrad), where he became a Marxist. He accordingly gave much enthusiastic support to Russian Marxism as represented by the Social Democratic Party. After the split in that party in 1903, Gorky supported its Bolshevik wing. But he was often at odds with the Bolshevik leader Lenin. Nor did Gorky ever, formally, become a member of Lenin's party, though his enormous earnings, which he largely gave to party funds, were for a time one of that organization's main sources of income. In 1901 the Marxist review *Zhizn* ("Life") was suppressed for publishing a short revolutionary poem by Gorky, "Pesnya o burevestnike" ("Song of the Stormy Petrel"). Gorky was arrested but released shortly afterward and went to the Crimea, having developed tuberculosis. In 1902 he was elected a member of the Russian Academy of Sciences, but his election was soon withdrawn for political reasons, an event that led to the resignations of Chekhov and Korolenko from the academy. At about this time Gorky founded a publishing business called *Znaniye* ("Knowledge"), which led to the emergence of a movement sometimes called the *Znaniye* school of fiction. *Znaniye* aimed to give a forum, insofar as censorship conditions permitted, to young writers with revolutionary proclivities whose work was "tendentious," a word that has commonly been used as a term of praise by Russian critics and readers. Gorky took a prominent part in the 1905 revolution and was arrested in the following year, being again quickly released, partly as the result of protests from abroad. He toured America in the company of his mistress, an event that led to his partial ostracism there and to a consequent reaction on his part against the United States expressed in stories about New York, *The City of the Yellow Devil* (1906).

Years of exile

On leaving Russia in 1906, Gorky spent seven years as a political exile, living mainly in his villa on Capri, which became an intellectual centre for politically disaffected Russians. Meanwhile, although his writings continued to enjoy the favour of ordinary Russian readers, he had lost much of his former popularity with the intelligentsia, who were becoming conscious of Gorky's defects. Though still essentially in alliance with Lenin's movement, he was somewhat out of favour even there because of his espousal of a religio-philosophical trend called *bogostroitelstvo* ("God-building"), preached in his novel *Confession* and regarded as a heresy by more orthodox Marxists. Politically, Gorky was a nuisance to his fellow Marxists because of his insistence on remaining independent, but his great influence was a powerful asset, which from their point of view outweighed such minor defects. During World War I he agreed with the Bolsheviks in opposing Russia's involvement in the struggle. But he opposed the Bolshevik seizure of power in November 1917, and went on to attack the victorious Lenin's dictatorial methods on the pages of his newspaper *Novaya zhizn* ("New Life") until July 1918, when his protests were silenced by the censorship on Lenin's orders. From 1919 onward Gorky cooperated with Lenin's government, also helping to relieve the miseries that his fellow writers shared with the rest of the population during the early postrevolutionary years. He was often able to see that they received payment, if only for work such as translating. He also did much during that time to ensure the preservation of works of art from destruction.

Autobiography

It is to the decade ending in 1923 that the production of Gorky's greatest masterpiece belongs. This is the autobiographical trilogy *Detstvo* (1913–14; Eng. trans., *My Childhood*, 1915), *V lyudyakh* (1915–16; Eng. trans., *In the World*, 1917), and *Moi universitety* (1923; Eng. trans., *My Universities*, 1952)—the last title being sardonic because Gorky's only university had been that of life, and his wish to study at Kazan University had been frustrated. This long work is one of the finest autobiographies in Russian. It deals only with the years of Gorky's childhood and early manhood and shows his strength as a now relatively extroverted writer, who had to some extent turned his back on the excessive philosophizing of his early period. It reveals him as an acute observer of detail with a flair for describing people—his own family, his numerous employers, and a panorama of minor but memorable figures who flit across his pages. In a way it is hardly the story of Gorky himself, for seldom was an autobiography more reticent (even his attempted suicide receives only a line or two). The book is permeated with a wonder at the mystery, cruelty, and colour of life, which, it might seem, Gorky was now less earnestly eager to understand or interpret, being content

to portray. But it does contain numerous messages, which he now tends to imply rather than to preach openly: notably protests against motiveless cruelty, continued emphasis on the importance of toughness and self-reliance ("I very early realized that a man is made by his resistance to the milieu which surrounds him"), and musings on the value of hard work often couched in his characteristic rhetorical style, as where he speaks of the dockers' "drunken joy" in unloading a Volga barge, a joy "than which only the embraces of a woman are sweeter."

My Universities was finished in Italy, to which Gorky emigrated. His villa in Sorrento became his base in the period 1921–28, when he made excursions to Germany and elsewhere, but he did not return to Russia. One reason for his retirement was poor health, but a disillusionment with the Soviet Union in the first years after the Revolution seems to have played a part in his decision. In 1928 he yielded to pressures to return, and the lavish official celebration there of his 60th birthday in that year was beyond anything he could have expected.

Return to the U.S.S.R.

In the following year he returned to the U.S.S.R. permanently, and he lived there until his death in 1936. His return coincided with the establishment of Stalin's total ascendancy, and Gorky became a prop of Stalinist political orthodoxy. He was now more than ever the undisputed leader of Soviet writers, and when the Soviet Writers' Union was founded in 1934 he became its first president. At the same time he helped to found the literary method of Socialist Realism, which was now imposed on all Soviet writers, and which obliged them—in effect—to become outright political propagandists.

Gorky remained active as a writer. Despite his close association with official Stalinist literary doctrine, almost all his later fiction is concerned with the period before the Revolution. In *Delo Artamonovykh* (1925; Eng. trans., *The Artamonov Business*, 1948), one of his best novels, he showed his continued interest in the rise and fall of prerevolutionary Russian capitalism. The immense and more ambitious *Zhizn Klima Samgina* (1927–36; "Life of Klim Samgin") is a tetralogy that attempts a portrait of the Russian intelligentsia between 1870 and 1924. There were more plays—*Yegor Bulychov i drugiye* (1932); *Dostigayev i drugiye* (1933; "Dostigaev and Others"; Eng. trans., *The Last Plays*, 1937)—but the most generally admired work to follow his autobiography is a volume of reminiscences of Russian writers (Eng. trans., *Reminiscences of Tolstoy, Chekhov and Andreyev*, 1949). Here the memoir of Tolstoy is so lively and free from the hagiographical approach traditional in Russian studies of their leading authors that it has sometimes been acclaimed as Gorky's masterpiece. Almost equally impressive is Gorky's study of Chekhov. At the other end of the scale come some of his pamphlets devoted to topical events and problems, such as his "Belomorkanal" (1934; Eng. trans., "The White Sea Canal," 1935), in which, as elsewhere, he glorified the most brutal aspects of Stalinism—in this case the construction of the canal by the forced labour of political prisoners.

Studies of writers

Some mystery attaches to Gorky's death, which occurred suddenly in 1936 while he was under medical treatment. Whether his death was natural or not is unknown, but it came to figure in the trial of Bukharin and others in 1938, at which it was claimed that Gorky had been the victim of an anti-Soviet plot by the "Bloc of Rightists and Trotskyites." The former police chief Yagoda, who was among the defendants, confessed to having ordered his death. Some Western authorities have suggested that Gorky was done to death on Stalin's orders, having finally become sickened by the excesses of Stalinist Russia, but there is little evidence of this except that it was characteristic of Stalin to frame others on the charge of accomplishing his own misdeeds.

ASSESSMENT

After his death Gorky was canonized as the patron saint of Soviet letters, the formula "Gorky said . . ." often being used to clinch a literary argument. His reputation abroad has also remained high, but it is doubtful whether posterity will deal with him so kindly. His success was partly due, both in the Soviet Union and to a lesser extent abroad, to political accident. His style, though gradually improving through the years, retained its original defects of excessive striving for effect, of working on the reader's nerves by the piling up of emotive adjectives, and by tending to overstate. Chekhov, his opposite in these matters, had given him good advice in the correspondence that followed Gorky's appeal for literary advice in the 1890s, but this counsel was only partly effective. Among Gorky's other defects, in addition to his weakness for philosophical digressions mentioned above, are his lack of any sense of humour and a certain coarseness of emotional grain. But his eye for physical detail, his talent for making his characters live, and his unrivalled knowledge of the Russian "lower depths" are weighty items on the credit side.

MAJOR WORKS

NOVELS: *Foma Gordeyev* (1899; *Foma Gordyeeff*, 1901; *The Man Who Was Afraid*, 1905; *Foma Gordeyev*, 1956); *Troye* (1900; *Three of Them*, 1905; *The Three*, 1959); *Mat* (1906; *Comrades*, 1907; *Mother*, 1911, 1921, 1950); *Zhizn nenuzhnago cheloveka* (1907–08; *The Spy*, 1908, 1969); *Ispoved* (1908; *A Confession*, 1910); *Leto* (1909); *Gorodok Okurov* (1909); *Zhizn Matveya Kozhemyakina* (1910–11); *Khozyain* (1913); *Delo Artamonovykh* (1925; *Decadence*, 1927; *The Artamonov Business*, 1948; *The Artamonovs*, 1952); *Zhizn Klima Samgina*, 4 pt. (1927–36; the parts being severally entitled in English: *Bystander*, 1930, *The Magnet*, 1931, *Other Fires*, 1933, and *The Specter*, 1938).

SHORT STORIES: The collection of sketches and stories *Ocherki i rasskazy*, 2 vol. (1898), included reissues of Gorky's first publication, "Makar Chudra" (1892), and of his first recognized success, "Chelkash" (1895; *Tchelkash*, 1902). Other notable stories are "Goremyka Pavel" (1894; *Orphan Paul*, 1946); "Starukha Izergil" (1895; *The Old Woman Izergil*, 1906); "Byvshye lyudi" (1897; *Creatures That Once Were Men*, 1905); "Suprugi Orlovy" and "Malva" (both also 1897; *The Orloff Couple* and *Malva*, 1901); "Dvadtsat shest i odna" (1899; *Twenty-Six Men and a Girl*, 1902, 1915); and the two series known as *Skazki ob Italii* (1911–13), and *Russkiye skazki* (1912).

PLAYS: *Meshchane* (1901); *Na dne* (1902; *The Lower Depths*, 1906, 1912, 1923; *At the Bottom*, 1930; *Down and Out*, 1933); *Dachniki* (1905); *Deti solntsa* (1905); *Varvary* (1905); *Vragi* (1906); *Posledniye* (1908); *Vassa Zheleznova* (first version 1910, second 1935); *Deti* (1910); *Chudaki* (1910); *Zykovy* (1913); *Somov i drugiye* (1931); *Yegor Bulychov i drugiye* (1932; *Yegor Bulichoff and Others*, 1937); *Dostigayev i drugiye* (1933; *Dostigaeff and the Others*, 1937).

AUTOBIOGRAPHY AND REMINISCENCES: *Detstvo* (1913–14; *My Childhood*, 1915; *Childhood*, 1950), *V lyudyakh* (1915–16; *In the World*, 1917), and *Moi universitety* (1923; *Reminiscences of My Youth*, 1924; *My Universities*, 1952), together constitute the work republished in English as *The Autobiography of Maxim Gorky* (1953). Supplementary to them are *Vremya Korolenko* (1923), *O pervoy lyubvi* (1923), and *Zametki iz dnevnika* (1924; *Fragments from My Diary*, 1924). Personal acquaintance is the basis of Gorky's *A.P. Chekhov: otryvki iz vospominanii* (1905; *Anton Tchekhov: Fragments of Recollections*, 1921), *Vospominaniya o Tolstom* (1919; *Reminiscences of Leo Nicolayevitch Tolstoi*, 1920), and *Vladimir Ilich Lenin* (1924 with supplements to 1931; *V. I. Lenin*, 1931; *Days with Lenin*, 1933, 1944; *Lenin: A Biographical Essay*, 1969).

POETRY: *Devushka i Smert* (written 1892 but not printed till 1917); *Pesnya o Burevestnike* (1901); *Chelovek* (1902).

OTHER WORKS: Some of Gorky's anti-American satires of 1906 are still remembered: *Odin iz koroley Respubliki; V Amerike;* and the series of New York sketches *Gorod zheltago dyabola.* In his lifetime collections were made of his numerous articles on current affairs, *Publitsisticheskiye stati* (1933), and of his pronouncements on literary questions, *O literature: stati i rechi 1928–35 gg.* (1935; expanded edition, . . . 1928–36 gg., 1937). His complete works, in 30 volumes, were published 1949-55. (R.F.Hi.)

BIBLIOGRAPHY. Major bibliographies on Gorky's life and work and on Gorky criticism are BORISS A. KALEPS (comp.), *Maxim Gorky (1868–1936): A Bibliography of Publications from and on Gorky in English, French, German, Italian, Spanish, and Latvian Languages* (1963); К.Д. МУРАТОВА, *Семинарий по Горькому* (1956), a comprehensive bibliography of almost exclusively Russian and Soviet works, arranged by topics; and С.Д. БАЛУХАТИЙ, *Критика о М.*

Горьком (1934), splendidly comprehensive within its chronological limitations (1893–1932). A very useful selective bibliography in English may be found in Weil (see below). The vast majority of manuscripts, personal papers, and other archival material relating to Gorky is kept at the Gorky Institute of World Literature in Moscow, unquestionably the major world centre of research on Gorky and his works.

Editions and translations: The best and most comprehensive collected edition of Gorky's work, including correspondence, is *Собрание сочинений в тридцати томах*, 30 vol. (1949–55). This is in most respects an admirably scholarly academic edition, though with notable, if inevitable, omissions—*e.g.*, Gorky's diatribes against Lenin and the Bolsheviks and some anti-Soviet pieces. Gorky's works have been widely translated into all the major languages of the world. Only insignificant fragments of his fiction remain untranslated into English. There are, however, no collected editions of his works in English translation and no major translator whom one would single out from the many. A useful short list of English translations of Gorky's works may be found in the bibliographical appendix to Wolfe (see below).

Biographical and critical studies: АКАДЕМИЯ НАУК СССР (Институт мировой литературы), *Летопись жизни и творчества А.М. Горького*, 4 vol. (1958–60), an impressive and valuable collection of biographical information, though highly selective—omits all biographical detail that might be interpreted as contradicting the official Soviet view of Gorky; И.А. ГРУЗДЕВ, *Горький и его время* (1938), an important biography by an outstanding Soviet biographer; F.M. BORRAS, *Maxim Gorky the Writer* (1967), a generally sound critical interpretation, though the material is rather weakly organized; NINA GOURFINKEL, *Gorki par lui-même* (1957; Eng. trans., *Gorky*, 1960), a short, fragmentary work, though with some valuable insights; RICHARD HARE, *Maxim Gorky, Romantic Realist and Conservative Revolutionary* (1962), marred by some rather unbalanced critical attitudes and a general sense of authorial antipathy toward his subject; A.S. KAUN, *Maxim Gorky and His Russia* (1931), a fascinating and sensitive account of Gorky and his career by an American who knew him—contains an outstanding section on Gorky's often stormy relationship with Lenin and the Bolsheviks and Gorky's ideological deviations; В.Т. ХОДАСЕВИЧ, «Горький (воспоминания),» *Современие записки*, 63:131–156 (1939), a profoundly personal—and yet, one feels, very accurate—portrait of a close friend by one of the great literary figures of the Russian émigré world; DAN LEVIN, *Stormy Petrel: The Life and Work of Maxim Gorky* (1965), a generally well-researched and sensitive account of Gorky the man, his life and career—much stronger on the biographical than the critical side and particularly vitiated by infelicities of style; IRWIN WEIL, *Gorky: His Literary Development and Influence on Soviet Intellectual Life* (1966), a good account of Gorky's outstanding features as a writer and an extremely interesting, if somewhat speculative, attempt to trace his influence on the general development of Soviet literature as well as individual Soviet writers; B.D. WOLFE, *The Bridge and the Abyss: The Troubled Friendship of Maxim Gorky and V.I. Lenin* (1967), a fascinating account of a complex relationship that revealed vital aspects of personality in both men.

Gounod, Charles

Among the group of French composers who upheld and developed the tradition of opera in France in the third quarter of the 19th century, Charles François Gounod is one of the most significant. He declared that "The composer who would achieve a successful career must create it through writing operas." Although his many other operatic works no longer enjoy their former popularity, his *Faust* maintains its worldwide reputation.

Gounod was born in Paris on June 17, 1818. His father, François Gounod, was a painter of some distinction. His mother, a woman of wide education, was a capable pianist and gave Gounod his early training in music. He was educated at the Lycée Saint-Louis, where he remained until 1835. After taking his degree in philosophy, he began to study music with the Bohemian composer Anton Reicha. On Reicha's death Gounod entered the Paris Conservatoire, where he studied under Fromental Halévy and Jean-François Lesueur. Three years later his cantata *Fernand* won him the Prix de Rome for music, an award that entailed a three-year stay in Rome at the Villa Medici.

In Italy he devoted much of his attention to the works of Giovanni da Palestrina, an Italian Renaissance composer, and was so deeply influenced by him that he wrote a mass in imitation of Palestrina's style; it was among his earliest important compositions. From Rome he proceeded to Vienna, where a mass and requiem, composed in Italy, were performed in 1842 and 1843. Returning to Paris, he passed through Prague, Dresden, and Berlin. He also spent four days in Leipzig with Felix Mendelssohn and heard a performance of Mendelssohn's *Scottish Symphony* as well as a Mendelssohn recital of organ works by Bach in the Thomaskirche.

Influence of Palestrina

In Paris, Gounod became organist and choirmaster at the Church of the Missions Étrangères, and for two years he mainly studied theology. In 1846 he entered the seminary of Saint-Sulpice but in 1847 decided against taking Holy Orders. A requiem and a *Te Deum* he had started writing the previous year remained unfinished, and he turned to composing for the operatic stage.

The reception of his earliest operas, *Sapho* (1851) and *La Nonne sanglante* (1854), was not very enthusiastic, in spite of favourable reviews by the composer Berlioz. In his *Messe de Sainte-Cécile* (1855) he attempted to blend the sacred with a more secular style of composition. An excursion into comic opera followed with *Le Médecin malgré lui* (1858; English title, *The Mock Doctor*), based on Molière's comedy. From 1852 Gounod worked on *Faust*, the production of which, on March 19, 1859, marked a new phase in the development of French opera. This work has continued to overshadow all of Gounod's subsequent stage works, including the fairly successful *Mireille*, based on a Provençal poem by Frédéric Mistral (1864), *Roméo et Juliette* (1867), and his later oratorios.

In 1852 Gounod had become conductor of the Orphéon Choral Society in Paris, for which he wrote a number of choral works, including two masses. From 1870 he spent five years in London, formed a choir to which he gave his name (and which later on became the Royal Choral Society), and devoted himself almost entirely to the writing of oratorios. *Gallia*, a lamentation for solo soprano, chorus, and orchestra, inspired by the French military defeat of 1870, was first performed at the Albert Hall, London, at the opening of the International Exhibition in London on May 1, 1871, and the oratorios *La Rédemption* and *Mors et Vita* (*Life and Death*), at the Birmingham festival, in 1882 and 1885.

He was made a *grand officier* of the Légion d'Honneur in 1888, and died at Saint-Cloud, near Paris, on October 18, 1893.

Assessment

Gounod's melodic vein is unmistakably original, though often oversentimental. He knew how to write for the voice and for the orchestra; but in his operas his sense of musical characterization, though rarely devoid of charm, is often excessively facile, and the religiosity displayed in his sacred music too often superficial. His *Meditation* (*Ave Maria*) superimposed on Bach's *Prelude in C Major* (from *The Well-Tempered Clavier*, Book I) illustrates both his inventiveness and ease as a melodist and his naïveté in matters of style. Yet, in the 1920s Gounod's

music owed to this very naïveté its prestige among the Neoclassicist musicians of those days, who admired Gounod for having been a "pure" (non-philosophical and nonliterary) composer. Even Stravinsky, in his *Poétique musicale*, praises not only *Faust* but also *Le Médecin malgré lui*, *La Colombe*, and *Philémon et Baucis*.

MAJOR WORKS

OPERAS: 13 operas, including: *Sapho* (1851); *La Nonne sanglante* (1854; libretto by Eugène Scribe and Casimir Delavigne based on M.G. Lewis' *Monk*); *Le Médecin malgré lui* (1858); *Faust* (1859); *Philémon et Baucis* (1860); *La Colombe* (1860); *La Reine de Saba* (1862); *Mireille* (1864); *Roméo et Juliette* (1867).

CHORAL MUSIC: Many oratorios, including *La Rédemption* (1882), *Mors et Vita* (1885); mass settings, including *Messe de Sainte-Cécile* (1855) and *Messe à la mémoire de Jeanne d'Arc* (1887); other settings of the liturgy; occasional pieces.

OTHER WORKS: Incidental music for Ernest Legouvé's *Les Deux Reines* (first produced 1872) and Jules Barbier's *Jeanne d'Arc* (1873); orchestral, chamber, and piano pieces, mostly now forgotten; more than 100 songs.

BIBLIOGRAPHY. CHARLES GOUNOD, *Autobiography* (1885), and *Mémoires d'un artiste* (Eng. trans. by A.E. CROCKER, 1896); C. BELLAIGUE, *Gounod* (1910), the standard biography; J.G. PROD'HOMME and A. DANDELOT, *Gounod: sa vie et ses oeuvres*, 2 vol. (1911), a study of his progress as a composer; P. LANDORMY, *Gounod* (1942), the most recent authoritative biography, and *Faust de Gounod: étude et analyse* (1944), a full study of the composer's most important work.
